Burmese literature remained alive throughout the colonial period, and, both in verse and in prose, native traditions continue to prevail. A later development is biography, which has become more popular than fiction. The Burma Translation Society, which is sponsored by the government, annually awards substantial cash prizes for the best translation, the best novel, and the best biography. There are state schools of Burmese dance, music, and drama, as well as state schools of fine arts, at Rangoon and Mandalay. The National Museum is at Rangoon, and there are regional museums at Mandalay and at the state level. (See also SOUTHEAST ASIAN PEOPLES, ARTS OF.)

There were 12 Burmese-language and two English-language newspapers at the time of the coup in 1962. Only one Burmese newspaper remains in private hands, the others having been nationalized. The government has its own official newspaper, *The Working People's Daily*. Broadcasting is under the control of the government information department. (M.H.Au./Ed.)

PROSPECTS FOR THE FUTURE

Burma has been passing through a period of political change and economic recession. Faced with internal problems, the country remains aloof from the rest of the world. The international community was at first intrigued by this tendency but then lost interest. An English newspaper report summed up the situation by suggesting that, if Burma could do without the world, then the world could very well do without Burma. Its three complex and interrelated problems are insurgency, the economy, and resultant social ills. The various insurgencies, Communist and ethnic, which led in 1962 to the Socialist revolution of military officers, were made worse by the Communist victories in Indochina in 1975. The second and central problem was the economy. Where growth occurred after 1962 it was slight and usually swallowed up by population growth. To obtain improvement in this area, Burma must initiate more effective central planning; end dependence of the export market on a very few commodities and the isolationism that prevents foreign assistance; and combat unemployment and inflation. The concomitant social ills include labour unrest, poor public health, and a black market, smuggling, and hoarding.

Some concessions by the government to increased private participation in the economy, especially in the important transportation sector, indicated a willingness in the government to consider alternatives to doctrinaire socialism in the resolution of the country's predicament.

Despite the strains, however, the country looks to a new generation, which has gained fresh experience in technology and management, to build a new economy. At the same time Burmese society seeks to preserve the

old values of individual liberty and social justice within a tribal framework. (Ed.)

Burma, History of

Burma lies on the western edge of the peninsula of Indochina and forms part of the region of Southeast Asia. In prehistoric times it was traversed, both along its coasts and down its river valleys, by band after band of migrating peoples on their way farther eastward and southward. During the first ten centuries of the Christian Era the overland trade route between China and India passed through Burma's borders, and merchant ships from India, Ceylon, and even farther west converged on its ports, which were also the termini of the portage routes across the narrow isthmus from what is now the Gulf of Thailand. Thus, Burma was the gateway of Southeast Asia.

The Indian merchants brought with them not only precious cargoes but also great cultural gifts in the form of religious, political, and legal ideas; and within a few decades Indian cultural traditions had remolded native society, native thought, and native arts and crafts. Although the new cultural treasures passed through to Southeast Asia, Burma never allowed its own native culture to be overwhelmed.

Surrounded on three sides by mountain walls and on the fourth by the sea, Burma has always been insular; and as a consequence, Burmese culture, in spite of the many Indian influences and in spite of its close affinity with the cultures of the other countries of Southeast Asia, has remained distinct and separate. For example, it rejected the Hindu Indian theory of a divine king and insisted that men and women are born free and equal.

The first area in Southeast Asia to receive Buddhism, because of its proximity to India, Burma became the centre of Theravāda Buddhism almost overnight in the 11th century, when the faith was being assailed not only in India and Southeast Asia but in the whole of Asia itself. The Buddhist doctrine of the equality of all men and women was superimposed with grace and harmony on the native tradition of social equality.

The unique nature of Burmese society and culture was noticed at the time of the British conquest (late 19th century) even by humble privates, whose conception of Burma as a "cleaner, greener land" was embodied by the British author Rudyard Kipling in "Mandalay." The historian G.E. Harvey wrote in *British Rule in Burma* that "there is, in Burmese life, not only a beauty that delights the eye but also a dignity which makes one proud of the human race."

BURMA UNTIL THE ADVENT OF BRITISH RULE (TO 1885)

The origins of civilization in Burma. The Irrawaddy River, flowing southward through the entire length of Burma, divides the country in two and its valley forms the central plain. The first human settlements in Burma appeared some 5,000 years ago in the middle portion of the Irrawaddy Valley. The stone and fossilized-wood tools used by those Paleolithic and Proto-Neolithic people have their own distinguishing features, and anthropologists have given their culture its own name—Anyathian (Burmese *anya*, "Upper Burma"). A discovery in 1969 by the Department of Archeology of the Burmese government of some cave paintings and stone tools in the eastern part of Burma's Shan State shows that that area, too, had Paleolithic and Proto-Neolithic settlements. Crude shards and ringstones found at the site appear to have been attached to stonecutting tools, to make them more suitable for digging; and woodcutting tools were probably used in clearing patches of the forest for cultivation, which would indicate that the shift to agriculture had already begun.

The first human settlements in Burma

The Anyathian people probably migrated down the Irrawaddy River, and the Shan cave people down the Salween. Thus, even during the stone ages, the general pattern of human migration and settlement for both Burma and the rest of mainland Southeast Asia had been fixed—tribal groups coming from the north over the mountains and then down the great rivers: the earlier or stronger groups settling in the valley to learn the art of wet-rice cultivation and the later or weaker groups being pushed into the mountainous parts to learn only the method of "slash and burn" rice growing. In those early times the Irrawaddy had not yet formed its great delta; and at its huge mouth and along the coast, the country was stormy, wild, and desolate.

The Stone Age Anyathians stayed far from the sea. The earliest arrivals on Burma's coast were Negritos, a fact remembered in Burmese folktales, which tell of dark-skinned, short-statured, fuzzy-haired, and human-flesh-eating ogres who dwelled at the mouths of great rivers and on islands in the sea; a Buddhist legend describes how monk-missionaries sent from India saved the people of Thaton from ogres who lived on nearby islands and raided the city in quest of human flesh. As to the Anyathians, even folk memory no longer knows them, and it cannot be said whether they died out or merged with the later arrivals in the Irrawaddy Valley. (For a discussion of associated physical features, see IRRAWADDY RIVER.)

The Mons of Lower Burma. The first people in Burma to leave definite traces of their settlement were the Mons. Speaking an Austro-Asiatic language, they were close cousins of the Khmers, with whom they originally came down the Mekong River. Later the Khmers followed the river southeastward to what is now Cambodia, and the Mons veered southwestward toward the source of the Me Nam River (Mae Nam Chao Phraya) and went down its valley. By at least the 3rd century BC the Mons not only occupied the entire Me Nam Valley but had also spread to the Sittang Valley, doubtless through the gaps in the eastern mountain wall of Burma. Their port capital was Thaton, not far from the isthmian portage routes; and through this window to the sea they saw India, in its full glory, united and peaceful under the emperor Aśoka and a flourishing centre of Theravāda Buddhism.

Origin of the Mons

Introduction of Indian culture. Aśoka sent a mission of Buddhist monks to Suvarnabhūmi, "the Golden Land"; although a few scholars still remain unconvinced, it seems definite that the Golden Land was the three Mon regions of Upper Me Nam, Lower Me Nam, and the Sittang Valley. The ancient monastic settlement of Kelasa, situated a few miles from Thaton and claimed by Burmese and Mon chronicles to have been founded by Aśoka's missionaries, was mentioned in early Ceylonese records as being represented at a great religious ceremony held in Ceylon in the 2nd century BC.

With the expansion of Indian commerce in Southeast Asia in the 1st century AD, Thaton's prosperity and importance increased. The expansion was sudden and revolutionary but peaceful, and the Indian merchants and seamen came to Thaton as friends rather than as conquistadores or colonists. Their numbers were never great, and their settlements were only temporary. Until the 8th century, when there was a scramble for the new lands of the Irrawaddy Delta, no conflicts developed between the Indians and the Mons. As a result, the Indians' cultural gifts were found acceptable.

Blending of Indian and native cultures. The Mons saw to it that their native culture was not abandoned or

displaced, and they worked for a harmonious blending of the old and new cultures. They brought many of their native animistic beliefs into the fold of Theravāda Buddhism. They enhanced the power and prestige of their king by adopting the Hindu ritual of coronation. They developed a new art of sculpture by blending the native tradition of wood carving with the Greco-Indian conventions of making images of the Buddha. They built *stūpas* on the Indian model and then developed new forms of temple architecture by a mixture of native and Indian traditions.

Mon culture

Within a few decades the Mons became the most advanced people in Southeast Asia, and they assumed the role of teachers to their neighbours, spreading Theravāda Buddhism and their new culture over the entire region. Their cousins, the Khmers, were the first to benefit, followed by the Burmese. Even in the 13th century, when their glory had passed and they were a conquered people in the Me Nam Valley, the Mons freely shared their cultural heritage with the new arrivals, the Tais.

The Tibeto-Burmese invasions. About the time the Mons were reaching the Me Nam Valley, some Tibeto-Burmese tribes were leaving their homeland on the southeastern slopes of the Tibetan Plateau. They had reached quite a high level of culture, but their way of life and their social values of individual equality were being threatened by the rival kingdoms of Tibet and China. Preferring physical hardship to political bondage, they started a long trek across the northern mountains of Burma; they entered the Upper Irrawaddy Valley, perhaps by the time of the Buddha (*c.* 500 BC). By Aśoka's time their spearhead, the Pyus and allied tribes, had founded their city-kingdoms, perhaps at Tagaung and certainly at Halingyi. They gradually moved southward, leaving along the way settlements that later became city-kingdoms. They stopped for a while at Taungdwingyi, and some tribes crossed the river and the mountains to Arakan. They finally reached the vicinity of modern Prome, only a few miles from what was then the apex of the Irrawaddy's mouth. At about the time of Christ, they founded the city of Śrī Kṣetra near modern Prome.

The Pyu state of Upper Burma. For long there had been a trade route between China and India that passed through northern Burma and then across the Chindwin Valley. The Pyus had gained full control of this route and had even provided an alternative routing—down the Irrawaddy to Śrī Kṣetra and then by sea to India and also to the portage routes and the islands. Because the Pyus were in control of the whole Irrawaddy Valley, Roman embassies to China in AD 97 and 121 chose the overland route through Burma for their journey.

Doubtless in the beginning the Pyus learned much from the Mons, but later they came into direct contact with Indian culture. They were so prosperous and powerful that they became the overlords of the Mon kingdom of Thaton and the portage routes. Chinese historical records noted that the Pyus claimed sovereignty over 18 kingdoms, many of them to the south of Burma.

Pyu life

The same Chinese records emphasized the humane nature of Pyu government and the elegance and grace of Pyu life. Fetters, chains, and prisons were unknown, and punishment of criminals was a few strokes with the whip. Gaily dressed in blue, the men wore gold ornaments on their hats and the women wore jewels in their hair. The Pyus lived in houses built of timber and roofed with tiles of lead and tin; they used golden knives and utensils and were surrounded by art objects of gold, green glass, jade, and crystal. The walls, the palace, and the monasteries were of glazed brick. Amid this luxury, the Pyus were devout Theravāda Buddhists. Their architects evolved the vaulted temple, which later found its golden age at Pagan. Their sons and daughters were disciplined and educated in monasteries or convents as novices.

Despite their power over the neighbouring regions and the elegance of their life, the Pyus remained a loosely knit medley of tribes. Retaining their old tribal values, the Pyus remained more democratic than the Mons, who possessed the institution of a hereditary chieftain (later king) and a hereditary nobility; but as a consequence, the Pyus were less united and disciplined. There were conflicts between Pyu tribal groups, resulting in changes of dynasties at Śrī Kṣetra.

The huge delta became silted up, and the Pyu city swiftly became inaccessible from the sea. The Mons—politically organized as the confederacy of Ramanna and embracing the three kingdoms of Thaton, Dvaravati, and Haripunjaya—asserted their claim to the newly emerged island of Pegu, in the mouth of the Irrawaddy, by attacking both the Pyus and the Indian merchant ships in the vicinity. In the 6th century a tribal war forced the Pyus and their loyal allies to abandon Śrī Kṣetra. There was a fresh merger of tribes, and in the process the Burmese, a people subject to the Pyus, became prominent for the first time.

Advent of the Pagan Burmese. The Pyus and their allies moved to Upper Burma, where they set up a new capital. The Burmese, still loyal, established a small settlement of their own. Early in the 9th century the Tai-Shans from their kingdom of Nanchao in South China mounted a series of raids on the cities of Indochina and even besieged Hanoi. The Mon and Khmer cities held firm, but the Pyu capital fell. The leadership of the Tibeto-Burmese tribes passed to the Burmese, and in 849 they founded their own city of Pagan and built a wall around it.

The founding of the city of Pagan

The Pagan kingdom (849–1287). By that time the Mons had become supreme in Lower Burma. They had occupied the whole of the Irrawaddy Delta, building the port of Bassein in the west and founding the city of Pegu in the centre. They could have stepped into the vacuum caused by the destruction of the Pyu kingdom, but they were not politically ambitious and perhaps did not relish going up the river into arid country.

Subjugation of Upper and Lower Burma. The Mons' reluctance allowed the infant Burmese kingdom to survive and grow. The Burmese had learned much from the Pyus, but they were cut off from the fountain of Buddhist culture, now transferred to Ceylon. Theravāda Buddhism had disappeared from India, and in its place were Mahāyāna Buddhism, its offshoot Tantrism, and a resurgent and aggressive Hinduism. The Burmese still controlled the overland route; along it from China and Nanchao came Mahāyāna Buddhism, and from Bengal came Tantrism. There was also a return to native animistic beliefs.

In 1044 Anawrahta came to the throne at Pagan, and his accession coincided with the seemingly final defeat of Theravāda Buddhism in Southeast Asia; the islands and the Khmers went over completely to Hinduism, and the Theravāda Mons were pressured by their neighbours into accepting certain Hindu beliefs. An orthodox monk, Shin Arahan, fled in protest to Pagan, where he was able to convert the young king to the Theravāda faith. The people also accepted it because there was still a vague remembrance that the Pyus had been Theravādins and because the faith's emphasis on the equality and dignity of the individual fitted their society and their prevailing mood. Anawrahta, declaring himself the champion of Theravāda Buddhism, challenged and subdued the Mahāyānist kingdom of Nanchao, annexed the animistic Shan Plateau, and conquered the Theravāda Mons. He united the whole of Burma into a single kingdom and founded the first Burmese empire. His work was continued by his great commander Kyanzittha, who was elected king; and the latter was followed by another great ruler, his grandson (Anawrahta's great-grandson), Alaungsithu.

The first Burmese empire

Anawrahta's subjugation of the Shans checked the flood of Tai-speaking mercenaries and migrants into Southeast Asia, and the strength of his kingdom brought peace to the region, now divided into two great empires, Khmer and Burmese. Anawrahta's dynasty of kings lasted until the 13th century. By that time, their great temples had been built and their message of Theravāda Buddhism had been carried not only to the Shans but also to the Khmers.

Destruction by the Mongols. A malaise seemed to have set in by the middle of the 13th century. Then came a demand for submission and tribute by the Mongol Kublai Khan. The proud Burmese refused and made a

valiant effort to stem the tide of invasion that followed; but it was unavailing, and Pagan fell to the Mongol armies in 1287.

Cultural changes in the Pagan period. Pagan was a fabulous kingdom even to its contemporaries, and Marco Polo was impressed by its splendour. Its many temples and monasteries testified to the prosperity of its people and the richness of its culture. The conquest of Thaton was the foundation of both its economy and its culture. All the ports of the country were in Burmese hands, and Pagan's temples were built by free artisans, who were paid their wages not only in money but also in kind and whose clothing, shelter, health, comfort, and safety were the responsibility of their employers (as evidenced by contemporary inscriptions, giving the monetary details connected with the construction and endowment of a temple).

Mon craftsmen, artisans, artists, architects, goldsmiths, and wood carvers—captured at Thaton—were taken to Pagan to teach their skills and arts to the Burmese, whose artistic traditions, inherited from the Pyus, had been lying dormant. The Burmese learned quickly and soon were able to stand shoulder to shoulder with Mon and Indian craftsmen. Mon monks and scholars taught the Burmese the Pāli language and the Buddhist scriptures; and the Burmese soon became scholars themselves, making Pagan the centre of Theravāda learning. Some of their religious commentaries came to be accepted as part of the Pāli canon by all Theravādins. The women of Pagan took part in all these activities, their freedom and equality doubly guaranteed by tribal usage and by Buddhist doctrine.

Devout and orthodox, the people of Pagan made Buddhism their way of life but retained those animistic beliefs that were found compatible with Buddhism. They set a pattern of religion, government, and society that later generations of Burmese followed almost without change. Temple frescoes show the Pagan people to have been simply dressed. Their utensils and implements were not of gold, and so their life was not so elegant as that of the Pyus (see also PAGAN).

Burma c. 1300–c. 1750. During the reigns of the last kings of Pagan, many Shans entered royal service as mercenaries. After the fall of Pagan these Burmanized Tai-speaking soldiers of fortune drove out the Mongols; but instead of restoring the fallen dynasty, they founded small kingdoms for themselves. Before invading Burma, Kublai Khan had conquered Nanchao and turned it into the Chinese province of Yunnan; when his armies had withdrawn, he encouraged the Shans to leave their old homeland and attack the Burmese and the Khmers. The consequence was the rise of a number of Tai-speaking kingdoms in the Me Nam Valley and the restoration of the kingdom of Pegu by the Mons of Lower Burma. In 1368 Upper Burma was unified under one kingdom, that of Ava, whose kings were half-Burmese and half-Shan and who proudly regarded themselves as Anawrahta's successors. They encouraged scholarship and learning, making their period a great age of Burmese literature. They wasted their resources, however, by waging a long war against the Mons.

The Shans of the Me Nam Valley fought both Pegu and Ava. In the meantime the small settlement of Burmese refugees at Toungoo, on the Pegu-Ava frontier, sought survival by playing Mon against Shan. The Shan refugees from Nanchao who were waiting in the north of Burma for an opportunity to win back their old kingdom decided to conquer Ava instead. They had not been won over to Buddhism; and in 1540 there was a massacre of monks, resulting in an exodus of Burmese to Toungoo. In the meantime the Mons at Pegu were achieving another golden age under wise rulers. Under Dhammazedi, Pegu became the centre of Theravādin scholarship and it also entered into close commercial relationship with Malacca, on the Malay Peninsula, an Islāmic kingdom before 1511 and a Portuguese possession thereafter. In 1531 Tabinshwehti became king of Toungoo, and within a few years he conquered Upper Burma from the Shans and Lower Burma from the Mons. Transferring his capital to Pegu, he made a great attempt to unite Burmese, Mon, and Shan into a single nation. He died in 1551 and was succeeded by his brother-in-law Bayinnaung. The Shans in the Me Nam Valley had consolidated their power under the kingdom of Ayutthaya (Siam), and they cast their eye on the Shan Plateau and Mon Lower Burma. Bayinnaung marched on to Ayutthaya and conquered the entire Me Nam Valley, thus founding the second Burmese empire. He used Portuguese mercenaries and Portuguese cannon, but he was determined to keep the Portuguese out of mainland Southeast Asia.

The second Burmese empire

Bayinnaung was a very able king, but after his death the empire broke up. Manipur (which had been subjugated in 1560) declared itself a free kingdom. Then the Mons revolted, the Siamese not only regained their independence but also ravaged Lower Burma, and the Portuguese founded a kingdom at Syriam. Bayinnaung's grandson, Anaukpetlun, in 1605 overcame all three and restored the Burmese kingdom, including Lower Burma. The Burmese, tired of war and international commerce, shifted their capital back to Ava. There were no more Mon rebellions and the kingdom remained at peace. Eventually, the kings became weak and power passed to the ministers.

The fall of the Ming dynasty in China (mid-17th century) resulted in occupation of Burmese territory by the armies of the fallen emperor and also by the pursuing armies of the new emperor. The raja of Manipur sent his raiders into Burma for loot. The Mons rose in rebellion, encouraged by the French in India. Assailed from all sides, Ava fell to the Mons in 1752; and the whole of Burma passed under Mon rule.

The Alaungpaya dynasty. It was soon proved, however, that only the Burmese king and his ministers had been defeated and not the people; before the year had ended a popular leader, Alaungpaya, drove the Mons out of Upper Burma and regained the Shan States. By 1758 he had regained Manipur and defeated the Mons and their French garrisons. The Siamese became alarmed and attempted to rouse the Shan chiefs to rebel. Alaungpaya retook Tenasserim, the site of the old portage kingdoms, and invaded Siam. Although his invasion failed and he himself died during the retreat in 1760, the Burmese now felt that, unless Siam were conquered, their kingdom would be insecure. The defeats suffered in 1752 had embittered them, and they decided to pursue a policy of aggrandizement and repression. Alaungpaya's son and successor, Hsinbyushin, sent his armies into Siam in 1766; they captured Ayutthaya in 1767. China, alarmed over the growing power of the Burmese, unsuccessfully invaded Burma four times during the period 1766–69.

The Burmese then reconquered Arakan (on the northwest coast of Burma) and occupied Assam, thus coming face to face with the British power in India. The result was the First Anglo-Burmese War (1824–26), in which Siam fought on the British side. The Burmese eventually had to sue for peace and lost Assam, Manipur, Arakan, and Tenasserim. (For a further discussion on British India, see also ASSAM.)

The Anglo-Burmese wars

The Second Anglo-Burmese War (1852) was provoked by the British, who wanted to close the gap in their coastline stretching from Calcutta to Singapore; it left the Burmese kingdom high and dry in Upper Burma. As the British became more and more interested in trade with China through its back door, they waited for a suitable pretext and in 1885 declared war on the Burmese for the third time. To meet international criticism of their action, the British gave the excuses that the last independent Burmese king, Thibaw (ruled 1878–85), was a tyrant and that he was intriguing to give France greater influence over the country. Neither of these charges seems to have had much foundation.

The administration of traditional Burma. In the government of old Burma the king was the chief executive and the final court of appeal, but there were checks on his power. He could not make laws, only edicts that would lapse with his death. Custom was the only recognized source of law, and even the king could be sued for civil wrongs. In addition, following the old tribal require-

ment that each chieftain was to be elected by the council of elders, the king had to be elected by the previous king's council of ministers. With the advent of strong kings, generally the election was merely a formality; but in times of crisis there were real elections.

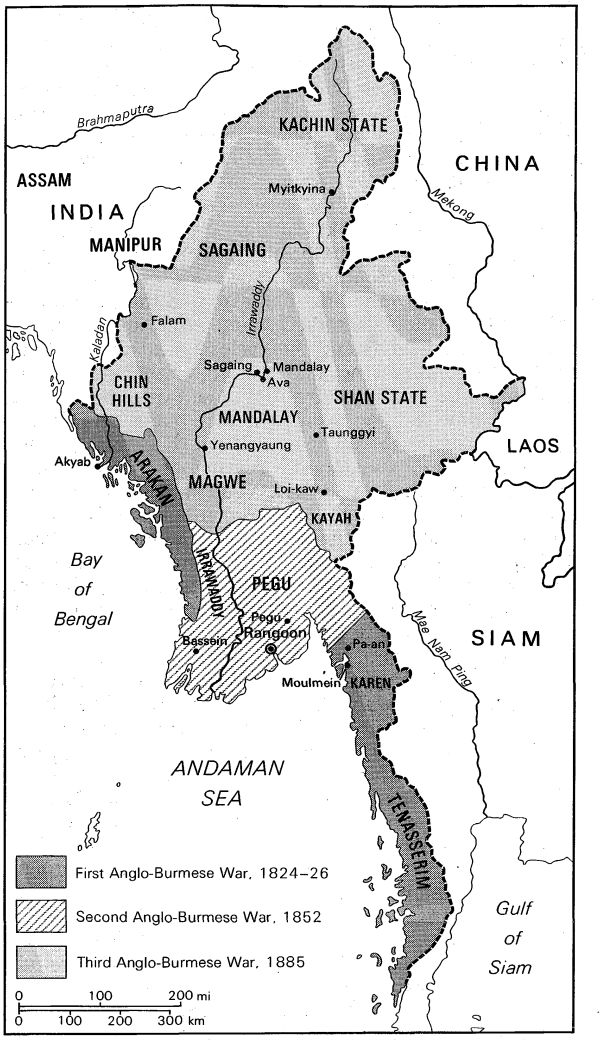
The king was also the patron of Buddhism and was expected to act as a humane ruler. Buddhist monks were not organized into a church, but there was a primate who, although appointed by the king, often proved to be his sternest critic. Although monks were outside the sphere of politics, they had the right to give sanctuary in that they could ask for the life of a condemned criminal. In practice this right was exercised only when there was some miscarriage of justice. Because monasteries also served as schools for all children, the monks were the teachers of the people and molded public opinion regarding the king's justice.

As a corollary to the centuries-old Burmese insistence that all men and women were born free and equal, there were no hereditary nobles. The king's officials were appointed, at least in theory, on their character and talent alone; and their appointments lapsed with the king's death.

The centre of government

The High Court of Justice was the centre of government. It had three wings—the treasury, the executive, and the judiciary. The judicial wing was the final court of appeal; in theory and often in practice the king presided over its deliberations. All proclamations and appointments that were made by the king became valid only when orders giving effect to them were issued by the executive wing.

Every province had a governor, to whom were delegated certain powers by the High Court of Justice; but there was always a right of appeal against all his decisions to the High Court. Local government was in the hands of "group-village headmen." Villages were grouped together according to their size and geography. Each village in a group was under an elected elder, and these elders together elected the headman, who was then given his appointment by the king. The institution of headman was almost hereditary: because of the need for continuity and experience, the elders usually gave preference to the son, brother, daughter, or even the widow of the former headman. The headman, like a governor, had the right of immediate audience with the king.



British territorial acquisitions in Burma.

THE EMERGENCE OF MODERN BURMA (SINCE 1885)

The Third Anglo-Burmese War lasted but a week; the Burmese never expected that hostilities would break out, and, realizing the hopelessness of the situation because of the disparity in arms, they offered no resistance. They also believed that the British aim was merely to replace King Thibaw with a Burmese prince who had been sheltered and groomed in India for the throne; and this belief seemed to be confirmed when the British commander called upon the High Court of Justice to continue to function. The British finally decided, however, not only to annex the whole kingdom but also to make it a province of India (effective January 1, 1886).

Burmese anti-Indian feelings

This was a bitter blow to Burmese pride. The Burmese had always been prejudiced against the Indians, calling them *kala* ("caste people"). In addition, they remembered that in Burma's three wars with the British, Indian troops had fought for their British masters. It was true that, after the war of 1824, Arakan and Tenasserim had been placed under British commissioners responsible to the British government of India and that, after the province of Pegu had been annexed in 1852, the whole territory of British Burma had been placed under a chief commissioner also responsible to the government of India. But these were temporary and makeshift arrangements, to be reconsidered in the light of experience. Burma seemed too big a territory to be attached to India, and moreover the Burmese were different from the Indians in race, language, society, way of life, attitude, and temperament. The Buddhist culture the Burmese had received from India had been modified and transformed so that it had become Burmese-Buddhist culture, while in India, Buddhism had been suppressed and discarded many centuries before. Even little Ceylon, despite its cultural, racial, and linguistic ties with India, was never made an Indian province.

The effects of colonialism. The Burmese refused to accept the British victory as final, and they resorted to guerrilla warfare against the British army of occupation. There were spontaneous uprisings all over the country, led by former officers of the disbanded royal army, former officials (including village headmen), and princes of the blood. They considered themselves soldiers still fighting the Third Anglo-Burmese War; but to the British the war had ended with the annexation of the kingdom and the fighters were rebels and bandits. For the next four years, although no martial law was proclaimed, the British military officers acted as both judge and jury in dealing with captured guerrillas. Villagers who aided the rebels were also sternly punished. There were mass executions and even cases of wholly massacred villages.

British attempts to end the rebellion

As the guerrillas fought on, the British tried to force the people into submission. Villages were burned; families who had supplied villages with their headmen were uprooted from their homes and sent away to Lower Burma; and strangers were appointed as headmen for the new villages the British had set up. The guerrillas resorted to cruel and desperate measures against the new village officials. Finally, the might of the British army prevailed, and by 1890—with thousands of guerrillas killed or executed—the struggle was over.

Although the British were successors to the Burmese kings, they did not wish to favour any one religion over another, and they were reluctant to patronize Burmese Buddhism. Queen Victoria, as empress, had proclaimed

strict British neutrality in religious affairs of the Indian peoples; but the position in India was different: it was the home of two rival religions, Hinduism and Islām. The patronage of Burmese Buddhism did not mean financial support, of which Burmese Buddhist monks were in no need (they could own no property, and such simple needs as robes, food, books, and medicine were met by donations from the public). Patronage involved authority; and although the king had been required to kneel before even a freshly ordained monk visiting him, it had been the king's right to appoint the primate, who exercised supervision and discipline among the ranks of the clergy all over the kingdom. The king had also had the right to attach two royal officials to the primate—the commissioner of ecclesiastical lands and the ecclesiastical censor. The duty of the commissioner had been to see that ecclesiastical lands were exempted from payment of taxes; but at the same time, he had seen to it that bogus and illegal endowments did not escape taxation. The duty of the censor had been to maintain a register of monks, which had given the king an indirect control over the clergy. The power of disrobing a wayward monk had lain only with the primate, but the same result could have been achieved by the censor scratching the monk's name from the register. This arrangement was designed to prevent unworthy persons from taking advantage of the people's respect and devotion for the clergy.

The British refusal of a plea by the clergy and the elders to continue this arrangement resulted in the appearance of pseudo-monks, who lowered the prestige of the Buddhist clergy and contributed to the failure of an attempt by Sir Arthur Phayre (chief commissioner of Lower Burma, 1862–67) to build a modern educational system using the monastic schools as its foundation. Phayre's successors recommended the foundation of government schools, but only a few were actually established. The government of India preferred to encourage foreign Christian missions to found schools by offering them "grants-in-aid."

Education under the British

Many mission schools were founded to which parents were forced to send their children because there were no alternatives. Because the teachers were missionaries, the lessons they gave were marked by repeated criticism of Buddhism and its culture. In the government schools the first teachers, British and Indian, were mere civil servants, unable and unwilling to continue the older traditions of education.

The British impact on the Burmese economy proved disastrous. This was not so much due to the usual economic exploitation of a country by a foreign ruler (the British were milder in this respect than were other colonial powers) as it was to the British policy of laissez-faire and to Burma's being made an Indian province. The British dream of a golden road to China through Burma could not be realized, but the opening of the Suez Canal in 1869 was equally golden, for it increased international demand for Burma's rice, which had never before been an important item of export. This development came in the wake of a change in Burma from a barter economy to a money economy. The Burmese peasant was both psychologically unprepared for and inexperienced in the use of cash; and under Burmese law, capital accumulations were almost impossible because the Burmese possessed no right of disposing property by will, so that a family estate had to be divided after the death of the parents among all sons and daughters.

The Irrawaddy Delta was swiftly cleared of its mangrove forests to become covered with rice fields. Even in 1857 the price of rice increased 25 percent; by 1890 the 1857 price had more than doubled and it continued to increase until the Depression in 1930. Tempted by the prevailing rice prices, the Burmese flocked to the delta; but in order to prepare the land for cultivation they had to borrow capital from Indian moneylenders from Madras at an interest rate of some 120 percent. The British banks would not grant loans on mortgage of rice land, and the British government had no policy for establishing land-mortgage banks or for making agricultural loans. Prevailing prices were high in the international market, but the local price was kept down by a handful of British firms that controlled wholesale trade and by Indian and Chinese merchants who controlled retail trade. Although the Burmese economy developed rapidly from 1890 to 1900, the Burmese people did not benefit from it. A railway had been built through the entire valley of the Irrawaddy, and hundreds of steamboats plied the entire length of the river; but the railway and the boats belonged to British companies. Roads had been built by the government, but they were meant for the swift transport of troops during frequent rebellions. A British company worked the ruby mines until they became exhausted. The extraction of oil and timber was monopolized by two British firms. The balance of trade was always in favour of Burma; but this was only on paper because there was no control or even record of foreign exchange remittances to their home countries by the British and Indian troops; the British, Indian, and Chinese merchants; the British and Indian civil servants; and the Indian labourers who came in thousands without any restrictions because they were merely travelling from one part of the Indian empire to another. With land values and rice prices soaring, the Indian moneylenders foreclosed mortgages at the earliest opportunity. The dispossessed farmers could not find employment even on their lost lands because, with a higher standard of living, they could not compete with Indian labourers. Burmese villagers, unemployed and lost in a disintegrating society, took to petty theft and robbery and soon acquired the reputation of being lazy and undisciplined.

The emergence of nationalism. Those Burmese who attended the new schools managed to gain admission to the clerical grades of government service, but even in those lower grades there was competition from Indians. Because science courses were not available, the professions of engineering and medicine were closed to the Burmese. Those who advanced to the government liberal arts college at Rangoon entered the middle grades of the civil service; a few went on to London to study law. When these young barristers returned to Burma they were looked upon as their new leaders by the people. Their sojourn in the liberal atmosphere of London had convinced these new leaders that some measure of political independence could be regained by negotiation. They first gave their attention to the national religion, culture, and education; in 1906 they founded the Young Men's Buddhist Association (YMBA) and established a number of schools supported by private donations and government grants-in-aid (the movement was not antigovernment). That same year the British, attempting to pacify the Indian National Congress, introduced some constitutional reforms in India. Only a few inferior changes were made in the Burmese constitution, but these confirmed the young leaders' faith in British liberalism. In 1920, however, when it was found that Burma would be excluded from new reforms introduced in India, the barristers led the people in a nationwide protest, which involved a boycott of British goods. In 1886, to humiliate the Burmese, the British had made Burma a part of India; they now found they could not exclude Burma from sharing benefits granted to India.

The new Burmese leaders

The following December, Rangoon College was raised to the status of a full university; but because its control was vested in a body of British professors and government nominees, its students went on strike. Younger schoolboys and schoolgirls followed suit. The strikers camped in the courtyards of monasteries, reviving memories of days when education was the concern of the monks. The general public and the Buddhist clergy gave full support to the strike. The University Act was amended, and the strike was settled; but many strikers refused to go back to mission and government schools. The YMBA schools, now calling themselves "National" schools, opened their doors to the strikers.

Constitutional reforms were finally granted in 1923; but the delay had split the leaders, some of whom, like the masses, were beginning to doubt whether political freedom could be attained by peaceful protest. In the University of Rangoon itself, students began to resent their

Thakin movement

British professors. A radical student group began protests, which came to be known as the Thakin movement (a term of derision, from *thakin,* "master," by which Burmese were required to address the British).

(M.H.Au.)

In 1931 Burmese peasants, under their leader Saya San, rose in rebellion. Armed only with swords and sticks, they resisted British and Indian troops for two years. The young Thakins won the trust of the villagers and emerged as leaders in place of the liberals. In 1936 university students again went on strike, and two of their leaders, U Nu and Aung San, joined the Thakin movement, adding strength to it. In 1937 the British government separated Burma from India, but the masses interpreted this as proof that the British planned to exclude Burma from the next phase of Indian reform.

When World War II broke out in Europe in 1939, the Burmese sympathized with Britain, but they wanted to bargain with the government before giving their support. A warrant was issued for the arrest of Aung San, but he escaped to China, where he attempted to contact radical groups for support. Japanese assistance was offered instead; he returned to Burma in secret, recruited 29 young men, and took them to Japan, where the "Thirty Comrades" received military training. The Japanese promised independence for Burma; hence, when Japanese troops reached Bangkok, Aung San announced the formation of the Burma Independence Army. Independence was not declared, however, and Aung San and his army began to conspire against Japan. When the Japanese administration learned of the plot, they disbanded the Independence Army and formed a smaller Burma Defense Army, with Aung San still as commander.

Ba Maw, the first prime minister under the 1937 constitution and later the leader of the opposition, was appointed head of state, with a Cabinet including Gen. Aung San and U Nu. In 1943, when the tide of battle started to turn against the Japanese, they declared Burma a fully sovereign state. But the Burmese government was still a mere facade, with the Japanese army ruling. Aung San contacted Lord Mountbatten, the Allied commander in Southeast Asia, offering cooperation, and in March 1945, on receiving Mountbatten's "go ahead," Aung San and his army joined the British side.

The AFPFL

After the liberation of Rangoon, Aung San and the Thakins formed a coalition of all parties under the name Anti-Fascist People's Freedom League (AFPFL). At this critical moment the British military administration showed their old prejudices. But Lord Mountbatten hastily sent a major general, Sir Hubert Rance, to head the administration; and Rance, with a conciliatory attitude, regained for the British the trust of Aung San and the general public. When the war ended, the military administration was withdrawn, and Rance was replaced by the former civilian governor, who formed a Cabinet consisting of older and more conservative politicians. The new administration arrested Aung San on a criminal charge. Surprised and angered, the Burmese people prepared for rebellion; but the British government in London wisely replaced the governor with Rance, now retired from the army. Rance formed a new Cabinet, including Aung San, and discussions for a peaceful transfer of power began. These were concluded in London in January 1947, when the British agreed to Burma's independence and its leaving the Commonwealth of Nations.

The Communist and conservative wings of the AFPFL were dissatisfied with the agreement. The Communists broke away and went underground, and the conservatives went into opposition. In July Aung San and most members of his Cabinet were assassinated by gunmen sent by U Saw, a former prime minister and now a conservative. Rance asked U Nu to form a new Cabinet.

Burmese independence

On January 4, 1948, Burma became the Union of Burma, a sovereign independent republic.

The national period. With its economy shattered and its towns and villages destroyed during the war, independent Burma needed some years of peace; a foreign policy of neutrality was decided upon, but because of internal strife no peace resulted. The Communists were the first insurgents, followed by Aung San's veterans, and then the Karens, the only ethnic minority on the plains; but the other minorities—Chins, Kachins, and Shans—who had been ruled separately by the British but who had enthusiastically joined the union, stood firm.

A division of Chinese Nationalist troops occupied parts of the Shan Plateau after China had fallen to the Communists in 1949; and because of the United States' general support for Nationalist China, Burma stopped accepting American aid and became prejudiced against all foreign aid. At the UN, Burma endeavoured to show impartiality. It was one of the first countries to recognize Israel and also the People's Republic of China.

In 1958 Burma was well on the road to internal peace and economic recovery when the ruling AFPFL was divided by personal quarrels between U Nu and his closest associates. Amid rumours of a military takeover, U Nu invited the army chief of staff, Gen. Ne Win—who had been a Thakin, one of the Thirty Comrades, and Aung San's second in command—to take the premiership. Ne Win prepared the country for general elections, which took place in February 1960. The opponents were the two sections of the AFPFL, and U Nu was returned to office with an absolute majority. His followers now quarrelled among themselves, however.

Socialist takeover. In March 1962 Gen. Ne Win led a coup d'etat and arrested U Nu, the chief justice, and Cabinet ministers. Suspending the constitution, he ruled the country with a revolutionary council made up of senior military officers. His stated purpose was to make Burma a socialist state. Land had been nationalized in U Nu's administration, and now all commerce and industry were nationalized as well; the economy did not improve, however. A one-party (Burma Socialist Programme Party) system was established, and measures were introduced to decentralize the administration. In April 1972 Gen. Ne Win and other members of the revolutionary council retired from the army.

New constitution

U Ne Win promised a new constitution, and in September 1971 representatives of the party's central committee, of the country's various ethnic groups, and of other interest groups were appointed to draft a document. Committee members toured extensively, inviting criticism and suggestions. A referendum to ratify the new constitution was held in December 1973, with more than 90 percent of nearly 15,000,000 eligible voters signifying approval. Elections to the Pyithu Hlutdaw (People's Council)—the supreme legislative, executive, and judicial authority—and to local People's Councils were held early in 1974; the new government was established on March 2 with U Ne Win as president of the Socialist Republic of the Union of Burma.

Despite the new political organization, Burma's economy continued to stagnate in the late 1970s. Student and worker unrest erupted periodically, and Communist and ethnic insurgency continued in the eastern part of the country.

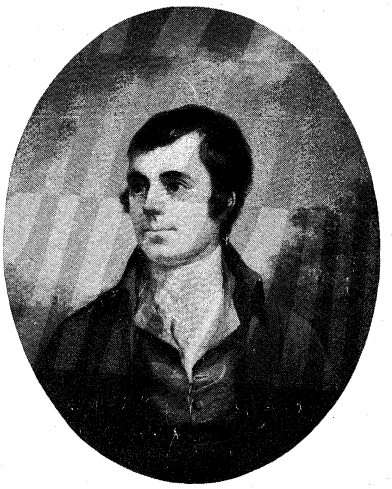
Burns, Robert

Robert Burns is the poet of the realized moment of experience, of human feelings purged of all the accretions and falsifications of idealization and generalization. The greatest Scottish poet after the Middles Ages, he is his country's national poet, celebrated annually with rites associated with no other man of letters anywhere.



Burns, oil painting by Alexander Nasmyth (1758–1840). In the National Portrait Gallery, London.

LIFE

Burns was born at Alloway, Ayrshire, on Jan. 25, 1759. His father had come to Ayrshire from Kincardineshire in an endeavour to improve his fortunes, but though he worked immensely hard first on the farm of Mount Oliphant, which he leased in 1766, and then on that of Lochlea, which he took in 1777, ill luck dogged him, and he died in 1784, worn out and bankrupt. It was watching his father being thus beaten down that helped to make Robert both a rebel against the social order of his day and a bitter satirist of all forms of religious and political thought that condoned or perpetuated inhumanity. He received some formal schooling from a teacher as well as sporadically from other sources; he acquired a superficial reading knowledge of French and a bare smattering of Latin, and he read most of the important 18th-century English writers as well as Shakespeare, Milton, and Dryden. His knowledge of Scottish literature was confined in his childhood to orally transmitted folk songs and folk tales together with a modernization of the late 15th-century poem "Wallace," a work that "poured a Scottish prejudice in my veins, which will boil along there till the flood-gates of life shut in eternal rest." Burns also studied biblical history, world geography, and English grammar; and he learned some physics, astronomy, and botany from such books as William Derham's *Physico-Theology* and *Astro-Theology* and John Ray's *The Wisdom of God Manifested in the Works of the Creation*, which presented scientific facts as arguments for the existence of God as a benevolent designer. Burns's religion throughout his adult life seem to have been a humanitarian deism.

Proud, restless, and full of a nameless ambition, the young Robert Burns did his share of hard work on the family farm. After his father's death he was head of the household and tenant of the farm of Mossgiel to which the family moved. But he had already started writing poetry, in which the tone of Scottish folk song and that of 18th-century sentimental and meditative poetry were strangely mingled. Early in 1783 he began to keep a commonplace book in which he entered his first poem (a song, written for a specific folk tune) in April, preceded by the comment: "There is certainly some connection between Love and Music and Poetry . . . I never had the least thought or inclination of turning Poet till I once got heartily in Love, and then Rhyme and Song were, in a manner, a spontaneous language of my heart." The poem is an unpretentious, lilting piece written in an English tipped with Scots, but it becomes pure neoclassic English in the final stanza. Shortly afterward he entered in the commonplace book sentimental, melodramatic, or melancholy pieces whose thought reflected the family misfortunes of the time and whose vocabulary and manner derived from minor 18th-century English poets. He was cultivating, in a heavily self-conscious way, a gloomy sensibility. But suddenly we come across a lively, swinging piece deriving from the Scottish folk tradition rather than from contemporary English sentimentalists: "My father was a farmer upon the Carrick border O." This was entered in the commonplace book in 1784, with an apologetic note that it was "miserably deficient in Versification." Meanwhile, his father's death freed him to seek male and female companionship where he would. He took sides against the dominant extreme Calvinist wing of the church in Ayrshire and championed a local gentleman, Gavin Hamilton, who had got into trouble with the Kirk Session for sabbath breaking. He had an affair with a servant girl at the farm, Elizabeth Paton, who in 1785 bore his first illegitimate child, and on the child's birth he welcomed it with a lively poem. This poem was written in a stanza that had had a long history in Scottish poetry and had been used by Allan Ramsay and Robert Fergusson. Even more purely in the Scottish literary tradition is "The Death and Dying Words of Poor Maillie," entered in the commonplace book in June 1785; this is a "mock testament" put into the mouth of a dying sheep, done with shrewd, ironical humour and considerable technical adroitness. Burns by now had available to him not only the Scottish folk tradition but also at least some of the traditions of Scottish "art" poetry, both as they came to him through Fergusson and as he found them for himself in 18th-century collections of older Scottish poetry.

First poetry

Burns developed rapidly throughout 1784 and 1785 as an "occasional" poet who more and more turned to verse to express his emotions of love, friendship, or amusement or his ironical contemplation of the social scene. But these were not spontaneous effusions by an almost-illiterate peasant. Burns was a conscious craftsman; his entries in the commonplace book reveal that from the beginning he was interested in the technical problems of versification. If he never learned to distinguish emotional control from emotional self-indulgence in 18th-century English poetry, he did learn to appreciate economy, cogency, and variety in the work of Pope and others, and, most important of all, he learned from older Scots literature to handle Scottish literary forms and stanza patterns, particularly in descriptive and satirical verse, with assurance and cunning. From the oral folk tradition he learned a great deal about song rhythms and the fitting of words to music; and out of his own Ayrshire speech, his knowledge of older Scots, and his reading in standard English, he fashioned a flexible Scots–English idiom which, though hardly a literary language in the sense that Robert Henryson's or William Dunbar's language was in 15th- and 16th-century Scottish verse, proved to be an effective medium for a poetry that was distinctly Scottish without being antiquarian.

Though he wrote poetry for his own amusement and that of his friends, Burns remained restless and dissatisfied. He won the reputation of being a dangerous rebel against orthodox religion, and when in 1786 he fell in love with Jean Armour, her father refused to allow her to marry Burns even though a child was on the way and under Scots law mutual consent followed by consummation constituted a legal marriage. Jean was persuaded by her father to go back on her promise; Robert, hurt and enraged, took up with another girl, Mary Campbell, who died soon after; on September 3 Jean bore him twins out of wedlock. Meanwhile, the farm was not prospering, and Burns, harassed by insoluble emotional and economic problems, thought of emigrating to Jamaica. But he first wanted to show his country what he could do. In the midst of his troubles with the Armours (Armour

threatened to sue him to provide for the upkeep of Jean's as yet unborn child) he went ahead with his plans for publishing a volume of his poems at the nearby town of Kilmarnock. It was entitled *Poems, Chiefly in the Scottish Dialect*, and appeared on July 31, 1786. Its success was immediate and overwhelming. Simple country folk and sophisticated Edinburgh critics alike hailed it, and the upshot was that Burns set out for Edinburgh on Nov. 27, 1786, to be lionized, patronized, and showered with well-meant but dangerous advice.

The Kilmarnock poems

The Kilmarnock volume was a remarkable mixture. It included a handful of first-rate Scots poems: "The Twa Dogs," "Scotch Drink," "The Holy Fair," "An Address to the Deil," "The Death and Dying Words of Poor Maillie," "To a Mouse," "To a Louse," and some others, including a number of verse letters addressed to various friends. There were also a few Scots poems in which he was unable to sustain his inspiration or that are spoiled by a confused purpose. In addition, there were six gloomy and histrionic poems in English, four songs, of which only one, "It Was Upon a Lammas Night," showed promise of his future greatness as a song writer, and, what to contemporary reviewers seemed the stars of the volume, "The Cotter's Saturday Night" and "To a Mountain Daisy."

Burns selected his Kilmarnock poems with care: he was anxious to impress a genteel Edinburgh audience. In his preface he played up to contemporary sentimental views about the natural man and the noble peasant, exaggerated his lack of education, pretended to a lack of natural resources (which was ridiculous in the light of the careful craftsmanship that his poetry displays), and in general acted a part. The trouble is that he was only half acting. He was uncertain enough about the genteel tradition to accept much of it at its face value, and though, to his ultimate glory, he kept returning to what his own instincts told him was the true path for him to follow, far too many of his poems are marred by a naïve and sentimental moralizing. "The Cotter's Saturday Night," which has stanzas of quiet beauty and impressive craftsmanship, also contains passages of intolerable histrionics and others where sharply etched realism and grandiose theatrical generalizations stand oddly side by side: Burns was not certain whether he was projecting a picture of Scottish peasant life from the inside or showing off the Scottish peasant for the edification of connoisseurs of sentimental beauties in Edinburgh.

Edinburgh unsettled Burns, and after a number of amorous and other adventures there, and several trips to other parts of Scotland, he settled in the summer of 1788 at a farm in Ellisland, Dumfriesshire, leased to him by an admirer who was nevertheless a shrewd landlord. At Edinburgh, too, he arranged for a new and enlarged edition (1787) of his poems, but little of significance was added to the Kilmarnock selection. Substantially, it was by the Kilmarnock poems that Burns was known in his lifetime. He found farming at Ellisland difficult, though he was helped by Jean Armour, with whom he had been reconciled and whom he finally married in 1788, to the annoyance of Mrs. Agnes Maclehose (the "Clarinda" of the poems), an Edinburgh woman, separated from her husband. Burns had been carrying on a violent flirtation with her, which produced some indifferent lyrics and, at the final parting, one great song, "Ae Fond Kiss."

Marriage

In Edinburgh Burns had met James Johnson, a keen collector of Scottish songs who was bringing out a series of volumes of songs with the music, and enlisted Burns's help in finding, editing, improving, and rewriting items. Burns was enthusiastic and soon became virtual editor of Johnson's *Scots Musical Museum*. Later, he became involved with a similar project for George Thomson, but Thomson was a more consciously genteel person than Johnson, and Burns had to fight with him to prevent him from "refining" words and music and so ruining their character. The six volumes of Johnson's *Scots Musical Museum* (1787–1803) and the eight parts of Thomson's *Select Collection of Original Scotish Airs for the Voice* (1793–1818) contain the bulk of Burns's songs. Burns spent the latter part of his life in assiduously collecting and writing songs to provide words for traditional Scottish airs and to keep Johnson and Thomson going. He regarded his work as service to Scotland and quixotically refused payment. The only poem he wrote after his Edinburgh visit that showed a hitherto unsuspected side of his poetic genius was *Tam o'Shanter*, a spirited, narrative poem in brilliantly handled eight-syllable couplets based on a folk legend associated with Alloway Kirk.

Meanwhile, Burns corresponded with and visited on terms of equality a great variety of literary and other people who were considerably "above" him socially. He was an admirable letter writer and a brilliant talker, and he could hold his own in any company. At the same time, he was still a struggling tenant farmer, and the attempt to keep himself going in two different social and intellectual capacities was wearing him down. After trying for a long time, he finally obtained a post in the excise service in 1789 and moved to Dumfries in 1791, where he lived until his death on July 21, 1796, caused by rheumatic heart disease contracted in his youth as a result of too much physical exertion on an inadequate diet. (The myth that Burns died of drink has long since been exploded.) His life at Dumfries was active. He wrote numerous "occasional" poems on contemporary political and other events and did an immense amount of work for the two song collections, in addition to carrying out his duties as exciseman. The outbreak of the French Revolution excited him, and some indiscreet outbursts nearly lost him his job at a time when the excesses of the French revolutionaries had provoked the fiercest political reaction in Scotland. But his reputation as a good exciseman and a politic but humiliating recantation saved him. It was his attitude to the French Revolution, too, that estranged him from Mrs. Dunlop, an elderly female admirer who was genuinely fond of Burns and had been a real friend to him.

ASSESSMENT

Burns was a man of great intellectual energy and force of character who, in a class-ridden society, never found an environment in which he could fully exercise his personality. After his death the lively literary lady Maria Riddell wrote a character sketch of him in the *Dumfries Journal* in which she said that his powers of conversation, his impromtu wit, his ability to grasp new ideas, his intolerance of stupidity and arrogance, his capacity for devastating ironic comment were in her opinion even more impressive than his poetry. But it was not only the class structure of his society, which led to his being alternately patronized and sentimentalized over, that constricted him. The fact is that Scottish culture in his day could provide no intellectual background that might replace the Calvinism that Burns rejected. The Edinburgh literati of Burns's day were second raters. But the problem was more than one of personalities. The only substitute for the rejected Calvinism seemed to be a sentimental deism, a facile belief in the good heart as all, and this was not a creed rich or complex enough to nourish great poetry. That Burns in spite of this produced so much fine poetry shows the strength of his unique and remarkable genius, and that he has become the Scottish national poet is a tribute to his hold on the popular imagination.

Burns perhaps exhibited his greatest poetic powers in his satires. There is also a remarkable craftsmanship in his verse letters, which display a most adroit counterpointing of the colloquial and the formal. But it is by his songs that Burns is best known, and it is his songs that have carried his reputation round the world. Burns is without doubt the greatest song writer Britain has produced. He found Scottish song in a confused and fragmentary state. Scottish airs had been popular since the latter part of the 17th century, and many collections of Scottish songs and song tunes appeared both in Edinburgh and London in the 18th century. But the great majority of older songs survived only in fragments.

Songs

Burns's aim was to recover as many airs and sets of words as he could, and where the existing words were fragmentary, impossibly coarse, or equally impossibly genteel, to re-create the song in the true spirit of the folk tradition. It was a staggering program, nothing less than the single-handed re-creation of the whole body of Scottish folk song. Further, Burns undertook to provide words to tunes that now existed only as dance tunes. He was anxious that all Scotland should be represented, and in his journeys scrupulously collected such songs and fragments as he could find to rework them into complete songs. His journeys can be traced in the provenance of the songs: a fisherman's song from Fife, an old Aberdeen folksong, a song about an alehouse keeper by the Moray Firth and innumerable love songs connected with particular hills, valleys, streams, and woods in various Scottish counties. If Burns had not been uncannily in tune with the folk spirit in Scottish song, he would be execrated today for having spoiled the original fragments by artificial improvements. But in fact he did not spoil them; he saved them from total corruption and disappearance and gave them new life and meaning and popularity.

Burns wrote all his songs to known tunes, sometimes writing several sets of words to the same air in an endeavor to find the most apt poem for a given melody. Many songs which, it is clear from a variety of evidence, must have been substantially written by Burns he never claimed as his. He never claimed "Auld Lang Syne," for example, which he described simply as an old fragment he had discovered, but the song we have is almost certainly his, though the chorus and probably the first stanza are old. (Burns wrote it for a simple and moving old air that is *not* the tune to which it is now sung, as Thomson set it to another tune.) The full extent of Burns's work on Scottish song will probably never be known.

It is positively miraculous that Burns was able to enter into the spirit of older folk song and re-create, out of an old chorus, such songs as "I'm O'er Young to Marry Yet," "Green Grow the Rashes, O," and a host of others. It is this uncanny ability to speak with the great anonymous voice of the Scottish people that explains the special feeling that Burns arouses, feelings that manifest themselves in the "Burns cult." But his songs are not all in a simple folk idiom, though most of them have that air of simplicity (whatever the subtleties below the surface) so necessary to a sung poem. There is the symbolic colour and imagery of "Open the Door to Me Oh" that so impressed William Butler Yeats:

The wan moon sets behind the white wave,
And time is setting with me, Oh!

A wonderful mixture of tenderness and swagger appears in "A Red, Red Rose," Burns's rewriting of an old fragment. In the controlled historical melancholy of the Jacobite songs Burns gives this romantic lost cause a new meaning in terms of human emotion:

Now a' is done that men can do,
And a' is done in vain:
My Love and Native Land fareweel,
For I maun cross the main, my dear,
For I maun cross the main.

In contrast there is a brilliant counterpointing of folk feeling and high ceremony, of simple emotion and pageantry, in the poem beginning "Go fetch to me a pint o' wine," where the whole atmosphere of medieval romance and ballad is concentrated in two stanzas. There is the magical tenderness of "O Lay Thy Loof in Mine Lass" though there the tune is particularly important. There is the lilting love song he composed to one of his wife's favourite airs, "The Posie":

O luv will venture in where it daur na weel be seen,
O luve will venture in where wisdom ance has been; . . .

There is that sprightly piece of ironic self-compliment, "There Was a Lad Was Born in Kyle." There is the moving benedictory cadence, so perfectly wrought together with the music, in "Ca' the Yowes to the Knowes":

Ghaist nor bogle shalt thou fear;
Thou'rt to Love and Heaven sae dear,
Nocht of Ill may come thee near,
My bonnie Dearie.

and the protective gentleness of "Oh, Wert Thou in the Cauld Blast," written as he lay dying for Jessie Lewars who helped nurse him, to her favourite air, "Lennox Love to Blantyre." Here the dying man reversed the actual roles of himself and the girl and wrote as the protecting male. (All excerpts from James Kinsley, *The Poems and Songs of Robert Burns;* Claredon Press, Oxford, 1968).

Lyrical diversity

Love songs, work songs, drinking songs—Burns achieved brilliant success in all three varieties. He is one of the few love poets who relates sex to paternity and maternity, who links the sexual ecstasy with the prospect of children, who never isolates sexual passion into a Platonic ideal removed from given human relationships but keeps it always grounded in the known facts of experience. And he could sing the songs of either sex. Where else in English—or Scottish—literature can be found the happy audacity of the song beginning "O Wha my babie-clouts will buy," the song he put into the mouth of Jean Armour when she was about to bear his child, which expresses both the female joy in sexual surrender and the female joy in maternity? Burns does not idealize lust, but he localizes and even domesticates it, something much more difficult to do. His bawdiest songs, derived from Scottish folk material, had to wait until 1965 before they were published for the general public in *The Merry Muses of Caledonia.* (A semiprivate edition had appeared six years earlier.) He is not a "romantic" poet. He never waxes enthusiastic over the mountains or the sea (he never mentions the former and very rarely the latter), but he sees the landscape of the countryside as a context within which the rhythms of human emotions and the farmer's year act themselves out.

MAJOR WORKS

Burns's first collection of *Poems, Chiefly in the Scottish Dialect* (July 1786; "the Kilmarnock edition"), contains 44 of Burns's best-known poems. The Edinburgh edition of April 1787 adds 22 poems, including "Address to the Unco Guid, or the Rigidly Righteous," "The Brigs of Ayr," and "Tam o' Shanter." The last edition to be supervised by Burns, 2 vol. (February 1793), adds another 19. James Johnson's collection, *The Scots Musical Museum,* 6 vol. (1787–1803), includes some 200 songs and fragments, with some airs, written, revised, or collected by Burns. More than 70 songs are included in George Thomson's *A Select Collection of Original Scotish Airs for the Voice,* 8 pt. (1793–1818).

BIBLIOGRAPHY. J.W. EGERER, *A Bibliography of Robert Burns* (1964), is the most complete listing of all the appearances of Burn's poetical and prose works between 1786 and 1802 and of all "formal" editions (including translations) up to the date of publication.

Editions: Many of Burns's poems and songs remained unpublished or uncollected in his lifetime; a full and definitive text of all those both acknowledged by him as his and now thought to be his may be found only in JAMES KINSLEY (ed.), *The Poems and Songs of Robert Burns,* 3 vol. (1968), containing full critical apparatus and commentary. A one-volume abridged edition without the apparatus and commentary appeared in 1969. Some famous earlier editions that include valuable biographical commentary are: J. CURRIE, *The Works of Robert Burns, with an Account of His Life and a Criticism on His Writings,* 4 vol. (1800); R. CHAMBERS (ed.), *The Life and Works of Robert Burns,* 4 vol. (1856–57), a work of massive scholarship, and its revision by W. WALLACE (the famous "Chambers-Wallace" edition, 1896), both of which are classics; and the centenary edition, W.E. HENLEY AND T.F. HENDERSON (eds.), *The Poetry of Robert Burns,* 4 vol. (1896–97), including valuable notes. The standard edition of Burns's letters is J. DE L. FERGUSON (ed.), *The Letters of Robert Burns,* 2 vol. (1931): Ferguson also has a useful one-volume *Selected Letters* (1953).

Biography and criticism: J.G. LOCKHART, *The Life of Robert Burns* (1828), was long a popular classic but contains some inaccuracies, The standard modern biography is F.B. SNYDER, *The Life of Robert Burns* (1932); although R.T. FITZHUGH, *Robert Burns: The Man and the Poet* (1970), adds some factual details and is very full. J. DE L. FERGUSON, *Pride and Passion: Robert Burns, 1759–1796* (1939), is an admirable portrait of Burns the man. D. DAICHES, *Robert Burns,* rev. ed. (1966), gives a full account of both the man and the poetry, while the same author's *Robert Burns and His World* (1971),

sets the man and his work clearly in the context of his time and place. T. CRAWFORD, *Burns: A Study of the Poems and Songs* (1960), is a critical and scholarly study for the student.

(D.Da.)

Burns

Burns are a major and unique problem in the field of injury and surgery. In the majority of other injuries or forms of surgery, a person usually remains in a precarious balance between life and death for only a few days and then either recuperates or succumbs. After one has experienced deep or extensive burns, his life remains in jeopardy for weeks; and he must receive intelligent and unremitting care if he is to survive.

The problems encountered in the treatment of burns were so great and so unfathomable that until recently only a few doctors would devote the time required to caring for burn patients. Probably in no other field of medicine has so little progress been made and treatment been so mismanaged. Only after World War II have there been significant advances in the theory and practice of burn trauma management.

Early treatments of burns

Since ancient times, burns have been mishandled. Emollient preparations with bizarre ingredients were placed on the burn wound as a standard form of treatment. Purgation and bleeding were popular treatments throughout the Middle Ages. Until recently the best form of treatment prescribed consisted of washing the burn wound with soap and water, leaving it exposed to the air, and giving the patient salt water to drink.

In 1607, Fabricius Hildanus recognized three degrees of burns. In 1750 David Cleghorn recognized that purgation was harmful to the patient. By 1905, some physicians were cognizant of the fluid and salt losses sustained by the burn patient. In some medical circles, intravenous salt solutions were prescribed. More appreciation of the enormous quantities of water, salt, and protein losses was shown by Frank Pell Underhill in 1930, by Oliver Cope and F.D. Moore in 1947, and by E.T. Evans in 1952. Although it had been performed earlier, skin grafting came upon a firm basis through the work of Jacques Louis Reverdin in 1869; Karl Thiersch in 1874; and Blair, Brown, and Davis in 1939.

Local treatments of all types have been tried through the centuries. No local treatment that was not actually harmful was used, however, until Alexander Burns Wallace, Truman Graves Blocker, and Edwin J. Pulaski popularized the exposure method of burn treatment in the late 1940s. This method had previously been described but had been discarded in favour of methods such as treatment with tannic acid, gentian violet, and concentrated silver nitrate.

The Brooke Army Surgical Research Group in San Antonio, Texas, emphasized in 1953 that septicemia was a major cause of death in burns. Probably the most important recent advance in the treatment of burns has been the local application of bacteriostatic agents. The Brooke Army Group also popularized homografting (grafts taken from another person) and heterografting (grafts taken from animals) as a means of temporary physiologic coverage of the burn wound. The patient with a deep burn must eventually be covered with his own skin, however, as skin from other people or animals is rejected, just as other transplants tend to be rejected, except among identical twins.

CLASSIFICATION OF BURNS

Classification of burns by degree

Depth. In the past, the depth of a burn has usually been classified as being one of three degrees: first, second, or third degree. The first-degree burn is a redness of the skin such as is seen in sunburn; the second-degree burn is a partial-thickness burn with blister formation such as is seen in hot-water burns; the third-degree burn is a full-thickness burn such as is seen in clothing burns (Figure 1).

The first and third classifications have remained essentially accepted but, in recent years, many different depths have been observed within the second-degree burn classification—the partial-thickness burns. E.R. Crews subdivides the second-degree classification into "superficial second-degree burns" and "deep second-degree burns." In part, this differentiation in classification within the second-degree burn category arose from the observation that spontaneous healing or epithelization occurs in some burned areas that, upon initial examination, appear to be full-thickness burns.

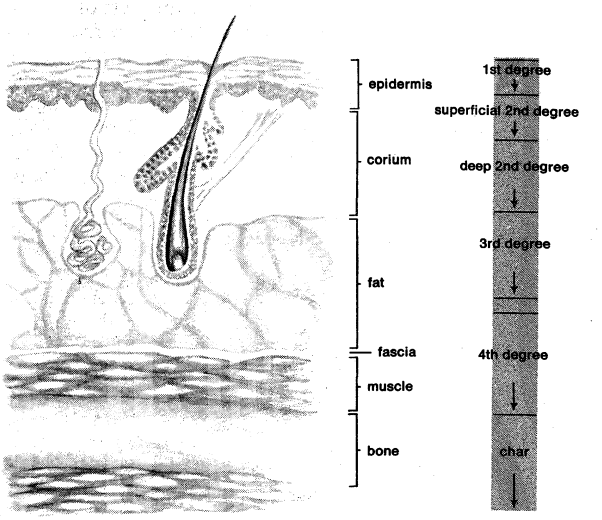

Figure 1: Depth of burn as classified by degree.

With newer drugs and improved methods in the use of bacteriostatic local agents (agents that suppress bacterial growth in the wound), the bacterial flora has been reduced to such an extent that there is little interference with spontaneous healing. Even though some of the deeper second-degree burns do not epithelize within the usual time (40 days), the grafting area is reduced and the graft takes are better, with a more satisfactory end result. In the past, partial-thickness burns were converted to full-thickness burns because of infection. Third-degree burns, or full-thickness burns, result in coagulation necrosis (death) of all layers of the skin. Deeper burns that involve fat, muscle, and bones may be classified as fourth-degree burns.

Without infection, superficial second-degree burns will heal in approximately two weeks. Deeper second-degree burns are not usually healed within three weeks; but within 21 to 30 days the crust is separated and one may observe deep layers of skin (corium) with a pigskin appearance, in contrast to raw or granulation tissue that is observed at this time in third-degree or full-thickness burns.

Area and relationship to survival. The area of the burn, the depth of the burn, and the age of the patient generally determine the survival of the burned patient. Except in the aged, the physician may expect survival with a much more extensive second-degree burn than in a full-thickness burn. Patients with second-degree burns over 70 percent of the body commonly survive. Patients with third-degree burns of this magnitude usually succumb; only rarely does a patient with a 50 percent or greater third-degree burn survive.

There are generally two methods of measuring the extent of the burn. Figure 2 illustrates the "Rule of Nines." With this method the physician can make an immediate gross estimate of the percentage of the body surface that is burned. Figure 3, the Lund and Browder method, illustrates a way of determining the exact percentage of the burn with greater precision. The latter method is more accurate in infants and children, since the proportional area of the head becomes less while the proportional area of the thighs and legs becomes greater with increasing age. A deep burn of 15 to 30 percent in the elderly patient will frequently be fatal because of the long periods of relative immobility, the lowered resistance among the elderly, and the more frequent complications.

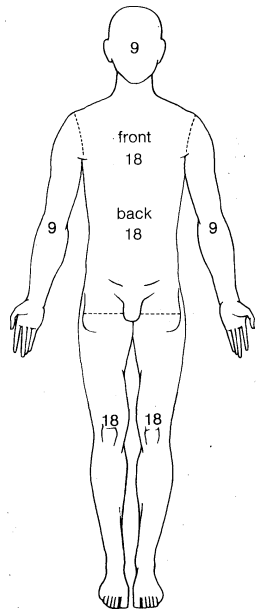

Figure 2: Estimation of percentage burn, rule of nines method.

To some extent, though not as much as in the past, the area of the body whereon a patient is burned determines somewhat his chances of survival and freedom from infection. Burns of the upper thighs, buttocks, perineum, and back more commonly become infected than other areas of the body. Circumferential burns are more prone to infection, and thus the incidence of morbidity and mortality is higher.

Occasionally burns deeper than a full thickness of the skin are incurred, as when a person or a part of his body is entrapped in a flame and not immediately extricated. Electrical burns are usually deep burns. These deep burns frequently go into the subcutaneous tissue and, at times, beyond and into the muscle, fascia, and bone. Such burns are of the fourth degree, also called black (because of the typical colour of the burn), or char, burns. Fourth-degree burns are of grave prognosis, particularly if they involve more than a small portion of the body. In these deep burns toxic materials may be released into the bloodstream. If the char burn involves only a small part of the body, it should be excised down to healthy tissue. If an extremity is involved, amputation may be indicated.

Respiratory burns are rare; when they do occur, they, too, are of grave prognosis. Smoke inhalation burns are more common. These burns occur in enclosed places from which a person cannot free himself within a few minutes. Carbon particles are inhaled into the tracheobronchial tree and cause much irritation of the tracheobronchial mucosa. There is a high instance of pneumonic complications in this type of burn. When smoke inhalation occurs with an extensive burn, it worsens the chances of survival.

PATHOLOGIC CHANGES AND PHYSIOLOGIC RESPONSES

The pathologic effects resulting from a burn are due mainly to the intensity and the duration of the heat. For example, if an area burned by boiling water is exposed to the air, the heat (100° C) is quickly dissipated, with a resultant superficial second-degree burn. Gasoline explosions, while of high heat intensity, are momentary and usually result in superficial burns. Hot cereal, hot tar, or prolonged immersion in hot water will inflict a deeper burn. Flaming clothes (fire burn) are of high-intensity heat, and clothing takes a relatively long time to burn completely. Such burns are usually full-thickness or deep second-degree burns. Other less common causes of burns include chemicals, chiefly strong acids and alkalies; X-radiation; and ultraviolet light. Internal burns are occasionally seen, such as the burning of the esophagus from swallowing lye.

Fluid losses in second-degree burns

Superficial second-degree burns. When the physician first observes superficial second-degree burns, often 30 minutes or more after burning, there is already blister formation with surrounding areas of redness. Some of the blisters are likely to have been ruptured. This is commonly called a "weeping burn," since fluid continues to weep from the surface for 24 to 36 hours. If a thick gauze dressing is applied, the dressing will usually become wet throughout within eight hours. In this type of burn, there is usually destruction of the epidermis. Contrary to popular belief, the visible fluid losses constitute only a small fraction of the total amount of fluid that is functionally lost; greater fluid losses occur deep in the wound. Underneath the wound surface, there is vasodilatation, loss of capillary integrity, with capillary permeability into the tissue spaces. This causes a leakage of fluid into the area immediately beneath the burned skin.

The fluid is mainly a salt solution, the composition of which approximates that of blood plasma. There is also some leakage of plasma, mainly of the albumin fraction; but this is of no great consequence in superficial burns. Thrombosis of small vessels in and around the wound is of little consequence in this type of burn. Fluid losses in the burn wound cease within 36 to 48 hours, and after 48 hours the fluid is slowly reabsorbed. Within approximately one week, the vascular continuity is restored. It takes approximately two weeks for this type of burn to heal if it does not become infected. The fluid and salt loss from the vascular system is considerable. This loss varies according to the percentage of the body surface area affected.

posterior trunk	13	both upper arms	8	both feet	7

Figure 3: Estimation of percentage burn, Lund and Browder method (see text).

Deep burns. All burns deeper than a superficial second-degree burn will be described herein as deep burns. This includes deep second-, third-, and fourth-degree burns. The pathologic physiology of these burns will be described as a unit, since the fluid losses are similar, although the destruction and stages of repair are different.

In these deep burns, there is an immediate coagulation necrosis of the skin. There is very little weeping from the surface. Immediately under the skin, in the subcutaneous tissue, there is a loss of integrity of the capillaries, the venules, and arterioles, with vascular occlusion and thrombosis. There is agglutination of red cells within all the surrounding small vessels. The deeper the burn, the more pronounced and widespread the thrombosis. As a result, there is generalized sludging of blood within the blood vessels in and around the area of the burn, causing decreased blood flow with hypoxia to the area of the burn. In deep burns, the nerve endings are destroyed, and there is little or no pain in the region of the burn.

The resultant injury causes a leakage of salt-rich and plasma-like fluid into the burn beneath the burn surface. This loss is uncontrollable, rapid, and persistent. Until it is reabsorbed by the body, this fluid remains stagnant; and there is almost no circulation underneath the burn wound surface. The body's immediate reaction is comparable to that seen with acute hemorrhage; there is rapid pulse, generalized vasoconstriction, and thirst; but there is not much immediate loss of red blood cells.

Loss of salts, proteins and plasma

The predominant losses in this injury are salt, water, and plasma proteins. The composition of the electrolyte loss approximates that of blood plasma. The plasma loss is mainly of the albumin fraction, since this molecule is smaller than that of the globulin. This loss approximates three grams per litre in the extravasated fluid. The body reacts by withdrawing salt water from the unburned interstitial tissue spaces until adequate intravenous fluid treatment has been given. The kidney stops functioning almost completely immediately after an extensive burn.

With these previously mentioned electrolyte and plasma protein losses, there is an increase in blood viscosity accompanied by a high hematocrit, or ratio of volume of packed cells to volume of whole blood. There is generalized impairment of blood flow throughout the body with a resultant generalized low oxygen level, dehydration, hyponatremia (low serum sodium), and metabolic acidosis. As a result, there is increased heart rate, vasoconstriction, decreased cardiac output, decreased venous return, and decreased pulse pressure and blood pressure. Because of increased peripheral resistance, increased blood viscosity, and hemoconcentration, there is a decreased effective blood volume.

Systemic reactions to deep burns

Within about an hour, in a large burn, if fluid replacement has not been adequately instituted, these losses begin to impair important organ functions. Signs of shock become manifest: there is paleness, coolness, restlessness, thirst, rapid pulse with evidence of impaired circulation, and a drop in blood pressure. If treatment is not begun early, or if it is given in inadequate measure, protective stress hormones are evoked in increasing quantities. These hormones, while protective during the immediate shock period, may cause an adverse effect once adequate treatment has been begun.

Fluid losses are greatest within the first few hours after burning. Thereafter, the losses are less rapid but continue and are persistent for 36 to 48 hours. These losses cease when the tissue pressure rises and equals that of capillary hydrostatic pressure and the capillary endothelium returns to normal beneath the damaged area. The degree of homeostatic pathologic change that occurs is determined by the time elapsing after the burn until intravenous fluid treatment is instituted and by the adequacy of the fluid treatment given. If treatment is adequate, with rapid replacement of a balanced salt solution, there is minimal alteration of physiologic responses, although some pathological body changes are inevitable—continued high hematocrit, high urinary specific gravity, rapid heart rate, and decreased cardiac output—with present methods of treatment.

If treatment is inadequate, there will be continued withdrawal of salt solutions from the unburned extravascular and extracellular spaces to replace the unremitting losses into the sequestered burn wound. There will be continued inadequate renal blood flow, with low urinary output and protracted inadequate circulation throughout the body. The longer this impaired circulation persists, the more damage to important organ functions will be incurred. This detriment may be reflected later in the course of the burn treatment.

After about the 48th hour, there is a sealing of the capillaries, and reabsorption of the extravasated fluid begins, chiefly by the way of the lymphatics. This reabsorption of fluids is slow and, in uncomplicated cases, takes approximately three to four days. The reabsorption of fluids is delayed if there is infection, and infection spreads rapidly with impaired circulation in the burn wound.

Clinically, one may observe the maximum accumulation of fluid in the tissues at the end of 24 hours after the occurrence of the burn. This may be most evident when a patient has been burned on the head and face. At this time, the head and face resemble a basketball, with the eyes completely closed. After reabsorption of fluid occurs, the contours of the burned surface become relatively normal.

In deep burns, the loss of integrity of the skin causes marked increase in water vaporization from the burn surface. This vaporization causes heat loss, and these processes continue until the integrity of the skin is regained either by re-epithelization or by skin grafting.

From the onset in a large burn, there is marked catabolism, or breakdown, with a negative nitrogen balance that continues until the patient has received a skin graft or until epithelization occurs. There are many obvious explanations for this, including caloric loss from evaporization, hypermetabolic stress due to adrenocortical hyperfunction, and the obvious need for reparative processes. Infection also increases catabolism.

There is a loss of potassium from both the burned tissues and hemolysis (or destruction) of erythrocytes. This results in early transient hyperkalemia (high blood potassium), which is usually of no clinical significance. After about the fourth day after the burn, there may be potassium depletion that requires replacement.

In a deep second-degree burn, a "crust" is formed out of the dried secretions from the burn wound. The dead skin in a third-degree burn is called an eschar. The crust or the eschar starts separating from the wound edges in about 14 days, and there is a continued slow separation thereafter between this dead tissue and the underlying healthy tissue. The separation may become complete in 21 to 40 days. Even after removal of the crust or eschar, there usually will remain numerous strands of dead tissue that must be removed before grafting. When removal of the crust is complete in a deep second-degree burn, the tissue has a pigskin appearance and numerous areas of deep skin follicles are evident. This tissue may epithelize if the burn is superficial, but if it is deep it will usually not heal without the aid of grafting. In full-thickness burns, when the removal of the eschar is complete, raw or granulation tissue is evident.

If there is infection in a deep second-degree burn, the septic growth may destroy the deeper skin (corium) and convert the injury to a full-thickness burn. If there is infection in a third-degree burn, it may invade deeper tissues and cause systemic infection or septicemia. Skin grafts usually are not successful on an infected wound.

Complications: liver, heart, lung, and gastrointestinal damage

As mentioned above the most obvious sign of enormous fluid losses in large burns is an almost complete renal shutdown. This is a reflection not only of the losses into the burn wound but also of the massive withdrawal of salt-containing fluid from the unburned tissue spaces throughout the body with resultant extreme dehydration. If fluid replacement is not prompt and adequate, the patient may succumb from the ensuing shock. Renal failure is a direct result of inadequate or late fluid replacement.

Liver damage, heart damage, and lung and brain damage are the result of prolonged impaired circulation aci-

dosis, and lack of oxygenation to the cells of these organs. Low levels of serum proteins always result from a large burn even though plasma has been used in the fluid treatment of the burn. This results in a low osmotic pressure in the vascular system. In the early stages of such a burn, treatment of shock with intravenous electrolytes is of primary importance. When sufficiently large amounts of electrolytes have been given intravenously to restore circulation and to produce adequate urinary output, and this urinary output is maintained, the physician may presume that he has mastered the shock phase of the treatment of the burn patient.

Gastrointestinal complications are common in large burns. Patients often suffer paralytic ileus (nonmechanical bowel obstruction) for several days following an extensive burn. The larger the burn, the more prolonged will be the ileus. Patients usually will not tolerate any liquids by mouth for one or two days after an extensive burn. They ordinarily will not tolerate any type of high-calorie diet for at least a week after their burn. Stomach swelling is a complication sometimes seen in burns. Patients with extensive burns have poor appetites, and it is extremely difficult to keep them in good nutrition; forced tube feeding may be required.

Not infrequently, patients with extensive burns develop ulcerations of the upper gastrointestinal tract called "Curling's ulcers." Such ulcers are most commonly seen in the stomach and duodenum, and frequently result in massive hemorrhage; they also may perforate into the abdominal cavity. Antacids and anticholinergic drugs have not been found to be of significant benefit. Gastrectomies often are necessary to control massive hemorrhage. These ulcerations usually manifest themselves during the first week but may occur later. The incidence of these ulcers in large burns, observed by a surgical research unit over a period of 13 years, was 13 percent. This complication carries a very high rate of mortality. It is E.R. Crew's opinion that these ulcers are of stress origin and are the result of late or inadequate fluid treatment during the shock phase.

Patients with large burns have a high metabolic rate and remain in negative nitrogen balance until their burn wounds are covered with a graft or epithelize. Avitaminosis is common, and these patients must receive large doses of vitamins, particularly B-complex and C.

Because the physician must give intravenous fluids over a prolonged period, thrombophlebitis—inflamation of the vein with formation of an obstructing blood clot—is common. This condition is usually chemical in nature; if there is also infection, the vein should be excised. Pulmonary emboli may occur but are rare.

In the infant, special care must be given to the administration of fluids as there is danger of overload or underload. Infants and children are also difficult feeding problems.

The aged suffer a high mortality and morbidity rate even with less extensive burns. Older people have low cardiopulmonary reserve and can be easily overloaded with fluids. Aging affects all the organs of the body; there is lowered resistance to infection. Old people do not tolerate remaining in one position over a prolonged period. They are difficult feeding problems and frequently become disoriented.

Complications: respiratory injury, infection

Respiratory burns are extremely serious. They are usually associated with large body burns. The inhaled heat does not commonly cause a burn below the vocal cords but will cause internal thermal injury of the mouth, posterior pharynx, and upper larynx. The ensuing edema usually necessitates tracheostomy. Smoke inhalation commonly is seen when a patient is trapped in an enclosed burning building. The carbon particles that are deposited throughout the tracheobronchial tree cause severe irritation to the tracheobronchial mucosa and predispose to pneumonic complications. Pneumonia, as a cause of death in burns, seems to be increasing even when there is no respiratory tract damage from the burn.

Burn-wound sepsis and septicemia are, at present, the most common cause of death in large burns. Sepsis during the first week after the burn is most commonly caused by *Staphylococcus aureus.* Later, after the second week, the most common causative organism of burn wound sepsis and septicemia is *Pseudomonas aeruginosa.* Other organisms commonly causing infection in burns are *Streptococcus, Proteus vulgaris, Aerobacter aerogenes,* and *Escherichia coli.* Viral and fungus septicemias are rare complications.

There are two major difficulties in treating deep infections in burns: first, the early recognition of an infective process and the determination of the causative organism in order to select the proper antibiotic; and, second, the prompt administration of the selected antibiotic. Thus, early burn symptoms such as disorientation, anorexia, gastric distention, and fever are indications for the administration of antibiotics that are effective against *Staphylococcus aureus.* Later deep infections, usually caused by *Pseudomonas,* are frequently manifested by purulent exudate, a discoloured and unhealthy appearance of the burn wound, redness surrounding the burn wound, and general deterioration of the patient's condition. The patient's temperature may be elevated or subnormal. Unfortunately, these later invaders of the burn wound, particularly *Pseudomonas,* are not particularly susceptible to any of the antibiotics now available. For this reason, it should be emphasized that intensive prophylactic local care of the burn wound is of prime importance in order to suppress the growth of these organisms before they become uncontrollable.

There are particular complications that occur when specific areas are burned. The ears are frequently burned when the head is burned. The skin over the ears is thin and chondritis is a common complication. Chondritis usually causes the loss of the structure of the ear, namely, the cartilage. Burns of the eyelids are not uncommon and, if deep, cause ectropion, which prevents the eyelids from closing. This necessitates suturing the lid margins together and early grafting of the eyelids.

In deep circumferential burns of an extremity, there is often a tourniquet-like effect that causes loss of circulation to the hands and feet. In these circumstances, incision through the eschar (escharotomy), particularly over the joints, is necessary to release this constricting effect and allow free blood flow to the distal part.

Cystitis may be a side effect because prolonged catheterization is necessary. At times, bladder stones are formed.

Deep burns often involve structures deeper than the skin, such as bones and joints. They occur with prolonged exposure to fire and also are seen in electrical burns. They are extremely difficult to treat and usually cause marked loss of function of the part. They are prone to infection and should have early excision for purposes of drainage. Repeated debridements are usually necessary.

Burns of the hands are common and are crippling if not treated correctly. The skin of the back of the hands and fingers is thin; if the tendons and joints are to be salvaged, intensive physical therapy and early grafting are necessary. Frequently hand burns are associated with extensive body burns, and it is often difficult to give adequate treatment simultaneously to the hands and to the body as a whole.

Contractures are a common complication of burns and usually occur over joints. The contractures are not as severe or disabling if grafting is done early. When contractures are severe or disabling, plastic surgery may be necessary later.

TREATMENT

Specialized treatment facilities. The care of burns requires dedication from doctors, nurses, and attending personnel. Burned patients are among the most difficult nursing problems in the field of medicine. Large burns require constant attention. During the shock phase, hourly recordings of intake and output of fluids are necessary, with a need for frequent adjustment of intravenous fluids. Cleanliness, isolation technique, nutrition, dressing changes, and the like are daily necessities throughout the

Burn treatment centres; emergency measures

course of burn treatment. To treat a hospitalized burn adequately, special treatment facilities should be available and should include doctors and nurses with knowledge of burn care. Since burn patients require isolation and special attention, they should be kept in the same area of the hospital where nurses are trained in burn care.

Several large burn disasters in recent years have indicated the necessity for burn treatment centres. Truman Graves Blocker, in Galveston, and the Brooke Army Group, in San Antonio, Texas, established the world's first well-known burn unit in the late 1940s. More recently, numerous burn units have been established. The Shriners have built, and support, three centres in the United States for the treatment of burned children. In Europe, burn centres or services exist in Rome; Birmingham, England; Edinburgh; and Prague.

Types of treatment. The depth of the burn is due in part to the duration of the heat; hence the burned area is cooled immediately to stop this process. If the burn is small, application of ice cubes is most beneficial. If the burn is large, the patient may be put in a shower or covered with towels soaked in ice water. No ointment or preparation of any type should be applied to the burn wound. The physician will have to clean the burn wound as part of the treatment, and it is much easier and less painful if the wound has not been covered by any preparation. If the clothes are in flames, a blanket may be wrapped around the body to extinguish the flames. The cooling procedures mentioned above are then followed.

After shock therapy (intravenous fluids) has been started, the burn wound and the body in general are thoroughly cleansed with a warm detergent solution and the dead tissue is debrided. This procedure is performed with the patient under intravenous narcotic analgesia. The patient is not given a general anesthetic.

In superficial burns of less than 15 percent of the body surface, except in infants and the aged, intravenous fluids are not necessary. The patient may drink a soda-salt solution for replacement.

In larger burns, intravenous replacement with a salt solution is a necessity. There is some disagreement among groups regarding the composition of the electrolytes that should be given and whether plasma expanders (dextran) should be used. The majority of authorities favour electrolytes that approximate the concentrations seen in blood plasma, namely, lactated Ringer's solution, since this is the composition of the loss in the burn wound. The rate of administration of intravenous fluids and the quantity given vary with the extent of the burn and the size or weight of the individual patient.

Intravenous fluid regimens

Many formulas have been devised for the rate and quantity of fluids that should be given during the first and second days after the burn, but none apply exactly to a particular patient. These formulas are useful only as a rough guide. Generally, the intravenous fluids are infused rapidly the first few hours; and when the urinary output approaches normal (50 cc per hour for an adult and 25 cc per hour for a child), the rate of administration of fluids is decreased. The kidney or the urinary output remains the most reliable indicator of adequate hydration.

In large burns, the rate of administration of fluids the first hour or two may approximate one or two litres per hour. Thereafter, when urinary output approaches normal or becomes excessive, the intravenous intake is sharply curtailed.

Many centres continue to use an intravenous fluid regimen consisting entirely of lactated Ringer's solution. Others simultaneously administer plasma after the first few hours of electrolyte administration. Some centres use dextran for this purpose, though more than two litres of this solution may cause a tendency to bleed.

In the aged or the infirm, central venous catheters are inserted into the superior vena cava to measure pressures in order to insure that overloads of fluid are not administered. Fluids in the amount of 10 to 20 percent of the patient's body weight may be necessary in the first two days of treatment of patients with extensive burns.

Generally, no more electrolytes or plasma are given after 48 hours. Intravenous fluids in the form of five percent glucose in water are continued after this time, and the patient is allowed oral fluids as desired. Intravenous fluids are continued until the patient can drink an adequate amount of water. Food is given as desired.

During the reabsorption phase, large amounts of urine that contain concentrated electrolytes are excreted. No attempts are made to force the patient to eat during the first week after a large burn, as a paralytic ileus continues during this time. Frequent feedings are encouraged when the patient is able to tolerate them.

"Closed" treatment and "exposure"

Accepted methods of treatment of "superficial second-degree burns" are either the closed treatment or the exposure treatment. The initial treatment consists of thorough cleansing of the burn wound with a warm detergent solution, copious irrigation, and debridement of the dead or blistered skin. This is usually done with intravenous narcotic analgesia. All of the blistered skin is removed and the burn and surrounding skin are thoroughly cleansed. If the burn patient is to be admitted to the hospital, the burn wound is exposed to the air. The wound and the surrounding skin are cleansed daily with a detergent solution. The dried secretions form a crust that falls away in about two weeks. If the patient is to be treated as an outpatient, the closed treatment is preferable. This consists of a water-soluble ointment dressing covered with a bulky gauze dressing and bandages securely applied. Most of these burns heal without incident in 14 days. Occasionally, such a burn will become infected; the patient will then require hospitalization for treatment of the infection.

Early forms of treatment

Before 1965, the most popular treatments for "deep burns" were the closed treatment and the exposure treatment. The closed treatment had many deficiencies. The physician was unable to sterilize the burn wound no matter how long he washed or whatever the agent used. The bacteria in the sweat glands and hair follicles could not be reached. The warm, moist environment on the burn surface in an enclosed dressing was an ideal situation for bacterial growth, and deep burns almost invariably became infected when the closed treatment was used. With the exposure type of treatment, better results were obtained, as in full-thickness burns there was a dry, hard eschar and in deep second-degree burns a dry, hard crust was formed. The dryness of the exposed wound inhibited bacterial growth. There were deficiencies in this type of treatment also; namely, when the patient was forced to lie on his burn (a circumferential burn) the warmth and moisture promoted bacterial proliferation. Furthermore, the dried eschar or crust did not promote epithelization in the deep second-degree burns. If there was any infection present in deep second-degree burns, they were readily converted into full-thickness burns.

In deep burns, before 1965, grafting was usually delayed until all the eschar and all the necrotic tissue was removed. This delay could last 25 to 40 days, and during this time many distressing complications could occur. Part of the wound would be debrided and the granulations exposed to infection, and part would still be covered with an eschar. Grafts would not take on the granulations at this time unless exposed to the air. When the surgeon finally completed his debridement in large burns, he would find that there was not enough donor skin on the patient's body to cover the exposed raw area. He would then graft whatever he could cover and would, of necessity, await re-epithelization from the donor areas (21 days), in order to reharvest additional grafts. If the original grafts took well, there was a chance of recovery. If they did not take, there was disaster. Meanwhile, during this interval of awaiting regrafting, the exposed granulation would become less receptive to grafting, and the patient's general condition would deteriorate. Homografts were used to solve some of these problems of coverage of the raw tissue. These grafts also had disadvantages as, if these homografts took as grafts, they would begin to be rejected by the body after the 15th day. One could not then graft these areas for an additional month.

The surgeon did not usually attempt to debride these large burn eschars surgically as there was always infection underneath, and surgery would predispose to a breakdown of the body defenses and open avenues to invasive infection that would usually cause septicemia and death of the patient.

Newer treatments

In 1965 two new forms of local treatment for burns evolved. One of these, was the use of silver nitrate wet soaks to cover the burn wound. The originator observed that concentrated silver nitrate, while it would kill bacteria, would also destroy live tissue. He recommended a dilute silver nitrate solution (0.5 percent), as this would inhibit bacterial growth and would not destroy living tissue. This treatment was to be given immediately after wound cleansing and debridement. The patient's burn wounds were completely wrapped in thick gauze bandages, and this gauze was kept saturated with the silver nitrate solution at all times. The treatment retarded bacterial growth and allowed epithelization in deep second-degree burns. The bacteriostatic effect was only on the surface of the burn wound and did not penetrate.

The second new treatment advocated was by the research group at Brooke Army Hospital. This treatment was with mafenide (Sulfamylon) in a water-soluble ointment applied to the burn wound with the gloved hand. The ointment was spread twice daily over the burn wound in a thin layer. The excess and dried ointment was removed once or twice daily in a Hubbard tank, an agitated bath that has been developed for this purpose. This treatment caused a marked diminution in bacterial growth on the burn wound and, particularly, it inhibited growth of *Pseudomonas*. The sulfa would penetrate the burn wound eschar or crust and be an effective bacteriostatic agent in the subcutaneous tissue. The surgeon could place grafts on granulation tissue alongside the eschar and the grafts would take.

A third form of treatment is credited to the Brooke Army Group. This is known as temporary homografting. As mentioned above, homografting (skin grafts taken from another person) had been used for a number of years, but it had disadvantages. The Brooke Army Group observed that if homografts were placed on the granulating tissue and were removed within four to five days, the grafts would not take and they could be reapplied in a similar manner indefinitely, being removed each time after four or five days. This procedure offered an excellent physiological coverage and eliminated the water vaporization and caloric loss and also eliminated bacterial growth from the wound.

The above forms of treatment were notable advances. Each has saved many lives that otherwise would have been lost. As with other forms of treatment, however, each of these forms has its imperfections, and there are elements of danger if the treatment is not used by experts familiar with the possible side effects.

Silver nitrate withdraws sodium, chloride, potassium, and calcium from the burn wound in direct proportion to the extent of the burn. These elements must be replaced daily, either orally or parenterally. The dressings must be constantly wet to avoid cauterization of newly formed epithelium. Silver nitrate stains everything it touches. This type of treatment is time-consuming and requires attentive nursing care.

Mafenide is absorbed and blocks carbonic anhydrase in the kidney, causing acidosis. The respiratory rate is increased during treatment. Pneumonia is not uncommon and, if it occurs, the treatment must be stopped or delayed. Mafenide also retards epithelization to some extent.

Temporary homografts are ideal if the physician or burn team can procure them or has the time to collect them. These homografts are usually taken from the body of a person recently deceased. Permission to do so must be secured, and the homografts must be taken in the operating room under sterile conditions. Acquiring these grafts takes considerable time and effort. If the grafts are used as "temporary homografts," large quantities of the grafts must be used and this requires many donors.

Only one institution, the Brooke Army Hospital, is geared to taking these grafts in quantities necessary for the treatment of many burns in this fashion, although other institutions are employing temporary homografts to a lesser extent.

Freeze-dried skin also is useful as a physiologic dressing or coverage, but its use is restricted because of limited facilities. Heterografts (skin grafts taken from animals) also have been used as temporary coverage.

Other types of local treatment are being developed to combat local infection; namely, other types of local bacteriostatic ointments such as gentamicin and silver sulfadiazine.

To expand donor skin coverage, grafts may be "meshed." Small slits are cut in the skin graft by a machine and, when expanded, form a type of lace network increasing the coverage two to three times the width of the graft.

Although antibiotics play an important role in the treatment of burns, antibiotics are rather ineffective once burn wound sepsis or septicemia has developed, particularly if *Pseudomonas* is the causative organism.

Nutrition and nursing care

Burned patients require a high intake of vitamins. Adults require supplemental B-complex and C vitamins. Infants and children require additional A and D vitamins.

Patients with large burns cannot be force-fed during the first week. The larger the burn, the more prolonged will be the paralytic ileus that accompanies all large burns. Hourly liquid feedings in small amounts are given after the second day.

After a week, or sooner if the burn is less extensive, the patient is placed on a high-calorie diet with frequent feedings. These patients must be kept well nourished if they are to survive. They generally stay in a negative nitrogen balance and continue to lose weight until they receive grafts.

These patients have little appetite and must be encouraged to eat more than they really desire. Numerous high-protein feedings have been devised in the past years, but all have been failures. They are unpalatable; and if given in large quantities or by tube feeding, they cause vomiting and diarrhea. Whole food has been found to be the feeding of choice. Even in infants, the choice of feedings, either orally or by tube, is strained baby food mixed with small quantities of milk. For adequate nutrition, nurses, aides, and even the family play an important role. Extensive burns usually involve the upper extremities, and the patients have no use of their hands and must be fed. Frequently, it may require an hour to get an adequate meal into a patient. Also, the patient may have particular likes and dislikes for certain foods. These food preferences must be catered to.

A patient with a large burn becomes extremely dependent upon those who care for him. He requires close nursing attention throughout the day and night. He is in constant discomfort. Tranquillizers are of benefit to lessen the discomfort.

After grafting, if the grafts take well, there is a dramatic psychological change in the behaviour of the patient. Whereas he has been querulous and dissatisfied, he now becomes smiling and good-natured and has an excessive appetite. In spite of cosmetic and functional deformities that may exist, he remains optimistic and is glad to be alive.

The surgical treatment employed in burns consists mainly of debridement, grafting, and plastic repairs after healing.

Skin grafts taken for burn coverage are split-thickness grafts taken between 0.008 and 0.012 inch in thickness. These usually are taken with an electric or air-driven dermatome. The donor areas commonly are covered with one layer of bandage gauze and exposed to the air. The recipient area is covered with the graft. This may be placed on the granulating surface of the wound with or without suturing. The grafted area either may be enclosed in a dressing or left exposed. There are many different techniques and dressing complexes used in grafting, but once the graft has been put in place, no slippage

must occur. Mesh-grafting and homografting have been previously discussed.

PROGNOSIS

Factors that affect prognosis

The prognosis in burn patients depends upon many factors: the extent of the burn, the depth of the burn, the age of the patient, the hospital facilities for the care of burns, and the knowledge and attention of the physicians and nurses who care for these patients. Expert care of burns decreases scarring, contractures, cosmetic deformities, hospitalization time, and morbidity and mortality.

In general, the aged succumb to a lesser burn than do young or middle-aged patients. Infants have a higher mortality rate than children or adults. The adequacy of early treatment of the shock phase alters the prognosis greatly. The health of the individual at the time of the burn varies the prognosis. Cardiovascular, renal, or liver dysfunction increases the mortality rate.

It has been established that at present the principal cause of death in large burns is infection. Hundreds of methods have been tried over the past years to combat or control infection, but it was not until 1965 that appreciable progress was made in this direction. Mafenide, silver nitrate dressings, gentamicin ointment, silver sulfadiazine ointment, and other bacteriostatic agents have shown promise in reducing infection in burn patients. Homografting and heterografting also are useful in combatting infection and are helpful as temporary coverage for the burn wound.

The prognosis with a deep burn covering 50 percent of the body surface is good in centres equipped to treat burns. The prognosis also is good for a superficial burn covering 70 to 80 percent of the body surface.

Formerly, when a person with what appeared to be a full-thickness burn that was caused by fire was admitted to a hospital, the burn actually became a full-thickness injury eventually; and the only epithelization that occurred came from the edges of the burn wound. At present with local infection controlled by bacteriostatic agents, many of these apparently deep burns turn out to be deep second-degree injuries that in many instances will epithelize and thus will not require grafting. Hospitalization time is now shortened, deformities decreased, and the results are much improved in the treatment of burns.

In spite of all the advances that have been made in the treatment of burn patients, large burns are still a catastrophe. Such burns average the most prolonged hospital time of any injury, and the cost of treating a burn is the greatest of any type of trauma or surgical event.

The yearly meetings of the American Burn Association, formed in 1967, attract personnel who are interested in burn care. This has added greatly to the dissemination of knowledge and has stimulated much research. The International Burn Society was established in 1965; this society meets every four years to disseminate current knowledge of burn therapy world wide.

It is now possible to save many more persons with extensive burns than in previous years; and as proficiency in saving patients with large burns grows, it becomes certain that most of the patients with smaller burns can be salvaged. Unfortunately, the more sophisticated regimens of burn treatment cannot be employed in many parts of the world. The local preparations mentioned as bacteriostatic agents are expensive and cannot be afforded in many countries even if these agents are available.

Bursa

Synovial and other bursas

A bursa is any small pouch or sac within the body. The bursas have been classified as adventitious, subcutaneous, and synovial. Adventitious, or accidental, bursas arise in soft tissues as a result of repeated subjections to unusual shearing stresses, particularly over bony prominences. Subcutaneous bursas ordinarily are ill-defined clefts at the junction of subcutaneous tissue and deep fasciae (sheets of fibrous tissue); these bursas acquire a distinct wall only when they become abnormal, and they are classified as adventitious by some authorities. Synovial bursas are thin-walled sacs that are interposed between tissues such as tendons, muscles, and bones, and are lined with synovial membrane, so called because it exudes synovia, a lubricating fluid. This article is concerned chiefly with the synovial bursas.

The precise number of bursas in man is not known. Some estimates are as high as 300; *Nomina Anatomica* lists 52. In Alexander Monro's classic treatise (1799), 156 are listed as recognizable with the naked eye, but this figure is probably excessive because it includes what later came to be distinguished as tendon sheaths, which differ from bursas only in that they envelop tendons. Most bursas are located near the large joints of the arms and legs. Three are present at the larynx.

Bursitis. The term "bursitis" comprehends all types of inflammation of the bursas. Bursas sometimes are involved along with the joints and tendon sheaths in rheumatoid arthritis and gout. Infectious agents introduced by penetrating wounds or borne by the bloodstream also may result in bursitis, but this is unusual. Tuberculous lesions restricted to bursas are rare occurrences and represent instances of infections borne by the bloodstream; more often the bursas are affected because they are next to centres of tuberculous infection in adjacent bones. The prepatellar bursa, located on the lower part of the kneecap, is especially subject to involvement in brucellosis (undulant fever). Although earlier medical literature described inflammation of the synovial membrane and bursitis as manifestations of early acquired syphilis, this view is not accepted today.

Causes of bursitis

The cause of most cases of bursitis appears to be one or another local mechanical irritation. Often the injury is of occupational origin and accordingly has been known for centuries as weaver's bottom (ischiogluteal bursitis); nun's or housemaid's knee (prepatellar bursitis); and soldier's heel (Achilles bursitis). A little less than 60% of cases occur in the shoulder region, a little over 20% at the knee, a little over 15% near the hip, and 5% elsewhere. The inflammatory reaction is not a distinctly particularized one and may or may not include deposition of calcium salts. The borderline between bursitis and other painful rheumatic conditions of the soft tissues is indistinct in many instances.

The commonest form of bursitis affects the subdeltoid bursa, which lies above the shoulder joint. Bursitis in this circumstance is not the primary abnormality, but results from degeneration and calcification of the adjacent rotator tendon. Direct injury is not usually the cause of calcium deposits and inflammation in the tendon; indeed, heavy labourers are less frequently affected than persons engaged in less strenuous occupations. The possibility that there is a constitutional predisposition to this type of degeneration has been considered, but little is known about such a cause. The bursa proper is affected only when debris from the tendon extends into it, this intru-

sion being the principal cause of an acutely painful shoulder. The condition occurs most often in middle age and is infrequent among young children. Women are twice as likely to have the condition as men. The onset may be sudden and unprovoked. Pain and tenderness are great and there is difficulty in raising the arm. The calcium deposits can be seen in X-ray films of the shoulder. No single method of dealing with the disorder in all affected persons is known, and response varies widely among individuals. Resting the arm and use of analgesics tend to lessen the discomfort, corticosteroids may reduce inflammation, and carefully graduated exercises may be used to lessen the possibility of lasting stiffness of the shoulder. Many months may pass before complete recovery is attained. Chronic inflammation of the bursa at the side of the hip joint—trochanteric bursitis—has a similar course.

The more clearly traumatic forms of bursitis are exemplified by "beat knee," a bursitis that develops below the kneecap of miners who must kneel over long periods to work the narrow coal seams of England. Bloody fluid distends the bursa and, unless removed early, may cause the walls of the bursa to become thickened permanently. Treatment, which involves protection from further irritation to the extent that this is possible, is otherwise similar to that for subdeltoid bursitis. A fair proportion of these lesions become infected as a consequence of injury to the overlying skin.

A bunion is an adventitious bursa that develops on the inner side of the base of the great toe in association with hallux valgus (deviation of the first toe so that it lies on top of or below the other toes). Wearing narrow, pointed shoes is a major contributory factor. Mild cases are relieved by use of proper shoes and care of the feet, but surgery may be necessary for correction of severe deformities.

Diseases of the bursa also occur in domestic animals. Capped elbow and capped hock are examples of chronic bursitis in horses, resulting from lying on hard floors, kicks, and similar injuries.

Tumours. Malignant synovial tumours typically arise from tissues about the joints proper rather than within them. The tissues around the joints must include bursas as well as the capsule and tendon sheaths, but synovial tumours confined to a bursa have not been recognized. A benign, tumourlike condition of synovial tissue, called pigmented villonodular synovitis, has occasionally been reported in bursas. So, too, has synovial chondromatosis, a rare disorder in which cartilaginous nodules proliferate in the lining of the sac.

Dis.*, 24:215–218 (May 1965), a brief evaluation of contemporary knowledge of bursae in historical perspective of Monro's treatise; J.L. HOLLANDER (ed.), *Arthritis and Allied Conditions* (1966), an authoritative textbook of rheumatology that includes several chapters dealing with bursitis.

(L.S.)

Burton, Sir Richard

One of the greatest British scholar-explorers of the 19th century, Sir Richard Burton, in a world in which there seemed to be little left to be discovered, sought out its few remaining mysteries. He was the first European to explore the forbidden Muslim city of Harer in Somaliland, he penetrated the secret cities of Mecca and Medina, and he discovered Lake Tanganyika. He was also a soldier, poet, botanist, geologist, and a leading ethnologist, linguist, and translator. Late in life his passion became the study and translation of the erotica and folk literature of the East, and today he is best known for his work in this field for which his Victorian contemporaries condemned him and for his still unexcelled translation of the *Arabian Nights*.

Early life and career. Born in Torquay, Devonshire, March 19, 1821, the son of Lieutenant Colonel Joseph Netterville Burton and Martha Baker, Burton was of mixed English, Irish, and possibly French ancestry. His father, retiring early from an unsuccessful army career,

chose to raise his two sons and daughter in France and Italy, where young Richard developed his astonishing talent for languages to such an extent that before matriculating at Trinity College, Oxford, in 1840, he had become fluent in French, Italian, and the Béarnais and Neapolitan dialects, as well as in Greek and Latin. But his continental upbringing left him ambivalent about his national identity. He called himself "a waif, a stray . . . a blaze of light, without a focus," and complained that "England is the only country where I never feel at home."

Offices in India

Expelled from Oxford in 1842 because of a minor breach of discipline, he went to India as subaltern officer in the 18th Regiment of Bombay Native Infantry during England's war with the Sind (now a province of West Pakistan). He mastered Arabic and Hindi and during his eight-year stay became proficient also in Marathi, Sindhi, Punjabi, Telugu, Pashto, and Miltani. Eventually in his travels over the world he learned 25 languages, with dialects that brought the number to 40.

As a favoured intelligence officer of Sir Charles James Napier, commander of the English forces in the Sind, Captain Burton went in disguise as a Muslim merchant in the bazaars, bringing back detailed reports. Napier in 1845 asked him to investigate the homosexual brothels in Karāchi; his explicit study resulted in their destruction; it also resulted, after Napier's departure, in the destruction of Burton's promising career, when the report was forwarded to Bombay by an unfriendly officer who hoped to see Burton dismissed in disgrace. Though the effort failed, Burton realized his reputation was irreparably clouded and returned, ill and disconsolate, to England.

From his 29th to his 32nd year he lived with his mother and sister in Boulogne, France, where he wrote four books on India, including *Sindh, and the Races That Inhabit the Valley of the Indus* (1851), a brilliant ethnological study, published before the new science of ethnology had a proper tradition against which its merits could be evaluated. Meanwhile he perfected his long-cherished plans for going to Mecca.

Exploration in Arabia. Disguising himself as a Pathan, an Afghanistan Muslim, in 1853 he went to Cairo, Suez, and Medina, then travelled the bandit-ridden route to the sacred city of Mecca, where at great risk he measured and sketched the mosque and holy Muslim shrine, the Kaʿbah. Though not the first non-Muslim to penetrate and describe the "mother of cities," Burton was the most sophisticated and the most accurate. His *Pilgrimage to El-Medinah and Mecca* (1855–56) was not only a great adventure narrative but also a classic commentary on Muslim life and manners, especially on the annual pilgrimage. Instead of returning to London to enjoy his sudden fame, however, he organized a new expedition in 1854 to the equally forbidden East African city of Harer and became the first European to enter this Muslim cita-

del without being executed. He described his adventures in *First Footsteps in East Africa* (1856).

By this time Burton had become fascinated by the idea of discovering the source of the White Nile and planned an expedition with three officers of the British East India Company, including John Hanning Speke in 1855, intending to push across Somaliland. Natives attacked the party near Berbera, however, killing one member of the party and seriously wounding Speke. Burton himself had a javelin hurled through his jaw and was forced to return to England. After recovery, in July 1855, he went to the Crimea to volunteer in the war against Russia. At the Dardanelles he helped train Turkish irregulars but saw no action at the front.

The Crimean War over, he turned again to the Nile search, leading an expedition inland from Zanzibar with John Speke in 1857–58. They suffered almost every kind of hardship Africa could inflict. When they finally arrived on the shores of Lake Tanganyika, Burton was so ill from malaria he could not walk, and Speke was virtually blind. Ailing, and disappointed by native information that the Rusizi River to the north poured into rather than out of the lake, Burton wished to return and prepare a new expedition. Speke, however, who had recovered more quickly, pushed on alone to the northeast and discovered Lake Victoria, which he was convinced was the true Nile source. Burton's unwillingness to accept this theory without further exploration led to quarrels with Speke and their eventual estrangement.

Discovery of Lake Tanganyika

Speke was the first to return to London, where he was lionized and given funds to return to Africa. Burton, largely ignored and denied financing for a new exploration of his own, felt betrayed. His *Lake Regions of Central Africa* (1860) attacked Speke's claims and exacerbated their by now public feud.

In 1860 Burton went off unexpectedly to the United States, where he travelled by stagecoach to the Mormon capital, Salt Lake City. The resulting volume, *City of the Saints* (1861), showed that he could write with sophistication about the nature of the Mormon Church, compose a vivid portrait of its leader, Brigham Young, and also be dispassionate about the Mormon practice of polygamy, which was then outraging most Americans. Shortly after his return from the United States, in January 1861, he and Isabel Arundell, the daughter of an aristocratic family, whom he had been courting since 1856, were married secretly.

Foreign office. Burton now entered the British Foreign Office as consul in Fernando Po, a Spanish island off the coast of West Africa. During his three years there, he made many short trips of exploration into West Africa, gathering enough material to fill five books. His explicit descriptions of tribal rituals concerning birth, marriage, and death, as well as fetishism, ritual murder, cannibalism, and bizarre sexual practices, though admired by modern anthropologists, won him no favour with the Foreign Office, which considered him eccentric if not dangerous.

Returning to London on leave, September 1864, Burton was invited to debate with Speke before the British Association for the Advancement of Science. Speke, who with the British soldier and explorer James Augustus Grant had made a memorable journey from Zanzibar to Lake Victoria and then down the whole length of the Nile, was expected to defend his conviction that Lake Victoria was the true Nile source. After the preliminary session on September 15, Speke went hunting, dying mysteriously as a result of a shotgun wound in his chest. The coroner's jury ruled the death an accident, but Burton believed it to be a suicide. He wrote in anguish to a friend, "The charitable say that he shot himself, the uncharitable say that I shot him."

Burton spent the next four years as consul in Santos, Brazil, where he wrote a book on the highlands of Brazil (1869) and translated *Vikram and the Vampire, or Tales of Hindu Devilry* (1870). He also began translating the works of the romantic Portuguese poet-explorer Luís de Camões, with whom he felt a deep sense of kinship. Yet his work did not help him to overcome his increasing aversion for Brazil. He took to drink, and finally he sent his devoted wife to London to obtain a better post for him. She succeeded in persuading the Foreign Secretary to appoint Burton consul in Damascus.

Back in the Near East, which he loved, Burton for a time was highly successful as a diplomat; but Muslim intrigue, complicated by the proselytizing indiscretions of his devoutly Catholic wife, resulted in his humiliating dismissal in August 1871. The details of this traumatic failure were recorded by Isabel Burton in her lively, defensive *Inner Life of Syria* (1875).

Dismissal from Damascus

Trieste. In 1872 Burton reluctantly accepted the consulate at Trieste, and although he considered it an ignominious exile, he eventually came to cherish it as his home. There he stayed until his death, publishing an astonishing variety of books. He wrote a book on Iceland, one on Etruscan Bologna, reflecting his passion for archaeology, a nostalgic volume on the Sind, two books on the gold mines of the Midian, and one on the African Gold Coast (now Ghana), none of which matched the great narratives of his earlier adventures. His *Book of the Sword* (1884), a dazzling piece of historical erudition, brought him no more financial success than any of the others. In 1880 he published his best original poetry, *The Kasidah*, written under a pseudonym and patterned after the *Rubáiyát of Omar Khayyám*.

In Trieste, Burton emerged as a translator of extraordinary virtuosity. He translated and annotated six volumes of Camões, a volume of Neopolitan Italian tales by Giambattista Basile, *Il Pentamerone*, and Latin poems by Catullus. What excited him most, however, was the erotica of the East. Taking it upon himself to introduce to the West the sexual wisdom of the ancient Eastern manuals on the art of love, he risked prosecution and imprisonment to translate and print secretly the *Kama Sutra of Vatsyayana* (1883), *Ananga Ranga* (1885), and *The Perfumed Garden of the Cheikh Nefzaoui* (1886). He also published openly, but privately, an unexpurgated sixteen-volume edition of the *Arabian Nights* (1885–1888), the translation of which was so exceptional for its fidelity, masculine vigour, and literary skill that it has frightened away all competitors. Moreover, he larded these volumes with ethnological footnotes and daring essays on pornography, homosexuality, and the sexual education of women. He railed against the "immodest modesty," the cant, and hypocrisy of his era, displaying psychological insights that anticipated both Havelock Ellis and Sigmund Freud. His *Nights* were praised by some for their robustness and honesty but attacked by others as "garbage of the brothels," "an appalling collection of degrading customs and statistics of vice."

Burton as translator

In February 1886 Burton won belated recognition for his services to the crown when Queen Victoria made him Knight Commander of St. Michael and St. George. He died of a heart attack in Trieste on Oct. 20, 1890. His wife, fearful lest her husband be thought vicious because he collected data on what Victorian England called vice, at once burned the projected new edition of *The Perfumed Garden* he had been annotating. She then wrote a biography of Burton in which she tried to fashion this Rabelaisian scholar-adventurer into a good Catholic, a faithful husband, and a refined and modest man. Afterward she burned almost all of his 40-year collection of diaries and journals. The loss to history and anthropology was monumental; the loss to Burton's biographers, irreparable.

BIBLIOGRAPHY. Burton wrote 43 volumes on his explorations and travels and over 100 articles, as well as almost 30 volumes of translations. These are meticulously listed in NORMAN PENZER, *Annotated Bibliography of Sir Richard Francis Burton* (1923, reprinted 1970). Some of the manuscript material that escaped Lady Burton's burning is now housed in the Royal Anthropological Institute of Great Britain and Ireland, London, which also has Burton's private library. ISABEL BURTON, *The Life of Captain Sir Richard F. Burton*, 2 vol. (1893), though highly romanticized, remains the best single source book. THOMAS WRIGHT, *The Life of Sir Richard Burton*, 2 vol. (1906, reprinted 1968), is largely

hostile; that by Burton's niece GEORGIANA STISTED, *The True Life of Capt. Sir Richard F. Burton* (1896), is a panegyric, with the hostility reserved for Burton's wife. For short but vivid and perceptive portraits, see FRANK HARRIS, *Contemporary Portraits* (1920) and *My Life and Loves* (1963); and an excellent account by ALAN MOOREHEAD, *The White Nile* (1960). Biographies by FAIRFAX DOWNEY, *Burton, Arabian Nights Adventurer* (1931); HUGH J. SCHONFIELD, *Richard Burton, Explorer* (1936); and SETON DEARDEN, *Burton of Arabia* (1937), are superficial; BYRON FARWELL, *Burton* (1963), is not. FAWN M. BRODIE, *The Devil Drives: A Life of Sir Richard Burton* (1967), is thoroughly documented and defines the psychological complexities of Burton's personality.

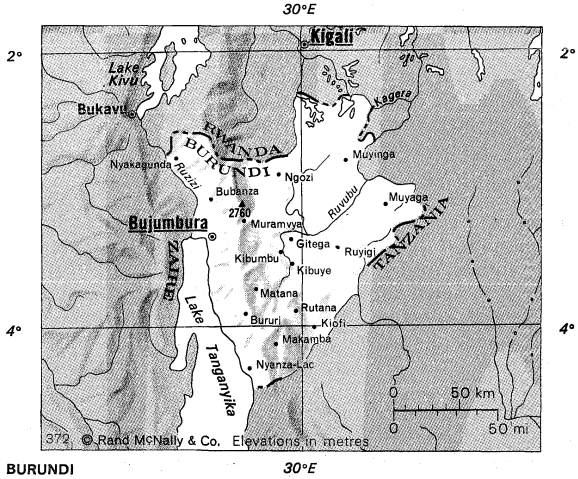
(F.M.B.)

Burundi

Burundi is a landlocked republic in eastern Africa south of the Equator; it has an area of 10,759 square miles (27,865 square kilometres) and a population of more than 3,500,000. Together with its neighbour Rwanda (*q.v.*), it is the most densely populated state in Africa, with more than 350 people to the square mile (135 per square kilometre). To the north it is bounded by Rwanda, to the east and south by Tanzania, to the southwest by Lake Tanganyika, and to the west by Zaire. The most southerly source of the Nile is considered to be the Kagera River, and the ultimate headstream of the Kagera, the Kigira-Mukasenyi, is located within the borders of Burundi. The capital is Bujumbura (population 110,000). Before independence in 1962, Burundi, called Urundi, was part of the United Nations Trust Territory of Ruanda–Urundi under Belgian administration.

For coverage of associated physical features, see EAST AFRICAN LAKES; EAST AFRICAN MOUNTAINS; and NILE RIVER; for coverage of historical aspects, see EAST AFRICA, HISTORY OF.

Burundi is a mountainous country, lying across the dividing crest of the Nile and Congo watersheds; most of



the country lies at an altitude of more than 5,000 feet (1,500 metres) above sea level. The people live primarily by subsistence agriculture; coffee is grown for export. Industry is little developed. Among the countries that help Burundi, Belgium provides the most important aid.

Historical note

Burundi as a political entity is about 400 years old; it came into existence when the tall, cattle-owning Tutsi (Batutsi), a Nilotic people from the north, established their rule over the original Hutu (Bahutu) population and a small number of Twa (Batwa) Pygmy inhabitants. Once dominated by its more powerful Tutsi-ruled sister state of Rwanda to the north, Burundi was administratively separated from it when a German colonial occupation was proclaimed in 1897. During World War I the country was occupied, in 1916, by Belgian forces from the Congo; after the war the League of Nations mandate for the two kingdoms was given to Belgium, which administered them jointly with the Congo. After World War II the two kingdoms were given the status of a United Nations trust territory. Bujumbura (then Usumbura) was the capital.

On July 1, 1962, the two territories became independent separately. Unlike Rwanda, where the *mwami* (king) was deposed before independence, a Tutsi *mwami* continued to rule in Burundi until 1966, when the country became a republic.

While more intermarriage has occurred between the Tutsi (less than one-fifth of the population) and the Hutu (more than four-fifths) in Burundi than it has in Rwanda, tension between the two groups has nevertheless led to repeated political upheavals.

Relief and drainage. Burundi mostly consists of a high plateau of ancient Precambrian rock standing on the eastern side of the East African Rift System that runs from north to south throughout eastern Africa. The Ruzizi River to the west and Lake Tanganyika to the southwest lie in the trough of the rift valley. From the lake the land rises steeply to the Congo–Nile divide, which reaches altitudes of about 8,500 feet. To the east of the divide, plateau surfaces slope gently toward the east and southeast at altitudes of between 5,000 and 6,500 feet (1,500–2,000 metres). The valley of the Ruvubu River, which flows to the northeast, cuts into the plateau. The Kigira-Mukasenyi is a tributary of the Ruvubu, one of the headstreams of the Kagera River, which forms part of the Rwanda–Burundi frontier. To the north, along the frontier with Rwanda, there are a few valleys occupied by shallow lakes.

The Congo–Nile divide

Climate, vegetation, and animal life. The climate is tropical, although moderated by altitude. The annual rainfall averages more than 55 inches (1,400 millimetres) in the highest parts of the country and less than 40 inches (1,000 millimetres) in the southwest, on the shores of Lake Tanganyika. The dry season lasts from May to August, and sometimes to September, although some rain occurs in August. Irregular rainfall sometimes adversely affects the crops and has caused famines. The average temperature on the plateau is about 70° F (21° C), with a maximum temperature of 91° F (33° C) and a minimum of 43° F (6° C) below 6,500 feet.

The mountain slopes, which are wetter and cooler than the rest of the country, are forested. On the plateau, wooded savanna is found at higher altitudes, giving way to more open savanna on the lower slopes. The animal life is varied and includes elephant, lion, leopard, hippopotamus, crocodile, buffalo, warthog, baboon, and antelope.

The landscape under human settlement. On the plateau, dwellings are dispersed, each house being surrounded by a plantation of banana trees, the fruit of which is used for brewing. There are virtually no villages. Of the total land area of the country, about 40 percent is under cultivation and another 26 percent is fallow; about 25 percent is used for pasture; the remainder is either forest or wasteland.

Bujumbura, the capital, is a port city standing at the northern end of Lake Tanganyika and is renowned for the scenic beauty of its setting. Belgians and Greeks are prominent in the commerce of its central business district; the Asian district is near the port, as is also the industrial sector. Numerous suburbs make up an unbroken sequence of African dwellings.

People and population. The population is primarily composed of three ethnic groups—the Hutu, the Tutsi, and the Twa. There is considerable intermarriage between the Hutu and Tutsi, whose social systems are not dissimilar. The Hutu, who constitute 85 percent of the population, are a Bantu people who, it is believed, originally came from the Chad–Niger area and appear to have entered central and eastern Africa in about the 2nd century AD. They are primarily agriculturists. The Tutsi, who originally came from the Nile Valley, or perhaps Ethiopia, and are related to the Galla peoples of eastern Africa, entered Burundi between the 15th and the 18th century. Averaging about five feet nine inches in height, they are cattle raisers; their cattle have characteristically lyre-shaped horns. The Twa are Pygmies; they were the first inhabitants of the country and are thought to have

Ethnic groups

entered it from the Congo. They were once forest dwellers and today are hunters and potters.

Three further minority groups are also to be found in the country. These are Europeans, who are mostly businessmen, missionaries, or technical assistance personnel; Africans from other countries, among whom refugees from Rwanda and Zaire are the most numerous; and Asians, who constitute the smallest minority of all and are engaged in commerce.

Kirundi and French are the official languages of Burundi, but Swahili is also spoken, and English is taught in some schools. Kirundi is spoken not only in Burundi but also in Rwanda and in other neighbouring countries. It has been estimated that, apart from 7,000,000 people who speak it in Burundi and Rwanda, it is also spoken by about 2,000,000 Tanzanians and about 1,000,000 people in the Bukavu area of Zaire, as well as by a smaller group in southern Uganda.

The principal forms of religion are the traditional religion, which is based on the veneration of ancestors, and Christianity, primarily Roman Catholicism. Christianity, to which the majority of the population adheres, is slowly displacing the traditional religion.

The rate of population growth is rapid, with a rate of increase of about 2 percent a year. Out of the total population of about 3,544,000, it is estimated that almost half are under the age of 15.

Agriculture

The national economy. The economy is primarily agricultural. The main cash crops are arabica coffee, most of which is sold to the United States and which accounts for more than 80 percent of the value of exports, and cotton, which represents another 8 percent. In order to diversify the economy, the European Development Fund is financing the establishment of tea plantations. Subsistence crops include millet, maize, beans, yams, potatoes, manioc, and other crops, as well as such tropical fruits as bananas, mangoes, papayas, and oranges. Cattle raising is regarded as particularly important since ownership of cattle has a social as well as an economic significance, and cattle are also used as security for contracts. Apart from cattle, sheep, goats, pigs, and poultry also are raised. Fish are caught in Lakes Tanganyika, Cohoba, and Rweru. Fishing usually takes place at night, except when there is a full moon, and traditional methods are employed; some commercial fishing, using modern techniques, also has been begun. Mining and manufacturing represent only a small sector of the economy. A small amount of bastnaesite (a weakly radioactive mineral), cassiterite (tin ore), and gold is worked, and manufacturing industries include brewing, soapmaking, and cotton milling. There is also a construction industry. Governmental revenue is raised principally from taxes and customs duties; Belgian aid is also significant. Additional aid for development has been received from the United States, West Germany, and United Nations agencies.

Transport. A network of roads and dirt tracks covers the country; there are no railroads. There is a good road from Bujumbura to Bukavu in the Congo, and other principal routes lead from Bujumbura to Gitega (formerly Kitega, once the seat of the *mwami* and for a brief period after independence, the capital) and to Kigali in Rwanda. An international airport is located at Bujumbura, connected by regular flights to East African, Congolese, and European airports. There are four small airports for local flights situated at Nyanza-Lac, Kiofi, Gitega, and Nyakagunda. Steamers on Lake Tanganyika sail regularly between Bujumbura and the ports of Kalemi (Albertville) in Zaire, and Kigoma in Tanzania.

Administration and social conditions. There are eight provinces, each administered by a governor appointed by the administration. Each province is divided into two or three districts (arrondissements), each of which is administered by a commissioner. Each district is divided into communes, to each of which an administrator is appointed. There are 18 districts and 78 communes. Since the proclamation of the republic in November 1966, Col. Michel Micombero has been president of the government. He is assisted by the General Assembly of the party. The sole political party is the Parti de l'Unité et du Progrès National du Burundi (Uprona).

There are local tribunals of customary law. Other courts, including courts of first instance and appeal, operate under codified law.

In the late 1960s there were about 183,000 pupils in primary schools, about 4,000 in secondary schools, and 4,200 in vocational schools. There is one university, the Université Officielle de Bujumbura. Both Catholic and Protestant missions conduct literacy courses for adults.

The country has about one doctor for every 58,000 people. Malaria is endemic, although its incidence has been reduced. Sleeping sickness does not occur on the plateau, but pulmonary diseases, particularly tuberculosis, are quite widespread. In the public health sector there is one main hospital and eight more hospitals or medical centres; there are also eight private hospitals, and more than 80 medical dispensaries.

Cultural life. National culture is traditional rather than written. It is composed in part of a considerable body of oral literature consisting of stories, legends, and fables, as well as poetry and songs. Music is played on various instruments, such as the harp (*inanga*), the *dingidi* (a single-stringed fiddle) and the *ikimbe* (a linguaphone). Burundi folk dancing is internationally famous. Newspapers in Bujumbura include a daily, and the national radio station, which broadcasts in Kirundi, French, and Swahili, is located there.

Prospects for the future. While economic development is progressing, its rapid growth is precluded by Burundi's landlocked situation: Dar es-Salaam in Tanzania, the nearest ocean port, is 710 miles away from Bujumbura. An increase in exports would lessen the country's dependence upon Belgian aid; it is hoped that the newly introduced tea plantations, which are being subsidized by the European Development Fund of the European Economic Community (EEC), as well as by the International Monetary Fund, may eventually earn as much export revenue for Burundi as is now obtained from coffee. Meanwhile, the rapid and continuing rate of population growth poses a further challenge to development planners. The strategic situation of Bujumbura, the capital, at the head of Lake Tanganyika guarantees it increasingly regional as well as national importance.

(P.-C.N.)

Business Associations, Law of

Business associations, from a legal viewpoint, are undertakings with more than one member, at least when they

Essential features of business associations

are formed, having assets distinct from the private assets of the members and a formal system of management, which may or may not include members of the association. The first feature, initial plurality of membership, distinguishes the business association from the business owned by one man; the latter does not need to be regulated internally by law because the single owner can do as he pleases with its assets; since he is personally liable for debts and obligations incurred in connection with the business, no special rules are needed to protect its creditors beyond the ordinary provisions of bankruptcy law. The second feature, the possession of distinct assets (or a distinct patrimony, as European lawyers would say), is essential for two purposes: to delimit the assets to which creditors of the association can resort to satisfy their claims (though in the case of some associations, such as the partnership, they can also compel the members to make good any deficiency), and to make clear what assets the managers of the association may use to carry on business for the members' benefit. The assets of an association are contributed directly or indirectly by its members: directly if a member transfers a business or property or investments of his own to the association in return for a share in its capital, and indirectly if a member pays the amount of his share of capital in cash and the association then uses his contribution and like contributions in cash made by other members to purchase a business, property, or investments. The third essential feature, a system of management, varies greatly. In a simple form of business association the members who provide the assets are entitled to participate in the management, and each member has an equal voice in management decisions unless otherwise agreed. In the more complex form of association, such as the company or corporation of the Anglo-Saxon countries, members have no immediate right to participate in the management of the association's affairs, though they are able to appoint and dismiss the managers, known in this case as directors, presidents, or administrators, and their consent is required for major changes in the company's structure or activities, such as reorganizations of its capital and mergers with other associations. Because the role of a member of a company or corporation is basically passive, he is known as a shareholder or stockholder, the emphasis being placed on his investment function. The managers of a business association, however, do not in law comprise all the persons who exercise discretion or make decisions. Even the senior executives of big corporations or companies are often merely employees, and like manual or clerical workers their legal relationship with the corporation is of no significance in considering the law governing the corporation. Whether an executive is a director, president, or administrator, and so an element in the company or corporation's legal structure, depends on purely formal considerations; if he is named as such in the document constituting the corporation, or if he is subsequently appointed or elected to hold such an office, it is irrelevant that his actual functions in running the corporation's business and the power or influence he wields are great or small. Nevertheless, for certain purposes, such as liability for defrauding creditors in English law and liability for deficiencies of assets in bankruptcy in French law, people who act like directors and participate in the management of the company's affairs are treated as such although they have not been formally appointed.

FORMS OF BUSINESS ASSOCIATION

Partnerships. The most important forms of business association, because the most numerous, are the partnership and the company or corporation. The distinguishing features of the partnership are the personal and unrestricted liability of each partner for the debts and obligations of the firm (whether he assented to them being incurred or not) and the right of each partner to participate in the management of the firm and to act as an agent of it in entering into legal transactions on its behalf. The civil law systems of the European countries have additionally always permitted a modified form of partnership, the limited partnership (*société en commandite, Kommanditgesellschaft, società in accomandita*) in which one or more of the partners are liable for the firm's debts only to the extent of the capital they contribute or agree to contribute, but such limited partners are prohibited from taking part in the management of the firm, and if they do, they become personally liable without limit for the debts of the firm, together with the general partners. Anglo-Saxon common law refused to recognize the limited partnership, and in the United States at the beginning of the 19th century only Louisiana, which was governed by French civil law, permitted such partnerships. During the 19th century, however, most of the states enacted legislation allowing limited partnerships to be formed, and in 1907 Great Britain adopted the limited partnership by statute, but it has not been much used there in practice. Another distinction between kinds of partnership made by the civil law system, which has no equivalent in Anglo-Saxon countries, is between civil and commercial partnerships. This distinction depends on whether the purposes for which the partnership is formed fall within the list of commercial activities in the country's commercial code or not. These codes always make manufacturing, dealing in, and transporting goods commercial activities, while professional and agricultural activities are always noncommercial. Consequently, a partnership of lawyers, doctors, or farmers is a civil partnership, governed exclusively by the civil code of the country concerned and untouched by its commercial code. No such distinction is made in the Anglo-Saxon countries, where professional and business partnerships are subject to the same rules as trading partnerships, with the one difference that only partners in a trading partnership have implied power to borrow on the firm's behalf.

Companies or corporations. The company or corporation, unlike the partnership, is formed not simply by an agreement entered into between its first members; it must also be registered at a public office or court designated by law, or otherwise obtain official acknowledgment of its existence. Under English and American law the company or corporation is incorporated by filing the company's constitution (memorandum and articles of association, articles or certificate of incorporation) signed by its first members at the Companies Registry in London or, in the U.S., at the office of the state secretary of state or corporation commissioner. In France, Germany, and Italy and the other countries subject to a civil law system, a notarized copy of the constitution is filed at the local commercial tribunal, and proof is tendered that the first members of the company have subscribed the whole or a prescribed fraction of the company's capital, and that assets transferred to the company in return for an allotment of its shares have been officially valued and found to be worth at least the amount of capital allotted for them. English and American law, together with the laws of the Netherlands and the Scandinavian countries, provide only one category of business company or corporation (in the Netherlands the *naamloze vennootschap*, in Sweden the *aktiebolag*), although all these systems of law make distinctions for tax purposes between private, or close, companies or corporations on the one hand and public companies or corporations on the other. English law also distinguishes between private and public companies for some purposes of company law; for example, a private company cannot have more than 50 members and cannot advertise subscriptions for its shares. Under the other civil law systems, however, a fundamental distinction is drawn between the public company (*société anonyme; Aktiengesellschaft; società per azioni*) and the private company (*société à responsabilité limitée, Gesellschaft mit beschränkter Haftung* [*G.m.b.H.*], *società a responsabilità limitata*), and in Germany the two kinds of company are governed by different enactments, as they were in France until 1966. Functionally, however, public and private companies are the same in all countries. Private companies are formed when there is no need to appeal to the public to subscribe for the company's shares

or to lend money to it, and often they are little more than incorporated partnerships whose directors hold all or most of the company's shares. Public companies are formed—or more usually created by the conversion of private companies into public ones—when the necessary capital cannot be supplied by the directors or their associates and it is necessary to raise funds from the public by publishing a prospectus and, in Great Britain and the British Commonwealth countries, obtaining a stock exchange listing for the shares or other securities offered. In a typical public company the directors hold only a small fraction of its shares, often less than 1 percent; and in Great Britain and the United States, at least, it is not uncommon for up to one-half of the funds raised by the company to be represented not by shares in the company but by loan securities such as debentures or bonds.

In Anglo-Saxon countries, public and private companies account for most of the business associations formed, and partnerships are now entered into only for professional activities. In European countries, the partnership in both its forms is still widely used for carrying on commercial undertakings, and in Germany a popular form of association combines both the partnership and the company. This is the *G.m.b.H. & Co.*, which is a limited partnership whose general partner (nominally liable without limit for the partnership's debts) is a private company and whose limited partners are the same persons as the shareholders of the company. The limited partners enjoy the benefit of limited liability for the partnership's debts, and by ensuring that most of the partnership's profits are paid to them as limited partners and not to them as shareholders in the private company, they largely avoid the incidence of corporation tax.

Other forms. Besides the partnership and the company or corporation there are a number of other forms of business association, of which some are developments or adaptations of the partnership or company, some are based on contract between the members or on a trust created for their benefit, and others are purely statutory creations. The first of these classes includes the cooperative society; the building society or home loan association and its German equivalent, the *Bausparkasse;* the trustee savings bank or people's or cooperative bank; the friendly society or mutual insurance association; and the American mutual fund investment company. The essential features of these associations are that they provide for the small or medium investor; and although they originated as contractual associations, they are now governed in most countries by special legislation and not by the law applicable to companies or corporations. The second class comprises the English unit trust and the European *fonds d'investissements* or *Investmentfonds*, which fulfill the same functions as the American mutual funds; the Massachusetts business trust (now little used, but providing a means of limiting the liability of participants in a business activity like the limited partnership); the foundation (*fondation, Stiftung*), a European organization with no equivalent in Anglo-Saxon countries, which has social or charitable objects and often carries on a business whose profits are devoted to those objects; and, finally, the cartel or trade association, which regulates the business activities of its individual members and is itself extensively regulated by antitrust and antimonopoly legislation. The third class of associations, those wholly created by statute, comprise corporations formed to carry on nationalized business undertakings (such as the Bank of England and the German Federal Railways) or to coexist with other businesses in the same field (such as the Italian Istituto per la Ricostruzione Industriale) or to fulfill a particular governmental function (such as the Atomic Energy Commission and the Tennessee Valley Authority). Such statutory associations usually have no share capital, though they do raise loans from the public. They are regarded in European law as being the creatures of public law, like departments and agencies of the government. In recent years, however, a hybrid between the state corporation and the privately owned corporation or company has appeared in the form of the mixed company or corporation (*société mixte*). In this kind of organization part of the association's share capital is held by the state or a state agency and part by private persons, this situation often resulting from a partial acquisition of the association's shares by the state. In only France and Italy are there special rules governing such associations; in Great Britain and Germany they are subject to the ordinary rules of company law.

HISTORY OF COMPANY LAW

From partnership to limited liability

Space precludes more than an outline of the history of the law governing business associations. Although a primitive form of partnership, the *societas*, existed under Roman law, it was not until the Middle Ages that the germ of the modern partnership and company appeared in Italy and France and spread by imitation to England and the countries of northern Europe. By the 16th century, the law relating to general and limited partnerships had been extensively developed in the Mediterranean countries and in some places codified, but the selective adoption of parts of this law by the courts in England and the complete exclusion of the limited partnership left the Anglo-Saxon common law in this field largely inarticulate. In the 16th and 17th centuries, overseas trading by the newly emerged nation-states was conducted mostly by privileged companies of merchants chartered by the monarch or the state, such as the English and Dutch East India companies and the French Mississippi Company, and in the 17th century the practice of incorporating companies by charter was extended to domestic undertakings which could afford to pay for the privilege. Merchants and lawyers, however, soon learned how to adapt the partnership so as to gain most of the benefits of incorporation by charter, and by the end of the 17th century unincorporated companies with transferable shares and elected boards of directors, which in law were merely large partnerships, became common. In France such companies were tolerated and partly regulated by the *Ordonnance de Commerce* of 1673, but in England they were legally suppressed by the Bubble Act of 1720, a measure enacted to stop the orgy of speculation in the shares of chartered and unincorporated companies.

The nineteenth century. Until the Bubble Act was repealed in 1825, no real development took place in English company law, though unincorporated companies had been extensively formed throughout the 18th century, and in the 1820s the shares of over a hundred of them were dealt in by stockbrokers who were members of the London Stock Exchange. In France, on the other hand, the law governing all forms of commercial companies and partnerships had been codified in the Commercial Code of 1807, and although it was not possible to form a public company or *société anonyme* without the authorization of the state until 1863, the French supreme court held in 1832 that a *société en commandite*, formed simply by an agreement registered in the local commercial court, could have freely transferable shares like the *société anonyme*. This heralded the *société en commandite par actions*, the prototype of the limited liability company in Europe. Meanwhile, New York State had enacted legislation in 1811 that permitted manufacturing companies to be incorporated and to obtain the benefit of limited liability merely by filing with the secretary of state a certificate setting out the essential features of the company's constitution. During the 19th century, all the states of the U.S. enacted similar legislation extending to all kinds of companies, but, because the corporation laws of the different states were enacted at different times and independently of each other, there was great diversity between them. In Great Britain, the incorporation of companies by mere registration at a public office was not authorized by legislation until 1844, and until 1855 members of such registered companies were liable personally for the company's debts like partners, the privilege of limited liability only being obtainable by special act of Parliament. In 1855 this privilege was made available to all registered companies, and in 1856 and 1862 there were enacted the major Companies Acts on which mod-

ern British company law is based. France enacted its major companies legislation in 1867, in many respects following the English pattern, though retaining distinctive features from the Commercial Code of 1807. Prussia adopted legislation based on the French Commercial Code in 1843, but it was not until 1870 that Germany permitted limited liability companies with transferable shares to be formed merely by registration. In one respect Germany took the lead, however, for it was the first country to establish the private company (*G.m.b.H.*) as a distinct category. This was done in 1892; Great Britain followed suit in 1907, but France not until 1925.

The twentieth century. The 20th century has been a period of continuous reform and modification of company law in all industrial countries. In the United States, some measure of correspondence between the legislation of the different states has been achieved, and in California an attempt has been made to codify corporation law. Despite the publication of a Uniform Business Corporation Act in 1928 and the American Bar Association's Model Business Corporation Act in 1946, however, there is still much diversity between the corporation laws of the different states, and the only area where complete uniformity prevails is in federal legislation governing the public issue of corporations' shares and bonds, the operation of the securities markets, the organization and conduct of mutual fund companies, and the terms of issue of corporation bonds and the protection of bondholders.

MANAGEMENT AND CONTROL

The structure of management

The simplest form of management is the partnership. In the Anglo-Saxon and the European civil law countries every partner is entitled to take part in the management of the firm's business, unless he is a limited partner; however, a partnership agreement may provide that an ordinary partner shall not participate in management, in which case he is a dormant partner but is still personally liable for the debts and obligations incurred by the other managing partners.

Corporations. The management structure of companies or corporations is more complex. The simplest is that envisaged by English, Belgian, Italian, and Scandinavian law, by which the shareholders of the company periodically elect a board of directors who collectively manage the company's affairs and reach decisions by a majority vote but also have the right to delegate any of their powers, or even the whole management of the company's business, to one or more of their number. Under this regime it is common for a managing director (*directeur général; direttore generale*) to be appointed, often with one or more assistant managing directors, and for the board of directors to authorize them to enter into all transactions needed for carrying on the company's business, subject only to the general supervision of the board and to its approval of particularly important measures, such as issuing shares or bonds or borrowing. The American system of management is a development of this basic pattern. By the laws of most of the states it is obligatory for the board of directors elected periodically by the shareholders to appoint certain executive officers, such as the president, vice president, treasurer, and secretary. The two latter have no management powers and fulfill the administrative functions that in an English company are the concern of its secretary; but the president, and in his absence the vice president, have by law or by delegation from the board of directors the same full powers of day-to-day management as are exercised in practice by an English managing director.

Public companies. The most complex management structures are those provided for public companies under German and French law. The management of private companies under these systems is confided to one or more managers (*gérants, Geschäftsführer*) who have the same powers as managing directors. In the case of public companies, however, German law imposes a two-tier structure, the lower tier consisting of a supervisory committee (*Aufsichtsrat*) whose members are elected periodically by the shareholders and the employees of the company in the proportion of two-thirds shareholder representatives and one-third employee representatives (except in the case of mining and steel companies where shareholders and employees are equally represented), and the upper tier consisting of a management board (*Vorstand*) comprising one or more persons appointed by the supervisory committee, but not from their own number. The affairs of the company are managed by the management board, subject to the supervision of the supervisory committee, to which it must report periodically and which can at any time require information or explanations. The supervisory committee is forbidden to undertake the management of the company itself, but the company's constitution may require its approval for particular transactions, such as borrowing or the establishment of branches overseas, and by law it is the supervisory committee that fixes the remuneration of the managers and has power to dismiss them. The French management structure for public companies offers two alternatives. Unless the company's constitution otherwise provides, the shareholders periodically elect a board of directors (*conseil d'administration*), which "is vested with the widest powers to act on behalf of the company," but which is also required to elect a president from its members who "undertakes on his own responsibility the general management of the company," so that in fact the board of directors' functions are reduced to supervising him. The similarity to the German pattern is obvious, and recent French legislation carries this further by openly permitting public companies to establish a supervisory committee (*conseil de surveillance*) and a management board (*directoire*) like the German equivalents as an alternative to the board of directors-president structure. In recent years Dutch and Italian public companies have tended to follow the German pattern of management, although it is not expressly sanctioned by the law of those countries. The Dutch *commissarissen* and the Italian *sindaci*, appointed by the shareholders, with legal functions not dissimilar from those of the auditors of companies in the Anglo-Saxon countries in the days before professional accountants took over audit work, have, probably because of the spread of professional auditing, taken over the task of supervising the directors and reporting on the wisdom and efficiency of their management to the shareholders.

The making of transactions

Contractual authority. A person who enters into a transaction with a partnership or company is less concerned with the structure of its management than with ensuring that the representatives of the firm he negotiates with have authority to bind it legally. In the case of a partnership, the Anglo-Saxon and civil law systems agree that the firm is bound if the representative is a partner (other than a limited one) and the transaction is relevant to the kind of business the firm carries on. The fact that the other partners repudiate the transaction or were not consulted beforehand, or that the partnership agreement restricts the authority of the partner who negotiates the transaction, does not prevent the transaction from binding the firm, though in the latter event in Anglo-Saxon law the other party to the transaction must have been ignorant of the restriction. The law is not so simple in the case of transactions negotiated by directors of companies, although in respect of transactions entered into on behalf of private companies the directors or managers individually have the same power to bind the company under French, German, and Belgian law as partners have to bind their firm. In the case of other companies, the powers of directors are, with some exceptions, limited first by the rule that the transaction in question should be relevant to the kind of business the company is authorized to carry on by its constitution, and secondly by the rule that the transaction must be authorized by the board of directors collectively. The first rule has been carried to extremes by Anglo-Saxon common law, which in effect obliges the person dealing with the company to inspect the company's constitution and to ensure at his peril that the transaction is authorized by it, though in some states of the U.S. legislation has made even unauthorized transactions valid if the person dealing with the company is

unaware that they are beyond the company's powers, and in all the states the transaction is binding if one of the parties has fulfilled his obligations under it. European civil law has always adopted a more generous attitude. By French law the transaction is valid if "within the limits of the objects of the company," which is interpreted as meaning if it is appropriate to carrying on the kind of business mentioned in the company's constitution. By German law the transaction is binding in all cases, even if totally unconnected with the company's business, unless the person dealing with the company conspired with its representative to defraud it. The second rule, requiring the collective approval of the board of directors for a transaction to bind a company, obviously does not apply to transactions entered into by the company's managing director or president or by an individual director to whom the board has delegated its authority, nor does it apply to transactions entered into by the president or management board of a French or German public company. But any other director has no more power than a shareholder to negotiate a transaction individually on behalf of his company, and in this respect his position is far weaker than that of a partner. The two rules here considered illustrate the difficulty experienced by the courts of different countries in trying to reconcile the conflicting claims of the shareholders—that their company's assets should only be used to satisfy obligations properly incurred on its behalf in conformity with its constitution— and of the outsider who deals in good faith with one or more directors or managers. On the whole, the law of the Anglo-Saxon countries has favoured the shareholders' claim, while civil law has favoured the outsider's.

Powers and duties

Directors. Company legislation in all countries imposes specific duties on directors, such as the duty to call a general meeting of shareholders once a year and on other occasions when demanded by a certain fraction of the shareholders. It also imposes certain prohibitions on directors, such as the absolute prohibition on borrowing from the company imposed by English and French law and the law of many states of the U.S. But over and above these specific provisions, every system of law also imposes on partners and directors general fiduciary duties to exercise their powers in the interests of the partnership or company and not for their private gain, and to avoid situations where their private interests conflict with those of their firm. American law has gone farthest in enlarging these almost ethical obligations. Like some other systems of law, it has made directors return unreasonably large remuneration and account for profits made out of business opportunities that they have diverted from the company to themselves. Also it has gone farther than many other systems by making directors compensate the company for any loss it has sustained from their competing with it or taking interests in competing firms, and by rendering them accountable to the company for personal gains made out of such activities and out of carrying on business activities in fields related to the company's into which the company may wish to expand in the future. English law does not go this far. Although it makes directors accountable for personal gains from use of the company's property, including trade secrets, knowledge of its customers and "know-how" generally, there is nothing to prevent a director from competing with the company unless he has contracted not to do so or has agreed to devote all his time to managing the company. European law has dealt with the question of competition by directors in express legislative provisions. German law prohibits members of the management board of a public company from carrying on any other business alone or in partnership, and from engaging in transactions in the company's business field, unless the supervisory committee consents; and Italian law prohibits all directors from competing with their company unless the shareholders resolve that they may. French law achieves the same result indirectly by forbidding any person from being president or a member of the management board of more than two public companies, or a member of the board of directors or supervisory committee of more than eight. In addition to his fiduciary duties, a director is, under all systems of law, subject to a duty to act carefully in managing his company's affairs, and he is liable to compensate it for all loss sustained as a result of his carelessness. Some legal systems have sought to establish the standard of care required by legislation. Under German law, the members of the management board and the supervisory committee of a public company must "exercise the care of a competent and conscientious business manager," and by Italian law all directors must exhibit "the diligence of a salaried agent." English law has not defined directors' duties of care in this way, and the courts have long held that they are not required to bring more skill to the performance of their functions than they in fact possess, nor to exercise more care than a reasonable man could be expected to do in handling his own affairs. In particular, under English law, directors are not obliged to supervise their fellow directors or to take any action against them unless they have cause to suspect their honesty. American common law is more exacting than this; it requires directors to show the same standard of care as is expected of the ordinary prudent director or businessman, and in some states their duty has been codified by legislation in similar terms.

The rights of ownership

Shareholders. The beneficiaries of sound management are the shareholders, and by the same token the shareholders are the primary sufferers if a company's affairs are mismanaged or badly managed. For this reason all systems of law make directors answerable to the shareholders to a greater or lesser degree. The first means of making this responsibility meaningful is the requirement imposed by the laws of all countries that a general meeting of shareholders be held annually, before which the directors must lay the company's audited annual accounts (balance sheet and profit and loss account, and sometimes group accounts if the company has subsidiaries) and a report by the directors on the company's activities during its last financial year and on its present position. Since directors are elected or re-elected by shareholders at these annual general meetings, the shareholders can express their disapproval of the directors' management of the company's affairs by electing a new board, or if only a fraction of the directors retire each year, by not re-electing those of them who present themselves for re-election. Where the company has a two-tier management structure, as have French and German public companies and American and English companies whose presidents or managing directors are appointed by the board of directors and not by the shareholders, a change in the composition of the board or supervisory committee does not result immediately in a change in the president, managing director, or management board, but since most systems of law permit the removal of the latter for any reason (though subject to the payment of damages if there is no good cause for the removal, or if it amounts to a breach of contract), the new board or supervisory committee may quickly effect a change in the management body. The statutory power of removal extends under all systems of law to the board of directors or supervisory committee as well, and can be exercised by the shareholders at extraordinary general meetings held at any time, so that to this extent the directors' answerability to the shareholders is continuous and not merely periodic. It is rare for most of the shareholders of big companies to attend annual or extraordinary general meetings personally; instead they avail themselves of the right given by all systems of law to appoint proxies to attend and vote on their behalf. The directors and opposing groups of shareholders who seek to displace them assiduously solicit proxy appointment from uncommitted shareholders by sending them circulars setting out their respective cases well in advance of the general meeting in question, and English and German law and the federal law of the United States confer limited rights on individual shareholders or minority groups of shareholders to have their solicitation material circulated by the company itself. The outcome of a contest for control of the board of directors

in such cases is usually known shortly before the general meeting is held when the time for notifying proxy appointments expires; the outcome is determined by the number of proxies each side has been able to obtain, and the meeting is then purely a formality. In Anglo-Saxon countries it is uncommon for shareholders to give proxies for more than one general meeting at a time unless they are members of an opposition group that acts collectively by forming a voting pool, but in Europe it is not uncommon for shareholders to authorize the banks with which they deposit their shares to exercise the voting rights attached to them for an indefinite period. To discourage this, the German law governing public companies provides that such an authority expires after 18 months, though it may be renewed by the shareholder, and the depositary bank must seek the instructions of the shareholder as to how it is to vote on each occasion a general meeting is held, and it may vote as it thinks fit only if he gives no instructions.

Shareholders' suits. The second way shareholders may call directors to account is by suing them for damages or other appropriate remedies. Under the law of the Anglo-Saxon countries, directors' duties are owed to the company, not to the shareholders individually, and so proceedings can be brought only if a general meeting of shareholders so resolves, or if the case is one where the law exceptionally permits one or more shareholders to sue on behalf of all of them to enforce the company's claim. In English law such representative actions can be brought only if the directors have infringed the fundamental provisions of the company's constitution, or if they control a majority of votes that can be cast at a general meeting and have been guilty of fraud or breach of fiduciary duty. American law is more liberal in allowing representative actions (known as derivative suits because the claim that is being enforced is derived from the company). Generally a shareholder may bring such an action if he has requested the directors and a meeting of shareholders to sue in the company's name and they have refused, and the only limitations imposed are that the shareholder must not be motivated by bad faith and the matter must not be the exercise of a reasonable business discretion by the directors. Under European law, legislation gives shareholders who hold a certain fraction of a public company's shares, usually one-tenth, the right to sue to enforce any claim of the company against its directors, and in France, Belgium, and Italy (but not in Germany) they may also sue individually to recover compensation for the fall in the value of their shares caused by mismanagement. Although English common law gives only very restricted rights to individual shareholders to remedy wrongs done to their company, legislation does permit them to petition the court for any appropriate form of relief if the persons who control the company (whether directors or not) have treated them oppressively over a period of time, and the court can, among other things, order the purchase of the petitioners' shares at a fair value by the persons in control, or the sale of the latter's shares so as to break up their control. American common law now recognizes that persons in control of a company do owe a fiduciary duty to minority shareholders and so are liable to compensate them if they sell their controlling shareholding to persons whom they know are likely to loot or mismanage the company, but there are as yet no legislative provisions in any of the states, or in any European country either, that go as far as the English provision for judicial relief against oppression.

SHARES AND OTHER SECURITIES

How company shares differ from those in a partnership

Under all systems of law a partner may assign his share or interest in a partnership to anyone he wishes unless the partnership agreement forbids this, but the assignment does not make the assignee a partner unless all of the other partners agree. If they do not, the assignee is merely entitled to receive the financial benefits attached to the share or interest without being able to take part in the management of the firm, but neither is he personally liable for the debts of the firm.

The shares of a company are quite different. In the first place, they are freely transferable unless the company's constitution imposes restrictions on their transfer, or, in French and Belgian law, unless the company is a private one, in which case transfers require the consent of the holders of three-quarters of the company's issued shares. The constitution of an English private company must always restrict the transfer of its shares for the company to qualify as private. The restriction is usually that the directors may refuse to register a transfer for any of several reasons, or that the other shareholders shall have the right to buy the shares at a fair price when the holder of them wishes to sell. In American law similar restrictions may be imposed, but unreasonable restrictions are disallowed by the courts. According to French and German law, the transfer of shares in public companies may be restricted only by being made subject to the consent of the board of directors or of the management board, but under French law if the directors do not find an alternative purchaser at a fair price within three months their consent is considered as given.

Limited liability. In the second place, shares in a company do not expose the original holder or a person to whom they have been transferred to unlimited liability in the way a partner (other than a limited one) is liable for the debts of his firm. Under all systems of law, except those of Belgium and some of the states of the U.S., all shares must have a nominal value expressed in money terms, such as \$10, £1, DM. 50 or Fr. 100, the latter two being the minimum permissible under German and French law. Although a company may issue shares for a subscription price greater than this nominal value, the excess being known as a share premium, it generally cannot issue them for less than that nominal value, and any part of the nominal value and the share premium that has not so far been paid is the measure of the shareholder's maximum liability to contribute if the company becomes insolvent. If shares are issued without a nominal value (no par value shares), the subscription price is fixed by the directors and is the measure of the shareholder's maximum liability to contribute. Usually the subscription price of shares is paid to the company fairly soon after they are issued; the period for payment of all the installments is rarely more than a year in Anglo-Saxon countries, and it is not uncommon for the whole subscription price to be payable when the shares are issued. The actual subscription price is influenced by general market factors, by the company's profit record and prospects, and by the market value of the company's existing shares. Although directors have a duty to obtain the best subscription price possible, they can offer new shares to existing shareholders at favourable prices, and those shareholders can benefit either by subscribing for the new shares or by selling their subscription rights to other persons. Under European legislation directors are bound to offer new shares to existing shareholders in the first place unless they resolve to forgo their pre-emptive rights. In most states of the U.S. (but not in Great Britain) such pre-emptive rights are implied if the new shares belong to the same class as existing shares, but the rights may be negated by the company's constitution.

The third difference between shares in companies and interests in partnerships is that a partner is automatically entitled to his share of profits of the firm as soon as they are ascertained, but a shareholder is only entitled to a dividend out of the company's profits when it has been declared. Under English law, dividends are declared at annual general meetings of shareholders, though the company's constitution usually provides that the shareholders cannot declare higher dividends than the directors recommend. Under American law dividends are usually declared by the directors, and if shareholders consider, in view of the company's profits, that too small a dividend has been paid, they may apply to the court to direct payment of a reasonable dividend. German law similarly protects shareholders of public companies against niggardly dividends by giving the annual general meeting power to dispose as it wishes of at least half the profit

shown by the company's annual accounts before making transfers to reserve, and with the same object Swedish law empowers the holders of 10 percent of a company's shares to require at least one-fifth of its accumulated profits and reserves to be distributed as a dividend, provided that the total distribution will not exceed one half of the profits of its last financial year.

Classes of shares. Companies may issue shares of different classes, the commonest classes being ordinary and preference, or in American terminology, common and preferred shares. The latter are entitled by the terms on which they are issued to payment of a dividend of a fixed amount (usually expressed as a percentage of their nominal value) out of the profits of the company before any dividend is paid to the ordinary shareholders. If the shares are cumulative preference shares, any unpaid part of a year's dividend is carried forward and added to the next year's dividend, and so on repeatedly if necessary until the arrears of preference dividend are paid off. The accumulation of arrears of preference dividend naturally depreciates the value of the ordinary shares, whose holders cannot be paid a dividend until the arrears of preference dividend have been paid. Consequently, it has been common in the United States (but not in Great Britain) for companies to issue noncumulative preference shares, giving their holders the right to a fixed preferential dividend each year if the company's profits are sufficient to pay it, but limiting the dividend to the amount of the profits of the year if they are insufficient to pay the preference dividend in full. Preference shares are not common in Europe, but under German and Italian law they have the distinction of being the only kind of shares that can be issued without voting rights in general meetings, all other shares carrying voting rights proportionate to their nominal value by law.

Bonds and debentures. In addition to shares, which constitute its capital, a company may issue debentures or bonds to raise loans, and since by their terms such loans are often repayable only 15 or 20 years after they are raised, the debentures or bonds of a company are referred to as its loan capital. Debentures or bonds may be issued to a few persons, but public companies often issue them to the investing public at large, and the problem then arises of providing for the representation of the bondholders by one or two persons who may enforce their rights on their behalf and may agree to, or call meetings of bondholders to consent to, modifications of any security given for the bonds. In Anglo-Saxon countries this is done by appointing a trustee for the bondholders or debenture holders and by vesting in it any security for the bonds, such as a mortgage of the company's land or, under British practice, a general charge on all the company's assets. In European countries, the bondholders by law have to be represented by an agent who is under a duty to protect the bondholders' interests and has the power to call meetings of bondholders so that they may consent to certain limited modifications of the company's obligations. The duties of trustees for bondholders or debenture holders have not been codified by statute in the United States or Great Britain, but in the United States they are now extensively governed by federal legislation. Because of the worldwide rise in commercial interest rates in recent years, American, British, and European companies have increasingly issued convertible bonds and debentures carrying a lower rate of interest than ordinary debentures but entitling the holder to convert them into ordinary shares of the company (expected to rise in value) at a specified rate of exchange on specified future dates or during a specified future period. The conversion rights, not yet protected by legislation in the United States and Great Britain, were by French and German law to ensure that they were not diluted by further issues of the company's shares or by it taking action adverse to the bondholders' interests.

CURRENT AND FUTURE PROBLEMS

Mergers. Of the many current and likely future developments in the laws of the industrialized countries, mergers, and employee participation call for particular mention, as also does the tendency of the company laws of the western European countries toward uniformity in all respects.

"Take-over" and "tender" bids

The most dramatic development in the field of business associations in recent years has been the wave of mergers of small and large companies with other concerns that have made "take-over" or "tender" bids. Until recently, the laws of few countries regulated such bids; probably the earliest was legislation in Great Britain in 1928 that enabled a bidding company, which had acquired 90 percent or more of the shares bid for, to acquire the outstanding shares at the bid price even against the wishes of their holders. The regulation of take-over bids is still more extensive in Great Britain than in any other country, and the law is supplemented by the rules of the stock exchanges (which are adhered to since bidding companies do not wish to lose the listing or quotation of their shares) and by the Code on Take Overs and Mergers (which is a set of rules for the fair conduct of take-over operations and the fair treatment of investors in the bidding company and the company that is bid for, conformity with these rules being ensured by the action of the banks and underwriters who participate). The law does little beyond requiring the bidding company to give full information about recent dealing prices in its shares and the shares bid for in the circular containing its offer to buy those shares or exchange them for shares newly issued by itself, and also to disclose in that circular any special arrangements it has with the directors of the company bid for in respect of their retirement or the acquisition of their shares. The detailed rules of the game are contained in the Code, which requires the bid to be notified to the board of the company bid for before it is published and to be kept secret until it is sent out simultaneously to all the shareholders concerned; forbids both companies and their associates from engaging in dealings in the shares of either company, which may create a false market; permits the bidding company to buy shares of the other company on the market outside the bid, but only on paying shareholders who accept the bid the average price paid for its market purchases if that is higher than the bid price; forbids a bidding company from declaring its bid unconditional and binding unless it has received so many acceptances that it holds more than half the votes that can be cast at a general meeting of the company bid for; enables an accepting shareholder to retract his acceptance if the bid is not declared unconditional within three weeks after it is made; requires the bidding company to allow a further period for late acceptances after the bid is declared unconditional; and finally, requires all shareholders to whom the bid is addressed to be treated with absolute equality, and in particular, if a bid for less than all the shares of a class is made and acceptances exceed the number of shares bid for, that the acceptances shall be scaled down proportionately. The Code probably sets the pattern of future legislation on this subject. As yet United States federal law has only required the filing and circulation of certain information in connection with tender bids and has not regulated the conduct of bids in detail, although the general provisions of federal law directed against fraud and fraudulent manipulations of security prices apply to the conduct of such bids as they do to other transactions in securities. European law has made no provision in respect of tender bids, beyond that in the German legislation enabling a public company that has acquired 95 percent of the shares of another company to acquire the remainder. Nevertheless, the Paris Stock Exchange and the Belgian Banking Commission do in fact exercise some control over tender bids.

Participation and profit sharing. The second topic that is likely to be of increasing significance in the future is participation by employees in the direction of the companies for whom they work. English and American law have so far only dealt with this matter by permitting companies to establish share subscription schemes under which employees may acquire shares in their employing

company at favourable prices, and share bonus schemes by which a fraction of the company's profits are set aside annually and used to acquire shares in the company for the benefit of employees by subscription or by purchase in the market. Although such schemes may involve a company financing the acquisition of shares in itself, they are recognized as lawful by legislation in Great Britain and several of the states of the U.S. But schemes of this kind are optional, and their outcome is simply that the number of shareholders of the company is increased; shares held by employees carry no special rights, and in any case they are either issued without votes in general meetings or carry only a small fraction of the votes that may be cast. European law has led the way toward a more positive position. As already stated, one-third (or in the mining and steel industries, one-half) of the members of the supervisory committee of German public companies are elected by its employees from a list of candidates nominated by the works council (*Betreibsrat*), an obligatory elected body of employees, which, among other things, manages employees' pension funds and has to be consulted on management measures affecting employees. The provisions relating to works councils and the election by employees of representatives to the supervisory committee also apply to private companies employing more than 500 persons, and their management structure consequently is the same as that of public companies. French law is weaker than German in providing for direct employee participation in management. It, too, provides for elected works councils (*comités d'entreprise*) where a business employs 50 or more persons, but employees are represented on the board of directors only if the company is a public one, and even then only by two nonvoting representatives appointed by the works council. On the other hand, French law is more advanced in entitling the employees of a company to share in its profits by making it compulsory for companies to establish share bonus schemes under which shares are periodically allotted to employees and paid for out of the company's profits. These shares carry the full rights of ordinary shares, but are nontransferable for five years after they are issued.

Uniform legislation in Europe. Another matter of current and future importance is the tendency in recent years for the companies legislation of the western European countries to become more homogeneous, largely as a result of the setting up of the European Economic Community (EEC). Most countries and states of the U.S. have long permitted companies formed in other countries or states to carry on business in their own territory, usually subject to filing particulars of the foreign company's constitution and periodic reports on its activities. But the law of the foreign country or state where the company was incorporated or where it has its central management still governs it, and inevitably there will be conflicts with the host country's laws and gaps in the application of the host country's own companies legislation to its foreign company. Moreover, it is usually impossible for companies formed in different countries to merge under the laws governing any of them, and the nearest practicable approach to a merger is the formation of parallel companies in each of the countries concerned and the distribution of their shares to the original shareholders of the merged businesses. Such difficulties would be overcome if a uniform companies law were enacted by each country or state, but this has proved impossible to achieve in the United States, though recently accomplished by the six states of Australia. Progress toward uniformity in western Europe is likely to be slow and will more likely come from the conscious adoption of the best provisions of other countries' legislation by the respective national legislatures than by the imposition of a uniform law by the authorities of the EEC. Draft legislation for the creation of companies of European type (*societas europea*) is under consideration by the EEC member states at the present time, and if adopted it will provide facilities for the formation of companies that will be subject to uniform rules and wll have uniform powers throughout the EEC.

BIBLIOGRAPHY

English law: L.C.B. GOWER, *The Principles of Modern Company Law* (1970); and R.R. PENNINGTON, *Company Law*, 2nd ed. (1967), are textbooks written primarily for students but may also be used by practitioners. They are, nevertheless, suitable for the reader who has some basic knowledge of business associations. R.R. PENNINGTON, *The Investor and the Law* (1968), is primarily a comparative study of the laws of the U.S. and the western European countries on investment law, with consideration given to questions relevant to business associations. M.A. WEINBERG, *Take-Overs and Amalgamations*, 2nd ed. (1967), is a practitioners' textbook on English Law. Two works intended for the general reader are A. RUBNER, *The Ensnared Shareholder* (1965); and G. GOYDER, *The Responsible Company* (1961).

American law: *Ballantine on Corporations*, rev. ed. (1946); G.D. HORNSTEIN, *Corporation Law and Practice* (1959); and *Lattin on Corporations*, 3rd ed. (1959), are standard student textbooks. The last two works contain more detail and are more up-to-date. E.R. ARANOW and H.A. EINHORN, *Proxy Contests for Corporate Control*, 2nd ed. (1968), is a detailed practitioner's book that the experienced reader will find interesting. A.A. BERLE and G.C. MEANS, *The Modern Corporation and Private Property*, rev. ed. (1968), is written on a more elementary level.

Other countries: W.G. FRIEDMANN and R.C. PUGH (eds.), *Legal Aspects of Foreign Investment* (1959); R.R. PENNINGTON, *Companies in the Common Market* (1970); and E.M. CHURCH, *Business Associations under French Law* (1960), are suitable works for the reader who has no knowledge of the company law of overseas countries. G. RIPERT and R. ROBLOT (eds.), *Traité Elémentaire de Droit Commercial*, 6th ed., vol. 1 (1968); A. HUECK, *Gesellschaftsrecht*, 13th ed. (1965); and A. GRAZIANI, *Diritto delle società*, 5th ed. (1963), are standard students' textbooks on French, German, and Italian company law. They presuppose a knowledge of basic European law.

(R.R.P.)

Business Cycles

Business cycles are best defined as fluctuations in the general level of economic activity, or more specifically, in the levels of employment, production, and prices. The Figure shows fluctuations in wholesale prices in four Western industrialized countries over the period from 1790 to 1940. Though some regularities in price movements are apparent, it is possible to ask whether the movements are regular enough to be called cycles.

The word cycle derives from the Greek word for circle. An object moving around a circle returns to its starting point; a wave motion, with upward and downward curves, may also be considered a cycle. The various movements characteristic of economic activity are not always as regular as waves, and for this reason some prefer to call them fluctuations.

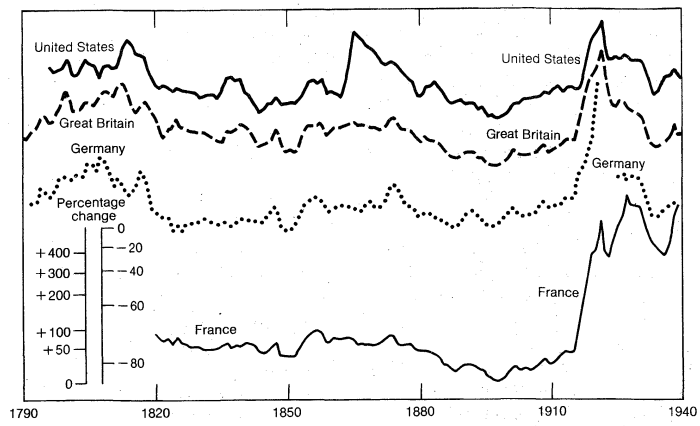
The varieties of cycles

There are many types of economic fluctuations. Because of the complexity of economic phenomena, it may be that there are as many types of fluctuations or cycles as there are economic variables. There are daily cycles in commuter traffic or the consumption of electricity, to cite only two examples. Almost every aspect of economic life displays seasonal variations: sales of coal or ice, deposits in savings banks, monetary circulation, agricultural production, purchases of clothing, travel, and so on. As one lengthens the span of observation, one finds new kinds of fluctuations such as the hog cycle and the wheat cycle, the inventory cycle, and the construction cycle. Finally, there are movements of general economic activity that extend over periods of years.

THE STATISTICAL STUDY OF CYCLES

Early observations. Modern economic history has recorded a number of periods of difficult times, often called depressions, during which the business economy was marked by sudden stock market declines, commercial bankruptcies, bank failures, and mounting unemployment. Such crises were once looked upon as pathological incidents or catastrophes in economic life, rather than as a normal part of it. The notion of a "cycle" implies a different view.

Juglar's eight-year cycle. The first authority to explore economic cycles as periodically recurring phenomena



Wholesale price indexes for United States, Great Britain, Germany, and France, 1790–1940.
Reprinted from A. Burns and W. Mitchell, *Measuring Business Cycles;* by permission of National Bureau of Economic Research

The wealth of data

was probably a French physician, Clément Juglar, in 1860. Other writers who developed Juglar's approach suggested that the cycles recur every nine or ten years, and distinguished three phases, or periods, of a typical cycle: prosperity, crisis, and liquidation. Subsequent analysis has tended to designate 1825, 1836, 1847, 1857, 1866, 1873, 1882, 1890, 1900, 1907, 1913, 1920, and 1929 as initial years of crisis. If that is correct, then the average interval between them was eight years, rather than nine or ten as suggested by Juglar. In the years since 1929, the regularity of business fluctuations has been somewhat offset by government anticyclical policies.

The so-called Juglar cycle has often been regarded as the true, or major, economic cycle, but several smaller cycles have also been distinguished. Close study of the interval between the peaks of the Juglar cycle suggests that partial setbacks occur during the expansion, or upswing, and that there are partial recoveries during the contraction, or downswing. These smaller cycles generally coincide with changes in business inventories, lasting an average of 40 months. Other small cycles result from changes in the demand for and supply of particular agricultural products such as hogs (three to four years), cotton (two years), and beef (five years in the Netherlands). Hide and leather production fluctuates in an 18-month cycle.

Kondratieff's waves. Longer cycles have also been studied. The construction industry has been found to have cycles of 17 to 18 years in the United States, and of 20 to 22 years in England. Finally, there are the long waves, or so-called Kondratieff cycles, named for a Russian economist, Nikolai D. Kondratieff, who showed that in the major Western countries during the 150 years from 1790 to 1940 it was possible to distinguish three periods of slow expansions and contractions of economic activity averaging 50 years in length:

1. 1792–1850	Expansion: 1792–1815	23 years
	Contraction: 1815–50	35 years
2. 1850–96	Expansion: 1850–73	23 years
	Contraction: 1873–96	23 years
3. 1896–1940	Expansion: 1896–1920	24 years
	Contraction: 1920–40	20 years

Only these three Kondratieff waves have been observed.

Some students of business cycles have analyzed them by statistical methods, in the hope of finding regularities that are not immediately apparent. One speculative theory has held that the larger cycles were built up from smaller ones. Thus, two seasonal cycles would produce a two-year cycle, two of which would produce a four-year cycle; two four-year cycles would become an eight-year, or Juglar, cycle, and so on. The hypothesis is not widely accepted.

Depressions and upswings. Cycles of varying lengths are closely bound up with economic growth. In 19th-century Germany, for example, upswings in total economic activity were associated with the growth of the railroad, metallurgy, textile, and building industries. Periodic crises brought slowdowns in growth. The crisis of 1873 led to a wave of financial and industrial bankruptcies; recovery started in 1877, when iron production ceased to fall, and by 1880 a new upswing was underway. The recession of 1882 was less severe than the previous one, but a slump that began in 1890 led to a serious depression, with complaints of overproduction.

Cycles in history

The year 1890 was also one of financial crisis in England and the United States. The British banking house of Baring Brothers failed, partly because of a revolution in Argentina. English pig-iron production fell from 8,300,000 tons in 1889 to 6,700,000 in 1892, and unemployment increased. That depression might have been less severe but for the international financial crisis, especially intense in the United States, where, in 1893, a stock market panic led to widespread bank failures.

The recession of 1900 was followed by an unusually vigorous upsurge in almost all of the Western economies. U.S. pig-iron production increased by more than 150 percent during the expansion, which lasted until 1907; building permits more than doubled; and freight traffic rose by more than 50 percent. Prices rose more and more rapidly as the U.S. economy approached full employment.

Deviations from cycle patterns. Cycles are compounded of many elements. Historical fluctuations in economic activity cannot be explained entirely in terms of combinations of cycles and subcycles; there is always some factor left over, some element that does not fit the pattern of other fluctuations. It is possible, for example, to analyze a particular fluctuation into three principal components: a long component or trend; a very short, seasonal component; and an intermediate component, or Juglar cycle. But these components cannot be found exactly recombined in another fluctuation because of a residual element in the original fluctuation that does not have a cyclical form. If the residual is small, it might be attributed to errors of calculation or of measurement. Or, the residual might be regarded as the result of such accidental events as epidemics, floods, earthquakes, riots, strikes, revolutions, or wars, which obviously cannot be fitted into a recurring pattern. On a more sophisticated statistical level, it can be treated as "random movement." If the random element is always present, it becomes an essential element of the analysis to be dealt with in terms of probability.

Problems of analyzing cycles

A more rigorous analysis has to go even further. One difficulty in separating out the components of economic movements is that the components are not perfectly independent of each other. The determination of a long component or trend assumes that the Juglar component is already known. In the same way, determining the Juglar component requires isolating it from the long-term component. Probably only the seasonal component can be isolated independently of the others, and that because it is immediately related to such noneconomic factors as climate or custom. To avoid such difficulties, researchers have tried looking for "hidden periodicities," using a mathematical technique known as harmonic analysis, or Fourier series. Two alternative methods are open to them: they may assume a certain periodicity and try to fit the statistical data to the resulting equation; or they may ask mathematicians to supply all of the possible periodicities contained in the data and then determine which are the most probable.

For practical purposes, it would be useful to know the typical shape of a cycle and how to recognize its peak and trough. A great amount of work has been done in what may be called the morphology of cycles. In the United States, Arthur F. Burns and Wesley C. Mitchell have based such studies on the assumption that at any specific time there are as many cycles as there are forms of economic activity or variables to be studied and have tried to measure these in relation to a "reference cycle," which they artificially constructed as a standard of comparison. The object in such studies was to describe the shape of each specific cycle; to analyze its phases; to measure its duration and velocity; and to measure the amplitude or size of the cycle.

In studying various cycles, it has been possible to construct "lead and lag indicators"—that is, statistical series with cyclical turning points consistently leading or lagging behind the turns in general business activity. Researchers using these methods have identified a number of series, each of which reaches its turning point from two to ten months before the turns in general business activity; and another group of series, which has followed the turns in business by two to seven months. Examples of leading series include published data for new business orders, residential building contracts, the stock market index, business failures, and the length of the average workweek. These and other leading indicators are widely used in economic forecasting.

THE DYNAMIC ANALYSIS OF CYCLES

A satisfactory explanation of cycles must isolate the forces and relationships that tend to produce these recurrent movements. There have been many theories of the business cycle. An understanding of them requires analysis of some of the factors that can cause cyclical movements.

Factors that may engender fluctuations

The multiplier and the accelerator. One such factor is the relationship between investment and consumption. Any new expenditure—*e.g.*, on building a road or a factory—generates several times as much income as the expenditure itself. This is so because those who are paid to build the road or factory will spend more of what they receive; their expenditures will thus become income for others, who will in their turn spend most of what they receive. Every new act of investment will, thus, have a stimulating effect on aggregate income. This relationship is known as the *investment multiplier.* Of itself, it cannot produce cyclical movements in the economy; it merely provides a positive impulse in an upward direction.

To the relationship between investment and consumption must be added that between consumer demand and investment. An increase in demand for refrigerators, for example, will eventually require increased investment in the facilities for producing them. This relationship is known as the *accelerator;* and it implies that an increase in national income will stimulate investment. As with the multiplier, it cannot of itself explain cyclical movements; it merely accounts for a fundamental instability.

It can be shown, however, that the multiplier and accelerator in combination may produce very strong cyclical movements. Thus, when an increase in investment occurs, it raises income by some larger amount, depending on the value of the multiplier. That increase in income may in turn induce a further increase in investment. The new investment will stimulate a further multiplier process, producing additional income and investment. In theory, the interaction might continue until a point is reached at which such resources as labour and capital are being fully utilized. At that point—with no increase in employment and, therefore, no rise in consumer demand—the operation of the accelerator would cease. That halt in demand, plus the lack of new capital, would cause new investment to decline and workers to be laid off. The process thus would go into reverse. The fluctuations in national income could take various forms, depending on the characteristics of the economy and the way in which the population allocated its income between consumption and savings. Such spending habits, of course, affect both the levels of consumer demand and capital investment. This theoretical analysis does not explain actual economic fluctuations; it is merely an aid to understanding them.

Other dynamic factors. The analysis can be made more realistic by taking into account three other factors. First, since the theoretical, wide-swinging cycles engendered by the interaction of the multiplier and the accelerator are observed to occur only within narrow limits, one may assume that although the economy has an inherent tendency to swing very widely there are limits beyond which it cannot go. The upper limit to the swings would be the point at which full employment or full capacity is reached; the lower limit is more difficult to define, but it would be established when the forces that make for long-term economic growth begin to operate. Thus, the upswing of a cycle stops when it meets the upper limit; and the downswing stops at the lower limit, resulting in continuous cyclical movements with an overall upward trend —a pattern corresponding to the one found in history.

Upper and lower limits to swings

The occurrence of time lags—the inevitable delays between every decision and its effects—provides another reason for expecting cyclical fluctuations to occur in any economic process. This phenomenon is illustrated, for example, in the relation between the action of a thermostat and the temperature of a room. A fall in room temperature causes the thermostat to turn on the heater; but there is a lag in time until the room warms up sufficiently to cause the thermostat to turn the heat off, whereupon the temperature begins to fall again. The shape of the curve of the temperature cycle will depend on the responsiveness of the thermostat and on the time required to raise the temperature of the room. By making various adjustments, it is possible to minimize the cycle, but it can never be eliminated entirely. In economic life, there are many such time lags: between the decision to invest and the completion of the project; between the farmer's decision to raise hogs and the arrival of pork chops at the store; between prices at the time of a decision and prices at the time the action is completed.

Random shocks, or what economists call exogenous factors, constitute the third type of phenomena affecting business cycles. These are such external disturbances to the system as weather changes, unexpected discoveries, political changes, wars, and so on. It is possible for such external impulses to cause cyclical motions within the system, in much the same way that striking a rocking horse with a stick will cause the horse to rock back and forth. The length of the cycle will be determined by the internal relationships of the system, but its intensity is governed by the external impulse.

THEORIES OF THE BUSINESS CYCLE

The analytic concepts above may be found in most of the realistic attempts to explain economic fluctuations. Theories of the business cycle, or, more properly, of economic fluctuations, may be classified in two groups: those that ascribe cyclical movements to external forces (exogenous factors); and those that attribute the fluctuations to internal forces (endogenous factors).

Exogenous theories. *Agricultural.* Perhaps the oldest theories of the business cycle are those that link their cause to fluctuations of the harvest. Since crops depend upon soil, climate, and other natural factors that in turn may be affected by biological or meteorological cycles, such cycles will transmit their effects through the harvests to the rest of the economy. The 19th-century English economist William Stanley Jevons thought he had found the key to such a process in the behaviour of sunspots, which seemed to display a ten-year cycle. His naive explanation could not long withstand critical examination. It had a certain interest, however, in suggesting a causal factor that was completely detached from the economic system and one that could not be influenced by it in turn.

Psychological. A number of writers have explored mass psychology and its consequences for economic behaviour. Individuals are strongly influenced by the beliefs of the group or groups to which they belong. There are times when the general mood is optimistic, and others when it is pessimistic. An English economist, Arthur C. Pigou, in his *Industrial Fluctuations* (1927), put forward a theory of "noncompensated errors." He pointed out that if individuals behave in a completely autonomous way their errors in expectations will tend to offset each other. But if they imitate each other, their errors will accumulate until they acquire a global magnitude that may have powerful economic effects. This follow-the-crowd tendency obviously operates as a factor in the ups and downs of the stock exchanges, financial booms and crashes, and the behaviour of investors. One can say, however, that the psychological factor is not enough to explain economic fluctuations; moods of optimism and pessimism must themselves rest upon economic factors.

Effects of wars and taxes

Political. Some observers have maintained that economic fluctuations result from political events. It is obvious that such events as the Napoleonic Wars, World Wars I and II, and even the Korean War of 1950–53 have had strong economic consequences. Even the imposition of a tax or an import restriction may have some dynamic effect upon the economy. The question is whether such political factors are capable of producing cyclical movements.

Technological. Ever since the Industrial Revolution at the end of the 18th century, technical innovations have followed each other without end but not without pause. There have been periods of innovation and quieter periods in which the innovations were being absorbed. The world has passed through the era of steam, the era of petroleum, and the era of electricity and has entered the era of atomic energy. It is possible that if a rhythm could be found in these waves of change, the same rhythm might be responsible for corresponding movements in the economy. But it is equally possible that the technical innovations themselves have been dictated by the prior needs of the economy.

Demographic. Even population has been postulated as a cause of economic fluctuations. There are, undeniably, cyclical movements of population; it is possible to find fluctuations in the rates of marriage, birth, mortality, and migration; but the extent to which such fluctuations may have been caused by economic conditions is not clear.

Endogenous theories. *Monetary.* Some writers have ascribed economic fluctuations to the existence of money. Changes in the money supply do not always conform to underlying economic changes, and it is not difficult to see how this lack of coordination could produce disturbances in the economic system. Thus, an increase in the total quantity of money, if it is not matched by an increase in economic activity, will tend to produce higher prices; the higher prices in turn may stimulate an investment boom, and so on.

The banking system, with its ability to expand the supply of credit in a time of boom and to contract the supply of credit in time of recession, may in this way amplify small economic fluctuations into major cycles of prosperity and depression. Some theorists have emphasized the influence of the rate of interest: if the rate fixed by the banking system does not correspond to the "natural" rate dictated by the requirements of the economy, the disparity may of itself induce an expansion or contraction in economic activity.

Underconsumption. In a progressive economy, production tends to expand more rapidly than consumption. The disparity results from the unequal distribution of income; the rich do not consume all their income, while the poor do not have sufficient income to meet their consumption needs. This imbalance between output and sales has led to theories that the business cycle is caused by overproduction or underconsumption. But the basic, underlying cause is society's inadequate provision for an even flow of savings out of the excess of what is produced over what is consumed. In other words, saving is out of step with the requirements of the economy; it is improperly distributed over time.

Imbalance between output and sales

Investment. The fact that changes in the supply of savings, or loanable funds, are not closely coordinated with changes in the rest of the economy lies at the heart of the numerous theories that link investment imbalance to the business cycle. Savings accumulate when there is no immediate outlet for them in the form of new investment opportunities. When times become more favourable, these savings are invested in new industrial projects, and a wave of investment occurs that sweeps the rest of the economy along with it. It is in this context that the tools of analysis—the accelerator and the multiplier—find their application: the new investment creates new income, which in turn acts as a further stimulus to investment. An early observer of this phenomenon, a Russian economist, Mikhayl Tugan-Baranovsky, in 1894 published a study of industrial crises in England in which he maintained that the cycle of investment continues until all the capital funds have been used up. Bank credit expands as the cycle progresses. Disproportions then begin to develop among the various branches of production as well as between production in general and consumption. These imbalances lead to a new period of stagnation and depression.

CYCLES AND PUBLIC POLICY

Controlling and damping the business cycle

The study of business fluctuations leads naturally to the question of what government and society can do to offset, or control them. Any action must begin with prediction. The problem of predicting business fluctuations is that they are not cycles in the sense that they display a regular and recurring pattern. The past serves as no sure guide to the future.

Forecasting. Much study has gone into the development of techniques for forecasting economic events—both for a whole national economy and for individual industries (see ECONOMIC FORECASTING). The best known approach involves finding statistical series that are leaders in an upturn or downturn; *i.e.*, the leading indicators such as stock prices or residential building contracts mentioned earlier. But these are easier to recognize in hindsight than at the time of occurrence because the behaviour of economic statistics is not always consistent—leading series do not always lead. Furthermore, it is not always easy to tell whether a downturn in a particular series is really a downturn or simply a minor irregularity in a continuing upward movement.

Another approach to the understanding and control of the cycle is through rather elaborate econometric models employing many simultaneous equations that describe the relationships of statistical series to one another over time. With modern computers, the necessary calculations can be made very quickly, and, to the extent that the equations themselves are an accurate representation of the economy and of the way its human components behave, the forecasts will be accurate (see ECONOMETRICS).

Regulation of the cycle. The econometric approach has been useful as an instrument of policy making. A Dutch economist, Jan Tinbergen, has distinguished three types of economic variables: those that cannot be influenced directly by government action; those that may be regarded as the targets of government action or policy (such as employment and national income); and those upon which a government can exert a direct influence (wage rates, government expenditures, tax rates, profit margins, and so forth). The aim of policy is to minimize cyclical fluctuations, not in the hope of making them disappear but in the belief that it is possible to avoid the extremes of inflation and depression.

There are various ways of doing this. Monetary policies seek to increase or decrease the money supply to counter the contracting or expanding phases, respectively, of a cycle; this is accomplished through the operation of the central banking system. The government can also influence the economy fiscally by raising or lowering taxes and expenditures, thereby stimulating business activity or damping it down; it can lower tax rates and spend more freely in times of recession and raise taxes and reduce its spending in times of inflation (see FISCAL AND MONETARY POLICY). The government may also intervene more directly in the economy by attempting to control wages, prices, and profits, or by stimulating or discouraging investment.

Postwar era of mild recessions

Since World War II, cycles have flattened out; the recessions have been mild; and the upswings have not proceeded to the extremes of former times. Over the years 1949–70, the Western industrial countries and Japan experienced a remarkable period of economic growth that showed no sign of abating. That record seemed to be attributable in part to countercyclical policies the governments had pursued. The increased proportion of governmental revenue expenditure in most national economies also tended to level the peaks and valleys of the cycle. Much of this fiscal weight acts countercyclically, automatically offsetting cyclical changes in income and expenditure. During a recession, income tax receipts fall off, while government expenditures on unemployment compensation and relief rise. Conversely, during an up-

swing, government income tax revenues rise faster than the level of economic activity and, as a damper on private spending, they thus help to restrain the upward movement of the economy.

Cycles under a planned economy. It has often been suggested that cycles and fluctuations might be eliminated altogether by thoroughgoing economic planning. In this view, the business cycle is a disease of the market economy; in a planned economy, there would be no market and hence no possibility of a cycle. The planning authority would map out the growth of the economy in advance for five or seven years, and it would control the execution of the plan so that there would be no serious disparity between expectations and results. It is not likely that any plan will ever be fulfilled exactly; in the history of planned economies, there are always discrepancies between what was originally planned and what was finally attained. These have to be corrected through new plans.

A particularly severe fluctuation occurred in the planned economy of Czechoslovakia in 1963. Difficulties became apparent in 1961, when planned production targets for basic industries were not met. Shortages in basic industries were communicated to other industries dependent on them. When the difficulties increased in 1962, the government decided to abandon the five-year plan (then half way through its second year) and replace it with a one-year plan to allow for reorganization; a seven-year plan, beginning in 1964, followed. Investments for the interim year of 1963 were slashed, and only a 1-percent increase in production was planned. But economic difficulties grew, made worse by a transportation crisis. To these troubles were added an unusually harsh winter and a drought-ridden summer, with the consequence that industrial output in 1963 fell below the level of 1962. In subsequent years, the economy swung upward again.

Fluctuations and cycles may be inherent in modern economies, whatever the nature of the controls imposed by society. It is possible that an economy in which there were no cycles would be incapable of growth.

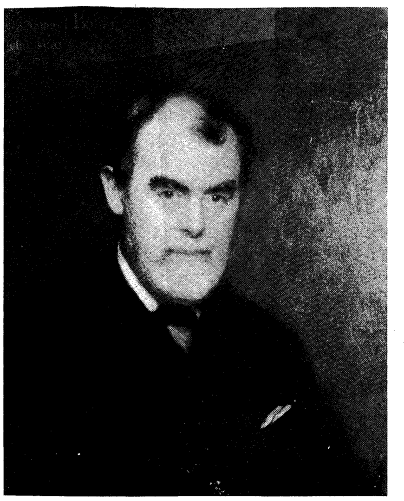
BIBLIOGRAPHY. Good introductions to the study of business cycles include: A.H. HANSEN, *Business Cycles and National Income*, enl. ed. (1964); R.A. GORDON, *Business Fluctuations*, 2nd ed. (1961); R.C.O. MATTHEWS, *The Business Cycle* (1962); E. LUNDBERG (ed.), *The Business Cycle in the Post-War World* (1955); and H. GUITTON, *Fluctuations et croissance économiques*, 3rd ed. (1969). Famous surveys of business cycle theories are J.A. SCHUMPETER, *Business Cycles: A Theoretical, Historical, and Statistical Analysis of the Capitalist Process*, 2 vol. (1939; abridged ed., 1964); and G. HABERLER, *Prosperity and Depression*, 5th ed. (1964); J. TINBERGEN, *Statistical Testing of Business Cycle Theories*, 2 vol. (1939, reprinted 1968), attempts to verify the theories surveyed in Haberler's work by econometric analysis. The nontheoretical approach to business cycle research is set forth in A.F. BURNS and W.C. MITCHELL, *Measuring Business Cycles* (1946); further developed in G.H. MOORE (ed.), *Business Cycle Indicators* (1961). Important articles are collected in the AMERICAN ECONOMIC ASSOCIATION, *Readings in Business Cycle Theory* (1944), and *Readings in Business Cycles* (1965).

(H.Gu.)

Butler, Samuel

The certainties of the Victorian Age met their match in Samuel Butler, the English novelist, essayist, and critic, whose *Erewhon* ("nowhere" rearranged) foreshadowed the collapse of the illusion of eternal progress as later exemplified in the satiric utopias of Aldous Huxley's *Brave New World* (1932) and George Orwell's *Nineteen Eighty-four* (1949), while his *Way of All Flesh* helped turn the tide against excessive parental dominance and religious rigidity.

The son of the Rev. Thomas Butler and grandson of Samuel Butler, headmaster of Shrewsbury School and later bishop of Lichfield, Butler was born at Langar Rectory, Nottinghamshire, on Dec. 4, 1835. After six years at Shrewsbury he went to St. John's College, Cambridge, and graduated in 1858. His father wished him to be a clergyman, and young Butler actually went as far as to do a little "slumming" in a London parish by way of preparation for holy orders. But the whole current of his highly independent and heretical nature was carrying him away from everything his father stood for: home, church, and Christianity itself—or what Christianity had appeared to mean at Langar Rectory. Butler returned to Cambridge and continued his musical studies and drawing, but after an unpleasant altercation with his father he left Cambridge, the church, and home and emigrated to New Zealand, where (with funds advanced by his father) he set up a sheep run in the Canterbury settlement.



Butler, oil painting by Charles Gogin, 1896. In the National Portrait Gallery, London.

Reaction to Darwin

When Darwin's *Origin of Species* (1859) came into his hands soon after his arrival in New Zealand, it took him by storm; he became "one of Mr. Darwin's many enthusiastic admirers," and a year or two later he told a friend that he had renounced Christianity altogether. Yet, as it proved, Christianity had by no means finished with him. For the next 25 years it was upon religion and evolution that Butler's attention was mainly fixed. At first he welcomed Darwinism because it enabled him to do without God (or rather, without his father's God). Later, having found a God of his own, he rejected Darwinism itself because it left God out. Thus, he antagonized both the church and the orthodox Darwinians and spent his life as a lonely outsider, or as Butler called himself after the biblical outcast, "an Ishmael." To the New Zealand *Press* he contributed several articles on Darwinian topics, of which two—"Darwin Among the Machines" (1863) and "Lucubratio Ebria" (1865)—were later worked up in *Erewhon*. Both show him already grappling with the central problem of his later thought: the relationship between mechanism and life. In "Darwin Among the Machines" he tries out the consequences of regarding machines as living organisms competing with man in the struggle for existence and so likely to win that they must at once be destroyed. In the "Lucubratio" he takes the opposite view that machines are extracorporeal limbs and that the more of these a man can tack on to himself the more highly evolved an organism he will be.

Return to England

Having doubled his capital in New Zealand, Butler returned to England (1864) and took the apartment in Clifford's Inn, London, which was to be his home for the rest of his life. In 1865 his *Evidence for the Resurrection of Jesus Christ . . . Critically Examined* appeared anonymously. For a few years he studied painting at Heatherley's art school and tried to convince himself that this was his vocation. Until 1876 he exhibited occasionally at the Royal Academy. One of his oil paintings, "Mr. Heatherley's Holiday" (1874), is in the Tate Gallery, London, and his "Family Prayers," in which the ethos of Langar Rectory is satirically conveyed, is at St. John's College, Cambridge. Later he tried his hand at musical composition, publishing *Gavottes, Minuets, Fugues and Other Short Pieces for the Piano* (1885), and *Narcissus*, a comic cantata in the style of Handel—whom he rated high above all other composers—in 1888; *Ulysses: An*

Oratorio appeared in 1904. It was typical of Butler to use his native gifts and mother wit in such exploits, and even in literature, his rightful territory, much of his work is that of the shrewd amateur who sets out alone to sling pebbles, small but lethal, at various Goliaths of the establishment. "I have never," he once said, "written on any subject unless I believed that the authorities on it were hopelessly wrong"; hence his assault on the citadels of orthodox Darwinism and orthodox Christianity; hence, later, his attempt to prove that the *Odyssey* was written in Sicily by a woman (*The Authoress of the Odyssey*, 1897); and hence his new interpretation of Shakespeare's sonnets (*Shakespeare's Sonnets Reconsidered, and in Part Rearranged*, 1899).

Erewhon

Erewhon (1872) made whatever reputation as a writer Butler enjoyed in his lifetime; it was the only one of his many books on which he made any profit worth mentioning, and he only made £69 3*s.* 10*d.* on that. Yet it was received by many as the best thing of its kind since *Gulliver's Travels*—that is to say, as a satire on contemporary life and thought conveyed by the time-honoured convention of travel in an imaginary country. The opening chapters, based upon Butler's recollections of the upper Rangitoto Mountains in New Zealand, are in an excellent narrative style; and a description of the hollow statues at the top of the pass, vibrating in the wind with unearthly chords, makes a highly effective transition to the strange land beyond. The landscape and people of Erewhon are idealized from northern Italy; its institutions are partly utopian and partly satiric inversions of our own world. Butler's two main themes, religion and evolution, appear respectively in "The Musical Banks" (churches) and in chapters called "Some Erewhonian Trials" and "The Book of the Machines." The Erewhonians have long ago abolished machines as dangerous competitors in the struggle for existence, and by punishing disease as a crime they have produced a race of great physical beauty and strength.

The Fair Haven (1873) is an ironical defense of Christianity, which under the guise of orthodox zeal undermines its miraculous foundations. Butler was dogged all through life by the sense of having been bamboozled by those who should have been his betters; he had been taken in by his parents and their religion; he was taken in again by friends, who returned neither the money nor the friendship they accepted from Butler for years; life itself, and the world, sometimes seemed to him a hollow sham. Was Darwin himself, his saviour from the world of Langar Rectory, now to prove a fraud as well? This was the suspicion that dawned upon him while writing *Life and Habit* (1878) and envenomed the series of evolutionary books that followed: *Evolution, Old and New* (1879), *Unconscious Memory* (1880), and *Luck or Cunning* (1887). Darwin had not really explained evolution at all, Butler reasoned, because he had not accounted for the variations on which natural selection worked. Where Darwin saw only chance, Butler saw the effort on the part of creatures to respond to felt needs. He conceived creatures as acquiring necessary habits (and organs to perform them) and transmitting these to their offspring as unconscious memories. He thus restored teleology to a world from which purpose had been excluded by Darwin, but instead of attributing the purpose to God he placed it within the creatures themselves as the life force.

The Way of All Flesh

Many regard *The Way of All Flesh*, published in 1903, the year after Butler's death, as his masterpiece. It certainly contains much of the quintessence of Butlerism (though the *Note-Books* are necessary to supplement it). This largely autobiographical novel tells, with ruthless wit, realism, and lack of sentiment, the story of Butler's escape from the suffocating moral atmosphere of his home circle. In it, the character Ernest Pontifex stands for Butler's early self and Overton for his mature self; Theobald and Christina are his parents; Towneley and Alethea represent "nice" people who "love God" in Butler's special sense of having "good health, good looks, good sense, experience, and a fair balance of cash in hand." The book was influential at the beginning of the anti-Victorian reaction, and Butler was saluted by G.B. Shaw as "the greatest English writer of the latter half of the nineteenth century." He died in London on June 18, 1902.

MAJOR WORKS

TOPOGRAPHICAL: *A First Year in Canterbury Settlement*, 1863 (ed. by R.A. Streatfield, with other early essays, 1914); *Alps and Sanctuaries of Piedmont and the Canton Ticino*, 1882; *Ex Voto: An Account of the Sacro Monte or New Jerusalem at Varallo-Sesia*, 1888.

SATIRICAL AND THEOLOGICAL: *The Evidence for the Resurrection of Jesus Christ, as Given by the Four Evangelists, Critically Examined*, 1865 (anon.); *Erewhon; or, Over the Range*, 1872 (anon.); *The Fair Haven*, 1873; *Erewhon Revisited*, 1901; *God the Known and God the Unknown*, 1909.

SCIENTIFIC: *Life and Habit: An Essay After a Completer View of Evolution*, 1878; *Evolution, Old and New*, 1879; *Unconscious Memory*, 1880; *Luck or Cunning as the Main Means of Organic Modification?*, 1887.

NOVEL: *The Way of All Flesh*, 1903.

MISCELLANEOUS: *A Lecture on the Humour of Homer*, 1892; *The Life and Letters of Dr. Samuel Butler*, 2 vol., 1896; *The Authoress of the Odyssey*, 1897; *The Iliad of Homer, Rendered into English Prose*, 1898; *Shakespeare's Sonnets Reconsidered, and in Part Rearranged*, 1899; *The Odyssey, Rendered into English Prose*, 1900; *Essays on Life, Art and Science*, 1904; *The Note-Books of Samuel Butler* (ed. H. Festing Jones), 1912.

MUSICAL COMPOSITIONS: *Gavotte, Minuets, Fugues and Other Short Pieces for the Piano*, 1885 (in collaboration with H. Festing Jones); *Narcissus*, 1888 (a comic cantata in the style of Handel); *Ulysses: An Oratorio*, 1904.

BIBLIOGRAPHY. The standard biography is H. FESTING JONES, *Samuel Butler, Author of Erewhon (1835–1902): A Memoir*, 2 vol. (1919). Studies on different aspects of Butler as man and writer include: M.R. GARNETT, *Samuel Butler and His Family Relations* (1926); C.G. STILLMAN, *Samuel Butler: A Mid-Victorian Modern* (1932); MALCOLM MUGGERIDGE, *The Earnest Atheist: A Study of Samuel Butler* (1936); P.N. KINGSMILL, *After Puritanism, 1850–1900* (1929); DESMOND MACCARTHY, *Collected Essays II* (1932). There is a bibliography of Butler's works and of books about him (up to 1919) in vol. 1 of Jones's *Memoir* (cited above). See also A.J. HOPPE, *A Bibliography of the Writings of Samuel Butler (Author of "Erewhon") and of Writings About Him* (1925, reprinted 1967); and S.B. HARKNESS, *The Career of Samuel Butler, 1835–1902: A Bibliography* (1955).

(B.W.)

Byrd, Richard E.

Rear Admiral Richard E. Byrd of the United States Navy, a 20th-century pioneer aviator and polar explorer, first won fame by his long-distance flights in the Arctic and over the Atlantic and is best known for his well-organized expeditions to the Antarctic, where he conducted scientific explorations, survived a winter alone near the South Pole, and, from his base, named Little America, on the edge of the Ross Sea, Antarctica, flew over and named hitherto undiscovered tracts of territory. The knowledge and experience he gained was of substantial benefit to subsequent expeditions to the south polar regions.

Byrd was born at Winchester, Virginia, on October 25, 1888. After attending Shenandoah Military Academy, the University of Virginia, and the U.S. Naval Academy, he learned flying at the U.S. Naval Air Station, Pensacola, Florida, and served in the navy with distinction until the end of World War I. After the war he turned his attention to developing navigational aids for aircraft; he developed plans for the first NC flying boat transatlantic flights, but he was deprived of a place in the principal aircraft. He also assisted with dirigibles built for transatlantic crossings. His polar career began in 1924 when he had command of a small naval aviation detachment with Comdr. D.B. MacMillan's Arctic expedition to western Greenland, based at Etah.

west Greenland had fired Byrd with the ambition to fly over the North Pole. He claimed this accomplishment on May 9, 1926, while acting as navigator, with a compatriot, Floyd Bennett, as pilot. According to his records, the return journey from King's Bay, Spitsbergen, took 15½ hours, with no mishaps beyond an oil leak from the starboard engine of his Fokker tri-motor airplane. For this feat he was awarded the U.S. Congressional Medal of Honor. (In the early 1970s, however, grave doubts were cast upon these records and, indeed, upon Byrd's claim to have reached the pole at all.) He later aided the U.S. aviator Charles A. Lindbergh with navigational training and the use of the specially extended runway for Lindbergh's transatlantic solo flight in May 1927.

Byrd next decided to make an attempt to fly the Atlantic from west to east; and in June 1927, with three companions, he made the flight in 42 hours, crash-landing in bad weather at Ver-sur-Mer on the coast of Brittany, France. For this successful flight he was made a Commandant of the French Legion of Honour; he and his crew also received the Medal for Valor from the Mayor of New York City.

In 1928 he announced his decision to explore the unknown regions of the Antarctic from the air. With large financial backing from such wealthy Americans as Edsel Ford and John D. Rockefeller, Jr., his fame was such that he could inspire the American public to contribute liberally to the estimated cost of the venture, which was about $400,000.

At Little America

His expedition, the largest and best equipped that ever had set out for the Antarctic, sailed south in October 1928. A substantial and well-supplied base, called Little America, was located on the face of the Ross Ice Shelf, a wide plain of shelf ice fronting the Ross Sea near an indentation in the ice cliff named the Bay of Whales. Flights were made from this base over the Antarctic continent. A range of high mountains, named the Rockefeller Mountains, was discovered; and a large tract of hitherto unknown territory beyond them was named Marie Byrd Land, after Byrd's wife. The following spring—*i.e.*, in November 1929, according to the Antarctic season—Byrd, as navigator, with three companions, flew from Little America to the South Pole and back in 19 hours with no mishap, except that a few of their provisions had to be thrown overboard in order to lighten the plane.

In 1933 a second Byrd expedition visited Little America with the aim of mapping and claiming land around the pole; he extended the exploration of Marie Byrd Land and continued his scientific observations. During the winter of 1934 (from March to August), Byrd spent five months alone in a hut at a weather station named Bolling Advance Base, buried beneath the Barrier face 123 miles (196 kilometres) south of Little America, enduring temperatures between −58° and −76° F (−50° and −60° C) and sometimes much lower. He was finally rescued in a desperately sick condition, suffering from frostbite and carbon-monoxide poisoning. This was perhaps his most controversial exploit.

Byrd led three subsequent expeditions while serving as director of U.S. government expeditions. For brief periods on each trip he continued personally to take an active part in exploration. At the request of Pres. Franklin D. Roosevelt he took command of the U.S. Antarctic service, which was terminated after its first year because of the approach of World War II. Bases were located at Little America and Stonington Island, Antarctic Peninsula. Byrd's discovery of Thurston Island greatly decreased the length of unexplored coast of the continent.

During World War II Byrd served on the staff of the chief of naval operations and, among other duties, evaluated Pacific islands as operational sites. His talent for organization and administration and his influence and skill in public relations led him to serve in many important governmental, patriotic, and humanitarian capacities.

After World War II Byrd was in charge of a program known as Operation High Jump, which claimed to have discovered and mapped 537,000 square miles (1,390,000 square kilometres) of Antarctic territory. Byrd flew into Little America from the deck of the aircraft carrier "Philippine Sea" north of the icepack, about 700 miles from the camp. He made a second flight over the South Pole and took part in several other flights. In 1955 Byrd was made officer in charge of the United States Antarctic programs, the senior authority for government Antarctic matters. He accompanied naval Operation Deep Freeze aboard the icebreaker "Glacier" and took his last exploratory flight over the heartland of Antarctica and once again over the South Pole on January 8, 1956.

Byrd's achievement

Byrd's major achievement was to apply the airplane, radio, and other modern technical resources to polar exploration. He did not agree with the Norwegian explorer Roald Amundsen (1872–1928) that the airplane one day would supplant exploration by the traditional means of using sledges and dogs. Rather, he believed that modern techniques of exploration should supplement the traditional methods that would always have the advantage of guaranteeing greater certainty and accuracy. All of his expeditions, therefore, carried dog teams, sledges, and personnel to handle them—a combination that was to prove efficient and to achieve results of great scientific value.

It is in his book *Alone*, which describes his experiences at Bolling Advance Base, that the character of the man can be glimpsed rather than in the more official account, *Little America*. The picture that emerges is that of a simple, homely man, devoted to his family and always full of consideration for others. There is no doubt that men trusted him and followed him, that his ability inspired confidence. He was officially cited 20 times for bravery or conspicuous conduct.

Byrd was also competent in public relations. Indeed, perhaps inevitably, his expeditions were surrounded by a glare of publicity that aroused criticism, particularly by commentators abroad. Press accounts of a "million dollar expedition" conveyed an impression of unlimited funds and profligate expenditure. But the impression was not true. Byrd was as pressed for money as any other polar explorer, and he had to rely largely on the public to provide the funds. Hence the tumult and the shouting. The U.S. public saw in him the virtues they most admired and placed their trust in him. Although Byrd himself knew the value of publicity, he always kept in mind his goal of professional achievement. When he died in Boston on March 11, 1957, he was an international hero. He was buried in Arlington National Cemetery, Virginia, with full military honours.

BIBLIOGRAPHY. RICHARD E. BYRD, *Little America* (1930), is an account of his aerial exploration in the Antarctic and his flight to the South Pole; *Skyward* (1928) is the official

report of his 1928 to 1930 expedition to the Antarctic, and his report of the flight to the North Pole and flight across the Atlantic; *Alone* (1938) describes his experiences at Bolling Advance Base. Works about Byrd include: CHARLES J.V. MURPHY, *Struggle: The Life and Exploits of Commander Richard E. Byrd* (1928), a biography; F. GREEN, *Dick Byrd, Air Explorer* (1928); and RICHARD MONTAGUE, *Oceans, Poles and Airmen* (1971), disputing Byrd's claim that he flew to the North Pole.

Byrd, William

The greatest English composer of the age of Shakespeare, William Byrd excelled in music that was religious in character and possessed a power and originality transcending the purely liturgical. Of his origins and early life virtually nothing is known; he was born in 1543, possibly in Lincolnshire. He was a pupil and protégé of the organist and composer Thomas Tallis. Byrd's first authenticated appointment was as organist at Lincoln Cathedral (February 27, 1563). In 1572 he moved to London to take up his post as a gentleman of the Chapel Royal, where he shared the duties of organist with Tallis.

Early life

The close personal and professional relationship between the two men had important musical consequences. In 1575 Elizabeth I granted them a joint monopoly for the importing, printing, publishing, and sale of music, and the printing of music paper. The first work under their imprint appeared in that year—a collection of *Cantiones Sacrae* dedicated to the Queen; of the 34 motets, Tallis contributed 16 and Byrd 18.

In 1577 Byrd moved to Harlington, Middlesex, where he and his family lived for the next 15 years. As a devout and lifelong Catholic he probably preferred the greater privacy of living outside London. Yet in spite of his close social contact with many other Catholics, some of whom were certainly implicated in treasonable activities, his own loyalty to the government was never questioned.

In 1585 Tallis died, and in the following year Byrd's wife, Julian. These sad events may have prompted him to set his musical house in order, for in the next three years he published four collections of his own music: *Psalms, Sonets, & songs of sadnes & pietie* (1588), *Songs of sundrie natures* (1589), and two further books of *Cantiones Sacrae* (1589 and 1591). The two secular volumes were dedicated, respectively, to Sir Christopher Hatton, the lord chancellor, and to Lord Hunsdon, the lord chamberlain and first cousin to the Queen. Both volumes of motets were dedicated to prominent Catholics: the Earl of Worcester, a great friend and patron of Byrd's, whose loyalty to the crown was unimpeachable, and Lord Lumley. Also in 1591 a manuscript volume of Byrd's keyboard music was prepared for "my Ladye Nevell" (probably Rachel, wife of Sir Edward Nevill), while many more keyboard pieces found their way into the volume known as the *Fitzwilliam Virginal Book*, copied by another well-known Catholic, Francis Tregian, during his imprisonment in the Fleet.

First collections of works

In 1592 or 1593 Byrd moved with his family to Stondon Massey, Essex, where he lived for the rest of his life. At the accession of James I the Catholics' prospects temporarily brightened, and this probably prompted Byrd's next three publications. In his collection of three masses and two books of *Gradualia* (1605, 1607), he attempted to provide single-handed a basic liturgical repertory, comprising music for the ordinary (*i.e.*, the unvarying parts of the mass) and for the proper (*i.e.*, the parts of the mass that vary according to the day or the feast) of all main feasts. It is significant that the dedicatees of both books of *Gradualia* were prominent Catholics ennobled within the first years of James's reign: the Earl of Northampton and Lord Petre of Writtle, another close friend of Byrd's. One further publication came from Byrd, the *Psalmes, Songs and Sonnets* of 1611, containing English sacred and secular music. He died on July 4, 1623.

Achievement and significance

Byrd's musical stature can hardly be overrated. He wrote extensively for every medium then available except, it seems, the lute. His virginal and organ music brought the English keyboard style to new heights and pointed the way to the achievements of other English composers, such as John Bull, Giles Farnaby, Orlando Gibbons, and Thomas Tomkins. In music for viol consort he also played an extremely important role, pioneering the development of the freely composed fantasia, which was to become the most important form of Jacobean and later composers. Although he admired Italian madrigals and as a publisher helped introduce them to England, Byrd's own secular vocal music is distinctly conservative; much of it is conceived for the old-fashioned medium of solo voice accompanied by viol consort, later abandoned by the English madrigalists, with Thomas Morley (Byrd's pupil) at their head. Byrd sometimes added texts to the polyphonic accompaniments of these songs, in effect making them madrigals.

Byrd's religious beliefs did not prevent him from composing a great deal of church music to English words, most of which has survived only in manuscript. Although this is of generally high quality it cannot be denied that Byrd maintained his highest consistent level in his Latin sacred music. Of this, the 1589 and 1591 sets of *Cantiones Sacrae* (mostly designed for the private edification of the Catholic circles Byrd moved in and therefore unrestricted by liturgical considerations) have an intensity unrivalled in England and a breadth of scale unknown on the Continent. Although the *Gradualia* are necessarily more concise and superficially more similar to the work of Giovanni da Palestrina and Tomás Luis de Victoria, with which Byrd was well acquainted, closer examination reveals their real individuality as well as an astonishingly consistent level of inspiration.

MAJOR WORKS

Roman Catholic church music

MASSES: Masses for three, four, and five voices.

MOTETS: Motets for from three to nine voices in *Cantiones Sacrae*, 1575; *Cantiones Sacrae*, books 1 and 2, 1589 and 1591; *Gradualia*, two books, 1605 and 1607.

Anglican church music

ANTHEMS: More than 20 motets, for from three to six voices, and for solo voice and viols, most in *Songs of sundrie natures*, 1589; and in the collection *Teares or Lamentations of a Sorrowful Soul* of Sir William Leighton, 1614.

PSALMS: About 20 in *Psalmes, Sonets, & songs of sadnes & pietie*, 1588; and *Songs of sundrie natures*, 1589.

MISCELLANEOUS: Litany for four voices; two complete services; two magnificats and a Nunc Dimittis; prayers and responses.

Songs and madrigals

MADRIGALS: About 50 madrigals in *Psalmes, Sonets, & songs of sadnes & pietie*, 1588; *Songs of sundrie natures*, 1589; *Musica Transalpina*, 1588; and *The first sett of Italian Madrigalls*, 1590.

SONGS: Songs for voices and viols in *Songs of sundrie natures*, 1589; and in *Psalmes, Songs, & sonnets of sadnes & pietie*, 1611; over 30 for voices and instruments in manuscript; about 40 rounds and canons.

Instrumental music

VIOLS: Fantasias in three to six parts; In nomines; pavans and galliards.

KEYBOARD: About 140 pieces for keyboard in *Parthenia*, manuscript collection written *c.* 1611; *My Ladye Nevells Booke*, manuscript collection written in 1591; *The Fitzwilliam Virginal Book*, manuscript collection written in *c.* 1612–19; and in *Will Forster's Book*, manuscript collection written in 1624.

BIBLIOGRAPHY. *The Collected Vocal Works of William Byrd*, 2 vol., ed. by E.H. FELLOWES (1937–50); and a more scholarly edition of the sacred works in vol. 2, 7, and 9 of *Tudor Church Music* (1921–28). See also E.H. FELLOWES, *William Byrd*, 2nd ed. (1948).

(J.J.No.)

Byron, Lord

The English poet and satirist Lord Byron was a colourful figure whose poetry and personality captured the imagination of Europe; his name became a symbol for the deepest romantic melancholy on the one hand and for the aspirations of political liberalism on the other. Renowned as the "gloomy egoist" of his autobiographical poem *Childe Harold's Pilgrimage* during most of the 19th century, he is now more generally esteemed for the satiric realism of his *Don Juan* and the facetious wit of his letters.

Byron, portrait by Richard Westall, 1813. In the National Portrait Gallery, London.

Early life. The poet's grandfather, second son of the fourth Lord Byron, was an admiral in the British navy, and his father was the handsome and profligate Capt. John Byron, who first seduced and later married the Marchioness of Carmarthen. On the death of his first wife (who bore him a daughter Augusta), the Captain married Catherine Gordon of Gight, an only child of a proud Scottish family that traced its ancestry to James I of Scotland. Mrs. Byron, after following her husband to Paris while he squandered most of her fortune, returned to England, where her son was born with a clubfoot on January 22, 1788, in London. She took her child, George Gordon, to Aberdeen, where they lived in lodgings on a meagre income. Her husband died in France in 1791. The boy, who early developed an extreme sensitivity to his lameness, attended the Aberdeen grammar school. His nurse, May Gray, helped to awaken precocious passions in him when he was only nine. This experience and a quite different one—his idealized love for his distant cousin Mary Duff at about the same period and a similar feeling for his cousin Margaret Parker—shaped his parallel and paradoxical attitudes toward women through the rest of his life.

In 1798, at the age of ten, George Gordon inherited the title and estates of his great-uncle, the "wicked" Lord Byron. His mother proudly took him to England. The boy fell in love with the ghostly halls and spacious grounds of Newstead Abbey, which had been presented to the Byrons by Henry VIII, and he and his mother lived in its ruins for a while. He was privately tutored in Nottingham, and his clubfoot was doctored by a quack named Lavender. John Hanson, Mrs. Byron's attorney, rescued him from the pernicious influence of May Gray, the tortures of Lavender, and the uneven temper of his mother. He took him to London, where a reputable doctor prescribed a brace and later a special boot, and in the autumn of 1799 Hanson sent him to a school at Dulwich.

Education

In 1801 Byron went to Harrow, one of England's most prestigious schools. His first years were marked by battles with the boys and quarrels with the masters, but later his friendships with younger boys fostered a romantic attachment to the school. It is possible that these friendships gave the first impetus to his sexual ambivalence, which became more pronounced at Cambridge and in Greece. The Rev. Joseph Drury, the headmaster, won his confidence and encouraged his participation in the "Speech Day" recitations that stimulated his early ambition to become a parliamentary orator. He spent the summer of 1803 with his mother at Southwell, near Nottingham, but he soon escaped to Newstead and stayed with his tenant, Lord Grey, while he courted his distant cousin, Mary Chaworth, at nearby Annesley Hall. This first adolescent love kept him from returning to Harrow in the autumn, and when Mary, already engaged, grew tired of "that lame boy," he indulged his grief by writing melancholy poetry; and she became the symbol of idealized and unattainable love.

Byron took "super-excellent" rooms at Trinity College, Cambridge, in 1805 and piled up debts at a rate that alarmed his mother. But after indulging in the conventional vices of the undergraduates, which did not much engross him, he spent his time with a few favourites and with a devoted chorister, John Edleston, for whom he developed "a violent, though *pure*, love and passion." After the first term, Byron indulged in dissipations in London that put him further into debt. He returned in the summer of 1806 to Southwell where he gathered his early poems in a volume privately printed in November with the title *Fugitive Pieces*. The following June his first published poems, *Hours of Idleness*, appeared. When he returned to Trinity for the autumn term, he formed a close friendship with John Cam Hobhouse, who stirred his interest in liberal Whiggism. At the beginning of 1808, he entered into "an abyss of sensuality" in London that threatened to undermine his health as well as his finances. A sarcastic critique of his *Hours of Idleness* that appeared in *The Edinburgh Review* caused Byron to revise a satire he had begun (modelled on the *Dunciad* of Alexander Pope) and to add some lines on Francis Jeffrey, the *Review*'s editor, whom Byron erroneously assumed to have been the reviewer. In the autumn he regained possession of Newstead from his tenant, furnished some of the empty halls, and entertained his friends there. On reaching his majority in January 1809, he took his seat in the House of Lords, published his satire anonymously as *English Bards and Scotch Reviewers*, and then embarked with his friend Hobhouse on a grand tour.

Travel abroad. They sailed on July 2, 1809, on the Lisbon packet, crossed Spain to Seville and Cádiz, and proceeded by Gibraltar to Malta. There Byron fell in love briefly with a married woman and almost fought a duel on her account. Byron and Hobhouse next landed at Préveza in western Greece and made an inland voyage to Janina (Ioánnina) and later to Tepelene in Albania to visit the cruel but mild-mannered despot Ali Pasha. On their return Byron began at Janina an autobiographical poem, *Childe Harold*, which he continued during the journey to Athens where they arrived on Christmas day. They lodged with a widow, whose daughter, Theresa Macri, Byron celebrated as "The Maid of Athens." In

Visit to Greece

March 1810 he sailed with Hobhouse for Constantinople by way of Smyrna, and, while becalmed at the mouth of the Hellespont, Byron visited the site of Troy and swam the channel from Sestos to Abydos in imitation of Leander. After two months in Constantinople, Byron returned to Athens, and Hobhouse went back to England. Byron's sojourn in Greece made a lasting impression on his mind and character. The "clime of the East," the freedom and open frankness in contrast to the English reserve and hypocrisy, had entered his blood, broadened his views of men and manners, and contributed to his lifelong nostalgia for that "land of the Sun." After visiting Veli Pasha, ruler of the Peloponnesus, at Tripolitza (Trípolis), he took lodgings in a Capuchin monastery in Athens. He bathed in the sea, made a journey to Soúnion —which inspired his "Isles of Greece"—and delighted in the sunshine and the moral tolerance of the people.

Return to England. Byron arrived in London on July 14, 1811, and his mother died on August 1 before he could reach her at Newstead. He was further shocked to learn that John Edleston, the beloved choirboy, had died in his absence. During the autumn, he met the poets Thomas Moore and Samuel Rogers, who introduced him to Holland House, the great literary and political centre. On February 27, 1812, he made his first speech in the House of Lords on the frame-breaking bill, going beyond even the radical Whigs in his humanitarian plea for the Nottingham weavers. At the beginning of March, *Childe Harold's Pilgrimage* was published by John Murray and took the town by storm. Besides furnishing a poetic travelogue of picturesque lands, it gave vent to the moods of melancholy and disillusionment of the post-Revolutionary and Napoleonic eras. And the poem voiced with a frankness unprecedented in the literature of the time the disparity between the romantic ideal and the world of reality. Byron was lionized in Whig society. The handsome poet with the clubfoot, curly auburn hair, pale face, and pouting lips, who had bared his soul in the melancholy verses of *Childe Harold*, was swept into a liaison with the passionate and eccentric Lady Caroline Lamb, daughter-in-law of Lord and Lady Melbourne. Although her open defiance of conventions shocked him and he was ultimately repelled by her reckless indiscretions, the scandal of an elopement was barely prevented by Hobhouse. Byron took consolation in the "autumnal charms" of Lady Oxford, who encouraged his political radicalism.

Publication of *Childe Harold's Pilgrimage*

During the summer of 1813, Byron apparently entered into intimate relations with his half sister Augusta Leigh. His confidante, Lady Melbourne, encouraged his flirtation with Lady Frances Webster as a diversion from this dangerous liaison. The agitations of these two love affairs and the sense of mingled guilt and exultation they aroused in his mind are reflected in the Oriental tales he wrote during the year, *The Giaour* and *The Bride of Abydos*. Despite his admiration for the objectivity and verbal skill of Pope's balanced satire, Byron indulged in the romantic concept of poetry as "the lava of the imagination whose eruption prevents an earthquake." He "spared" Lady Frances while their relations remained still platonic, but it was not so easy to break with Augusta. The affair went on through the winter and summer of 1814, while his emotions found vent in the gloomy and remorseful Oriental tales, *The Corsair* (which sold 10,000 copies on the day of publication) and *Lara*.

Marriage

Seeking escape in marriage, in September he proposed to and was accepted by Lady Melbourne's niece, Anne Isabella (Annabella) Milbanke, only child of Sir Ralph and Lady Judith (*née* Noel) Milbanke. She had met Byron at Melbourne House in 1812 and had intrigued him by her innocence and her serious conversation. He had proposed to her through Lady Melbourne when he was trying to extricate himself from the affair with Caroline Lamb. She refused but later renewed the correspondence that led to the second proposal. The marriage took place on January 2, 1815. After a honeymoon "not all sunshine," the Byrons, in March, settled in a large house at 13 Piccadilly Terrace, London. Delays in negotiations to sell Newstead left them financially embarrassed and before long bailiffs were in the house. Byron escaped to the house of John Murray, his publisher, where he met Walter Scott, and to the Theatre Royal in Drury Lane, where he had become one of the subcommittee of management. Augusta had come for a visit to Piccadilly Terrace, and Byron, exasperated by debts, irritated by Annabella's humourless sensitivity, and liberated by drink, talked wildly and hinted at past sins.

Lady Byron gave birth to a daughter, Augusta Ada, on December 10, and on January 15 she left with the child for a visit to her parents. Two weeks later Byron received word from her father that she would not return to him. The reasons for her decision were never given and rumours began to fly, most of them centring on Byron's relations with Augusta Leigh. When the rumours grew, Byron signed the legal separation papers, parted fondly from Augusta, and went abroad, never returning to England.

Exile abroad. After visiting the battlefield of Waterloo, which inspired some stanzas of a new canto of *Childe Harold*, he followed the Rhine into Switzerland. At the Villa Diodati, near Geneva, he was on friendly terms with Shelley and his entourage, which included William Godwin's daughter Mary, who was Shelley's wife, and Godwin's stepdaughter by a second marriage, Claire Clairmont, who had insinuated herself into a liaison with Byron before he left England. A boat trip to the head of the lake with Shelley gave Byron material for his "Prisoner of Chillon," and he completed the third canto of *Childe Harold* at Diodati (published November 18, 1816). The French writer Madame de Staël, whom he visited at Coppet, tried to effect a reconciliation between him and his wife but was rebuffed by Lady Byron. At the end of the summer the Shelley party left for England, Claire carrying Byron's illegitimate daughter (born January 12, 1817, and named Allegra by Byron). A tour of the Bernese Oberland with Hobhouse provided the scenery for *Manfred* (published June 16, 1817), a Faustian poetic drama that reflected Byron's brooding sense of guilt and remorse and the wider frustrations of the romantic spirit doomed by the reflection that man is "half dust, half deity, alike unfit to sink or soar."

Friendship with Shelley

On October 5 Byron and Hobhouse left Diodati for Italy. After a stop in Milan, they arrived in Venice on November 10. Byron was not disappointed in the seagirt city, which had always been, he wrote, "(next to the East) the greenest island of my imagination." He took lodgings in the house of a draper with whose dark-eyed wife, Marianna Segati, he proceeded to fall in love. He studied Armenian at the monastery of S. Lazzaro and occasionally attended the literary and artistic gatherings of the Countess Albrizzi, "the de Staël of Venice." In May he joined Hobhouse in Rome and rode over the ruins, gathering impressions that he recorded in a fourth canto of *Childe Harold* (published April 28, 1818). At a summer villa at La Mira on the Brenta River, he also wrote *Beppo*, a rollicking satire on Italian manners. There he met Margarita Cogni, wife of a baker, who followed him to Venice and eventually replaced Marianna Segati in his affections. When he leased the Palazzo Mocenigo on the Grand Canal in May 1818, she became his housekeeper. His descriptions of the vagaries of this "gentle tigress" are among the most entertaining passages in his letters from Italy. During the summer he completed the first canto of *Don Juan* (cantos I and II published July 15, 1819), a picaresque verse satire in the manner of *Beppo*, with more pointed references to his own experiences. In *Don Juan* he freed himself from the excessive melancholy of *Childe Harold* and the mannered style that accompanied those romantic moods and revealed other sides of his character and personality—his satiric wit, and his unique view of the comic rather than the tragic discrepancy between reality and appearance, desire and fulfillment. Claire had sent his illegitimate daughter Allegra for him to raise and was continually annoying him with admonitions. The sale of Newstead Abbey in the autumn of 1818 for £94,500 finally cleared most of his debts, which had risen to £34,000, and left him with

First work on *Don Juan*

an income of £3,300. And since he had come abroad, his yearly earnings from writing had averaged more than £2,000.

Shelley and other visitors, in 1818, had found Byron grown fat, with hair long and turning gray, looking older than his years, and sunk in sexual promiscuity. A chance meeting with the Countess Teresa Guiccioli in April 1819 changed the course of his life. In a few days he fell completely in love with Teresa, who was only 19 and married to a wealthy and eccentric man nearly three times her age. Byron followed her to Ravenna, and, later in the summer, she accompanied him back to Venice and stayed at his villa at La Mira until her husband called for her. In October Byron presented Thomas Moore, who came for a visit, with the manuscript of his memoirs, which Moore sold to Murray for 2,000 guineas but which was burned at the insistence of Hobhouse and Murray after Byron's death. Byron returned to Ravenna in January 1820, as Teresa's accepted *cavalier servente* (gentleman-in-waiting). He won the friendship of her father and brother, the Counts Ruggero and Pietro Gamba, who initiated him into the secret revolutionary society of the Carbonari. In Ravenna he was brought into closer touch with the life of the Italian people than he had ever been in Venice. He gave arms to the Carbonari and alms to the poor. It was one of the happiest and most productive periods of his life. He wrote there *The Prophecy of Dante;* cantos III, IV, and V of *Don Juan;* the poetic dramas *Marino Faliero, Sardanapalus, The Two Foscari,* and *Cain* (all published in 1821); and his satire on the poet Robert Southey, *The Vision of Judgment.* When Teresa's father and brother were exiled for their part in an abortive uprising and she, now separated from her husband, was forced to follow them, Byron reluctantly removed to Pisa where Shelley had rented the Casa Lanfranchi on the Arno River for him. He arrived on November 1, 1821, having left his daughter Allegra in a convent near Ravenna where, despite the protests of Claire, he had sent her to be educated.

Byron paid daily visits to Teresa, whose father and brother had found temporary asylum in Pisa. Suspected and watched by government spies as a dangerous revolutionary, he made no friends among the natives. The death of his mother-in-law in January 1822 gave him an additional income of £3,000. By the terms of the will, he henceforth took the name of Noel Byron. The comfortable routine into which he had settled was broken in March by an unfortunate affray ending with the stabbing of a dragoon by one of Byron's servants. Close upon this came word of the death of Allegra in the convent on April 20. Shelley had rented a house on the Bay of Lerici, and Byron leased a villa near Leghorn for the summer, taking Teresa and the Gambas with him.

Work with Shelley and Hunt on *The Liberal*

There the poet and essayist Leigh Hunt found him on July 1, when he arrived from England to join with Shelley and Byron in the editing of a new periodical. Shelley came from Lerici to help install Hunt and his family in the lower floor of Byron's house in Florence. At the same time, the Gambas were expelled from Tuscany, and Byron returned with Teresa to Pisa. The drowning of Shelley on July 8 left Hunt entirely dependent on Byron, who had already "loaned" him £250 for his passage and furnished an apartment for him and his family. Byron found Hunt an agreeable companion, but their relations were somewhat strained by Mrs. Hunt's moral condescension and by the depredations of her six uninhibited children. Byron contributed his *Vision of Judgment* to the first number of the new periodical, *The Liberal,* which was published in London by Hunt's brother John (October 15, 1822). At the end of September he moved his entire household to a suburb of Genoa, where the Gambas had found asylum and had taken a large house for him. Mary Shelley had leased another house nearby for herself and the Hunts.

Byron's interest in the periodical had waned, but he continued to support Hunt and to give manuscripts to *The Liberal.* After a quarrel with his publisher, John Murray, Byron gave all his later work, including cantos VI to XVI of *Don Juan, The Age of Bronze,* and *The Island,* to John Hunt. Restive in the domesticity of his life with Teresa Guiccioli and longing for the opportunity for some noble action that would vindicate and redeem him in the eyes of his countrymen, Byron seized eagerly the offer from the London Greek Committee, which came in April 1823, to act as its agent in aiding the Greeks in their war for independence from the Turks. He prepared to take supplies and money to the scene of the struggle. In the meantime, the arrival in Genoa of the Countess of Blessington and her party turned his thoughts nostalgically to England. His last weeks in Italy were made hectic by quarrels with Leigh Hunt and Mary Shelley and by the emotional strain of the final parting from Teresa.

Role in war for Greek independence

On July 16, Byron left Genoa on a chartered ship, the "Hercules," accompanied by the adventurer Edward Trelawny and the young count Pietro Gamba, Teresa's brother. They arrived at the Ionian island of Cephalonia on August 2, and Byron settled in the village of Metaxáta to await developments. After a trip to Ithaca, he tried to promote the floating in London of a loan for the Greeks. He was avidly wooed by the Greek factions, all eager for his cash and influence. Finally, he sent £4,000 of his own money to prepare the Greek fleet for sea service and then sailed for Missolonghi (Mesolóngian) on December 29 to join Prince Aléxandros Mavrokordátos, leader of the forces in western Greece.

With tremendous energy he entered into the plans to attack the Turkish-held fortress of Lepanto. He employed a fire master to prepare artillery and took under his own command and pay the Suliote soldiers, reputedly the bravest of the Greeks. In addition he made efforts to unite eastern and western Greece by effecting a reconciliation of the factions. But a serious illness on February 15, 1824, followed by the usual remedy of bleeding, weakened him at the same time that an insurrection of the Suliotes opened his eyes to their cupidity. Though his enthusiasm for the Greek cause was undiminished, he had thenceforth a more realistic view of the obstacles and was often depressed. He was also suffering from the emotional strain of an unequal friendship with Loukas Chalandritsanos, a Greek boy, whom he had brought as a page from Cephalonia and to whom he addressed his last agonized poems, including his lines on completing his 36th year. He still fixed his hopes on the Greek loan and the uniting of the dissident parties. He was planning to attend a conference with Odysseus and other leaders at Salona when, drenched by a sudden downpour during his daily ride, he contracted a fever, which was aggravated by the bleeding insisted on by the doctors. After a painful and pathetic illness of ten days, he died on April 19, 1824. Deeply mourned throughout the land, he became a symbol of disinterested patriotism and a Greek national hero. His body was brought back to England and, refused burial in Westminster Abbey, was placed in the vault of his ancestors in Hucknall Torkard Church near Newstead. Ironically, 145 years after his death, in 1969, a memorial to Byron was finally placed on the floor of the Abbey.

MAJOR WORKS

Hours of Idleness: A Series of Poems, Original and Translated (1807); *English Bards and Scotch Reviewers: A Satire* (1809); *Childe Harold's Pilgrimage: A Romaunt,* cantos i and ii (1812); canto iii (1816); canto iv (1818); *The Giaour: A Fragment of a Turkish Tale* (1813); *The Bride of Abydos: A Turkish Tale* (1813); *The Corsair: A Tale* (1814); *Lara: A Tale,* with *Jacqueline: A Tale,* by Samuel Rogers (1814); *The Siege of Corinth: A Poem,* pub. with *Parisina: A Poem* (1816); *Poems* (1816); *The Prisoner of Chillon, and Other Poems* (1816); *The Lament of Tasso* (1817); *Manfred: A Dramatic Poem* (1817); *Beppo: A Venetian Story* (1818); *Mazeppa: A Poem* (1819); *Don Juan,* cantos i and ii (1819); cantos iii-v (1821); cantos vi-viii, cantos ix-xi, and cantos xii-xiv (all 1823); cantos xv-xvi (1824); *Marino Faliero: Doge of Venice,* pub. with *The Prophecy of Dante: A Poem* (1821); *Sardanapalus: A Tragedy; The Two Foscari: A Tragedy; Cain: A Mystery* (1821); *The Vision of Judgment,* first pub. in *The Liberal* (1822).

BIBLIOGRAPHY. The fullest bibliography of first editions is T.J. WISE, *A Bibliography of the Writings in Verse and Prose of . . . Byron . . .,* 2 vol. (1932–33, reprinted 1963);

for first, later, and foreign editions see that by E.H. COLERIDGE in vol. 7 of his edition of the poetry (cited below). For Byroniana, see SAMUEL C. CHEW, *Byron in England* (1924); and E.J. LOVELL, "Byron," in FRANK JORDAN (ed.), *The English Romantic Poets: A Review of Research and Criticism* (1971).

Editions: The standard edition of the works remains *Letters and Journals*, ed. by R.E. PROTHERO, 6 vol. (1898–1901); *Poetry*, ed. by E.H. COLERIDGE (1898–1904). The best 1-volume edition is *The Complete Poetical Works . . .*, ed. by PAUL ELMER MORE (1905). Other accessible editions include: *Poems*, ed. by G. POCOCK, Everyman's Library, rev. ed., 3 vol. (1948); *Selections . . .*, ed. by PETER QUENNELL, the Nonesuch edition (1949); *The Selected Poetry . . .*, ed. by L.A. MARCHAND, Modern Library edition (1951; rev. ed., 1967); *Selected Poetry and Letters*, ed. by E. BOSTETTER (1951). For *Don Juan*, the fullest critical edition is *Byron's Don Juan: A Variorum Edition*, by T.G. STEFFAN and W.W. PRATT, 4 vol. (1957); the best 1-volume edition is *Don Juan*, ed. by L.A. MARCHAND (1958). Additional letters are in *Lord Byron's Correspondence . . .*, ed. by JOHN MURRAY, 2 vol. (1922); and *Byron: A Self-Portrait . . .*, ed. by PETER QUENNELL, 2 vol. (1950).

Biographical works: The definitive modern biography is L.A. MARCHAND, *Byron: A Biography*, 3 vol. (1957); supplemented and updated in *Byron: A Portrait* (1970). Memoirs by contemporaries include: R.C. DALLAS, *Recollections of the Life of . . . Byron (1808–1814)* (1824); T. MEDWIN, *Journal of the Conversations of . . . Byron . . . at Pisa* (1824; ed. by E.J. LOVELL, 1966); P. GAMBA, *A Narrative of . . . Byron's Last Journey to Greece* (1825); W. PARRY, *The Last Days of . . . Byron* (1825); J.H. LEIGH HUNT, *Lord Byron and Some of His Contemporaries*, 2nd ed. (1828); T. MOORE, *Letters and Journals of . . . Byron: With Notices of His Life*, 2 vol. (1830), the first "official" biography; COUNTESS OF BLESSINGTON, *Conversations of Lord Byron* (1834; ed. by E.J. LOVELL, 1969); E.J. TRELAWNY, *Recollections of the Last Days of Shelley and Byron* (1858); E.J. LOVELL, JR. (ed.), *His Very Self and Voice: Collected Conversations of . . . Byron* (1954).

Among later biographies and biographical studies should be noted: J. CORDY JEAFFRESON, *The Real Lord Byron*, 2 vol. (1883); E. MAYNE, *Byron* (1924), and *The Life and Letters of . . . Lady Noel Byron* (1929); HAROLD NICOLSON, *Byron: The Last Journey* (1924; rev. ed., 1940); ANDRE MAUROIS, *Don Juan; ou, la vie de Byron* (1930; Eng. trans., *Byron*, 1930); P. QUENNELL, *Byron: The Years of Fame* (1935; new ed., 1967) and *Byron in Italy* (1941); W.A. BORST, *Lord Byron's First Pilgrimage* (1948); IRIS ORIGO, *The Last Attachment* (1949), the story of Byron and the Countess Guiccioli; C.L. CLINE, *Byron, Shelley and Their Pisan Circle* (1952); G. WILSON KNIGHT, *Lord Byron: Christian Virtues* (1952) and *Lord Byron's Marriage* (1957). See also DORIS L. MOORE, *The Late Lord Byron* (1961), on the posthumous reputation of Byron; and MALCOLM ELWIN, *Lord Byron's Wife* (1962), based on the Lovelace Papers (Lady Byron's papers).

Criticism: E.J. LOVELL, *Byron: The Record of a Quest* (1949); A. RUTHERFORD, *Byron: A Critical Study* (1961), and (comp.), *Byron: The Critical Heritage* (1970), a collection of 19th-century critiques; P. WEST (ed.), *Byron: A Collection of Critical Essays* (1963), 20th-century views; L.A. MARCHAND, *Byron's Poetry: A Critical Introduction* (1965); JEROME J. MCGANN, *Fiery Dust: Byron's Poetic Development* (1968); M.K. JOSEPH, *Byron, the Poet* (1964); on *Don Juan*, E.F. BOYD, *Don Juan: A Critical Study* (1945); G.M. RIDENOUR, *The Style of Don Juan* (1960).

Byzantine Empire

The very name Byzantine illustrates the misconceptions to which the empire's history has often been subject, for its inhabitants would hardly have considered the term appropriate to themselves or to their state. Theirs was, in their view, none other than the Roman Empire, founded shortly before the beginning of the Christian Era by God's grace to unify his people in preparation for the coming of his Son. Proud of that Christian and Roman heritage, convinced that their earthly empire so nearly resembled the heavenly pattern that it could never change, they called themselves Romaioi, or Romans. Modern historians agree with them only in part. The term East Rome accurately described the political unit embracing the Eastern provinces of the old Roman Empire until 476, while there were yet two emperors. The same term may even be used until the last half of the 6th century, as long as men continued to act and think according to patterns not unlike those prevailing in an earlier Roman Empire. These same centuries nonetheless witnessed changes so profound in their cumulative effect that after the 7th century state and society in the East differed markedly from their earlier forms. In an effort to recognize that distinction, historians traditionally have described the medieval empire as "Byzantine."

Origin of the designation "Byzantine"

The latter term is derived from the name Byzantium, borne by a colony of ancient Greek foundation on the European side of the Bosporus, midway between the Mediterranean and the Black Sea: the city was, by virtue of its location, a natural transit point between Europe and Asia Minor (Anatolia). Refounded as the "new Rome" by the emperor Constantine in 330, it was endowed by him with the name Constantinople, the city of Constantine. The derivation from Byzantium is suggestive in that it emphasizes a central aspect of Byzantine civilization: the degree to which the empire's administrative and intellectual life found a focus at Constantinople from 330 to 1453, the year of the city's last and unsuccessful defense under the 12th Constantine. The circumstances of the last defense are suggestive, too, for in 1453 the ancient, medieval, and modern worlds seemed briefly to meet. The last Constantine fell in defense of the new Rome built by the first Constantine. Walls that had held firm in the early Middle Ages against German, Hun, Avar, Slav, and Arab were breached finally by modern artillery, in the mysteries of which European technicians had instructed the most successful of the Central Asian invaders: the Ottoman Turks. In short, the Byzantine Empire, by virtue of its geographical position and its long continuity, unites a number of worlds: geographically, that of Asia and that of Europe; chronologically, that of classical antiquity and that of the Renaissance.

The fortunes of the empire thus were intimately entwined with those of peoples whose achievements and failures constitute the medieval history of both Europe and Asia. Nor did hostility always characterize the relations between Byzantines and those whom they considered "barbarian." Even though the Byzantine intellectual firmly believed that civilization ended with the boundaries of his world, he opened it to the barbarian, provided that the latter (with his kin) would accept Baptism and render loyalty to the emperor. Thanks to the settlements that resulted from such policies, many a name seemingly Greek disguises another of different origin: Slavic, perhaps, or Turkish. Barbarian illiteracy, in consequence, obscures the early generations of more than one family destined to rise to prominence in the empire's military or civil service. Byzantium was a melting-pot society, characterized during its earlier centuries by a degree of social mobility that belies the stereotype, often applied to it, of an immobile, caste-ridden society.

A source of strength in the early Middle Ages, Byzantium's central geographical position served it ill after the 10th century. The conquests of that age presented new problems of organization and assimilation; and these the emperors had to confront at precisely the time when older questions of economic and social policy pressed for answers in a new and acute form. Satisfactory solutions were never found. Bitter ethnic and religious hostility marked the history of the empire's later centuries, weakening it in the face of new enemies descending upon it from east and west. The empire finally collapsed when its administrative structures could no longer support the burden of leadership thrust upon it by military conquests it had won in the European and Asian worlds.

Problems of Byzantine historiography

Sources of Byzantine history. Research in Byzantine history can be as frustrating as it is fascinating, thanks to certain unique characteristics of the sources. First of all, linguistic problems are monumental. Since the historical experience of almost all medieval peoples impinged upon that of Byzantium, the historian may have to consult materials written in a bewildering array of languages. Even Byzantine Greek itself is a double language: the "pure" language of the intellectual class, rooted in the Greek of ancient Athens and the New Testament, and the demotic, or popular living tongue, spoken in city and

village. Second, the historical record is far from satisfactory for all places and all periods. As a result of the high degree of centralization in Constantinople, most materials (whether literary, legal, or economic) are concerned with the affairs of that city and not of the provinces. Nor are all periods equally well represented. From the end of the 6th century to the second half of the 8th century, the record must be pieced together from an extremely small number of chronicles, legal codes, ecclesiastical documents, and saints' lives. After about 800, the sources become increasingly abundant, permitting the historian to investigate a much wider range of problems, including even the economic and social conditions of specific villages. Third, the sources frequently display no sense of historical development or even any high degree of historical consciousness. The Byzantine intellectual often described his own world in terms of the past, borrowing whole passages from earlier authors to delineate contemporary practice. The modern historian, in consequence, may be misled in one of two ways: either he may read long-vanished patterns into a later era, or, more insidiously, he may assume that nothing Byzantine ever changed, forgetting that, if the Byzantine people were overly conscious of the past and of an almost burdensome cultural heritage, the struggle for survival had made pragmatists of them. They had learned to observe clearly the world of the outsider as well as their own, however little they liked or respected the stranger outside their gates.

I. The empire to 867

THE ROMAN AND CHRISTIAN BACKGROUND

Unity and diversity in the late Roman Empire. The Roman Empire, the ancestor of the Byzantine, remarkably blended unity and diversity, the former being by far the better known since its constituents are the predominant features of Roman civilization. The common Latin language, the coinage, the "international" army of the Roman legions, the urban network, the law, and the Greco-Roman heritage of civic culture loomed largest among those bonds that Augustus and his successors hoped would bring unity and peace to a Mediterranean world exhausted by centuries of civil war. To strengthen these sinews of imperial civilization, the emperors hoped that a lively and spontaneous trade might develop among the several provinces. At the pinnacle of this world stood the emperor himself, the man of wisdom who would shelter the state from whatever mishaps fortune had darkly hidden. The emperor alone could provide this protection since, as the embodiment of all the virtues, he possessed in perfection those qualities displayed only imperfectly by his individual subjects.

The Roman formula of combatting fortune by reason and therewith assuring unity throughout the Mediterranean world worked surprisingly well in view of the pressures for disunity that time was to multiply. Conquest had brought regions of diverse background under Roman rule. The Eastern provinces were ancient and populous centres of that urban life that for millennia had defined the character of Mediterranean civilization. The Western provinces had only lately entered upon their own course of urban development under the not always tender ministrations of their Roman masters.

Each of the aspects of unity enumerated above had its other side. Not everyone understood or spoke Latin. Paralleling and sometimes influencing Roman law were local customs and practices, understandably tenacious by reason of their antiquity. Pagan temples, Jewish synagogues, Christian baptisteries attest to the range of organized religions with which the official forms of the Roman state, including those of emperor worship, could not always peacefully coexist. And far from unifying the Roman world, economic growth often created self-sufficient units in the several regions, provinces, or great estates.

Given the obstacles against which the masters of the Roman state struggled, it is altogether remarkable that Roman patriotism was ever more than an empty formula, that cultivated gentlemen from the Pillars of Hercules to the Black Sea were aware that they had "something" in common. This "something" might be defined as the Greco-Roman civic tradition in the widest sense of its institutional, intellectual, and emotional implications. Grateful for the conditions of peace that fostered it, men of wealth and culture dedicated their time and resources to glorifying that tradition through adornment of the cities that exemplified it and through education of the young who they hoped might perpetuate it.

Greco-Roman civic tradition

Upon this world the barbarians descended after about AD 150. To protect the frontier against them, warrior emperors devoted whatever energies they could spare from the constant struggle to reassert control over provinces where local regimes emerged. In view of the ensuing warfare, the widespread incidence of disease, and the rapid turnover among the occupants of the imperial throne, it would be easy to assume that little was left of either the traditional fabric of Greco-Roman society or the bureaucratic structure designed to support it.

Neither assumption is accurate. Devastation was haphazard, and some regions suffered while others did not. In fact, the economy and society of the empire as a whole during that period was more diverse than it had ever been. Impelled by necessity or lured by profit, men moved from province to province. Social disorder opened avenues to eminence and wealth that the more stable order of an earlier age had closed to the talented and the ambitious. For personal and dynastic reasons, emperors favoured certain towns and provinces at the expense of others, and the erratic course of succession to the throne, coupled with a resulting constant change among the top administrative officials, largely deprived economic and social policies of recognizable consistency.

The reforms of Diocletian and Constantine. The definition of consistent policy in imperial affairs was the

achievement of two great soldier-emperors, Diocletian (ruled 284–305) and Constantine (324–337), who together ended a century of anarchy and refounded the Roman state. There are many similarities between them, not the least being the range of problems to which they addressed themselves: both had learned from the 3rd-century anarchy that one man alone and unaided could not hope to control the multiform Roman world and protect its frontiers; as soldiers, both considered reform of the army of prime necessity in an age that demanded the utmost mobility in striking power; both found the old Rome and Italy an unsatisfactory military base for the bulk of the imperial forces. Deeply influenced by the soldier's penchant for hierarchy, system, and order, a taste that they shared with many of their contemporaries as well as the emperors who preceded them, they were appalled by the lack of system and the disorder characteristic of the economy and the society in which they lived. Both, in consequence, were eager to refine and regularize certain desperate expedients that had been adopted by their rough military predecessors to conduct the affairs of the Roman state. Whatever their personal religious convictions, both, finally, believed that imperial affairs would not prosper unless the emperor's subjects worshipped the right gods in the right way.

The means they adopted to achieve these ends differ so profoundly that the one, Diocletian, looks to the past and ends the history of Rome; the other, Constantine, looks to the future and founds the history of Byzantium. Thus, in the matter of succession to the imperial office, Diocletian adopted precedents he could have found in the practices of the 2nd century AD. He associated with himself a co-emperor, or Augustus. Each Augustus then adopted a young colleague, or Caesar, to share in the rule and eventually to succeed the senior partner. This rule of four, or tetrarchy, failed of its purpose, and Constantine replaced it with the dynastic principle of hereditary succession, a procedure generally followed in subsequent centuries. To divide administrative responsibilities, Constantine replaced the single praetorian prefect, who had traditionally exercised both military and civil functions in close proximity to the emperor, with regional prefects established in the provinces and enjoying civil authority alone. In the course of the 4th century, four great "regional prefectures" emerged from these Constantinian beginnings, and the practice of separating civil from military authority persisted until the 7th century.

Rule of succession

Contrasts in other areas of imperial policy are equally striking. Diocletian persecuted Christians and sought to revive the ancestral religion. Constantine, a convert to the new faith, raised it to the status of a "permitted religion." Diocletian established his headquarters at Nicomedia, a city that never rose above the status of a provincial centre during the Middle Ages, while Constantinople, the city of Constantine's foundation, flourished mightily. Diocletian sought to bring order into the economy by controlling wages and prices and by initiating a currency reform based upon a new gold piece, the aureus, struck at the rate of 60 to the pound of gold. The controls failed and the aureus vanished, to be succeeded by Constantine's gold solidus. The latter piece, struck at the lighter weight of 72 to the gold pound, remained the standard for centuries. For whatever reason, in summary, Constantine's policies proved extraordinarily fruitful. Some of them—notably hereditary succession, the recognition of Christianity, the currency reform, and the foundation of the capital—determined in a lasting way the several aspects of Byzantine civilization with which they are associated.

Yet it would be a mistake to consider Constantine a revolutionary or to overlook those areas in which, rather than innovating, he followed precedent. Earlier emperors had sought to constrain groups of men to perform certain tasks that were deemed vital to the survival of the state but that proved unremunerative or repellent to those forced to assume the burden. Such tasks included the tillage of the soil, which was the work of the peasant, or *colonus;* the transport of cheap bulky goods to the metropolitan centres of Rome or Constantinople, which was the work of the shipmaster, or *navicularius;* and services rendered by the *curiales,* members of the municipal senate charged with the assessment and collection of local taxes. Constantine's laws in many instances extended or even rendered hereditary these enforced responsibilities, thus laying the foundations for the system of *collegia,* or hereditary state guilds, that was to be so noteworthy a feature of late-Roman social life. Of particular importance, he required the *colonus* (peasant) to remain in the locality to which the tax lists ascribed him.

THE 5TH CENTURY: PERSISTENCE OF GRECO-ROMAN CIVILIZATION IN THE EAST

Whether innovative or traditional, Constantine's measures determined the thrust and direction of imperial policy throughout the 4th century and into the 5th. The state of the empire in 395 may, in fact, be described in terms of the outcome of Constantine's work. The dynastic principle was established so firmly that the emperor who died in that year, Theodosius I, could bequeath the imperial office jointly to his sons, both of whom were young and incompetent: Arcadius in the East and Honorius in the West. Never again would one man rule over the full extent of the empire in both its halves. Constantinople had probably grown to a population of between 200,000 and 500,000; in the 5th century the emperors sought to restrain rather than promote its growth. After 391 Christianity was far more than one among many religions: from that year onward, imperial decree prohibited all forms of pagan cult, and the temples were closed. Imperial pressure was often manifest at the church councils of the 4th century, with the emperor assuming a role he was destined to fill again during the 5th century in defining and suppressing heresy.

Economic and social policies. The empire's economy had prospered in a spotty fashion. Certain provinces, or parts of provinces such as northern Italy, flourished commercially as well as agriculturally. Constantinople, in particular, influenced urban growth and the exploitation of agricultural frontiers. Balkan towns along the roads leading to the great city prospered, while others not so favoured languished and even disappeared. Untilled land in the hilly regions of northern Syria fell under the plow to supply foodstuffs for the masses of Constantinople. As the 4th century progressed, not only did Constantine's solidus remain indeed solid gold, but evidence drawn from a wide range of sources suggests that gold in any form was far more abundant than it had been for at least two centuries. It may be that new sources of supply for the precious metal had been discovered; perhaps in spoils plundered from pagan temples, perhaps from mines newly exploited in western Africa and newly available to the lands of the empire, thanks to the appearance of camel-driving nomads who transported the gold across the Sahara to the Mediterranean coastline of North Africa.

Economic prosperity

The extreme social mobility noted in the late 3rd and early 4th centuries seems less characteristic of the second half of the latter century. Certainly the emperors continued their efforts to bind men collectively to their socially necessary tasks, but the repetition of laws tying the *colonus* to his estate, the *navicularius* to his ship, and the *curialis* to his municipal senate suggests that these edicts had little effect. Indeed, it would be a mistake to conclude from such legislation that Roman society was universally and uniformly organized in castes determined in response to imperial orders. There was always a distinction between what an emperor wanted and what he could obtain, and, as the foregoing survey has suggested, there were distinctions among the provinces as well.

Even before the end of the first quarter of the 5th century, these provincial differences were visible; and, in no small degree, they help to explain the survival of imperial government and Greco-Roman civilization in the East while both eventually perished in the West. Throughout the Eastern provinces, population levels seem to have remained higher, and the emperors in Constantinople never had to search (at least until the 6th century) for men to fill the ranks of their armies. As might be expected in those eastern lands in which urban civilization was sev-

eral centuries old, cities persisted and, with them, a merchant class and a monetary economy. Eastern merchants, known in the sources as Syrians, assumed the carrying trade between East and West, often establishing colonies in the beleaguered cities of the latter region.

Most important, the emperor in the East never lost access to, or control over, his sources of manpower and money. An older and probably more wealthy senatorial class, or aristocracy, in the West consolidated its great estates and assumed a form of protection or patronage over the labouring rural classes, depriving the state of desperately needed military and financial services. The senatorial class in the East seems to have been of more recent origin, its beginnings to be found among those favourites or parvenus who had followed Constantine to his new capital. By the early 5th century, their wealth seems to have been, individually, much less than the resources at the disposal of their Western counterparts; their estates were far more scattered, their rural dependents less numerous. They were thus less able to challenge the imperial will and less able to interpose themselves between the state, on the one hand, and its potential soldiers or taxpayers, on the other.

Relations with the barbarians. These differences between Eastern and Western social structures, together with certain geographical features, account for the different reception found by the Germanic invaders of the 4th and 5th centuries in East and West. Although the Germanic people had eddied about the Danube and Rhine frontiers of the empire since the 2nd century, their major inroads were made only in the latter half of the 4th century, when the ferocious Huns drove the Ostrogoths and Visigoths to seek refuge within the Danubian frontier of the empire. The initial interaction between Roman and barbarian was far from amicable; the Romans seemed to have exploited their unwelcome guests, and the Goths rose in anger, defeating an East Roman army at Adrianople in 378 and killing the Eastern emperor in command. Emperor Theodosius (ruled 384–395) adopted a different policy, granting the Goths lands and according them the legal status of allies, or *foederati*, who fought within the ranks of the Roman armies as autonomous units under their own leaders.

Battle of Adrianople

Neither in West nor East did Theodosius' policy of accommodation and alliance prove popular. The Goths, like most Germanic peoples with the exception of the Franks and the Lombards, had been converted to Arian Christianity, which the Catholic, or Orthodox, Romans considered a dangerous heresy. The warlike ways of the Germans found little favour with a senatorial aristocracy essentially pacifist in its outlook, and the early 5th century is marked in both halves of the empire by reactions against Germanic leaders in high office. At Constantinople in 400, for example, the citizens rose against the senior officer of the imperial guard (*magister militum*), Gainas, slaughtering him together with his Gothic followers. Although this particular revolt was, in many respects, less productive of immediate results than similar episodes in the West, and the Germanic leaders later reappeared in roles of command throughout the East, the latter acted thenceforth as individuals without the support of those nearly autonomous groups of soldiers that western barbarian commanders continued to enjoy.

Furthermore, the East made good use of its resources in gold, in native manpower, and in diplomacy, while quickly learning how best to play off one enemy against another. In the reign of Theodosius II (408–450), the Huns under their chieftain Attila received subsidies of gold that both kept them in a state of uneasy peace with the Eastern Empire and may have proved profitable to those merchants of Constantinople who traded with the barbarians. When Marcian (ruled 450–457) refused to continue the subsidies, Attila was diverted from revenge by the prospect of conquests in the West. He never returned to challenge the Eastern Empire, and, with his death in 453, his Hunnic empire fell apart. Both Marcian and his successor, Leo I (ruled 457–474), had ruled under the tutelage of the Alan, Aspar, until Leo resolved to challenge Aspar's pre-eminence and the influence of the Goths elsewhere in the empire by favouring the warlike Isaurians and their chieftain, Tarasicodissa, whom he married to the imperial princess, Ariadne. The Isaurian followers of Tarasicodissa, who was to survive a stormy reign as the Emperor Zeno (474–491), were rough mountain folk from southern Anatolia and culturally probably even more barbarous than the Goths or the other Germans. Yet, in that they were the subjects of the Roman emperor in the East, they were undoubtedly Romans and proved an effective instrument to counter the Gothic challenge at Constantinople. In the prefecture of Illyricum, Zeno ended the menace of Theodoric the Amal by persuading him (488) to venture with his Ostrogoths into Italy. The latter province lay in the hands of the German chieftain Odoacer, who in 476 had deposed Romulus Augustus, the last Roman emperor in the West. Thus, by suggesting that Theodoric conquer Italy as his Ostrogothic kingdom, Zeno maintained at least a nominal supremacy in that western land while ridding the Eastern Empire of an unruly subordinate.

Dissolution of the Western Empire

With Zeno's death and the accession of the Roman civil servant Anastasius I (ruled 491–518), Isaurian occupation of the imperial office ended, but it was not until 498 that the forces of the new emperor effectively took the measure of Isaurian resistance. After the victory of that year, the loyal subject of the Eastern Roman emperor could breathe easily: Isaurians had been used to beat Germans, but the wild mountain folk had, in their turn, failed to take permanent possession of the imperial office. Imperial authority had maintained its integrity in the East while the Western Empire had dissolved into a number of successor states: the Angles and Saxons had invaded Britain as early as 410; the Visigoths possessed portions of Spain since 417, and the Vandals entered Africa in 428; the Franks, under Clovis, had begun their conquest of central and southern Gaul in 481; Theodoric was destined to rule in Italy until 526.

Religious controversy. If ethnic hostility within the empire was less a menace around the year 500 than it had often been in the past, dissensions stemming from religious controversy seriously threatened imperial unity, and the political history of the next century cannot be understood without some examination of the so-called Monophysite heresy. The latter was the second great heresy in the Eastern Empire, the first having been the dispute occasioned by the teachings of the Alexandrian presbyter Arius, who, in an effort to maintain the uniqueness and majesty of God the Father, had taught that he alone had existed from eternity, while God the Son had been created in time. Thanks in part to imperial support, the Arian heresy had persisted throughout the 4th century and was definitively condemned only in 381 with promulgation of the doctrine that Father and Son were of one substance and thus coexistent.

The Monophysite heresy

If the Fathers of the 4th century quarrelled over the relations between God the Father and God the Son, those of the 5th century faced the problem of defining the relationship of the two natures—the human and the divine—within God the Son, Christ Jesus. The theologians of Alexandria generally held that the divine and human natures were united indistinguishably, whereas those of Antioch taught that two natures coexisted separately in Christ, the latter being "the chosen vessel of the Godhead . . . the man born of Mary." In the course of the 5th century, these two contrasting theological positions became the subject of a struggle for supremacy among the rival sees of Constantinople, Alexandria, and Rome. Nestorius, patriarch of Constantinople in 428, adopted the Antiochene formula, which, in his hands, came to stress the human nature of Christ to the neglect of the divine. His opponents (first the Alexandrian patriarch, Cyril, and later Cyril's followers, Dioscourus and Eutyches) in reaction emphasized the single divine nature of Christ, the result of the Incarnation. Their belief in Monophysitism, or the one nature of Christ as God the Son, became extraordinarily popular throughout the provinces of Egypt and Syria. Rome, in the person of Pope Leo I, declared in contrast for Dyophysitism, a creed teaching that two natures, perfect and perfectly distinct, existed in the single

person of Christ. At the Council of Chalcedon (451), the latter view triumphed thanks to the support of Constantinople, which changed its position and condemned both Nestorianism, or the emphasis on the human nature of Christ, and Monophysitism, or the belief in the single divine nature.

More important for the purposes of military and political history than the theological details of the conflict was the impact Monophysitism produced on the several regions of the Mediterranean world. Partly because it provided a formula to express resistance to Constantinople's imperial rule, Monophysitism persisted in Egypt and Syria. Until these two provinces were lost to Islām in the 7th century, each Eastern emperor had somehow to cope with their separatist tendencies as expressed in the heresy. He had either to take arms against Monophysitism and attempt to extirpate it by force, to formulate a creed that would somehow blend it with Dyophysitism, or frankly to adopt the heresy as his own belief. None of these three alternatives proved successful, and religious hostility was not the least of the disaffections that led Egypt and Syria to yield, rather readily, to the Arab conqueror. If ever the East Roman emperor was to reassert his authority in the West, he necessarily had to discover a formula that would satisfy Western orthodoxy while not alienating Eastern Monophysitism.

The empire at the end of the 5th century. In the reign of Anastasius I (491–518), all these tendencies of the 5th century found their focus: the sense of *Romanitas*, which demanded a Roman rather than an Isaurian or a German emperor, the conflict between orthodoxy and Monophysitism, and the persisting economic prosperity of the Eastern Roman Empire. Acclaimed and elected as the Roman and orthodox emperor who would end both the hated hegemony of the Isaurians and the detested activity of the Monophysite heretics, Anastasius succeeded in the first of these objectives while failing in the second. While he defeated the Isaurians and transported many of them from their Anatolian homeland into Thrace, he gradually came to support the Monophysite heresy despite the professions of orthodoxy he had made upon the occasion of his coronation. If his policies won him followers in Egypt and Syria, they alienated his orthodox subjects and led, finally, to constant unrest and civil war.

Anastasius I

Anastasius' economic policies were far more successful; if they did not provide the basis for the noteworthy achievements of the 6th century in military affairs and the gentler arts of civilization, they at least explain why the Eastern Empire prospered in those respects during the period in question. An inflation of the copper currency, prevailing since the age of Constantine, finally ended with welcome results for those members of the lower classes who conducted their operations in the base metal. Responsibility for the collection of municipal taxes was taken from the members of the local senate and assigned to agents of the praetorian prefect. Trade and industry were probably stimulated by the termination of the *chrysargyron*, a tax in gold paid by the urban classes. If, by way of compensating for the resulting loss to the state, the rural classes had then to pay the land tax in money rather than kind, the mere fact that gold could be presumed to be available in the countryside is a striking index of rural prosperity. In the East, the economic resurgence of the 4th century had persisted, and it is not surprising that Anastasius enriched the treasury to the extent of 320,000 pounds of gold during the course of his reign.

With such financial resources at their disposal, the Emperor's successors could reasonably hope to reassert Roman authority among the western Germanic successor states, provided they could accomplish two objectives: first, they must heal the religious discord among their subjects; second, they must protect the eastern frontier against the threat of Sāsānian Persia. Since the 6th century was, in fact, to witness concurrent warfare on both fronts, some knowledge of the age-old rivalry between Rome and Persia is essential to an understanding of the problems confronted by the greatest among Anastasius' successors, Justinian I (ruled 527–565), as he undertook the conquest of the West.

In 224 the ancient Persian Empire had passed into the hands of a new dynasty, the Sāsānians, whose regime brought new life to the enfeebled state. Having assured firm control over the vast lands already subject to them, the Sāsānians took up anew the old struggle with Rome for northern Mesopotamia and its fortress cities of Edessa and Nisibis, lying between the Tigris and the Euphrates. In the course of the 4th century, new sources of hostility emerged as East Rome became a Christian empire. Partly by reaction, Sāsānian Persia strengthened the ecclesiastical organization that served its Zoroastrian religion; intolerance and persecution became the order of the day within Persia, and strife between the empires assumed something of the character of religious warfare. Hostilities were exacerbated when Armenia, lying to the north between the two realms, converted to Christianity and thus seemed to menace the religious integrity of Persia. If small-scale warfare during the 4th and 5th centuries rarely erupted into major expeditions, the threat to Rome nonetheless remained constant, demanding vigilance and the construction of satisfactory fortifications. By 518, the balance might be said to have tipped in the favour of Persia as it won away the cities of Theodosiopolis, Amida, and Nisibis.

The rise of Sāsānian Persia

THE 6TH CENTURY: FROM EAST ROME TO BYZANTIUM

The 6th century opens, in effect, with the death of Anastasius and the accession of the Balkan soldier who replaced him, Justin I (ruled 518–527). During most of Justin's reign, actual power lay in the hands of his nephew and successor, Justinian I (527–565). The following account of these more than 40 years of Justinian's effective rule is based upon the works of Justinian's contemporary, the historian Procopius. The latter wrote a laudatory account of the Emperor's military achievements in his *History of the Wars* and coupled it in his *Secret History* with a venomous threefold attack upon the Emperor's personal life, the character of the empress Theodora, and the conduct of the empire's internal administration. Justinian's reign may be divided into three periods: (1) an initial age of conquest and cultural achievement extending until the decade of the 540s; (2) ten years of crisis and near disaster during the 540s; and (3) the last decade of the reign, in which mood, temper, and social realities more nearly resembled those to be found under Justinian's successors than those prevailing throughout the first years of his own reign. After 550, it is possible to begin to speak of a medieval Byzantine, rather than an ancient East Roman, empire. Of the four traumas that eventually transformed the one into the other—namely, pestilence, warfare, social upheaval, and the Arab Muslim assault of the 630s—the first two were features of Justinian's reign, and these the following account will emphasize.

The accession of Justinian I

The years of achievement to 540. Justinian is but one example of the civilizing magic that Constantinople often worked upon the heirs of those who ventured within its walls. Justin, the uncle, was a rude and illiterate soldier; Justinian, the nephew, was a cultivated gentleman, adept at theology, a mighty builder of churches, and a sponsor of the codification of Roman law. All these accomplishments are, in the deepest sense of the word, civilian, and it is easy to forget that Justinian's empire was almost constantly at war during his reign. The history of East Rome during that period illustrates, in classical fashion, how the impact of war can transform ideas and institutions alike.

The reign opened with external warfare and internal strife. From Lazica to the Arabian Desert, the Persian frontier blazed into action in a series of campaigns in which many of the generals later destined for fame in the West first demonstrated their capacities. The strength of the East Roman armies is revealed in the fact that, while containing Persian might, Justinian could nonetheless dispatch troops to attack the Huns in the Crimea and to maintain the Danubian frontier against a host of enemies. In 532 he abandoned military operations for diplomacy, negotiating, at the cost of considerable tribute, an "Endless Peace" with the Persian king, Khosrow, which freed the Roman's hands for operations in another quarter of

the globe. Thus Justinian attained the first of the objectives needed for reconquest in the West: peace in the East.

Even before his accession, Justinian had aided in the attainment of the second. Shortly after his proclamation as emperor, Justin had summoned a council of bishops at Constantinople. The council reversed the policies of Anastasius, accepted the orthodox formula of Chalcedon, and called for negotiations with the pope. Justinian had personally participated in the ensuing discussions, which restored communion between Rome and all the Eastern churches save Egypt. No longer could a barbarian king hope to maintain the loyalties of his Catholic subjects by persuading them that a Monophysite emperor ruled in the East.

The Nika Revolt

In the same year of 532, Justinian survived a revolt in Constantinople, stemming from the Nika (*i.e.*, "conquer") riots, which initially threatened his life no less than his throne but, in the event, only strengthened his position. To understand the course of events, it is essential to remember that Constantinople, like other great East Roman cities, had often to depend upon its urban militia, or demes, to defend its walls. Coinciding with divisions within the demes were factions organized to support rival charioteers competing in the horse races: the Blues and the Greens. In addition to their sporting and military functions, the Blues and the Greens also played a political role during the emperor's appearance at the horse races in the Hippodrome. In a rhythmical chant, they would present popular grievances, thereby serving as the only effective channel of protest whereby popular discontent could reach the emperor's ordinarily inaccessible ear. The Blues tended to draw their leadership from the landholding senatorial aristocracy, a class usually orthodox in its sympathies; the Greens, in contrast, found their leaders among men whose wealth was based upon trade and industry and whose theological sympathies lay with the Monophysites. Given these social and religious differences, accentuated by residence in different quarters of Constantinople, it is not surprising that Blues and Greens were often at each other's throats.

The Nika riot of 532 was one of the rare occasions when the two factions united in opposition to the imperial government. Angered at the severity with which the urban prefect had suppressed a riot, Blues and Greens first freed their leaders from prison and then insisted that Justinian dismiss from office two of his most unpopular officials: John of Cappadocia and Tribonian. Even though the Emperor yielded to their demands, the crowd was not appeased, converted its riot into a revolt, and proclaimed a nephew of Anastasius as emperor. Justinian was saved only because the empress, Theodora, refused to yield. Justinian's able general, Belisarius, sequestered the rebels in the Hippodrome and slaughtered them to the number of 30,000. The leaders were executed, and their estates passed, at least temporarily, into the Emperor's hands.

After 532 Justinian ruled more firmly than ever before. With the subsequent proclamation of the "Endless Peace," he could hope to use his earlier won reputation as a champion of Chalcedonian orthodoxy and appeal to those Western Romans who preferred the rule of a Catholic Roman emperor to that of an Arian German kinglet. In these early years of the 530s, Justinian could indeed pose as the pattern of a Roman and Christian emperor. Latin was his language, and his knowledge of Roman history and antiquities was profound. In 529 his officials had completed a major collection of the laws and decrees of the emperors promulgated since the reign of Hadrian. Known as the Code of Justinian and partly founded upon the 5th-century Code of Theodosius, this collection of imperial edicts pales before the Digest completed under Tribonian's direction in 533. In the latter work, order and system was found in (or forced upon) the contradictory rulings of the great Roman jurists; to facilitate instruction in the schools of law, a textbook, the Institutes, was designed to accompany the Digest. Meanwhile, architects and builders worked apace to complete the new Church of the Holy Wisdom, Hagia Sophia, designed to replace an older church destroyed in the course of the Nika riots. In five years they had constructed the edifice, and it stands today as one of the major monuments of architectural history.

Promulgation of legal code

In 533 the moment had clearly come to reassert Christian Roman authority in the West, and Vandal North Africa seemed the most promising theatre of operations. Although a major expedition mounted under Leo I had failed to win back the province, political conditions in the Vandal monarchy had lately altered to the Eastern emperor's favour. When King Hilderich was deposed and replaced, Justinian could rightfully protest this action taken against a monarch who had ceased persecution of North African Catholics and had allied himself with Constantinople. The Eastern merchants favoured military action in the West, but Justinian's generals were reluctant; possibly for that reason, only a small force was dispatched in tentative fashion under Belisarius. Success came with surprising ease after two engagements, and in 534 Justinian could set about organizing this new addition to the provinces of the Roman Empire.

These were, in fact, years of major provincial reorganization, and not in North Africa alone. A series of edicts dated in 535 and 536, clearly conceived as part of a master plan by the prefect, John of Cappadocia, altered administrative, judicial, and military structures in Thrace and Asia Minor. In general, John sought to provide a simplified and economical administrative structure in which overlapping jurisdictions were abolished, civil and military functions were sometimes combined in violation of Constantinian principles, and a reduced number of officials were provided with greater salaries to secure better personnel and to end the lure of bribery.

In the prefaces to his edicts, Justinian boasted of his reconstituted authority in North Africa, hinted at greater conquests to come, and—in return for the benefits his decrees were to provide—urged his subjects to pay their taxes promptly so that there might be "one harmony between ruler and ruled." Quite clearly the Emperor was organizing the state for the most strenuous military effort, and, later (possibly in 539), reforms were extended to Egypt, whence the export of grain was absolutely essential for the support of expeditionary armies and Constantinople.

Campaigns in Italy

Developments during 534 and 535 in Ostrogothic Italy made it the most likely victim after the fall of Vandal North Africa. When Theodoric died in 526, he was succeeded by a minor grandson for whom Theodoric's daughter, Amalasuntha, acted as regent. Upon the boy's death, Amalasuntha attempted to seize power in her own right and contrived at the assassination of three of her chief enemies. Her diplomatic relations with the Eastern emperor had always been marked by cordiality and even dependency; thus, when Amalasuntha, in turn, met her death in a blood feud mounted by the slain men's families, Justinian seized the opportunity to protest the murder.

In 535, as in 533, a small, tentative expedition sent to the west—in this instance, to Sicily—met with easy success. At first the Goths negotiated; then they stiffened their resistance, deposed their king, Theodahad, in favour of a stronger man, Witigis, and attempted to block Belisarius' armies as they entered the Italian peninsula. Here the progress of East Roman arms proved slower, and victory did not come until 540 when Belisarius captured Ravenna, the last major stronghold in the north, and—with it—King Witigis, a number of Gothic nobles, and the royal treasure.

All were dispatched to Constantinople, where Justinian was presumably thankful for the termination of hostilities in the West. Throughout the 530s, Justinian's generals almost constantly had to fight to preserve imperial authority in the new province of North Africa and in the Balkans as well. In 539 a Gothic embassy reached Persia, and the information it provided caused the king, Khosrow, to grow restive under the constraints of the "Endless Peace." During the next year (the same year [540] that a Bulgar force raided Macedonia and reached the long walls of Constantinople), Khosrow's armies reached even

Antioch in the pursuit of booty and blackmail. They returned unhurt, and 541 witnessed the Persian capture of a fortress in Lazica. In Italy, meanwhile, the Goths chose a new king, Totila, under whose able leadership the military situation in that land was soon to be transformed.

The crisis of midcentury. At last the menace of simultaneous war on two fronts threatened Justinian's plans. During the 550s, his armies were to prove equal to the challenge, but a major disaster prevented them from so doing between 541 and about 548. The disaster was the bubonic plague of 541–543, the first of those shocks, or traumas, mentioned earlier, that would eventually transform East Rome into the medieval Byzantine Empire. The plague was first noted in Egypt, and from there it passed through Syria and Asia Minor to Constantinople. By 543 it had reached Italy and Africa, and it may also have attacked the Persian armies on campaign in that year. In East Asia, the disease has persisted into the 20th century, providing medical science with an opportunity to view its causes and course. Transmitted by fleas to men from infected rodents, the plague attacks the glands and early manifests itself by swellings (buboes) in armpit and groin, whence the name bubonic. To judge from Procopius' description of its symptoms at Constantinople in 542, the disease then appeared in its more virulent pneumonic form, wherein the bacilli settle in the lungs of the victims. The appearance of the pneumonic form was particularly ominous: the latter may be transmitted directly from man to man, spreading the infection all the more readily and producing exceptionally high mortality rates. Comparative studies, based upon statistics derived from incidence of the same disease in late-medieval Europe, suggest that between one-third and one-half the population of Constantinople may well have died, while the lesser cities of the empire and the countryside by no means remained immune.

Outbreak of bubonic plague

The short-term impact of the plague may be seen in several forms of human activity during the 540s. Justinian's legislation of those years is understandably preoccupied with wills and intestate succession. Labour was scarce, and workers demanded wages so high that Justinian sought to control them by edict, as the monarchs of France and England were to do during the plague of the 14th century. In military affairs, above all, the record of those years is one of defeat, stagnation, and missed opportunities. Rather than effective Roman opposition, it was Khosrow's own weariness of an unprofitable war that led him to sign a treaty of peace in 545, accepting tribute from Justinian and preserving Persian conquests in Lazica. Huns, Sclaveni, Antae, and Bulgars ravaged Thrace and Illyricum, meeting only slight opposition from Roman armies. In Africa, a garrison diminished by plague nervously faced the threat of Moorish invasion. In Italy, Totila took the offensive, capturing southern Italy and Naples and even (546) forcing his way into Rome despite Belisarius' efforts to relieve the siege. Desperately, Justinian's great general called for reinforcements from the east; if ever they came, they were slow in arriving and proved numerically less than adequate to the task confronting them.

The last years of Justinian I. After about 548, Roman fortunes improved, and, by the mid-550s, Justinian had won victories in most theatres of operation, with the notable and ominous exception of the Balkans. A tour of the frontiers might begin with the east. In 551 the fortress of Petra was recovered from the Persians, but fighting continued in Lazica until a 50 years' peace, signed in 561, defined relations between the two great empires. On balance, the advantage lay with Justinian. Although the latter agreed to continue payment of tribute in the amount of 30,000 solidi a year, Khosrow, in return, abandoned his claims to Lazica and undertook not to persecute his Christian subjects. The treaty also regulated trade between Rome and Persia, since rivalry between the two great powers had always had its economic aspects, focussed primarily upon the silk trade. Raw silk reached Constantinople through Persian intermediaries, either by a land route leading from China through Persia or by the agency of Persian merchants in the Indian Ocean. The need to break this Persian monopoly had led Justinian to search for new routes and new peoples to serve as intermediaries: in the south, the Ethiopian merchants of the kingdom of Aksum; in the north, the peoples around the Crimea and in the Caucasian kingdom of Lazica, as well as the Turks of the steppes beyond the Black Sea. Other valuable commodities were exchanged in the Black Sea region, including textiles, jewelry, and wine from East Rome for the furs, leather, and slaves offered by the barbarians; yet, silk remained the commodity of prime interest. It was fortunate, then, that before 561 East Roman agents had smuggled silkworms from China into Constantinople, establishing a silk industry that would liberate the empire from dependence on Persia and become one of medieval Byzantium's most important economic operations.

The silk trade

In the West, Justinian's successes were even more spectacular. By 550 the Moorish threat had ended in North Africa. In 552 the armies of Justinian had intervened in a quarrel among the Visigothic rulers of Spain, and the East Roman troops overstayed the invitation extended them, seizing the opportunity to occupy on a more permanent basis certain towns in the southeastern corner of the Iberian Peninsula. Most important of all, Italy was recovered. Early in the 550s, Justinian assembled a vast army composed not only of Romans but also of barbarians, including Lombards, Heruli, and Gepids, as well as Persian deserters. Command of this host eventually was given to an unlikely but, as events were to prove, able commander: the eunuch and chamberlain Narses. In two decisive battles (Busta Gallorum and Mons Lactarius), the East Roman general defeated first Totila and then his successor, Teias. The Goths agreed to leave Italy. Despite the continued resistance of certain Gothic garrisons, coupled with the intervention of Franks and Alamanni, after 554 the land was essentially a province of the East Roman Empire.

Balkan affairs

In view of the wide mixture of peoples that descended upon it, the Balkans present a far more complex situation, and the Romans used a wider variety of tactics to contain the barbarians. After the Kutrigur Bulgar attack of 540, Justinian worked to extend a system of fortifications that ran in three zones through the Balkans and as far south as the Pass of Thermopylae. Fortresses, strongholds, and watchtowers were not, however, enough. The Slavs plundered Thrace in 545 and returned in 548 to menace Dyrrhachium; in 550 the Sclaveni, a Slavic people, reached a point about 40 miles (60 kilometres) from Constantinople. The major invasion came in 559, when the Kutrigur Bulgars, accompanied by Sclaveni, crossed the Danube and divided their force into three columns. One reached Thermopylae; a second, the Gallipoli Peninsula near Constantinople; and the third, the suburbs of Constantinople itself, which the aged Belisarius had to defend with an unlikely force of civilians, demesmen, and a few veterans. Worried by Roman naval action on the Danube, which seemed to menace the escape route home, the Kutrigurs returned north and found themselves under attack from the Utigurs, a people whose support Justinian's agents had earlier connived at and won by suitable bribes. The two peoples weakened each other in warfare, of which the episode of 559 was not the first instance, and this was precisely the result at which Byzantine diplomacy was aimed.

As long as the financial resources remained adequate, diplomacy proved the most satisfactory weapon in an age when military manpower was a scarce and precious commodity. Justinian's subordinates were to perfect it in their relationships with Balkan and south Russian peoples. For, if the Central Asian lands constituted a great reservoir of people, whence a new menace constantly emerged, the very proliferation of enemies meant that one might be used against another through skillful combination of bribery, treaty, and perfidy. East Roman relations in the late 6th century with the Avars, a Mongol people seeking refuge from the Turks, provide an excellent example of this "defensive imperialism." The Avar ambassadors reached Constantinople in 557, and, if they did not receive the lands they demanded, they were

loaded with precious gifts and allied by treaty with the empire. The Avars moved westward from south Russia, subjugating Utigurs, Kutrigurs, and Slavic peoples to the profit of the empire. At the end of Justinian's reign, they stood on the Danube, a nomadic people hungry for lands and additional subsidies and by no means unskilled themselves in a sort of perfidious diplomacy that would help them pursue their objectives.

Impact of the bubonic plague

No summary of the quiet, but ominous, last years of Justinian's reign would be complete without some notice of the continuing attacks of bubonic plague and the impact they were to continue to produce until the 8th century. As have other societies subjected to devastation from warfare or disease, East Roman society might have compensated for its losses of the 540s had the survivors married early and produced more children in the succeeding generations. Two developments prevented recovery. Monasticism, with its demands for celibacy, grew apace in the 6th century, and the plague returned sporadically to attack those infants who might have replaced fallen members of the older generations.

The resulting shortage of manpower affected several aspects of a state and society that perceptibly were losing their Roman character and assuming their Byzantine. The construction of new churches, so noteworthy a feature of the earlier years, ceased as men did little more than rebuild or add to existing structures. An increasing need for taxes, together with a decreasing number of taxpayers, evoked stringent laws forcing members of a village tax group to assume collective responsibility for vacant or unproductive lands. This, contemporary sources avow, was a burden difficult to assume, in view of the shortage of agricultural workers after the plague. Finally, the armies that won the victories described above in east and west were largely victorious only because Justinian manned them as never before with barbarians: Goths, Armenians, Heruli, Gepids, Saracens, and Persians—to name only the most prominent. It was far from easy to maintain discipline among so motley an army; yet, once the unruly barbarian accepted the quieter life of the garrison soldier, he tended to lose his fighting capacity and prove, once the test came, of little value against the still warlike barbarian facing him beyond the frontier. The army, in short, was a creation of war and kept its quality only by participating in battlefield action, but further expansive warfare could hardly be undertaken by a society chronically short of men and money.

In summary, the East Roman (or better, the Byzantine) state of the late 6th century seemed to confront many of the same threats that had destroyed the Western Empire in the 5th century. Barbarians pressed upon it from beyond the Balkan frontier, and peoples of barbarian origin manned the armies defending it. Wealth accumulated during the 5th century had been expended; and, to satisfy the basic economic and military needs of state and society, there were too few native Romans. If the Byzantine Empire avoided the fate of West Rome, it did so only because it was to combine valour and good luck with certain advantages of institutions, emotions, and attitudes that the older empire had failed to enjoy. One advantage already described, diplomatic skill, blends institutional and attitudinal change, for diplomacy would never have succeeded had not the Byzantine statesmen been far more curious and knowing than Justinian's 5th-century predecessor about the habits, customs, and movements of the barbarian peoples. The Byzantine's attitude had changed in yet another way. He was willing to accept the barbarian within his society provided that the latter, in his turn, accept orthodox Christianity and the emperor's authority. Christianity was often, to be sure, a veneer that cracked in moments of crisis, permitting a very old paganism to emerge, while loyalty to the emperor could be forsworn and often was. Despite these shortcomings, the Christian faith and the ecclesiastical institutions defined in the 6th century proved better instruments by far to unite men and stimulate their morale than the pagan literary culture of the Greco-Roman world.

Christian culture of the Byzantine Empire. Justinian's legislation dealt with almost every aspect of the Christian life: entrance into it by conversion and Baptism; administration of the sacraments that marked its several stages; proper conduct of the laity to avoid the wrath God would surely visit upon a sinful people; finally, the standards to be followed by those who lived the particularly holy life of the secular or monastic clergy. Pagans were ordered to attend church and accept Baptism, while a purge thinned their ranks in Constantinople, and masses of them were converted by missionaries in Asia Minor. Only the orthodox wife might enjoy the privileges of her dowry; Jews and Samaritans were denied, in addition to other

The Byzantine Empire at the death of Justinian in AD 565.

civil disabilities, the privilege of testamentary inheritance unless they converted. A woman who worked as an actress might better serve God were she to forswear any oath she had taken, even though before God, to remain in that immoral profession. Blasphemy and sacrilege were forbidden, lest famine, earthquake, and pestilence punish the Christian society. Surely God would take vengeance upon Constantinople, as he had upon Sodom and Gomorrah, should the homosexual persist in his "unnatural" ways.

Justinian regulated the size of churches and monasteries, forbade them to profit from the sale of property, and complained of those priests and bishops who were unlearned in the forms of the liturgy. His efforts to improve the quality of the secular clergy, or those who conducted the affairs of the church in the world, were most opportune. The best possible men were needed, for, in most East Roman cities during the 6th century, imperial and civic officials gradually resigned many of their functions to the bishop, or patriarch. The latter collected taxes, dispensed justice, provided charity, organized commerce, negotiated with barbarians, and even mustered the soldiers. By the early 7th century, the typical Byzantine city, viewed from without, actually or potentially resembled a fortress; viewed from within, it was essentially a religious community under ecclesiastical leadership. Nor did Justinian neglect the monastic clergy, or those who had removed themselves from the world. Drawing upon the regulations to be found in the writings of the 4th-century Church Father St. Basil of Caesarea, as well as the acts of 4th- and 5th-century church councils, he ordered the cenobitic (or collective) form of monastic life in a fashion so minute that later codes, including the rule of St. Theodore the Studite in the 9th century, only develop the Justinianic foundation.

Probably the least successful of Justinian's ecclesiastical policies were those adopted in an attempt to reconcile Monophysites and orthodox Chalcedonians. After the success of negotiations that had done so much to conciliate the West during the reign of Justin I, Justinian attempted to win over the moderate Monophysites, separating them from the extremists. Of the complicated series of events that ensued, only the results need be noted. In developing a creed acceptable to the moderate Monophysites of the East, Justinian alienated the Chalcedonians of the West and thus sacrificed his earlier gains in that quarter. The extreme Monophysites refused to yield. Reacting against Justinian's persecutions, they strengthened their own ecclesiastical organization, with the result that many of the fortress cities noted above, especially those of Egypt and Syria, owed allegiance to Monophysite ecclesiastical leadership. To his successors, then, Justinian bequeathed the same religious problem he had inherited from Anastasius.

If, in contrast, his regulation of the Christian life proved successful, it was largely because his subjects themselves were ready to accept it. Traditional Greco-Roman culture was, to be sure, surprisingly tenacious and even productive during the 6th century and was always to remain the treasured possession of an intellectual elite in Byzantium; but the same century witnessed the growth of a Christian culture to rival it. Magnificent hymns written by St. Romanos Melodos mark the striking development of the liturgy during Justinian's reign, a development that was not without its social implications. Whereas traditional pagan culture was literary and its pursuit or enjoyment thereby limited to the leisured and wealthy, the Christian liturgical celebration and its musical component were available to all, regardless of place or position. Biography, too, became both markedly Christian and markedly popular. Throughout the countryside and the city, holy men appeared in legend or in fact, exorcising demons, healing the sick, feeding the hungry, and warding off the invader. Following the pattern used in the 4th century by Athanasius to write the life of St. Anthony, hagiographers recorded the deeds of these extraordinary men, creating in the saint's life a form of literature that began to flower in the 6th and 7th centuries.

The rise of popular Christian culture

The vitality and pervasiveness of popular Christian culture manifested themselves most strongly in the veneration increasingly accorded the icon, an abstract and simplified image of Christ, the Virgin, or the saints. Notable for the timeless quality that its setting suggested and for the power expressed in the eyes of its subject, the icon seemingly violated the Second Commandment's explicit injunction against the veneration of any religious images. Since many in the early centuries of the church so believed, and in the 8th century the image breakers, or iconoclasts, were to adopt similar views, hostility toward images was nearly as tenacious an aspect of Christianity as it had been of Judaism before it.

The contrasting view—a willingness to accept images as a normal feature of Christian practice—would not have prevailed had it not satisfied certain powerful needs as Christianity spread among Gentiles long accustomed to representations of the divinity and among Hellenized Jews who had themselves earlier broken with the Mosaic commandment. The convert all the more readily accepted use of the image if he had brought into his Christianity, as many did, a heritage of Neoplatonism. The latter school taught that, through contemplation of that which could be seen (*i.e.*, the image of Christ), the mind might rise to contemplation of that which could not be seen (*i.e.*, the essence of Christ). From a belief that the seen suggests the unseen, it is but a short step to a belief that the seen contains the unseen and that the image deserves veneration because divine power somehow resides in it.

Men of the 4th century were encouraged to take such a step, influenced as they were by the analogous veneration that the Romans had long accorded the image of the emperor. Although the first Christians rejected this practice of their pagan contemporaries and refused to adore the image of a pagan emperor, their successors of the 4th century were less hesitant to render such honour to the images of the Christian emperors following Constantine. Since the emperor was God's vicegerent on Earth and his empire reflected the heavenly realm, the Christian must venerate, to an equal or greater degree, Christ and His saints. Thus the Second Commandment finally lost much of its force. Icons appeared in both private and public use during the last half of the 6th century: as a channel of divinity for the individual and as a talisman to guarantee success in battle. During the dark years following the end of Justinian I's reign, no other element of popular Christian belief better stimulated that high morale without which the Byzantine Empire would not have survived.

The successors of Justinian: 565–610. Until Heraclius arrived to save the empire in 610, inconsistency and contradiction marked the policies adopted by the emperors, a reflection of their inability to solve the problems Justinian had bequeathed his successors. Justin II (565–578) haughtily refused to continue the payment of tribute to Avar or Persian, thereby preserving the resources of the treasury, which he further increased by levying new taxes. Praiseworthy as his refusal to submit to blackmail may seem, Justin's intransigence only increased the menace to the empire. His successor, Tiberius (578–582), removed the taxes and, choosing between his enemies, awarded subsidies to the Avars while taking military action against the Persians. Although Tiberius' general, Maurice, led an effective campaign on the eastern frontier, subsidies failed to restrain the Avars. They captured the Balkan fortress of Sirmium in 582, while the Slavs began inroads across the Danube that would take them, within 50 years, into Macedonia, Thrace, and Greece.

Justin II

The accession of Maurice in 582 inaugurated a reign of 20 years marked by success against Persia, a reorganization of Byzantine government in the west, and the practice of economies during his Balkan campaigns that, however unavoidable, would destroy him in 602. Byzantine efforts against Sāsānian Persia were rewarded in 591 by a fortunate accident. The lawful claimant to the Persian throne, Khosrow II, appealed to Maurice for aid against the rebels who had challenged his succession. In gratitude for this support, Khosrow abandoned the frontier cities and the claims to Armenia, the two major sources of contention between Byzantium and Persia. The terms of the

treaty gave Byzantium access, in Armenia, to a land rich in the soldiers it desperately needed and, equally important, an opportunity to concentrate on other frontiers where the situation had worsened.

The exarchate of Carthage and Ravenna

Confronted by a Visigothic resurgence in Spain and by the results of a Lombard invasion of Italy (568), which was steadily confining Byzantine power to Ravenna, Venice, and Calabria-Sicily in the south, Maurice developed a form of military government throughout the relatively secure province of North Africa and in whatever regions were left in Italy. He abandoned the old principle of separating civil from military powers, placing both in the hands of the generals, or exarchs, located, respectively, at Carthage and Ravenna. Their provinces, or exarchates, were subdivided into duchies composed of garrison centres that were manned not by professional soldiers but by conscript local landholders. The exarchate system of military government seems to have worked well: North Africa was generally quiet despite Moorish threats; and in 597 the ailing Maurice had intended to install his second son as emperor throughout those western possessions in which he had clearly not lost interest.

But the major thrust of his efforts during the last years of his reign was to be found in the Balkans, where, by dint of constant campaigning, his armies had forced the Avars back across the Danube by 602. In the course of these military operations, Maurice made two mistakes: the first weakened him; the second destroyed him together with his dynasty. Rather than constantly accompanying his armies in the field, as his 7th- and 8th-century successors were to do, Maurice remained for the most part in Constantinople, losing an opportunity to engage the personal loyalty of his troops. He could not count on their obedience when he issued unwelcome commands from afar that decreased their pay in 588, ordered them to accept uniforms and weapons in kind rather than in cash equivalents, and, in 602, required the soldiers to establish winter quarters in enemy lands across the Danube, lest their requirements prove too great a strain on the agricultural and financial resources of the empire's provinces south of the river. Exasperated by this last demand, the soldiers rose in revolt, put a junior officer named Phocas at their head, and marched on Constantinople. Blues and Greens united against Maurice, and the aged emperor watched as his five sons were slaughtered before he himself met a barbarous death.

The ensuing reign of Phocas (602–610) may be described as a disaster. Khosrow seized the opportunity offered him by the murder of his benefactor, Maurice, to initiate a war of revenge that led Persian armies into the Anatolian heartland. Subsidies again failed to restrain the barbarians north of the Danube; after 602 the frontier crumbled, not to be restored save at the cost of centuries of warfare. Lacking a legitimate title, holding his crown only by right of conquest, Phocas found himself confronted by constant revolt and rebellion. To contemporaries, the coincidence of pestilence, endemic warfare, and social upheaval seemed to herald the coming of the Antichrist, the resurrection of the dead, and the end of the world.

But it was a human saviour who appeared, albeit under divine auspices. Heraclius, son of the Exarch of Africa, set sail from the western extremes of the empire, placing his fleet under the protection of an icon of the Virgin against Phocas, stigmatized in the sources as the "corrupter of virgins." In the course of his voyage along the northern shores of the Mediterranean, Heraclius added to his forces and arrived at Constantinople in 610 to be hailed as a saviour. With the warm support of the Green faction, he quickly bested his enemy, decapitating Phocas and, with him, those the latter had advanced to high civil and military office. There were, in consequence, few experienced counsellors to aid Heraclius, for, among the men of prominence under Phocas—and earlier under Maurice—few survived to greet the new emperor.

THE 7TH CENTURY: THE HERACLIANS AND THE CHALLENGE OF ISLAM

Heraclius and the origin of the themes. The most threatening problem Heraclius faced was the external menace of the Avars and the Persians, and neither people abated its pressure during the first years of the new reign. The Avars almost captured the Emperor in 617 during a conference outside the long walls protecting the capital. The Persians penetrated Asia Minor and then turned to the south, capturing Jerusalem and Alexandria (in Egypt). The great days of the Persian Achaemenid Empire seemed to have come again, and there was little in the recent history of the Byzantine emperors that would encourage Heraclius to place much faith in the future. He clearly could not hope to survive unless he kept under arms the troops he had brought with him; yet, the fate of Maurice demonstrated that this would be no easy task, given the empire's lack of financial and agricultural resources.

Three sources of Heraclius' strength

Three sources of strength enabled Heraclius to turn defeat into victory. The first was the pattern of military government as he and the nucleus of his army would have known it in the exarchates of North Africa or Ravenna. As it had been in the West, so it now was in the East. Civil problems were inseparable from the military: Heraclius could not hope to dispense justice, collect taxes, protect the church, and assure the future to his dynasty unless military power reinforced his orders. A system of military government, the exarchate, had accomplished these objectives so well in the West that, in a moment of despair, Heraclius sought to return to the land of his origins. In all likelihood, he applied similar principles of military rule to his possessions throughout Asia Minor, granting his generals (*stratēgoi*) both civil and military authority over those lands that they occupied with their "themes," as the army groups, or corps, were called in the first years of the 7th century.

Secondly, during the social upheaval of the past decade, the imperial treasury had doubtless seized the estates of prominent individuals who had been executed either during Phocas' reign of terror or after the latter's death. In consequence, though the treasury lacked money, it nonetheless possessed land in abundance, and Heraclius could easily have supported with grants of land those cavalry soldiers whose expenses in horses and armament he could not hope to meet with cash. If this hypothesis is correct, then, even before 622, themes, or army groups—including the guards (Opsikioi), the Armenians (Armeniakoi), and the Easterners (Anatolikoi)—were given lands and settled throughout Asia Minor in so permanent a fashion that, before the century was out, the lands occupied by these themes were identified by the names of those who occupied them. The Opsikioi were to be found in the Opsikion theme, the Armeniakoi in the Armeniakon, and the Anatolikoi in the Anatolikon. The term theme ceased thereafter to identify an army group and described instead the medieval Byzantine unit of local administration, the theme under the authority of the themal commander, the general (*stratēgos*).

When Heraclius "went out into the lands of the themes" in 622, thereby undertaking a struggle of seven years' duration against the Persians, he utilized the third of his sources of strength: the religious. The warfare that ensued was nothing less than a holy war: it was partly financed by the treasure placed by the church at the disposal of the state; the Emperor's soldiers called upon God to aid them as they charged into battle; and they took comfort in the miraculous image of Christ that preceded them in their line of march. A brief summary of the campaign unfortunately gives no idea of the difficulties Heraclius encountered as he liberated Asia Minor (622), fought in Armenia with allies found among the Christian Caucasian peoples, the Lazi, the Abasgi, and the Iberians (624), and struggled in far-distant Lazica while Constantinople withstood a combined siege of Avars and Persians (626). An alliance with the Khazars, a Turkic people from north of the Caucasus, proved of material assistance in those years and of lasting import in Byzantine diplomacy. Heraclius finally destroyed the main Persian host at Nineveh in 627 and, after occupying Dastagird in 628, savoured the full flavour of triumph when his enemy, Khosrow, was deposed and murdered. The Byzantine emperor might well have believed that, if

Defeat of the Persians

the earlier success of the Persians signalized the resurrection of the Achaemenid Empire, his own successes had realized the dreams of Caesar, Augustus, and Trajan.

Yet this was a war fought by medieval Byzantium and not by ancient Rome. Its spirit was manifest in 630, when Heraclius triumphantly restored the True Cross to Jerusalem, whence the Persians had stolen it, and—even more—when Constantinople resisted the Avar–Persian assault of 626. During the attack, the patriarch Sergius maintained the morale of the valiant garrison by proceeding about the walls, bearing the image of Christ to ward off fire, and by painting upon the gates of the western walls images of the Virgin and child to ward off attacks launched by the Avars—the "breed of darkness." The Avars withdrew when Byzantine ships defeated the canoes manned by Slavs, upon whom the nomad Avars depended for their naval strength. The latter never recovered from their defeat. As their empire crumbled, new peoples from the Black Sea to the Balkans emerged to seize power: the Bulgars of Kuvrat, the Slavs under Samo, and the Serbs and Croats whom Heraclius permitted to settle in the northwest Balkans once they had accepted Christianity.

As for the Byzantine defenders of Constantinople, they celebrated their victory by singing Romanos' great Akithistos hymn, with choir and crowd alternating in the chant of the "Alleluia." The hymn, still sung in a Lenten service, commemorates those days when Constantinople survived as a fortress under ecclesiastical leadership, its defenders protected by the icons and united by their liturgy. This they sang in Greek, as befitted a people whose culture was now Greek and no longer Latin.

The successors of Heraclius: Islām and the Bulgars. In the same year that Heraclius went out into the themes, Muḥammad made his withdrawal (*hijrah*) from Mecca to Medina, where he established the *ummah*, or Muslim community. Upon the Prophet's death in 632, the caliphs, or successors, channelled the energies of the Arab Bedouin by launching them upon a purposive and organized plan of conquest. The results were spectacular: a Byzantine army was defeated at the Battle of the Yarmūk River (636), thereby opening Palestine and Syria to Arab Muslim control. Alexandria capitulated in 642, removing forever the province of Egypt from Byzantine authority. The Arabs had, meanwhile, advanced into Mesopotamia, capturing the royal city of Ctesiphon and, eventually, defeating an army under command of the Persian king himself. So ended the long history of Persia under Achaemenids, Parthians, and Sāsānians; further conquests were shortly to initiate that region's Islāmic phase (see further IRAN, HISTORY OF; CALIPHATE, EMPIRE OF THE).

The rise of Islām

At least three aspects of the contemporary situation of Byzantium and Persia account for the phenomenal ease with which the Arabs overcame their enemies: first, both empires, exhausted by wars, had demobilized before 632; second, both had ceased to support those client states on the frontiers of the Arabian Peninsula that had restrained the Bedouin of the desert for a century past; third, and particularly in reference to Byzantium, religious controversy had weakened the loyalties that Syrians and Egyptians rendered to Constantinople. Heraclius had sought in 638 to placate Monophysite sentiment in these two provinces by promulgating the doctrine of Monothelitism, holding that Christ, although of two natures, had but one will. Neither in the East nor in the West did this compromise prove successful. The victorious Muslims granted religious freedom to the Christian community in Alexandria, for example, and the Alexandrians quickly recalled their exiled Monophysite patriarch to rule over them, subject only to the ultimate political authority of the conquerors. In such a fashion the city persisted as a religious community under an Arab Muslim domination more welcome and more tolerant than that of Byzantium.

The aging Heraclius was unequal to the task of containing this new menace, and it was left to his successors—Constantine III (ruled 641), Constans II (641–668), Constantine IV (668–685), and Justinian II (685–695, 705–711)—to do so. This bare list of emperors obscures the family conflicts that often imperilled the succession, but gradually the principle was established that, even if brothers ruled as co-emperors, the senior's authority would prevail. Although strife between Blues and Greens persisted throughout the century, internal revolt failed to imperil the dynasty until the reign of Justinian II. The latter was deposed and mutilated in 695. With the aid of the Bulgars, he returned in 705 to reassume rule and wreak a vengeance so terrible that his second deposition, and death, in 711 is surprising only in its delay of six years. From 711 until 717 the fortunes of the empire foundered; in that year, Leo, *stratēgos* of the Anatolikon theme, arrived as a second Heraclius to found a dynasty that would rescue the empire from its new enemies, the Arab Muslims and the Bulgars.

Three features distinguish the military history of the years 641–717: first, an increasing use of sea power on the part of the Arabs; second, a renewed threat in the Balkans occasioned by the appearance of the Onogur Huns, known in contemporary sources as the Bulgars; third, a persisting interest among the emperors in their western possessions, despite the gradual attrition of Byzantine authority in the exarchates of Carthage and Ravenna. Thanks to the control that the Arabs gradually asserted over the sea routes to Constantinople, they climaxed their earlier assaults on Armenia and Asia Minor with a four years' siege of the great city itself (674–678). Defeated in this last attempt by the use of Greek fire, an inflammable liquid of uncertain composition, the Arabs signed a 30 years' truce, according to which they agreed to pay tribute in money, men, and horses. Lured by the unsettled conditions following upon Justinian's second deposition, they renewed their assaults by land and sea, and the year 717 found the Arabs again besieging Constantinople.

The Bulgar menace

On the Balkan frontier, meanwhile, the Bulgars assumed the role abdicated by the Avars after 626. A pagan people whom the Khazars had forced toward the Danube Delta in the latter part of the 7th century, they eluded Constantine IV's attempts to defeat them in 681. By virtue of a treaty signed in that year, as well as others dating from 705 and 716, the Bulgars were recognized as an independent kingdom, occupying (to the humiliation of Byzantium) lands south of the Danube down into the Thracian plain. While the Bulgars had thus deprived the empire of control in the north and central Balkans, the Byzantines could take comfort in the expeditions of 658 and 688 launched by Constans and Justinian II into Macedonia and in the formation of the themes of Thrace (687) and Hellas (695), evidence that Byzantine authority was beginning to prevail along the peninsular coastline and in certain parts of Greece where Slavs had penetrated.

In the West, the situation was less reassuring. Monothelitism had evoked a hostile reception among the churches of North Africa and Italy, and the resulting disaffection had encouraged the exarchs of both Carthage (646) and Ravenna (652) to revolt. By the end of the century, Africa had been largely lost to Muslim conquerors who would, in 711, seize the last outpost at Septem. For the moment, at least, Sicily and the scattered Italian possessions remained secure. Constans, in fact, undertook operations against the Lombards, and he apparently intended to move his capital to Sicily, before his assassination ended the career of the last Eastern emperor to venture into the West. In summary: Leo in 717 ruled over an empire humiliated by the presence of pagan barbarians upon Balkan soil rightfully considered "Roman," threatened by an attack upon its Anatolian heartland and its capital, and reduced, finally, in the West to Sicily and the remnants of the Ravenna exarchate.

Economics and institutions

However dismal the military record, institutional and economic developments had permitted the empire to survive and were to provide foundations for greater success in the centuries to come. The themal system had taken root and, with it, probably the institution of soldiers' properties. Military service was a hereditary occupation: the eldest son assumed the burden of service, supported primarily by revenues from other members of the family

who worked the land in the villages. This last was a task easier to accomplish at the end of the 7th century thanks to the colonies of Slavs and other peoples brought into the empire and settled in the rural areas by Heraclius, Constantine IV, and Justinian II. In the 8th and 9th centuries, other emperors, including Leo III, Constantine V, and Nicephorus I, were to continue the practice, thus ending the population decline that had long eroded the ranks of Byzantine society. There are unmistakable signs of agricultural expansion even before 800; and, at about that time, urban life, which had never vanished in Asia Minor, began to flourish and expand in the Balkans. To judge from the evidence of the Farmer's Law, dated in the 7th century, the technological base of Byzantine society was more advanced than that of contemporary western Europe: iron tools could be found in the villages; water mills dotted the landscape; and field-sown beans provided a diet rich in protein. None of these advances was to characterize western European agriculture until the 10th century. Byzantine agriculture enjoyed the further advantage of a highly developed tradition of careful farming that persisted even in the darkest days, enabling the peasant to make the most of the soil upon which he worked. The invasions had even provided a form of stimulus to development: having lost first its Egyptian granary and, later, its North African and Sicilian resources, the empire had to live essentially, although not totally, from whatever it could produce in the lands remaining to it. The invasions had also, in all probability, broken up many a large estate, and the small peasant holding seems to have been the "normal" form of rural organization in this period. Although collective village organization persisted in the form of the rural commune and, with it, certain collective agricultural practices, the state seems to have made little or no attempt to bind the peasant to the soil upon which the tax registers had inscribed him. While Byzantium remained a slave-owning society, the *colonus* of the later Roman Empire had vanished, and a greater degree of freedom and mobility characterized agricultural relationships during the 7th and 8th centuries.

So it was, too, in trade and commerce. After the loss of Egypt and North Africa, the grain fleets manned by hereditary shipmasters disappeared; in their place there emerged the independent merchant, of sufficient importance to call forth a code of customary law, the Rhodian Sea Law, to regulate his practices. Military and religious hostilities failed to check him as he traded with the Bulgars in Thrace and, through Cyprus, with the Arabs. Despite constant warfare, this was, in short, a healthier society than the late Roman, and its chances of survival were further increased when the sixth general council (681) condemned Monotheletism and anathematized its adherents. With Egypt and Syria under Muslim rule, it was no longer necessary to placate Eastern Monophysitism, and it seemed that doctrinal discord would no longer separate Constantinople from the West. Events were to prove otherwise.

THE AGE OF ICONOCLASM: 717–867

For more than a century after the accession of Leo III (717–741), a persisting theme in Byzantine history may be found in the attempts made by the emperors, often with wide popular support, to eliminate a practice that had earlier played a major part in creating the morale essential to survival: namely, the veneration of icons.

The veneration of icons

The latter sentiment had grown in intensity during the 7th century: the council in Trullo of 691–692 had decreed that Christ should be represented in human form rather than, symbolically, as the lamb. The reigning emperor, Justinian II, had taken the unprecedented step of placing the image of Christ on his coinage while proclaiming himself the "slave of God." Evidence of a reaction against such iconophile (or image venerating) doctrines and practices may be found early in the 8th century, but full-fledged Iconoclasm (or destruction of the images) emerged as an imperial policy only when Leo III issued his decrees of 730. Under his son, Constantine V (ruled 741–775), the iconoclastic movement intensified, taking the form of violent persecution of the monastic clergy, the foremost defenders of the iconophile position. The Council of Nicaea in 787 restored iconophile doctrine at the instigation of the empress Irene, but military reversals led Leo V to resurrect in 815 the iconoclastic policies associated with Constantine V, one of Byzantium's most successful generals. Not until 843 were the icons definitively restored to their places of worship and icon veneration solemnly proclaimed as orthodox belief. Even this brief summary suggests that the Emperor's fortunes on the battlefield were of no small moment in determining his attitude toward the icons, those channels whence superhuman power descended to man. An account of the age of Iconoclasm opens appropriately, then, with its military history.

The reigns of Leo III (the Isaurian) and Constantine V. Almost immediately upon Leo's accession, the empire's fortunes improved markedly. With the aid of the Bulgars, he turned back the Muslim assault in 718 and, in the intervals of warfare during the next 20 years, addressed himself to the task of reorganizing and consolidating the themes in Asia Minor. Thanks to the assistance of the traditional allies, the Khazars, Leo's reign concluded with a major victory, won again at the expense of the Arabs, at Acroinon (740). His successor, Constantine, had first to fight his way to the throne, suppressing a revolt of the Opsikion and Armeniakon themes launched by his brother-in-law Artavasdos. During the next few years, internal disorder in the Muslim world played into Constantine's hands as the ʿAbbāsid house fought to seize the caliphate from the Umayyads. With his enemy thus weakened, Constantine won noteworthy victories in northern Syria, transferring the prisoners he had there captured to Thrace in preparation for the wars against the Bulgars that were to occupy him from 756 to 775. In no fewer than nine campaigns, he undermined Bulgar strength so thoroughly that the northern enemy seemed permanently weakened, if not crushed. Even the venom used by the iconophile chroniclers of Constantine's reign cannot disguise the enormous popularity his victories won him.

In later centuries, the folk of Constantinople would stand by his tomb, seeking his aid against whatever enemy imperilled the city's defenses.

Constantine's weak successors. His successors all but let slip the gains won by the great iconoclast. Constantine's son Leo IV died prematurely in 780, leaving to succeed him his ten-year-old son, Constantine VI, under the regency of the empress Irene. Not much can be said for Constantine, and Irene's policies as regent and (after the deposition and blinding of her son at her orders) as sole ruler from 797 to 802 were all but disasterous. Her iconophile policies alienated many among the themal troops, who were still loyal to the memory of the great warrior emperor, Constantine V. In an effort to maintain her popularity among the monkish defenders of the icons and with the population of Constantinople, she rebated taxes to which these groups were subject, as well as reducing the customs duties levied outside the port of Constantinople, at Abydos and Hieros. The consequent loss to the treasury weighed all the more severely since victories won by the Arabs in Asia Minor (781) and by the Bulgars (792) led both peoples to demand and receive tribute as the price of peace. A revolt of the higher palace officials led to Irene's deposition in 802, and the so-called Isaurian dynasty of Leo III ended with her death, in exile, on the isle of Lesbos.

The empress Irene

In the face of the Bulgar menace, none of the following three emperors succeeded in founding a dynasty. Nicephorus I (ruled 802–811), the able finance minister who succeeded Irene, reimposed the taxes that the Empress had remitted and instituted other reforms that provide some insight into the financial administration of the empire during the early 9th century. In the tradition of Constantine V, Nicephorus strengthened the fortifications of Thrace by settling, in that theme, colonists from Asia Minor.

Taking arms himself, he led his troops against the new and vigorous Bulgar khan, Krum, only to meet defeat and death at the latter's hands. His successor, Michael I

Rangabe (811–813), fared little better; internal dissensions broke up his army as it faced Krum near Adrianople, and the resulting defeat cost Michael his throne. In only one respect does he occupy an important place in the annals of the Byzantine Empire. The first emperor to bear a family name, Michael's use of the patronymic, Rangabe, bears witness to the emergence of the great families whose accumulation of landed properties would soon threaten the integrity of those smallholders upon whom the empire depended for its taxes and its military service. The name in question seems a Hellenized form of a Slav original (*rokavu*), and, if so, Michael's ethnic origin and that of his successor, Leo the Armenian (ruled 813–820), provide evidence enough of the degree to which Byzantium in the 9th century had become not only a melting-pot society but, further, a society in which even the highest office lay open to the man with the wits and stamina to seize it. Leo fell victim to assassination, but before his death events beyond his control had improved the empire's situation. Krum died suddenly in 814 as he was preparing an attack upon Constantinople, and his son, Omortag, arranged a peace with the Byzantine Empire in order to protect the western frontiers of his Bulgar empire against the pressures exerted by Frankish expansion under Charlemagne and his successors. Since the death of the caliph, Hārūn ar-Rashīd, had resulted in civil war in the Muslim world, hostilities from that quarter ceased. Leo used the breathing space to reconstruct those Thracian cities that the Bulgars had earlier destroyed. His work indicates the degree of gradual Byzantine penetration into the coastal fringes of the Balkan Peninsula, as does the number of themes organized in that same region during the early 9th century: those of Macedonia, Thessalonica, Dyrrhachium, Dalmatia, and the Strymon.

Michael II and Thomas the Slav

The new emperor, Michael II, the Amorian, was indeed able to establish a dynasty, his son Theophilus (829–842) and his grandson Michael III (842–867) each occupying the throne in turn, but none would have forecast so happy a future during Michael II's first years. One Thomas the Slav, Michael's former comrade in arms, gave himself out to be the unfortunate Constantine VI and secured his coronation at the hands of the Patriarch of Antioch, with the willing permission of the Muslim caliph under whose jurisdiction Antioch lay. Thomas thereupon marched upon Constantinople at the head of a motley force of Caucasian peoples whose sole bonds were to be found in their devotion to iconophile doctrine and their hatred of Michael's Iconoclasm. Assisted by Omortag and relying upon the defenses of Constantinople, Michael defeated his enemy, but the episode suggests the tensions beneath the surface of Byzantine society: the social malaise, the ethnic hostility, and the persisting discord created by iconoclasm. All these may explain the weakness displayed throughout Theophilus' reign, when a Muslim army defeated the Emperor himself (838) as a prelude to the capture of the fortress of Amorium in Asia Minor. It may also explain the concurrent decline of Byzantine strength in the Mediterranean, manifest in the capture of Crete by the Arabs (826) and in the initiation of attacks upon Sicily that finally secured the island for the world of Islām. Iconoclasm certainly played its part in the further alienation of East from West, and a closer examination of its doctrines will suggest why this may have been.

The Iconoclastic Controversy. Iconoclasts and iconophiles (or iconodules) agreed on one fundamental point: a Christian people could not prosper unless it assumed the right attitude toward the holy images, or icons. They disagreed, of course, on what that attitude should be. Each could discover supporting arguments in the writings of the early church, and it is essential to remember that the debate over images is as old as Christian art. The fundamentals of Iconoclasm were by no means an 8th-century discovery. The ablest defender of the iconophile position was, however, the 8th-century theologian St. John of Damascus. Drawing upon Neoplatonic doctrine, John suggested that the image was but a symbol; the creation of the icon was justified since, by virtue of the Incarnation, God had himself become man.

The iconoclasts responded by pointing to the express wording of the Second Commandment. The condemnation therein contained of idolatry seems to have weighed heavily with Leo III, who may have been influenced by Islām, a religion that strictly prohibited the use of religious images. The latter point is debatable, as is the contention that Iconoclasm was particularly an expression of religious sentiment to be found in the eastern themes of the empire. There is little doubt, however, that Monophysitism influenced the ideas of Constantine V and, through him, the course of debate during the last half of the 8th century. In the eyes of the Monophysite, who believed in the single, indistinguishable, divine nature of Christ, the iconophile was guilty of sacrilege. Either he was a Nestorian, reducing the divine nature to human terms in the image, or he was a Chalcedonian Dyophysite, radically distinguishing that which man could not distinguish. Still another consideration favouring iconoclasm may be found in the intimate connection of iconoclastic doctrine with the emperor's conception of his role as God's vicegerent on Earth. During the late 6th and 7th centuries, iconophile emperors had viewed themselves in a "pietistic" fashion, emphasizing their devotion and subservience to God. Constantine V, on the other hand, pridefully replaced the icons with imperial portraits and with representations of his own victories. Viewed in this light, Iconoclasm signalled a rebirth of imperial confidence; and, so deservedly great was Constantine's reputation, so dismal the accomplishments of his successors, that a Leo V, for one, could easily believe that God favoured the iconoclastic battalions.

Under Constantine V, the struggle against the icons became a struggle against their chief defenders, the monastic community. The immediate destruction wrought by Constantine and his zealous subordinates is, however, of less moment than the lasting effect of the persecution on the orthodox clergy. Briefly put, the church became an institution rent by factions, wherein popular discontent found a means of expression to replace the Blues and the Greens, whose significance steadily waned during the 8th century. Intransigent iconophiles looked for their leaders among the monks of the monastery of Stoudion, and they found one in the person of the monastery's abbot, St. Theodore the Studite (759–826). In the patriarch Ignatius (847–858; 867–877) they discovered a spokesman after their own hearts: one drawn from the monastic ranks and contemptuous of all the allurements that the world of secular learning seemed to offer. More significant than the men to be found on the other extreme, iconoclast patriarchs including Anastasius and John Grammaticus, were the representatives of the moderate party: the patriarchs Tarasius, Nicephorus, Methodius, and Photius. Although iconophile in sympathy, the latter group enjoyed little rapport with the monastic zealots. Unlike the average monk, they were often educated laymen, trained in the imperial service and ready to compromise with imperial authority.

Byzantine relations with Catholic Europe

Not only was Iconoclasm a major episode in the history of the Byzantine, or Orthodox, Church, it also permanently affected relations between the empire and Catholic Europe. The Lombard advance, it may be remembered, had restricted Byzantine authority in Italy to the Exarchate of Ravenna, and to that quarter the popes of the 7th century, themselves ordinarily of Greek or Syrian origin, turned for protection against the common enemy. During the 8th century, two issues alienated Rome from Constantinople: Iconoclasm and quarrels stemming from the question of who should enjoy ecclesiastical jurisdiction over Illyricum and over Calabria in south Italy. Pope Gregory II refused to accept the iconoclastic doctrines of Leo III; and his successor, Gregory III, had openly to condemn them at a council. Once Ravenna fell to the Lombards, and the exarchate ceased to exist in 751, the Pope had to seek a new protector. This he found in the person of the Frankish leader Pepin III, who sought some form of sanction to legitimize his seizure of the crown from the feeble hands of the last representative of the Merovingian dynasty. Thus Pope Stephen anointed Pepin as king of the Franks in 754, and the latter entered Italy

to take arms against the Lombard king. Even the restoration of icon veneration in 787 failed to bridge the differences between orthodox Byzantium and Catholic Europe, for the advisers of Pepin's son and successor, Charlemagne, condemned the iconophile position as heartily as an earlier generation had rejected the iconoclast decrees of Leo III. Nor could the men of Charlemagne's time admit that a woman—the empress Irene—might properly assume the dignity of emperor of the Romans. For all these reasons, Charlemagne, king of the Franks and Lombards by right of conquest, assented to his coronation as emperor of the Romans on Christmas Day, 800, by Pope Leo III. No longer a barbarian king, Charlemagne became, by virtue of the symbolism of the age, a new Constantine. This the Byzantine chancery could not accept, for, if there were one God, one faith, and one truth, then there could be but one empire and one emperor; surely that emperor ruled in Constantinople, not in Charlemagne's Aachen. Subsequent disputes between Rome and Constantinople seemed often to centre upon matters of ecclesiastical discipline; underlying these differences were two more powerful considerations, neither of which could be ignored. According to theory there could be but one empire; clearly, there were two. And between Rome and Constantinople there stood two groups of peoples open to conversion: the Slavs of central Europe and the Bulgars in the Balkans. From which of the two jurisdictions would these people accept their Christian discipline? To which, in consequence, would they owe their spiritual allegiance?

The reign of Michael III

The reign of Michael III draws together these and other threads from the past. Veneration of the icons was definitely rehabilitated in 843, in so diplomatic a fashion that the restoration, in itself, produced no new rifts although old factionalisms persisted with the appointment of a monk, Ignatius, as patriarch. The latter's intransigent zealotry found little favour with Caesar Bardas, Michael's uncle, who had seized power from the Empress Regent in 856. Two years later, Ignatius was deposed and replaced by a moderate: the scholar and layman Photius. No single person better exemplifies the new age, nor, indeed, did any other play a larger part in the cultural rebirth and missionary activity among the Slavs, Bulgars, and Russians that marks the middle of the 9th century. The same aggressive and enterprising spirit is manifest in the military successes won on the Asia Minor frontier, culminating in Petronas' victory at Poson (863) over the Muslim emir of Melitene.

In Sicily, and throughout the Mediterranean, Byzantine arms were less successful, but, thanks to Photius' diplomatic skill, the see of Constantinople maintained its position against Rome during the so-called Photian Schism. When Pope Nicholas I challenged Photius' elevation to the patriarchate, deploring as uncanonical the six days' speed with which he had been advanced through the successive ranks of the hierarchy, the Byzantine patriarch refused to bow. He skillfully persuaded Nicholas' delegates to a council, summoned at Constantinople to investigate the matter, that he was the lawful patriarch despite the persisting claims of the rival Ignatian faction. Nicholas, alleging that his men had been bribed, excommunicated Photius; a council at Constantinople responded (867) by excommunicating Nicholas in turn. The immediate issues between the two sees were matters of ecclesiastical supremacy, the liturgy, and clerical discipline; behind these sources of division lay the question, mentioned above, of jurisdiction over the converts in Bulgaria. And behind that question may be found centuries of growing separation between the minds and institutions of the eastern and the western Mediterranean worlds, symbolized in the roles assumed by two among the major protagonists in the Photian Schism. It was the supreme spiritual authority, the pope, who hurled anathemas from the west, but it was God's vicegerent on Earth, the emperor Michael III, who presided at the council of 867.

Michael did not long survive this moment of triumph. In that very year, he was murdered by his favourite, Basil, who, on his bloody path to the throne, had earlier disposed of Caesar Bardas. As had Heraclius and Leo III before him, Basil came to found a dynasty, in this instance the Macedonian house. Unlike his predecessors, he came not as a saviour but as a peasant adventurer, to seize an already sound empire whose next centuries were to be its greatest. (J.L.Te.)

II. From 867 to the Ottoman conquest

THE MACEDONIAN ERA: 867–1025

Under the Macedonians, at least until the death of Basil II in 1025, the empire enjoyed a golden age. Its armies regained the initiative against the Arabs in the East, and its missionaries evangelized the Slavs, extending Byzantine influence in Russia and the Balkans. And, despite the rough military character of many of the emperors, there was a renaissance in Byzantine letters and important developments in law and administration. At the same time there were signs of decay: resources were squandered at an alarming rate; there was growing estrangement from the West; and a social revolution in Anatolia was to undermine the economic and military strength of the empire.

The empire was in theory an elective monarchy with no law of succession. But the desire to found and perpetuate a dynasty was strong, and it was often encouraged by popular sentiment. This was especially true in relation to the Macedonian dynasty, the founder of which Basil I, murdered his way to the throne in 867. Probably of Armenian descent, though they had settled in Macedonia, Basil's family was far from distinguished and can hardly have expected to produce a line of emperors that lasted through six generations and 189 years. But, having acquired the imperial crown, Basil tried to make sure that his family would not lose it and nominated three of his sons as co-emperors. Though he was his least favourite, through the scholarly Leo VI, who succeeded him in 886, the succession was at least secure. Even the three soldier-emperors who usurped the throne during the Macedonian era were conscious, in varying degrees, that they were protecting the rights of a legitimate heir during a minority: Romanus I Lecapenus for Constantine VII, the son of Leo VI; and Nicephorus Phocas and John Tzimisces for Basil II, the grandson of Constantine VII.

Founding of the dynasty

The Macedonian Emperors, 867–1025

name	reign dates
Basil I	867–886
Leo VI	886–912
Constantine VII	913–959
Romanus I*	919–944
Romanus II	959–963
Nicephorus II	963–969
John I	969–976
Basil II	976–1025

*Ruled in Constantine's name.

Military revival. A reassertion of Byzantine military and naval power in the East began with victories over the Arabs by Michael III's general Petronas in 856. From 863 the initiative lay with the Byzantines. The struggle with the Arabs, which had long been a struggle for survival, became a mounting offensive that reached its brilliant climax in the 10th century. By 867 a well-defined boundary existed between the Byzantine Empire and the territory of the 'Abbāsid caliphate. Its weakest point was in the Taurus Mountains above Syria and Antioch. Basil I (reigned 867–886) directed his operations against this point, recovered Cyprus for a while, and campaigned against the Paulicians, a heretical Christian sect whose anti-imperial propaganda was effective in Anatolia. But the conflict with Islām was one that concerned the whole empire, in the West as well as in the East, by sea as well as by land. In 902 the Arabs completed the conquest of Sicily, but they were kept out of the Byzantine province of South Italy, for whose defense Basil I had even made some effort to cooperate with the Western emperor Louis II. The worst damage, however, was done by Arab pi-

rates who had taken over the island of Crete. In 904 they plundered Thessalonica, carrying off quantities of loot and prisoners. Leo VI sent a naval expedition to Crete in 911, but the Muslims drove it off and humiliated the Byzantine navy off Chios in 912.

Success of Eastern offensive

On the eastern frontier, the Byzantine offensive was sustained with great success during the reign of Romanus I Lecapenus by an Armenian general John Curcuas (Gurgen), who captured Melitene (934) and then Edessa (943), advancing across the Euphrates into the caliph's territory. It was Curcuas who paved the way for the campaigns of the two soldier-emperors of the next generation. In 961 Nicephorus Phocas, then domestic (commander) of the armies in the West, reconquered Crete and destroyed the Arab fleet that had terrorized the Aegean for 150 years; he thereby restored Byzantine naval supremacy in the eastern Mediterranean. In 962 his strategy achieved unexpected triumphs all along the eastern frontier and culminated in the capture of Aleppo in Syria. When he was proclaimed emperor in March 963 Nicephorus appointed another Armenian general, John Tzimisces, as domestic of the East, though he retained personal command of operations against the Arabs. By 965 he had driven them out of Cyprus and was poised for the reconquest of Syria. The revived morale and confidence of Byzantium in the East showed itself in the crusading zeal of Nicephorus Phocas and John Tzimisces for the reconquest of Syria and the Holy Land. The ground lost to Islām in the 7th century was thus fast being regained; and although Jerusalem was never reached, the important Christian city of Antioch, seat of one of the patriarchs, was recaptured in 969. These victories were achieved largely by the new cavalry force built up by Nicephorus Phocas. In the areas recovered from the Arabs, land was distributed in military holdings with the interests of the cavalry in mind. But the victories were achieved at the expense of the western provinces, and an attempt to recover Sicily ended in failure in 965.

The campaigns of John Tzimisces, who usurped the throne in 969, were directed against the Emir of Mosul on the Tigris and against the new Fāṭimid Caliph of Egypt, who had designs on Syria. By 975 almost all of Syria and Palestine, from Caesarea to Antioch, as well as a large part of Mesopotamia far to the east of the Euphrates, was in Byzantine control. The way seemed open for Tzimisces to advance to the ʿAbbāsid capital of Baghdad on the one hand and to Jerusalem and Egypt on the other. But he died in 976 and his successor, Basil II, the legitimate heir of the Macedonian house, concentrated most of his resources on overcoming the Bulgars in Europe, though he did not abandon the idea of further reconquest in the East. The Kingdom of Georgia (Iberia) was incorporated in the empire by treaty. Part of Armenia was annexed, with the rest of it to pass to Byzantium on the death of its king. Basil II personally led two punitive expeditions against the Fāṭimids in Syria, but otherwise his eastern policy was to hold and to consolidate what had already been gained. The gains can be measured by the number of new themes (provinces) created by the early 11th century in the area between Vaspurakan in the Caucasus and Antioch in Syria. The annexation of Armenia, the homeland of many of the great Byzantine emperors and soldiers, helped to solidify the eastern wall of the Byzantine Empire for nearly a century.

Relations with the Slavs and Bulgars. Although imperial territory in the East could be reclaimed only by military conquest, in the Balkans and in Greece the work of reclamation could be assisted by the diplomatic weapon of evangelization. The Slavs and the Bulgars could be brought within the Byzantine orbit by conversion to Christianity. The conversion of the Slavs was instigated by the Patriarch Photius and carried out by the monks Cyril and Methodius from Thessalonica. Their invention of the Slavonic alphabet (Cyrillic and Glagolitic) made possible the translation of the Bible and the Greek liturgy, and brought literacy as well as the Christian faith to the Slavic peoples. The work began in the Slavic Kingdom of Moravia and spread to Serbia and Bulgaria. Latin missionaries resented what they considered to be Byzantine interference among the northern Slavs, and there were repeated clashes of interest that further damaged relations between the sees of Rome and Constantinople. The conversion of the Bulgars became a competition between the two churches and was ably exploited by the Bulgar king Boris until, in 870, he opted for Orthodox Christianity on condition of having an archbishop of his own.

Conversion of the Slavs

Bulgarian wars. The trade with Constantinople that followed the missionaries whetted the appetites of the Slavs and Bulgars for a larger share in the material wealth of Byzantium. Symeon of Bulgaria, who succeeded his father Boris in 893 and who had been educated at Constantinople, proved to be an even more dangerous enemy than the Arabs. His efforts to become emperor dominated Byzantine history for some 15 years. In 913 he brought his army to the walls of Constantinople, demanding the imperial title. The patriarch, Nicholas Mysticus, appeased Symeon for a time, but it was Romanus Lecapenus who, by patience and diplomacy, undermined the power of the Bulgars and thwarted Symeon's ambitions. Symeon died in 927, and his son Peter came to terms with Byzantium and married a granddaughter of Romanus.

Relations with Russia. The Russians lay far outside the Roman jurisdiction. Their warships, sailing down the Dnepr from Kiev to the Black Sea, first attacked Constantinople in 860. They were beaten off, and almost at once Byzantine missionaries were sent into Russia. The Russians had been granted trading rights in Constantinople in 911. But in 941 and 944, led by Prince Igor, they returned to the attack. Both assaults were repelled and Romanus I set about breaking down the hostility and isolationism of the Russians by diplomatic and commercial contacts. In 957 Igor's widow Olga was baptized and paid a state visit to Constantinople during the reign of Constantine VII; her influence enabled Byzantine missionaries to work with greater security in Russia, thus spreading Christianity and Byzantine culture. Olga's son Svyatoslav was pleased to serve the empire as an ally against the Bulgars in 968–969, though his ambition to occupy Bulgaria led to war with Byzantium in which he was defeated and killed. In 971 John Tzimisces accomplished the double feat of humiliating the Russians and reducing Bulgaria to the status of a client kingdom. Byzantine influence over Russia reached its climax when Vladimir of Kiev, who had helped Basil II to gain his throne, received as his reward the hand of the Emperor's sister in marriage and was baptized in 989. The mass conversion of the Russian people followed, with the establishment of an official Russian Church subordinate to the patriarch of Constantinople.

Bulgar revolt. The Bulgars, however, were not content to be vassals of Byzantium and rebelled under Samuel, youngest of the four sons of a provincial governor in Macedonia. Samuel made his capital at Ochrida and created a Bulgarian empire stretching from the Adriatic to the Black Sea and even, for a while, into Greece, though Thessalonica remained Byzantine. The final settlement of the Bulgar problem was worked out by Basil II in a ruthless and methodical military campaign lasting for some 20 years, until, by 1018, the last resistance was crushed. Samuel's dominions became an integral part of the Byzantine Empire and were divided into three new themes. At the same time the Slav principalities of Serbia (Rascia and Dioclea) and Croatia became vassal states of Byzantium, and the Adriatic port of Dyrrhachium came under Byzantine control. Not since the days of Justinian had the empire covered so much European territory. But the annexation of Bulgaria meant that the Danube was now the only line of defense against the more northerly tribes, such as the Pechenegs, Cumans, and Magyars.

Bulgars crushed by Basil II

Estrangement from the West. The extension of Byzantine interests to the Adriatic, furthermore, had raised again the question of Byzantine claims to South Italy and, indeed, to the whole western part of the old Roman Empire. The physical separation of that empire into East and West had been emphasized by the settlement of the

Slavs in the Balkan Peninsula and in Greece, and since the 7th century the two worlds had developed in their different ways. Their differences had been manifested in ecclesiastical conflicts, such as the Photian Schism. The conversion of the Slavs had produced bitterness between the agents of the rival jurisdictions. But the re-establishment of Byzantine authority in Greece and eastern Europe, added to the gains against the Muslim powers in Asia, reinforced the Byzantine belief in the universality of the empire, to which Italy and the West must surely be reunited in time. Until that time came, the fiction was maintained that the rulers of western Europe, like those of the Slavs, held their authority by virtue of their special relationship with the one true emperor in Constantinople.

Holy Roman Empire founded in the West

It was sometimes suggested that a marriage alliance might bring together the Eastern and Western parts of the empire and so provide for a united defense against the common enemy in Sicily—the Arabs. In 944 Romanus II, son of Constantine VII, married a daughter of Hugh of Provence, the Carolingian claimant to Italy. Constantine VII also kept up diplomatic contact with Otto I, the Saxon king of Germany. But the case was dramatically altered when Otto was crowned emperor of the Romans in 962, for this was a direct affront to the unique position of the Byzantine emperor. Otto tried, and failed, to establish his claim, either by force in the Byzantine province in Italy or by negotiation in Constantinople. His ambassador Liudprand of Cremona wrote an account of his mission to Nicephorus Phocas in 968 and of the Emperor's scornful rejection of a proposed marriage between Otto's son and a Byzantine princess. The incident vividly demonstrates the superior attitude of the Byzantines toward the West in the 10th century. John Tzimisces relented to the extent of arranging for one of his own relatives to marry Otto II in 972, though the arrangement implied no recognition of a Western claim to the empire. Basil II agreed that Otto III also should marry a Byzantine princess. But this union was never achieved; and subsequently Basil reorganized the administration of Byzantine Italy and was preparing another campaign against the Arabs in Sicily at the time of his death in 1025. The myth of the universal Roman Empire died hard.

Culture and administration. The Iconoclastic Controversy had aggravated the estrangement of the Byzantine Church and Empire from the West. But it helped to define the tenets of Orthodoxy; and it had an effect on the character of Byzantine society for the future. On the one hand, the church acquired a new unity and vitality: its missionaries spread the Orthodox faith in new quarters of the world, its monasteries proliferated, and its spiritual tradition was carried forward by the sermons and writings of the Patriarch Photius in the 9th century and of Symeon the New Theologian in the 10th and 11th centuries. On the other hand, the empire became more aware of its Greco-Roman heritage. Interest in classical Greek scholarship revived following the re-organization of the University of Constantinople under Michael III. The revival was fostered and patronized particularly by the scholar-emperor Constantine VII Porphyrogenitus, who saw to the compilation of three great works on the administration, the court ceremonies, and the provinces of his empire. He also commissioned a history of the age to which he contributed a biography of his grandfather Basil I. The age produced little original research, but lexicons (such as the 10th-century *Suda*), anthologies, encyclopaedias, and commentaries (such as the *Lexicon* and *Bibliotheca* of Photius) were produced in great number. The soldier-emperors of the 10th century were less interested in intellectual pursuits, but scholarship received a new impetus in the 11th century with Michael Psellus.

The founder of the dynasty, Basil I, and his son Leo VI, made plain their intention to inaugurate a new era by a restatement of the imperial law. Basil hoped to make a complete revision of the legal code, but only a preliminary textbook (*Procheiron*) with an introduction (*Epanagoge*) appeared during his reign. Leo VI, however, accomplished the work with the publication of the 60 books of the *Basilica*, which Hellenized the legal code of Justinian and made it more intelligible and accessible to lawyers. Additions and corrections to meet the needs of the time were incorporated in Leo's 113 *Novels*, which represent the last substantial reform of the civil law in Byzantium. Enshrined in this legislation was the principle of the absolute autocracy of the emperor as being himself the law. The Senate, the last vestige of Roman republican institutions, was abolished. Only in the matter of the spiritual welfare of his subjects did the emperor recognize any limits to his authority. The ideal relationship of a dyarchy between emperor and patriarch, the body and the soul of the empire, was written into the *Epanagoge* of Basil I, in a section probably composed by Photius.

Growth of bureaucracy

The administration in this period was ever more closely centralized in Constantinople, with an increasingly complex and numerous bureaucracy of officials who received their appointments and their salaries from the emperor. The emperor also controlled the elaborate machinery of the foreign and diplomatic service. Some of his civil servants, however, were powerful enough to play the part of kingmakers, notably Basil, the chamberlain who engineered the ascent to the throne of Nicephorus Phocas and John Tzimisces. Order and the regulation of trade, commerce, and industry in the capital were in the hands of the Prefect of the City, whose functions are outlined in the 9th-century *Book of the Eparch*. He was responsible for organizing and controlling the guilds or colleges of craftsmen and retailers, whose legal rights and duties to the state were strictly circumscribed and supervised. The provinces in Europe and Asia were administered according to their territorial division into themes, which, by the 10th century, numbered over 30. The themes, though subdivided and reduced in size, retained their military character. Their governors, or *stratēgoi*, combined military and civil authority and were directly answerable to the emperor, who appointed them. The army and the navy were, for the most part, recruited from the ranks of soldier-farmers who held hereditary grants of land within the territory of each theme. The border districts were protected by contingents of frontier troops, led by their own officers or lords of the marches. Their exploits and adventures were romanticized in the 10th-century folk-epic of *Digenis Akritas*. But warfare was studied and perfected as a science, and it was the subject of treatises such as the *Tactica* of Leo VI, derived from the *Strategicon* of the emperor Maurice.

Social and economic change. The wars of reconquest on the eastern frontier in this period and the general military orientation of imperial policy brought to the fore a new class of aristocracy, whose wealth and power was based on land ownership and who held most of the higher military posts. Trade and industry in the cities were so rigidly controlled by the government that almost the only profitable form of investment for private enterprise was the acquisition of landed property. The military aristocracy, therefore, took to buying up the farms of free peasants and soldiers and reducing their owners to varying forms of dependence. As the empire grew stronger, the rich became richer. Given the system of agriculture prevailing in Anatolia and the Balkans, every failure of crops, every famine, drought, or plague produced a quota of destitute peasant-soldiers willing to turn themselves and their land over to the protection of a prosperous and ambitious landlord. The first emperor to see the danger in this development was Romanus I Lecapenus, who, in 922 and 934, passed laws to defend the small landowners against the acquisitive instincts of the "powerful"; for he realized that the economic as well as the military strength of the empire depended on the maintenance within the theme system of the institution of free, yet tax-paying, soldier-farmers and peasants in village communities. (Only freemen owed military service.)

Growth of landholding aristocracy

Successive emperors after Romanus I enforced and extended his agrarian legislation. But the cost of the campaigns of reconquest from the Arabs had to be met by higher taxation, which drove many of the poorer peasants to sell their lands and to seek security as tenant-farmers. Nicephorus Phocas, who belonged to one of the

aristocratic landowning families of Anatolia, was naturally reluctant to act against members of his own class, though he adhered to the principle that the rights of the poor should be safeguarded. His laws about land tenure were particularly directed towards the creation of a more mobile force of heavy-armed cavalry recruited from those who could afford the equipment, which inevitably brought changes in the social structure of the peasant militia. On the other hand, Nicephorus took a firm line to prevent the accumulation of further land by the church, and he forbade any addition to the number of monasteries, whose estates, already extensive, were unproductive to the economy.

The last emperor to attempt to deal with the problem of land ownership seriously was Basil II, whose rise to the throne had involved the empire in a bitter and costly war against the aristocratic Sclerus and Phocas families. In 996 Basil promulgated comprehensive punitive legislation against the landed families, ordering the restitution of land acquired from the peasantry since 922 and requiring proof of title to other land going back in some cases as far as 1,000 years. Further, the system of collective responsibility for the payment of outstanding taxes known as the *allelengyon* now devolved not on the rest of the village community but on the nearest large landowner, whether lay or ecclesiastical. Basil's conquest of Bulgaria somewhat altered the social and economic pattern of the empire, for new themes were created there in which there was no long tradition of a landed aristocracy as in Anatolia. After his death in 1025 the powerful hit back, and the government in Constantinople was no longer able to check the absorption of small freeholders by the great landowners and the consequent feudalization of the empire.

This process was particularly disastrous for the military establishment. The success and prestige of the Byzantine Empire in the Macedonian era to a large extent depended on the unrivalled efficiency of its army in Anatolia. A professional force, yet mainly native to the soil and so directly concerned with the defense of that soil, it had no equal in the Western or the Arab world at the time. And yet it was in this institution that the seeds of decay and disintegration took root; for most of the army's commanders were drawn from the great landowners of Anatolia, who had acquired their riches and their status by undermining the social and economic structure on which its recruitment depended. Basil II had restrained them with such an iron hand that a reaction was inevitable after his death. Indeed, it is doubtful if Byzantine society could have tolerated another Basil II, for all his triumphs. Soured by long years of civil war at the start of his reign, ascetic and uncultured by nature, Basil embodied the least attractive features of Byzantine autocracy. Some have called him the greatest of all the emperors. But the virtue of philanthropy, which the Byzantines prized and commended in their rulers, was not a part of his greatness; and the qualities that lent refinement to the Byzantine character, among them a love of learning and the arts, were not fostered during his reign. Yet, while Basil was busily earning his title of Bulgaroctonus (Bulgar Slayer), St. Symeon the New Theologian was exploring the love of God for man in some of the most poetic homilies in all mystical literature.

BYZANTINE DECLINE AND SUBJECTION TO WESTERN INFLUENCES: 1025–1260

Basil II never married. But after his death his relatives remained in possession of the throne until 1056, less because of their efficiency than because of a general feeling among the Byzantine people that the prosperity of the empire was connected with the continuity of the Macedonian dynasty. When Basil's brother Constantine VIII died in 1028, the line was continued in his two daughters, Zoe and Theodora. Zoe was married three times: to Romanus III Argyrus (ruled 1028–34), to Michael IV (1034–41), and to Constantine IX Monomachus (1042–55), who outlived her. When Constantine IX died in 1055, Zoe's sister Theodora reigned alone as empress until her death a year later.

The later Macedonians

The great emperors of the golden age, not all of them members of the Macedonian family, molded the history of that age. The successors of Basil II were rather the creatures of circumstances in that they did not make and seldom molded. In the 56 years from 1025 to 1081, there were 13 emperors. An attempt made by Constantine X Ducas to found a new dynasty was disastrously unsuccessful. Not until the rise of Alexius I Comnenus to power, in 1081, was stability restored by an ensured succession in the Comnenus family, who ruled for over 100 years (1081–1185).

11th-century weakness. The state of the Byzantine Empire in the 11th century may be compared to that of the Roman Empire in the 3rd century, when, after a long period of secure prosperity, new pressures from beyond the frontiers aggravated the latent tensions in society. The brief reigns of Basil II's heirs reflected, and were often the product of, a division in the Byzantine ruling class, a conflict between the military aristocracy of the provinces and the civilian aristocracy, or bureaucracy, of Constantinople. Each faction put up rival emperors. The sophisticated urban aristocracy favoured rulers who would reverse the militaristic trend of the empire, and

The Byzantine Empire in 1025.

who would expand the civil service and supply them and their families with lucrative offices and decorative titles. The military families, whose wealth lay not in the capital but in the provinces, and who had been penalized by Basil II's legislation, favoured emperors who were soldiers and not civil servants. In this they were more realistic, for in the latter part of the 11th century it became ever clearer that the empire's military strength was no longer sufficient to hold back its enemies. The landowners in the provinces appreciated the dangers more readily than the government in Constantinople, and they made those dangers an excuse to enlarge their estates in defiance of all the laws passed in the 10th century. The theme system in Anatolia, which had been the basis of the empire's defensive and offensive power, was rapidly breaking down at the very moment when its new enemies were gathering their strength.

On the other hand, the urban aristocracy of Constantinople, reacting against the brutalization of war, strove to make the city a centre of culture and sophistication. The university was endowed with a new charter by Constantine IX in 1045, partly to ensure a steady flow of educated civil servants for the bureaucracy. The law school was revived under the jurist John Xiphilinus; the school of philosophy was chaired by Michael Psellus, whose researches into every field of knowledge earned him a reputation for omniscience and a great following of brilliant pupils. Psellus—courtier, statesman, philosopher, and historian—is in himself an advertisement for the liveliness of Byzantine society in the 11th century. What he and others like him failed to take into account was that their empire was more and more expending the resources and living on the reputation built up by the Macedonian emperors.

Arrival of new enemies. The new enemies that emerged in the 11th century, unlike the Arabs or the Bulgars, had no cause to respect that reputation. They appeared almost simultaneously on the northern, the eastern, and the western frontiers. It was nothing new for the Byzantines to have to fight on two fronts at once. But the task required a soldier on the throne. The Pechenegs, a Turkic tribe, had long been known as the northern neighbours of the Bulgars. Constantine VII had thought them to be valuable allies against the Bulgars, Magyars, and Russians. But after the conquest of Bulgaria, the Pechenegs began to raid across the Danube into what was now Byzantine territory. Constantine IX allowed them to settle south of the river, where their numbers and their ambitions increased. By the mid-11th century they were a constant menace to the peace in Thrace and Macedonia, and they encouraged the spirit of revolt among the Bogomil heretics in Bulgaria. It was left to Alexius I to avert a crisis by defeating the Pechenegs in battle in 1091.

Seljuq Turks in the East

The new arrivals on the eastern frontier were the Seljuq Turks, whose conquests were to change the whole shape of the Muslim and Byzantine worlds. In 1055, having conquered Persia, they entered Baghdad, and their prince assumed the title of sultan and protector of the ʿAbbāsid caliphate. Before long they asserted their authority to the borders of Fāṭimid Egypt and Byzantine Anatolia. They made their first explorations across the Byzantine frontier into Armenia in 1065 and, in 1067, as far west as Caesarea in central Anatolia. The raiders were inspired by the Muslim idea of holy war, and there was at first nothing systematic about their invasion. They found it surprisingly easy, however, to plunder the countryside and isolate the cities, owing to the long neglect of the eastern frontier defenses by the emperors in Constantinople. The emergency lent weight to the military aristocracy in Anatolia who, in 1068, finally secured the election of one of their own number, Romanus IV Diogenes, as emperor. Romanus assembled an army to deal with what he saw as a large-scale military operation. It was a sign of the times that it was mainly composed of foreign mercenaries.

Battle of Manzikert

In August 1071 it was defeated at Manzikert, near Lake Van in Armenia. Romanus was taken prisoner by the Seljuq sultan, Alp Arslan. He was allowed to buy his freedom after signing a treaty, but the opposition in Constantinople refused to have him back as emperor and installed their own candidate, Michael VII. Romanus was treacherously blinded. The Seljuqs were thus justified in continuing their raids and were even encouraged to do so. Michael VII invited Alp Arslan to help him against his rivals, Nicephorus Bryennius and Nicephorus Botaneiates, each of whom proclaimed himself emperor at Adrianople in 1077 and at Nicaea in 1078. In the four years of ensuing civil war there were no troops to defend the eastern frontier. By 1081 the Turks had reached Nicaea. The heart of the empire's military and economic strength, which the Arabs had never mastered, was now under Turkish rule.

The new enemies in the West were the Normans, who began their conquest of South Italy early in the 11th century. Basil II's project of recovering Sicily from the Arabs had been almost realized in 1042 by the one great general of the post-Macedonian era, George Maniaces, who was recalled by Constantine IX and killed as a pretender to the throne. The Normans thereafter made steady progress in Italy. Led by Robert Guiscard, they carried all before them; in April 1071, Bari, the last remaining Byzantine stronghold, fell after a three-year siege. Byzantine rule in Italy and the hope of a reconquest of Sicily were at an end.

The disasters at Manzikert and at Bari, at opposite extremes of the empire, in the same year 1071, graphically illustrate the decline of Byzantine power. The final loss of Italy seemed to underline the fact of the permanent division between the Greek East and the Latin West, which was now not only geographical and political but also increasingly cultural and ecclesiastical. In 1054 a state of schism had been declared between the churches of Rome and Constantinople. The political context of the event was the Norman invasion of Italy, which at the time was a matter of as much concern to the papacy as it was to Byzantium. But the event itself, the excommunication of the patriarch Michael Cerularius by Cardinal Humbert in Constantinople, symbolized an irreconcilable difference in ideology. The reform movement in the Roman Church had emphasized an ideal of the universal role of the papacy that was wholly incompatible with Byzantine tradition. Both sides also deliberately aggravated their differences by reviving all the disputed points of theology and ritual that had become battle cries during the Photian Schism in the 9th century. The schism of 1054 passed unnoticed by contemporary Byzantine historians; its significance as a turning point in East–West relations was fully realized only later.

Schism between churches

Alexius I and the First Crusade. But even the events of 1071 had not made the decline of Byzantium irretrievable. The shrinking of its boundaries reduced the empire from its status as a dominating world power to that of a small Greek state fighting for survival. That survival now depended on the new political, commercial, and ecclesiastical forces in the West, for it could no longer draw on its former military and economic resources in Anatolia. The civil aristocracy of Constantinople yielded with a bad grace. After four years of civil war, the military lords triumphed with the accession of Alexius I Comnenus, the greatest soldier and statesman to hold the throne since Basil II. The history of his reign was written in elegant Greek by his daughter Anna Comnena; and, as she remarks, it began with an empire beset by enemies on all sides. The Normans captured Dyrrhachium in 1081 and planned to advance overland to Thessalonica. Alexius called on the Venetians to help him, but Robert Guiscard's death in 1085 temporarily eased the Norman problem. The following year the Seljuq sultan died, and the sultanate was split by internal rivalries. Fortune thus played into Alexius's hands by ridding him of two of his besetting enemies. By his own efforts, however, he defeated the Pechenegs in 1091.

The Venetians had been pleased to help drive the Normans out of the Adriatic Sea but demanded a heavy price. In 1082 Alexius granted them trading privileges in Constantinople and elsewhere on terms calculated to outbid Byzantine merchants. This charter was the cornerstone of the commercial empire of Venice in the

eastern Mediterranean. But it fed the flames of Byzantine resentment against the Latins; and it provoked the rich, who might have been encouraged to invest their capital in shipbuilding and trade, to rely on the more familiar security of landed property.

The terms that Alexius made with his enemies in the first ten years of his reign were not meant to be permanent. He fully expected to win back Anatolia from the Seljuqs; his plans, however, were not given time to mature, for matters were precipitated by the arrival in the East of the first Crusaders from western Europe (1096). Alexius had undoubtedly solicited the help of mercenary troops from the West but not for the liberation of the Holy Land from the infidel. The urgent need was the protection of Constantinople and the recovery of Anatolia. The Byzantines were more realistic about their Muslim neighbours than the distant popes and princes of the West. Jerusalem had finally been taken by the Seljuqs in 1077, but the most immediate threat to Byzantium came from the Pechenegs and the Normans. Alexius was tactful in his dealings with the pope and ready to discuss the differences between the churches.

Involvement in the First Crusade

But neither party foresaw the consequences of Pope Urban II's appeal in 1095 for recruits to fight a Holy War. The response in western Europe was overwhelming. The motives of those who took the cross as crusaders ranged from religious enthusiasm to a mere spirit of adventure or a hope of gain; and it was no comfort to Alexius to learn that four of the eight leaders of the First Crusade were Normans, among them Bohomund, the son of Robert Guiscard. Since the crusade had to pass through Constantinople, however, the emperor had some control over it. He required its leaders to swear to restore to the empire any towns or territories they might conquer from the Turks on their way to the Holy Land. In return, he gave them guides and a military escort. Still, the cost was enormous, for the crusaders had to be supplied with food or live off the land as they went.

Nicaea fell to them in 1097 and was duly handed over to the emperor in accord with the agreement. In 1098 they reached, and captured, Antioch. Here the trouble started. Bohomund refused to turn over the city and instead set up his own principality of Antioch. His example was imitated in the establishment of the Latin Kingdom of Jerusalem, which fell to the crusaders in 1099, and of the counties of Edessa and Tripoli. The crusaders settled down to colonize and defend the coast of Palestine and Syria and to quarrel among themselves. While they did so, Alexius was able to establish a new and more secure boundary between Byzantium and Islām through the middle of Anatolia. Full advantage was taken of the prevailing rivalry between the Seljuq sultans at Konya and the Dānishmends emirs at Melitene; and a limit was set to the westward expansion of the Turks.

The First Crusade thus brought some benefits to Byzantium. But nothing could reconcile the emperor to Bohomund of Antioch. In 1107 Bohomund, who had returned to the West, mounted a new invasion of the empire from Italy. Alexius was ready for him and defeated him at Dyrrhachium in 1108. Byzantine prestige was higher than it had been for many years, but the empire could barely afford to sustain the part of a great power. Alexius reconstituted the army and re-created the fleet, but only by means of stabilizing the gold coinage at one-third of its original value and by imposing a number of supplementary taxes. It became normal practice for taxes to be farmed out, which meant that the collectors recouped their outlay on their own terms. People in the provinces had the added burden of providing materials and labour for defense, communications, and provisions for the army, which now included very large numbers of foreigners. The supply of native soldiers had virtually ceased with the disappearance or absorption of their military holdings. But Alexius promoted an alternative source of native manpower by extending the system of granting estates in *pronoia* (by favour of the emperor), and tying the grant to the military obligation. The recipient of a *pronoia* was entitled to all the revenues of his estate and to the taxes payable by his tenants (*paroikoi*), on condition of equipping himself as a mounted cavalryman with a varying number of troops. He was in absolute possession of his property until it reverted to the crown upon his death. Similarly, Alexius tried to promote more profitable development of the estates of the church by granting them to the management of laymen as *charisticia* or benefices. As an expedient, the *pronoia* system had obvious advantages both for the state and for the military aristocracy who were its main beneficiaries. But in the long term it inevitably hastened the fragmentation of the empire among the landed families and the breakdown of centralized government that the 10th-century emperors had laboured to avert.

The *pronoia* system

Later Comneni. The domestic and foreign policies of Alexius I were continued by his son John II (reigned 1118–43) and his grandson Manuel I Comnenus (reigned 1143–80). The 12th century saw a growing involvement of the Western powers in the affairs of the East, as well as an increasingly complex political situation in Europe. In Asia, too, matters were complicated by the continuing conflict between the Seljuqs and the Dānishmends (a rival Turkish dynasty) by the emergence of the kingdom of Lesser Armenia in Cilicia, and by the activities of the crusader states. Foreign relations and skillful diplomacy became of paramount importance for the Byzantines. John II tried and failed to break what was fast becoming the Venetian monopoly of Byzantine trade, and he sought to come to terms with the new kingdom of Hungary, to whose ruler he was related by marriage. Alexius I had seen the importance of Hungary, lying between the Western and Byzantine empires, a neighbour of the Venetians and the Serbs. More ominous still was the establishment of the Norman Kingdom of the Two Sicilies under Roger II in 1130. But John II astutely allied himself with the Western emperor against it.

Manuel I realized even more clearly that Byzantium could not presume to ignore or offend the new powers in the West, and he went out of his way to understand and to appease them. Certain aspects of the Western way of life appealed to Manuel. His first and second wives were both Westerners, and Latins were welcomed at his court and even granted estates and official appointments. This policy was distasteful to most of his subjects; and it was unfortunate for his intentions that the Second Crusade occurred early in his reign (1147), for it aggravated the bitterness between Greeks and Latins and brought Byzantium deeper than ever into the tangled politics of western Europe. Its leaders were Louis VII of France and the emperor Conrad III, and its failure was blamed on Byzantine treachery. The French king discussed with Roger of Sicily the prospect of attacking Constantinople; and in 1147 Roger invaded Greece. But Manuel retained the personal friendship and the alliance of Conrad III against the Normans and even planned a joint Byzantine-German campaign against them in Italy.

Appeasement of the West

No such cooperation was possible with Conrad's successor, Frederick I Barbarossa, after 1152. To Frederick, the alliance between the Holy Roman Empire and what he called "the kingdom of the Greeks" was not one between equals. Manuel launched a vain invasion of the Norman kingdom on his own account in 1154; but it was too late for a revival of Byzantine imperialism in the West. It was hard for the Byzantines to accept the fact that their empire might soon become simply one among a number of Christian principalities.

In the Balkans and in the Latin East Manuel was more successful. His armies won back much of the northwest Balkans and almost conquered Hungary, reducing it to a client kingdom of Byzantium. The Serbs, too, under their leader Stephen Nemanja, were kept under control, while Manuel's dramatic recovery of Antioch in 1159 caused the crusaders to treat the Emperor with a new respect. But in Anatolia he overreached himself. To forestall the formation of a single Turkish sultanate, Manuel invaded the Seljuq territory of Rūm in 1176. His army was surrounded and annihilated at Myriocephalon. The battle marked the end of the Byzantine counteroffensive against the Turks begun by Alexius I. Its outcome delighted the Western emperor, Frederick Barbarossa, who had sup-

ported the Seljuq sultan of Rūm against Manuel and who now openly threatened to take over the Byzantine Empire by force.

Manuel's personal relationships with the crusaders and with other Westerners remained cordial to the end. But his policies had antagonized the Holy Roman Empire, the papacy, the Normans, and, not least, the Venetians. His effort to revive Byzantine prestige in Italy and the Balkans, and his treaties with Genoa (1169) and Pisa (1170), roused the suspicions of Venice; and in 1171, following an anti-Latin demonstration in Constantinople, all Venetians in the empire were arrested and their property was confiscated. The Venetians did not forget this episode. They, too, began to think in terms of putting Constantinople under Western control as the only means of securing their interest in Byzantine trade.

Manuel's policies antagonized many of his own people as well. His favouritism to the Latins was unpopular, as was his lavish granting of estates in *pronoia*. A reaction set in shortly after his death in 1180, originated by his cousin Andronicus Comnenus, who ascended to the throne after another anti-Latin riot in Constantinople. Andronicus murdered Manuel's widow and son Alexius II. He posed as the champion of Byzantine patriotism and of the oppressed peasantry. But to enforce his reforms he behaved like a tyrant. By undermining the power of the aristocracy he weakened the empire's defenses and undid much of Manuel's work. The King of Hungary broke his treaty; Stephen Nemanja of Serbia declared his independence from Byzantium and founded a new Serbian kingdom. Within the empire, too, disintegration proceeded. In 1185 Isaac Comnenus, governor of Cyprus, set himself up as independent ruler of the island. In the same year the Normans again invaded Greece and captured Thessalonica. The news prompted a counter-revolution in Constantinople and Andronicus was murdered.

He was the last of the Comnenian family to wear the crown. His successor Isaac II Angelus was brought to power by the aristocracy. His reign, and, still more, that of his brother Alexius III, saw the collapse of what remained of the centralized machinery of Byzantine government and defense. Isaac tried at least to keep his foreign enemies in check. The Normans were driven out of Greece in 1185. But in 1186 the Bulgars began a rebellion that was to lead to the formation of the Second Bulgarian Empire. Matters were not made easier by the arrival of the Third Crusade, provoked by the loss of Jerusalem to the Muslim leader Saladin in 1187. One of its leaders was Frederick Barbarossa, whose avowed intention was to conquer Constantinople. He died on his way to Syria. But Richard I the Lion-Heart of England appropriated Cyprus from Isaac Comnenus, and the island never again reverted to Byzantine rule.

The Fourth Crusade and the establishment of the Latin Empire. In 1195 Isaac II was deposed and blinded by his brother Alexius III. The Westerners, who had again blamed the failure of their crusade on the Byzantines, saw ways of exploiting the situation. The emperor Henry VI had united the Norman kingdom of Sicily with the Holy Roman Empire. He inherited the ambitions of both to master Constantinople, and his brother, Philip of Swabia, was married to a daughter of the dethroned Isaac II. Alexius bought off the danger by paying tribute to Henry. But Henry died in 1197. The idea had now gained ground in the West that the conquest of Constantinople would solve a number of problems and would be of benefit not only to trade but also to the future of the crusade and the church. In 1198 Innocent III was elected pope. The new rulers of Hungary, Serbia, and Bulgaria all turned to him for the recognition of the sovereignty that Byzantium would not give them.

Conquest and colonization by the West

It was under Innocent's inspiration that the Fourth Crusade was launched, and it was by the diversion of that crusade from its purpose and objective that the conquest and colonization of the Byzantine Empire by the West was realized. A multiplicity of causes and coincidences led up to the event; but the ambition of Venice, which supplied the ships, must rank high among them. A plausible excuse was offered by the cause of restoring Isaac II, whose son Alexius IV had escaped to the West to seek help, and who made lavish promises of reward to his benefactors. But when, in 1203, the crusaders drove Alexius III out of Constantinople, Isaac II and his son proved incapable either of fulfilling the promises or of stifling the anti-Latin prejudice of their people, who proclaimed an emperor of their own in the person of Alexius V. The Venetians and crusaders therefore felt justified in taking their own reward by conquering and dividing Constantinople and the Byzantine provinces among themselves. The city fell to them in April 1204. They worked off their resentment against the inhabitants in an unparalleled orgy of looting and destruction, which did irreparable damage to the city and immeasurable harm to East–West understanding.

The Venetians, led by their doge, Enrico Dandolo, gained most from the enterprise by appropriating the principal harbours and islands on the trade routes. The crusaders set about the conquest of the European and Asiatic provinces. The first Latin emperor, Baldwin I, was the suzerain of the feudal principalities that they established in Thrace, Thessalonica, Athens, and the Morea (Peloponnese). He soon came into conflict with the ruler of Bulgaria. Still more serious was the opposition offered by the three provincial centres of Byzantine resistance. At Trebizond (Trabzon) on the Black Sea, two brothers of the Comnenian family laid claim to the imperial title. In Epirus in northwestern Greece Michael Angelus Ducas, a relative of Alexius III, made his capital at Arta and harrassed the crusader states in Thessaly. The third centre of resistance was based on the city of Nicaea in Anatolia, where Theodore I Lascaris, another relative of Alexius III, was crowned as emperor by a patriarch of his own making in 1208. Of the three, Nicaea lay nearest to Constantinople, between the Latin empire and the Seljuq sultanate of Rūm; and its emperors proved worthy of the Byzantine traditions of fighting on two fronts at once and of skillful diplomacy. Theodore Lascaris and his son-in-law John III Vatatzes built up at Nicaea a microcosm of the Byzantine Empire and church in exile. The Latins were thus never able to gain a permanent foothold in Anatolia; and even in Europe their position was constantly threatened by the Byzantine rulers of northern Greece, though in the centre and south of the country their conquests were more lasting.

The most successful of the Latin emperors was Baldwin's brother, Henry of Flanders, after whose death in 1216 the Latin empire lost the initiative and the recovery of Constantinople became a foreseeable goal for the Byzantines in exile. The Latin regime was prolonged less by its own vitality than by the inability of the successor states of Epirus and Nicaea to cooperate. In 1224 Theodore Ducas of Epirus, who had extended his territories across the north of Greece and far into Bulgaria, wrested Thessalonica from the Latins and was crowned emperor there in defiance of the Emperor in Nicaea. In 1230, however, he was defeated in battle against the Bulgars before reaching Constantinople; and his defeat gave John Vatatzes the chance to extend his own empire into Europe, to ally with the Bulgars, and so to encircle Constantinople. Theodore's successor was made to renounce his imperial title, and Thessalonica surrendered to the empire of Nicaea in 1246. The Mongol invasion of Anatolia, which had meanwhile thrown the East into confusion, was of great benefit to Nicaea, for it weakened the Seljuq sultanate and isolated the rival empire of Trebizond.

John Vatatzes might well have crowned his achievements by taking Constantinople had he not died in 1254. When his son Theodore II Lascaris (1254–58) died in 1258, leaving an infant son, John IV, the regency and then the throne in Nicaea were taken over by Michael VIII Palaeologus (reigned 1259–82). Michael came of one of the aristocratic families of Nicaea whom Theodore II had mistrusted. But it was he who carried the work of the Lascarid emperors to its logical conclusion. The Byzantine state in Epirus had revived under Michael II Ducas, who set his sights on Thessalonica. Despite several efforts to reach a diplomatic settlement, the issue between the rival contenders had finally to be resolved in

The accession of Michael Palaeologus

battle at Pelagonia in Macedonia in 1259. Michael II was supported by William of Villehardouin, the French prince of the Morea, and by Manfred, the Hohenstaufen king of Sicily. The victory went to the army of Nicaea. Two years later a general of that army entered Constantinople. The last of the Latin emperors, Baldwin II, fled to Italy; and the Venetians were dispossessed of their lucrative commercial centre. In August 1261 Michael VIII was crowned as emperor in Constantinople; the boy heir to the throne of Nicaea, John IV Lascaris, was blinded and imprisoned. In this way, the dynasty of Palaeologus, the last to reign in Constantinople, was inaugurated.

THE EMPIRE UNDER THE PALAEOLOGI: 1261–1453

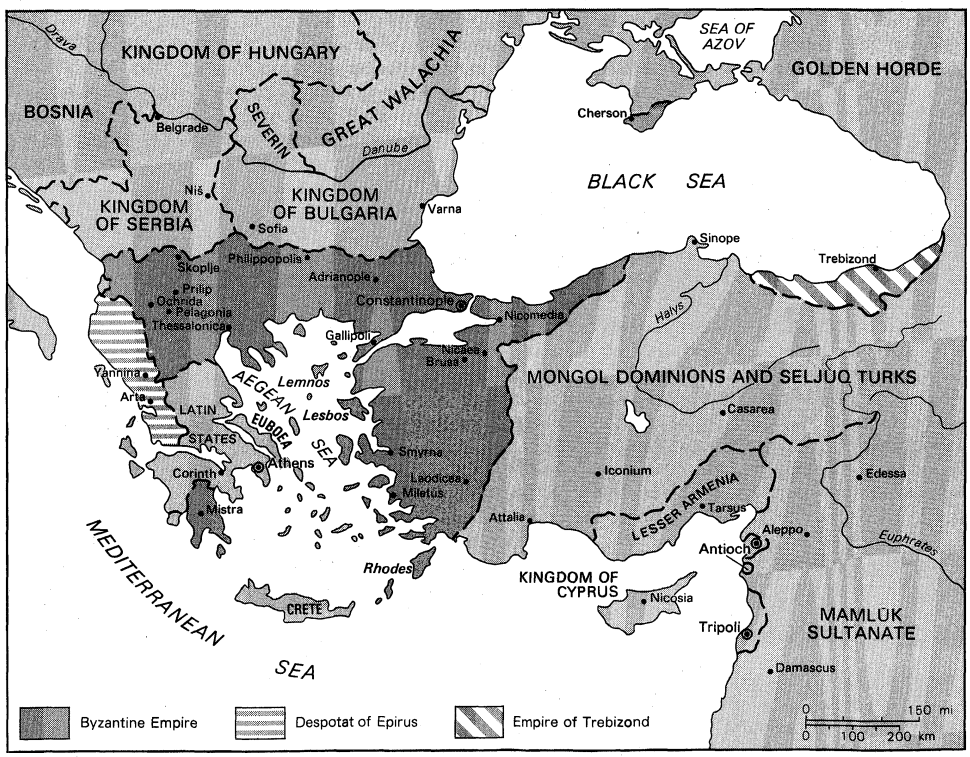
The empire in exile at Nicaea had become a manageable and almost self-sufficient unit, with a thriving economy based on agriculture and, latterly, on trade with the Seljuqs. It had no navy but the land frontiers in Anatolia, policed by well-paid troops, were stronger than they had been since the 12th century. By stretching the frontiers into Europe the empire had not dissipated its strength; for the possession of Thessalonica balanced that of Nicaea. When the seat of government was moved from Nicaea to Constantinople, that balance was upset, the economy was re-oriented, and the defense system in Anatolia began to break down. Constantinople was still the New Jerusalem for the Byzantines. To leave it in foreign hands was unthinkable. But after the dismemberment of the empire by the Fourth Crusade, the city was no longer the focal point of an integrated structure. It was more like an immense city-state in the midst of a number of more or less independent provinces. Much of Greece and the islands remained in French or Italian hands. The Byzantine rulers of Epirus and Thessaly, like the emperors in Trebizond, refused to recognize Michael VIII as emperor. His treatment of the Lascarid heir of Nicaea, for which the patriarch Arsenius excommunicated him, appalled many of his own subjects and provoked what was known as the Arsenite schism in the Byzantine Church. Many in Anatolia, loyal to the memory of the Lascarid emperors who had enriched and protected them, condemned Michael VIII as a usurper.

Michael VIII. The new dynasty was thus founded in an atmosphere of dissension. But its founder was determined that it should succeed. He took measures for the rehabilitation, repopulation, and defense of Constantinople. He stimulated a revival of trade by granting privileges to Italian merchants. The Genoese, who had agreed to lend him ships for the recovery of the city from their Venetian rivals, were especially favoured; and soon they had built their own commercial colony at Galata opposite Constantinople, and cornered most of what had long been a Venetian monopoly. Inevitably, this led to a conflict between Genoa and Venice, of which the Byzantines were the main victims. Some territory was taken back from the Latins, notably in the Morea and the Greek islands. But little was added to the imperial revenue; and Michael VIII's campaigns there and against Epirus and Thessaly ate up the resources that had been accumulated by the emperors at Nicaea.

Threat of reconquest by the West

The dominating influence on Byzantine policy for most of Michael's reign was the threat of reconquest by the Western powers. Charles of Anjou, the brother of the French king Louis IX, displaced Manfred of Sicily and inherited his title in 1266, organizing a coalition of all parties interested in re-establishing the Latin empire and posing as the pope's champion to lead a crusade against the schismatic Greeks. Michael VIII countered this threat by offering to submit the Church of Constantinople to the see of Rome, thereby inviting the pope's protection and removing the only moral pretext for a repetition of the Fourth Crusade. The offer to reunite the churches had been made as a diplomatic ploy to previous popes by previous emperors, but never in such compelling circumstances. Pope Gregory X accepted it at its face value; and at the second Council of Lyons in 1274 a Byzantine delegation professed obedience to the Holy See in the name of their emperor. Michael's policy, sincere or not, was violently opposed by most of his people; and he had to persecute and imprison large numbers of them in order to persuade the papacy that the union of the churches was being implemented. Later popes were not convinced by the pretense. In 1281 Charles of Anjou invaded the empire. His army was beaten back in Albania, but he at once prepared a new invasion by sea, supported by Venice, Serbia, Bulgaria, and the separatist rulers of northern Greece. His plans, however, were wrecked in 1282 by a rebellion in Sicily known as the Sicilian Ves-

From W. Shepherd, *Historical Atlas;* Barnes & Noble Books, New York



The remnants of the Byzantine Empire in 1265.

pers and by the intervention of Peter III of Aragon, which the Byzantines encouraged. Michael VIII died at the end of the same year. He had saved his empire from its most persistent enemy, but he died condemned by his church and people as a heretic and a traitor.

Neglect of Eastern defenses

Whatever sins he may have committed in the eyes of the Orthodox Church, it is true that Michael VIII, by concentrating on the danger from the West, neglected, if he did not betray, the eastern provinces where he had come to power. Frontier defense troops in Anatolia were withdrawn to Europe or neglected, and bands of Turkish raiders, driven westward by the upheaval of the Mongol invasion, began to penetrate into Byzantine territory. Like the Seljuqs in the 11th century, the new arrivals found little organized opposition. Some of the local Byzantines even collaborated with them out of their own antipathy to the emperor in Constantinople. By about 1280 the Turks were plundering the fertile valleys of western Anatolia, cutting communications between the Greek cities; and their emirs were beginning to carve out small principalities. Michael VIII's network of diplomacy covered the Mongols of Iran and of the Golden Horde in Russia, as well as the Mamlūks of Egypt. But diplomacy was ineffective against Muslim *ghāzīs* (warriors inspired by the ideal of holy war); by the time the threat from Italy was removed in 1282, it was almost too late to save Byzantine Anatolia, even by military measures.

Nor was it possible to raise armies to fight in Europe and Asia simultaneously. The native recruitment fostered by the Comnenian emperors had fallen off since 1261. Estates held in *pronoia* had now become hereditary possessions of their landlords, who ignored or were relieved of the obligation to render military service to the government. The knights of the Fourth Crusade had found many familiar elements of feudalism in the social structure of the Byzantine provinces. By the end of the 13th century the development had gone much further. The officers of the Byzantine army were still mostly drawn from the native aristocracy. But the troops were hired, and the cost of maintaining a large army in Europe, added to the lavish subsidies that Michael VIII paid to his friends and allies, crippled the economy.

Andronicus II. Michael's son Andronicus II (reigned 1282–1328) unwisely attempted to economize by cutting down the size of the army and disbanding the navy. Unemployed Byzantine sailors sold their services to the new Turkish emirs, who were already raiding the Aegean islands. The Genoese became the suppliers and defenders of Constantinople by sea, which excited the jealousy of the Venetians to the pitch of war and led to the first of a series of naval battles off Constantinople in 1296. In reaction against his father's policy, Andronicus II pursued a line of almost total isolation from the papacy and the West. The union of Lyons was solemnly repudiated and Orthodoxy restored, to the deep satisfaction of most Byzantines. But there were still divisive conflicts in society. The Arsenite schism in the church was not healed until 1310; the rulers of Epirus and Thessaly remained defiant and kept contact with the successors of Charles of Anjou in Italy; and the people of Anatolia aired their grievances in rebellion. As the Turks encroached on their land, refugees in growing numbers fled to the coast or to Constantinople, bringing new problems for the government.

Appearance of Ottoman Turks

In 1302 a band of Turkish warriors defeated the Byzantine army near Nicomedia in northwestern Anatolia. Its leader, Osman I, was the founder of the Osmanlı or Ottoman people, who were soon to overrun the Byzantine Empire in Europe. His activities were so far on a smaller scale than those of some of the other Turkish emirs. But Nicomedia was dangerously near to Constantinople.

In 1303 Andronicus hired a professional army of mercenaries, the Catalan Company, who had been fighting in Sicily. The Catalans made one successful counterattack against the Turks in Anatolia. But they were unruly and unpopular; and when their leader was murdered they turned against their employers. For some years they used the Gallipoli Peninsula as a base from which to ravage Thrace, inviting thousands of Turks to come over and help them. The Catalans finally moved west; in 1311 they conquered Athens from the French and established the Catalan Duchy of Athens and Thebes. The Turks whom they left behind were not ejected from Gallipoli until 1312. The cost of hiring the Catalans, and then of repairing the damage that they had done, had to be met by desperate measures. The face value of the Byzantine gold coin or *hyperpyron* was lowered when its gold content was reduced to a mere 50 percent; and the people had to bear still greater burdens of taxation—some extracted from the landlords of Macedonia and northern Thrace, some payable in kind by farmers. Inflation and rising prices led to near famine in Constantinople, the population of which was swollen by vast numbers of refugees. Unscrupulous merchants made great black-market profits.

Cultural revival. Materially, the empire seemed almost beyond hope of recovery in the early 14th century, but spiritually and culturally it showed a remarkable vitality. The church, no longer troubled over the question of union with Rome, grew in prestige and authority. The patriarchs of Constantinople commanded the respect of all the Orthodox Churches, even beyond the imperial boundaries; and Andronicus II, himself a pious theologian, yielded to the patriarch the ancient right of imperial jurisdiction over the monastic settlement on Mt. Athos, which prospered at a time when other centres of Byzantine monasticism were being occupied by the Turks.

Mysticism and scholarship

There was a new flowering of the Byzantine mystical tradition in a movement known as Hesychasm, whose chief spokesman was Gregory Palamas, a monk from Athos. The theology of the Hesychasts was thought to be heterodox by some theologians; and a controversy arose in the second quarter of the 14th century that had political undertones and was as disruptive to the church and state as the Iconoclastic dispute had been in an earlier age. It was not resolved until 1351.

The revival of mystical speculation and the monastic life may have been in part a reaction against the contemporary revival of secular literature and learning. Scholarship of all kinds was patronized by Andronicus II, whose court was likened to the Lyceum of antiquity. As in the 11th century, interest was mainly centred on a rediscovery of ancient Greek learning. The scholar Maximus Planudes compiled a famous anthology and translated a number of Latin works into Greek, though knowledge of Latin was rare and most of the Byzantine scholars prided themselves on having in their Hellenic heritage an exclusive possession that set them apart from the Latins. A notable exception was Demetrius Cydones who, like Michael Psellus, managed affairs of state for a number of emperors for close to 50 years. Cydones translated the works of Thomas Aquinas into Greek; he was the forerunner of a minority of Byzantine intellectuals who joined the Roman Church and looked to the West to save their empire from ruin. More typical of his class was Theodore Metochites, the Grand Logothete or chancellor of Andronicus II, whose encyclopaedic learning rivalled that of Psellus. His pupil Nicephorus Gregoras, in addition to his researches in philosophy, theology, mathematics, and astronomy, wrote a history of his age. The tradition of Byzantine historiography, maintained by George Acropolites, the historian of the Empire of Nicaea, was continued in the 14th century by George Pachymeres, by Gregoras, and finally by the Emperor John VI Cantacuzenus, who wrote his memoirs after his abdication in 1354.

Andronicus III and John Cantacuzenus. The histories they wrote tell more of politics and personalities than of the underlying social and economic tensions in their society that were to find expression in a series of civil wars. Trouble broke out in 1320 when Andronicus II, purely for family reasons, disinherited his grandson Andronicus III. The cause of the young emperor was taken up by his friends and there was periodic warfare from 1321 to 1328, when the older Andronicus had to yield the throne. It was in some ways a victory for the younger generation of the aristocracy, of whom the leading light was John Cantacuzenus. It was he who guided

the empire's policies during the reign of Andronicus III (1328–41). They were men of greater drive and determination, but the years of fighting had made recovery still more difficult and given new chances to their enemies. In 1329 they fought and lost a battle at Pelekanon (near Nicomedia) against Osman's son, Orchan, whose Turkish warriors went on to capture Nicaea in 1331 and Nicomedia in 1337. Northwestern Anatolia, once the heart of the empire, was now lost. There seemed no alternative but to accept the fact and to come to terms with the Ottomans and the other Turkish emirs. By so doing, Andronicus III and Cantacuzenus were able to call on the services of almost limitless numbers of Turkish soldiers to fight for them against their other enemies: the Italians in the Aegean islands, and the Serbs and the Bulgars in Macedonia and Thrace.

The power of Serbia, which Andronicus II had managed to control by diplomatic means, grew alarmingly after the accession of Stefan Dušan to the Serbian throne in 1331. Dušan exploited to the full the numerous embarrassments of the Byzantines and in 1346 announced his ambitions by having himself crowned as emperor of the Serbs and Greeks. The greatest practical achievement of Andronicus III was the restoration to Byzantine rule of the long separated provinces of Epirus and Thessaly. But only a few years later, in 1348, the whole of northern Greece was swallowed up in the Serbian Empire of Stefan Dušan.

Outbreak of civil war

When Andronicus III died in 1341, civil war broke out for a second time. The contestants on that occasion were John Cantacuzenus, who had expected to act as regent for the boy-heir John V, and his political rivals led by his former partisan Alexius Apocaucus, the patriarch John Calecas, and the empress-mother Anne of Savoy, who held power in Constantinople. Cantacuzenus, befriended and then rejected by Dušan of Serbia, was crowned as the Emperor John VI in Thrace in 1346; and, with the help of Turkish troops, he fought his way to victory in the following year. Like Romanus Lecapenus, he protested that he was no more than the protector of the legitimate heir to the throne, John V Palaeologus. His brief reign, from 1347 to 1354, might have turned the tide of Byzantine misfortunes had not the second civil war provoked unprecedented social and political consequences. In the cities of Thrace and Macedonia the people vented their dissatisfaction with the ruling aristocracy by revolution. It was directed mainly against Cantacuzenus and the class that he represented. The movement was most memorable and lasting in Thessalonica, where a faction known as the Zealots seized power in a coup d'etat and governed the city as an almost independent commune until 1350.

The second civil war was consequently even more destructive of property and ruinous to the economy than the first. At the same time, in 1347, the Black Death decimated the population of Constantinople and other parts of the empire. John VI Cantacuzenus, nevertheless, did what he could to restore the economy and stability of the empire. To coordinate the scattered fragments of its territory he assigned them as appanages to individual members of the imperial family. His son Manuel took over the province of the Morea in 1349 with the rank of despot and governed it with growing success until his death in 1380. His eldest son, Matthew, was given a principality in Thrace; while the junior emperor John V, who had married a daughter of Cantacuzenus, ruled in Thessalonica after 1351. This somewhat feudal system of imperial government was to be continued by the successors of John VI, sometimes making for stability but more often for rivalry between the various princes or Despots.

Cantacuzenus also tried but failed to weaken the economic stranglehold of the Genoese by rebuilding a Byzantine war fleet and merchant navy. The effort involved him in warfare, first on his own and then as an unwilling partner of the Venetians against the Genoese, from which Byzantium emerged as the loser. The revenue of the Genoese colony at Galata, derived from custom dues, was now far greater than that of Constantinople. The empire's poverty was reflected in dilapidated buildings and falling standards of luxury. The crown jewels had been pawned to Venice during the civil war, and the Byzantine gold coin, hopelessly devalued, had given place in international trade to the Venetian ducat. More and more, Byzantium was at the mercy of its foreign competitors and enemies, who promoted and exploited the political and family rivalries among the ruling class. John Cantacuzenus was never popular as an emperor, and feeling against him came to a head when some of his Ottoman mercenaries took the occasion of the destruction of Gallipoli by earthquake to occupy and fortify the city in March 1354. It

The Byzantine Empire in 1355.

Turkish occupation of Gallipoli

was their first permanent establishment in Europe, at the key point of the crossing from Asia. In November of the same year John V Palaeologus, encouraged by the anti-Cantacuzenist Party, forced his way into Constantinople. In December Cantacuzenus abdicated and became a monk. Though his son Matthew, who had by then been crowned as co-emperor, fought on for a few years, the dynasty of Cantacuzenus was not perpetuated.

Turkish expansion. John Cantacuzenus's relationship with the Turks had been based on personal friendship with their leaders, among them Orchan, to whom he gave his daughter in marriage. But once the Turks had set up a base on European soil and had seen the possibilities of further conquest, such relationships were no longer practicable. Stefan Dušan, who very nearly realized his ambition to found a new Serbo-Byzantine empire, was the only man who might have prevented the subsequent rapid expansion of the Turks into the Balkans, but he died in 1355 and his empire split up. The new emperor, John V, hoped that the Western world would sense the danger and in 1355 he addressed an appeal for help to the Pope. The popes were concerned for the fate of the Christian East but guarded in their offers to Constantinople so long as the Byzantine Church remained in schism from Rome. In 1366 John V visited Hungary to beg for help, but in vain. In the same year his cousin Amadeo, count of Savoy, brought a small force to Constantinople and recaptured Gallipoli from the Turks, who had by then advanced far into Thrace. Amadeo persuaded the emperor to go to Rome and make his personal submission to the Holy See in 1369. On his way home, John was detained at Venice as an insolvent debtor; and, during his absence, the Turks scored their first victory over the successors of Stefan Dušan on the Marica River near Adrianople in 1371. The whole of Macedonia was now open to them. The remaining Serbian princes and the ruler of Bulgaria became their vassals; and in 1373 the Emperor was forced to do the same.

Byzantium was now a vassal state of the Turks, pledged to pay tribute and to provide military assistance to the Ottoman sultan. The possession of Constantinople thereafter was disputed by the Emperor's sons and grandsons in a series of revolutions, which were encouraged and sometimes instigated by the Turks, the Genoese, or the Venetians. John V's son Andronicus IV, aided by the Genoese and the sultan Murad I, mastered the city for three years (1376–79). He rewarded the Turks by giving back Gallipoli to them, and Murad made his first European capital at Adrianople. The Venetians helped John V to regain his throne in 1379, and the empire was once again divided into appanages under his sons. Only his second son, Manuel, showed any independence of action. For nearly five years, from 1382 to 1387, Manuel reigned as emperor at Thessalonica and laboured to make it a rallying point for resistance against the encroaching Turks. But the city fell to Murad's army in April 1387. When the Turks then drove deeper into Macedonia, the Serbs again organized a counteroffensive, but were overwhelmed at Kossovo in 1389.

Manuel II and respite from the Turks. The loss of Thessalonica and the Battle of Kossovo sealed Constantinople off by land. The new sultan Bayezid I (1389–1402) intended to make it his capital; when Manuel II came to that throne at his father's death in 1391, the Sultan warned him that he was emperor only inside the city walls. The Turks already controlled the rest of Byzantine Europe, except for the south of Greece.

In 1393 Bayezid completed his conquest of Bulgaria, and soon afterward he laid siege to Constantinople. The blockade was to last for many years, though the city could resist so long as its walls remained intact. Manuel II, like his father, pinned his hopes of rescue on the West. A great crusade against the Turks was organized by the King of Hungary; but it was defeated at Nicopolis on the Danube in 1396. In 1399 the French marshal, Boucicaut, who had been at Nicopolis and had returned to the relief of Constantinople with a small army, persuaded Manuel to travel to western Europe to put the Byzantine case in person. From the end of 1399 to June 1403 the Emperor visited in Italy, France, and England, leaving his nephew John VII in charge of Constantinople. Manuel's journey did something to stimulate Western interest in Greek learning. His friend and ambassador in the West, Manuel Chrysoloras, a pupil of Demetrius Cydones, was appointed to teach Greek at Florence. The Pope instituted a defense fund for Constantinople, even though Manuel did not offer to submit the Byzantine Church to Rome as an incentive. Interest and sympathy were forthcoming, but little in the way of practical help. During Manuel's absence, however, the Ottomans were defeated at Ankara by the Mongol leader Timur (Tamerlane) in July 1402. Bayezid was captured and his empire in Asia was shattered. His four sons contended with each other to secure possession of the European provinces, which had been little affected by the Mongol invasion, and to reunite the Ottoman dominions. In these wholly unexpected circumstances the Byzantines found themselves the favoured allies first of one Turkish contender, then of another. The blockade of Constantinople was lifted. Thessalonica—with Mt. Athos and other places—was restored to Byzantine rule; and the payment of tribute to the sultan was annulled. In 1413 Mehmed I, helped and promoted by the emperor Manuel, triumphed over his rivals and became sultan of the reintegrated Ottoman Empire.

Appeals of Manuel II in western Europe

During his reign, from 1413 to 1421, the Byzantines enjoyed their last respite. Manuel II, aware that it could not last, made the most of it by strengthening the defenses and administration of the fragments of his empire. The most flourishing province in the last years was the Despotate of the Morea. Its prosperity had been built up first by the sons of John Cantacuzenus (who died there in 1383), and then by the son and grandson of John V—Theodore I and Theodore II Palaeologus. Its capital city of Mistra became a haven for Byzantine scholars and artists and a centre of the last revival of Byzantine culture, packed with churches, monasteries, and palaces. Among its scholars was George Gemistus Plethon, a platonist who dreamed of a rebirth of Hellenism on Hellenic soil.

Final Turkish assault. When Murad II became sultan, in 1421, the days of Constantinople and of Hellenism were numbered. In 1422 Murad revoked all the privileges accorded to the Byzantines by his father and laid siege to Constantinople. His armies invaded Greece and blockaded Thessalonica. The city was then a possession of Manuel II's son Andronicus, who in 1423 handed it over to the Venetians. For seven years Thessalonica was a Venetian colony, until, in March 1430, the Sultan assaulted and captured it. Meanwhile, Manuel II had died in 1425, leaving his son John VIII as emperor. John, who had already travelled to Venice and Hungary in search of help, was prepared to reopen negotiations for the union of the churches as a means of stirring the conscience of Western Christendom. His father had been skeptical about the benefits of such a policy, knowing that it would antagonize most of his own people and arouse the suspicion of the Turks. The proposal was made, however, at the Council of Florence in 1439, attended by the emperor John VIII, his patriarch, and many Orthodox bishops and dignitaries. After protracted and difficult discussions, they agreed to submit to the authority of Rome. The union of Florence was badly received by the citizens of Constantinople and by most of the Orthodox world. But it had its notable adherents, such as the bishops Bessarion of Nicaea and Isidore of Kiev, both of whom retired to Italy as cardinals of the Roman Church. Bessarion's learning and library helped to encourage further Western interest in Greek scholarship. The union of Florence also helped to stimulate a crusade against the Turks. Once again it was led by the king of Hungary, Vladislaw III of Poland, supported by George Branković of Serbia and by János Hunyadi of Transylvania. But there were disagreements among its leaders, and the Christian army was annihilated at Varna in 1444.

Fall of Thessalonica

The Byzantine collapse and the Ottoman triumph followed swiftly thereafter. In 1448 Constantine XI, the last emperor, left Mistra for Constantinople when his brother

John VIII died without issue. His two other brothers, Thomas and Demetrius, continued to govern the Morea, the last surviving Byzantine province. In 1449 the new sultan, Mehmed II, began to prepare for the final assault on Constantinople. No further substantial help came from the West, and the formal celebration of the union of the Churches in Hagia Sophia in 1452 was greeted with a storm of protest. Even in their extremity, the Byzantines would not buy their freedom at the expense of their Orthodox faith. They found the prospect of being ruled by the Turks less odious than that of being indebted to the Latins. When the crisis came, however, the Venetians in Constantinople, and a Genoese contingent commanded by Giovanni Giustiniani, wholeheartedly cooperated in the defense of the city, though the Genoese at Galata declared their neutrality. Mehmed II laid siege to the walls in April 1453. His ships were obstructed by a chain that the Byzantines had thrown across the mouth of the Golden Horn. The ships were therefore dragged overland to the harbour from the seaward side, bypassing the defenses. The Sultan's heavy artillery continually bombarded the land walls until, on May 29, some of his soldiers forced their way in. Giustiniani was mortally wounded. The emperor Constantine was last seen fighting on foot at one of the gates.

The Sultan allowed his victorious troops three days and nights of plunder before he took possession of his new capital. The Ottoman Empire had now superseded the Byzantine Empire; and some Greeks, like the contemporary historian Critobulus of Imbros, recognized the logic of the change by bestowing on the Sultan all the attributes of the emperor. The material structure of the empire, which had for long been crumbling, was now under the management of the sultan-basileus. But the Orthodox faith was less susceptible to change. The Sultan acknowledged the fact that the church had proved to be the most enduring element in the Byzantine world; and he gave the Patriarch of Constantinople an unprecedented measure of temporal authority by making him answerable for all Christians living under Ottoman rule.

The last pockets of resistance were eliminated soon after 1453. Athens fell to the Turks in 1456; and in 1460 the two Despots of the Morea surrendered. Thomas fled to Italy, Demetrius to the Sultan's court. In 1461 Trebizond, capital of the last Greek empire, which had maintained its precarious independence by paying court to Turks and Mongols alike, finally succumbed; and the transformation of the Byzantine world into the Ottoman world was at last complete. (D.M.N.)

BIBLIOGRAPHY. The following surveys and analyses provide brief introductions to Byzantine history and civilization: N.H. BAYNES and H. ST. L.B. MOSS (eds.), *Byzantium: An Introduction to East Roman Civilization* (1948); J.M. HUSSEY, *The Byzantine World*, 3rd rev. ed. (1967); R.J.H. JENKINS, *Byzantium and Byzantinism* (1963); and P.D. WHITTING, *Byzantium: An Introduction* (1971). Brief general characterizations of various aspects of Byzantine civilization may be found in the collected essays of two masters of Byzantine studies: N.H. BAYNES, *Byzantine Studies and Other Essays* (1955); and FRANZ DOLGER, *Byzanz und die europäische Staatenwelt* (1953) and *Paraspora* (1961). Deeper study of Byzantine history should begin with GEORGE OSTROGORSKY, *Geschichte des byzantinischen Staates* (1965; Eng. trans., *History of the Byzantine State*, 2nd ed., 1968); and may continue with *The Cambridge Medieval History*, vol. 4, pt. 1–2, *The Byzantine Empire*, 2nd ed. (1966–67), a collective survey of uneven quality that suffers from its adoption of the year 717 as a starting point for Byzantine history. Geographical relationships are discussed in ALFRED PHILIPPSON, *Das byzantinische Reich als geographische Erscheinung* (1938); and its church and theology in H.G. BECK, *Kirche und theologische Literatur im byzantinischen Reich* (1959). By far the most profound and extensive work in Byzantine studies before World War I had been completed in imperial Russia, A.A. VASILIEV, *History of the Byzantine Empire, 324–1453*, 2nd ed. rev. (1952, reprinted 1964; orig. pub. in Russian, 1917), provides a thorough bibliography; M.V. LEVCHENKO, *Byzance des origines à 1453* (1949; orig. pub. in Russian, 1940), illustrates the Marxist approach in the Soviet Union, where, since World War II, Byzantine history has undergone a renaissance. Current work is published in a number of periodicals of international character: *Byzantinische Zeitschrift* (Munich); *Byzantion* (Brussels); *Byzantinoslavica* (Prague); *Dumbarton Oaks Papers* (Washington, D.C.); *Travaux et Mémoires* (Paris); *Vizantiiskii Vremennik* (Moscow and Leningrad).

The Roman and Christian background: The first two chapters, by Moss and Matthews, in *The Cambridge Medieval History*, vol. 4, will introduce the reader to the problems discussed in this section. Further reading might include the brief and extremely provocative sketch by PETER BROWN, *The World of Late Antiquity* (1971), excellent for cultural history; and at the other extreme of length, A.H.M. JONES, *The Later Roman Empire, 284–602: A Social, Economic, and Administrative Survey*, 2 vol. (1964), which will probably remain one of the monuments of 20th-century scholarship on the period.

The 5th and 6th centuries: Two older works provide a more extensive coverage than that found in Jones's *Later Roman Empire:* J.B. BURY, *History of the Later Roman Empire from the Death of Theodosius I. to the Death of Justinian (A.D. 395 to A.D. 565)*, 2nd ed., 2 vol. (1923, reprinted 1958); and ERNST STEIN, *Histoire du Bas-Empire*, 2 vol. (1949–59). The 1960s and early 1970s saw the publication of a number of new works on Justinian of varying merit: BERTHOLD RUBIN, *Das Zeitalter Justinians*, vol. 1 (1960); J.W. BARKER, *Justinian and the Later Roman Empire* (1966); ROBERT BROWNING, *Justinian and Theodora* (1971); and THOMAS FITZGERALD, *Justinian the Great: Roman Emperor of the East* (1970). The conclusions presented herein are justified in detail in JOHN L. TEALL, "The Barbarians in Justinian's Armies," *Speculum*, 40:294–322 (1965). Since the end of the century was first studied in a sophisticated fashion by ERNST STEIN, *Studien zur Geschichte des byzantinischen Reiches* (1919), it has received less attention than it should.

The 7th century and the Heraclian reforms: A general overview of the age and its problems will be found in *Dumbarton Oaks Papers*, vol. 13 (1959), a collection of papers, including important studies by Ostrogorsky on the significance of the Slavic invasions and on the cities, by Charanis on ethnic mixture, and by Lopez on trade. R.J.H. JENKINS, *Byzantium: The Imperial Centuries, A.D. 610–1071* (1966), provides a survey of this and the following three centuries that, though founded on sound scholarship, reads like a novel. For a contrasting opinion on the foundation of the themes, see PAUL LEMERLE, "Esquisse pour une histoire agraire de Byzance," *Revue historique*, 219:32–74, 254–284 and 220:43–94 (1958), an important survey of agrarian institutions from the 4th to the 11th century. A detailed defense of the position taken above, with references to other studies, will be found in JOHN L. TEALL, "The Byzantine Agricultural Tradition," *Dumbarton Oaks Papers*, 25:33–59 (1971), which also deals with agricultural technology and problems of land settlement. Byzantium's position in eastern Europe is presented in masterly fashion by DIMITRI OBOLENSKY, "The Empire and Its Northern Neighbors," *The Cambridge Medieval History*, vol. 4, and in the same author's *Byzantine Commonwealth* (1971). A convenient history of Iconoclasm is E.J. MARTIN, *A History of the Iconoclastic Controversy* (1930).

The 9th century: The standard survey remains J.B. BURY, *A History of the Eastern Roman Empire . . ., A.D. 802–867* (1912, reprinted 1965); but to FRANCIS DVORNIK must be given much of the credit for the subsequent revision of views on the period, particularly on the significance of the reign of Michael III. A number of Dvornik's important works have recently been reprinted with new introductions: *Les Légendes de Constantin et de méthode vues de Byzance*, 2nd ed. (1969); *Les Slaves, Byzance et Rome au IXème siècle* (1926, reprinted 1970); and *The Photian Schism* (1948, reprinted 1970); see also his *Byzantine Missions Among the Slavs* (1970). The work of another distinguished revisionist is summarized in, but not well represented by, the chapter he prepared for *The Cambridge Medieval History*, vol. 4: HENRI GREGOIRE, "The Amorians and Macedonians, 842–1025." Arab-Byzantine warfare is narrated in A.A. VASILIEV, *Byzance et les Arabes*, vol. 1, *La Dynastie d'Amorium, 820–867* (1935).

The Macedonian dynasty (867–1025): J.B. BURY, *The Imperial Administrative System in the Ninth Century* (1911, reprinted 1958); FRANCIS DVORNIK, *The Photian Schism* (1948, reprinted 1970); J.M. HUSSEY, *Church and Learning in the Byzantine Empire, 867–1185* (1937, reprinted 1963); R.J.H. JENKINS, *Byzantium: The Imperial Centuries, A.D. 610–1071* (1966); STEVEN RUNCIMAN, *A History of the First Bulgarian Empire* (1930), *The Eastern Schism* (1955), and *The Emperor Romanus Lecapenus and His Reign* (1929, reprinted 1963); GUSTAVE SCHLUMBERGER, *L'Epopée byzantine à la fin du X^e siècle*, 3 vol. (1896–1905); A.A.VASILIEV, *Byzance et les Arabes*, vol. 2, pt. 1–2 (1950–68); ALBERT VOGT, *Basile I^er, Empereur de Byzance (867–886) et la civilisation byzantine à la fin du IX^e siècle* (1908).

Byzantine decline and subjection to Western influence (1025–1260): C.M. BRAND, *Byzantium Confronts the West, 1180–*

1204 (1968); FERDINAND CHALANDON, *Les Comnènes*, vol 1, *Essai sur le règne d'Alexis I^er Comnène, 1081–1118* and vol. 2, *Jean II Comnène, 1118–1143, et Manuel I Comnène, 1143–1180* (1900–13); ALICE GARDNER, *The Lascarids of Nicaea* (1912); R.J.H. JENKINS, *The Byzantine Empire on the Eve of the Crusades* (1953); OKTAWIESZ JUREWICZ, *Andronikos I. Komnenos* (1962; Eng. trans., 1970); D.M. NICOL, *The Despotate of Epiros* (1957); GEORGE OSTROGORSKY, *Pour l'histoire de la féodalité byzantine* (1954), and "Agrarian Conditions in the Byzantine Empire in the Middle Ages," in *The Cambridge Economic History of Europe*, 2nd ed., vol. 1, ch. 5 (1966); D.I. POLEMIS, *The Doukai: A Contribution to Byzantine Prosopography* (1968); STEVEN RUNCIMAN, *A History of the Crusades*, 3 vol. (1951–54, reprinted 1962–66); K.M. SETTON (ed.), *A History of the Crusades:* vol. 1, *The First Hundred Years*, ed. by M.W. BALDWIN; vol. 2, *The Later Crusades, 1189–1311*, ed. by R.L. WOLFF and H.W. HAZARD (1955, 1962).

The empire under the Palaeologi (1261–1453): FRANZ BABINGER, *Mehmed der Eroberer und seine Zeit* (1953; French trans., 1963); J.W. BARKER, *Manuel II Palaeologus (1391–1425): A Study in Late Byzantine Statesmanship* (1969); U.V. BOSCH, *Kaiser Andronikos III. Palaiologos* (1965); D.J. (D.M.N./J.L.Te.)

Cabral, Pedro Álvares

Though other Europeans had preceded him to that part of the world, Pedro Álvares Cabral is generally credited with discovering Brazil, in 1500. Cabral, who lived from 1467 or 1468 to 1520, was one of the foremost of the Portuguese navigators who brought fame to their homeland during the Age of Discovery.

Cabral, medallion by an unknown artist, 16th century. From the Mosterio dos Jerónimos, Portugal.
By courtesy of the Secretaria de Estado da Informacao Cultura Popular e Turismo, Lisbon

Born in Belmonte, Portugal, the son of Fernão Cabral, a nobleman, and of Isabel de Gouveia, he was heir to a long tradition of service to the throne. He himself enjoyed the esteem of King Manuel I of Portugal, from whom he received various privileges in 1497; these included a personal allowance, the title of counsellor to his highness, and the habit of the military Order of Christ. Three years later the King entrusted him with the command of the second major expedition to India, expressing "the great confidence we have in Pedralvares de Gouveia, nobleman of our household." Cabral was named admiral in supreme command of 13 ships, which set out from Lisbon on March 9, 1500. He was to follow the route taken earlier by Vasco da Gama, to strengthen commercial ties, and to further the conquest his predecessor had begun.

The expedition to India

In accordance with da Gama's instructions, based on his experiences during the first voyage, Cabral was to sail southwest so as to bypass the becalmed waters of the Gulf of Guinea. This course, which later became known as the "circle around Brazil," had the added advantage of providing the Portuguese with opportunity to reconnoitre along the coast of the lands to the west, which they had previously sighted and which belonged to them in accordance with the Treaty of Tordesillas (1494).

Discovery of Brazil

Sailing westward under favourable conditions, on April 22, Cabral discovered the land he named Island of the True Cross. Later renamed Holy Cross by King Manuel, the country ultimately took its modern name, Brazil, from a kind of wood it produces, *pau-brasil*, which is used in dye processing.

Cabral is reported to have made a special effort to treat the natives kindly, receiving them on board his caravel. Nonetheless, he took formal possession of the country and dispatched one of his ships to Portugal to inform the King. Henceforth, maps of the region showed Portugal as ruler of a great expanse of land with vaguely defined boundaries that came to serve as a point of call on the long voyage from Europe to the Cape of Good Hope and the Indian Ocean.

After a stay of only ten days in Brazil, Cabral sailed for India, in a voyage that was plagued by a series of misfortunes. On May 29, while the fleet was rounding the Cape of Good Hope, four ships were lost with all hands aboard; Bartolomeu Dias, the Portuguese who had discovered the cape in 1488, was one of those who perished in this disaster. The remaining ships cast anchor on September 13, 1500, at Calicut, India, where the *zamorin* (Muslim ruler) welcomed Cabral and allowed him to establish a fortified trading post. Disputes with Muslim traders soon arose, however, and on December 17 a large Muslim force attacked the trading post. Most of the Portuguese defenders were killed before reinforcements could arrive from the Portuguese fleet lying at anchor in the harbour.

Cabral retaliated by bombarding the city, and then by capturing ten Muslim vessels and executing their crews. He then sailed for the Indian port of Cochin, farther south, where he was affably received and permitted to trade for precious spices, with which he loaded his six remaining ships. Cabral also made port at Carangolos and Cananor on the same coast, completed his cargo, and on January 16, 1501, began the return voyage to Portugal. On his way, however, two ships foundered, and it was with only four vessels that Cabral finally reached the mouth of the Tagus River in Portugal on June 23, 1501.

Rivalry with Vasco da Gama

King Manuel was pleased at the outcome of the undertaking, in spite of the misfortunes that had beset it; he is said to have at first favoured making Cabral head of a new and more powerful expedition, but in the end it was Vasco da Gama and not Cabral who was appointed to that command. Accounts differ as to the reason for the King's change of heart. One chronicler attributes it to disagreement over division of authority within the new fleet; another offers the explanation that da Gama opposed the appointment of Cabral on the grounds that da Gama himself already held the title admiral of all the fleets that might leave Portugal for India and that the disasters of Cabral's expedition should disqualify him for the new mission.

Whatever the true explanation, the discoverer of Brazil

held no further position of authority at the Portuguese court. He retired to his estate in the Beira Baixa province of Portugal and spent his remaining years there. He died in 1520 in Santarém, Portugal, where his tomb was identified in 1848 by the Brazilian historian Francisco Adolfo Varnhagen.

In 1968, the year that marked the fifth centenary of the birth of Cabral, Brazil and Portugal honoured the memory of the "admiral of the fleet" in joint festivities. Both Rio de Janeiro and Lisbon have erected monuments in his honour.

Cactales

The cacti are curious, often spiny, fleshy-stemmed plants constituting the family Cactaceae, order Cactales, characteristic of and well adapted to dry regions. Although the cacti are native to the Americas—with one possible exception (see below)—they are cultivated widely throughout the world for their bizarre forms and often striking blossoms. Cacti are easily grown from cuttings or from seeds; they are adapted to warm, arid indoor conditions and require little care once established.

General features. *Importance.* Cacti are economic plants in Mexico, parts of Central and South America, and the Caribbean region. Various species are cultivated for food, including vast complexes of prickly pears, especially of *Opuntia ficus-indica*, and torch cacti (*Cereus*). Drinks prepared from some cactus fruits have been a popular native medicine for fevers. In Mexico, leaves of chollas, resembling string beans, are eaten. In Latin America, species of *Opuntia*, *Cereus*, and other genera are planted around houses, often forming an impenetrable barrier. Barrel cacti (*Echinocactus* and *Ferocactus*) are a source of water in emergencies.

Cacti are cultivated chiefly for their ornamental features and general hardiness. They can be grafted easily, and many rare species are propagated by grafting upon more vigorous stocks. Many small cacti are suitable for home cultivation. Without water, most cacti persist but do not grow. Some species, however, do require periodic drought. Many species grow well in warm weather in full sun, provided there is adequate soil moisture, but others require some shade.

Appearance. Most cacti are composed of stems and have no leaves. The leaves, when present, are usually greatly reduced; they may occur only temporarily at the growing end of the plant. Only in the genera *Pereskia* and *Pereskiopsis*, restricted to the tropics, do the leaves fit the popular conception of leaves.

Size range

Cacti vary greatly in size and general appearance, from button-like peyote (*Lophophora*) and low clumps of prickly pear (*Opuntia*) to upright columns of barrel cacti (*Ferocactus* and *Echinocactus*) and the imposing saguaro (*Cereus giganteus* or *Carnegiea gigantea*) trees. Some of the climbing tropical species—such as those of the leaf cactus (*Epiphyllum*) and some species of *Rhipsalis*—have thin, flattened stems. Regardless of its shape, degree of elongation, or branching, the cactus stem is succulent (having fleshy, moisture-conserving tissue) and greatly enlarged as storage tissue. The appearance of the plant varies also according to whether the stem surface is smooth or ornamented with protruding tubercles, ridges, or grooves.

Distribution. The Cactaceae are native through most of the length of North and South America, from British Columbia and Alberta southward. The northernmost limit is along the Peace River in Canada; the southernmost limit extends far into Chile and Argentina. The only representatives of the family possibly native to the Old World are members of the genus *Rhipsalis*, occurring in East Africa, Madagascar, and Ceylon. Whether these plants are native or were introduced in these tropical areas is a matter of disagreement, as is the possibility of dispersal of this highly specialized group from the Western Hemisphere to the Eastern Hemisphere.

Various species of *Opuntia* and some other genera have been introduced into the Mediterranean region, and some have grown wild there since shortly after the discovery of America. Species of *Opuntia* are widely naturalized in India, the Malayan region, Hawaii, and Australia. In Australia and eastern Cape Province in South Africa, they have become pests difficult to eradicate.

Natural history. *Life cycle.* The characteristic feature of cactus seedlings is the pair of large seed leaves (cotyledons), which tend to be succulent, sometimes markedly so. From seed some species reach the flowering stage in two or three years, and both flowers and fruits may be developed even on stems that still retain juvenile characters. (This curious feature led to the naming of many supposed species on the basis of plants that seemed to be mature because of reproduction but that did not have the expected type of spines.)

Usually within a few years the succulent stem assumes the characteristic form and appendages for the species. In the prickly pears, in which the adult stem is composed of flattened joints arranged end to end, the portion developed in the first year of growth is cylinder-like for several months, the upper portion gradually becoming flattened, and the joints developed later being flat.

Most cacti reach a considerable relative size within five or ten years, but some grow much slower. Information concerning the age of older plants usually is lacking because the woody parts are very thin; counting of growth rings requires sectioning and careful study with a compound microscope. The saguaro, or giant cactus, is estimated to attain ages in the hundreds of years.

Pollination is mostly by insects or birds, though sometimes by other animals such as bats. Because there is no precise mechanism governing the pathway of pollinators, the process of pollination tends to be haphazard, at least in most of the larger flowers of the open as opposed to the tubular types. Most flowers open in the daytime and are visited by day-flying insects or birds, but many, and especially such species as the saguaro and the various species of *Cereus*, open at night. As with other night-pollinated plants the night blooming cacti tend to be white flowered.

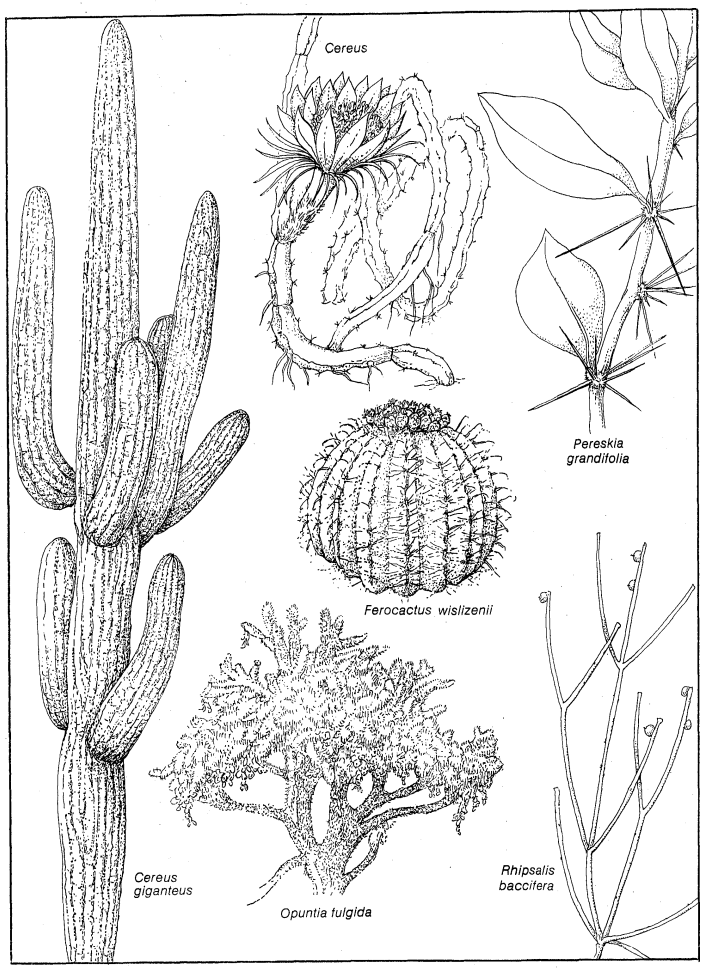
Adaptations to arid conditions

Ecology. Cacti are admirably adapted to dry environmental conditions through such features as the thick water-retaining stem, extensive root system, and lack of leaves.

The stems of prickly pears concentrate water over the flat surfaces of the joints that either drips or streams from the curved lower margins, thereby increasing the amount of water in the soil just under the plant. Some species of cacti have spines that point downward; water collected on the spines, even from light mists, is directed in droplets to the ground. The saguaro's downward-pointed spines during its earlier years of growth collect water and repel rodents that might eat the succulent stems to secure water. In older saguaros the stem above about the four- or five-foot level produces another not downward-directed type of spine. For plants growing near the lower edge of a rock or a crack between rocks, the amount of water available from a relatively light rain may be greatly increased, as it would for a plant living under the edge of a roof.

The root systems of cacti are shallow and widespreading. They remain receptive to moisture through many months of dry weather and immediately soak up even the scantiest rainfall. Substances from the roots of some desert plants, and perhaps some of the cacti, prevent the invasion of any other plants nearby, thus increasing the chance of continued survival for established plants. The absence of leaves reduces the ratio of plant surface to internal plant volume, as does the thickening of the stems, thus aiding water retention.

Within their natural range, cacti occur in a wide variety of soil types. Frequently, a species is restricted to a particular type of rock formation, such as limestone or igne-



Representative cacti.
Drawing by M. Pahl

ous rock. A few species are confined to localized rock outcroppings, a limitation particularly striking in the genus *Pediocactus*, in which eight of its 11 species are found on special rock ledges on the Colorado Plateau or on gypsum-rich soil.

Some species are associated with tropical rain forests, as in the Everglades in Florida, where species of *Opuntia* and *Cereus* occur at points at which the water table may be only a few inches below the surface. Most species are sensitive to cold, but many grow in regions with cold winters, as in the United States on the Great Plains and in the Great Basin and the Rocky Mountains.

Form and function. *Vegetative characteristics.* Many other plants, succulent and essentially leafless, are often confused with cacti. A large group of spurges (*Euphorbia* species) occurring in Africa includes many plants with long cylindroid stems similar in appearance to cacti. These plants, common in cultivation, are distinguished readily by their milky juice, a feature rare in cacti and supposedly absent in cacti with elongated stems. Yuccas and the century plants (*Agave* species) often are confused with cacti, but they are distinguished readily by succulence of the leaves rather than the stems.

Distinctive structure

Cacti can be distinguished from all other succulent plants by the presence of spines in areoles, special clearly defined areas, each developed from a lateral bud of the stem. Areoles are universal in the cactus family (at least in the juvenile phase) and have so far not been found in any other plant family. Almost all species of cactus have tufts of stiff sharp spines. In some species the mature plant may not have spines, but it does have areoles, which are filled with hair or sharp, barbed structures called glochids. The more obvious characters of the cactus family, in combination with areoles, are reduction or lack of leaves, unusual floral formation, and distinctive fruit and seed.

The leaves, if discernible, are reduced in size (except in *Pereskia*, as indicated above). In *Opuntia* they appear only on young joints of the stem and fall off after a month or more of growth. They are relatively small and succulent and range from conical to elongated and cylindroid. In most genera the leaves are not visible to the unaided eye but are represented by a hump of tissue just below a spine-bearing areole.

Reproductive characteristics. Frequently the flowers are large, attractive, and white or brightly coloured. All the genera have a floral tube that invests the ovary, and, except in *Pereskia*, adheres to its surface. The portion of the tube covering the ovary usually develops small, inconspicuous scales, which increase gradually in size upward on the free portion of the floral tube above the ovary. They grade into sepaloid flower parts and, farther up, into petaloid parts. There are many conspicuous stamens (pollen-bearing organs) and three to 20 or more stigmas (parts that receive pollen) arising from a single style. In some groups, especially *Opuntia*, there is only a short floral tube above the ovary, but in others, as with some species of *Cereus*, the tube may be very long. The fusion of the floral tube with the surface of the ovary occurs in all species of cacti except *Pereskia* and in many other flowering plants. A flower which has this feature is described as epigynous, and its ovary is said to be inferior.

The ovary and the investing floral tube may develop into a fleshy and often edible fruit. It is one-chambered, and the numerous ovules borne on the walls give rise to numerous seeds. The ovules usually are campylotropous; that is, curved between the hilum (point of attachment to the stalk) and the opening through which the pollen tube enters (micropyle).

The flowers usually are associated with a spine-bearing areole, but in *Mammillaria* (fishhook cacti) they may be

produced in a special areole between the elongated tubercles of the stem surface or they may be in this position but have no visible connection with an areole. The flowers develop either inside the spine-bearing part of the areole or in an area either merging with it or remote from it and connected by an isthmus.

Evolution and relationships. Because of the lack of fossils, the evolutionary course of the cacti is difficult to trace. One *Opuntia*-like fossil has been uncovered, but evidence suggests that it may not represent a cactus at all. Primitive living cacti may suggest lineage. The greatest number of primitive features is preserved in *Pereskia*. The flowers of some species are perigynous (floral tube surrounds the ovary) instead of epigynous; the stems are only moderately succulent; the leaves, though succulent, are similar to those of many other plants. The wood and reproductive parts reveal other primitive features. Of particular significance is the similarity of the carpels of *Pereskia pititache* to those of the primitive tropical woody plants of the buttercup order of other taxonomic systems (Ranales). The carpels are unsealed, which may indicate origin of the cacti from a very primitive stock and an early separation in evolutionary development from the Ranales or from developmental lines ancestral to the Ranales and to related groups. One of these lines of development may have branched off long ago to the ancestors of the order Caryophyllales, as indicated by the features held in common between that order and the cacti.

Origin of cacti

The numerous differences between these two groups indicates that they separated as far back as the Late Mesozoic Era (about 130,000,000 years ago).

Classification. *Distinguishing taxonomic features.* The features used in separating cacti from other succulents are listed above (see *Form and function*). The family Cactaceae apparently is not closely related to any other plant family.

Annotated classification. The Cactaceae are considered by some authorities as the sole family of the order Cactales, as in this article. Certain plant taxonomists, however, group the Cactaceae with the families of the pink order (Caryophyllales). The proper disposition of the family, therefore, has not been clearly determined; unless future research reveals otherwise, it seems appropriate to consider it as constituting a distinct order.

ORDER CACTALES

Coextensive with the family Cactaceae.

Family Cactaceae

Stems succulent, ranging from minute to as much as 50 feet long and up to 2½ feet in diameter, smooth or covered with ribs and tubercles (knobby projections). Leaves usually absent in adult plants; when present, they are large, flat, and persistent (*Pereskia* and *Pereskiopsis*) or conical to cylindroidal and short-lived. Areoles are present in the leaf axils or their structural equivalents and are arranged spirally on the surface of a smooth stem or on the apices of the tubercles, when present, and bear spines (spines rarely absent on the adult stem but present in juvenile stages). Flowers and fruits develop within or associated with a spine-bearing areole. The flower, except in some species of *Pereskia*, is epigynous, but of different origin than the epigyny of other flowering plants; the floral tube is developed from the receptacle, usually bears scale leaves and areoles; the superior floral tube or cup (the part above and free from the ovary) sometimes tubular; scale leaves of the floral tube show a gradation into the sepaloid outer perianth parts and these grade into the petaloid inner perianth parts. Stamens are numerous, spirally arranged. Carpels (structures constituting the innermost whorl of the flower), from 3 to 20, are arranged in a circle; one style; stigmas as many as the carpels; the ovary at maturity with one chamber; numerous ovules and seeds; ovules usually campylotropous (curving between the hilum and the micropyle) or sometimes amphitropous or orthotropous. Fruit variable; seeds of various colours (usually brown, black, reddish, gray, or white) and shapes. From 800 to 1,500 valid species. Distributional centres—Mexico and the South American deserts. The better known genera include *Melocactus* (melon-thistle, or Turk's-cap, cactus), *Ferocactus* and *Echinocactus* (barrel cacti), *Echinocereus* (hedgehog cactus), *Cereus* (torch cactus), *Mammillaria* and *Coryphantha* (fishhook, or pincushion, cacti), *Epiphyllum* (leaf cactus), *Opuntia* (prickly pears and chollas), and *Pereskia*.

Critical appraisal. The cacti stand alone, not being related closely to any other group of flowering plants. They do share some features in common with the orders Ranales, Myrtales, Rosales, and others, but the relationship to any of them is not close.

Similarities to other plant groups

The order Cactales, consisting of the single family Cactaceae, has been included recently by several authorities in the Caryophyllales. This proposed alliance first arose from the obvious succulence of the Cactaceae and a subfamily of the family Aizoaceae. These families are similar to the cacti in features of the pollen grains, in the development of the embryo sac (megagametophyte), and in the campylotropus ovules with the food in reserve in the perisperm. In the cacti, however, the ovules may be in a variety of positions other than the campylotropous condition. Betacyanin pigments occur in the Caryophyllales as well as in the Cactaceae, indicating a link between the groups; they have been assumed to occur in no other groups of plants.

The Aizoaceae, despite similarities, lack a number of the characteristic features of the cacti. Leaves of the Aizoaceae usually are opposite; those of the Cactaceae are alternate. The leaves are conspicuously succulent, while in cacti the stems are succulent. The Aizoaceae do not have spines in areoles, as do cacti. The flowers are superficially similar, but in the Aizoaceae there are no leaves on the floral cup (tube) and leaves do not grade into sepaloid and petaloid parts. In the Aizoaceae the fruit has partitions at maturity, unlike the cacti. There is more than one style instead of the single style in the Cactaceae.

Similarities of the cacti and other groups, accompanied by numerous differences, indicate the derivation of these groups from a common ancestry. The major taxa and even the species of living flowering plants were mostly derived from ancestors that were wholly or partly displaced and that usually have become extinct, leaving no recognizable remains behind.

(L.Be.)

Caesar, Julius

A Roman general, dictator, and statesman, Caesar changed the course of the history of the Greco-Roman world decisively and irreversibly. The Greco-Roman society has been extinct for so long that most of the names of its great men mean little to the average, educated modern man. But Caesar's name, like Alexander's, is still on people's lips throughout the Christian and Islāmic worlds. Even people who know nothing of Caesar as a historic personality are familiar with his family name as a title signifying a ruler who is in some sense uniquely supreme or paramount—the meaning of *Kaiser* in German, *tsar* in the Slavonic languages, and *qayṣar* in the languages of the Islāmic world.

Caesar's gens (clan) name, Julius (Iulius), is also familiar in the Christian world; for in Caesar's lifetime the Roman month Quintilis, in which he was born, was renamed "July" in his honour. This name has survived Caesar's assassination and the fall of the Roman Empire. So has Caesar's reform of the calendar. The old Roman calendar was inaccurate and manipulated for political purposes. Caesar's calendar, the Julian calendar, is still

partially in force in the Eastern Orthodox Christian countries; and the Gregorian calendar, now in use in the West, is the Julian, slightly corrected by Pope Gregory XIII.

FAMILY BACKGROUND AND EARLY CAREER

Caesar's gens, the Julii, were patricians; *i.e.*, members of Rome's original aristocracy, which had coalesced in the 4th century BC with a number of leading plebeian (commoner) families to form the nobility that had been the governing class in Rome since then. By Caesar's time, the number of surviving patrician gentes was small; and in the gens Julia the Caesares seem to have been the only surviving family. Though some of the most powerful noble families were patrician, patrician blood was no longer a political advantage; it was actually a handicap, since a patrician was debarred from holding the paraconstitutional but powerful office of tribune of the plebs. The Julii Caesares traced their lineage back to the goddess Venus, but the family was not snobbish or conservative-minded. It was also not rich or influential or even distinguished.

Alinari

Caesar, marble bust. In the Capitoline Museum, Rome.

A Roman noble won distinction for himself and his family by securing election to a series of public offices, which culminated in the consulship, with the censorship possibly to follow. This was a difficult task for even the ablest and most gifted noble unless he was backed by substantial family wealth and influence. Rome's victory over Carthage in the Second Punic War (218–201 BC) had made Rome the paramount power in the Mediterranean basin; an influential Roman noble family's clients (that is, protégés who, in return, gave their patrons their political support) might include kings and even whole nations, besides numerous private individuals. The requirements and the costs of a Roman political career in Caesar's day were high, and the competition was severe; but the potential profits were of enormous magnitude. One of the perquisites of the praetorship and the consulship was the government of a province, which gave ample opportunities for plunder. The whole Mediterranean world was, in fact, at the mercy of the Roman nobility and of a new class of Roman businessmen, the equities ("knights"), which had grown rich on military contracts and on tax farming.

Military manpower was supplied by the Roman peasantry. This class had been partly dispossessed by an economic revolution following on the devastation caused by the Second Punic War. The Roman governing class had consequently come to be hated and discredited at home and abroad. From 133 onward there had been a series of alternate revolutionary and counter-revolutionary paroxysms. It was evident that the present misgovernment of the Roman state and the Greco-Roman world by the Roman nobility could not continue indefinitely and it was fairly clear that the most probable alternative was some form of military dictatorship backed by dispossessed Italian peasants who had turned to long-term military service.

The traditional competition among members of the Roman nobility for office and the spoils of office was thus threatening to turn into a desperate race for seizing autocratic power. The Julii Caesares did not seem to be in the running. It was true that Sextus Caesar, who was perhaps the dictator's uncle, had been one of the consuls for 91; and Lucius Caesar, one of the consuls for 90, was a distant cousin, whose son and namesake was consul for 64. In 90, Rome's Italian allies had seceded from Rome because of the Roman government's obstinate refusal to grant them Roman citizenship, and, as consul, Lucius Caesar had introduced emergency legislation for granting citizenship to the citizens of all Italian ally states that had not taken up arms or that had returned to their allegiance. The Julii Caesares

Whoever had been consul in this critical year would have had to initiate such legislation, whatever his personal political predilections. There is evidence, however, that the Julii Caesares, though patricians, had already committed themselves to the antinobility party. An aunt of the future dictator had married Gaius Marius, a self-made man (*novus homo*) who had forced his way up to the summit by his military ability and had made the momentous innovation of recruiting his armies from the dispossessed peasants.

The date of Caesar the dictator's birth has long been disputed. The day was July 12 or 13; the traditional (and perhaps most probable) year is 100; but if this date is correct, Caesar must have held each of his offices two years in advance of the legal minimum age. His father, Gaius Caesar, died when Caesar was but 16; his mother, Aurelia, was a notable woman, and it seems certain that he owed much to her.

In spite of the inadequacy of his resources, Caesar seems to have chosen a political career as a matter of course. From the beginning, he probably privately aimed at winning office, not just for the sake of the honours but in order to achieve the power to put the misgoverned Roman state and Greco-Roman world into better order in accordance with ideas of his own. It is improbable that Caesar deliberately sought monarchical power until after he had crossed the Rubicon in 49, though sufficient power to impose his will, as he was determined to do, proved to mean monarchical power.

In 84 Caesar committed himself publicly to the radical side by marrying Cornelia, a daughter of Lucius Cornelius Cinna, a noble who was Marius' associate in revolution. In 83 Lucius Cornelius Sulla returned to Italy from the East and led the successful counter-revolution of 83–82; Sulla then ordered Caesar to divorce Cornelia. Caesar refused and came close to losing not only his property (such as it was) but his life as well. He found it advisable to remove himself from Italy and to do military service, first in the province of Asia and then in Cilicia. Sulla

In 78, after Sulla's death, he returned to Rome and started on his political career in the conventional way, by acting as a prosecuting advocate—of course, in his case, against prominent Sullan counter-revolutionaries. His first target, Gnaeus Cornelius Dolabella, was defended by Quintus Hortensius, the leading advocate of the day, and was acquitted by the extortion-court jury, composed exclusively of senators.

Caesar then went to Rhodes to study oratory under a famous professor, Molon. En route he was captured by pirates (one of the symptoms of the anarchy into which the Roman nobility had allowed the Mediterranean world to fall). Caesar raised his ransom, raised a naval force, captured his captors, and had them crucified—all this as a private individual holding no public office. In 74, when Mithridates VI Eupator, king of Pontus, renewed war on the Romans, Caesar raised a private army to combat him.

In his absence from Rome, Caesar was made a member of the politico-ecclesiastical college of pontifices; and on

his return he gained one of the elective military tribuneships. Caesar now worked to undo the Sullan constitution in cooperation with Pompey (Gnaeus Pompeius), who had started his career as a lieutenant of Sulla but had changed sides since Sulla's death. In 69 or 68 Caesar was elected quaestor (the first rung on the Roman political ladder). In the same year his wife, Cornelia, and his aunt Julia, Marius' widow, died; in public funeral orations in their honour, Caesar found opportunities for praising Cinna and Marius. Caesar afterward married Pompeia, a distant relative of Pompey. Caesar served his quaestorship in the province of Farther Spain (modern Andalusia and Portugal).

Caesar as political figure

Caesar was elected one of the curule aediles for 65, and he celebrated his tenure of this office by unusually lavish expenditure with borrowed money. He was elected pontifex maximus in 63 by a political dodge. By now he had become a controversial political figure. After the suppression of Catiline's conspiracy in 63, Caesar, as well as the millionaire Marcus Licinius Crassus, was accused of complicity. It seems unlikely that either of them had committed himself to Catiline; but Caesar proposed in the Senate a more merciful alternative to the death penalty, which the consul Cicero was asking for the arrested conspirators. In the uproar in the Senate, Caesar's motion was defeated.

Caesar was elected a praetor for 62. Toward the end of the year of his praetorship, a scandal was caused by Publius Clodius in Caesar's house at the celebration there of the rites, for women only, of Bona Dea (a Roman deity of fruitfulness, both in the Earth and in women). Caesar consequently divorced Pompeia. He obtained the governorship of Farther Spain for 61–60. His creditors did not let him leave Rome until Crassus had gone bail for a quarter of his debts; but a military expedition beyond the northwest frontier of his province enabled Caesar to win loot for himself as well as for his soldiers, with a balance left over for the treasury. This partial financial recovery enabled him, after his return to Rome in 60, to stand for the consulship for 59.

The first triumvirate and the conquest of Gaul. The value of the consulship lay in the lucrative provincial governorship to which it would normally lead. On the eve of the consular elections for 59, the Senate sought to allot to the two future consuls for 59, as their proconsular provinces, the unprofitable supervision of forests and cattle trails in Italy. The Senate also secured by massive bribery the election of an anti-Caesarean, Marcus Calpurnius Bibulus. But they failed to prevent Caesar's election as the other consul.

Caesar now succeeded in organizing an irresistible coalition of political bosses. Pompey had carried out his mission to put the East in order with notable success, but after his return to Italy and his disbandment of his army in 62, the Senate had thwarted him—particularly by preventing him from securing land allotments for his veterans. Caesar, who had assiduously cultivated Pompey's friendship, now entered into a secret pact with him. Caesar's master stroke was to persuade Crassus to join the partnership, the so-called first triumvirate. Crassus—like Pompey, a former lieutenant of Sulla—had been one of the most active of Pompey's obstructors so far. Only Caesar, on good terms with both, was in a position to reconcile them. Early in 59, Pompey sealed his alliance with Caesar by marrying Caesar's only child, Julia. Caesar married Calpurnia, daughter of Lucius Piso, who became consul in 58.

As consul, Caesar introduced a bill for the allotment of Roman public lands in Italy, on which the first charge was to be a provision for Pompey's soldiers. The bill was vetoed by three tribunes of the plebs, and Caesar's colleague Bibulus announced his intention of preventing the transaction of public business by watching the skies for portents whenever the public assembly was convened. Caesar then cowed the opposition by employing some of Pompey's veterans to make a riot, and the distribution was carried out. Pompey's settlement of the East was ratified *en bloc* by an act negotiated by an agent of Caesar, the tribune of the plebs Publius Vatinius. Caesar himself initiated a noncontroversial and much-needed act for punishing misconduct by governors of provinces.

Another act negotiated by Vatinius gave Caesar Cisalpine Gaul (between the Alps, the Apennines, and the Adriatic) and Illyricum. His tenure was to last until Feb. 28, 54. When the governor-designate of Transalpine Gaul suddenly died, this province, also, was assigned to Caesar at Pompey's instance. Cisalpine Gaul gave Caesar a military recruiting ground; Transalpine Gaul gave him a springboard for conquests beyond Rome's northwest frontier.

Caesar's Roman strategy

Between 58 and 50, Caesar conquered the rest of Gaul up to the left bank of the Rhine and subjugated it so effectively that it remained passive under Roman rule throughout the Roman civil wars between 49 and 31. This achievement was all the more amazing, considering that the Romans did not possess any great superiority in military equipment over the north European barbarians. Indeed, the Gallic cavalry was probably superior to the Roman, horseman for horseman. Rome's military superiority lay in strategy, tactics, discipline, and military engineering. In Gaul, Rome also had the advantage of being able to deal separately with dozens of relatively small, independent states. Caesar conquered these piecemeal, and the concerted attempt made by a number of them in 52 to shake off the Roman yoke came too late.

Great though this achievement was, its relative importance in Caesar's career and in Roman history has been overestimated in Western tradition (as have his brief raids on Britain). In Caesar's mind his conquest of Gaul was probably carried out only a means to his ultimate end. He was acquiring the military manpower, the plunder, and the prestige that he needed to secure a free hand for the prosecution of the task of reorganizing the Roman state and the rest of the Greco-Roman world. This final achievement of Caesar's looms much larger than his conquest of Gaul, when it is viewed in the wider setting of world history and not just in the narrower setting of the Greco-Roman civilization's present daughter civilization in the West.

In 58 Rome's northwestern frontier, established in 125, ran from the Alps down the left bank of the upper Rhône River to the Pyrenees, skirting the southeastern foot of the Cévennes and including the upper basin of the Garonne River without reaching the Gallic shore of the Atlantic. In 58 Caesar intervened beyond this line, first to drive back the Helvetii, who had been migrating westward from their home in what is now central Switzerland. He then crushed Ariovistus, a German soldier of fortune from beyond the Rhine. In 57 Caesar subdued the distant and warlike Belgic group of Gallic peoples in the north, while his lieutenant Publius Licinius Crassus subdued what are now the regions of Normandy and Brittany.

In 56 the Veneti, in what is now southern Brittany, started a revolt in the northwest that was supported by the still unconquered Morini on the Gallic coast of the Straits of Dover and the Menapii along the south bank of the lower Rhine. Caesar reconquered the Veneti with some difficulty and treated them barbarously. He could not finish off the conquest of the Morini and Menapii before the end of the campaigning season of 56; and in the winter of 56–55 the Menapii were temporarily expelled from their home by two immigrant German peoples, the Usipetes and Tencteri. These peoples were exterminated by Caesar in 55. In the same year he bridged the Rhine just below Koblenz to raid Germany on the other side of the river, and then crossed the Channel to raid Britain. In 54 he raided Britain again and subdued a serious revolt in northeastern Gaul. In 53 he subdued further revolts in Gaul and bridged the Rhine again for a second raid.

Vercingetorix

The crisis of Caesar's Gallic war came in 52. The peoples of central Gaul found a national leader in the Arvernian Vercingetorix. They planned to cut off the

Roman forces from Caesar, who had been wintering on the other side of the Alps. They even attempted to invade the western end of the old Roman province of Gallia Transalpina. Vercingetorix wanted to avoid pitched battles and sieges and to defeat the Romans by cutting off their supplies—partly by cavalry operations and partly by "scorched earth"—but he could not persuade his countrymen to adopt this painful policy wholeheartedly.

The Bituriges insisted on standing siege in their town Avaricum (Bourges), and Vercingetorix was unable to save it from being taken by storm within one month. Caesar then besieged Vercingetorix in Gergovia near modern Clermont-Ferrand. A Roman attempt to storm Gergovia was repulsed and resulted in heavy Roman losses—the first outright defeat that Caesar had suffered in Gaul. Caesar then defeated an attack on the Roman army on the march and was thus able to besiege Vercingetorix in Alesia, to the northwest of Dijon. Alesia, like Gergovia, was a position of great natural strength, and a large Gallic army came to relieve it; but this army was repulsed and dispersed by Caesar, and Vercingetorix then capitulated.

During the winter of 52–51 and the campaigning season of 51, Caesar crushed a number of sporadic further revolts. The most determined of these rebels were the Bellovaci, between the rivers Seine and Somme, around Beauvais. Another rebel force stood siege in the south in the natural fortress of Uxellodunum (perhaps the Puy d'Issolu on the Dordogne) until its water supply gave out. Caesar had the survivors' hands cut off. He spent the year 50 in organizing the newly conquered territory. After that, he was ready to settle his accounts with his opponents at home.

Antecedents and outcome of the civil war of 49–45. During his conquest of Gaul, Caesar had been equally busy in preserving and improving his position at home. He used part of his growing wealth from Gallic loot to hire political agents in Rome.

Dissolution of the triumvirate

Meanwhile the cohesion of the triumvirate had been placed under strain. Pompey had soon become restive toward his alarmingly successful ally Caesar, as had Crassus toward his old enemy Pompey. The alliance was patched up in April 56 at a conference at Luca (Lucca), just inside Caesar's province of Cisalpine Gaul. It was arranged that Pompey and Crassus were to be the consuls for 55 and were to get laws promulgated prolonging Caesar's provincial commands for another five years and giving Crassus a five-year term in Syria and Pompey a five-year term in Spain. These laws were duly passed. Crassus was then eliminated by an annihilating defeat at the Parthians' hands in 53. The marriage link between Pompey and Caesar had been broken by Julia's death in 54. After this, Pompey irresolutely veered further and further away from Caesar, until, when the breach finally came, Pompey found himself committed to the nobility's side, though he and the nobility never trusted each other.

The issue was whether there should or should not be an interval between the date at which Caesar was to resign his provincial governorships and, therewith, the command over his armies and the date at which he would enter his proposed second consulship. If there were to be an interval, Caesar would be a private person during that time, vulnerable to attack by his enemies; if prosecuted and convicted, he would be ruined politically and might possibly lose his life. Caesar had to make sure that, until his entry on his second consulship, he should continue to hold at least one province with the military force to guarantee his security.

This issue had already been the object of a series of political manoeuvres and countermanoeuvres at Rome. The dates on which the issue turned are all in doubt. As had been agreed at Luca in 56, Caesar's commands had been prolonged for five years, apparently until Feb. 28, 49, but this is not certain. In 52, a year in which Pompey was elected sole consul and given a five-year provincial command in Spain, Caesar was allowed by a law sponsored by all ten tribunes to stand for the consulship *in absentia*. If he were to stand in 49 for the consulship for 48, he would be out of office, and therefore in danger, during the last ten months of 49. As a safeguard for Caesar against this, there seems to have been an understanding—possibly a private one at Luca in 56 between him and Pompey—that the question of a successor to Caesar in his commands should not be raised in the Senate before March 1, 50. This manoeuvre would have ensured that Caesar would retain his commands until the end of 49. However, the question of replacing Caesar was actually raised in the Senate a number of times from 51 onward; each time Caesar had the dangerous proposals vetoed by tribunes of the plebs who were his agents—particularly Gaius Scribonius Curio in 50 and Mark Antony in 49.

The issue was brought to a head by one of the consuls for 50, Gaius Claudius Marcellus. He obtained resolutions from the Senate that Caesar should lay down his command (presumably at its terminal date) but that Pompey should not lay down his command simultaneously. Curio then obtained on Dec. 1, 50, a resolution (by 370 votes to 22) that both men should lay down their commands simultaneously. Next day Marcellus (without authorization from the Senate) offered the command over all troops in Italy to Pompey, together with the power to raise more; and Pompey accepted. On Jan. 1, 49, the Senate received from Caesar a proposal that he and Pompey should lay down their commands simultaneously. Caesar's message was peremptory, and the Senate resolved that Caesar should be treated as a public enemy if he did not lay down his command "by a date to be fixed."

Caesar crosses the Rubicon

On Jan. 10–11, 49, Caesar led his troops across the little river Rubicon, the boundary between his province of Cisalpine Gaul and Italy proper. He thus committed the first act of war. This was not, however, the heart of the matter. The actual question of substance was whether the misgovernment of the Greco-Roman world by the Roman nobility should be allowed to continue or whether it should be replaced by an autocratic regime. Either alternative would result in a disastrous civil war. The subsequent partial recuperation of the Greco-Roman world under the principate suggests, however, that Caesarism was the lesser evil.

The civil war was a tragedy, for war was not wanted either by Caesar or by Pompey or even by a considerable part of the nobility, while the bulk of the Roman citizen body ardently hoped for the preservation of peace. By this time, however, the three parties that counted politically were all entrapped. Caesar's success in building up his political power had made the champions of the old regime so implacably hostile to him that he was now faced with a choice between putting himself at his enemies' mercy or seizing the monopoly of power at which he was accused of aiming. He found that he could not extricate himself from this dilemma by reducing his demands, as he eventually did, to the absolute minimum required for his security. As for Pompey, his growing jealousy of Caesar had led him so far toward the nobility that he could not come to terms with Caesar again without loss of face.

The first bout of the civil war moved swiftly. In 49 Caesar drove his opponents out of Italy to the eastern side of the Straits of Otranto. He then crushed Pompey's army in Spain. Toward the end of 49, he followed Pompey across the Adriatic and retrieved a reverse at Dyrrachium by winning a decisive victory at Pharsalus on Aug. 9, 48. Caesar pursued Pompey from Thessaly to Egypt, where he was murdered by an officer of King Ptolemy. Caesar wintered in Alexandria, fighting with the populace and dallying with Queen Cleopatra. In 47 he fought a brief local war in northeastern Anatolia with Pharnaces, king of the Cimmerian Bosporus, who was trying to regain his father Mithradates' kingdom of Pontus. Caesar's famous words, *Veni, vidi, vici* ("I came, I saw, I conquered"), are his own account of this campaign.

Caesar then returned to Rome, but a few months later,

now with the title of dictator, he left for Africa, where his opponents had rallied. In 46 he crushed their army at Thapsus and returned to Rome, only to leave in November for Farther Spain to deal with a fresh outbreak of resistance, which he crushed on March 17, 45, at Munda. He then returned to Rome to start putting the Greco-Roman world in order. He had less than a year's grace for this huge task of reconstruction before his assassination in the Senate House at Rome on March 15, 44 (the Ides of March).

Caesar's death

Caesar's death was partly due to his clemency and impatience, which, in combination, were dangerous for his personal security. Caesar had not hesitated to commit atrocities against "barbarians" when it had suited him, but he was almost consistently magnanimous in his treatment of his defeated Roman opponents. Thus clemency was probably not just a matter of policy. Caesar's earliest experience in his political career had been Sulla's implacable persecution of his defeated domestic opponents. Caesar amnestied his opponents wholesale and gave a number of them responsible positions in his new regime. Gaius Cassius Longinus, who was the moving spirit in the plot to murder him, and Marcus Junius Brutus, the symbolic embodiment of Roman republicanism, were both former enemies. *Et tu, Brute* ("You too, Brutus") was Caesar's expression of his particular anguish at being stabbed by a man whom he had forgiven, trusted, and loved.

There were, however, also a number of ex-Caesareans among the 60 conspirators. They had been goaded into this volte-face by the increasingly monarchical trend of Caesar's regime and, perhaps at least as much, by the aristocratic disdain that inhibited Caesar from taking any trouble to sugar the bitter pill. Some stood to lose, rather than to gain, personally by the removal of the autocrat who had made their political fortunes. But even if they were acting on principle, they were blind to the truth that the reign of the Roman nobility was broken beyond recall and that even Caesar might not have been able to overthrow the *ancien régime* if its destruction had not been long overdue. They also failed to recognize that by making Caesar a martyr they were creating his posthumous political fortune.

If Caesar had not been murdered in 44, he might have lived on for 15 or 20 years. His physical constitution was unusually tough, though in his last years he had several epileptic seizures. What would he have done with this time? The answer can only be guessed from what he did do in the few months available. He found time in the year 46 to reform the Roman calendar. In 45 he enacted a law laying down a standard pattern for the constitutions of the *municipia*, which were by this time the units of local self-government in most of the territory inhabited by Roman citizens. In 59 Caesar had already resurrected the city of Capua, which the republican Roman regime more than 150 years earlier had deprived of its juridical corporate personality; he now resurrected the other two great cities, Carthage and Corinth, that his predecessors had destroyed. This was only a part of what he did to resettle his discharged soldiers and the urban proletariat of Rome. He was also generous in granting Roman citizenship to aliens. (He had given it to all of Cisalpine Gaul, north of the Po, in 49.) He increased the size of the Senate and made its personnel more representative of the whole Roman citizenry.

At his death, Caesar was on the point of starting out on a new military campaign to avenge and retrieve Crassus' disastrous defeat in 53 by the Parthians. Would Caesar have succeeded in recapturing for the Greco-Roman world the extinct Seleucid monarchy's lost dominions east of the Euphrates, particularly Babylonia? The fate of Crassus' army had shown that the terrain in northern Mesopotamia favoured Parthian cavalry against Roman infantry. Would Caesar's military genius have outweighed this handicap? And would Rome's hitherto inexhaustible reservoir of military manpower have sufficed for this additional call upon it? Only guesses are possible, for Caesar's assassination condemned the Romans to another 13 years of civil war, and Rome would never again possess sufficient manpower to conquer and hold Babylonia.

PERSONALITY AND REPUTATION

Caesar was not and is not lovable. His generosity to defeated opponents, magnanimous though it was, did not win their affection. He won his soldiers' devotion by the victories that his intellectual ability, applied to warfare, brought them. Yet, though not lovable, Caesar was and is attractive, indeed fascinating. His political achievement required ability, in effect amounting to genius, in several different fields, including administration and generalship besides the minor arts of wire pulling and propaganda.

In all these, Caesar was a supreme virtuoso. But if he had not also been something more than this he would not have been the supremely great man that he undoubtedly was.

Caesar was great beyond—and even in conflict with—the requirements of his political ambition. He showed a human spiritual greatness in his generosity to defeated opponents, which was partly responsible for his assassination. (The merciless Sulla abdicated and died in his bed.)

Speeches and writings

Another field in which Caesar's genius went far beyond the requirements of his political ambition was his writings. Of these, his speeches, letters, and pamphlets are lost. Only his accounts (both incomplete and supplemented by other hands) of the Gallic War and the civil war survive. Caesar ranked as a masterly public speaker in an age in which he was in competition first with Hortensius and then with Cicero.

All Caesar's speeches and writings, lost and extant, apparently served political purposes. He turned his funeral orations for his wife and for his aunt to account, for political propaganda. His accounts of his wars are subtly contrived to make the unsuspecting reader see Caesar's acts in the light that Caesar chooses. The accounts are written in the form of terse, dry, factual reports that look impersonal and objective, yet every recorded fact has been carefully selected and presented. As for the lost *Anticato*, a reply to Cicero's eulogy of Caesar's dead opponent Marcus Porcius Cato, it is a testimony to Caesar's political insight that he made the time to write it, in spite of the overwhelming military, administrative, and legislative demands on him. He realized that Cato, in giving his life for his cause (46), had made himself posthumously into a much more potent political force than he had ever been in his lifetime. Caesar was right, from his point of view, to try to put salt on Cato's tail. He did not succeed, however. For the next 150 years, Cato the martyr continued to be a nuisance, sometimes a menace, to Caesar's successors.

The mark of Caesar's genius in his writings is that though they were written for propaganda they are nevertheless of outstanding literary merit. A reader who has seen through their prosaic purpose can ignore it and appreciate them as splendid works of art.

Caesar's most amazing characteristic is his energy, intellectual and physical. He prepared his seven books on the Gallic War for publication in 51 when he still had serious revolts in Gaul on his hands, and he wrote his books on the civil war and his *Anticato* in the hectic years between 49 and 44. His physical energy was of the same order. For instance, in the winter of 57–56 he found time to visit his third province, Illyria, as well as Cisalpine Gaul; and in the interval between his campaigns of 55 and 54 he transacted public business in Cisalpine Gaul and went to Illyria to settle accounts with the Pirustae, a turbulent tribe in what is now Albania. In 49 he marched, within a single campaigning season, from the Rubicon to Brundisium and from Brundisium to Spain. At Alexandria, probably aged 53, he saved himself from sudden death by his prowess as a swimmer.

Caesar's physical vitality perhaps partly accounts for his sexual incontinence. His sexual escapades were out of the ordinary, even by contemporary Greek and Roman

standards. It was rumoured that, during his first visit to the East, he had had homosexual relations with King Nicomedes of Bithynia. The rumour is credible, though not proved, and was repeated throughout Caesar's life. There is no doubt of Caesar's heterosexual affairs, many of them with married women. Probably Caesar looked upon these as trivial recreations. Yet he involved himself at least twice in escapades that might have wrecked his career. If he did in fact have an affair with Pompey's wife, Mucia, he was risking his entente with Pompey. A more notorious, though not quite so hazardous, affair was his liaison with Cleopatra. By dallying with her at Alexandria, he risked the loss of what he had just won at Pharsalus. By allowing her to visit him in Rome in 46, he flouted public feeling and added to the list of tactless acts that, cumulatively, goaded old comrades and amnestied enemies into assassinating him.

Caesar's achievement

This cool-headed man of genius with an erratic vein of sexual exuberance undoubtedly changed the course of history at the western end of the Old World. By liquidating the scandalous and bankrupt rule of the Roman nobility, he gave the Roman state—and with it the Greco-Roman civilization—a reprieve that lasted for more than 600 years in the East and for more than 400 years in the relatively backward West. Caesar substituted for the Roman oligarchy an autocracy that could never afterward be abolished. If he had not done this when he did it, Rome and the Greco-Roman world might have succumbed, before the beginning of the Christian era, to barbarian invaders in the West and to the Parthian Empire in the East. The prolongation of the life of the Greco-Roman civilization had important historical effects. Under the Roman Empire the Near East was impregnated with Hellenism for six or seven more centuries. But for this, the Hellenic element might not have been present in sufficient strength to make its decisive impact on Christianity and Islām. Gaul, too, would have sunk deeper into barbarism when the Franks overran it, if it had not been associated with the civilized Mediterranean world for more than 500 years as a result of Caesar's conquest.

Caesar's political achievement was limited. Its effects were confined to the western end of the Old World and were comparatively short-lived by Chinese or ancient Egyptian standards. The Chinese state founded by Shih Huang Ti in the 3rd century BC still stands, and its future may be still greater than its past. Yet, even if Caesar were to prove to have been of lesser stature than this Chinese colossus, he would still remain a giant by comparison with the common run of human beings (see also ROME, HISTORY OF).

MAJOR WORKS

Military Commentaries: in seven books, *Commentarii de bello Gallico*, covering the years 58–52 BC, written in 52–51 BC (*The Gallic War*, 1917); in three books, *Commentarii de bello civili*, covering the year 49–48 BC, written probably in 45 BC (*The Civil Wars*, 1914; *Caesar's War Commentaries*, 1953).

De bello Alexandrino (*The Alexandrian War*, 1955); *De bello Africo* (*The African War*, 1955); and *De bello Hispaniensi* (*The Spanish War*, 1955), though ascribed by the manuscripts of Caesar, are generally regarded as of uncertain authorship. Caesar's speeches, letters, and pamphlets are all lost.

A translation of Caesar's works is available in the Loeb series (1914–55), and in the Penguin Classics series (1951 and 1967).

BIBLIOGRAPHY

Ancient works: CAESAR, *De bello Gallico*, books i-vii (Book viii, covering events of 51 BC, was written after Caesar's death by AULUS HIRTIUS), ed. by T. RICE HOLMES (1914); *De bello civili*, books i-iii. The *Bellum Alexandrinium* (the wars of 47 BC), ed. by F. KRANER *et al.*, 12th ed. (1959), *De bello Africo*, and *De bello Hispaniensi* are all anonymous but contemporary with Caesar and included with his works; CICERO, various letters and speeches (see CICERO, MARCUS TULLIUS: *Bibliography*); SALLUST, *Epistulae ad Caesarem* (the authenticity of these two memoranda addresses to Caesar has, however, been questioned); APPIAN, *Civil Wars*, book ii; CASSIUS DIO, books XXXVII–XLIV; PLUTARCH, *Lives of Caesar, Pompey, and Crassus;* SUETONIUS, *Divus Julius;* VELLEIUS PATERCULUS, ii, 41–56.

Modern works: THEODOR MOMMSEN, *Römische Geschichte*, 3 vol. (1854–56; Eng. trans., *The History of Rome*, vol. 4–5, rev. ed., 1895); G. FERRERO, *Grandezza e decadenza di Roma*, 5 vol. (1902–07; Eng. trans., *The Greatness and Decline of Rome*, vol. 1–2, 1907–09); T.R.E. HOLMES, *Caesar's Conquest of Gaul*, 2nd ed. (1911), and *Ancient Britain and the Invasions of Julius Caesar*, esp. ch. 6–8, 2nd ed. (1936); E. MEYER, *Caesars Monarchie und das Principat des Pompejus*, 3rd ed. (1922); M. CARY *et al.*, in *Cambridge Ancient History*, vol. 9, ch. 11–13 and 15–18 (1932); J. CARCOPINO, *Histoire romaine*, vol. 2, *César*, 2nd ed. (1940); R. SYME, *The Roman Revolution* (1939); L.R. TAYLOR, *Party Politics in the Age of Caesar* (1949); M. GELZER, *Caesar: Der Politiker und Staatsmann*, 6th ed. (1960; Eng. trans., *Caesar: Politician and Statesman*, 1968); and A.H. MCDONALD, *Republican Rome* (1966).

(A.J.T.)

Cairo

Cairo (al-Qāhirah, meaning "Victorious"), capital of Egypt, with at least 5,500,000 inhabitants, is the largest city in Africa and the eighth largest city in the world. This ancient metropolis (over 1,000 years on the same site with the same name) stands on the banks of the Nile, primarily on the eastern shore, some 500 miles downstream from the Aswān High Dam, and just before the lower Nile separates into the Rosetta and Damietta branches.

The environment

Cairo is a place of vivid contrasts. Along the well-irrigated shoreline, lush tropical vegetation, tall palms, flowering flame trees, and white skyscrapers are profiled against a cloudless sky; the older inland quarters to the east, beneath the foothills of the Arabian Desert and the rocky promontories of the Muqaṭṭam Hills and the Red Mountain (al-Jabal al-Aḥmar, with its petrified forest), are brown and ochre coloured. The typical desert climate contrasts daytime dry heat (summer highs, 90°–110° F) with cool summer nights (65°–75° F) freshened by Nile breezes. During the brief winter, days are warmed by the strong Tropic of Cancer sun, but nights are quite cool and often damp. A healthful climate has long made Cairo a renowned winter resort.

The city juxtaposes ancient and new, East and West. The Great Pyramids near Memphis stand at the southwestern edge of the metropolis, and an obelisk in the northeast marks the site of Heliopolis (where Plato once studied); the newest landmark is the elegant, air-conditioned Sheraton Hotel overlooking the Nile from the western bank. Between these extremes are other architectural monuments dating from Roman, Arab, and Turkish times. In addition to department stores, cinemas, hotels, and town houses, Cairo contains a large functioning bazaar and an extensive medieval city liberally endowed with over 400 registered historic monuments (mosques, mausoleums, crenelated walls, and massive gateways) dating from AD 130 to the early 19th century—the largest number in any African or Middle Eastern city.

Inhabitants are equally diverse. Africans, Turks, and Arabs have long mingled at this geographic crossroad. Unsophisticated peasants from the rural hinterland pass bankers, lawyers, and turbanned shaykhs. Some workers run steel mills and textile factories, while others hand hammer and inlay delicate metal trays in tiny workshops. A small proportion of women still veil, wrapped in voluminous black cloaks; others wear Parisian miniskirts. The crowded streets form a common meeting ground for all these various elements.

HISTORY

Although ruined Memphis, 14 miles south of Cairo, was a metropolis 5,000 years ago, and about 2,000 years ago the Romans occupied a town on the site of Cairo called Babylon (now the Miṣr al-Qadīmah quarter), the seed from which contemporary Cairo sprang was the town of Fusṭāṭ, founded at Babylon in AD 641 by ʿAmr ibn al-ʿĀṣ, commander of the Arabs who brought Islām to Egypt. Successor dynasties added royal suburbs (al-ʿAskar, founded in 750 by the Umayyads; al-Qaṭāʾiʿ, founded in

The Mosque of as-Sultān Hasan, built c. 1361, with modern Cairo in the background.
Annan Photo Features

870 by Aḥmad ibn Ṭūlūn) to the increasingly prosperous commercial and industrial port city of al-Fusṭāṭ. Today, little remains of these early developments in the southern part of the city, except the tower of Trajan (AD 130), the mosques of ʿAmr ibn al-ʿĀṣ (641) and Aḥmad ibn Ṭūlūn (878), and the partially excavated mounds covering the site of al-Fusṭāṭ.

In 969 adherents of a dissident Islāmic sect, the Fāṭimids, invaded Egypt from what is now Tunisia. The conquering general, Jawhar, established a new rectangular walled city northeast of existing settlements. Initially named al-Manṣūrīyah, the city was rechristened al-Qāhirah in 973–974 when the Fāṭimid caliph al-Muʿizz arrived to make it the capital of a dynasty that lasted for 200 years. Al-Qāhirah and al-Fusṭāṭ coexisted until 1168, when unfortified al-Fusṭāṭ was set on fire to protect Cairo from the crusaders. The crusaders were driven off by a Sunnī (orthodox Islāmic) army from Syria, after which the victorious commander, Saladin, founded the Ayyūbid dynasty, which controlled a vast empire from Cairo.

The Mamlūk era

Even though al-Fusṭāṭ was partially rebuilt, Cairo itself became transformed from a royal enclave into an imperial metropolis. Saladin further extended the 11th-century walls built by a high official called Badr al-Jamālī (the northern and southern walls and three main gates, Bāb al-Futuḥ, Bāb an-Naṣr, and Bāb Zuwaylah, are still extant) and constructed a citadel on the Muqaṭṭam spur (now dominated by the Muḥammad ʿAlī Mosque). After 1260, when Baybars I became the first Mamlūk sultan of undisputed legitimacy, Cairo served as the capital of the Mamlūk empire, which governed Egypt and the Fertile Crescent until 1516.

Medieval Cairo reached its apogee during the Mamlūk era. By about 1340, almost 500,000 persons lived in an area five times greater than the original Fāṭimid walled city, and Cairo had become the greatest city of Africa, Europe, and Asia Minor. Its al-Azhar University was the principal seat of Islāmic learning. The city was a key link in the profitable East–West spice trade, and the recipient of tribute from a wealthy empire. Most of Cairo's greatest architectural masterpieces were built during this epoch.

Decline set in thereafter—sporadically at first, and then precipitously. The population was decimated by plagues, including the Black Death in 1348. Timur Lenk (Tamerlane) ravaged the eastern frontier in about 1400. The spice trade monopoly was broken by Vasco da Gama's voyage to India (1498). Finally, political autonomy was lost to the conquering Turks, who, after 1517, reduced Cairo to a provincial capital. In 1798 when Napoleon's campaigns brought him to Cairo, less than 300,000 people were living in the city and its two port suburbs, Miṣr al-Qadīmah and Būlāq. The Turks returned after Napolean's defeat in 1801. In 1805 Muḥammad ʿAli, commander of an Albanian contingent, was appointed pasha, thus founding the dynasty that ruled Egypt until his great great grandson, Farouk I, abdicated in 1952.

Modern urban growth began in the 1830s, but only in the reign of Ismāʿīl (1863–79) was the city fundamentally transformed. Eager to westernize Cairo and influenced by Baron Haussmann's renovation of Paris, Ismāʿīl ordered the construction of a European-style city to the west of the medieval core. French city-planning methods dominated the design of the districts of Azbakīyah (with its new park), ʿAbdīn, and Ismāʿīlīyah—all now central zones of contemporary Cairo. By the end of the century these districts were well developed, but with the rise of British hegemony from 1882 onward, they became transformed into a colonial enclave. Following the overthrow of the monarchy in 1952, however, the number and power of foreign residents declined.

During the 20th century, Cairo grew spectacularly in both population and area. Transport improvements fostered the growth of suburban Heliopolis and al-Maʿādī; flood control permitted riverfront development; bridges encouraged settlement of islands (Rawḍah and az-Zamālik) and of the western bank. By midcentury the city was primarily growing northward into the fertile Delta, a trend further encouraged by industrialization. The most recent postrevolution addition to Cairo is Naṣr City, a planned community reclaimed from the desert near Heliopolis, which eventually should house 500,000 residents.

THE CONTEMPORARY CITY

Cairo is fan-shaped, narrowest in the south, where the river valley is wedged between desert escarpments, widest in the north, where the valley blends into the Delta. Expansion into the desert is blocked by terrain and by the expense of irrigation. Over the centuries the city grew toward the river, on the newly flood-free land left by a receding river channel. Recently, however, under the stimulus of industrial development, the city has been elongating north and south.

The governorate (*muḥāfaẓah*) of Cairo is one of 25 major districts into which Egypt is administratively divided. The boundaries of the governorate do not encompass the entire urbanized area of the metropolis and include some agricultural zones. Ḥulwān, an industrial satellite in the extreme south, is included, but the industrial satellites in the far north (Shubrā al-Khaymah, etc.) and the developed western bank are excluded. Between 500,000 and 1,000,000 people live in the urbanized area outside the governorate boundaries.

Sectors of the city

The organization of the metropolitan complex is understandable only in the context of the city's history. The three oldest areas constitute an interior slum virtually surrounding the westernized core. The largest of these is the Fāṭimid city with its pre-19th-century extensions (al-Jamālīyah, ad-Darb al-Aḥmar, Bāb ash-Sharʿīyah, eastern as-Sayyidah Zaynab, northern al-Khalīfah). In this densely settled zone containing the oldest buildings are most of Cairo's historic monuments, from the Mosque of Baybars I at the northern edge to Saladin's Citadel in the south. Among the major bazaars near al-Azhar Mosque in the central walled city are the Khān al-Khalīlī (1390) and the markets for gold articles, copper ware, textiles, rugs, amber, spices, and leather goods. Two major thoroughfares run north–south: Muʿizz li-Dīn Allāh, which bisects the old city and contains the major mosques and markets; and Khalīj Street (now Port Said), which runs along the bed of an ancient canal that once marked the western border of Fāṭimid Cairo. Only two streets connect the old city with the modern central business district: Mūski Street (built in the 19th century) and al-Azhar Street (1931). A final diagonal links the central business district with the Citadel Qalaʿah Street, formerly Boulevard Muḥammad ʿAlī, built in 1874. Most other streets are narrow, twisting, and often dead end. Motor vehicles are confined to major thoroughfares.

The two older quarters are Būlāq and Miṣr al-Qadīmah (al-Fusṭāṭ), formerly port suburbs of Cairo. Būlāq, an island until 1340 and the main port by 1560, became an industrial quarter in the early 19th century. It contains small workshops, the National Press, textile factories, and trade schools. A poor population, including many village migrants, is housed there at extremely high densities (about 260,000 persons per square mile). The mosques of Abū al-ʿAlā' and Sinān Pasha are among the few historic buildings remaining. Miṣr al-Qadīmah is an even poorer quarter, although only a small section is ancient. The walled compound of Babylon, with its semi-submerged Roman bastion, its Coptic churches and museum, and its ancient synagogue and houses, is virtually intact, as is the reconstructed ʿAmr Mosque nearby. The area is inhabited by extremely poor town dwellers, by potters whose simple kilns overlook ruined al-Fusṭāṭ, and by farmers tilling the rich alluvial soil between Cairo and Ḥulwān. Only suburban al-Maʿādī, built by the British, interposes a contemporary note.

In sharp contrast is the modern downtown area of Cairo (Azbakīyah) and the elegant associated commercial-residential sections of Ismāʿīlīyah, Qaṣr an-Nīl, and Garden City, which stretch between the old city and the Nile and spread onto the island of az-Zamālik just offshore. Particularly along the river, near the Qaṣr an-Nīl bridge (still flanked by statues of lions placed there in Ismāʿīl Pasha's time) is situated the district that constitutes the "showcase" of Cairo. The major thoroughfare is the Corniche, a highway paralleling the river, built since the overthrow of the monarchy. From north to south are aligned the imposing Television Building, the Cathedral, the Baladīyah (Municipality) Building, the Nile Hilton Hotel (with the Egyptian Museum standing behind it), and the Semiramis and Shepheard's hotels. Also in the vicinity are the intricately curved streets of Garden City, lined with tall apartment houses. Az-Zamālik, opposite the Corniche, is the site of hotels, the new Cairo Tower, gardens, a racetrack, and sporting and officers' clubs, as well as elegant housing.

Between the imposing Nile front and the ancient inland quarters is a transitional zone (al-Mūski, Bāb al-Lūq, eastern ʿAbdīn, an-Naṣrīyah, al-Ḥilmīyah) of lower middle class status. Chiefly developed in the 19th century, it contains the National Library, the Museum of Islāmic Art, and the ʿAbdīn Palace Museum and archives.

"The City of the Dead"

Along the eastern edge of the metropolis are extensive cemeteries—a zone known as "the City of the Dead," which has no counterpart outside Egypt. In a vast, dusty, ochre-coloured zone unserviced by municipal utilities are to be found exquisite shrine-mosques and mausoleums of early religious leaders (such as that of Imām ash-Shāfiʿī, an al-Fusṭāṭ resident and founder of Egypt's major legal tradition) and of Mamlūk sultans (among the most beautiful are the memorials of Qā'it Bāy, Barqūq, and Qalā'un). More modest and recent structures are also found here. Particularly since the population increase that occurred during World War II, housing, shops, etc., have been added to "the City of the Dead." About 100,000 Cairenes now live there, for the most part without government sanction.

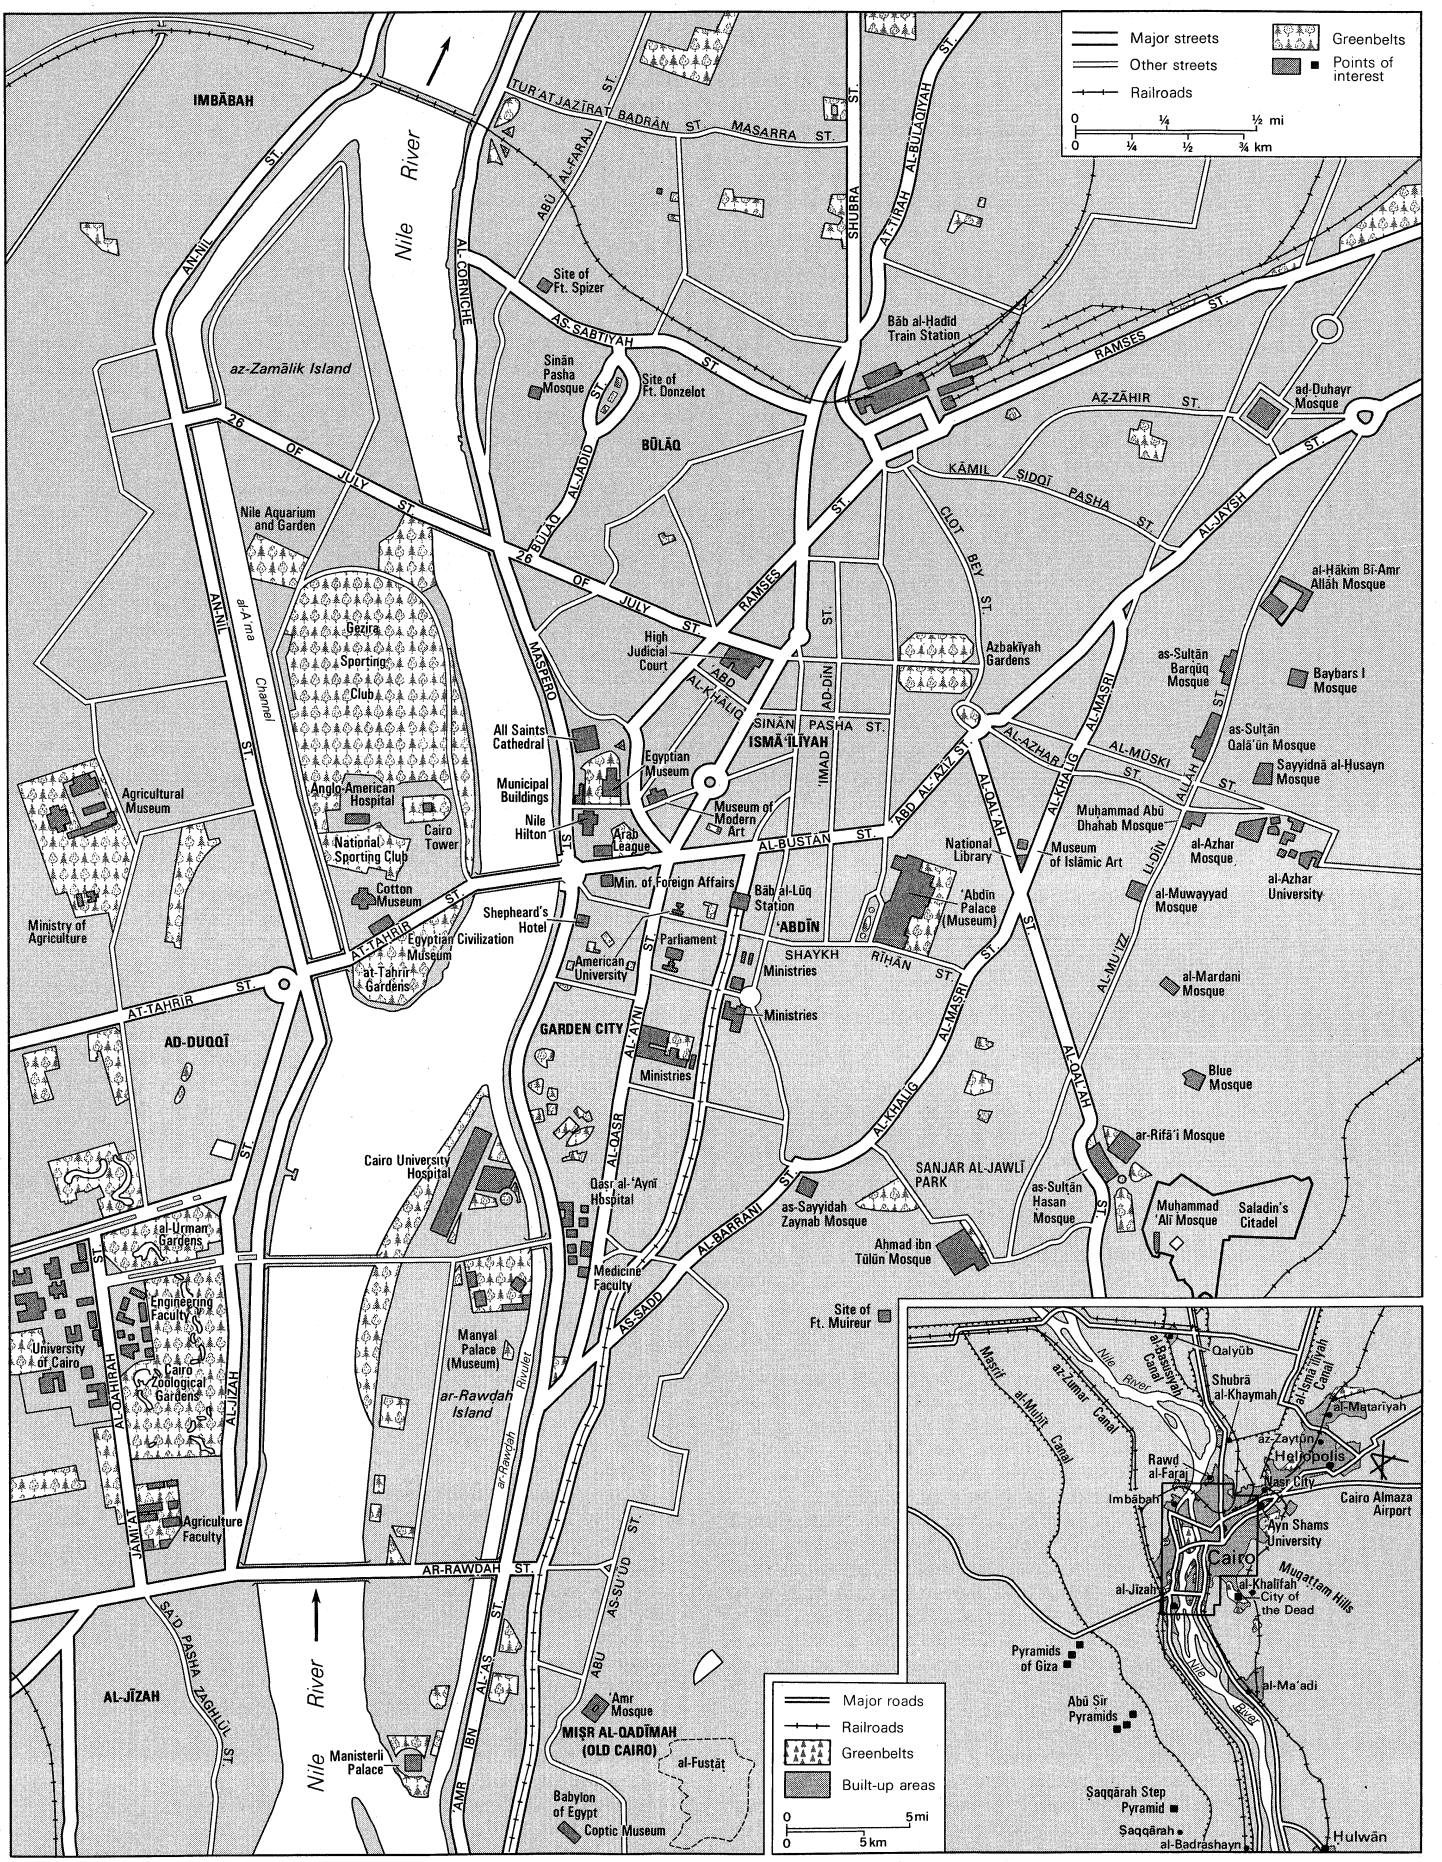
The northern and western peripheries have been growing dramatically in recent decades, and most of Cairo's population now lives in these newer quarters. On the west bank, and on the island of Rawḍah, land has been converted from agricultural to urban use. In these areas are located developed residential quarters (ad-Duqqī, and al-Jīzah or Giza), the Zoological and Botanical Gardens, the Agricultural Museum, and the campus of the University of Cairo. Large-scale housing projects built here include the Workers' City in Imbābah (1950), as well as Madīnāt al-Muhandisīn (Engineers' City), and Madīnat al-Awqāf (Waqf City), both begun in the 1960s. Expansion has also taken place to the north. Beginning about 1905 but expanding substantially in the 1920s, the northern quarters of Rawḍ al-Faraj, Shubra, Sharabīyah, al-Qubbah, al-ʿAbbāsīyah, al-Maṭarīyah, az-Zaytūn, and Miṣr al-Jadīdah (Heliopolis) gained population. By 1927 they contained some 300,000 of Cairo's 1,000,000 inhabitants. Since that time urban developments have increasingly encroached on agricultural land and have been extended into the desert periphery by elaborate irrigation schemes. Heliopolis, first conceived in 1905, and Naṣr City, a new town begun in 1958, are examples of such developments. By 1960 the northern quarters contained 1,600,000 people. Income levels of the inhabitants of Rawḍ al-Faraj along the Nile are at a lower level than those living in az-Zaytūn; income levels rise still further in Shubra and are the highest in Heliopolis. A rural population still inhabits the northern fringe.

Architectural styles. Building styles in Cairo are related to the historic period during which each quarter developed. In the oldest sections, two- to four-story structures prevail, most built of fired brick covered with plaster and sometimes shored with half-timbering. Wood, being rare, is used frugally. Some of the oldest homes have windows covered with delicately turned wooden lattices (*mashrabīyah*) and massive wooden doors decorated with inlay, brass, or iron nailheads, indicating past elegance. The traditional dwellings (of which only a few remain intact) open onto fountained courtyards and have separate male and female quarters; the traditional workshops and warehouse inns (of which more have survived) have galleries overlooking the interior court.

European architectural influences

Parts of Cairo built in the 19th century reveal exaggerated European influences—highly ornate stone exteriors, cupolas, and Romanesque doorways. While this ungainly style, darkened with time, predominates in the transitional zone, perhaps the most outlandish examples are the later Palace of Sakākīnī (northeast of Baybars I Mosque) and the Hindu Versailles of Baron Empain, founder of Heliopolis.

In the more modern Western quarters, built at the turn of the century, the architectural style is Parisian; most of the moderately tall buildings are of stone or poured concrete. Closer to the Nile, and on the islands, contemporary Mediterranean style predominates. Tall reinforced concrete and glass structures with balconies are decorated with tile. In these less derivative forms, Egyptian architectural genius, so noticeable in the clean, almost stark



Cairo and (inset) its metropolitan area.

lines of the ancient temples, seems again to be re-emerging.

The monuments of the eastern cemeteries are Mamlūk in design, each topped by a plain or fluted dome; the lesser tombs are simpler rectangles. Houses there and in the rural fringe areas are habitually of mud or of crudely fired brick, resembling village housing in the hinterland.

In the newest quarters on the west and north the more elegant districts have both handsome elevator apartments and one- or two-story "villas," whose high walls enclose colourful gardens. Lower middle and working class housing consists exclusively of concrete multiflat structures, gray or yellow-beige in colour, often with shops occupying the ground floor. The poorest zones contain three- or five-story walk-ups, often of crudely fired redbrick.

Since it almost never rains, all roofs are flat. In all quarters commercial uses are scattered among the dwellings, and in the poorer quarters one also finds an occasional industrial workshop.

Demography. Previously diverse, ethnically and religiously, Cairo's population is now becoming increasingly homogeneous. Over 90 percent are Muslims, the remainder being chiefly Egyptian Christians of Coptic faith. Only a small proportion are Catholic or Protestant, and these are largely Europeans. A tiny fragment of an ancient Jewish community remains. Members of the once dominant foreign groups (English, French, Swiss, Belgian) had mostly left by 1957; the more modest Italian and Greek communities remained and have been joined by Arab nationals (Syrians, Palestinians, Sudanese), as well as by the diplomatic and technical personnel from eastern Europe. Today, differences of status within the Egyptian population depend largely on place of origin (one-third of Cairo's residents were born in rural Egypt), class, and degree of modernity.

Population growth

Cairo's total population has been growing at an ever increasing rate. It doubled during the 19th century—from 300,000 in 1800 to 600,000 by 1900. By 1930 it had almost doubled again, stimulated by the population movements of World War I and by postwar economic growth. During the next 20 years population doubled once more, exceeding 2,000,000 by 1947, again largely as a result of wartime migration. By this time the death rate had also begun to drop sharply, and to the stream of migration was added growth due to an excess of births over deaths. Cairo's population had climbed to 3,353,000 (with slightly contracted boundaries) by 1960, to 4,220,000 by 1966, and, had rates continued unchanged, would have reached 5,000,000 in 1970. The Arab–Israeli War in 1967, however, forced the evacuation of between 500,000 and 1,000,000 residents of the canal cities of Suez, Port Said, and Ismailia. Most resettled in and around Cairo, inflating the present population to between 5,000,000 and 6,000,000 in the city, and 6,000,000 to 6,500,000 in the metropolitan area.

Cairo has been growing even faster than the rapidly multiplying population of Egypt, and these trends are likely to persist for some time. Projections suggest a population of 40,000,000 for the country and over 7,000,000 for the capital city by 1980. Such a rate of growth has posed serious problems for the city.

Transportation. Cairo is served by an international airport (recently rebuilt) beyond Heliopolis and by train service to other major cities. Air-conditioned trains connect Alexandria with the Bāb al-Ḥadīd Train Station in Cairo, and there is overnight sleeper train service to Luxor and Aswān. The city itself has mass transit facilities. A metro connects suburban Heliopolis with Bāb al-Ḥadīd station, and another suburban train links al-Maʿādī with Bāb al-Lūq station in the south. Plans to link these two terminals by a subway under the central business district and also to supplement it by an underground circle route are being made. Electric tramcars, overhead-wire streetcars, and buses thread through all but the Fāṭimid quarters. Local assembly plants are making an increasing number of private automobiles available. Taxis are ubiquitous and their fares cheap. A few horse-drawn carriages are still to be seen, and carts, camels, and donkeys are sometimes seen in the old city.

Housing and public utilities. Population growth has sorely taxed Cairo's housing since World War II. Occupancy densities are high, except in the wealthy quarters. In 1947 the average number of persons per room was two; by 1960, density had reached 2.3 and is now even higher. The most pressing need is for low-cost mass housing. Before the 1952 Revolution, luxury apartment houses were an attractive investment; Cairo had no public housing except for the recently completed Workers' City, built by the Ministry of Awqāf (Charity). Since 1952 the construction of subsidized middle- and low-income housing has been vigorously undertaken. Approximately 17,000 dwelling units were added between 1960 and 1965, but an estimated 30,000 units per year are required to accommodate the growing population, replace dilapidated units, and reduce densities.

Housing development

Equally pressing is the need to expand municipal services. Gas and water systems have existed since the 1860s and electrical and sewerage systems since the early 20th century. Not all houses in the oldest quarters have yet been connected, however, and the cemetery zones are only sparsely served. Nile water is filtered and purified, and tap water is both safe and pleasant to drink. In 1965 the sewerage system was substantially renovated and its capacity enlarged.

Economic life. From its inception the economy of Cairo has been based on governmental functions, commerce, trade, and industrial production. Especially since the 1920s, the modern productive sector has expanded dramatically. Large-scale industrialization since the 1952 Revolution has built upon previous developments in textiles (utilizing the long-staple cotton for which Egypt is famous) and food processing, which consists of canning and freezing the wide variety of fruits and vegetables grown in the fertile Delta, as well as processing the tobacco and sugarcane grown in Upper Egypt. In addition to the production of iron and steel, consumer goods, such as cars, refrigerators, etc., are made. Especially since 1956 the output of a wide variety of smaller consumer goods has been increased.

Although about one-half of Cairo's predominantly male labour force now works in the expanding modern sector of the economy, both on the assembly lines and in auxiliary commercial and financial institutions, a substantial traditional sector still survives, in which craftsmanship and individual relationships play an important role.

Cairo's significance within the nation

Cairo is the primary national centre for modern economic production and financial control. In 1957, although Cairo contained only 12.5% of Egypt's population, it contained 27.4% of the nation's large-firm industrial workers, accounted for 16% of all value added through manufacturing, and consumed 48% of all electric power produced. Some 39% of all gross trade establishments, 23% of all banking firms, 39% of all brokerage houses, one-fourth of all transport and warehouse companies, and about one-third of all sports, amusement, cafés, restaurants, and hotels in the country were concentrated in Cairo. In 1960 the city had 52% of Egypt's private telephones.

Industrial expansion and concentration has nevertheless not resulted in productive employment for all of Cairo's rapidly increasing labour force. About one-third of all workers are engaged in personal services, many of which are of only dubious productivity and viability. Five-year industrialization plans are directed to mobilizing this labour force.

Administration. Before 1949 Cairo was anomalously administered by a combination of national policy makers and local administrators. In 1949 the municipality (*baladīyah*) of Cairo was created, being inaugurated, together with a town council, in 1950. In 1960 a new Ministry for Local Administration was established, after which it promulgated a uniform system for local governments. Although subsequently modified, the basic changes introduced have been retained, including the merger of the *baladīyah* with the *muḥāfaẓah* (governorate) of Cairo.

In 1960 law established a municipal council for Cairo (Majlis Muḥāfaẓah al-Qāhirah), presided over by the governor. Of the 85 members of this council, 26 plus the governor are ex officio, representing the Arab Socialist Union and various national ministries, 16 are technicians (economists, lawyers, engineers, and educators) appointed for their competence, and 42—two from each of Cairo's 21 electoral-administrative districts—are representatives elected through the Arab Socialist Union. Fiscal capacity has, however, lagged behind legal powers. The central government still maintains financial control over local programs and budgets.

Health, security, and education. The number of health and medical facilities concentrated in Cairo is in contrast to those available elsewhere in the country. There are over ten government general hospitals with a bed capacity of close to 20,000, including the enormous general hospitals of Qaṣr al-ʿAynī, Dimardash, and the mental hospital at ʿAbbāssīyah. The city is also served by numerous smaller private hospitals (such as Dūr al-Shifā', the Italian Hospital, and the Anglo-American hospital). In 1960 there were 49 decentralized public clinics and dispensaries. Recently, these have been increased in number and have taken on additional functions as birth-control centres. Special clinics and nine public hospitals are devoted to prevalent eye diseases (chiefly trachoma).

Cairo has a relatively low crime rate, and there are only some 3,000 persons incarcerated in Cairo's prisons. Fire rates are equally low, possibly due to the absence of wood-frame construction and the still low utilization of electrical appliances. A large municipal police force, mostly for traffic, and a relatively small fire protection department suffice for the city's needs.

Primary education is compulsory, and the illiteracy rate, previously extremely high, especially for females, has been rapidly reduced. In 1961 Cairo had 88 nursery schools, 794 primary schools, 260 secondary schools, 62 technical institutes, 15 pre-university superior schools, as well as 303 foreign schools (mostly with religious affiliations) providing education to various levels. The total number of students enrolled exceeded 600,000. Since then, both the number of schools and, even more, the number of pupils has risen markedly.

Higher education

Cairo is also the centre of higher education in the country and attracts students not only from Egypt but also from other Arab countries. The various faculties of the University of Cairo produce the country's largest number of college graduates and specialized professionals (doctors, lawyers, engineers). In the academic year of 1967–68, some 43,127 students were enrolled on its campuses. The second largest institution was ʿAin Shams, with an enrollment of 38,214. Both schools have increased their enrollments considerably since 1960. Al-Azhar University, which previously specialized in religious subjects and language and literature but which is being expanded to include teaching in the sciences on its new supplementary campus in Naṣr City, is the third most important university, with 21,054 students in 1966–67. The considerably smaller privately run American University in Cairo offers instruction in English in various arts and sciences.

Cultural life, mass media, and recreation. Cairo is the cultural capital of the Middle East as well as the region's chief mass media centre. For many centuries the region's major religious and cultural institutions have been concentrated there. During the 19th century European cultural institutions, such as theatre and opera, were added. The Baroque Opera House (destroyed by fire, 1971), where music by Egyptian composers was sometimes heard, was home to the Cairo Symphony Orchestra and host to guest ballet and opera companies, including the indigenous Reda Folklore Ballet Troop.

Egypt has long been famous for its musical and dramatic talent. Particularly in recent years there has been a renaissance of the legitimate Arabic theatre. Virtually all Arabic films (except some from Beirut) are produced by Cairo's five major companies or by smaller and more short-lived Cairene companies. The leading cinema stars, as well as the most popular musical entertainers of the Arab world (such as Umm Kulthūm and ʿAbd al-Wahhāb), make Cairo their headquarters. Egyptian radio, especially the influential "Voice of the Arabs" program, is beamed throughout North Africa, into the Fertile Crescent, and south into Africa.

Cairo's press exercises a similarly wide influence in the Arabic-speaking countries. Cairo's daily newspapers—the semi-official organ *al-Ahrām, al-Jumhūrīyah, al-Akhbār,* and *al-Masāʾ*—circulate abroad as well as throughout Egypt, as do such weeklies as *al-Muṣawwar* and *Rose al-Yūsuf.* Most books in circulation in the Middle East are printed by the National Press of Egypt, Dār al-Maʿārif, or other local presses. Since 1959 Cairo has had television; in 1970 three channels were transmitting for a combined 20 hours daily.

Cairo is rich in museums, such as the Egyptian Museum on Maydān Taḥrīr, which displays the treasures of Tutankhamen; the Coptic Museum in Miṣr al-Qadīmah, specializing in pre-Islāmic icons, textiles, and stone; the Museum of Islāmic Art in Bāb al-Khalq, with Mamlūk Qur'āns and objects of wood, brass, inlay, and glass; the War (Citadel) Museum; and the Turkish-style Manyal Palace Museum (on Rawḍah). The mosques of Cairo offer as rich a store as any museum.

The Cairo Zoological Gardens in al-Jīzah contain extensive collections of rare tropical animals in a garden setting. Popular public haunts include the Corniche, Azbakīyah, and the Botanical Gardens. Entertainment facilities available include sailboat trips up the Nile, as well as innumerable Nile-front cafés, restaurant boats, and nightclubs. In addition to the older sporting facilities on az-Zamālik (racetracks, swimming clubs, gardens), there is a racetrack at Heliopolis. Naṣr City has playing fields as well as the Cairo Stadium.

Calcium Products and Production

A metallic element, calcium was so named by the English chemist Sir Humphry Davy because of its occurrence in chalk. Though it does not occur in the free state, its compounds are widely distributed. It is the fifth most abundant element in the earth's crust; it constitutes 3.63 percent of the igneous rocks and 3.22 percent of the entire crust of the earth. It is found in gypsum and related minerals.

Natural occurrence of calcium

Forms of calcium occur as fluorite and (with calcium phosphate) as apatite. Many minerals, notably feldspars and zeolites, contain calcium silicates. Asbestos is composed of calcium magnesium silicate. Calcium phosphate is the principal inorganic constituent of bones; it also occurs as the mineral phosphorite. Calcium carbonate (calcite) occurs in limestone, chalk, marble, dolomite, eggshells, pearls, coral, stalactites, stalagmites, and the shells of many marine creatures.

Production. In 1808 Davy showed that lime is a compound of oxygen and a metal, which he named calcium. While calcium was formerly produced by electrolysis of anhydrous calcium chloride, practically all commercial production now is by the reduction of lime by aluminum in heated retorts under low pressures. Calcium distills out of the reaction mass and is collected in a cool section of the retort or in a condenser. Calcium metal is costly and production is small.

Uses. Calcium is used in making alloys of aluminum, copper, lead, magnesium, and other base metals. It is an important deoxidizer for chromium–nickel, chromium–nickel–iron, and related resistance high-temperature al-

loys and for nickel, steel, and tin bronzes. It is an evacuating agent (getter) to remove residual gases in the production of high-vacuum products such as electron tubes. It has been employed as a reducing agent in the preparation of chromium, thorium, uranium, zirconium, and other metals from their oxides; as a dehydrating agent for organic liquids; a desulfurizer for petroleum fractions; and a decomposing agent for thiophenes and mercaptans. As calcium–lead, it is employed on telephone cables and in storage batteries.

Calcium is necessary in the human diet and a deficiency of it leads to diseases of the body resulting from the lack of material for bone formation.

Compounds. Calcium carbonate (calcite, $CaCO_3$) occurs in all limestones, other minerals, and in some naturally hard waters. Precipitated chalk is calcium carbonate prepared by mixing solutions of calcium chloride and a soluble carbonate. Tooth powders, white polishes, and cements are made with calcium carbonate.

Lime, calx, or quicklime is calcium oxide (CaO), a strongly caustic ingredient used for making mortars and plasters. Calcium hydroxide [$Ca(OH)_2$], slaked lime, is important in the production of mortars, plasters, and cements. In these materials, which set as they dry, the hydroxide combines with carbon dioxide in the air to form calcium carbonate. Lime has many uses in industry as a cheap alkali and in agriculture as an agent for removing excess soil acidity.

Calcium peroxide (CaO_2) is obtained by the addition of hydrogen peroxide to limewater; the resulting calcium hydrate ($CaO_2 \cdot 8H_2O$) loses water on being heated to 130° C and forms the peroxide—a pale, buff-coloured powder sometimes used for bleaching and antiseptic purposes.

Calcium phosphide (Ca_3P_2), a dangerous fire hazard, is obtained by passing phosphorus vapour over strongly heated lime. It is used in marine signal lights because it decomposes on contact with water to produce spontaneously inflammable hydrogen phosphide.

Calcium phosphate

Calcium phosphate [$Ca_3(PO_4)_2$] is the principal inorganic constituent of bones and of bone ash; it occurs as phosphorite [$Ca_3(PO_4)_2$] in Florida, Tennessee, parts of the western United States, and northern Africa. The acid salt [$CaH_3(PO_4)_2$] is obtained by evaporating a solution of the normal salt in hydrochloric or nitric acid; it is very soluble and, with calcium sulfate, is a superphosphate plant food, produced by treating mineral phosphates with sulfuric acid. In medicine calcium phosphate is used as a source of phosphorus. It is used as a polishing powder in dentifrices. Calcium phosphate is used in manufacturing milk glass, porcelains, pottery, and enamelling. It is a mineral supplement in animal feeds.

Calcium sulfate ($CaSO_4$) occurs in nature as gypsum, alabaster, anhydrite, satin spar, selenite, and terra alba. In water it is one of the salts causing permanent hardness; *i.e.*, hardness not removed by boiling. Calcium sulfate, a white polishing powder, is used to make plaster of Paris, which is a semihydrate ($CaSO_4 \cdot \frac{1}{2}H_2O$), and cements, particularly Keene's cement. It is a white pigment in paints. In paper manufacturing it is used as filler, size, and glaze.

Calcium sulfide (CaS), erroneously called sulfurated lime, is produced by heating the sulfate with charcoal or by heating lime in a current of hydrogen sulfide. Calcium sulfide has been used medically to treat acne and boils. It is a depilatory in leather manufacturing. Luminous calcium sulfide, called Canton's phosphorus, used in luminous paints and varnish, is made by igniting a mixture of calcium carbonate and sulfur with tiny amounts of bismuth or manganese salts.

Calcium chloride

Calcium chloride ($CaCl_2$), water soluble and moisture absorbing (deliquescent), occurs in many natural waters and is a by-product of several industrial processes. The crystals may contain two, four, or six molecules of water for each gram molecular weight of the salt. The hexahydrate and dihydrate are used for antifreeze and refrigerating solutions and for laying dust on roads. The anhydrous chloride, obtained by heating the crystals above 200° C in a current of hydrogen chloride, is used as a drying agent. Bleaching powder is usually a mixture of the basic chloride [$CaCl_2 \cdot Ca(OH)_2(H_2O)$] and the basic hypochlorite [$Ca(OCl)_2 \cdot 2Ca(OH)_2$]. It is made by exposing thin layers of slaked lime to chlorine at 30° to 40° C.

Calcium fluoride (CaF_2) occurs as the mineral fluorite and can be prepared as a white precipitate by mixing solutions of calcium chloride and sodium fluoride. It is used to increase the fluidity of the waste products (slag) in ferrous metallurgy. Single pure crystals are made for use in spectroscopy.

Calcium hydride (CaH_2), sometimes called hydrolith, is obtained by heating the metal in a current of hydrogen. This compound is easily transported and on treatment with water yields hydrogen. It is used as a portable source of hydrogen. Calcium hydride is used to reduce rare metals from their oxides and as a drying agent.

Calcium silicide, calcium boride, and calcium carbide are used in metallurgical work as gas-removing agents, as reducing agents, and as sources of calcium for alloys. Often, however, in (highly specialized) alloy work, examples of which are the nickel–chromium and nickel–chromium–iron materials for high-temperature service, these compounds may introduce undesirable materials from which the metallic calcium is free.

Alloys. Calcium–silicon, made in the electric furnace from lime, silica, and carbon, is a deoxidizer and degasifier for iron, steel, and high-tensile-strength cast irons. It is added either to the furnace in the final stages of processing or at the time of casting. Both calcium and silicon are active deoxidizers and their reaction products are a slag with a low melting point, giving a clean steel ingot with improved fluidity and freedom from holes (blowholes) caused by captured gases.

Calcium–manganese–silicon, also made in the electric furnace, similar to calcium–silicon but with manganese ore as an addition, is sometimes preferred to calcium–silicon for the additional effect of the manganese.

Calcutta

Calcutta, the capital of West Bengal, is India's largest city and one of its major ports. It is located on the east bank of the River Hooghly, an arm of the Ganges River, about 80 miles (128 kilometres) upstream from the head of the Bay of Bengal; here the port city developed as a point of transshipment from water to land and from river to sea. A city of commerce and manufacture, it is the dominant urban centre of eastern India. It has a population estimated to be about 3,100,000.

Origin of the name

The city's name is an anglicized version of Kalikātā. According to some, Kalikātā is derived from the Bengali word Kālīkshetra (field of the goddess Kālī); others hold that the name is derived from the Sanskirt word *kola* ("hog"), because there were many hogs near the settlement and a hog market nearby. Still another version is that Calcutta derived its name from a village industry in which *kali* (slaked lime) was prepared from *kātā* (burnt shells). For an associated physical feature, see GANGES RIVER.

HISTORY

While the village of Calcutta was recorded as existing in 1596, its history as a British settlement dates from the establishment of a trading post there by Job Charnock, an agent of the English East India Company, in 1690. Charnock had previously had disputes with officials of the Mughal Empire at the river port of Hooghly and had been obliged to leave, after which he attempted unsuccessfully to establish himself at other places down the river. When the Mughal officials, not wishing to lose

what they had gained from the English company's commerce, permitted Charnock to return once more, he chose Calcutta as the seat of his operations. The site was apparently carefully selected, being protected by the Hooghly River on the west and by salt lakes three miles to the east. Rival Dutch and French settlements were higher up the river on the west bank, so that access from the sea was not threatened, as it was at the port of Hooghly. The river at this point was also wide and deep; the only disadvantage was that the marshes to the east made the spot unhealthy. Moreover, before the coming of the English, three local villages—Sutanati, Kalikātā, and Govindpore, which were later to become parts of Calcutta—had been chosen as places to settle by Indian merchants who had migrated from the silted-up port of Satgaon, farther upstream. The presence of these merchants may have been to some extent responsible for Charnock's choice of the site.

By 1696, when a rebellion broke out in the nearby district of Burdwān, the Mughal provincial administration had become friendly to the straggling settlement. The servants of the company, who asked for permission to fortify their trading post, or factory, were given permission in general terms to defend themselves. The rebels were easily crushed by the Mughal government, but the settlers' defensive structure of brick and mud remained and, in 1700, came to be known as Ft. William. In 1698 the English obtained letters patent that granted them the privilege of purchasing the zamindari right (the right of revenue collection; in effect, the ownership) of the three villages.

Ft. William

The grant of trade rights. In 1717 the Mughal emperor granted the East India Company freedom of trade in return for a yearly payment of 3,000 rupees; this arrangement gave a great impetus to the growth of Calcutta. A large number of Indian merchants flocked to the city. The servants of the company, under the company's flag, carried on a duty-free private trade. When the Marāthās from the southwest began incursions against the Mughals in the western districts of Bengal in 1742, the English obtained permission from the Nawab (ruler) of Bengal to dig an entrenchment to form a moat on the land side. This came to be known as the Maratha Ditch. Although it was not completed to the southern end of the settlement, it marked the city's boundary on the landward side.

In 1756 the Nawab's successor, Sirāj-ud-Dawla, captured the fort and sacked the town. Calcutta was recaptured in 1757 by Robert Clive, one of the founders of British power in India, and by the British admiral Charles Watson. The Nawab was defeated shortly afterward at Plassey, after which British rule in Bengal was assured. Govindpore was cleared of its tiger jungle, and the new Ft. William was built on its present site, overlooking the Hooghly at Calcutta, where it became the symbol of British military ascendancy.

The capital of British India. Calcutta did not become the capital of British India until 1772, when the first governor general, Warren Hastings, transferred all important offices to the city from Murshidābād, the provincial Mughal capital. In 1773 Bombay and Madras became subordinate to the government at Ft. William. A supreme court administering English law began to exercise original jurisdiction over the city as far as the Maratha Ditch (now Circular Road, both Upper and Lower).

In 1706 the population of Calcutta was about 10,000 to 12,000. By 1752 it had increased to about 118,000 and by 1822 to 300,000. The White (British) Town was built on ground that had been raised and drained. There were so many palaces in the British sector of the city that it was named the "city of palaces." Outside the British town were built the mansions of the newly rich, as well as clusters of huts. The names of different quarters of the city—such as Kumartuli (the potters' district) and Sankaripara (the conch-shell workers' district)—still indicate the various occupational castes of the people who became residents of the growing metropolis. Two cities—one British, one Indian—came to coexist in Calcutta.

Calcutta at this time was described as a pestilential town. There were few good roads. In 1817 a Lottery Committee was constituted to finance public improvement by means of lotteries, and between 1817 and 1836 it took some effective measures to improve conditions. Some wide paved roads—Cornwallis Street, College Street, Wellington Street, Wellesley Street, and Wood Street—were constructed, as also were several squares, including Cornwallis Square, College Square, and Wellesley Square.

Development of the port

From trade to empire. By successive stages, as British power extended over the subcontinent, the whole of northern India became a hinterland for the port of Calcutta. There was a seemingly limitless market for the manufacturers of England, and Calcutta was the port of entry. The abolition of inland customs duties in 1835 created an open market. The construction of railways further quickened the tempo of business life. British merchants in Calcutta specialized in the jute, coal, iron, and plantation industries. British banking and insurance also flourished. The Indian sector of Calcutta also became a busy hub of commerce and was thronged with merchants from all parts of India and many other parts of Asia. As the administrative headquarters of British India, Calcutta also became the intellectual centre of the subcontinent.

20th-century problems. The 20th century marked the beginning of Calcutta's woes. Lord Curzon partitioned Bengal in 1905, making Dacca the capital of eastern Bengal and Assam. Insistent agitation led to the annulment of this partition, but in 1912 the capital of British India was removed from Calcutta to Delhi, where the government could enjoy relative calm. Last came the blow of the second partition of Bengal in 1947.

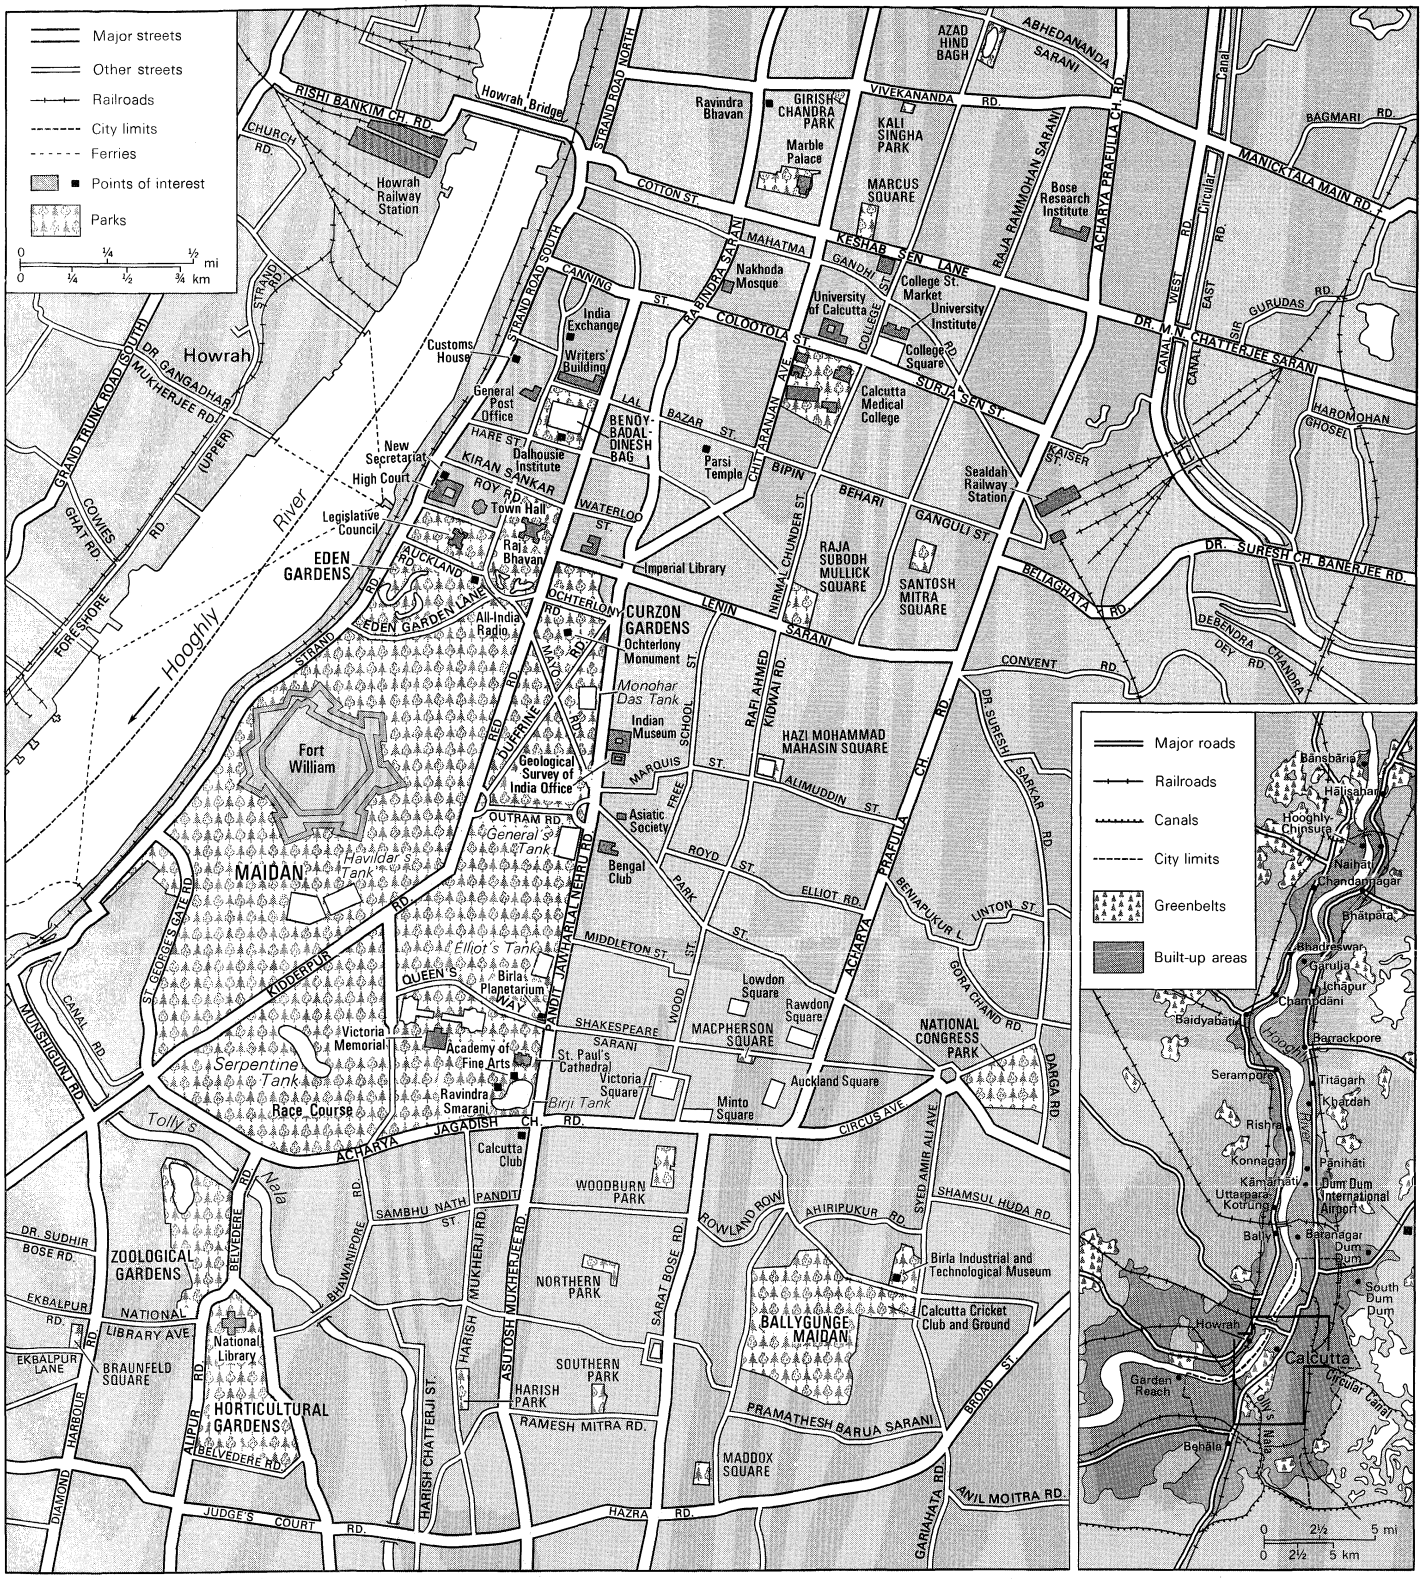
As the century progressed and Calcutta's population grew larger, social problems also became more insistent, as did demands for home rule for India. Communal riots occurred in 1926, and, when Gandhi called for noncompliance with unjust laws, serious riots occurred in 1930. In World War II, Japanese air raids upon the Calcutta docks caused heavy loss of life. The most serious riots of all took place in 1946, when the partition of British India became imminent, and tensions between Muslims and Hindus reached their height. In 1947 the partition of Bengal between India and Pakistan constituted a serious setback for Calcutta, which became the capital of West Bengal only, losing the trade of a part of its former hinterland. At the same time, millions of refugees from East Pakistan flocked to Calcutta, aggravating social problems and increasing overcrowding, which had already assumed serious proportions.

THE CONTEMPORARY CITY

The setting. The city site, as already mentioned, appears to have been originally selected partly because of its easily defensible position and partly because of its favourable trading location. The low, swampy, hot, and humid riverbank otherwise has little to recommend it. Its maximum elevation is 30 feet above sea level. Eastward from the river the land slopes away to marshes and swamplands. Similar topography on the west bank of the river has confined the metropolitan area to a strip three to five miles wide on either bank of the river. Reclamation of lowland is now in progress; the success of the Salt Lake Reclamation Project on the northeastern fringe of the city has demonstrated that the limits of land use and occupation can be expanded.

Size and suburbs

The city proper has an area of about 40 square miles (about 100 square kilometres), but the metropolitan area as a whole consists of about 500 square miles (about 1,300 square kilometres), consisting of 3 corporations, 1 cantonment, 26 municipalities, and 44 municipal urban areas located on both banks of the Hooghly. The principal suburbs of Calcutta are Howrah (on the west bank), Baranagar to the north, South Dum Dum to the northeast, the South Suburban Area (Behāla) to the south, and Garden Reach in the southwest. The whole area forms a single metropolis held together by close economic ties.



Central Calcutta and (inset) its metropolitan area.

Climate. Calcutta has a subtropical climate with a seasonal regime of monsoons (rain-bearing winds). The maximum temperature reaches about 108° F (42° C) and the minimum temperature about 44° F (7° C). The average annual rainfall is 64 inches. About 80 percent of this falls from June to September, the period of the monsoon. These months are very humid and sometimes sultry. During October and November the rainfall dwindles. The winter months, from about the end of November to the end of February, are pleasant and rainless; fogs and mists occasionally reduce visibility in the early-morning hours at this season, as also do thick blankets of smog in the evenings. The atmospheric pollution has increased by from 50 to 100 percent since 1951. Thermal-generating stations, which burn coal, are a primary cause of this pollution, but monsoon winds act as cleansing agents by bringing in fresh air masses and also hastening the removal of water pollution.

The city plan, streets, and land use. Calcutta, with the exception of certain areas where Europeans formerly lived, has grown haphazardly, and until recently systematic planning was unknown. This haphazard develop-

ment is most noticeable in the fringe areas around the central core formed by the city of Calcutta and the suburb of Howrah. It has encouraged the development of a pattern of daily commuting that has overburdened Calcutta's roads, utilities, and other municipal facilities.

The street plan

Local streets are narrow. Motorized transport is a recent development. There is only one expressway—the Calcutta to Dum Dum highway. In 1967 there were about 116 miles of main roads in Calcutta and Howrah and about 185 miles in the rest of the metropolitan district. These main roads form a grid pattern in central Calcutta, but elsewhere road planning has a haphazard character. Part of the reason for this has been the difficulty of providing enough river crossings; for the same reason, most streets and highways have a north to south orientation. Nullahs (watercourses) and canals that require bridging have also been important factors in influencing the road pattern.

Transportation. *Urban transport.* While the city, with its immediate suburbs, has a total of about 500 miles of surfaced roads, their poor condition poses an acute problem. The mass-transportation system, which is entirely on the surface until completion of the Dum Dum–Tollyganj subway (see below), depends on trams and buses. In Calcutta and Howrah there are 26 tram routes, consisting of about 40 miles of double-track tramways. Trams are under government management. Buses are run by the state government and by private companies. The public-transport system generally has about 1,100 buses and 450 trams in service; they carry about 1,000,000,000 passengers a year.

Construction began in 1973 on India's first subway system, a 10.3-mile (16.5-kilometre) north–south line between Dum Dum and Tollyganj that was to be completed in about six years and that would serve 1,390,000 persons daily in its first year of operation.

The connection between Calcutta and its hinterland to the west depends upon two bridges over the Hooghly—the Howrah Bridge and, farther north, the Bally Bridge. Construction of a third bridge is planned. The Howrah Bridge, Calcutta's main link with the hinterland, carries eight lanes of vehicular traffic, has two tramway tracks in the centre, and is one of the most heavily used bridges in the world.

Intercity transport. The Grand Trunk Road (National Highway No. 2) is one of the oldest road routes in India. It runs for about 1,000 miles, from Calcutta to Kashmir, and is the main route connecting the port with northern India. Other national highways connect Calcutta with the west coast of India, the northern part of West Bengal, and the frontier with Bangladesh.

Two railway stations—Howrah on the west bank and Sealdah on the east—serve the railway networks running north and south as well as those running east and west. More than 250,000 suburban passengers arrive and depart daily from these two stations.

Calcutta's major air terminal, at Dum Dum, serves about 120 international and domestic flights each day. (For the role of sea transport, see below *Economic life.*)

Demography. According to the 1971 census the population of the city of Calcutta was 3,150,000, although the population of the entire metropolitan area is over 7,000,000. The transient population, of which a considerable proportion is commuters, numbers about 1,000,000. The total population of the city during daylight hours may therefore be estimated at about 4,000,000. At the time of the 1971 census, Hindus numbered 2,620,000, Muslims 450,000, and Christians 40,000, with Sikhs, Jains, Buddhists, and others accounting for the rest. The Bengali-speaking population represented (in 1961) 66 percent of the whole, Hindi-speaking 20 percent, Urdu-speaking 9 percent, Oriya 2 percent, and others 3 percent. Calcutta is not only an Indian city: it is also cosmopolitan. Apart from Indians, other groups present include Bengalis, British, Nepalis, Chinese, Americans, Australians, Burmese, Armenians, Africans, Portuguese, Irish, Dutch, French, Italians, Danes, Israelis, and Iranians.

The density of population is about 78,000 per square mile—about 160 persons per developed acre and 300 persons per residential acre. But averages are misleading. In a district known as Ward No. 72, for example, density is 127 persons per residential acre, while in some of the wards (districts) in north Calcutta the density is above 1,000 per acre. In 20 wards of north Calcutta, density was 590 persons per acre in 1961. There are few multi-storied buildings in this area. People live mostly in single-, double-, or three-storied buildings. Overcrowding has reached virtually intolerable proportions.

A socio-economic survey of the city of Calcutta made during the decade of the 1950s drew attention to certain demographic features in the city. There was a large number of migrants, who fell into one of two categories. Ordinary migrants were those who came from other states of India in search of employment—mostly from Bihār, Orissa, and eastern Uttar Pradesh. They were male and married but led a single life in Calcutta. Most of them were unskilled manual workers, but some were skilled labourers or traders. Deprived of family life, though married, they lent an element of instability to the city's life. This also explained the excessive predominance of males—1,900,000, as compared with 1,200,000 females, at the time of the 1971 census. The second category of migrants included refugees from East Pakistan (Bangladesh); in 1967 these numbered about 400,000 in Calcutta and its immediate neighbourhood.

The housing shortage

Housing. The city is faced with an immense housing shortage. In 1973 it was estimated that there were at least 200,000 pavement dwellers in the city. Of 366,000 persons living in institutional shelters in the Calcutta metropolitan district, probably more than two-thirds live in the city itself. There are more than 600,000 housing units in the city, about three-quarters used for dwelling purposes only. The average number of persons per household is almost five, and the average number of persons per room is about three. Most of the units are very small.

There are 3,000 bustees, or slums, housing 189,000 families. A bustee is officially defined as "a collection of huts standing on a plot of land of at least one-sixth of an acre." There also are bustees built on less than one-sixth of an acre. The majority of huts are unventilated single-story rooms, often dilapidated. They have few sanitary facilities, and there is very little open space. The government is sponsoring a bustee-improvement program.

Architectural features. In contemporary Calcutta the skyline is broken in some areas by skyscrapers and tall multi-story blocks. The cityscape is changing very rapidly. Chowringhee area in central Calcutta, once a row of palatial houses, has been given up to offices, hotels, and shops. In north and central Calcutta, buildings are still mainly two or three stories high. In south and south central Calcutta, multi-storied apartment buildings prevail.

In 1875 there were 21 Christian churches and chapels listed in Calcutta; today some of them are in ruins. Calcutta is full of temples, both large and small; most of them are shrines attached to houses, which explains the absence of monumental temples to the Hindu deities.

Western architectural influences

Western influence is dominant in Calcutta's old architectural monuments. Government House (now Raj Bhavan) is an imitation of Kedleston Hall in Derbyshire; the High Court resembles the Cloth Hall at Ypres, Belg.; the Town Hall is in Grecian style with Doric-Hellenic portico; St. Paul's Cathedral is of Indo-Gothic-style architecture; the Writers' Building is of Gothic-style architecture with statuary on top; the Indian Museum is in Italian style; and the General Post Office, with its majestic dome, has Corinthian columns. The beautiful column of the Ochterlony Monument is 165 feet high—its base is Egyptian, its column Syrian, and its cupola in the Turkish style. The Victoria Memorial represents an attempt to combine classical Western influence with Mughal architecture; the Nakhoda Mosque is modelled on Akbar's Tomb at Sikandra; the Birla Planetarium is based on the Buddhist stupa (monument) at Sāñchī.

The West Bengal Legislative Council is a dignified building in the modern architectural style. The Ramakrishna Mission Institute of Culture, the most important example of post-independence construction, represents an attempt to interpret the cultural heritage of India.

Economic life. Calcutta is eastern India's financial headquarters, as well as a great commercial entrepôt, and the centre of an industrial urban district. Its port provides an outlet for the products of the tea gardens of Assam and Meghalaya and West Bengal's jute industry. Although Calcutta's economy is inseparably connected with the Calcutta conurbation and with the hinterland as a whole, few industries, except for jute, are linked directly to the port.

The port of Calcutta. In normal years the Calcutta port handles—in terms of value—25 percent of India's import cargoes and 40 percent of its export cargoes. Some decline in traffic occurred in the late 1960s, partly because of problems encountered in dredging silt from the river and partly because of labour problems. Calcutta imports better quality steel and iron and exports crude steel and pig iron. Other commodities imported include salt, petroleum, asphalt, bitumen, cement, fertilizers, machinery, and railway materials. Among commodities exported are coal, ores, gunnies (jute sacking), tea, sugar, bones and bone meal, scrap iron, and other cargo. Import of food grains, formerly the largest single import in terms of total tonnage, was expected to end in 1972. Transport, storage, wholesaling, and retailing requirements for all these exports and imports are concentrated in Calcutta. The Calcutta port accounts for the bulk of India's foreign exchange.

Imports and exports

Banking and commerce. Of the foreign banks in India, almost one-third are in Calcutta. They account for somewhat more than 33 percent of all deposits in foreign banks in India and almost the same percentage of all advances. The Calcutta stock exchange plays an important part in the organized financial market of the country.

In addition, the controlling agency for coal mines is in Calcutta. Jute mills and large-scale engineering industries are also controlled from the city. The Bengal Chamber of Commerce and Industry, the Bengal National Chamber of Commerce and Industry, and the Indian Chamber of Commerce are based in Calcutta. The products of Calcutta's hinterland include coal, iron, manganese, mica, petroleum, tea, and jute. Calcutta is the eastern region's shipping centre; it is also a major centre for printing, publishing, and newspaper circulation, as well as for recreation and entertainment.

Manufactured products

Industry. Calcutta is the world's largest processor of jute; the city also manufactures, processes, and distributes such consumer goods as rice products, wheat, flour products, sweetmeats, dairy products, edible oils, tobacco, betel nuts, nonalcoholic drinks, toilet and textile products, hosiery goods, bedding materials, and footwear. Its factories also produce tires, tubes, transport vehicles, electric motors, electroplated wares, type foundries, dyes, varnishes, chemicals, plywood, tea chests, soap, ink, pencils, iron and steel goods, paper, and textiles.

Overall economy. That the city's economy is primarily mercantile is reflected in the fact that almost 40 percent of all workers are employed in the distributive trades. There are, however, 40,000 workers on the payrolls of the port authorities alone. Other important occupational classifications include public service in different government departments, the armed forces, the police, the banks, and the Life Insurance Corporation of India. Private services include the stock exchange, medical and educational services, legal services, accountancy and credit firms, chambers of commerce, various public utility services, such as the municipal corporation, electricity and gas companies, tramways, bus service, and construction works. The number of persons with unearned incomes has diminished with the abolition in 1954 of the zamindars (revenue-collection) system. The problem of unemployment in Calcutta is, to a considerable extent, educated unemployment—that is, unemployment among people educated for clerical and other white-collar jobs.

Administration and social services. *Governmental institutions.* As Calcutta is the capital of West Bengal, the governor resides in the city in the historic Raj Bhavan. The state Legislative Assembly is located in the city, as is also the Secretariat, known as Writers' Building, housing the state ministries in charge of different departments. The Calcutta High Court, exercising original jurisdiction over the city and appellate jurisdiction over West Bengal, is also located there. A number of government of India institutions, including the National Library, the Indian Museum, the Geological Survey of India, and the Indian Meteorological Department, are also in the city.

Municipal government is carried on by the Municipal Corporation of Calcutta, which is composed of 100 members representing the 100 wards into which the city is divided and who are elected on the basis of adult franchise. The members annually elect a mayor, a deputy mayor, and a number of committees to conduct the activities of the corporation. A commissioner, the executive head of the corporation, is responsible to its elected membership.

Other important governmental institutions are the Calcutta Improvement Trust, the Calcutta Metropolitan Planning Organization, the Calcutta Metropolitan Water and Sanitation Authority, and the Calcutta Metropolitan District Authority, which has executive functions.

Public utilities. A daily total of 116,000,000 gallons of filtered water is supplied from the main waterworks located 22 miles from the city, as well as from 175 major wells and some smaller wells. It has been estimated, however, that the total supply of filtered water required to meet the city's needs is 240,000,000 gallons per day. High salinity of the water supply in the dry months results from the use of the Hooghly River. The construction of Farakka Barrage on the Ganges, 240 miles upriver from Calcutta, due for completion in 1973, will ensure a saline-free water supply for the city. About 80,000,000 gallons of unfiltered water per day are supplied for watering the city streets and for use by the fire brigade, but many bustee residents use this water for their daily needs. This circumstance was largely responsible for the former prevalence of cholera during the summer months; chlorination of unfiltered water and cholera inoculation have now brought this disease under control. The total elimination of the unfiltered water supply has been recommended.

Water supplies

Municipal Calcutta has more than 400 miles of sewers and less than 400 miles of surface drains, about 44 percent of the total area of the city still remaining unsupplied with sewers. Accumulation of silt has narrowed many sewer channels. The system of removing garbage and of garbage dumping is unsatisfactory and needs improvement. Unsanitary methods of human-waste disposal persist in the unsewered part of the city.

Although Calcutta is supplied with electricity by the Calcutta Electric Supply Corporation, West Bengal State Electricity Board, Durgapur Power Station, Bandel Thermal Power Station, and Damodar Valley Corporation Grid, there is still a gap between generating capacity and potential demand.

Health and safety. Malaria has been eradicated from the city, and death from enteric fever has been brought under control. Death rates from cholera, smallpox, influenza, and tuberculosis have declined. There are 36 hospitals, apart from private clinics, as well as free dispensaries run by the Municipal Corporation of Calcutta and charitable trusts. There are four medical colleges. The city has about 7,000 registered medical practitioners, both men and women, practicing modern medicine, almost 800 practicing traditional Hindu medicine, and 600 practitioners of homeopathic medicine. The number of doctors per 1,000 people is greater in Calcutta than in most parts of the country, but the city is also a medical centre for the northeast region of India, and the hospitals are always overcrowded. For those who can afford them, there are also many nursing homes.

Medical facilities

Administration of the Calcutta police force is vested in the city's commissioner of police, as is direction of the suburban police force. The city is divided into four police divisions. The fire brigade, with a fleet of vehicles and well-trained personnel, has its headquarters in central Calcutta.

Jawaharlal Nehru (formerly Chowringhee) Road, a main street in Calcutta overlooking the Maidan, the city's largest park.
J. Allan Cash

Public safety had become a serious problem in the 1970s, when there was an alarming increase in crimes and murders as a result of interparty clashes. The city's police force was considerably strengthened in consequence.

Education. Almost 70 percent of the primary education age group (six to ten years) attend primary schools; of these, one-third attend free primary schools run by the municipal corporation. The rest attend recognized schools that are under private management. About 60 percent of boys and 40 percent of girls from the ages of 11 to 14 receive secondary education; about 30 percent of boys and 20 percent of girls in the age group 14 to 16 receive education in recognized schools, both governmental and private. All recognized schools, in both the secondary and higher-secondary categories, are supervised by the Board of Secondary Education.

The universities

The three universities are the University of Calcutta, Jadavpur University, and Rabindra Bharati University. The University of Calcutta has 50 colleges in the city, as well as many outside. It has faculties of agriculture, arts (humanities), commerce, dental science, education, engineering, fine arts and music, home science, journalism, law, library science, technology, social welfare, business management, and veterinary science. Besides these colleges, university colleges of arts (humanities), science, and medicine specialize in postgraduate teaching and research. Jadavpur University has three faculties—arts (humanities), science, and engineering. Rabindra Bharati University specializes in humanities and the fine arts (dance, drama, and music). The colleges are all overcrowded.

Research institutions include the Indian Statistical Institute, the Indian Association for the Cultivation of Science, the Bose Research Institute (natural science), and the All-India Institute of Hygiene and Public Health.

Cultural life. Calcutta is the most important cultural centre of India. Besides the three universities, the Asiatic Society of Bengal, the Bangiya Sahitya Parishad, the Ramakrishna Mission Institute of Culture, the Academy of Fine Arts, the Birla Academy of Art and Culture, the Maha Bodhi Society, the Iran Society, and the Calcutta Historical Society are among the organizations that contribute to the cultural life of the city. All branches of the arts are pursued, and crafts play an important role. Cinematic films are produced in the city's film studios.

Rabindranath Tagore in 1937 inaugurated the first All-Bengal Music Conference in Calcutta, and a number of music conferences are held every year. The Society of Working Artists, the Society of Progressive Artists, the Society of Oriental Art, the Painters' Front, and other bodies present annual shows.

Theatre and films

There is no permanent English-language theatre in Calcutta, but English plays are staged by amateur dramatic clubs, and there are six theatres that regularly stage Bengali dramas. There are almost 80 cinemas. English, Bengali, Hindi, and Urdu films are regularly shown.

The Indian Museum on Jawaharlal Nehru Road (formerly Chowringhee Road) is the oldest in India. The archaeology and numismatic sections contain the most valuable collections. The exhibits at Victoria Memorial Hall trace Britain's relations with India. The Asutosh Museum of Indian Art in the University of Calcutta has exhibits of the folk art of Bengal among its collections.

Valuable library collections are to be found in the Asiatic Society, Bangiya Sahitya Parishad, and the University of Calcutta; special mention should be made of the National Library, which is the largest in India, with holdings of 10,000,000 books and 2,000 original manuscripts.

Press, radio, and television. Three English-language daily newspapers and six Bengali-language dailies are published in Calcutta and have large circulations throughout eastern India. Hindi daily newspapers number five and Urdu dailies four; there is also a Punjabi-language daily. Bengali-language periodicals are more numerous than ever before. There are some English-language weeklies and monthly magazines. Akashbani Bhavan, the All-India Radio station, is located in the city, and the establishment of a television station is planned.

Recreation. There are 170 parks, squares, and open spaces maintained by the Corporation of Calcutta. There is, however, very little open space in the overcrowded parts of the city. The Maidan (1,283 acres) is the most famous open space; the major soccer, cricket, and hockey fields are located there. Adjacent to the Maidan is one of the oldest cricket fields in the world, in the Eden Gardens. There are two racecourses and two golf courses within the city. Rowing at the Lake Club and at the Bengal Rowing Club is popular. The Zoological Gardens are spread over an area of 45 acres. The Indian Botanical Gardens, on the western bank of the river, cover an area of about 270 acres and have a river frontage of almost 6,000 feet. Their famed herbarium contains about 40,000 species of plants.

(N.K.S.)

Calder, Alexander

Alexander Calder, known throughout the world as the artist who made sculpture move, was one of the few artists in history who could lay claim to the creation of a new art form. This form, the mobile, greatly extended the limits and possibilities of the art of sculpture. Although isolated experiments in the introduction of motion into sculpture had preceded his work, Calder was the first to realize the full implications of the element of motion and explored these implications in hundreds of variations.

Alexander Calder was born on July 22, 1898, in Lawnton, Pennsylvania, now a part of the city of Philadelphia. He was the son and grandson of sculptors, and his mother was an accomplished painter; he grew up in the atmosphere of American academic art of the early 20th century. Despite this environment, he seems to have had little inclination to become an artist himself. Aside from an unusual amount of travelling and moving around, necessitated in part by his father's health, Calder's youth and interests were typical of middle-class American boys growing up in the early years of the century. His reminiscences of his early activities—which are remarkable for their completeness—have to do largely with family affairs, sports, and relations with his classmates. Perhaps the only indication of his subsequent career lay in his facility for making things and his enjoyment of gadgets.

Early interests

After study at the Stevens Institute of Technology in Hoboken, New Jersey, he graduated in 1919 with a degree in mechanical engineering. For a time he travelled widely and held various engineering jobs. In 1922 he took drawing lessons at a night school in New York and in 1923 entered the Art Students League, where he was influenced by painters of the New York scene, the so-called Ashcan School, of which the painters John Sloan and George Luks were among the leaders. At this point, his aspirations, like those of many American artists of the time, did not extend much beyond securing a well-paying job in illustration or commercial art. In 1924 he began doing illustrations for the *National Police Gazette*, for which he covered prize fights and the circus.

After several other routine commercial illustrating jobs, Calder decided in 1926 to go to Paris, the world centre for modern art. In Paris, while working on sculpture, he began, for his own amusement, to make toylike animals of wood and wire. Out of these he developed a miniature circus (Whitney Museum of American Art, New York City), performances of which were attended by many of the leading artists and literary figures in Paris. The little circus figures, as well as his interest in continuous line drawings, led Calder to the creation of wire sculptures, such as the figure of a woman seven feet high entitled "Spring" and "Romulus and Remus," a group that included a she-wolf 11 feet long.

Creation of wire sculpture

Among the artists he met in Paris through his circus exhibitions, perhaps the most crucial for his subsequent career was the Spanish Surrealist painter Joan Miró. Although Surrealism was reaching its first major peak in the late 1920s, Calder does not seem to have been conscious of the movement; in fact throughout his career he isolated himself from the "art world." With Miró, however, he established an immediate rapport, and a lasting friendship was formed.

In 1930 Calder met the Dutch painter Piet Mondrian and visited his studio, an event that made him suddenly aware of the modern movement in painting and that influenced his work in the direction of the abstract. In the winter of 1931–32 he began to make motor-driven sculptures, consisting of various geometrical shapes. The name mobile was given to them by Marcel Duchamp. Aesthetically, movement, because of the changing relationships between the various elements, gave the sculpture a continually changing composition. The following year, when Calder exhibited similar works that did not move, Jean Arp described them as stabiles, a term that Calder continued to use. Beginning in 1932 most of his mobiles were given their movement by air currents.

In 1931, while fashioning a wedding ring for his marriage, Calder formed an interest in making jewelry. Also in 1931 he produced illustrations for an edition of the *Fables of Aesop*. Illustrations for a number of other books followed in the 1940s.

During the 1930s Calder further developed the concept of the mobile. The first major manifestation of his work was at the Paris World's Fair of 1937, where he created his so-called mercury fountain for the Spanish pavilion. In this sculpture, movement was introduced by a stream of mercury striking a plate that was attached to a swivelling rod. From this point, Calder's reputation expanded continually through annual exhibitions in Europe and America, climaxed by a showing at the Museum of Modern Art in New York City in 1943.

First major mobiles

Although Calder's early mobiles and stabiles were on a relatively small scale, he increasingly moved toward monumentality in his later works. One very large stabile organization was an acoustical ceiling, which he designed in 1952 for the auditorium of the Universidad Central de Venezuela in Caracas. In 1961 an exhibition on motion in art, which originated at the Stedelijk Museum in Amsterdam, emphasized the work of Calder and his followers. During the 1960s his accomplishments were recognized through major exhibitions in Kassel, West Germany; at the Solomon R. Guggenheim Museum, New York City; and at the Musée d'Art Moderne de la Ville de Paris.

In 1931, Calder was married to Louisa Cushing James, and after their marriage the Calders travelled continually, not only between France and the United States but to South America and Asia. In 1955 and 1956 they visited India, where Calder created 11 mobiles.

In the 1970s Calder's studio was at Saché, near Tours. There he designed his major stabiles and experimented

with free-form drawings and paintings. His normal method with large-scale works was to create a small model, the enlargement of which he supervised at a foundry in Tours. Although Calder lived most of the time in France, he maintained a home in Roxbury, Connecticut, where his house and his studio were filled with mobiles and stabiles. He died of a heart attack in New York City on November 11, 1976.

MAJOR WORKS

"Josephine Baker" (1926; private collection); "Romulus and Remus" (1928; Solomon R. Guggenheim Museum, New York); "Helen Wills" (1928; collection of the artist); "The Horse" (1928; Museum of Modern Art, New York); "Spring" (*c.* 1929; Solomon R. Guggenheim Museum, New York); "Portrait of Shepard Vogelgesang" (1930; Shepard Vogelgesang Collection, New York); "Kiki's Nose" (1931; private collection, Paris); "Dancing Torpedo Shape" (1932; Berkshire Museum, Pittsfield, Massachusetts); "Calderberry Bush" (1932; private collection, New York); "White Frame" (1934; collection of the artist); "A Universe" (1934; Museum of Modern Art, New York); "The Circle" (1934; Agnes Rindge Claflin Collection, Poughkeepsie, New York); "Steel Fish" (1934; Virginia Museum of Fine Arts, Richmond, Virginia); "Hanging Mobile" (1936; Meric Callery Collection, New York); "Dancers and Sphere" (1936; collection of the artist); "Whale" (1937; Museum of Modern Art, New York); "Tight Rope" (1937; collection of the artist); "Lobster Trap and Fish Tail" (1939; Museum of Modern Art, New York); "Spherical Triangle" (1939; collection of the artist); "Thirteen Spines" (1940; collection of the artist); "Black Beast" (1940; collection of the artist); "Hour Glass" (1941; Catherine White Collection, New York); "Cockatoo" (1941; C. Earle Miller Collection, Downingtown, Pennsylvania); "Red Petals" (1942; The Arts Club of Chicago); "Little Tree" (1942; Edgar Kaufmann, Jr., Collection, New York); "Horizontal Spines" (1942; Addison Gallery of American Art, Phillips Academy, Andover, Massachusetts); "Constellation with Red Object" (1943; Museum of Modern Art, New York); "The Water Lily" (1945; Pauling Donnelly Collection, Chicago); "Bayonets Menacing a Flower" (1945; Washington University Gallery of Art, St. Louis, Missouri); "Red and White on Post" (1948; collection of the artist); "Jacaranda" (1949; Wallace K. Harrison Collection, New York); "Blériot" (1949; Ida Chagall Collection, Paris); "El Corcovado" (1951; José Luis Sert Collection, Lattingtown, Long Island, New York); "Universe" (1974; Sears Tower, Chicago).

BIBLIOGRAPHY. ALEXANDER CALDER, *An Autobiography with Pictures* (1966), dictated by Calder to his son-in-law Jean Davidson, is perhaps the best picture of the artist as an individual. It suggests his personality and includes most of the details concerning his life and career. H.H. ARNASON, *Calder* (1966), is a critical biography with photographs by PEDRO E. GUERRERO that traces the development of Calder as an artist; H.H. ARNASON and UGO MULAS, *Calder* (1971), is a photographic document with anthology, comments, and quotations from Calder and many friends who knew him throughout his career. This work and the preceding one contain bibliographies by and about the artist. JAMES J. SWEENEY, *Alexander Calder* (1951), an exhibition catalog of the Museum of Modern Art, New York, is the first major study of Calder with the most complete bibliography to 1951.

(H.H.A.)

Calderón de la Barca, Pedro

The dramatist and poet Pedro Calderón de la Barca, who was to succeed Lope de Vega as the greatest Spanish dramatist of his age, was born at Madrid on Jan. 17, 1600. His father, a fairly well-to-do government official who died in 1615, was a man of harsh and dictatorial temper. Strained family relations apparently had a profound effect on the youthful Calderón, for several of his plays show a preoccupation with the psychological and moral effects of unnatural family life, presenting anarchical behaviour directly traced to the abuse of paternal authority.

Career. Destined for the church, Calderón matriculated at the University of Alcalá in 1614 but transferred a year later to Salamanca, where he continued his studies in arts, law, and probably theology until 1619 or 1620. Abandoning an ecclesiastical career, he entered the service of the constable of Castile and in 1623 began to write plays for the court, rapidly becoming the leading member of the small group of dramatic poets whom Philip IV gathered around him. In 1636 the King made him a Knight of the Military Order of St. James. Calderón's popularity was not confined to the court, for these early plays were also acclaimed in the public theatres, and on the death of Lope de Vega (1635) Calderón became the master of the Spanish stage. On the outbreak of the Catalan rebellion he enlisted in 1640 in a cavalry company of knights of the military orders and served with distinction until 1642, when he was invalided out of the army. In 1645 he entered the service of the Duke of Alba, probably as secretary. A few years later an illegitimate son was born to him; nothing is known about the mother, and the idea that sorrow at her death led him to return to his first vocation, the priesthood, is pure surmise. He was ordained in 1651 and announced that he would write no more for the stage. This intention he kept as regards the public theatres, but at the King's command he continued to write regularly for the court theatre. He also wrote each year the two Corpus Christi plays for Madrid (see below *Religious plays*). Appointed a prebendary of Toledo cathedral, he took up residence in 1653. The fine meditative religious poem *Psalle et sile* ("Sing Psalms and Keep Silent") is of this period. Receiving permission to hold his prebend without residence, he returned to Madrid in 1657 and was appointed honorary chaplain to the king in 1663. He died in Madrid on May 25, 1681.

Ordination

Aesthetic milieu and achievement. The court patronage that Calderón enjoyed constitutes the most important single influence in the development of his art.

The court drama grew out of the popular drama, and at first there was no distinction in themes and style between the two. The construction, however, of a special theatre in the new palace, the Buen Retiro, completed in 1633, made possible spectacular productions beyond the resources of the public stage. The court plays became a distinctive Baroque genre, combining drama with dancing, music, and the visual arts and departing from contemporary life into the world of classical mythology and ancient history. Thus Calderón, as court dramatist, became associated with the rise of opera in Spain. In 1648 he wrote *El jardín de Falerina* ("The Garden of Falerina"), the first of his zarzuelas, plays in two acts with alternating spoken and sung dialogue. In 1660 he wrote his first opera, the one-act *La púrpura de la rosa* ("The Purple of the Rose"), with all of the dialogue set to music. This was followed by *Celos aun del aire matan* (1660; "Jealousy Even of the Air Can Kill"), an opera in three acts with music by Juan Hidalgo. As in the Italian tradition, the music was subordinate to the poetry, and all of Calderón's musical plays are poetic dramas in their own right.

Calderón's drama must be placed within the context of the court theatre, with its conscious development of an unrealistic and stylized art form. For two centuries after his death his pre-eminence remained unchallenged, but the realistic canons of criticism that came to the fore toward the end of the 19th century produced a reaction in favour of the more "lifelike" drama of Lope de Vega. Calderón appeared mannered and conventional: the structure of his plots artificially contrived, his characters stiff and unconvincing, his verse often affected and rhetorical. Although he used technical devices and stylistic mannerisms that by constant repetition became conventional, Calderón remained sufficiently detached to make his characters, on occasion, poke fun at his own conventions. This detachment indicates a conception of art as a formal medium that employs its artistic devices so as to compress and abstract the externals of human life the better to express its essentials.

Dramaturgy and craftsmanship

In this direction Calderón developed the dramatic form and conventions established by Lope de Vega, based on primacy of action over characterization, with unity in the theme rather than in the plot. He created a tightly knit structure of his own, while leaving intact the formal framework of Lope's drama. From the start he manifested his technical skill by utilizing the characters and incidents of his plots in the development of a dominant idea. As his art matured his plots became more complex and the action more constricted and compact. The creation of complex dramatic patterns in which the artistic effect arises from perception of the totality of the design

through the inseparability of the parts is Calderón's greatest achievement as a craftsman. *The Painter of His Own Dishonor* (*c.* 1645) and *La cisma de Ingalaterra* (*c.* 1627; "The Schism of England") are masterly examples of this technique, in which poetic imagery, characters, and action are subtly interconnected by dominant symbols that elucidate the significance of the theme. Although rhetorical devices typical of the Spanish Baroque style remained a feature of his diction, his verse developed away from excessive ornamentation toward a taut style compressed and controlled by a penetrating mind.

Secular plays. The difficulties that Calderón's art presents to the modern reader have tended to obscure the originality of his themes. Accepting the conventions of the comedy of intrigue, a favourite form on the Spanish stage, he used them for a fundamentally serious purpose: *The Phantom Lady* (1629) is a neat and lively example. In *Casa con dos puertas, mala es de guardar* (1629; "A House with Two Doors Is Difficult to Guard") the intrigues of secret courtship and the disguises that it necessitates are so presented that the traditional seclusion of women on which these intrigues are based is shown to create social disorder by breeding enmity and endangering love and friendship. *No siempre lo peor es cierto* (*c.* 1640; "The Worst Is Not Always True") and *No hay cosa como callar* (1639; "Silence Is Golden") mark the peak of this development: although the conventions of comedy remain, the overtones are tragic. Both plays also implicitly criticize the accepted code of honour. Calderón's rejection of the rigid assumptions of the code of honour is evident also in his tragedies. In the famous *The Mayor of Zalamea* (*c.* 1640), the secrecy and the vengeance demanded by the code are rejected. This play also presents a powerful contrast between the aristocracy and the people: the degeneration of the aristocratic ideal is exposed, wealth is associated with manual labour, and honour is shown to be the consequence and prerogative of moral integrity regardless of class. Yet Calderón's humanity has been questioned in connection with *The Surgeon of His Honour* (1635). The critics who allege that he approves of the murder of an innocent wife because honour demands it overlook the fact that the horror one feels at this deed is precisely what he intended.

Contrasts of human values in secular plays

Calderón's tragic view of life is, however, wider than his preoccupation with the social code of honour. A keynote is his deep-seated realization that a man can be responsible through his own wrongdoing for the wrongdoing of another. This realization probably derives from Calderón's own family experience. In *Devotion to the Cross* (*c.* 1625) and *Three Judgments at a Blow* (*c.* 1637) the heart of the tragedy lies in the fact that the greatest sinner is also the most sinned against—in that others, before he was born, had begun to dig his grave. *The Painter of His Own Dishonor* (*c.* 1645) is built on a similar plot.

The human predicament, as seen by Calderón, lies in the fact that while each man is separated from all other men, his fate is ineluctably intertwined with theirs. He is caught in circumstances that are the collective responsibility of all, yet, being the prisoner of his own limited vision, he cannot perceive the consequences of these circumstances. Connected with this is another keynote of Calderón's drama, that of "confusion," the difficulty of seeing clearly and choosing correctly from among the maze of possibilities that life offers. In *Life Is a Dream* (1635) the material and social advantages that life can bestow are shown to be dreamlike and transient.

The fully developed court plays are best represented by *La hija del aire* (1653; "The Daughter of the Air"). This play in two parts dramatizes the legend of Semiramis (the warrior queen of Babylon whose greed for political power led her to conceal and impersonate her son on his accession). It is often considered Calderón's masterpiece. Highly stylized, it conveys a strong impression of violence. It presents, with considerable complexity, the contrast between passion and reason. Passion, in its self-seeking, in its grasping for power and devouring of everything in the urge to domination, breeds disorder and leads to destruction; reason, in its sacrificing of self-interest to justice and loyalty, produces order. This basic contrast underlies the themes of Calderón's last period, its various aspects being expanded in a number of interesting variations, many directly concerned with the positive values of civilization. Though none has the intensity of *La hija del aire,* most exemplify a thoughtful, dignified, and restrained art. Mythological themes predominate, with a more or less allegorical treatment, as in *Eco y Narciso* (1661; "Echo and Narcissus"), *La estatua de Prometeo* (1669; "The Statue of Prometheus"), and *Fieras afemina amor* (1669; "Wild Beasts Are Tamed by Love").

Religious plays. Calderón's vision of the human world in his secular plays is one of confusion and discord arising out of the inevitable clash of values in the natural order—honour in conflict with love, ambition with loyalty, peace with justice, and so on. The values underlying his thought in these plays are based on natural reason: prudence and social cooperation through unselfishness, trust, and love. His religious plays round off his view of life by confronting natural values with supernatural ones. The most characteristic of these religious plays, following the tradition established outside Spain by the Jesuit drama, are based on stories of conversion and martyrdom, usually of the saints of the early church. One of the most beautiful is *The Constant Prince* (1629), which dramatizes the martyrdom of Prince Ferdinand of Portugal. *The Wonder-Working Magician* (1637) is a more complex religious play; *The Two Lovers of Heaven* (date unknown); and *El Joséf de las mujeres* (*c.* 1640; "The Joseph of Womankind") are the most subtle and difficult. The basic human experience upon which Calderón relies for rational support of religious faith is decay and death and the consequent incapacity of the world to fulfill its promise of happiness. This promise is centred in such natural values as beauty, love, wealth, and power that, although true values if pursued with prudence, cannot satisfy the mind's aspiration for truth or the heart's longing for happiness. Only the apprehension of an "infinite Good" can assuage the restlessness of men.

This religious philosophy is given its most moving expression, in terms of Christian dogma, in the *autos sacramentales.* Seventy-six of these allegorical plays, written for open-air performance on the Feast of Corpus Christi, are extant. In them Calderón brought the tradition of the medieval morality play to a high degree of artistic perfection. The range of his scriptural, patristic, and scholastic learning, together with the assurance of his structural technique and poetic diction, enable him to endow the abstract concepts of dogmatic and moral theology with convincing dramatic life. At their weakest the *autos* tend to depend for their effect upon the ingenuity of their allegories, but at their best they are imbued with profound moral and spiritual insight, and with a poetic feeling varying from tenderness to forcefulness. *Belshazzar's Feast* (*c.* 1630) and *The Great Theatre of the World* (*c.* 1635) are fine examples of the early style; the greater complexity of his middle period is represented by *No hay más fortuna que Dios* (*c.* 1652; "There Is No Fortune but God") and *Lo que va del hombre a Dios* (1652–57; "The Gulf Between Man and God"). But his highest achievement in this type of drama is to be found among those *autos* of his old age that dramatize the dogmas of the Fall and the redemption, notably *La Viña del Señor* (1674; "The Lord's Vineyard"), *La nave del mercader* (1674; "The Merchant's Ship"), *El nuevo hospicio de pobres* (1675; "The New Hospital for the Poor"), *El día mayor de los días* (1678; "The Greatest Day of Days"), and *El pastor fido* (1678; "The Faithful Shepherd"). Here is found Calderón's most moving expression of his compassionate understanding of human waywardness.

Religious allegorical plays

To have found a dramatic form that conveys the doctrines of the Christian faith gives Calderón a special place in literature. But his greatness is not confined to this; the depth and consistency of his thought, his supremely intelligent craftsmanship and artistic integrity, his psychological insight, and the rationality and humanity of his moral standards make him one of the major figures of world drama.

MAJOR WORKS

COMEDIAS: Of Calderón's more than 100 *comedias* the following are some of the best known. *La devoción de la cruz* (*c.* 1625; *Devotion to the Cross* in *Four Plays*, trans. by E. Honig, 1961); *La cisma de Ingalaterra* (*c.* 1627); *El purgatorio de San Patricio* (*c.* 1628; *The Purgatory of St. Patrick* in *Calderón's Dramas*, trans. by D.F. MacCarthy, 1873); *El príncipe constante* (1629; *The Constant Prince* in *Six Plays*, trans. by D.F. MacCarthy, rev. by H.W. Wells, 1960); *Casa con dos puertas, mala es de guardar* (1629); *La dama duende* (1629; *The Phantom Lady* in *Four Plays*); *De una causa dos efectos* (*c.* 1631–32); *La banda y la flor* (1632); *Amar después de la muerte* (1633; *Love After Death*, trans. by Roy Campbell, 1960); *La vida es sueño* (1635; *Life Is a Dream*, trans. by Roy Campbell, 1959); *A secreto agravio, secreta venganza* (1635; *Secret Vengeance for Secret Insult* in *Four Plays*); *El médico de su honra* (1635; *The Surgeon of His Honour*, trans. by Roy Campbell, 1960); *Las tres justicias en una* (*c.* 1637; *Three Judgments at a Blow* in *Eight Dramas of Calderón*, trans. by E.E. Fitzgerald, 1906); *El mágico prodigioso* (1637; *The Wonder-Working Magician* in *Six Plays*); *La niña de Gómez Arias* (*c.* 1638); *No hay cosa como callar* (1639); *El alcalde de Zalamea* (*c.* 1640; *The Mayor of Zalamea*, trans. by W.E. Colford, 1958); *El Josef de las mujeres* (*c.* 1640); *No siempre lo peor es cierto* (*c.* 1640); *El pintor de su deshonra* (*c.* 1645; *The Painter of His Own Dishonor* in *Eight Dramas of Calderón*); *El jardín de Falerina* (1648), the first of Calderón's zarzuelas, plays in two acts with alternating spoken and sung dialogue; *La hija del aire*, 2 pt. (1653); *La púrpura de la rosa* (1660), one-act opera; *Celos, aun del aire matan* (1660), three-act opera with music by Juan Hidalgo, some of which has not come to light; *Eco y Narciso* (1661); *Fieras afemina amor* (1669); *La estatua de Prometeo* (1669). For other English translations, see those by D.F. MacCarthy (ten plays and *autos*, 1853–73), rev. by H.W. Wells (1960); and *Eight Dramas of Calderón*, which is freely translated by E.E. Fitzgerald (1906).

AUTOS SACRAMENTALES: Seventy-six of these allegorical plays, written for open-air performance on the Feast of Corpus Christi, are extant. The following are some of the best known: *La cena de Baltasar* (*c.* 1630; *Belshazzar's Feast* in *Six Plays*); *El gran teatro del mundo* (*c.* 1635; *The Great Theatre of the World*, trans. by R.C. Trench, 1856); *No hay más fortuna que Dios* (*c.* 1652); *Lo que va del hombre a Dios* (1652–57); *La viña del Señor* (1674); *La nave del mercader* (1674); *El nuevo hospicio de pobres* (1675); *El pastor fido* (1678); *El día mayor de los días* (1678).

BIBLIOGRAPHY. *Biblioteca de autores españoles*, vol. 7, 9, 12, 14 (1944–45); *Obras completas*, new ed., vol. 1, *Dramas*, vol. 2, *Comedias*, both ed. by A. VALBUENA BRIONES; and vol. 3, *Autos sacramentales*, ed. by A. VALBUENA PRAT (1960–67). These editions are not critical or scholarly. Annotated editions, of varying quality, are the 5 vol. (1951–56) of *Selected Comedias and Autos* in the *Clásicos Castellanos*, and 3 vol. of *Tragedies*, ed. by F. RUIZ RAMON (1967–69). Scholarly texts are to be found only among editions of individual plays, for which see *Calderón de la Barca Studies, 1951–69*, ed. by J.H. PARKER and A.M. FOX, pp. 25–59 (1971).

The only attempt at a full biography is E. COTARELO Y MORI, *Ensayo sobre la vida y obras de D. Pedro Calderón de la Barca* (1924). The best general studies are: of the *Autos*, A.A. PARKER, *The Allegorical Drama of Calderón* (1943, reprinted 1968), and E. FRUTOS, *La filosofía de Calderón en sus Autos Sacramentales* (1952); of the *Comedias*, A.E. SLOMAN, *The Dramatic Craftsmanship of Calderón* (1958), and *Critical Essays on the Theatre of Calderón*, ed. by B.W. WARDROPPER (1965).

Calderón's art and thought are being re-assessed in studies still confined to journals. A critical guide to these is (for 1940–58) in the article by H. FLASCHE in *Deutsche Vierteljahrsschrift für Literaturwissenschaft und Geistesgeschichte*, vol. 32, pp. 613–643 (1958); and (for 1951–69) in *Calderón de la Barca Studies*. The University of Hamburg publishes, under the direction of H. FLASCHE, as a subsection of its *Hamburger Romanistische Studien*, a series of studies, including critical editions of *autos*, under the title of *Calderoniana;* 6 vol. have so far (1971) appeared. The existence of an Anglo-American school of criticism has been affirmed and its principles discussed by R.D.F. PRING-MILL in *Litterae Hispanae et Lusitanae*, ed. by H. FLASCHE (1968).

(A.A.P.)

Calendar

A calendar is a means of grouping days in ways convenient for regulating civil life and religious observances and for historical and scientific purposes. The word is derived from the Latin *calendarium*, meaning interest register, or account book, itself a derivation from *calendae* (or *kalendae*), the first day of the Roman month, the day on which future market days, feasts, and other occasions were proclaimed.

The development of a calendar is vital for the study of chronology, since this is concerned with reckoning time by regular divisions, or periods, and using these to date events. It is essential, too, for any civilization that needs to measure periods for agricultural, business, domestic, or other reasons. The first practical calendar to evolve from these requirements was the Egyptian, and it was this that the Romans developed into the Julian calendar that served western Europe for more than 1,500 years. The Gregorian calendar was a further improvement and is now almost universally adopted because it satisfactorily draws into one system the dating of religious festivals based on the phases of the Moon and seasonal activities determined by the movement of the Sun. Such a calendar system is complex, since the periods of the Moon's phases and the Sun's motion are incompatible; but by adopting regular cycles of days and comparatively simple rules for their application, the calendar provides a year with an error of less than half a minute.

This article is divided into the following sections:

I. Early calendar systems
- Standard units and cycles
- Time determination by stars, sun, and moon
- Complex cycles
- The early Roman calendar
- The Jewish calendar
- The Muslim calendar

II. The western calendar and calendar reforms
- The Julian calendar
- The Gregorian calendar
- Calendar reform since the mid-18th century

III. Ancient Middle Eastern calendar systems
- Lunisolar calendars in antiquity
- Ancient Greek calendars in relation to the Middle East
- The Egyptian calendar

IV. The Far East
- The Hindu calendar
- The Chinese calendar

V. Calendar systems of the Americas
- The Maya calendar system
- The Mexican (Aztec) calendar
- Peru: The Inca calendar
- North American Indian time counts

I. Early calendar systems

STANDARD UNITS AND CYCLES

The basic unit of computation in a calendar is the day, and although days are now measured from midnight to midnight, this has not always been so. Astronomers, for instance, from about the 2nd century AD until 1925 counted days from noon to noon. In earlier civilizations and among primitive peoples, where there was less communication between different settlements or groups, different methods of reckoning the day presented no difficulties. Most primitive tribes used a dawn-to-dawn reckoning, calling a succession of days so many dawns, or suns; and this system was continued by the Babylonians and Greeks, who counted a day from sunrise to sunrise. In Egypt, a midnight-to-midnight reckoning was adopted; the Jews and, later, the Italians counted from sunset to sunset. The Teutons counted nights, and from them the grouping of 14 days called a fortnight is derived.

Divisions of the day

There was also great variety in the ways in which the day was subdivided. The Sumerians, for example, divided it into six watches, three during daylight and three during the night; the Jews adopted a similar method. The length of the watches was not constant but varied with the season, the day watches being the longer in summer and the night watches in the winter. Such seasonal variations in divisions of the day became customary in antiquity since they corresponded to the length of the Sun's time above the horizon, at maximum in summer and minimum in winter. Only with the advent of mechanical clocks in western Europe at the end of the 13th century did seasonal (unequal) hours become inconvenient.

Most early Western civilizations used 24 seasonal hours

in the day—12 hours of daylight and 12 of darkness. This was the practice of the Greeks, the Egyptians, and the Romans, and of Western Christendom so far as civil reckoning was concerned. The church adopted its own canonical hours for reckoning daily worship: there were seven of these—matins, prime, terce, sext, none, vespers, and compline—but in secular affairs the system of 24 hours held sway. This number, 2×12, or 24, was derived from the Sumerian sexagesimal method of reckoning, based on gradations of 60 ($5 \times 12 = 60$) rather than on multiples of 10, even though the 24-hour-day itself was an Egyptian invention. The Babylonians—the successors of the Sumerians—used a 12-hour division of the day, and their hours were double hours, with only 12 to cover both day and night. They were among the few to have hours of the same length throughout the year because the Babylonians believed the Sun and Moon to travel through the same number of divisions in the sky during each day and night period.

Origins of the week

Once the day is divided into parts, the next task is to gather numbers of days into groups. Among primitive peoples, it was common to count moons (months) rather than days, but later a shorter period than the month was thought more convenient, and an interval between market days was adopted. It varied widely. In West Africa some tribes used a four-day interval; in central Asia five days was customary; the Assyrians adopted six days and the Egyptians, ten days, whereas the Babylonians attached particular significance to the days of the lunation that were multiples of seven. In ancient Rome there was a *nundinae*, or nine-day, period between weekly markets, although because of the Roman method of inclusive numeration a *nundinae* contained what would now be called eight days.

The seven-day week may owe its origin partly to the four (approximately) seven-day phases of the Moon and partly to the Babylonian belief in hebdomadism—the sacredness of the number seven—which itself was probably related to the seven planets. Moreover, by the 1st century BC the Jewish seven-day week seems to have become adopted throughout the Roman world, and this exerted its due influence on Christendom. The origin of the names of the days of the week appears to be astrological and to have been derived from the Latin or Scandinavian god whose hour started the day.

Table 1: Weekday Names

planets	Latin name	French name	Saxon usage	English name
Sun	Dies Solis	Dimanche	Sun's Day	Sunday
Moon	Dies Lunae	Lundi	Moon's Day	Monday
Mars	Dies Martis	Mardi	Tiw's Day	Tuesday
Mercury	Dies Mercurii	Mercredi	Woden's Day	Wednesday
Jupiter	Dies Jovis	Jeudi	Thor's Day	Thursday
Venus	Dies Veneris	Vendredi	Frigg's Day	Friday
Saturn	Dies Saturni	Samedi	Saterne's Day	Saturday

The month is based on the lunation, that period in which the Moon completes a cycle of its phases. Lasting approximately 29½ days, it is easy to recognize and short enough for the days to be counted without using large numbers. In addition, it is very close to the menstrual period of women and also to the duration of cyclic behaviour in some marine creatures. Thus, the month possessed great significance and was often the governing period for religious observances, of which the dating of Easter is a notable example. All early calendars were, essentially, collections of months, the Babylonians using 29- and 30-day periods alternately, the Egyptians fixing the duration of all months at 30 days, with the Greeks copying them, and the Romans in the Julian calendar having a rather more complex system using one 28-day period with the others of either 30 or 31 days.

The seasons

The month is not suitable for determining the seasons, for these are a solar, not a lunar, phenomenon. Seasons vary in different parts of the world—in tropical countries there are just the rainy and dry periods, but elsewhere there are successions of wider changes. In Egypt, the annual flooding of the Nile was followed by seeding and then harvest, and three seasons were recognized; but in Greece and other more northern countries there was a succession of four seasons of slightly different lengths. However many there seemed to be, it was everywhere recognized that seasons were related to the Sun and that they could be determined from solar observations. These might consist of noting the varying length of the midday shadow cast by a stick thrust vertically into the ground or follow the far more sophisticated procedure of deducing the Sun's position against the background of the stars. In either case the result was a year of 365 days, a period incompatible with the 29½-day lunation. To find some simple relationship between the two was the problem that faced all calendar makers from Babylonian times onward.

TIME DETERMINATION BY STARS, SUN, AND MOON

Measurement of the day, the month, and the year

Celestial bodies provide the basic standards for determining the periods of a calendar. Their movement as they rise and set is now known to be a reflection of the Earth's rotation, which, although not precisely uniform, can conveniently be averaged out to provide a suitable calendar day. The day can be measured either by the stars or by the Sun. If the stars are used, then the interval is called the sidereal day and is defined by the period between two passages of a star (more precisely of the vernal equinox, a reference point on the celestial sphere) across the meridian: it is 23 hours, 56 minutes, 4.10 seconds of mean solar time (see below). The interval between two passages of the Sun across the meridian is a solar day. In practice, since the rate of the Sun's motion varies with the seasons, use is made of a fictitious Sun that always moves across the sky at an even rate. This period of constant length, far more convenient for civil purposes, is the mean solar day, which has a duration in sidereal time of 24 hours, 3 minutes, 56.55 seconds. It is longer than the sidereal day because the motion of the Earth in its orbit during the period between two transits of the Sun means that the Earth must complete more than a whole revolution to bring the Sun back to the meridian. The mean solar day is the period used in calendar computation.

The month is determined by the Moon's passage around the Earth, and, as in the case of the day, there are several ways in which it can be defined. In essence, these are of two kinds: first, the period taken by the Moon to complete an orbit of the Earth and, second, the time taken by the Moon to complete a cycle of phases. For astronomically primitive societies, orbital measures were too sophisticated, and the month was determined by noting the interval between the appearance of one thin crescent Moon and the next—in other words, from one new Moon to another. But however the phases are defined, the interval is now known to be 29.53059 days. Known as the synodic month, it is longer than the orbital month, just as the solar day is longer than the sidereal, and for a similar reason. It grew to be the basis of the calendar month.

The year is the period taken by the Earth to complete an orbit around the Sun and, again, there are a number of ways in which this can be measured. But for calculating a calendar that is to remain in step with the seasons, it is most convenient to use the tropical year, since this refers directly to the Sun's apparent annual motion north and south; it is defined as the interval between successive passages of the Sun through the vernal equinox (*i.e.*, when it crosses the celestial equator late in March) and amounts to 365.242199 mean solar days.

The tropical year and the synodic month are incommensurable, 12 synodic months amounting to 354.36706 days, almost 11 days shorter than the tropical year. Moreover, neither is composed of a complete number of days, so that to compile any calendar that keeps in step with the Moon's phases or with the seasons it is necessary to insert days at appropriate intervals; such additions are known as intercalations.

In primitive lunar calendars, intercalation was often achieved by taking alternately months of 29 and 30 days. When, in order to keep dates in step with the seasons, a solar calendar was adopted, some greater difference be-

tween the months and the Moon's phases was bound to occur. And the solar calendar presented an even more fundamental problem—that of finding the precise length of the tropical year. Observations of cyclic changes in plant or animal life were far too inaccurate, and astronomical observations became necessary. Since the stars are not visible when the Sun is in the sky, some indirect way had to be found to determine its precise location among them. In tropical and subtropical countries it was possible to use the method of heliacal risings. Here the first task was to determine the constellations around the whole sky through which the Sun appears to move in the course of a year. Then, by observing the stars rising in the east just after sunset it was possible to know which were precisely opposite in the sky, where the Sun lay at that time. Such heliacal risings could, therefore, be used to determine the seasons and the tropical year. In temperate countries, the angle at which stars rise up from the horizon is not steep enough for this method to be adopted, so that there wood or stone structures were built to mark out points along the horizon to allow analogous observations to be made.

Locating the Sun among the stars

Stonehenge

The most famous of these is Stonehenge in Wiltshire, England, where the original structure appears to have been built about 2000 BC and additions made at intervals several centuries later. It is composed of a series of holes, stones, and archways arranged mostly in circles, the outermost ring of holes having 56 marked positions, the inner ones 30 and 29, respectively. In addition, there is a large stone—the heel stone—set to the northeast, as well as some smaller stone markers. Observations were made by lining up holes or stones with the heel stone or one of the other markers and watching for the appearance of the Sun or Moon against that point on the horizon that lay in the same straight line. The extreme north and south positions on the horizon of the Sun—the summer and winter solstices—were particularly noted, while the inner circles, with their 29 and 30 marked positions, allowed "hollow" and "full" (29- or 30-day) lunar months to be counted off. To obtain other astronomical information, such as the advent of eclipses, observations were made from various different positions, especially those on the outer circle of stones. More than 600 contemporaneous structures of an analogous but simpler kind have been discovered in Britain and Brittany. It appears, then, that astronomical observation for calendrical purposes was a widespread practice in some temperate countries three to four millennia ago.

Today a solar calendar is kept in step with the seasons by a fixed rule of intercalation. But although the Egyptians, who used the heliacal rising of Sirius to determine the annual inundation of the Nile, knew that the tropical year was about 365.25 days in length, they still used a 365-day year without intercalation. This meant that the calendar date of Sirius' rising became increasingly out of step with the original dates as the years progressed. In consequence, while the agricultural seasons were regulated by the heliacal rising of Sirius, the civil calendar ran its own separate course. It was not until well into Roman times that an intercalary day once every four years was instituted to retain coincidence. Without such a rule, the agricultural calendar had to be determined solely by astronomical observation.

COMPLEX CYCLES

Although the incommensurability of months and years and the fact that neither occupied a whole number of days was recognized quite early in all the great civilizations, it was also appreciated that the difference between calendar dates and the celestial phenomena due to occur on them would first grow and then diminish and that a time would come when they were once more in coincidence. The succession of differences and coincidences would be cyclic, recurring time and again as the years passed. An early recognition of this was the Egyptian Sothic cycle. The 365-day year used in the Egyptian calendar was in error with respect to the heliacal risings of the star Sirius (Sothis) by one quarter of a day per tropical year. This amounted to one day every four tropical years, or one whole Egyptian calendar year every 1,460 tropical years (4 × 365), which was equivalent to 1,461 Egyptian calendar years. After this period the heliacal rising and setting of Sothis would again coincide with the calendar dates (see below, *The Egyptian calendar*).

The main use of cycles was to try to find some commensurable basis for lunar and solar calendars, and the most famous of all the early attempts was that usually attributed to Cleostratus of Tenedos (*c.* 500 BC) and Eudoxus of Cnidus (390–*c.*340 BC), often known as the *octaëteris*. Modern scholarship shows Cleostratus to be a somewhat shadowy figure, and it has also become clear that a cycle of this kind was adopted in Babylon between 529 and 504 BC. Whatever its exact origins, the cycle covered eight years, as its name implies; and since in the 6th century BC the year was accepted to be 365 days in length, the *octaëteris* amounted to 8 × 365, or 2,920 days. This was very close to the total of 99 lunations (99 × 29.5 = 2,920.5 days), so this cycle gave a worthwhile link between lunar and solar calendars. When, in the 4th century BC, the accepted length of the year became 365.25 days, the total number of solar calendar days involved became 2,922, and it was then realized that the *octaëteris* was not so satisfactory a cycle as supposed, since the 29.5-day lunation period was still used.

The *octaëteris*

Another early and important cycle was the saros, essentially an eclipse cycle. There has been some confusion over its precise nature because the name is derived from the Babylonian word *shār* or *shāru*, which could mean either "universe" or the number 3,600 (*i.e.*, 60 × 60). In the latter sense it was used by Berosus (*c.* 290 BC) and a few later authors to refer to a period of 3,600 years. Its first astronomical use appears in an anonymous encyclopaedia called the *Suda Lexicon* (*Suidas Lexicon*), of about 1000 AD. There it was said to be a measure of 222 months used by the Chaldeans, and, although this cannot be quite correct, it is certainly clear that by the 4th century BC the Babylonians did know something of an 18-year or 216-month (18 × 12) cycle of eclipses. What is now known as the saros and appears as such in astronomical textbooks (still usually credited to the Babylonians) is a period of 18 years 11⅓ days (or with one day more or less, depending on how many leap years are involved), after which a series of eclipses is repeated (see ECLIPSE, OCCULTATION, AND TRANSIT).

The saros

In Central America an independent system of cycles was established (see below *Calendar systems of the Americas*).

The most significant of all the early attempts to provide some commensurability between a religious lunar calendar and the tropical year was the Metonic cycle. This was first devised about 430 BC by the astronomer Meton of Athens. Meton worked with another Athenian astronomer, Euctemon, and made a series of observations of the solstices, when the Sun's noonday shadow cast by a vertical pillar, or gnomon, reaches its annual maximum or minimum, to determine the length for the tropical year. Taking a synodic month to be 29.5 days, they then computed the difference between 12 of these lunations and their tropical year, which amounted to 11 days. It could therefore be removed by intercalating a month of 33 days every third year. But months were measured in whole days, and Meton and Euctemon wanted a long-term rule that would be as accurate as they could make it, so they settled on a 19-year cycle. This cycle consisted of 12 years of 12 lunar months each and seven years each of 13 lunar months, a total of 235 lunar months. If this total of 235 lunations is taken to contain 110 hollow months of 29 days and 125 full months of 30 days, the total comes to (110 × 29) + (125 × 30), or 6,940 days. The difference between this lunar calendar and a solar calendar of 365 days amounted to only five days in 19 years and, in addition, gave an average length for the tropical year of 365.25 days, a much-improved value that was, however, allowed to make no difference to daily reckoning in the civil calendar. But the greatest advantage of this cycle was that it laid down a lunar calendar that possessed a definite rule for inserting intercalary months and kept in step with a cycle of the tropi-

The Metonic cycle

cal years. It also gave a more accurate average value for the tropical year and was so successful that it formed the basis of the calendar adopted in the Seleucid Empire (Mesopotamia) and was used in the Jewish calendar and the calendar of the Christian Church; it also influenced Indian astronomical teaching.

The Metonic cycle was improved by both Callippus and Hipparchus. Callippus of Cyzicus (*c.* 370–300 BC) was perhaps the foremost astronomer of his day. He formed what has been called the Callippic period, essentially a cycle of four Metonic periods. It was more accurate than the original Metonic cycle and made use of the fact that 365.25 days is a more precise value for the tropical year than 365 days. The Callippic period consisted of 4 × 235, or 940 lunar months, but its distribution of hollow and full months was different from Meton's. Instead of having totals of 440 hollow and 500 full months, Callippus adopted 441 hollow and 499 full, thus reducing the length of four Metonic cycles by one day. The total days involved therefore became (441 × 29) + (499 × 30), or 27,759, and 27,759 ÷ (19 × 4) gives 365.25 days exactly. Thus the Callippic cycle fitted 940 lunar months precisely to 76 tropical years of 365.25 days.

Hipparchus, who flourished in Rhodes about 150 BC and was probably the greatest observational astronomer of antiquity, discovered from his own observations and those of others made over the previous 150 years that the equinoxes, where the ecliptic (the Sun's apparent path) crosses the celestial equator (the celestial equivalent of the terrestrial Equator), were not fixed in space but moved slowly in a westerly direction. The movement is small, amounting to no more than 2° in 150 years, and it is known now as the precession of the equinoxes. Calendrically, it was an important discovery because the tropical year is measured with reference to the equinoxes, and precession reduced the value accepted by Callippus. Hipparchus calculated the tropical year to have a length of 365.242 days, which was very close to the present 365.242199 days; he also computed the precise length of a lunation, using a "great year" of four Callippic cycles. He arrived at the value of 29.53058 days for a lunation, which, again, is comparable with the present-day figure, 29.53059 days.

Precession of the equinoxes

The calendar dating of historical events, and the determination of how many days have elapsed since some astronomical or other occurrence are difficult for a number of reasons. Leap years have to be inserted, but not always regularly, months have changed their lengths and new ones have been added from time to time, years have commenced on varying dates and their lengths have been computed in various ways. Since historical dating must take all these factors into account, it occurred to the 16th-century French classicist and literary scholar Joseph Justus Scaliger (1540–1609) that a consecutive numbering system could be of inestimable help. This he thought should be arranged as a cyclic period of great length and he worked out the system that is known as the Julian period, in honour of his father Julius Caesar Scaliger (1484–1558). He published his proposals in Paris in 1583 under the title *De Emendatione Temporum.*

The Julian period is a cycle of 7,980 years. It is based on the Metonic Cycle of 19 years, a "solar cycle" of 28 years, and the Indiction cycle of 15 years. The so-called solar cycle was a period after which the days of the seven-day week repeated on the same dates. Since one year contains 52 weeks of seven days, plus one day, the days of the week would repeat every seven years were no leap year to intervene. A Julian calendar (see below) leap year cycle is four years, therefore the days of the week repeat on the same dates every 4 × 7 = 28 years. The cycle of the Indiction was a fiscal, not an astronomical, period. It first appears in tax receipts for Egypt in AD 303, and probably took its origin in a periodic 15-year taxation census that followed Diocletian's reconquest of Egypt in AD 297. By multiplying the Metonic, solar, and Indiction cycles together, Scaliger obtained his cycle of 7,980 years (19 × 28 × 15 = 7,980), a period of sufficient length to cover most previous and future historical dates required at any one time.

Cycle of Indiction

Scaliger, tracing each of the three cycles back in time, found that all coincided in the year 4713 BC, on the Julian calendar reckoning. On the information available to him, he believed this to be a date considerably before any historical events. He therefore set the beginning of the first Julian period at Jan. 1, 4713 BC. The years of the Julian period are not now used, but the day number is still used in astronomy and in preparing calendar tables, for it is the only record where days are free from combination into weeks and months.

A number of non-astronomical natural signs have also been used in determining the seasons. In the Mediterranean area, such indications change rapidly, and Hesiod (*c.* 800 BC) mentions a wide variety: the cry of migrating cranes, which indicated a time for plowing and sowing; the time when snails climb up plants, after which digging in vineyards should cease; and so on. An unwitting approximation to the tropical year may also be obtained by intercalation, using a simple lunar calendar and observations of animal behaviour. Such an unusual situation has grown up among the Yami fishermen of Botel-Tobago Island, near Taiwan. They use a calendar based on phases of the Moon, and some time about March (the precise date depends on the degree of error of their lunar calendar compared with the tropical year) they go out in boats with lighted flares. If flying fish appear, the fishing season is allowed to commence, but if the lunar calendar is too far out of step with the seasons, the flying fish will not rise. Fishing is then postponed for another lunation, which they insert in the lunar calendar, thus having a year of 13 instead of the usual 12 lunations.

Non-astronomical cycles

THE EARLY ROMAN CALENDAR

This originated as a local calendar in the city of Rome, supposedly drawn up by Romulus some seven or eight centuries BC. The year began in March and consisted of ten months, six of 30 days and four of 31 days, making a total of 304 days: it ended in December, to be followed by what seems to have been an uncounted winter gap. Numa Pompilius, traditionally the second king of Rome (715?–673? BC), is supposed to have added two extra months, January and February, to fill the gap and to have increased the total number of days by 50, making 354. To obtain sufficient days for his new months, he is then said to have deducted one day from the 30-day months, thus having 56 days to divide between January and February. But since the Romans had, or had developed, a superstitious dread of even numbers, January was given an extra day; February was still left with an even number of days, but as that month was given over to the infernal gods, this was considered appropriate. The system allowed the year of 12 months to have 355 days, an uneven number.

The so-called Roman Republican calendar was supposedly introduced by the Etruscan Tarquinius Priscius (616–579 BC), traditionally the fifth king of Rome. He wanted the year to begin in January since it contained the festival of the god of gates (later the god of all beginnings), but expulsion of the Etruscan dynasty in 510 BC led to this particular reform being dropped. The Roman Republican calendar still contained only 355 days, with February having 28 days; March, May, Quintilis (July), and October 31 days each; January, April, June, Sextilis (August), September, November, and December 29 days. It was basically a lunar calendar and short by 10¼ days of a 365¼-day tropical year, so in order to prevent it from becoming too far out of step with the seasons, an intercalary month, Intercalans, or Mercedonius (from *merces* meaning wages, since workmen were paid at this time of year), was inserted between February 23 and 24. It consisted of 27 or 28 days and was added once every two years; and in historical times at least, the remaining five days of February were omitted. The intercalation was therefore equivalent to an additional 22 or 23 days, so that in a four-year period the total days in the calendar amounted to (4 × 355) + 22 + 23, or 1,465: this gave an average of 366.25 days per year.

Intercalation was the duty of the Pontifices, a board that assisted the chief magistrate in his sacrificial func-

tions. The reasons for their decisions were kept secret, but because of some negligence and a measure of ignorance and corruption, the intercalations were irregular, and seasonal chaos resulted. In spite of this and the fact that it was over a day too long compared with the tropical year, much of the modified Roman Republican calendar was carried over into the Gregorian calendar now in general use. (C.A.R.)

THE JEWISH CALENDAR

The structure of the calendar. The Jewish calendar in use today is lunisolar, the years being solar and the months lunar, but it also allows for a week of seven days. Because the year exceeds 12 lunar months by about 11 days, a 13th month of 30 days is intercalated in the third, sixth, eighth, 11th, 14th, 17th, and 19th years of a 19-year cycle. Arrangements akin to this procedure are well attested in ancient Babylon (see below *Sumero-Babylonian Calendars*). Among the Jews, however, a regular sequence of intercalation in fixed intervals is stated in the sources to have been introduced as late as the 4th century of the Christian Era and dates from the period of Exile. For practical purposes—*e.g.*, for reckoning the commencement of sabbaths—the day begins at sunset; but the calendar day of 24 hours always begins at 6 PM. The hour is divided into 1,080 parts (*ḥalaqim;* this division is originally Babylonian), each part (*ḥeleq*) equalling 3⅓ seconds. The *ḥeleq* is further divided into 76 *regaʿim.*

The synodic month is the average interval between two mean conjunctions of the Sun and Moon, when these bodies are as near as possible in the sky, which is reckoned at 29 days 12 hours 44 minutes 3⅓ seconds; a conjunction is called a *molad.* This is also a Babylonian value. In the calendar month, however, only complete days are reckoned, the "full" month containing 30 days and the "defective" month 29 days. The months Nisan, Sivan (Siwan), Av, Tishri, Shevaṭ, and, in a leap year, First Adar are always full; Iyyar, Tammuz, Elul, Ṭevet, and Adar (known as Second Adar, or Adar Sheni, in a leap year) are always defective, while Ḥeshvan (Ḥeshwan) and Kislev (Kislew) vary. The calendar, thus, is schematic and independent of the true New Moon. The number of days in a year varies. The number of days in a synodic month multiplied by 12 in a common year and by 13 in a leap year would yield fractional figures. Hence, again reckoning complete days only, the common year has 353, 354, or 355 days and the leap year 383, 384, or 385 days. A year in which both Ḥeshvan and Kislev are full, called complete (*shelema*), has 355 or (if a leap year) 385 days; a normal (*sedura*) year, in which Ḥeshvan is defective and Kislev full, has 354 or 384 days; while a defective (*ḥasera*) year, in which both these months are defective, has 353 or 383 days. The character of a year (*qeviʿa,* literally "fixing") is described by three Hebrew letters, the first and third giving, respectively, the days of the weeks on which the New Year occurs and Passover begins, while the second is the initial of the Hebrew word for defective, normal, or complete. There are 14 types of *qeviʿot,* seven in common and seven in leap years. The New Year begins on Tishri 1, which may be the day of the *molad* of Tishri but is often delayed by one or two days for various reasons. Thus, in order to prevent the Day of Atonement (Tishri 10) from falling on a Friday or a Sunday and the seventh day of Tabernacles (Tishri 21) from falling on a Saturday, the new year must avoid commencing on Sundays, Wednesdays, or Fridays. Again, if the *molad* of Tishri occurs at noon or later, the new year is delayed by one or, if this would cause it to fall as above, two days. These delays (*deḥiyyot*) necessitate, by reason of the above-mentioned limits on the number of days in the year, two other delays.

"Full" and "defective" months

The mean beginning of the four seasons is called *tequfa* (literally "orbit," or "course"); the *tequfa* of Nisan denotes the mean Sun at the vernal equinox, that of Tammuz the mean Sun at the summer solstice, that of Tishri the mean Sun at the autumn equinox, and that of Ṭevet the mean Sun at the winter solstice. As 52 weeks are the equivalent to 364 days, and the length of the solar year is nearly 365¼ days, the *tequfot* move forward in the week by about 1¼ days each year. Accordingly, reckoning the length of the year at the approximate value of 365¼ days, they are held to revert after 28 years (28 × 1¼ = 35 days) to the same hour on the same day of the week (Tuesday, 6 PM) as at the beginning. This cycle is called the great, or solar, cycle (*maḥzor gadol or ḥamma*). The present Jewish calendar is mainly based on the more accurate value 365 days, five hours, 55 minutes, $25\frac{25}{57}$ seconds—in excess of the true tropical year by about 6 minutes, 40 seconds. Thus, it is advanced by one day in about 228 years with regard to the equinox.

The seasons in the Jewish calendar

To a far greater extent than the solar cycle of 28 years, the Jewish calendar employs, as mentioned above, a small, or lunar, cycle (*maḥzor qaṭan*) of 19 years, adjusting the lunar months to the solar years by intercalations. Passover, on Nisan 15, is not to begin before the spring *tequfa,* and so the intercalary month is added after Adar. The *maḥzor qaṭan* is akin to the Metonic cycle, a 19-year cycle proposed by the Athenian astronomer Meton in about 432 BC in which seven months were intercalated, and is based on the nearly correct notion that 235 lunar months are equal to 19 solar years. As, however, 19 "years" of 12 lunar months contain only 228 lunar months, seven intercalations are needed at the intervals set forth above in a 19-year cycle to bring it up to the required 235 months.

The Jewish Era in use today is that dated from the supposed year of the Creation (designated *anno mundi* or AM) with its epoch, or beginning, in 3761 BC. The Jewish year 5735 AM, the 16th in the 302nd lunar cycle and the 23rd in the 205th solar cycle, is a regular year of 12 months, or 354 days. The *qeviʿa* is, using the three respective letters of the Hebrew alphabet as two numerals and an initial in the manner indicated in the second paragraph above, GKH, which indicates that Rosh Hashana (New Year) begins on the third (G = 3) and Passover on the fifth (H = 5) day of the week and that the year is regular (K = *ke-sidra*); *i.e.*, Ḥeshvan is defective—29 days, and Kislev full—30 days. This Jewish year (1974–75 of the Christian Era) begins September 17, 1974, and ends September 5, 1975. Neglecting the thousands, current Jewish years AM are converted into years of the current Christian Era by adding 239 or 240—239 from the Jewish New Year (about September) to December 31 and 240 from January 1 to the eve of the Jewish New Year. The adjustment differs slightly for the conversion of dates of now-antiquated versions of the Jewish Era of the Creation and the Christian Era, or both. Tables for the exact conversion of such dates are available.

Months and important days. The months of the Jewish year and the notable days are as follows:

Tishri: 1–2, Rosh Hashana (New Year); 3, Fast of Gedaliah; 10, Yom Kippur (Day of Atonement); 15–21, Sukkot (Tabernacles); 22, Shemini Atzeret (Eighth Day of Solemn Assembly); 23, Simḥat Torah (Rejoicing of the Law).
Ḥeshvan.
Kislev: 25, Ḥanukka (Festival of Lights) begins.
Tevet: 2 or 3, Ḥanukka ends; 10, Fast.
Shevaṭ: 15, New Year for Trees (Mishna).
Adar: 13, Fast of Esther; 14–15, Purim (Lots).
Second Adar (Adar Sheni) or ve-Adar (intercalated month); Adar holidays fall in ve-Adar during leap years.
Nisan: 15–22, Pesaḥ (Passover).
Iyyar: 5, Israel Independence Day.
Sivan: 6–7, Shavuot (Feast of Weeks [Pentecost]).
Tammuz: 17, Fast (Mishna).
Av: 9, Fast (Mishna).
Elul. (E.J.Wi.)

The calendar in Jewish history. For the months of the Jewish year and the notable days of the Jewish calendar see JEWISH RELIGIOUS YEAR. Present knowledge of the pre-exilic Jewish calendar is both limited and uncertain. The Bible refers to calendar matters only incidentally, and the dating of components of Mosaic Law remains doubtful. The earliest datable source for the Hebrew calendar is the Gezer Calendar, written probably in the age of Solomon, in the late 10th century BC. The inscription indicates the length of main agricultural tasks within the cycle of 12 lunations. The calendar term here

is yereaḥ, which in Hebrew denotes both "moon" and "month." The second Hebrew term for month, *ḥodesh*, properly means the "newness" of the lunar crescent. Thus, the Hebrew months were lunar. They are not named in pre-exilic sources except in the biblical report of the building of Solomon's Temple in I Kings, where the names of three months, two of them also attested in the Phoenician calendar, are given; the months are usually numbered rather than named. The "beginning of the months" was the month of the Passover. In some passages, the Passover month is that of *ḥodesh ha-aviv*, the lunation that coincides with the barley being in the ear. Thus, the Hebrew calendar is tied in with the course of the Sun, that determines ripening of the grain. It is not known how the lunar year of 354 days was adjusted to the Sun year of 365 days. The Bible never mentions intercalation. The year *shana*, properly "change" (of seasons), was the agricultural and, thus, liturgical year. There is no reference to the New Year's day in the Bible.

After the conquest of Jerusalem (587 BC), the Babylonians introduced their cyclic calendar (see below *Sumero-Babylonian calendars*) and the reckoning of their regnal years from Nisanu 1, about the spring equinox. The Jews now had a finite calendar year with a New Year's day, and they adopted the Babylonian month names, which they continue to use. From 587 BC until AD 70, the Jewish civil year was Babylonian, except for the period of Alexander the Great and the Ptolemies (332–200 BC), when the Macedonian calendar (see below *Ancient Greek calendars in relation to the Middle East: Earliest sources*) was used. The situation after the destruction of the Temple in Jerusalem in AD 70 remains unclear. It is not known whether the Romans introduced their Julian calendar or the calendar that the Jews of Palestine used after AD 70 for their business transactions. There is no calendar reference in the New Testament; the contemporary Aramaic documents from Judaea are rare and prove only that the Jews dated events according to the years of the Roman emperors. The abundant data in the Talmudic sources concern only the religious calendar.

Use of the New Moon

In the latter, the commencement of the month was determined by the observation of the crescent New Moon, and the date of the Passover was tied in with the ripening of barley. The actual witnessing of the New Moon and observing of the stand of crops in Judaea were required for the functioning of the religious calendar (see below *Muslim calendar*). The Jews of the Diaspora, who generally used the civil calendar of their respective countries, were informed by messengers from Palestine about the coming festivals. This practice is already attested for 143 BC. After the destruction of the Temple in AD 70, rabbinic leaders took over from the priests the fixing of the religious calendar. Visual observation of the New Moon was supplemented and toward AD 200, in fact, supplanted by secret astronomical calculation. But the Diaspora, or Dispersion, was often reluctant to wait for the arbitrary decision of the calendar makers in the Holy Land. Thus, in Syrian Antioch in AD 328–342, the Passover was always celebrated in (Julian) March, the month of the spring equinox, without regard to the Palestinian rules and rulings. To preserve the unity of Israel, the patriarch Hillel II, in 358/359, published the "secret" of calendar making, which essentially consisted of the use of the Babylonian 19-year cycle with some modifications required by the Jewish ritual.

The application of these principles occasioned controversies as late as the 10th century AD. In the 8th century, the Karaites, following Muslim practice, returned to the actual observation of the crescent New Moon and of the stand of barley in Judaea. But some centuries later they also had to use a precalculated calendar. The Samaritans, likewise, used a computed calendar.

Because of the importance of the sabbath as a time divider, the seven-day week served as a time unit in Jewish worship and life. As long as the length of a year and of every month remained unpredictable, it was convenient to count weeks. The origin of the biblical septenary, or seven-day, week remains unknown; its days were counted from Sunday on. A visionary, probably writing in the Persian or early Hellenistic age under the name of the prediluvian Enoch, suggested the religious calendar of 364 days, or 52 weeks, based on the week, in which all festivals always fall on the same weekday. His idea was later taken up by the Dead Sea Scrolls people. (E.J.Bi.)

THE MUSLIM CALENDAR

The Muslim Era is computed from the starting point of the year of the emigration (Hegira); that is, from the year in which Muḥammad, the prophet of Islām, migrated from Mecca to Medina, 622 AD. The second caliph, ʿUmar I, who reigned 634–644, set the first day of the month Muḥarram as the beginning of the year (see table of months and days); that is, July 16, 622, which had already been fixed by the Qur'an as the first day of the year.

Table 2: Muslim Months and Days

	days		days
Muḥarram	30	Rajab	30
Ṣafar	29	Sha ʿbān	29
Rabīʿ I	30	Ramaḍān	30
Rabīʿ II	29	Shawwāl	29
Jumādā I	30	Dhū al-Qa ʿdah	30
Jumādā II	29	Dhū al-Ḥijjah	29

The years of the Muslim calendar are lunar and always consist of 12 lunar months alternately 30 and 29 days long, beginning with the approximate New Moon. The year has 354 days, but the last month (Dhū al-Ḥijjah) sometimes has an intercalated day, bringing it up to 30 days and making a total of 355 days for that year. The months do not keep to the same seasons in relation to the Sun, because there are no intercalations of months. The months regress through all the seasons every 32½ years.

The names of the months and the number of days in each are given in the accompanying Table.

Ramaḍān

Ramaḍān, the ninth month, is observed throughout the Muslim world as a month of fasting. According to the Qur'an, Muslims must see the New Moon with the naked eye before they can begin their fast. The practice has arisen that two witnesses should testify to this before a *qāḍī* (judge), who, if satisfied, communicates the news to the *muftī* (the interpreter of Muslim law), who orders the beginning of the fast. It has become usual for Middle Eastern Arab countries to accept, with reservations, the verdict of Cairo. Should the New Moon prove to be invisible, then the month Shaʿbān, immediately preceding Ramaḍān, will be reckoned as 30 days in length, and the fast will begin on the day following the last day of this month. The end of the fast follows the same procedure.

The era of the Hegira is the official era in Saudi Arabia, Yemen, and the principalities of the Persian Gulf. Egypt, Syria, Jordan, and Morocco use both the Muslim and the Christian eras. In all Muslim countries, people use the Muslim Era in private, even though the Christian Era may be in official use.

Some Muslim countries have made a compromise on this matter. Turkey, as early as 1088 AH (AD 1677), took over the solar (Julian) year with its month names but kept the Muslim Era. March 1 was taken as the beginning of the year (commonly called *marti year*, after the Turkish word *mart*, for March). Late in the 19th century, the Gregorian calendar was adopted. In the 20th century, Pres. Mustafa Kemal Atatürk ordered a complete change to the Christian Era. Iran, under Reza Shah Pahlavi (reigned 1925–41), also adopted the solar year but with Persian names for the months and keeping the Muslim Era. March 21 is the beginning of the Iranian year. Thus, the Iranian year 1349 began on March 21, 1970. This era is still in use officially. (N.A.Z.)

II. The western calendar and calendar reforms

The calendar now in general worldwide use had its origin in the desire for a solar calendar that kept in step with the seasons and possessed fixed rules of intercalation. Be-

cause it developed in Western Christendom, it had also to provide a method for dating movable religious feasts, the timing of which had been based on a lunar reckoning. To reconcile the lunar and solar schemes, features of the Roman Republican calendar and the Egyptian calendar were combined.

The Roman Republican calendar was basically a lunar reckoning and became increasingly out of phase with the seasons as time passed. By about 50 BC the vernal equinox that should have fallen late in March fell on the Ides of May, some eight weeks later, and it was plain that this error would continue to increase. Moreover, the behaviour of the Pontifices made it necessary to seek a fixed rule of intercalation in order to put an end to arbitrariness in inserting months.

In addition to the problem of intercalation, it was clear that the average Roman Republican year of 366.25 days would always show a continually increasing disparity with the seasons, amounting to one month every 30 years, or three months a century. But the great difficulty facing any reformer was that there seemed to be no way of effecting a change that would still allow the months to remain in step with the phases of the Moon and the year with the seasons. It was necessary to make a fundamental break with traditional reckoning to devise an efficient seasonal calendar.

THE JULIAN CALENDAR

In the mid-1st century BC Julius Caesar invited Sosigenes, an Alexandrian astronomer, to advise him about the reform of the calendar, and Sosigenes decided that the only practical step was to abandon the lunar calendar altogether. Months must be arranged on a seasonal basis, and a tropical (solar) year used, as in the Egyptian calendar, but with its length taken as 365¼ days, a value more accurate than the Egyptians' 365.

To remove the immense discrepancy between calendar date and equinox, it was decided that the year known in modern times as 46 BC should have two intercalations. The first was the customary intercalation of the Roman Republican calendar due that year, the insertion of 23 days following February 23. The second intercalation, to bring the calendar in step with the equinoxes, was achieved by inserting two additional months between the end of November and the beginning of December. This insertion amounted to an addition of 67 days, making a total intercalation for the year of 90 days, and causing the beginning of March, 45 BC in the Roman Republican calendar, to fall on what is still called January 1 of the Julian calendar.

Previous errors having been corrected, the next step was to prevent their recurrence. Here Sosigenes' suggestion about a tropical year was adopted and any pretence to a lunar calendar rejected. The figure of 365.25 days was accepted for the tropical year, and to achieve this by a simple civil reckoning, Caesar directed that a calendar year of 365 days be adopted and that an extra day be intercalated between February 23 and 24 every fourth year. Since February ordinarily had 28 days, February 23 was the sixth day before the Kalendae, or beginning of March, and known as the *sexto-kalendae;* the intercalary day, when it appeared, came the day after, and was therefore called the *bis-sexto-kalendae*. This practice led to the term bissextile being used to refer to such a leap year.

Leap year

The name leap year is a later connotation, probably derived from the Old Norse *hlaupa* ("to leap") and used because, in a bissextile year, any fixed festival after February leaps forward, falling on the next weekday but one to that on which it fell the previous year, not on the next weekday as it would do in an ordinary year.

In Caesar's edict, the intercalary day was known as a *punctum temporis* (point of time), and anyone born that day had subsequent birthdays on February 23 (the day before); but lawyers then and in medieval times raised a number of arguments about its precise interpretation. Also, the Pontifices misinterpreted the edict and inserted the intercalation too frequently. The error arose because of the Roman practice of inclusive numbering, so that an intercalation once every fourth year meant to them intercalating every three years, because a bissextile year was counted as the first year of the next four year period. This error continued undetected for 36 years, during which period 12 days instead of nine were added. The emperor Augustus made a correction by omitting intercalary days between 8 BC and AD 4. In consequence it was not until 48 years after 45 BC that the Julian calendar came into proper operation, a fact that is important in chronology but is often forgotten.

Months of the Julian calendar

It seems that the months of the Julian calendar were taken over from the Roman Republican calendar but were slightly modified to give a more even pattern of numbering. The Republican calendar months of March, May, and Quintilis (July), which had each possessed 31 days, were retained unaltered. Although there is doubt about the details, changes seem probably to have occurred as follows. Except for October, all the months that had previously had only 29 days had either one or two days added. January, September, and November received two days, bringing their totals to 31, while April, June, Sextilis (August), and December received one day each, bringing their totals to 30. October was reduced by one day to a total of 30 days, and February increased to 29 days, or 30 in a bissextile year. With the exception of February, the scheme resulted in months having 30 or 31 days alternately throughout the year. And in order to help farmers, Caesar issued an almanac showing on which dates of his new calendar various seasonal astronomical phenomena would occur.

These arrangements for the months can only have remained in force for a short time, because in 8 BC changes were made by Augustus. In 44 BC, the second year of the Julian calendar, the Senate had decided to alter the name of the month Quintilis to Julius (July), in honour of Julius Caesar, and in 8 BC Augustus prevailed upon them to change the name of Sextilis to Augustus (August), in his honour. Perhaps because Augustus felt that his month must have at least as many days as Julius Caesar's, February was reduced to 28 days and August increased to 31. But because this made three 31 day months (July, August, and September) appear in succession, Augustus is supposed to have reduced September to 30 days, added a day to October to make it 31 days, reduced November by one day to 30 days, and increased December from 30 to 31 days, giving the months the lengths they have today.

Divisions of the month

The Julian calendar retained the Roman Republican calendar method of numbering the days of the month. Compared with the present system, the Roman numbering seems to run backward, for the first day of the month was known as the Kalendae, but subsequent days were not enumerated as so many after the Kalendae but as so many before the following Nonae ("nones"), the day called nonae being the ninth day before the Ides (from *iduare*, meaning "to divide"), which occurred in the middle of the month and were supposed to coincide with the full moon. Days after the Nonae and before the Ides were numbered as so many before the Ides, and those after the Ides as so many before the Kalendae of the next month.

There were no weeks in the original Julian calendar, but days were designated either *dies fasti* or *dies nefasti*, the former being business days and days on which the courts were open: this had been the practice in the Roman Republican calendar. Julius Caesar designated his additional days all as *dies fasti*, and they were added at the end of the month so that there was no interference with the dates traditionally fixed for *dies comitiales* (days when public assemblies might be convened) and *dies festi* and *dies feriae* (religious festivals and holy days). Originally, then, the Julian calendar had a permanent set of dates for administrative matters. The official introduction of the seven-day week by the Emperor Constantine I in the 4th century AD disrupted this arrangement.

It appears, from the date of insertion of the intercalary month in the Roman Republican calendar and the habit of designating years by the names of the consuls, that the calendar year had originally commenced in March, which was the date when the new consul took office. In 222 BC the date of assuming duties was fixed as March

15, but in 153 BC it was transferred to the Kalendae of January, and there it remained. January therefore became the first month of the year, and in the western region of the Roman Empire, this practice was carried over into the Julian calendar. In the eastern provinces, however, years were often reckoned from the accession of the reigning emperor, the second beginning on the first new year's day after the accession; and the date on which this occurred varied from one province to another.

Fixing of January as the first month

THE GREGORIAN CALENDAR

The Julian calendar year of 365.25 days was too long, since the correct value for the tropical year is 365.242199 days. This error of 11 minutes 14 seconds per year amounted to almost one and a half days in two centuries, and seven days in 1,000 years. Once again the calendar became increasingly out of phase with the seasons. From time to time, the problem was placed before church councils, but no action was taken because the astronomers who were consulted doubted whether enough precise information was available for a really accurate value of the tropical year to be obtained. By 1545, however, the vernal equinox, which was used in determining Easter, had moved ten days from its proper date; and in December, when the Council of Trent met for the first of its sessions, it authorized Pope Paul III to take action to correct the error. Correction required a solution, however, that neither Paul III nor his successors were able to obtain in satisfactory form until nearly 1572, the year of election of Pope Gregory XIII. Gregory found various proposals awaiting him and agreed to issue a bull that the Jesuit astronomer Christopher Clavius (1537–1612) began to draw up, using suggestions made by the astronomer and physician Luigi Lilio (also known as Aloysius Lilius; died 1576).

The papal bull appeared in February 1582. First, in order to bring the vernal equinox back to March 21, the day following the Feast of St. Francis (that is, October 5) was to become October 15, thus omitting ten days. Second, to bring the year closer to the true tropical year, a value of 365.2422 days was accepted. This value differed by 0.0078 days per year from the Julian calendar reckoning, amounting to 0.78 days per century, or 3.12 days every 400 years. It was therefore promulgated that three out of every four centennial years should be common years, that is, not leap years; and this practice led to the rule that no centennial years should be leap years unless exactly divisible by 400. Thus, 1700, 1800 and 1900 were not leap years, as they would have been in the Julian calendar, but the year 2000 will be. The bull also laid down rules for calculating the date of Easter.

The date of Easter; epacts. Easter was the most important feast of the Christian Church, and its place in the calendar determined the position of the rest of the Church's movable feasts. Because its timing depended on both the Moon's phases and the vernal equinox, ecclesiastical authorities had to seek some way of reconciling lunar and solar calendars. Some simple form of computation, usable by non-astronomers in remote places, was desirable. There was no easy or obvious solution, and to make things more difficult there was no unanimous agreement on the way in which Easter should be calculated, even on a lunar calendar.

Easter, being the festival of the Resurrection, had to depend on the dating of the Crucifixion, which occurred three days earlier and just before the Jewish Passover. The Passover was celebrated on the 14th day of Nisan, the first month in the Jewish religious year—that is, the lunar month the 14th day of which falls on or next after the vernal equinox. The Christian churches in the eastern Mediterranean area celebrated Easter on the 14th of Nisan on whatever day of the week it might fall, but the rest of Christendom adopted a more elaborate reckoning to ensure that it was celebrated on a Sunday in the Passover week.

Dependence on the Passover

To determine precisely how the Resurrection and Easter Day should be dated, reference was made to the Gospels; but even as early as the 2nd century AD, difficulties had arisen since the synoptic Gospels (Matthew, Mark, and Luke) appeared to give a different date from the Gospel According to John for the Crucifixion. This difference led to controversy that was later exacerbated by another difficulty caused by the Jewish reckoning of a day from sunset to sunset. The question arose of how the evening of the 14th day should be calculated, and some—the quintadecimans—claimed that it meant one particular evening, but others—the quartadecimans—claimed that it meant the evening before, since sunset heralded a new day. Both sides had their protagonists, the Eastern churches supporting the quartadecimans, the Western churches the quintadecimans. The question was finally decided at the Council of Nicaea, in 325, in favour of the quintadecimans, and the Western church agreed. The Eastern churches decided to retain the quartadeciman position, and the church in England, which had few links with the European churches at this time, retained the quartadeciman position until Roman missionaries arrived in the 6th century, when a change was made. The dating of Easter in the Gregorian calendar was based on the decision of the Council of Nicaea, which decreed that Easter should be celebrated on the Sunday immediately following the Full Moon that fell on or after the vernal equinox, which they took as March 21. The Council also ordered that if this Sunday either coincided with the Jewish Passover or with the Easter Day of the quartadecimans, the festival should be held seven days later.

With these provisions in mind, the problem could be broken down into two parts: first, devising a simple but effective way of calculating the days of the week for any date in the year and, second, determining the date of the Full Moons in any year. The first part was solved by the use of a letter code derived from a similar Roman system adopted for determining market days. For ecclesiastical use, the code gave what was known as the Sunday, or dominical, letter.

Dominical letters

The seven letters A through G are each assigned to a day, consecutively from January 1 so that January 1 appears as A, January 2 as B, to January 7 which appears as G, the cycle then continuing with January 8 as A, January 9 as B, and so on. Then in any year the first Sunday is bound to be assigned to one of the letters A–G in the first cycle, and all Sundays in the year possess that dominical letter. For example, if the first Sunday falls on January 3, C will be the dominical letter for the whole year. No dominical letter is placed against the intercalary day, February 29, but since it is still counted as a weekday and given a name, the series of letters moves back one day every leap year after intercalation. Thus, a leap year beginning with the dominical letter C will change to a year with the dominical letter D on March 1; and in lists of dominical letters, all leap years are given a double letter notation, in the example just quoted, CD. It is not difficult to see what dominical letter or letters apply to any particular year, and it is also a comparatively simple matter to draw up a table of dominical letters for use in determining Easter Sunday. The possible dates on which Easter Sunday can fall are written down—they run from March 22 through April 25—and against them the dominical letters for a cycle of seven years. Once the dominical letter for a year is known, the possible Sundays for celebrating Easter can be read directly from the table. This system does not, of course, completely determine Easter; to do so, additional information is required.

This must provide dates for Full Moons throughout the year, and for this a lunar cycle like the Metonic cycle was originally used. Tables were prepared, again using the range of dates on which Easter Sunday could appear, and against each date a number from 1 through to 19 was placed. This number indicated which of the 19 years of the lunar cycle would give a Full Moon on that day. From medieval times these were known as golden numbers, possibly from a name used by the Greeks for the numbers on the Metonic cycle or because gold is the colour used for them in manuscript calendars.

Golden numbers

The system of golden numbers was introduced in 530, but they were arranged as they should have been if adopted at the Council of Nicaea two centuries earlier; and the cycle was taken to begin in a year when the New

Moon fell on January 1. Working backward, this date was found to have occurred in the year preceding AD 1, and therefore the golden number for any year is found by dividing the year by 19, then adding one to the remainder. If the result is zero, the golden number for the year is 19.

To compute the date of Easter, the medieval chronologer computed the golden number for the year and then consulted his table to see by which date this number lay. Having found this date, that of the first Full Moon after March 20, he consulted his table of dominical letters and saw the next date against which the dominical letter for that year appeared; this was the Sunday to be designated Easter. The method, modified for dropping centennial leap years as practiced in the Gregorian calendar, is still given in the English prayer book, although it was officially discarded when the Gregorian calendar was introduced.

The system of golden numbers was eventually rejected because the astronomical Full Moon could differ by as much as two days from the date they indicated. It was Lilius (see above *The Gregorian calendar*) who had proposed a more accurate system based on one that had already been in use unofficially while the Julian calendar was still in force. Called the epact—the word is derived from the Greek *epagein*, meaning "to intercalate"—this was again a system of numbers concerned with the Moon's phases, but now indicating the age of the Moon on the first day of the year, and from which the age of the Moon on any day of the year may be found, at least approximately, by counting, using alternately months of 29 and 30 days.

The epact as previously used was not, however, completely accurate because, like the golden number, it had been based on the Metonic cycle. This cycle occupied a period of 6,939.75 days, whereas it should have lasted for 6,939.9 days; and although the difference is small, it does amount to one day in a little over 307 years, so that after this period, New Moons occur one day earlier than indicated. When the Gregorian calendar was adopted, this difference was taken into account. It was assumed, for convenience, that the error of one day could be said to occur once every 312½ years, so that an eight-day error appeared once every 2,500 years. A one-day change on certain centennial years was then instituted by making the computed age of the Moon one day later seven times, at 300-year intervals, and an eighth time after a subsequent 400 years. This operation was known as the lunar correction, but it was not the only correction required; there was another.

Lunar and solar corrections

Because the Gregorian calendar used a more accurate value for the tropical year than the Julian calendar and achieved this by omitting most centennial leap years, Clavius (see above *The Gregorian calendar*) decided that when the cycle of epacts reached an ordinary centennial year, the number of the epact should be reduced by one; this reduction became known as the solar correction.

One advantage of the epact number was that it showed the age of the Moon on January 1 and so permitted a simple calculation of the dates of New Moon and Full Moon for the ensuing year. Another was that it lent itself to the construction of cycles of 30 epact numbers, each diminishing by one from the previous cycle, so that when it became necessary at certain centennial years to shift from one cycle to another, there would still be a cycle ready that retained a correct relationship between dates and New Moons.

For determining Easter, a table was prepared of the golden numbers, 1 through 19, and below them the cycles of epacts for about 7,000 years; after this time, all the epact cycles are repeated. A second table was then drawn up, giving the dates of Easter Full Moons for different epact numbers. Once the epact for the year was known, the date of the Easter Full Moon could be immediately obtained, while consultation of a table of dominical letters showed which was the next Sunday. Thus, the Gregorian system of epacts, while more accurate than the old golden numbers, still forced the chronologer to consult complex astronomical tables.

Adoption in various countries. The derivation of the term style for a type of calendar seems to have originated some time soon after the 6th century as a result of developments in calendar computation in the previous 200 years. In AD 463, Victorius (or Victorinus) of Aquitaine, who had been appointed by Pope Hilarius to undertake calendar revision, devised the Great Paschal (*i.e.*, Passover) period, sometimes later referred to as the Victorian Period. It was a combination of the solar cycle of 28 years and the Metonic 19-year cycle, bringing the Full Moon back to the same day of the month, and amounted to 28 × 19, or 532 years. In the 6th century, this period was used by Dionysius Exiguus (Denis the Little) in computing the date of Easter, because it gave the day of the week for any day in any year, and so it also became known as the Dionysian period. Dionysius took the year now called AD 532 as the first year of a new Great Paschal period and the year now designated 1 BC as the beginning of the previous cycle. In the 6th century it was the general belief that this was the year of Christ's birth, and because of this Dionysius introduced the concept of numbering years consecutively through the Christian era. The method was adopted by some scholars but seems only to have become widely used after its popularization by the Venerable Bede of Jarrow (?673–735), whose reputation for scholarship was very high in Western Christendom in the 8th century. This system of BC/AD numbering threw into relief the different practices, or styles, of reckoning the beginning of the year then in use. When the Gregorian calendar firmly established January 1 as the beginning of its year, it was widely referred to as the New Style calendar, with the Julian the Old Style calendar. In Britain, under the Julian calendar, the year had first begun on December 25 and then, from the 14th century onward, on March 25.

The Great Paschal period

Because of the division of the Eastern and Western Christian churches and of Protestants and Roman Catholics, the obvious advantages of the Gregorian calendar were not accepted everywhere, and in some places adoption was extremely slow. In France, Italy, Luxembourg, Portugal, and Spain, the New Style calendar was adopted in 1582, and by most of the German Roman Catholic states as well as by Belgium and part of the Netherlands by 1584. Switzerland's change was gradual, beginning in 1583 and being completed only in 1812. Hungary adopted the New Style in 1587, and then there was a pause of more than a century before the first Protestant countries moved over from the Old Style calendar. In 1699–1700, Denmark and the Dutch and German Protestant states embraced the New Style, although the Germans declined to adopt the rules laid down for determining Easter, preferring to rely on astronomical tables and specifying the use of the *Tabulae Rudolphinae* (*Rudolphine Tables*), based on the 16th-century observations of Tycho Brahe. They acceded to the Gregorian calendar rules for Easter only in 1776. Britain adopted the New Style in 1752 and Sweden in 1753, although, because the Swedes had in 1740 followed the German Protestants in using their astronomical methods for determining Easter, they declined to adopt the Gregorian calendar rules until 1844. Japan adopted the New Style in 1873; Egypt in 1875; and between 1912 and 1917 it was accepted by Albania, Bulgaria, China, Estonia, Latvia, Lithuania, Romania, Turkey, and Yugoslavia. Soviet Russia adopted the New Style in 1918; Greece in 1923.

Adoption of the New Style by Protestant countries

In Britain and the British dominions, the change was made when the difference between the New and Old Style calendars amounted to 11 days, by naming the day after September 2, 1752, as September 14, 1752; but there was much public misunderstanding, and in Britain rioters demanded "give us back our 11 days," even though legislation authorizing the change had been framed to avoid injustice and financial hardship. Alaska retained the Old Style calendar until 1867, when it was transferred from Russia to the United States.

CALENDAR REFORM SINCE THE MID-18TH CENTURY

The French Republican calendar. In late-18th-century France, with the approach of the French Revolution,

demands began to be made for a radical change in the civil calendar that would divorce it completely from any ecclesiastical connections. The first attacks on the Gregorian calendar and proposals for reform came in 1785 and 1788, the changes being primarily designed to divest the calendar of all its Christian associations. After the storming of the Bastille in July 1789, demands became more vociferous, and a new calendar, to start from "the first year of liberty," was widely spoken about. In 1793 the National Convention appointed Charles-Gilbert Romme, president of the committee of public instruction, to take charge of the reform. Technical matters were entrusted to the mathematicians Joseph-Louis Lagrange and Gaspard Monge and the renaming of the months to the Paris deputy to the convention, Fabre d'Eglantine. The results of their deliberations were submitted to the convention in September of the same year and were immediately accepted, it being promulgated that the new calendar should become law on October 5.

The French Republican calendar, as it came to be known, was taken to have begun on September 22, 1792, the day of the proclamation of the Republic and, in that year, the date also of the autumnal equinox. All future years were to begin on the same date. The total number of days in the year was 365, the same as in the Julian and Gregorian calendars, and this was divided into 12 months of 30 days each, the remaining five days being devoted to festivals and vacations. These were to fall between September 17 and 22 and were specified, in order, to be festivals of virtue, genius, labour, opinion, and rewards. In a leap year an extra festival was to be added—the festival of the Revolution. Leap years were retained at the same frequency as in the Gregorian calendar, but it was enacted that the first leap year should be year 3, not year 4 as it would have been if the Gregorian calendar had been followed precisely in this respect. Each four-year period was to be known as a *Franciade*.

Weeks and *décades*

The seven-day week was abandoned, and each 30-day month was divided into three periods of ten days called *décades*, the last day of a *décade* being a rest day. It was also agreed that each day should be divided into decimal parts, but this was not popular in practice and was allowed to fall into disuse.

The months themselves were renamed so that all previous associations should be lost, and Fabre d'Eglantine chose descriptive names as follows (the descriptive nature and Gregorian calendar dates for 1793–95 are given in parentheses): Vendémiaire ("vintage," September 22 to October 21), Brumaire ("mist," October 22 to November 20), Frimaire ("frost," November 21 to December 20), Nivôse ("snow," December 21 to January 19), Pluviôse ("rain," January 20 to February 18), Ventôse ("wind," February 19 to March 20), Germinal ("seed-time," March 21 to April 19), Floréal ("blossom," April 20 to May 19), Prairial ("meadow," May 20 to June 18), Messidor ("harvest," June 19 to July 18), Thermidor ("heat," July 19 to August 17), and Fructidor ("fruits," August 18 to September 16).

The French Republican calendar was short-lived, for while it was satisfactory enough internally, it clearly made for difficulties in communication abroad because its months continually changed their relationship to dates in the Gregorian calendar. In September 1805, under the Napoleonic regime, the calendar was virtually abandoned, and on January 1, 1806, it was replaced by the Gregorian calendar. The lack of success of the French Republican calendar has no doubt decided other regimes against adopting any similar system, for when Soviet Russia undertook its calendar reform in February 1918, it merely moved from the Julian calendar to the Gregorian, with a loss of 13 days, so that February 1 became February 13. In 1929, a Revolutionary calendar was proposed for the U.S.S.R., but never put into use.

Modern schemes for reform. The current calendar is not without defects, and reforms are still being proposed. Astronomically, it really calls for no improvement, but the seven-day week and the different lengths of months are unsatisfactory to some. Clearly, if the calendar could have all festivals and all rest days fixed on the same dates every year, as in the original Julian calendar, this arrangement would be more convenient, and two general schemes have been put forward—the International Fixed Calendar and the World Calendar.

The International Fixed Calendar is essentially a perpetual Gregorian calendar, in which the year is divided into 13 months, each of 28 days, with an additional day at the end. Present month names are retained, but a new month named Sol is intercalated between June and July. The additional day follows December 28 and bears no designation of month date or weekday name, while the same would be true of the day intercalated in a leap year after June 28. In this calendar, every month begins on a Sunday and ends on a Saturday.

It is claimed that the International Fixed Calendar does not conveniently divide into quarters for business reckoning; and the World Calendar is designed to remedy this deficiency, being divided into four quarters of 91 days each, with an additional day at the end of the year. In each quarter, the first month is of 31 days and the second and third of 30 days each. The extra day comes after December 30 and bears no month or weekday designation, nor does the intercalated leap year day which follows June 30. In this calendar January 1, April 1, July 1, and October 1 are all Sundays. Critics point out that each month extends over part of five weeks, and each month within a given quarter begins on a different day. Nevertheless, both these proposed reforms seem to be improvements over the present system that contains so many variables. (C.A.R.)

III. Ancient Middle Eastern calendar systems

LUNISOLAR CALENDARS IN ANTIQUITY

The lunisolar calendar, in which months are lunar but years are solar—that is, are brought into line with the course of the Sun—was used in the early civilizations of the whole Middle East, except Egypt, and in Greece. The formula was probably invented in Mesopotamia in the 3rd millennium BC. Study of cuneiform tablets found in this region facilitates tracing the development of time reckoning back to the 27th century BC, near the invention of writing. The evidence shows that the calendar is a contrivance for dividing the flow of time into units that suit man's current needs. Though calendar makers put to use time signs offered by nature, say the Moon phases, they rearranged reality to make it fit man's constructions.

Sumero-Babylonian calendars. In Mesopotamia the natural year (that is, the Sun year) was divided into two seasons, the "summer," which included the barley harvest in the second half of May or in the beginning of June, and the "winter," which roughly corresponded to today's fall–winter. Three seasons (Assyria) and four seasons (Anatolia) were counted in northerly countries, but in Mesopotamia the bipartition of the year seemed natural. As late as *c.* 1800 BC, the prognoses for the welfare of the city of Mari, on the middle Euphrates, were taken for six months.

The months began at the first visibility of the New Moon. In the 8th century BC, court astronomers still reported to the Assyrian kings the observation of the New Moon. The names of the months differed from city to city, and within the same Sumerian city a month could have several names: derived from festivals, from tasks (*e.g.*, sheepshearing) usually performed in the given month, and so on, according to the needs of the respective group or office. On the other hand, as early as the 27th century BC, the Sumerians had used artificial time units in referring to the tenure of some high official—*e.g.*, on N-day of the turn of office of PN, governor. The Sumerian administration also needed a time unit comprising the whole vegetation cycle; for example, from the delivery of new barley and the settling of pertinent accounts to the next crop. This financial year began about two months after barley cutting. For other purposes, a year began before or with the harvest. This fluctuating and discontinuous year was not precise enough for the meticulous accounting of Sumerian scribes, who by 2400 BC already used the schematic year of $30 \times 12 = 360$ days.

The royal year

At about the same time, the idea of a royal year took precise shape, beginning probably at the time of barley harvest, when the king celebrated the new (agricultural) year by offering first fruits to gods in expectation of their blessings for the year. When, in the course of this year, some royal exploit (conquest, temple building, and so on) demonstrated that the fates had been fixed favourably by the celestial powers, the year was named accordingly; for example, as the year in which "the temple of Ningirsu was built." Until the naming, a year was described as that "following the year named (after such and such event)." The use of the date formulas was supplanted in Babylonia by the counting of regnal years in the 17th century BC. But, up to the end of their state (612 BC), the Assyrians kept the naming of years after the official called the eponym (known as *limmu*), because the lot by which he was annually chosen was inscribed with a blessing: "May (god Ashur) prosper the crops of Assyria in the year of *limmu* PN."

The use of lunar reckoning began to prevail in the 21st century BC. The lunar year probably owed its success to economic progress. A barley loan could be measured out to the lender at the next year's threshing floor. The wider use of silver as the standard of value demanded more flexible payment terms. A man hiring a servant in the lunar month of Kislimu for a year knew that the engagement would end at the return of the same month, without counting days or periods of office between two dates. At the city of Mari in about 1800 BC, the allocations were already reckoned on the basis of 29- and 30-day lunar months. In the 18th century BC, the Babylonian Empire standardized the year by adopting the calendar of the Sumerian sacred city of Nippur. The power and the cultural prestige of Babylon assured the success of the lunar year, which began on Nisanu 1, in the spring. When, in the 17th century BC, the dating by regnal years became usual, the period between the accession day and the next Nisanu 1 was described as "the beginning of the kingship of PN," and the regnal years were counted from this Nisanu 1.

It was necessary for the lunar year of about 354 days to be brought into line with the solar year of approximately 365 days, which determines the growth of vegetation. This was accomplished by the use of an intercalated month. Thus, in the 21st century BC, a special name for the intercalated month *iti dirig* appears in the sources. The intercalation was operated haphazardly, according to real or imagined needs, and each Sumerian city inserted months at will; *e.g.*, 11 months in 18 years or two months in the same year. Later, the empires centralized the intercalation, and as late as 541 BC it was proclaimed by royal fiat. Improvements in astronomical knowledge eventually made possible the regularization of the calendar by the insertion of extra months; and, under the Persian kings (*c.* 380 BC), Babylonian calendar calculators succeeded in computing an almost perfect equivalence in a lunisolar cycle of 19 years and 235 months with intercalations in the years 3, 6, 8, 11, 14, 17, and 19 of the cycle. The new year's day (Nisanu 1) now oscillated around the spring equinox within the period of 27 days. (The corresponding figure for the present Easter cycle is 35 days.)

Babylonian months

The Babylonian month names were Nisanu, Ayaru, Simanu, Du'uzu, Abu, Ululu, Tashritu, Arakhsamna, Kislimu, Tebetu, Shabatu, Adaru. The month Adaru II was intercalated six times within the 19-year cycle but never in the year that was 17th of the cycle, when Ululu II was inserted. Thus, the Babylonian calendar until the end preserved a vestige of the original bipartition of the natural year into two seasons, just as the Babylonian months to the end remained truly lunar and began when the New Moon was first visible in the evening. The day began at sunset. The night and the daylight period were each divided into three watches and 12 hours. Sundials and water clocks served to count hours.

The influence of the Babylonian calendar was seen in many continued customs and usages of its neighbour and vassal states long after the Babylonian Empire had been succeeded by others. In particular, the Jewish calendar in use at relatively late dates employed similar systems of intercalation of months, month names, and other details (see above *The Jewish calendar*). The Jewish adoption of Babylonian calendar customs dates from the period of Exile (586–516 BC).

Other calendars used in the ancient Near East. *The Assyrians and the Hittites.* Of the calendars of other peoples of the ancient Near East, very little is known. Thus, though the names of all or of some months are known, their order is not. The months were probably everywhere lunar, but evidence for intercalation is often lacking; for instance, in Assyria. For accounting, the Assyrians also used a kind of week, of five days, as it seems, identified by the name of an eponymous official. Thus, a loan could be made and interest calculated for a number of weeks in advance and independently of the vagaries of the civil year. In the city of Ashur, the years bore the name of a yearly official *limmu*. As late as about 1070 BC, his installation date was not fixed in the calendar. From about 1100 BC, however, Babylonian month names began to supplant Assyrian names, and, when Assyria became a world power, it used the Babylonian lunisolar calendar.

The calendar of the Hittite Empire is known even less well. As in Babylonia, the first Hittite month was that of first fruits, and, on its beginning, the gods determined the fates.

Iran. At about the time of the conquest of Babylonia in 538 BC, Persian kings made the Babylonian cyclic calendar standard throughout the Persian Empire, from the Indus to the Nile. Aramaic documents from Persian Egypt, for instance, bear Babylonian dates besides the Egyptian. Similarly, the royal years were reckoned in Babylonian style, from Nisanu 1. It is probable, however, that at the court itself the counting of regnal years began with the accession day. The Seleucids and, afterward, the Parthian rulers of Iran maintained the Babylonian calendar. The fiscal administration in northern Iran, from the 1st century BC, at least, used Zoroastrian month and day names in documents in Pahlavi (the Iranian language of Sāsānian Persia). The origin and history of the Zoroastrian calendar year of 12 months of 30 days, plus five days (that is, 365 days), remain unknown. It became official under the Sāsānian dynasty, from about AD 226 until the Arab conquest in 621. The Arabs introduced the Muslim lunar year, but the Persians continued to use the Sāsānian solar year, which in 1079 was made equal to the Julian year by the introduction of the leap year.

The Zoroastrian calendar

ANCIENT GREEK CALENDARS IN RELATION TO THE MIDDLE EAST

Earliest sources. The earliest sources (clay tablets of the 13th century BC, the writings of Homer and Hesiod) imply the use of lunar months; Hesiod also uses reckoning determined by the observation of constellations and star groups; *e.g.*, the harvest coincides with the visible rising of the star group known as the Pleiades before dawn. This simultaneous use of civil and natural calendars is characteristic of Greek time reckoning. In the classical age and later, the months, named after festivals of the city, began in principle with the New Moon. The lunar year of 12 months and about 354 days was to be matched with the solar year by inserting an extra month every other year. The Macedonians used this system as late as the 3rd century BC, although 25 lunar months amount to about 737 days, while two solar years count about 730 days. In fact, as the evidence from the second half of the 5th century BC shows, at this early time the calendar was already no longer tied in with the phases of the Moon. The cities, rather, intercalated months and added or omitted days at will to adjust the calendar to the course of the Sun and stars and also for the sake of convenience, as, for instance, to postpone or advance a festival without changing its traditional calendar date. The calendric New Moon could disagree by many days with the true New Moon, and in the 2nd century BC Athenian documents listed side by side both the calendar date and that according to the Moon. Thus, the lunar months that were in principle parallel might diverge widely in different cities. Astronomers such as Meton, who in 432 BC cal-

culated a 19-year lunisolar cycle, were not heeded by the politicians, who clung to their calendar-making power.

Civil and natural years compared

The year. The civil year (*etos*) was similarly dissociated from the natural year (*eniautos*). It was the tenure term of an official or priest, roughly corresponding to the lunar year, or to six months; it gave his name to his time period. In Athens, for instance, the year began on Hekatombaion 1, roughly midsummer, when the new archon entered his office, and the year was designated by his name; *e.g.*, "when Callimedes was archon"—that is, 360–359 BC. There was no new year's festival.

As the archon's year was of indefinite and unpredictable length, the Athenian administration for accounting, for the dates of popular assemblies, etc., used turns of office of the sections (prytanies) of the Council (Boule), which each had fixed length within the year. The common citizen used, along with the civil months, the seasonal time reckoning based on the direct observation of the Moon's phases and on the appearance and setting of fixed stars. A device (called a *parapēgma*) with movable pegs indicated the approximate correspondence between, for example, the rising of the star Arcturus and the civil date.

After Alexander's conquest of the Persian Empire, the Macedonian calendar (see above *Earliest sources*) came to be widely used by the Greeks in the East, though in Egypt it was supplanted by the Egyptian year at the end of the 3rd century BC. The Seleucids, from the beginning, adapted the Macedonian year to the Babylonian 19-year cycle (see above *Sumero-Babylonian calendars*). Yet, Greek cities clung to their arbitrary system of time reckoning even after the introduction of the Julian calendar throughout the Roman Empire. As late as *c.* AD 200, they used the antiquated *octaëteris; i.e.*, the intercalation of three months in eight years, to keep the calendar roughly in step with the solar year.

Months, days, seasons. The Athenian months were called Hekatombaion (in midsummer), Metageitnion, Boedromion, Pyanepsion, Maimakterion, Poseideion, Gamelion, Anthesterion, Elaphebolion, Mounychion, Thargelion, and Skirophorion. The position of the intercalary month varied. Each month, in principle, consisted of 30 days, but in roughly six months the next to last day, the 29th, was omitted. The days were numbered within each of the three decades of the month. Thus, for example, Hekatombaion 16th was called "6th after the 10th of Hekatombaion." The Macedonian months were Dios (in fall), Apellaios, Audynaios, Peritios, Dystros, Xanthikos, Artemisios, Daisios, Panemos, Loos, Gorpiaios, and Hyperberetaios. In the Seleucid calendar, Dios was identified with the Babylonian Tashritu, Apellaios with Arakhsamna, and so on.

On the Babylonian pattern, the daylight time and the night were divided into four "watches" and 12 hours each. Thus, the length of an hour oscillated between approximately 45 and 75 present-day minutes, according to the season. Water clocks, gnomons, and, after *c.* 300 BC, sundials roughly indicated time. The season division was originally bipartite as in Babylonia—summer and winter—but four seasons were already attested by about 650 BC. (E.J.Bi.)

THE EGYPTIAN CALENDAR

The ancient Egyptians originally employed a calendar based upon the Moon, and, like many peoples throughout the world, they regulated their lunar calendar by means of a star. For them the year was governed by the star Sirius (Egyptian, Sothis, *Spdt*) and corresponded closely to the true solar year, being 12 minutes shorter. Certain difficulties, however, are inherent in any lunar calendar because the Moon's motion around the Earth in terms of days is not an equal divisor of the 365¼-day solar year. To solve this problem the Egyptians invented

The civil year

a schematized civil year of 365 days divided into three seasons, each of which consisted of four months of 30 days each. To complete the year, five intercalary days were added at its end, so that the 12 months were equal to 360 days plus five extra days. This civil calendar was derived from the lunar calendar (using months) and the agricultural, or Nile, fluctuations (using seasons); it was, however, no longer directly connected to either and thus was not controlled by them. The civil calendar served government and administration, while the lunar calendar continued to regulate religious affairs and everyday life.

In time, the discrepancy between the civil calendar and the older lunar structure became obvious. Because the lunar calendar was controlled by the rising of Sirius, its months would correspond to the same season each year, while the civil calendar would move through the seasons because the civil year was about one-fourth day shorter than the solar year. Hence, every four years it would fall behind the solar year by one day, and after 1,460 years it would again agree with the lunisolar calendar. Such a period of time is called a Sothic cycle.

The Sothic cycle

Because of the discrepancy between these two calendars, the Egyptians established a second lunar calendar based upon the civil year and not, as the older one had been, upon the sighting of Sirius. It was schematic and artificial, and its purpose was to determine religious celebrations and duties. In order to keep it in general agreement with the civil year, a month was intercalated every time the first day of the lunar year came before the first day of the civil year; later, a 25-year cycle of intercalation was introduced. The original lunar calendar, however, was not abandoned but was retained primarily for agriculture because of its agreement with the seasons. Thus, the ancient Egyptians operated with three calendars, each for a different purpose.

The only unit of time that was larger than a year was the reign of a king. The usual custom of dating by reign was: "year 1, 2, 3 . . ., etc., of King So-and-So," and with each new king the counting reverted back to year One. King lists recorded consecutive rulers and the total years of their respective reigns.

The civil year (*rnpt*) was divided into three seasons, commonly translated: Inundation, when the Nile overflowed the agricultural land; Going Forth, the time of planting when the Nile returned to its bed; and Deficiency, the time of low water and harvest.

The months (*3bdw*) of the civil calendar were numbered according to their respective seasons and were not listed by any particular name—*e.g.*, third month of Inundation—but for religious purposes the months had names. How early these names were employed in the later lunar calendar is obscure.

The days (*hrw*) in the civil calendar were also indicated by number and listed according to their respective months. Thus a full civil date would be: "Regnal year 1, fourth month of Inundation, day 5, under the majesty of King So-and-So." In the lunar calendar, however, each day had a specific name and from some of these names it can be seen that the four quarters or chief phases of the Moon were recognized, although the Egyptians did not use these quarters to divide the month into smaller segments, such as weeks. Unlike most people who used a lunar calendar, the Egyptians began their day with sunrise instead of sunset because they began their month, and consequently their day, by the disappearance of the old Moon just before dawn. Others calculated their month by the first sighting of a new moon or new crescent after sunset and thus began their day in the evening.

Designation of days

The hours (*wnwt*) of the day were divided into two parts, 12 hours of daylight and 12 hours of darkness. An hour was not 1/24 of the entire day, but was 1/12 of the actual time between sunrise and sunset or 1/12 of the time between sunset and sunrise. Because of the variation in the amount of daylight and darkness between summer and winter, the length of the Egyptian hour changed accordingly. Both water clocks and sundials were constructed with notations to indicate the hours for the different months and seasons of the year. The standard hour of constant length was never employed in ancient Egypt. (J.D.Sc.)

IV. The Far East

THE HINDU CALENDAR

While the Republic of India has adopted the Gregorian calendar for its secular life, its Hindu religious life continues to be governed by the traditional Hindu calendar.

This calendar, based primarily on the lunar revolutions, is adapted to solar reckoning.

Early history. The oldest system, in many respects the basis of the classical one, is known from texts of about 1000 BC. It divides an approximate solar year of 360 days into 12 lunar months of 27 (according to the early Vedic text Taittirīya Saṃhitā 4.4.10.1-3) or 28 (according to the Atharvaveda, the fourth of the Vedas, 19.7.1.) days. The resulting discrepancy was resolved by the intercalation of a leap month every 60 months. Time was reckoned by the position marked off in constellations on the ecliptic in which the Moon rises daily in the course of one lunation (the period from New Moon to New Moon) and the Sun rises monthly in the course of one year. These constellations (*nakṣatra*) each measure an arc of 13°20′ of the ecliptic circle. The positions of the Moon were directly observable, and those of the Sun inferred from the Moon's position at Full Moon, when the Sun is in opposition to the Moon. The position of the Sun at midnight was calculated from the *nakṣatra* that culminated on the meridian at that time, the Sun then being in opposition to that *nakṣatra*. The year was divided into three thirds of four months, each of which would be introduced by a special religious rite, the *cāturmāsya* (four-month rite). Each of these periods was further divided into two parts (seasons or *ṛtu*): spring, (*vasanta*) from mid-March until mid-May; summer (*grīṣma*), from mid-May until mid-July; the rains (*varṣa*), from mid-July until mid-September; autumn (*śarad*), from mid-September until mid-November; winter (*hemanta*), from mid-November until mid-January; and the dews (*śiśira*), from mid-January until mid-March. The spring months in early times were Madhu and Mādhava, the summer months Śukra and Śuci, the rainy months Nabhas and Nabhasya, the autumn months Īṣa and Ūrja, the winter months Sahas and Sahasya, and the dewy months Tapas and Tapasya. The month, counted from Full Moon to Full Moon, was divided into two halves (*pakṣa* "wing") of waning (*kṛṣṇa*) and waxing (*śukla*) Moon, and a special ritual (*darśapūrṇamāsa*, "new and full moon rites") was prescribed on the days of New Moon (*amāvasya*) and Full Moon (*pūrṇimās*). The month had theoretically 30 days (*tithi;* see below), and the day (*divasa*) 30 hours (*muhūrta*).

The *nakṣatra*

This picture is essentially confirmed by the first treatise on time reckoning, the *Jyotiṣa-vedāṅga* ("Vedic auxiliary [text] concerning the luminaries") of about 100 BC, which adds a larger unit of five years (*yuga*) to the divisions. A further old distinction is that of two year moieties, the *uttarāyaṇa* ("northern course"), when the Sun rises every morning farther north, and the *dakṣiṇāyana* ("southern course"), when it rises progressively farther south.

The classical calendar. In its classic form (*Sūrya-siddhānta*, 4th century AD) the calendar continues from the one above with some refinements. With the influence of Hellenism, Greek and Mesopotamian astronomy and astrology were introduced. Though astronomy and time reckoning previously were dictated by the requirements of rituals, the time of which had to be fixed correctly, and not for purposes of divination, the new astrology came into vogue for casting horoscopes and making predictions. Zodiacal time measurement was now used side by side with the older *nakṣatra* one. The *nakṣatra* section of the ecliptic (13°20′) was divided into four parts of 3°20′ each; thus, two full *nakṣatra*s and a quarter of one make up one zodiac period, or sign (30°). The year began with the entry of the Sun (*saṃkrānti*) in the sign of Aries. The names of the signs (*rāśi*) were taken over and mostly translated into Sanskrit: *meṣa* ("ram," Aries), *vṛṣabha* ("bull," Taurus), *mithuna* ("pair," Gemini), *karkaṭa* ("crab," Cancer), *siṃha* ("lion," Leo), *kanyā* ("maiden," Virgo), *tulā* ("scale," Libra), *vṛścika* ("scorpion," Scorpius), *dhanus* ("bow," Sagittarius), *makara* ("crocodile," Capricornus), *kumbha* ("water jar," Aquarius), *mīna* ("fish," Pisces).

The precession of the vernal equinox from the Sun's entry into Aries to some point in Pisces, with similar consequences for the summer solstice, autumnal equinox, and winter solstice, has led to two different methods of calculating the *saṃkrānti* (entry) of the Sun into a sign: the precession (*ayana*) is not accounted for in the *nirayana* system (without *ayana*), which thus dates the actual *saṃkrānti* correctly but identifies it wrongly with the equinox or solstice, and the *sāyana* system (with *ayana*), which thus dates the equinox and solstice correctly but identifies it wrongly with the *saṃkrānti*.

While the solar system has extreme importance for astrology, which, it is claimed, governs a person's life as an individual or part of a social system, the sacred time continues to be reckoned by the lunar *nakṣatra* system. The lunar day (*tithi*), a thirtieth part of the lunar month, remains the basic unit. Thus, as the lunar month is only about 29½ solar days, the *tithi* does not coincide with the natural day (*ahorātra*). The convention is that that *tithi* is in force for the natural day that happened to occur at the dawn of that day. Therefore, a *tithi* beginning after dawn one day and expiring before dawn the next day is eliminated, not being counted in that month, and there is a break in the day sequence.

The names of the *nakṣatra*s, to which correspond the *tithi*s in the monthly lunar cycle and segments of months in the annual solar cycle, are derived from the constellations on the horizon at that time and have remained the same. The names of the months have changed: Caitra (March-April), Vaiśākha (April-May), Jyaiṣṭha (May-June), Āṣāḍha (June-July), Śrāvaṇa (July-August), Bhādrapada (August-September), Āśvina (September-October), Kārttika (October-November), Mārgaśīrṣa (November-December), Pauṣa (December-January), Māgha (January-February), and Phālguna (February-March).

Month names

In this calendar the date of an event takes the following form: month, fortnight (either waning or waxing Moon), name (usually the number) of the *tithi* in that fortnight, and the year of that era which the writer follows. Identification, particularly of the *tithi*, is often quite complicated, since it requires knowledge of the time of sunrise on that day and which thirtieth of the lunar month was in force then.

Eventually, India also adopted the seven-day week (*saptāha*) from the West and named the days after the corresponding planets: Sunday after the Sun, *ravivāra*; Monday after the Moon, *somavāra*; Tuesday after Mars, *maṅgalavāra*; Wednesday after Mercury, *budhavāra*; Thursday after Jupiter, *bṛhaspativāra*; Friday after Venus, *śukravāra*; and Saturday after Saturn, *śanivāra*.

A further refinement of the calendar was the introduction into dating of the place of the year according to its place in the revolution of the planet Jupiter, called *bṛhaspati* in Sanskrit. Jupiter has a sidereal period (with respect to the "fixed" stars) of 11 years, 314 days, and 839 minutes, which brings it in nearly 12 years back into its conjunction with the stars from which it began its orbit. Its synodic period brings it into conjunction with the Sun every 398 days and 88 minutes, a little more than a year. Thus, Jupiter in a period of almost 12 years passes about the same series of *nakṣatra*s that the Sun passes in one year and, in a year, about the same *nakṣatra*s as the Sun in a month. A year then can be dated as the month of a 12-year cycle of Jupiter, and the date is given as, for example, grand month of Caitra. This is extended to a unit of five cycles, or the 60-year cycle of Jupiter (*bṛhaspaticakra*), and a "century" of 60 years is formed. This system is known from the 6th century AD onward.

At the other end of the scale, more precision is brought to the day. Every *tithi* is divided into two halves, called *karaṇas*. The natural day is divided into units ranging from a *vipala* (0.4 seconds) to a *ghaṭikā* (24 minutes) and an "hour" (*muhūrta*) of 48 minutes; the full natural day has 30 such hours. The day starts at dawn; the first six *ghaṭikā*s are early morning, the second set of six midmorning, the third midday, the fourth afternoon, the fifth evening. Night lasts through three units (*yāma*) of time: six *ghaṭikā*s after sundown, or early night; two of midnight, four of dawn.

All Hindu festivals and almost all Indian festivals are dated according to the above calendar.

The sacred calendar. There are a few secular state holidays (*e.g.*, Independence Day) and some solar holidays, such as the entry of the Sun into the sign of Aries

(*meṣa-saṃkrānti*), marking the beginning of the new astrological year, which in 1958–59 fell on January 14; the Sun's entry into the sign of Capricornus (*makara-saṃkrānti*), which marks the winter solstice but has coalesced with a hoary harvest festival, which in southern India is very widely celebrated as the Poṅgal festival; and the *mahāviṣuva* day, which is New Year's Eve. But all other important festivals are based on the lunar calendar. As a result of the high specialization of deities and events celebrated in different regions, there are hundreds of such festivals, most of which are observed in smaller areas, though some have India-wide followings. A highly selective list of the major ones, national and regional, follows.

The Gregorian dates given are, except as noted, those valid for 1958–59.

Rāmanavamī ("ninth of Rāma"), on Caitra Ś. (= *śukla*, "waxing fortnight") 9 (in the Gregorian calendar of 1957–58, April 8), celebrates Rāma's restoration to the throne of Ayodhyā.

Rathayātrā ("pilgrimage of the chariot"), Āṣāḍha Ś. 2, June 29, is the famous Juggernaut (Jagannātha) festival of the temple complex at Puri, Orissa.

Janmāṣṭamī ("eighth day of the birth"), Śrāvaṇa K. (= *kṛṣṇa*, "waning fortnight") 8, August 19, is the birthday of the god Kṛṣṇa.

Gaṇeśacaturthī ("fourth of Gaṇeśa"), Bhādrapada Ś. 4, August 28, is observed in honour of the elephant-headed god Gaṇeśa, a particular favourite of Mahārāshtra.

Durgā-pūjā ("homage to Durgā"), Āśvina Ś. 7–10, September 30–October 3, is special to Bengal, in honour of the destructive and creative goddess Durgā.

Daśahrā ("ten days"), or Dussera, Āśvina 7–10, September 30–October 3, is parallel to Durgā-pūjā, celebrating Rāma's victory over Rāvaṇa, and traditionally the beginning of the warring season.

Lakṣmīpūjā ("homage to Lakṣmī"), Āśvina Ś. 15, October 8; is the date on which commercial books are closed, new annual records begun, and business paraphernalia honoured; for Lakṣmī is the goddess of good fortune.

Dīpāvalī, Dīwālī ("strings of lights"), Āśvina K. 14 and Kārttika Ś. 1, October 21–22, is the festival of lights, when light is carried from the waning to the waxing fortnight and presents are exchanged.

Mahā-śivarātri ("night of great Śiva"), Māgha K. 14, February 16, is when the dangerous but, if placated, benevolent god Śiva is honoured on the blackest night of the month.

Dolāyātrā ("swing festival"), Phālguna S. 15, March 5, is the scene of the famous hook-swinging rites of Orissa.

Holī (name of a demoness), Phālguna S. 15, March 26–27, is a fertility and role-changing festival, scene of great fun-poking at superiors.

Gurū Nānak Jayantī, Kārttika S. 15, November 26, is the birthday of Nānak, the founder of the sect of Sikhism.

The eras. Not before the first century BC is there any evidence that the years of events were recorded in well-defined eras, whether by cycles, as the Olympic Games in Greece and the tenures of consuls in Rome, or the Roman year dating from the foundation of the city. Perhaps under outside influence, eras were begun but were without universal appeal, and few have remained influential. Among those are (1) the Vikrama era, begun 58 BC; (2) the Śaka era, begun 78 AD (these two are the most commonly used); (3) the Gupta era begun 320 AD; (4) the Harṣa era, begun 606 AD. All these were dated from some significant historical event. Of more mythological interest is the Kali era (Kali being the latest and most decadent period in the system of the four *Yugas*), which is supposed to have started at the dawn of February 18, 3102 BC. (J.A.B.v.B.)

THE CHINESE CALENDAR

Evidences from the Shang oracle bone inscriptions show that at least by the 14th century BC the Shang Chinese had established the solar year at 365¼ days and lunation (the time between New Moons) at 29½ days. In the calendar that the Shang people used, the seasons of the year and the phases of the Moon were all supposedly accounted for. One of the two methods that they used to make this calendar was to add an extra month of 29 or 30 days, which they termed the 13th month, to the end of a regular 12-month year. Evidence also suggests that the Chinese developed the Metonic cycle (see above *Early calendar systems: Complex cycles*), *i.e.*, 19 years with a total of 235 months, about a century ahead of Meton's first calculation (no later than the early spring and autumn period, 722–481 BC). During this cycle of 19 years there were seven intercalations of months. The other method, which was abandoned soon after the Shang people started to adopt it, was to insert an extra month between any two months of a regular year. Possibly, a lack of astronomical and arithmetical knowledge allowed them to do this.

By the 3rd century BC, the first method of intercalation was gradually falling into disfavour, while the establishment of the meteorological cycle, the *erh-shih-ssu chieh-ch'i*, during this period officially revised the second method. This meteorological cycle contained 24 points each beginning one of the periods named consecutively the Spring Begins, the Rain Water, the Excited Insects, the Vernal Equinox, the Clear and Bright, the Grain Rains, the Summer Begins, the Grain Fills, the Grain in Ear, the Summer Solstice, the Slight Heat, the Great Heat, the Autumn Begins, the Limit of Heat, the White Dew, the Autumn Equinox, the Cold Dew, the Hoar Frost Descends, the Winter Begins, the Little Snow, the Heavy Snow, the Winter Solstice, the Little Cold, and the Severe Cold. The establishment of this cycle required a fair amount of astronomical understanding of the Earth as a celestial body, and without elaborate equipment it is impossible to collect the necessary information. Modern scholars acknowledge the superiority of pre-Sung Chinese astronomy (at least until about the 13th century AD) over that of other, contemporary nations, yet in its earliest stage the only tool used was an upright pillar with which the sky was measured.

Names of the points

The 24 points within the meteorological cycle coincide with points 15° apart on the ecliptic (the plane of the Earth's yearly journey around the Sun or, if it is thought that the Sun turns around the Earth, the apparent journey of the Sun against the stars). It takes about 15.2 days for the Sun to travel from one of these points to another (because the ecliptic is a complete circle of 360°), and the sun needs 365¼ days to finish its journey in this cycle. Supposedly, each of the 12 months of the year contains two points, but, because a lunar month has only 29½ days and the two points share about 30.4 days, there is always the chance that a lunar month will fail to contain both points, though the distance between any two given points is only 15°. If such an occasion occurs, the intercalation of an extra month takes place. For instance, one may find a year with two "Julys" or with two "Augusts" in the Chinese calendar. In fact, the exact length of the month in the Chinese calendar is either 30 days or 29 days—a phenomenon which reflects its lunar origin. Also, the meteorological cycle means essentially a solar year. The Chinese thus consider their calendar as *yin-yang li*, or a "lunar–solar calendar."

The *yin-yang li*

Although the *yin-yang li* has been continuously employed by the Chinese, foreign calendars were introduced to the Chinese, the Hindu calendar, for instance, during the T'ang dynasty (618–907), and were once used concurrently with the native calendar. This situation also held true for the Muslim calendar, which was introduced during the Yüan dynasty (1279–1368). The Gregorian calendar was taken to China by Jesuit missionaries in 1582, the very year that it was first used by Europeans. Not until 1912, after the general public adopted the Gregorian calendar, did the *yin-yang li* lose its primary importance.

One of the most distinguished characteristics of the Chinese calendar is its time-honoured day-count system. By combining the ten celestial stems, *kan*, and the 12 terrestrial branches, *chih*, into 60 units, the Shang Chinese counted the days with *kan–chih* combinations cycli-

cally. For more than 3,000 years, no one has ever tried to discard the *kan–chih* day-count system. Out of this method there developed the idea of *hsün*, ten days, which some scholars would render into English as "week." The *kan–chih* combinations probably were adopted for year count by Han emperors during the 2nd century AD.

The *yin-yang li* may have been preceded by a pure lunar calendar because there is one occurrence of the "14th month" and one occurrence of the "15th month" in the Shang oracle bone inscriptions. Unless there was a drastic change in the computation, it is quite inconceivable that an extra 90 days should have been added to a regular year. Julius Caesar had made 45 BC into a year of 445 days for the sake of the adoption of the Julian calendar in the next year. Presumably, the Shang king could have done the same for similar reasons. From the above discussion on the intercalation of months, it is clear that within the *yin-yang li* the details of the lunar calendar are more important than those of the solar calendar. In a solar calendar the 24 meteorological points would recur on the same days every year. Moreover, if a solar calendar were adopted first, then the problem of intercalation would be more related to the intercalation of days rather than intercalation of months.

Many traditional Chinese scholars tried to synchronize the discrepancy between the lunation and the solar year. Some even developed their own ways of computation embodying accounts of eclipses and of other astronomical phenomena. These writings constitute the bulk of the traditional almanacs. In the estimation of modern scholars, there were at least 102 kinds of almanacs known, some used regularly. The validity or the popularity of each of these almanacs depends heavily on the author's proficiency in handling planetary cycles. In the past these authors competed with one another for the position of calendar master in the Imperial court, even though mistakes in their almanacs could bring them punishment, including death. (Ch.L.)

V. Calendar systems of the Americas

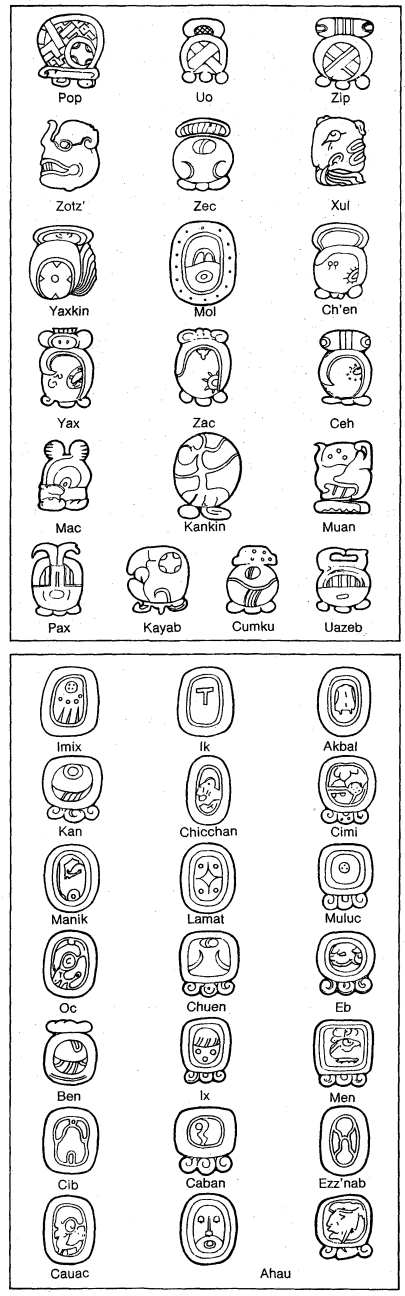
THE MAYA CALENDAR SYSTEM

The basic structure of the Maya calendar is common to all calendars of Meso-America (*i.e.*, the civilized part of ancient Middle America). It consists of a ritual cycle of 260 named days and a year of 365 days. These cycles, running concurrently, form a longer cycle of 18,980 days, or 52 years of 365 days, called a "Calendar Round," at the end of which a designated day recurs in the same position in the year.

The "Calendar Round"

The native Maya name for the 260-day cycle is unknown. Some authorities call it the *tzolkin* (Count of Days); others refer to it as the Divinatory Calendar, the Ritual Calendar, or simply the day cycle. It is formed by the combination of numerals 1 through 13, meshing day by day with an ordered series of 20 names (see figure). The names of the days differ in the languages of Mesoamerica, but there is enough correspondence of meaning to permit the correlation of the known series, and there is reason to think that all day cycles were synchronous. The days were believed to have a fateful character, and the Tzolkin was used principally in divination. Certain passages in the *Dresden Codex*, one of the three Maya manuscripts that survived the conquest, show various Tzolkins divided into four parts of 65 days each, or into five parts of 52 days. The parts are in turn subdivided into a series of irregular intervals, and each interval is accompanied by a group of hieroglyphs and by an illustration, usually depicting a deity performing some simple act. The hieroglyphs apparently give a prognostication, but just how the Maya determined the omens is not known.

The 365-day year was divided into 18 named months of 20 days each, with an additional five days of evil omen, named Vazeh. In late times, the Maya named the years after their first days. Since both the year and the number (20) of names of days are divisible by five, only four names combined with 13 numbers could begin the year. These were called Year Bearers and were assigned in order to the four quarters of the world with their four associated colours. Unlike day cycles, years were not synchronous in all regions. They began at different times and in different seasons, and even among Maya-speaking peoples there was imperfect concordance of the months. Some differences may be due to postconquest attempts to keep the native year in step with the Christian calendar; others no doubt have an earlier origin.



The Maya calendar.

The manner of recording historical dates is peculiar to the ancient Maya calendar. The Maya did not use the names of years for this purpose. To identify a date of the Calendar Round, they designated the day by its numeral and name, and added the name of the current month, indicating the number of its days that had elapsed by prefixing one of the numerals from 0 through 19. A date written in this way will occur once in every Calendar Round, at intervals of 52 years.

This was not good enough to link events over longer periods of time. Maya interest in history, genealogy, and astrology required accurate records of events far in the past. To connect dates to one another, the Maya expressed distances between them by a count of days and

their multiples. They used what was essentially a vigesimal place-value system of numeration, which is one based on a count of 20, but modified it by substituting 18 for 20 as the multiplier of units of the second order, so that each unit in the third place had the value of 360 days instead of 400. In monumental inscriptions, the digits are usually accompanied by the names of the periods their units represent, although in the manuscripts the period names are omitted and placement alone indicates the value of the units. The period names in ascending order are: *kin* (day); *uinal* (20 days); *tun* (18 *uinals* or 360 days); *katun* (20 *tuns* or 7,200 days); *baktun* or cycle—native name unknown—(20 *katuns* or 144,000 days); and so on up to higher periods. By introducing an odd multiplier to form the *tun*, the Maya made multiplication and division difficult, and there are in the *Dresden Codex* long tables of multiples of numbers that could be more simply manipulated by addition and subtraction.

Period names

To correlate all historical records and to anchor dates firmly in time, the Maya established the "Long Count," a continuous count of time from a base date, 4 Ahau 8 Cumku, which completed a round of 13 *baktuns* far in the past. There were several ways in which one could indicate the position of a Calendar Round dated in the Long Count. The most direct and unambiguous was to use an Initial-Series (IS) notation. The series begins with an outsized composition of signs called the Initial-Series-introducing glyph, which is followed by a count of periods written in descending order. On the earliest known monument, Stela 29 from Tikal in Guatemala, the Initial Series reads: 8 *baktuns*, 12 *katuns*, 14 *tuns*, 8 *uinals*, 15 *kins*, which is written: IS. 8.12.14.8.15. It shows that the Calendar Round date that follows falls 1,243,615 days (just under 3,405 years) after the 4 Ahau 8 Cumku on which the Long Count is based. Stela 29 is broken, and its Calendar Round date is missing, but from the information above, it can be calculated to have been 13 Men 3 Zip (the 195th day of the Tzolkin, the 44th of the year).

Normally, only the opening date of an inscription is written as an Initial Series. From this date, distance numbers, called Secondary Series (SS), lead back or forward to other dates in the record, which frequently ends with a Period-Ending (PE) date. This is a statement that a given date completes a whole number of *tuns* or *katuns* in the next higher period of the Long Count. Such a notation identifies the date unambiguously within the historic period. The latest Period Ending recorded on a given monument is also known as its Dedicatory Date (DD), for it was a common custom to set up monuments on the completion of *katuns* of the Long Count and sometimes also at the end of every five or ten *tuns*. The Maya also celebrated *katun* and five-*tun* "anniversaries" of important dates and recorded them in much the same way as the period endings.

Period-Ending dates gradually took the place of Initial Series, and, in northern Yucatán, where Mayan sites of the latest period are located, a new method of notation dispensed with distance numbers altogether by noting after a Calendar Round date the number of the current *tun* in a Long Count *katun* named by its last day. Long Count *katuns* end with the name Ahau (Lord), combined with one of 13 numerals; and their names form a Katun Round of 13 *katuns*. This round is portrayed in Spanish colonial manuscripts as a ring of faces depicting the Lords. There are also recorded prophesies for *tuns* and *katuns*, which make many allusions to history, for the Maya seem to have conceived time, and even history itself, as a series of cyclical, recurring events.

The discontinuance of Initial-Series notations some centuries before the conquest of Mexico by Spain makes all attempted correlations of the Maya count with the Christian calendar somewhat uncertain, for such correlations are all based on the assumption that the Katun Round of early colonial times was continuous with the ancient Long Count. The correlation most in favour now equates the 4 Ahau 8 Cumku that begins the Maya count with the Julian day 584,283 (see above *Complex cycles*). According to this correlation, the *katun* 13 Ahau that is said to have ended shortly before the foundation of Mérida, Yucatán, ended on November 14, 1539, by the Gregorian calendar, and it was the Long Count *katun* 11.16.0.0.0. 13 Ahau 8 Xul. Some tests of archaeological material by the radiocarbon method corroborate this correlation; but results are not sufficiently uniform to resolve all doubts, and some archaeologists would prefer to place the foundation of Mérida in the neighbourhood of 12.9.0.0.0. in the Maya count. Correlations based on astronomical data so far have been in conflict with historical evidence, and none has gained a significant degree of acceptance.

The basic elements of the Maya calendar have little to do with astronomy. A lunar count was, however, included in a Supplementary Series appended to Initial-Series dates. The series is composed of hieroglyphs labelled Glyphs *G*, *F*, *E* or *D*, *C*, *B*, and *A*, and a varying number of others. Glyph *G* changes its form daily, making a round of nine days, possibly corresponding to the nine gods of the night hours or Mexican Lords of the Night. Glyph *F* is closely associated with Glyph *G* and does not vary. Glyphs *E* and *D* have numerical coefficients that give the age of the current Moon within an error of two or three days; Glyph *C* places it in a lunar half year; and Glyph *A* shows whether it is made up of 29 or 30 days. The meaning of Glyph *B* is unknown. There are discrepancies in the lunar records from different sites, but during a period of about 80 years, called the Period of Uniformity, a standard system of grouping six alternating 29- and 30-day moons was used everywhere.

Lunar correlations

Occasionally included with the Supplementary Series is a date marking the conclusion of an 819-day cycle shortly before the date of Initial Series. The number of days in this cycle is obtained by multiplying together 13, 9, and 7, all very significant numbers in Maya mythology.

It has been suggested that certain other dates, called determinants, indicate with a remarkable degree of accuracy how far the 365-day year had diverged from the solar year since the beginning of the Long Count, but this hypothesis is questioned by some scholars. The identification of certain architectural assemblages as observatories of solstices and equinoxes is equally difficult to substantiate. So far, it has not been demonstrated how the Maya reckoned the seasons of their agricultural cycle or whether they observed the tropical or the sidereal year.

In colonial times, the star group known as the Pleiades was used to mark divisions of the night, and the constellation Gemini was also observed. A computation table in the *Dresden Codex* records intervals of possible eclipses of the Sun and Moon. Another correlates five revolutions of the planet Venus around the Sun with eight 365-day years and projects the count for 104 years, when it returns to the beginning Tzolkin date. Three sets of month positions associated with the cycle suggest its periodic correction. Other computations have not been adequately explained, among them some very long numbers that transcend the Long Count. Such numbers appear also on monuments and indicate a grandiose conception of the complexity and the almost infinite extent of time.

THE MEXICAN (AZTEC) CALENDAR

The calendar of the Aztec was derived from earlier calendars in the Valley of Mexico and was basically similar to that of the Maya. The ritual day cycle was called Tonalpohualli and was formed, as was the Maya Tzolkin, by the concurrence of a cycle of numerals 1 through 13 with a cycle of 20 day names, many of them similar to the day names of the Maya. The Tonalpohualli could be divided into four or five equal parts, each of four assigned to a world quarter and a colour and including the centre of the world if the parts were five. To the Aztec, the 13-day period defined by the day numerals was of prime importance, and each of 20 such periods was under the patronage of a specific deity. A similar list of 20 deities was associated with individual day names, and, in addition, there was a list of 13 deities designated as Lords of the Day, each accompanied by a flying crea-

ture, and a list of nine deities known as Lords of the Night. The lists of deities vary somewhat in different sources. They were probably used to determine the fate of the days by the Tonalpouhque, who were priests trained in calendrical divination. These priests were consulted as to lucky days whenever an important enterprise was undertaken or when a child was born. Children were often named after the day of their birth; and tribal gods, who were legendary heroes of the past, also bore calendar names.

The Aztec and Maya systems compared

The Aztec year of 365 days was also similar to the year of the Maya, though probably not synchronous with it. It had 18 named months of 20 days each and an additional five days, called *nemontemi*, which were considered to be very unlucky. Though some colonial historians mention the use of intercalary days, in Aztec annals there is no indication of a correction in the length of the year. The years were named after days that fall at intervals of 365 days, and most scholars believe that these days held a fixed position in the year, though there appears to be some disagreement as to whether this position was the first day, the last day of the first month, or the last day of the last month, as was suggested by a distinguished Mexican scholar. Since 20 and 365 are both divisible by five, only four day names—Acatl (Reed), Tecpatl (Flint), Calli (House), and Tochtli (Rabbit)—figure in the names of the 52 years that form a cycle with the Tonalpohualli. The cycle begins with a year 2 Reed and ends with a year 1 Rabbit, which was regarded as a dangerous year of bad omen. At the end of such a cycle, all household utensils and idols were discarded and replaced by new ones, temples were renovated, and human sacrifice was offered to the Sun at midnight on a mountain top as people awaited a new dawn.

The year served to fix the time of festivals, which took place at the end of each month. The new year was celebrated by the making of a new fire, and a more elaborate ceremony was held every four years, when the cycle had run through the four day names. Every eight years was celebrated the coincidence of the year with the 584-day period of the planet Venus, and two 52-year cycles formed "One Old Age," when the day cycle, the year, and the period of Venus all came together. All these periods were noted also by the Maya.

Where the Aztec differed most significantly from the Maya was in their more primitive number system and in their less precise way of recording dates. Normally, they noted only the day on which an event occurred and the name of the current year. This is ambiguous, since the same day, as designated in the way mentioned above, can occur twice in a year. Moreover, years of the same name recur at 52-year intervals, and Spanish colonial annals often disagree as to the length of time between two events. Other discrepancies in the records are only partially explained by the fact that different towns started their year with different months. The most widely accepted correlation of the calendar of Tenochtitlán with the Christian Julian calendar is based on the entrance of Cortés into that city on November 8, 1519, and on the surrender of Cuauhtémoc on August 13, 1521. According to this correlation, the first date was a day 8 Wind, the ninth day of the month Quecholli, in a year 1 Reed, the 13th year of a cycle.

The Mexicans, as all other Meso-Americans, believed in the periodic destruction and re-creation of the world. The famous "Calendar Stone" in the Museo Nacional de Antropología (National Museum of Anthropology) in Mexico depicts in its central panel the date 4 Ollin (movement), on which they anticipated that their current world would be destroyed by earthquake, and within it the dates of previous holocausts: 4 Tiger, 4 Wind, 4 Rain, and 4 Water.

PERU: THE INCA CALENDAR

So little is known about the calendar used by the Inca that one can hardly make a statement about it for which a contrary opinion cannot be found. Some workers in the field even assert that there was no formal calendar but only a simple count of lunations. Since there was no written language used by the Inca, it is impossible to check contradictory statements made by early colonial chroniclers. It is widely believed that the quipus of the Inca contain calendrical notations, but no satisfactory demonstration of this is possible.

Most historians agree that the Inca had a calendar based on the observation of both the Sun and the Moon, but it is not clear how the lunar count was related to the year. Names of 12 lunar months are recorded, as well as their association with festivities of the agricultural cycle; but there is no suggestion of the use of a numerical system for counting time, although a quinary decimal system, with names of numbers at least up to 10,000, was used for other purposes. The organization of work on the basis of a week of nine days suggests the further possibility of a count by triads that could result in a formal month of 30 days.

A count of this sort was described by Alexander von Humboldt (see below *Bibliography*) for a Chibcha tribe living in the mountainous region of Colombia. The description is based on an earlier manuscript by a village priest, and one authority has dismissed it as "wholly imaginary," but this is not necessarily the case. The smallest unit of this calendar was a numerical count of three days, which, interacting with a similar count of ten days, formed a standard 30-day "month." Every third year was made up of 13 moons, the others having 12. This formed a cycle of 37 moons, and 20 of these cycles made up a period of 60 years, which was subdivided into four parts and could be multiplied by 100. A period of 20 months is also mentioned. Although the account of the Chibcha system cannot be accepted at face value, if there is any truth in it at all it is suggestive of devices that may have been used also by the Inca.

Attempts to identify calendrical matter in the archaeological remains of the central highlands have not been successful, although at one time the Gateway of the Sun at Tiahuanaco and the Echenique Plaque were much discussed in this regard. Assertions by early historians that the Inca observed solstices and equinoxes are somewhat suspect, too, as is also, particularly, the mention by one investigator of a vertical shadow pole set in a circular space presumably to measure the passage of the seasons by the lengths of the shadow. It is generally conceded, however, that planting seasons were fixed by the observation of the Sun against rows of small square masonry towers built on the skyline to the east and west of Cuzco, in Peru.

In one account, it is said that the Inca Viracocha established a year of 12 months, each beginning with the New Moon, and that his successor, Pachacuti, finding confusion in regard to the year, built the sun towers in order to keep a check on the calendar. Since Pachacuti reigned less than a century before the conquest, it may be that the contradictions and the meagreness of information on the Inca calendar are due to the fact that the system was still in the process of being revised when the Spaniards first arrived.

NORTH AMERICAN INDIAN TIME COUNTS

No North American tribe had a true calendar—a single integrated system of denoting days and longer periods of time. Usually, intervals of time were counted independently of one another. The day was a basic unit recognized by all tribes, but there is no record of aboriginal names for days. A common device for keeping track of days was a bundle of sticks of known number, from which one was extracted for every day that passed, until the bundle was exhausted. Longer periods of time were usually counted by moons, which began with the New Moon, or conjunction of the Sun and Moon. Years were divided into four seasons, occasionally five, and when counted were usually designated by one of the seasons; *e.g.*, an Indian might say that a certain event had happened ten winters ago. Among sedentary agricultural tribes, the cycle of the seasons was of great ritual importance, but the time of the beginning of the year varied. Some observed it about the time of the vernal equinox, others in the fall. The Hopi tribe of northern Arizona

held a new-fire ceremony in November. The Creek ceremony, known as the "Busk," was held late in July or in August, but it is said that each town set its own date for the celebration.

As years were determined by seasons and not by a fixed number of days, the correlation of moons and years was also approximate and not a function of a daily count. Most tribes reckoned 12 moons to a year. Some northern tribes, notably those of New England, and the Cree tribes, counted 13. The Indians of the northwest coast divided their years into two parts, counting six moons to each part, and the Kiowa split one of their 12 moons between two unequal seasons, beginning their year with a Full Moon.

The naming of moons

The naming of moons is perhaps the first step in transforming them into months. The Zuni Indians of New Mexico named the first six moons of the year, referring to the remainder by colour designations associated with the four cardinal (horizontal) directions, and the zenith and the nadir. Only a few Indian tribes attempted a more precise correlation of moons and years. The Creeks are said to have added a moon between each pair of years, and the Haida from time to time inserted a "between moon" in the division of their year into two parts. It is said that an unspecified tribe of the Sioux or the Chippewa made a practice of adding a "lost moon" when 30 moons had waned.

A tally of years following an important event was sometimes kept on a notched stick. The best known record commemorates the spectacular meteoric shower (the Leonids, see METEOR) of 1833. Some northern tribes recorded series of events by pictographs, and one such record, said to have been originally painted on a buffalo robe, and known as the "Lone-dog Winter Count," covers a period of 71 years beginning with 1800.

Early explorers had little opportunity to learn about the calendrical devices of the Indians, which were probably held sacred and secret. Contact with white people and their Christian calendar doubtless altered many aboriginal practices. Thus, present knowledge of the systems used in the past may not reflect their true complexity. (T.P.)

BIBLIOGRAPHY. Little material on the calendar is available in English. The main detailed and readable book on both the development of the calendar and its calculation and possible reform is ALEXANDER PHILIPS, *The Calendar: Its History, Structure and Improvement* (1921), which does not, however, contain some of the more recent results of investigations into Babylonian, Roman, and earlier calendar methods. A shorter and more up-to-date reference is the section on the calendar in the *Explanatory Supplement to the Astronomical Ephemeris and the American Ephemeris and Nautical Almanac* (HMSO, 1961). A standard text by F.K. Ginzel, *Handbuch der mathematischen und technischen Chronologie das Zeitrechnungswesen der Völker*, 3 vol. (1906–14), is even older than Philips' book and the same criticism applies.

Sumero-Babylonian: A comprehensive and up-to-date study of Sumerian and Babylonian calendars is lacking. See references to special studies in E.J. BICKERMAN, *Chronology of the Ancient World* (1968). On astronomy and calendar, see OTTO NEUGEBAUER, *The Exact Sciences in Antiquity*, 2nd ed. (1957); and his chapter on "Ancient Mathematics and Astronomy," in the *History of Technology*, ed. by CHARLES SINGER *et al.*, vol. 1 (1954). On the later Babylonian calendar cycle, see RICHARD A. PARKER and WALDO H. DUBBERSTEIN, *Babylonian Chronology 626 B.C.–A.D. 75* (1956). Current bibliography is published in the quarterly review *Orientalia*.

Neighbours of Babylonia: (Assyria): HILDEGARD LEWY, *The Cambridge Ancient History*, 3rd ed., vol. 1, pt. 2, ch. 25 (1971), learned and whimsical; and on the "week," see also *The Assyrian Dictionary*, vol. 5 (1956). *(Hittites)*: ALBRECHT GOETZE, *Kleinasien* (1933, reprinted 1957). *(Ugarit)*: CYRUS H. GORDON, *Ugaritic Textbook* (1965). *(Phoenicians)*: JOHN B. PECKHAM, *The Development of the Late Phoenician Scripts* (1968). *(Mari)*: *Archives royales de Mari XII*, vol. 2 (1964). *(Iran)*: E.J. BICKERMAN in *The Cambridge History of Iran*, vol. 3.

Jewish: The oldest systematic and complete book on the present fixed Jewish calendar is the work of ABRAHAM BAR HIYYA (born *c.* 1065), known as Savasorda of Barcelona, that bears the title *Sefer ha-'Ibbur*, ed. by HERSCHELL FILIPOWSKI (1851). A précis of this is contained in a section (ch. 6–10) in book 3, treatise 8—"Sanctification of the New Moon"—in *The Code of Moses Maimonides* (1135–1204); English by SOLOMON GANDZ in the "Yale Judaica Series" (YJS), vol. 11 (1956), with notes by the translator, and "Astronomical Commentary" by OTTO NEUGEBAUER; rev. and suppl. in the relevant parts of "Addenda and Corrigenda" by ERNEST WIESENBERG, in YJS, vol. 14 (1961). Additional details of the Jewish calendar of both the rabbinic and sectarian varieties have been outlined by JACOB LICHT and E.J. WIESENBERG in *Encyclopaedia Judaica*, vol. 5, pp. 43–53 (1971).

Early Egyptian: NEUGEBAUER (*op. cit.*) is easy to understand; see also his *Commentary on the Astronomical Treatise* (1969), which is well done and recent; and "The Origin of the Egyptian Calendar," *J. Near Eastern Stud.*, 1:396–403 (1942), important for its discussion of the origin of the older lunar calendar. OTTO NEUGEBAUER and RICHARD A. PARKER (eds. and trans.), *Egyptian Astronomical Texts*, 3 vol. (1960–69), is detailed, but does have some good general discussions. RICHARD A. PARKER, *The Calendars of Ancient Egypt* (1950), is the best on the subject—all older material is out of date; his "Lunar Dates of Thutmose III and Ramesses II," *J. Near Eastern Stud.*, 16:39–43 (1957), is important for later lunar dates. H.E. WINLOCK, "The Origin of the Ancient Egyptian Calendar," *Proc. Am. Phil. Soc.*, 83:447–64 (1940), is also an important discussion.

Early Greek: For the *octaëteris*, D.R. DICKS, "Solstices, Equinoxes, and the Presocratics," *J. Hellenic Stud.*, 86:26–40 (1966), is the best recent discussion of the subject; see also his *Early Greek Astronomy to Aristotle* (1970). STERLING DOW and ROBERT F. HEALEY, *A Sacred Calendar of Eleusis* (1965), is good for another calendar besides that of Athens. BENJAMIN D. MERITT, *The Athenian Year* (1961), contains the latest reconstruction of the Athenian civil years. For a discussion of water clocks, see OTTO NEUGEBAUER and H.B. VAN HOESEN, *Greek Horoscopes* (1959). WILLIAM K. PRITCHETT, *Ancient Athenian Calendars on Stone* (1963), is good for the Athenian calendar. See also his "Gaming Tables and I.G., I², 324," *Hesperia*, 34:131–147 (1965); and, with OTTO NEUGEBAUER, *The Calendars of Athens* (1947), still the most important on the subject, with only minor changes—one should use with it BICKERMAN (*op. cit.*); and ALAN E. SAMUEL, *Greek and Roman Chronology* (1972).

India: The most complete account of the lunar-solar calendar of India may be found in "Indian Calendar," ch. 5 of the *Calendar Reform Committee Report* of the Government of India (1955). A good summary of the materials was published by JEAN FILLIOZAT in "Notions de chronologie," an appendix of the encyclopaedic work on Indian history and culture, *L'Inde classique* by LOUIS RENOU and JEAN FILLIOZAT, vol. 2 (1953).

Chinese: CH'EN CHIH-WU, *Yin li yang li yin-yang li* (1957); CHU WEN-HSIN, *Li fa t'ung chih* (1945); the definitive history of science in China, JOSEPH NEEDHAM and WANG LING, *Science and Civilisation in China*, vol. 3 (1959); T'UNG TSO-PIN, *Yin li pu* (1945).

Pre-Columbian: The following are useful and authoritative references for the Maya calendar: SYLVANUS G. MORLEY, *An Introduction to the Study of the Maya Hieroglyphs* (1915); the most complete and authoritative account is J. ERIC S. THOMPSON, *Maya Hieroglyphic Writing: An Introduction*, 2nd ed. (1960). For the Mexican calendar: ALFONSO CASO, "El Calendario Mexicano," *Memorias de la Academia Mexicana de la Historia*, vol. 17, no. 1 (1958); and *Thirteen Masterpieces of Mexican Archaeology* (1938). For the Inca calendar: ALEXANDER VON HUMBOLDT, *Vues des cordillères, et monuments des peuples indigènes de l'Amérique*, 2 vol. (1816); A.L. KROEBER, "The Chibcha," in *The Handbook of South American Indians*, ed. by JULIAN H. STEWARD, vol. 2 (1946); and JOHN HOWLAND ROWE, "Inca Culture at the Time of the Spanish Conquest. Astronomy and the Calendar," *ibid.*

For North American Indian chronologies, see the chapter by CYRUS THOMAS, "Calendar," in *The Handbook of American Indians North of Mexico*, ed. by FREDERICK W. HODGE, vol. 1 (1907).

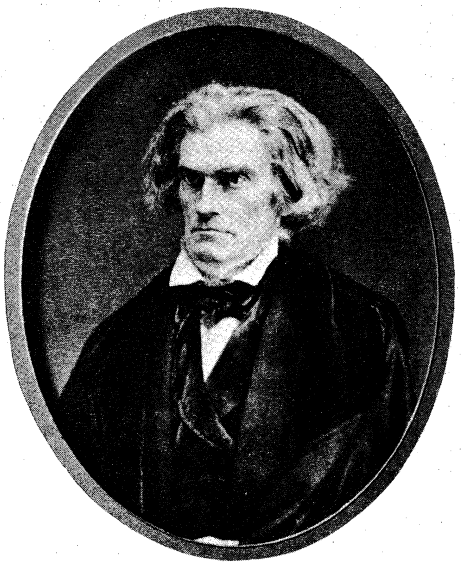
Calhoun, John C.

John Caldwell Calhoun, United States congressman, secretary of war, vice president, senator, secretary of state, and perennial seeker after the presidency, served in public life constantly from the time he was elected to Congress in 1811 as a war hawk from South Carolina until his death in 1850. He has become the symbol of the Old South, of whose undoing, many have thought, he was

the chief agent. Certainly the Civil War was too vast an event for the main responsibility to be placed upon any one man, but it may well be argued that Calhoun contributed as much to its coming as did William Lloyd Garrison, the Abolitionist, and Abraham Lincoln.



Calhoun, daguerreotype by Mathew Brady, *c.* 1849.
By courtesy of the Library of Congress, Washington, D.C.

The man himself is an enigma. A staunch nationalist during the first half of his public life, one who told Alexander Hamilton's son in 1823 that his father's attempt to develop a strong federal government "as developed by the measures of Washington's administration is the only true policy for this country," Calhoun became in the latter part of his career an unwavering champion of states' rights as laid down in the Constitution. Yet he said shortly before his death, "If I am judged by my acts, I trust I shall be found as firm a friend of the Union as any man in it. . . . If I shall have any place in the memory of posterity it will be in consequence of my deep attachment to it."

Early years

Calhoun was born on March 18, 1782, in Abbeville district, South Carolina, into a well-to-do Scots–Irish pioneer family that had recently migrated from Pennsylvania to the Carolina Piedmont. Two years after enrolling in a local academy at age 18, he entered the junior class at Yale, where he graduated with distinction. After spending a year at a law school at Litchfield, Connecticut, and further study in the office of a prominent Federalist in Charleston, he was admitted to the bar but abandoned its practice after his marriage in 1811 to his cousin, Floride Bonneau Calhoun, an heiress whose modest fortune enabled him to become a planter-statesman. An ardent Jeffersonian Republican who called for war with Britain as early as 1807, he was elected to the state legislature in 1808 and in 1811 to the national House of Representatives. There he functioned as one of Speaker Henry Clay's main lieutenants, and, in his capacity as chairman of the foreign relations committee, he introduced the declaration of war against Britain in June 1812. His service as majority floor leader during the hostilities led a colleague to call him the "young Hercules who carried the war on his shoulders."

Political career. In the postwar session he was chairman of the committees that introduced the bills for the second Bank of the United States, a permanent road system, and a standing army and modern navy; he also vigorously supported the protective tariff of 1816. Thus, during this period, Calhoun was the intellectual father of American nationalism. In 1817 President Monroe appointed Calhoun secretary of war, and his distinguished performance in that post, as well as his previous legislative prominence, led his friend John Quincy Adams, then secretary of state, to declare that his Carolina colleague "is above all sectional and factious prejudices more than any other statesman of this Union with whom I have ever acted."

Calhoun had won rapid recognition by his parliamentary skill as one of the ranking leaders of the Republican Party; yet his eagerness for personal advancement, his glib exuberance in debate, and his egotism aroused an undercurrent of distrust. Former secretary of the treasury Albert Gallatin, commenting on Calhoun's nomination for president in 1821 by a rump group of northern congressmen, called him "a smart fellow, one of the first among second-rate men, but of lax political principles and a disordinate ambition not over-delicate in the means of satisfying itself."

To a degree not exceeded by that of any of his contemporaries, Calhoun was consumed by a burning passion to achieve the presidency. He vigorously sought the office three times, and, each time he thought he had a chance. During each attempt to attain the office, an anonymous eulogistic biography appeared in print. These were largely autobiographies, written in the third person, the last of them published in 1843.

Champion of states' rights. In the 1830s Calhoun became as extreme in his devotion to strict construction of the Constitution as he had earlier been in his support of nationalism. In the summer of 1831 he openly avowed his belief in nullification, a position which he had three years earlier anonymously advanced in the *South Carolina Exposition and Protest.* Each state was sovereign, Calhoun contended, and the Constitution was a compact among the sovereign states. Therefore, any one state (not the Supreme Court) could declare an act of Congress unconstitutional. The proponents of the nullified measure, according to the theory, would then have to get an amendment to the Constitution—which requires a two-thirds vote of each house of Congress and ratification by three-fourths of the states—confirming the power of Congress to take such action.

Although the tariff was the specific issue in the nullification crisis of 1832–33, what Calhoun was actually fighting for was protection of the South's "peculiar institution," Negro slavery, which someday might be abolished by a northern majority in Congress, perhaps with financial compensation to the owners, as the British Parliament decreed in 1833. The tariff, Calhoun put forth in one of his public letters, is "of vastly inferior importance to the great question to which it has given rise . . . the right of a state to interpose, in the last resort, in order to arrest an unconstitutional act of the General Government."

To Calhoun's chagrin, a majority of the Southern states formally and vehemently rejected his abstruse doctrine of nullification. Even Jefferson Davis, who believed in the right of a state to secede from the Union, denied the right of a state to nullify a Congressional act. And the octogenarian former president James Madison, whose Virginia Resolution of 1798 Calhoun used as his authority, publicly refuted him.

A genius unto himself, Calhoun lacked the capacity for close friendship and eventually drove most of his associates into active enmity, not least among them Pres. Andrew Jackson. His banishment by Jackson was, however, mainly a matter of bad luck. No one did more to make Jackson president than Calhoun, and his prospects in 1828 were most promising. "I was a candidate for re-election (as vice president) on a ticket with General Jackson himself," he wrote later, "with a certain prospect of the triumphant success of the ticket, and a fair prospect of the highest office to which an American citizen can aspire." But through his wife, Calhoun became involved in a boycott by the wives of the Cabinet members of the wife of the Secretary of War, and in the end Jackson fired his whole Cabinet and broke with the Vice President. Late in 1832 Calhoun resigned his post, was elected to the Senate, and vainly debated Daniel Webster in defense of his cherished doctrine of nullification. The last 20 years of his life he spent in the Senate working to unite the South against the radical Abolitionist attack on slavery. His efforts were in vain, however. His exuberant defense of slavery as a "positive good" aroused a strong

Quarrel with President Jackson

anti-Southern feeling in the free states, and at the same time he never did unify the South.

Assessment. After his death, in Washington on March 31, 1850, his protégé, James H. Hammond, said that

> pre-eminent as he was intellectually above all the men of this age as I believe, he was so wanting in judgment in the managing of men, was so unyielding and unpersuasive, that he never could consolidate sufficient power to accomplish anything great, of himself and [in] due season . . . and the jealousy of him—his towering genius and uncompromising temper, has had much effect in preventing the South from uniting to resist [evil].

Calhoun as political theorist

Two posthumous books on government and his many cogent speeches in Congress have gained for Calhoun a reputation as one of America's foremost original political theorists. He preceded Karl Marx in advancing the economic interpretation of history, but most of his basic ideas, particularly that of nullification, he acquired outright from James Madison, who was 30 years his senior. Calhoun is remembered as the defender of minorities, but he had no use for any minority—certainly not labourers or Abolitionists—except the southern minority. His solution for the problem of the preservation of the Union was to give the South everything it demanded. He was truly devoted both to the Union and to the South, and, fortunately, death took him before he had to choose between them. But with rare insight, in 1850 he told a friend that the Union was doomed to dissolution: "I fix its probable occurrence within twelve years or three Presidential terms."

In his thinking, Calhoun worked the problem back as if from the answer at the end of the mathematics primer. With his objective in mind, he chose a seemingly innocuous premise and then proceeded with hard logic to the desired conclusion. The historian William P. Trent said in the 1890s that he "started with the conclusion he wanted and reasoned back to the premises. . . . Calhoun led thought rather than men, and lacking imagination, he led thought badly."

Calhoun's life was a tragedy in both the Greek and the Shakespearean sense. The gods thirsted after him, but he helped them along. Almost his last words were "The South! The poor South!" The poet Walt Whitman heard a Union soldier say shortly after Appomattox that the true monuments to Calhoun were the wasted farms and the gaunt chimneys scattered over the Southern Confederacy.

Biographies: CHARLES M. WILTSE, *John C. Calhoun*, 3 vol. (1944–51), the definitive biography, with an excessive pro-Calhoun bias; MARGARET L. COIT, *John C. Calhoun: American Portrait* (1950), laudatory; GERALD M. CAPERS, *John C. Calhoun, Opportunist: A Reappraisal* (1960), brief and critical; RICHARD N. CURRENT, *John C. Calhoun* (1963), emphasis on the significance of Calhoun's thought for the present. See also RICHARD HOFSTADTER, "Calhoun: The Marx of the Master Class," in *The American Political Tradition and the Men Who Made It*, ch. 4 (1948), an incisive essay; and "From Calhoun to the Dixiecrats," *Social Research*, 16:135–150 (1949).

(G.M.C.)

California

During the 1960s, immigration to California was so great that it was described as giving a westward tilt to the United States. California surpassed New York to become the most populous state in the nation, and its gross economic product was exceeded by only five nations in the world. The fluid nature of its social, economic, and political life, so much affected by the streams of persons from other states, gave California an aura of a laboratory for the testing of new modes of living.

The 19,953,134 Californians recorded by the census of 1970 make up the second most urban population in the nation, centred mainly along the coast, with more than half of it in the Los Angeles and San Francisco complexes. As in most of America's larger states, the capital, Sacramento, is not one of the major population or economic centres. With an area of 158,693 square miles (411,013 square kilometres)—exceeded only by Alaska and Texas—the state is bounded on the north by Oregon, on the east by Nevada and Arizona, on the south by the Mexican state of Baja ("lower") California, and on the west by the Pacific Ocean.

The state's physical contrasts

Since its admission to the Union in 1850 as the 31st state, California has been recognized as a land of stunning physical contrasts: from the rainy northern coast to the parched Colorado Desert of the south. The Sierra Nevada exceeds the Rocky Mountains in height. Within 85 miles of each other lie Mt. Whitney and Death Valley, respectively 14,494 and 282 feet (4,418 and 86 metres) above and below sea level, the highest and lowest points in the 48 coterminous states. In spite of its urbanization, California has also become the principal agricultural state of the nation; yet only about 15 percent of its area is urban or cultivated. Nearly half of its land is federally owned, with national parks and monuments in every part of the state devoted to irreplaceable forest, desert, mountain, and other natural resources. (For related information see UNITED STATES; UNITED STATES, HISTORY OF THE; PACIFIC COAST RANGES; SIERRA NEVADA RANGE; DEATH VALLEY; SAN FRANCISCO; and LOS ANGELES.)

THE HISTORY OF CALIFORNIA

Exploration. Modern California derives from the discovery of gold at Sutter's Mill in 1848, just nine days before Mexico signed the Treaty of Guadalupe Hidalgo, ceding to the United States a vast area of the Southwest that included all of present-day California. The region had received scant attention from Europeans for more than three centuries after its first sighting in 1542 by the Spanish navigator Juan Rodríguez Cabrillo. The merchant Sebastián Vizcaíno sailed the Southern California coast in 1602, naming San Diego, Santa Catalina Island, Santa Barbara, and Monterey Bay. Despite these early explorations, however, California was left to its relatively primitive Indians—an estimated 130,000 of them when the Spanish discovered California in 1542.

Settlement. Pressure for settlement came from missionaries anxious to convert the Indians and from the intrusion—more threatened than real—of Russian and British traders, primarily in search of sea-otter pelts. In 1769 the Spanish viceroy dispatched land and sea expeditions from Baja California, and the Franciscan friar Junípero Serra established the first mission at San Diego. Gaspar de Portolá set up a military outpost in 1770 at Monterey. Colonization began after 1773 with the opening of an overland supply route across the southwestern deserts.

Establishment of the Spanish missions

The 21 missions established by Serra and his successors were the strongest factors in developing California. While attempting the Christianization of the Indians, the padres taught them farming and crafts. Softened by the mild environment and lured by gifts and song, the Indians rarely attacked; instead they drifted into the missions to live. With their labours, the padres irrigated vast ranches and traded hides, tallow, wine, brandy, olive oil, grain, and leatherwork for the manufactured goods brought by Yankee trading vessels around Cape Horn.

American colonization and acquisition. Secularization of the missions was sought by Spanish–Mexican settlers known as Californios when Mexico became independent of Spain in 1821. Between 1833 and 1840, the mission ranches were parcelled out to political favourites by the Mexican government. The padres withdrew, and the Indians, racked by the white man's diseases and driven off the mission lands, were cruelly exploited and diminished. In 1841 the first wagon train of settlers left Missouri for California. The American colony grew slowly, but in 1846 the Northwest became a part of the United States, and American settlers at Sonoma proclaimed an independent California republic. In May the United States declared war on Mexico, and in July the American flag was raised at Monterey. Only minor skirmishes occurred before the Californios surrendered to troops under John

C. Frémont near Los Angeles in January 1847. Within a year, the form of today's continental United States was nearly cast.

The Gold Rush. Early in 1848, James Wilson Marshall, a carpenter from New Jersey, picked up nuggets of gold from the American River at the site of a sawmill he was building near Coloma. By August, the hillsides above the river were strewn with the tents and wood huts of the first 4,000 miners. From the East, prospectors sailed around Cape Horn or risked disease in hiking across the Isthmus of Panama. The hardiest took the 2,000-mile overland route, along which cholera proved a greater killer than Indians. About 40,000 came to San Francisco by sea alone in 1849. Some 6,000 wagons, carrying as many more, moved west that year over the California Trail. Few of the prospectors struck it rich. The work was hard, prices were high, and living conditions were primitive. The wiser emigrants became farmers and storekeepers.

Gold hastened statehood in 1850, and though the Gold Rush peaked in 1852, the momentum of settlement did not subside. Nearly $2,000,000,000 in gold was taken from the earth before mining became almost totally dormant, yet in 1970 alone the income from California's agriculture was double that of all the gold ever mined there.

Growth as a state. As gold had buoyed statehood, so statehood buoyed immigration. Cheap land and the hope of a fresh start lured soldiers west after the Civil War. Service on the first transcontinental railroad began in 1869. The tide of immigration first moved toward southern California around 1900, spurred by citrus, oil, and some wariness of San Francisco after the earthquake and fire of 1906. Land booms came and went. The state nearly doubled in population every 20 years from 1860 to 1960. San Francisco remained the financial and corporate centre until after the mid-20th century, when the southern one-third of the state had exceeded all the rest in population. Agriculture in inland valleys and industry in the cities boomed. World War II expanded aircraft plants and shipyards. During the 1950s, research and educational facilities burgeoned as the movement of people to the West Coast came to include an unusual share of scientists and academicians.

Early 20th-century immigration

THE NATURAL LANDSCAPE

California offers startling contrasts of landscape and examples of physical diversity. Summer temperatures in its low-lying southern desert compare with the highest of Africa's Sahara, and winter temperatures atop the Sierra Nevada are Arctic. Rainfall may range from extremes of 174 inches (4,420 millimetres) in the northwest to traces in the southeastern desert, but moderate temperatures and rainfall prevail along the coast. Monthly average temperature is about 65° F (18° C) in Los Angeles and 57° F (14° C) in San Francisco. Annual precipitation is about 15 inches in Los Angeles and 21 inches in San Francisco.

The moderate climate has been a major factor in the concentration of settlement along the coast, where cool ocean breezes hold off heat, and temperatures seldom exceed 90° F (32° C) or drop to freezing. Low humidity usually prevails. Climate changes rapidly with the altitude extremes of California, and the coastal cities are only hours away from mountain skiing or desert sports.

Coast ranges. The long coastline is mountainous, most dramatically in the Santa Lucia Range south of San Francisco, where the homes of Big Sur perch on cliffs 800 feet above the sea. Hills of lesser height flank entrances to the coast's three major natural harbours, at San Diego, San Francisco, and Eureka. Coastal mountains, made up of many indistinct chains, are from 20 to 40 miles in width and from 2,000 to 8,000 feet in height.

The mountains of California

Sierra Nevada. Eastern portions of the state, particularly in the south and extreme northeast, are occupied by sparsely settled desert, high in the north and low and increasingly hot in the south. The majestic Sierra Nevada rises to the west of this desert, extending for 430 miles. The eastern escarpment is sheer, dropping 10,000 feet within ten miles near Owens Lake. On the west, the range slopes to the Central Valley, comprising the San Joaquin and Sacramento valleys, in gradually declining foothills. From the wall that rises near volcanic Lassen Peak in the north, the Sierra Nevada extends south for 430 miles, to the fringes of Los Angeles. It is 50 to 80 miles in width and 27,000 square miles in area. Aside from Mt. Whitney, ten other peaks exceed 14,000 feet in altitude. East–west passes are few and high, some in excess of 9,000 feet.

The largest lake of the Sierra Nevada and one of the loveliest in the United States is Lake Tahoe, astride the California–Nevada border at 6,225 feet. A mountain-ringed Alpine lake almost 200 square miles in area, it ranks fifth in the world in mean depth: the 1,200-foot line runs near shore, and maximum depth exceeds 1,600 feet. Elsewhere in the Sierra lie more than 1,200 smaller lakes, some above the timberline in regions of tumbled granite and smooth-walled canyons. There are three national parks within these highlands: Kings Canyon, Sequoia, and Yosemite—the latter rising from the purplish foothills of the Mother Lode gold country through ice-carved valleys of the Merced and Tuolumne rivers, with their waterfalls and granite domes.

Central Valley. In a north-south arc through the centre of California, the Central Valley runs for 450 miles, forming a deep trough between the Coast Ranges to its west and the Sierra Nevada to its east. The valley constitutes the state's agricultural heartland. Its single opening is the delta through which the Sacramento and San Joaquin rivers drain into San Francisco Bay. The valley is sealed off at the northeast by the Cascade Range and at the northwest by the Klamath Mountains. This far north is rugged and sparsely populated terrain, heavily timbered and wet on its coastal side, drier and barren in the higher northeast. In the south, the Central Valley is closed off by the transverse ranges, notably the Tehachapi Mountains, which are popularly regarded as a dividing wall between southern and central California.

Coastal settlement and forests. Southern California's dense settlement lies along a coastal plateau and in valleys ranging from 40 to 60 miles inland. North of the Tehachapis, where the Coast Ranges move closer to the shore, population becomes sparser along the coast. The populous coastal area around San Francisco Bay gives way to the more primitive northern coast, where lumbering and fishing villages lie beside creeks and rivers flowing from the Coast Ranges. This is the area of coastal redwood forests and Redwood National Park. These trees, among the tallest in the world, may reach 300 feet in height, 15 to 20 feet in diameter, and 2,000 years in age. Before European settlement, the redwoods covered an estimated 1,500,000 acres (600,000 hectares) of California. Most redwood forests have been cut, but 86,700 acres (35,100 hectares) of redwoods are protected in state and national parks.

The redwood forests

Deserts. Temperature contrasts are great. The Colorado Desert of southeastern California has summer temperatures up to 130° F (54° C), nearly the highest temperatures recorded on earth, with annual rainfall averaging 2 to 3 inches (50 to 75 millimetres). More than 4,000 square miles of this desert lie below sea level. The 300-square-mile inland Salton Sea, below sea level, was created in 1905–07 when the Colorado River broke out of its channels. Northward, in the higher Mojave Desert, temperatures are somewhat less oppressive. Still relatively untouched by development, this area of more than 25,000 square miles reaches from the Tehachapi and Sierra Nevada to the Colorado River. It has some mining, several military reservations, and aviation test facilities. Farther north, the eastern desert lies from 4,000 to 7,500 feet in altitude, with temperatures ranging from 75° F (24° C) to −25° F (−32° C). It remains sparsely populated.

Water resources. Water is chronically scarce in southern California and the desert regions, but excesses of rain and snowmelt cause winter flooding along the rivers of the northern coast. More than 70 inches (1,800 millimetres) of rain falls at Crescent City, near the Oregon border, about 370 miles north of San Francisco; and the vil-

lage of Honeydew, in the redwoods of Humboldt County, has received as much as 174 inches in a year. Southern California, in contrast, has 60 percent of the state's population and about 2 percent of its water, with an average annual rainfall of 15 inches (380 millimetres), entirely in the winter months. Complex systems of dams and aqueducts move water from north to south, but not without citizen protests. The Colorado River Aqueduct moves water from that river, at the Arizona border, across the Southern California desert and mountains to serve 119 communities. The California State Water Project, launched in 1960, is the largest water-transfer system undertaken in history. Still incomplete in the early 1970s, it is designed to deliver an additional 1,800,000,000 gallons daily from the Sacramento and San Joaquin rivers near San Francisco to communities as far south as the Mexican border.

Long-distance transportation of water

THE PEOPLE OF CALIFORNIA

Spanish and Indian heritages. The aboriginal Indian population and Spanish settlers of the 18th and 19th centuries are of only vestigial importance in contemporary California. Spanish influence is minor except in architecture and place-names. The many Californians with Spanish surnames reflect largely the 20th-century immigration from Mexico—to escape that nation's revolution in 1910–17 or, in recent years, to find agricultural jobs. Of the Indian population in 1970—slightly over 90,000—some 12,500 lived on 76 reservations totalling more than 450,000 acres. Though among the most deprived minorities, Indians are now increasing in number.

The historical mix. The first settlers from the California Trail were mostly Middle Western farmers of Anglo-Saxon descent. With the Gold Rush, a more cosmopolitan mix appeared. Ships sailed into San Francisco from the Atlantic seaboard, Europe, and the Orient. In 1850 more than half of the Californians were in their 20s, typically male and single. Only a few hundred Chinese were in the state in 1850, but two years later one in ten was Chinese, most imported for menial labour. Irish labourers came with the railroad-construction boom in the 1860s. The Irish, French, and Italians tended to settle in San Francisco. As Los Angeles began to grow at the end of the 19th century, it lured Mexicans, Russians, and Japanese, but primarily a further Anglo-Saxon surge from the Middle West.

Racial discrimination. Discrimination grew strong, especially against Orientals. An alien land law intended to discourage ownership of land by Orientals was not ruled unconstitutional until 1952. At one time, the testimony of Chinese in courts was declared void. Separate schools for Orientals were authorized by law until 1936, and it was 1943 before the Chinese exclusion act was repealed by Congress. As Chinese discrimination flared, Japanese were encouraged to immigrate, and in 1900 alone more than 12,000 entered California. Prospering as farmers, they came to control more than 10 percent of the farmland by 1920 though making up only 2 percent of the population. Los Angeles became the centre of the nation's Japanese community as San Francisco's Chinatown became its largest Chinese settlement.

Discrimination against the Japanese smoldered until World War II, when about 93,000 Japanese–Americans lived in the state. Some 60 percent were American-born citizens known as Nisei; most of the others were Issei, older adults who had immigrated before Congress halted their influx in 1924. Never eligible for naturalization, the Issei were classed as enemy aliens. During 1942 almost all of California's Japanese–Americans, both Nisei and Issei, were moved from their farms and homes to isolated inland camps and held under guard until 1945. At the end of the war they found their property sold for taxes or storage fees and their enclaves overrun. After years of litigation, about 26,000 claimants were reimbursed for their losses at about one-third of claimed valuation. About 85 percent of the Japanese–Americans had been farmers, but with their land gone, they became gardeners or went into businesses and professions.

Now typically highly educated, the third generation of Japanese–Americans, the Sansei, occupies a respected role in Southern California. By 1970 the Japanese–American community of Los Angeles was estimated to be in excess of 150,000. More than half of the 250,000 Chinese in the country were estimated to be in California, predominantly in San Francisco. With a stream of refugees from Hong Kong and Taiwan, the population of San Francisco's Chinatown rose between 1950 and 1970 from about 25,000 to more than 70,000.

Blacks and Mexicans. Few Negroes settled in California until World War II, but between 1940 and 1970 the black population of San Francisco rose from about 5,000 to about 100,000 and in Los Angeles, from 64,000 to more than 500,000, nearly 20 percent of the population. California showed the greatest gain of any state in Negro population between 1950 and 1960, with those leaving the Southern states attracted to life in cities like Los Angeles and Oakland despite unemployment rates reaching over 30 percent.

More than half of the nation's Mexican–Americans, or Chicanos, live in California. Chicano communities in the early 1970s were experiencing increasingly frequent confrontations with police and other officials, especially in Los Angeles, in protests against discrimination and unemployment. None had reached the proportion, however, of the black riots that levelled much of Los Angeles' Watts area in 1965.

Religion. Both traditional churchgoing and interest in flamboyant mystical or evangelical sects declined steadily in California in the years following World War II. By 1970 it was estimated that about 40 percent of Californians listed church affiliations, below the national average. Jewry was strongest in the Fairfax and Beverly Hills areas of the Los Angeles Basin, Roman Catholicism in San Francisco, and fundamentalist Prostestant sects in those parts of Southern California inhabited by migrants from the South and Southwest. The Church of Jesus Christ of Latter-day Saints (Mormons), with headquarters in scantily populated Utah, listed California as the leading state in number of members. Even those of conventional faiths in California resort to unconventional techniques, advertising worship services in newspapers, offering free bus service, and employing public relations councillors.

Throughout most of the first half of the 20th century, Los Angeles was notorious for its exotic cults. Aimee Semple McPherson, whose Angelus Temple boasted 35,000 members, is the best remembered of such evangelists; she died in 1944 after an overdose of sedatives. Faith healers still are popular. Scientology, calling itself "the common people's science of life betterment," thrived in Southern California under the leadership of a former film writer, L. Ron Hubbard. Zen Buddhism has enjoyed a popular wave in San Francisco in the 1950s, with English-born Alan Watts serving as its Occidental interpreter to a following that included the "Beat Generation" of that era, forerunner of the later hippies.

Demography. The native-born American, however, remained the dominant factor in California's growth phenomenon in the mid-20th century. Many of the workers who flooded the defense industries during World War II remained as residents, along with hundreds of thousands who first visited the state as servicemen. Los Angeles grew from 1,500,000 to 2,700,000 between 1940 and 1965. About three-fifths of the 1970 population was concentrated south of the Tehachapi Mountains in about one-fourth of the state's area, and most of this in the small coastal area.

Present-day migratory patterns

By 1970, however, net immigration was showing year to year declines. Accompanied by a birth rate decline equal to the national average, this trend indicated a levelling off of the state's growth. A newer direction of migration was seen from the crowded cities of California to rural areas and cities of the Rocky Mountain states. As in other areas, the 1970s brought a submergence of California's historic passion for growth and bigness, and the American's westering urge appeared to be ebbing with the urban build-up on the nation's West Coast. Demographers were predicting continued population increases

for California that probably will maintain its rank as most populous state, but those predictions were scaled down from earlier years.

THE STATE'S ECONOMY

Economic overview

In economic terms, California is more aptly compared with nations than states. In 1967 its gross product—the dollar value of goods and services—exceeded $88,000,000,000, a total surpassed only by that of the United States as a whole and of the Soviet Union, West Germany, France, and Japan. Its per-capita income exceeds that of any nation. In the recession years of 1969–71, with rising unemployment in the aerospace and film industries, the California economy was bulwarked by diversification. Federal spending has been high throughout California history, but it has undergone a transition from that of colonization-type funds to the present expenditures involving both the state's natural resources and its wealth of human resources of brains and skills.

From the Gold Rush on, Californians have shown ingenious mastery of the state's resources, and their innovative society has created its own economic momentum. Industry has triumphed over remoteness; lacking iron and coal deposits, it has oriented toward light industry. Financiers have been imaginative in seeking and employing capital, and in the early 1970s many of the nation's largest banks and corporations were California-based, the latter principally involved in aerospace, electronics, computers, and oil and gas. California supplanted New York in 1965 as the leading state in export of manufactured goods. The state is dominant in aerospace, agriculture, wine making, and the film and television industries. Despite soaring taxes, the California climate and its social freedoms continued to attract high-income immigration and technologically oriented industry.

Agriculture. The foundation of California wealth lies in agriculture. Its fields and orchards yield more than 200 agricultural products of astonishing diversity from more than 8,000,000 acres of irrigated farmland. In 1970 grapes ranked first in value, followed by hay, tomatoes, and cotton. California produces about one-third of the nation's canned and frozen vegetables and fruits. The state is first in production of tomatoes, sugar beets, strawberries, beef cattle, and turkeys. In 1970, annual cash farm receipts were nearly $4,500,000,000, more than the combined value of aerospace production and transportation equipment, the next largest industries, and more than four times that of petroleum production. About half of this output comes from the Central Valley, which is irrigated through a labyrinth of dams, canals, and power and pumping plants. Engineers estimate that almost $4,000,000,000 must be invested by the year 2000 to bring under cultivation 3,000,000 more acres of irrigable farmland in the valley.

The state's agricultural supremacy dates from 1947, when its farm output first exceeded that of any other state. The growing season of nine to ten months makes Fresno, Kern, and Tulare counties the top three counties in the nation in value of farm produce. Most farms are huge, and more than two-thirds of farm income is earned by less than 15 percent of the farms. Many large landholdings have derived from federal land grants to railroads, notably the Southern Pacific, which in 1919 was the state's largest landowner. Such farms have tended to become agricultural assembly lines with absentee owners, high mechanization and productivity, and persistent labour strife. Most farms specialize in one or two crops: almonds grow north of Sacramento; cotton and forage crops, figs, and grapes near Fresno; and in the wet delta, asparagus, tomatoes, rice, safflower, and sugar beets. Such specialization has been enhanced by agricultural research at the University of California at Davis; this institution also counsels the California wine industry in its production of 80 percent of the wine consumed in the United States. The citrus industry, almost destroyed in the 1940s by a virus, ranks second to that of Florida in production of oranges.

Farming as big business

Premium wine grapes grow in the picturesque Napa and Sonoma valleys north of San Francisco and in adjacent areas. The Imperial Valley in the Colorado Desert in the extreme south, though smaller in area than the Central Valley, has about 500,000 irrigated areas of farmland. Other major farming areas include the Coachella Valley near Palm Springs, where dates and grapefruit grow, and the Salinas Valley and Monterey Bay region.

The farm-labour pool is made up of low-income labourers, including many migrants and more than 25,000 Mexican nationals permitted to cross the border in harvest seasons. Long abused, migrant labourers were organizing in the late 1960s under the leadership of César Chavez and began lengthy strikes that drew nationwide support in the form of consumer boycotts.

Mineral resources. Petroleum production grew rapidly after 1895, with oil strikes in the Los Angeles–Long Beach area. California led all states in petroleum production from 1900 to 1936 and ranked second until 1958. Although in 1968 production reached an all-time daily high of more than 1,000,000 barrels, reserves were being depleted at a rapid rate, and fuel and natural gas were being imported. Petroleum continued, however, to exceed the total production of all other minerals in value of production. Gold mining did not resume after World War II. Other production includes natural gas, cement, sand and gravel, borate, soda, and salt.

Fisheries and forestry. California ranked second among states in 1970 in the value of commercial fishery products landed. Largely ocean fishing, the yield included albacore and bluefin tuna, mackerel, sole, squid, sardine, and salmon. Tuna accounts for more than 50 percent of the catch. Forest industries rank fifth in number of employees and sixth in value of products. Ownership of commercial forest land is almost equally divided between public agencies and private interests, with a total of more than 17,000,000 acres in use.

Industry, tourism, and the military. The aircraft plants and shipyards were supplemented after World War II by branch plants of many Eastern and Middle Western industries. Federal research-and-development funds allocated to California organizations also contributed to the dynamic postwar economy. Despite mercurial rises and declines responding to the shifting population, construction became a major industry. By the mid-1960s, an enormous impact was being made by the more than $2,000,000,000 spent annually by the nearly 15,000,000 tourists from other states.

All federal military services have major facilities in California, significantly affecting both the social and economic life of the state. San Diego, Long Beach, and San Francisco are home-port naval bases. Recruit training is the major role of naval and marine corps bases in San Diego, and infantry training takes place at Fort Ord near Monterey. Camp Pendleton, a marine base, encompasses the last large undeveloped area along the southern California coast. Air force activity centres around the Vandenberg base on the central coast and six other air commands, including the remote and esoteric test facilities on the Mojave Desert.

Transportation. His transportation, primarily the automobile and the airplane, is in part both cause and product of the restless mobility of the Californian, who moves his residence more often than the average American and travels considerably more both for business and pleasure. California has the greatest concentration of motor vehicles on earth and the most extensive system of multilane divided freeways. At the end of 1970 there were nearly 14,000,000 registered motor vehicles and 3,655 miles of multilane divided freeway. Compact San Francisco, with about 7,000 cars per square mile, choked in the early 1970s while awaiting completion of a Bay Area Rapid Transit system to improve mass transit, which has been lacklustre throughout California.

The freeway system

The freeway system is so extensive that one can drive on toll-free, high-speed arterials from San Diego almost 500 miles northward through Los Angeles and the Central Valley without encountering any traffic signals or stop signs. Freeway construction continued despite growing public opposition based on ugliness, pollution, and usurpation of private and community property rights.

The rise of the freeway system after World War II coincided in Los Angeles with the demise of a 1,200-mile interurban rail system that at one time had been the nation's lengthiest. The lack of a conventional urban core in Los Angeles, along with low population densities, dims the prospects for any rapid-transit system.

Transport of goods in California is predominantly by trucks, and agricultural and trucking lobbies have joined those of the automobile clubs, freeway builders, and the oil industry to perpetuate freeway development. The intricate canals and waterways of the Sacramento River Delta carry some waterborne freight traffic, and there is some coastal freight traffic.

Air commuting increased phenomenally from 1950 to 1970. The air corridor connecting San Francisco, Los Angeles, and San Diego grew in volume beyond that linking Washington, New York, and Boston. Air-traffic congestion has grown critical, but not yet so dire as that of the ground traffic in the vicinity of airports.

ADMINISTRATION AND SOCIAL CONDITIONS

Structure of government. California is governed under a constitution framed in 1878–79, its detail reflecting the disillusionment of the period with rampant graft. Before a series of deletions began in 1966, it had grown longer than any governmental constitution except those of Louisiana and India. Reform has often been undertaken in California through constitutional amendment. Those instituted by Governor Hiram Johnson in 1911 included provisions for voter initiative of and referendum on legislation, recall of elected officials, the direct primary, women's suffrage, and a unique system that allowed candidates to run in primaries of opposing political parties. Since 1962 constitutional revision may be made by voters without calling a convention. In 1966 voters approved a great number of additional amendments.

State executive officers are elected for four-year terms, with members of more than 50 boards and commissions being appointed by the governor. The legislature comprises a senate of 40 members and assembly of 80 members. Reapportionment in the mid-1960s gave legislative dominance to populous southern California at the expense of rural areas.

The judicial system has five levels, including the seven-member Supreme Court, district courts of appeal, Superior, municipal, and justice courts. Superior courts are the major trial courts, whereas the more numerous municipal districts hear lesser matters.

In 1970 local government was conducted through more than 5,200 agencies, including 58 counties and 404 incorporated cities, a lower number than in other populous states. Under the constitution, counties and cities may establish charters or accept general-law provisions and statutory laws. Cities operate under variations of mayor–council–manager control. Los Angeles and San Francisco operate under mayor–council, and San Diego and San Jose employ city managers assuming a larger share of administrative duty.

Amorphousness of state politics

Politics. Volunteer party organizations often have usurped roles ordinarily fulfilled by the Democratic and Republican party structure. The parties are forbidden to endorse any candidate prior to the primary, but unofficial organizations do so and are often better funded and organized than the party structure. To overcome this party ineffectiveness, candidates turn to professional campaign managers to enhance their public images.

Attempts at machine politics have proven ineffectual because of voter mobility, lack of party entrenchment, and the prime role of civil service in bestowing jobs. The vastness of the state and political cleavages between the more liberal north and conservative south make it difficult for one party to sweep statewide offices, even with majority registration. Before abolition of cross-filing in 1959, candidates of one party sometimes avoided facing general elections by sweeping the primary elections of both parties. Traditional party alignments seem less significant to many California voters, and heavy cross-overs are common despite heavy Democratic pluralities in voter registration.

Finances. High property taxes provide the chief source of local revenue. Rising income, sales, and gasoline taxes support state expenditures dominated by highway building, education, and welfare costs. The California budget for 1970–71 was estimated at nearly $5,000,000,000.

Education. California is oriented toward tax-supported, public educational institutions. The two-year junior or community college was introduced in California in 1907, and by 1970 there were 93 such colleges with 650,000 full-time students. Nineteen four-year state colleges, with 242,000 students, and the nine-campus University of California system, with 109,000 students, completed the public higher-education structure and absorbed a state budget that exceeded $700,000,000. The University Extension system claimed 200,000 enrollments in more than 9,000 courses at over 300 locations throughout the state. About 10 percent of California schoolchildren and a slightly lower percentage of college-age students attended private schools.

Higher education

A landmark in California higher education was achieved in 1960 with a master plan that attempted to avoid overlapping roles in the complex system of public colleges and universities. In general, the top one-eighth of high school graduates is eligible to enroll at one of the nine university campuses, which retain supervision over doctoral degrees. The four-year state colleges draw from among the top one-third of high school graduates. High school graduates from the lower two-thirds of their classes attend two-year colleges and often are able to transfer at the end of that period to one of the four-year campuses.

During a period of rapid expansion in the 1960s, new University of California campuses were developed at Irvine, Santa Cruz and San Diego, augmenting older campuses at Berkeley, Los Angeles, Davis, Riverside, Santa Barbara, and San Francisco (site of a medical school only). The new campuses at Santa Cruz and San Diego were established on variations of the Oxford University system of numerous small independent colleges sharing limited central facilities or services. By 1972 budget restrictions had severely hampered the scheduled development of new colleges within these two campuses, and student enrollment had fallen below projections; consequently, the addition of new colleges began to drop behind schedule. Among new colleges opened was a third college at San Diego emphasizing minorities studies and weighted with black and Chicano enrollment. The college immediately became embroiled in community and academic controversy, with critics challenging its somewhat lower scholastic standards of admission, Other campuses at all levels were increasing minorities studies, most often within existing frameworks.

Berkeley, the original campus, was founded in 1868 and has remained one of the most prestigious, academic communities in the nation. This campus attracted the earliest and heaviest volume of militant demonstration beginning in 1964 with the Free Speech Movement, which led in 1967 to dismissal by university regents of Clark Kerr, the respected university president who had been the major architect of the master plan of 1960 and of the new campuses.

In 1970 the university system counted 15 Nobel Prize laureates on its faculties, encompassed two nuclear laboratories, nearly 100 research and experiment stations, and about 50,000 employees. It was involved in overseas projects in more than 50 nations and over 1,000 courses were in its catalogs.

Health and welfare. At the end of 1970, 2,400,000 Californians—about 12 percent of the population—were receiving welfare or Medi-Cal (health) benefits. With about 10 percent of the U.S. population, California had 16 percent of the nation's welfare cases. In recipients of public assistance money payments per 1,000 population, California was exceeded only by Puerto Rico, Louisiana, and Mississippi.

For years California has been considered a liberal state in the extent of its health and welfare statutes. Its mental health programs have been advanced. State funds

are dispersed through four major systems: aid to families with dependent children, aid to totally disabled, aid to blind, and old age security. The rapidly increasing dollar cost of these programs between 1960 and 1970 made continuation of California's traditionally generous posture a matter of fierce political debate. Gov. Ronald Reagan proposed welfare reforms, and some curtailment of benefits was legislated. Poverty, however, especially among Mexican-Americans and blacks, many of them recently immigrated to California, continued as a blemish on the general economic prosperity, and funding of these programs continued to mount. In 1969, state contributions to public assistance programs in California totalled more than $450,000,000, exclusive of medical assistance.

In Watts, a district of south Los Angeles which saw the nation's first modern socially directed violence in 1965, poverty worsened between 1960 and 1965 at a time when real family incomes in Southern California rose 10 percent. In predominantly black Watts, about one-half of the families received less than the poverty-line income in 1965. Unemployment continued high in Watts, and a majority of its residents received public assistance. Similar pockets of poverty existed in all other major California cities. In East Los Angeles, the predominantly Mexican-American community numbered 66 percent of the population in 1960; unemployment has decreased in subsequent years, but living conditions for a large proportion of the population are considered marginal.

Nonetheless, innovation distinguished the structure of California's health and welfare programs. The number of mentally ill in state hospitals declined sharply from 1959 to 1970, partly through introduction of psychotropic drugs and availability of federal funds for nursing home care, but also through a marked expansion of state-funded mental health programs at the community level. In 1968 the legislature established a county-operated community mental health service in each county with over 100,000 population. In 1969 a landmark act allowed involuntary treatment of chronic alcoholics and those who are gravely disabled or dangerous to themselves or others.

In the beleaguered Medi-Cal program of medical aid, computer systems were being established to go into use statewide by 1973, enabling rapid processing of claims. Uniform, detachable label ID cards were issued in 1971 to control services and validate claims. These and other procedures were an attempt to eliminate abuse and delay that had brought the program near to foundering.

CULTURAL LIFE AND INSTITUTIONS

It still seems too soon to speak of any cultural tradition that is rooted in California. As a state it has harboured —and sometimes given birth to—a notable procession of creative people in all the arts, yet much of their work has not been necessarily associable with the region. Much of the cultural ferment of California is an outflowing in which self-indulgence seems as prominent a motivation as creativity.

California's culture has not yet hardened in form. It is marked by widespread public involvement with the arts and brash enthusiasm for cultural trappings as symbols of achievement, often in the form of lavish expenditures to erect galleries, museums, and concert halls. Just as patrons of the performing arts began to believe they had established a strong base for support of these arts when their buildings were completed, an antipathy toward traditional culture appeared to have overcome a substantial portion of oncoming generations.

Literature. Early writers associated with California came from elsewhere: Bret Harte, born in New York; Mark Twain, in Missouri; Joaquin Miller, in Indiana; and Ambrose Bierce, in Ohio. But the San Francisco of Gold Rush days provided an eager audience for their writing, as it did for theatre and music. There followed a line of writers who came as close to establishing a regional tradition as have artists in any medium. Jack London, chronicler of men amidst frontier violence, was born in San Francisco. Frank Norris and Upton Sinclair, who opposed the social ills of their times in a foreshadowing of the later work of John Steinbeck and, to a lesser degree, of William Saroyan, were California born but left the state in the 1940s. To extol its natural wonders, California produced the naturalist John Muir, the progenitor of a school of environmental writers that became prominent in the 1960s and 1970s. Robinson Jeffers, who lived in California from 1914 until his death in 1962, was the state's most renowned poet. An influx of literary figures as screenwriters into Hollywood in the 1930s and 1940s established little in the way of regional cultural tradition, and the California milieu became instead a favourite target of satire in such novels as Nathanael West's *The Day of the Locust*, Evelyn Waugh's *The Loved One*, and others by F. Scott Fitzgerald, Budd Schulberg, Raymond Chandler, and Ross MacDonald.

Visual and performing arts. In painting, San Francisco produced David Park, Elmer Bischoff, and Richard Diebenkorn. Los Angeles seemed more successful as a marketplace for art, with a thriving colony of galleries along La Cienega Boulevard that ranked second only to Manhattan's Madison Avenue. The numerous wealthy art collectors in southern California were prominent in funding the Los Angeles County Museum of Art, which opened in 1965 and had more than twice as many persons in its first year than the Louvre in Paris in that same year. The Music Center of Los Angeles County is a concert and theatre complex constructed during the 1960s by private contributions.

A California Arts Commission was charged in 1963 with establishing "the paramount position of this state in the nation and in the world as a cultural center." Hobbled by a low budget, its contribution has been limited largely to inventorying the arts in California and to token sponsorships. Tax-supported state institutions, most prominently the University of California and its extension program, aggressively pursue performers and audiences in dance recitals, plays and films, concerts, and lectures. The Theater Group of the University of California at Los Angeles is one of the most innovative in America. Experimental theatre in San Francisco has bloomed from time to time, especially with the Actor's Workshop between 1952 and 1965, after which the company moved to New York City. An often distinguished mixture of light and avant-garde theatre is offered throughout the year at several theatres, including the community-sponsored Old Globe Theater in San Diego. Amateur theatrical groups are everywhere, as are community orchestras, chamber-music societies, and weekend artists. Communities such as those at Carmel, Big Sur, and Sausalito have harboured communities of workers in diverse arts. The symphony orchestras of San Francisco and Los Angeles have achieved international recognition, as has the San Francisco Opera Company. San Diego supports an increasingly fine symphony orchestra, opera, and ballet company through voluntary donations to a combined-arts council.

Mass media. Hollywood still is responsible for the bulk of the national movie and television output, and as such it remains an international symbol of glamour. An increasing number of national magazines and periodicals emanate from California editorial offices. Metropolitan California newspapers decreased in number between 1940 and 1970, but total circulation grew, led by the *Los Angeles Times*, with the largest number of readers in the state.

PROSPECTS

Some patterns of California development have seemed innovative—ranging from those of campus revolt to branch banking and the professional management of political campaigns, from youth cultism to the ranch-style house and the submergence of the two-party political system. Since so many Californians have come from other states, presumably in search of new life-styles, the appearance of such patterns has led to the popular image of California as a state where acute observers may apprise future directions of American life. Valid or not, that image has placed California affairs under scrutiny both in the popular media and scholarly research.

In the 1970s, however, the Californian's tolerance for innovation and social experiment was viewed by some as an invitation to the destruction of its institutions. Welfare abuses and campus militancy became rallying points of conservatives who deplored the permissiveness of California society. Political alliances seemed to be in flux, with spokesmen for emerging minorities finding common cause with environmentalists. Critical state budgetary problems threatened advances in education and social improvement. So strong had sentiment become against continued rapid growth that even selective taxes aimed at new immigrants were proposed in 1971. It appeared that the period of boosterism in California had finally come to an end.

BIBLIOGRAPHY. For amplification of general points of view on California, see NEIL MORGAN, *The California Syndrome* (1969) and *The Pacific States*, rev. ed. (1970). Older but invaluable are CAREY MCWILLIAMS, *Southern California Country: An Island on the Land* (1946) and *California: The Great Exception* (1949).

Early California histories by H.H. BANCROFT and T. HITTELL are invaluable. Bancroft's voluminous works include: *History of California, 1542–1890*, 7 vol. (1884–90); *California Pastoral, 1769–1848* (1888); *California Inter Pocula, 1848–56* (1888); and *Popular Tribunals*, 2 vol. (1887). Hittell's is *History of California*, 4 vol. (1885–97). More recent California histories include: J.W. CAUGHEY, *California*, rev. ed. (1953); WALTON BEAN, *California: An Interpretive History* (1968); ANDREW F. ROLLE, *California: A History*, 2nd ed. (1969); and ROBERT GLASS CLELAND, *From Wilderness to Empire: A History of California*, ed. by GLENN S. DUMKE (1959). The best regional overview is EARL POMEROY, *The Pacific Slope* (1965).

Of detailed value but variable accuracy is the FEDERAL WRITERS' PROJECT, *California: A Guide to the Golden State*, rev. ed. (1967). More accurate as guidebooks are *Northern California*, 3rd ed. (1970), and *Southern California*, 3rd ed. (1970), published by SUNSET BOOKS; and ANDREW HEPBURN, *Complete Guide to Northern California* and *Complete Guide to Southern California* (both 1962).

For geography and the landscape, see DAVID W. LANTIS, RODNEY STEINER, and ARTHUR E. KARINEN, *California: Land of Contrast* (1963). Among JOHN MUIR'S many important works on California is *The Mountains of California* (1894). Among the best books on San Francisco's earthquake is WILLIAM BRONSON, *The Earth Shook, The Sky Burned* (1959). FRANCIS P. FARQUHAR combines history and geography in *History of the Sierra Nevada* (1965). The standard work on Yosemite is VIRGINIA and ANSEL ADAMS, *Guide to Yosemite* (1963).

A still outstanding work on immigration to California is that by MARY R. COOLIDGE, *Chinese Immigration* (1909). Important works are BERNARD DEVOTO, *The Course of Empire* (1952), *Across the Wide Missouri* (1947), and *The Year of Decision: 1846* (1942). A large bibliography of Gold Rush history may be found in JOHN WALTON CAUGHEY, *Gold Is the Cornerstone* (1948). A good current guidebook is *Gold Rush Country* (1967).

An early economic history of California is that by ROBERT G. CLELAND and OSGOOD HARDY, *March of Industry* (1929). Economic affairs of more recent years are discussed in CAREY MCWILLIAMS, *California: The Great Exception* (1949); and NEIL MORGAN, *Westward Tilt* (1963). For railroad history, see OSCAR LEWIS, *The Big Four* (1938); on labour, IRA B. CROSS, *A History of the Labor Movement in California* (1935).

The best book about California politics is GLADWIN HILL, *Dancing Bear: An Inside Look at California Politics* (1968). An overview of California politics is found in GEORGE E. MOWRY, *The California Progressives 1900–1920* (1951); and FRANK H. JONAS, *Western Politics* (1961). A fine novel of California politics is EUGENE BURDICK, *The Ninth Wave* (1956).

(N.Mo.)

Californian Indians

Native peoples found in California were only generally circumscribed by the present state boundaries. Some of the peoples within these boundaries were culturally intimate with other areas neighbouring California. The Colorado River groups, such as the Mohave and Yuma, shared traditions with both the Southwest (Arizona and New Mexico) and southern California, whereas the peoples of the Sierra Nevada, such as the Washo, shared traditions with the Great Basin peoples. In northern California were to be found native traditions of the Northwest Coast (see SOUTHWEST AMERICAN INDIANS; NORTH AMERICAN GREAT BASIN INDIANS; and NORTHWEST COAST INDIANS). The remaining native groups occupied the greater part of California and they represented indigenous cultural developments.

A conservative estimate of the pre-Spanish population of California is 275,000, making it one of the most populous culture areas of native North America. Various ecologic features—seacoasts, tidelands, river and lake areas, valleys, deserts, and foothills—and various historical traditions contributed to great cultural diversity. Thus there existed a seemingly endless variety of local environmental niches, each contributing advantages and disadvantages to human adaptation.

The peoples of California were politically stable, sedentary, and conservative and less in conflict with one another than was usually the case in other areas of North America; and neighbouring groups often developed elaborate systems of economic exchange of goods and services. The Californian Indians reached peaks of cultural attainment rarely seen among peoples depending almost wholly for subsistence on hunting, fishing, and the gathering of wild plant foods.

Distribution of Californian Indians.

TRADITIONAL CULTURE PATTERNS

Local and territorial organization. California was occupied by a large number of cultural groups that have been described as ethnic nationalities—that is, groups of people sharing common linguistic, social, and cultural traditions and recognizing themselves as part of a single culture distinct from that of other groups. Excepting the Colorado River peoples (Mohave and Yuma) and perhaps some Chumash groups, these ethnic nationalities had no centralized governmental structures; instead, each group comprised independent territorial and political units that may be termed tribelets, tightly organized polities that were smaller than the average groupings in most other parts of North America. Populations in these tribelets

"Tribelet" organization

ranged from a hundred to a few thousand people, depending on the richness of locally available resources; tribelet territories ranged in size from about 50 to 1,000 square miles (150 to 3,000 square kilometres).

Within each tribelet there might be only one principal village in which all the people lived and from which some of them ranged for short periods of time to collect food, hunt, or visit other tribelets for ritual or economic purposes. In some tribelets there was a principal village surrounded by settlements of people who came to the principal village for ritual, social, economic, and political occasions. In other tribelets there were two or more villages, each having various satellite settlements and one serving as a "capital" or central village. Here a principal chief would usually reside, and major rituals and political and economic affairs would be held.

Community organization of tribelet villages was varied, but basic patterns are discernible. Among the Miwok and the peoples south of them, village ownership was usually based on clan arrangements, whereas in northern California land ownership was based more on territorial principles than on kinship ties. Bilateral or nonlineal descent organization usually occurred where village land ownership was not clan based, as in the case of the southeastern desert-dwelling peoples, although exceptions to this occurred in the far northern part of the state.

Kinship and status patterns. Marriage was almost always a matter arranged by the families because it created long-range economic and social bonds between families. Generally the families exchanged goods at the time of the marriage, the bulk of goods coming from the husband's family. In most cases the wife resided with the husband's family and was taught the ways of the husband's group by the mother-in-law. Levirate (widow marriage to the brother of the deceased) and sororate (widower marriage to the sister of the deceased) were widely observed, maintaining relationships between already connected families and stabilizing child-care conditions. Men could often have more than one wife; this was particularly true of chiefs and shamans (medicine men) because heavy social responsibilities were required of their offices and because political ties between groups could thereby be established.

The aged served as the teachers and advisers. Young adults were active in subsistence, and the elders prepared the children for adulthood. The aged made most of the decisions concerning legal disputes and economic crises.

Role of the chief

The role of chief was generally an inherited position providing political stability to the group (though in northern California no formal chief appears to have existed). Women in some groups, such as the Pomo, were chosen as chiefs or "little chiefs." The chief was an economic administrator whose instructions to his people ranged from very general admonitions to very specific directions for particular tasks, such as indicating where food was available and how many people it would require to collect it. He redistributed the economic resources of his community and, through donations from members of the village, maintained resources from which emergency needs of individuals could be met. He was the major decision maker and the final authority in most villages, but he had the aid of a council consisting of such persons as heads of extended families, ritualists, assistant chiefs, and shamans. In some areas the chief functioned as a priest, maintaining the ceremonial house and ritual artifacts.

The chief was generally a conspicuously different person, wealthier, more elaborately dressed, and frequently displaying the symbols of his office. He was treated with great respect. Chiefs' families, in fact, formed a superstratum of the community elites, especially in areas in which lineage development was present.

Shamans and ritualists

Shamans served not only as healers and diviners but also as psychiatrists, artists, and poets. They defined and described the world of the sacred and regulated the fortune of souls before and after death, thereby serving as mediators between the profane and sacred worlds. Most tribelets in California had one or more shamans, usually men. Shamans were active in political life, working with other leaders and placing their powers at the disposal of the community.

Alongside chiefs and shamans in native California there were ritualists—dancers, singers, fire tenders—who were carefully trained in their crafts, and they functioned intimately within the political, economic, and religious spheres of their communities. They were men or women who acquired considerable respect and often wealth because of their skills and placement in the social structure. In effect, they were members of the power elite. When performing, ritualists were usually costumed in headdresses, dance skirts, wands, jewelry, and other items.

Socialization and education. Formal learning was a continuous process in native California life. Older persons instructed children through elaborate tales containing lessons concerning behaviour and values. Constant supervision—provided by adults, older siblings, or other relatives—instructed and reminded the child about how things should be done.

Rites of passage

The dramatic time of the educational process occurred during rites of passage, when individuals were graduating into new status positions. The girls' puberty ceremony, for example, generally consisted of a time of isolation because the girl was considered very dangerous when she began to menstruate. During this time, which varied from several days to several weeks, an older woman would care for the girl and instruct her in her role as an adult. Ceremonies for boys' initiation were less common and, when carried out, were usually less formal, involving instruction in the manly things to do and prediction of the boys' future religious, economic, or political careers.

Sometimes education was quite institutionalized. Young Chumash men, for instance, purchased positions from guildlike associations of specialists in order to receive apprenticeship as professional artisans of some kind, while young Pomo men were charged a fee to be trained as apprentices by recognized professional craftsmen.

Leaders and specialists continued their training on a less formal level throughout their lifetimes. A man destined to become chief received his learning from others (such as ritualists and shamans) and continued to receive such instruction even after assumption of office.

Economic systems. *Settlement patterns.* In most of California the villages were occupied the year round, with small groups moving out only for short periods of time to hunt or collect food. In areas poor in economic resources, people moved more frequently, only temporarily gathering together in large groups for such activities as antelope drives and piñon-nut harvests. Riverine and coastal peoples as a rule enjoyed more stable settlements than those living in the desert and foothills.

Housing

House types varied throughout California from permanent, carefully constructed houses occupied for a lifetime or more to the most temporary type of structure, such as a brush shelter, as dictated by circumstances. Types of houses ranged from wood-framed (northern California), earth-covered (various areas), semi-subterranean (Sacramento area), and brush (desert areas) to thatched palm (southern California). Communal and ceremonial houses were found throughout the region and were often large enough to hold several hundred people for rituals or festivals. Domestic houses ranged in size from five or six feet (almost two metres) in diameter to apartment-style houses in which several families lived together in adjoining units. Another common type of housing consisted of the sweathouses, earth-covered permanent structures that were used by most Californians (the Colorado River groups and the northern Paiute, on the margins of California, were exceptions); sweating was usually a daily activity for men.

Patterns of production and technology. Food production in native California centred on hunting, fishing, and collecting wild plant foods. Men usually hunted and fished while women collected plant foods and small game. Hunting and fishing equipment such as bows and arrows, throwing sticks, fishing gear, snares, and traps were made by men; women manufactured clothing, nets, baskets, pots, and other cooking utensils. Older people commonly made the productive equipment, whereas younger adults performed the harder labours of production using the implements.

For coastal Californians, shellfish, deep-sea fish, surf fish, acorns, and game were the main subsistence staples; peoples in the riverine and lake areas relied on fish, acorns, tule, game, and waterfowl. Native groups of the foothills, valleys, and plains depended on acorns, tule, game, and fish; and those living in the desert regions sought piñon nuts, mesquite, and game (especially antelope and rabbit) and practiced some marginal agriculture.

Special technologies

There were also various special technological devices. The Chumash of southern coastal California made large seagoing plank canoes, which allowed them to hunt large sea mammals. Peoples living on the bays and lakes used tule balsas or rafts, while riverine groups had flat-bottom dugouts (canoes made by hollowing out large logs). Techniques of food preservation included drying, hermetic sealing, and leaching of some foods high in acid content. Milling and grinding equipment was common.

Property and exchange systems. Concepts of property tended to vary in degree rather than kind throughout California. Everywhere, property was owned by individuals, family groups, lineages, communities, or larger political groups such as clans. In general, socially defined groups (such as clans and villages) owned the land and protected it against infringement from other groups. Individuals, lineages, or extended families usually owned exclusive rights only to certain food-collecting, fishing, and hunting areas. Such resources as obsidian mines or areas where medicinal plants grew might be owned by either groups or individuals. Individual articles could be acquired by manufacture, inheritance, purchase, or gift.

Goods and foodstuffs were distributed through two main institutions—reciprocal exchange between kin and "trade fairs," often ritualized. Both operated similarly in that they served as a redistribution and banking system for spoilable foodstuffs; a group with a surplus of foods, that is, would bring it to another group and exchange it for goods (such as shells), which could be used in the future to acquire foodstuffs in return.

There were professional traders in most California groups who travelled long distances among many ethnic nationalities. Goods from as far away as Arizona and New Mexico were exchanged by coastal peoples. Generally, shells from the coastal areas were valued and exchanged for products of the inland areas, such as obsidian or food. Medicines, manufactured goods such as baskets, and other objects were also commonly exchanged in these systems.

Religion. Throughout native California religious institutions were intensely and intimately associated with all other institutions—political, economic, social, and legal. In all the groups there were shamans, religious leaders who served as intermediaries between the supernatural world and the world of man. Priests and other ritualists were common in many groups.

Kuksu and Toloache religions

Two religious systems—the Kuksu and the Toloache—were associated with social organizations into which initiates were formally indoctrinated. In the Kuksu religion common to northern California (as among the Pomo, Yuki, Maidu, Wintun), members "impersonated" spiritual beings and engaged in very distinctive, colourful, and dramatic rituals with special paraphernalia, costumes, and equipment, usually in large public communal houses. Within the Toloache religion of southern California (as among the Luiseño and Diegueño), initiates performed while drinking a hallucinogenic decoction made of Datura meteloides, which put them in a trance and allegedly provided them with supernatural knowledge about their future life and role as members of the sacred societies. In both religions special instruction was a significant factor in the recruitment of members into the ritual society. Members exercised considerable economic, political, and social influence.

Religions on the Colorado River differed slightly because they were not concerned with developing formal organizations and recruitment procedures. Individuals received religious information through dreams; and members recited long narrative texts, explaining the creation of the world, the travel of culture heroes, and the adventures of historic figures.

In the northwest there was another informally structured religious system. It was associated with rituals concerned with world renewal (as in the white-deerskin dance), in which privately owned myths were recited. One communal need served by these ceremonies was that of restructuring relationships in societies lacking the rigid social ordering found in many other native California groups. The display of costumes and valuable possessions (such as white deerskins or delicately chipped obsidian blades) reaffirmed social ranking, and the success of the ritual reaffirmed the orderly relationship of man to the supernatural.

Use of magic

The use of supernatural power to control events or transform reality was basic to every California group. Generally, magic was used in attempts to control the weather, increase the harvest of crops, and foretell the future. Magic was deemed not only the cause of sickness and death but also the principal means of curing many diseases. Sometimes magic was considered as an agent to protect oneself, to punish wrongdoers, or to satisfy personal ends.

Arts and crafts. Oral literature was the art form for which native California was most renowned—especially esoteric and elaborate creation tales and epic poems. There were also songs with accompanying narratives, tales of victory, recollections of recent events or daily activities, and airs of love. Songs were usually short but could, in narrative form, last for days. Singing was accompanied by the sounds of rattles, whistles, or drums.

Visual art forms ranged from decoration on items of daily use (such as baskets and tools) to elaborate rock paintings and rock engravings. California natives are generally most remembered for their exquisite basketwork, though pottery in the eastern desert was shaped and decorated handsomely. Costuming, particularly in relation to the Kuksu religion, involved the creation of elaborate headdresses, skirts, feathered costumes, and so on, which were often symbolic of supernatural beings. Body painting was also popular.

Incising or pecking designs into rock was practiced in various parts of the area, and rock paintings were widespread. They were associated probably with individual and group rituals and hunting and gathering activities on the one hand and served as simple trail markers or indicators of food or water on the other.

EVOLUTION OF CULTURES TODAY

Today native Californians are rural peoples residing mainly on reservations or rancherias. There is, however, a long-established pattern of individuals moving to urban areas to find work when necessary but considering their reservation or rancheria as "home," as a place where they will be welcomed upon return. In this manner many native Californians may live away from their lands for the better part of a lifetime and yet come back at last to a way of life compatible with their cultural ideals and involving their family and friends. Many individuals come and go sporadically, depending upon economic conditions; some live only seasonally on the reservations. Native Californians move from depressed areas to towns, villages, and cities, however, not only to find employment but also to arrange for schooling for their children and to find the amenities of life that are often totally lacking in the more remote Indian lands.

Depressed economic conditions in many areas

As industries have moved into some rural areas, the nearby reservations have become more attractive; people can now often find regular work at home the year round. In many areas, the permanent populations of reservations are expanding, particularly with more young people with children. In other more remote rural areas, the economic situation remains bleak, and few people are able to subsist on the lands that once maintained their parents and grandparents. The main problem seems to be the dwindling water supply. Whereas 75 years ago rural natives could maintain a living by farming, stock raising, hunting, and gathering, today the giant urban areas have siphoned off much of the water, leaving many mountain valleys dry and unsuitable for agriculture. Several legal suits to stop this are now in the California courts.

According to California state-government sources, there are approximately 80 Indian settlements defined as either reservations or rancherias, each with a population varying from a few people to several hundred. Within each there may be tribal lands, which belong in common to all of the members; allotted lands, which are owned by individuals or collections of individuals through inheritance; and assigned lands, which are owned by the reservation as a group but assigned to the specified use of certain individuals.

Since the United States government withdrew most federal responsibility for native Californians in 1955, reservations have become relatively autonomous. Each reservation or rancheria has an elected body of officials, known variously as a business committee or tribal council, which acts as a liaison between the people and such outside interests as the U.S. Bureau of Indian Affairs, business corporations desiring the purchase or lease of reservation lands, public utilities concerned with seeking rights-of-way across lands, and individuals having some form of business with the group. The council acts with the advice and consent of the people in dispersing tribally owned assets such as the lands or funds, and it also acts as the receiving agent for grants from various economic-development or relief organizations of the government. It is often involved in litigation with the government or other agencies concerning tribal grievances, and today it almost invariably participates directly in planning economic and social development programs for the future protection of the group's assets.

Generally speaking, native Californians have adopted much of the ways of the European world. In clothing, housing, transportation, education, and often religion, they are not significantly distinguishable from other people residing in California. In more subtle ways, however, native culture, attitudes, ritual, and psychology are still viable throughout the state from north to south. Wherever there are native populations, one finds ceremonial houses, ritual, and the continued use and manufacture of ritual materials, as well as occasional use of native foods.

Attempts to preserve the cultural heritages

Many arts and crafts, especially basket weaving, have been maintained. The Indian languages, though spoken less and less as first languages, are being maintained and revived for cultural and nostalgic reasons. On some reservations there are cultural centres and museums helping to preserve the culture and languages, and on other reservations and in some local school districts classes in native languages and culture are being offered to both children and adults. Various organizations of native Californians, such as the American Indian Historical Society and the California Indian Education Association, are aggressively examining, criticizing, and providing new teaching materials for schoolteachers who deal with native Californians in the classrooms.

On the other hand, few if any traces of traditional cultures remain in some areas of California today. These areas generally coincide with what are today the major population centres of California, from San Francisco and Oakland south to San Diego. A new form of native American cultural development is under way, however, as Indians from all over the United States, not only from rural California but also from reservations in the central great plains of the United States and the Southwest, gravitate to these major urban areas, bringing with them diverse tribal and cultural backgrounds that add up to a new measure of cultural diversity in urban life. Many of these people came in large numbers during World War II, often to work in defense industries, while others came in large numbers after the war as part of the aggressive planning and development of the Bureau of Indian Affairs in the 1950s. These moves led to serious problems among some of the relocatees because Bureau of Indian Affairs coordination was ineptly carried out, with the result that many native American groups have had to develop their own self-help organizations to care for their people in the cities. A pattern of replicating the institutions of the cultural groups they came from is apparent throughout the state. Dance groups as well as educational and political groups have developed generally along lines of cultural similarity. There are, for example, Navajo clubs, Hopi clubs, and so on.

BIBLIOGRAPHY. A.L. KROEBER, *Handbook of the Indians of California*, 2nd ed. (1953); ROBERT F. HEIZER and M.A. WHIPPLE (eds.), *California Indians: A Source Book*, 2nd ed. (1971); and EDWARD S. CURTIS, *The North American Indian*, vol. 15–16 (1907, reprinted 1970), provide the most general summaries of native California cultures, although each source is not wholly representative of the latest thoughts. More recent accounts appear in various publications of the University of California, such as *Anthropological Records, University of California Publications in American Archaeology and Ethnology*, and the *Reports of the University of California Archaeological Research Facility*. Many new interpretations of native California cultures are also contained in the *Annual Reports of the Archaeological Survey of the University of California at Los Angeles*. Several books of interest containing new theoretical views or data, which are more representative of current scholarly views, are RAYMOND C. WHITE, *Luiseño Social Organization* (1963); LOWELL JOHN BEAN, *Mukat's People* (1972); JACK D. FORBES, *Native Americans of California and Nevada* (1968); and ROBERT F. HEIZER and ALAN ALMQUIST, *The Other Californians* (1971). Books recently prepared for the nonspecialist, which are very readable, are THEODORA KROEBER, *Ishi i tuå världar* (1963; Eng. trans., *Ishi in Two Worlds*, 1964); and ROBERT F. HEIZER and THEODORA KROEBER, *Almost Ancestors* (1968). B.W. and E.G. AGINSKY, *Deep Valley* (1967), provides a readable fictional account of the Pomo Indians.

(Lo.J.B.)

Caliphate, Empire of the

The Empire of the Caliphate, or Caliphal Empire, was a state comprising the entire Islāmic community and the lands under Muslim domination in the centuries following the death of the Prophet Muḥammad (AD 632). In the name of Allah and Islām, Arab armies extended the theocracy founded by Muḥammad and his successors, the caliphs, beyond its original home in western Arabia until, by the early 8th century, it included most of Southwest Asia, North Africa, and Spain. The impetus of expansion enabled the Patriarchal and Umayyad caliphs (632–750) to maintain the unity of the empire. Once the state reached its territorial limits under the ʿAbbāsid dynasty (750–1258), however, the inadequacies of the central government and the cultural tensions between Arabs and non-Arabs became evident. A slow process of disintegration set in as rival caliphates and local dynasties sprang up in various parts of the Islāmic world. By the early 10th century the ʿAbbāsids no longer had any real political power, though most Muslims continued to regard them as religious leaders until the extinction of their line. Later, the ideal of a politically united Islām remained strong, but was never again achieved.

The article contains the following sections:

I. The rise of the Arab empire, 622–750
  The consolidation of Islām and Arab expansion
    The foundation of the Muslim community (622–632)
    The four "Patriarchal Caliphs," 632–661
  The Umayyad Caliphate, 661–750
    The consolidation of the caliphate, 661–684
    The zenith of Umayyad power, 684–715
    The later Umayyads, 715–750
  Government and society, 632–750
    Administration of the Arab lands
    Cultural life under the Umayyads
II. The ʿAbbāsid Empire
  The ʿAbbāsid Caliphate, 750–945
    The establishment of the new dynasty, 750–786
    The ʿAbbāsids at their zenith, 786–861
    Increasing difficulties and decline, 861–945
  The eclipse of the ʿAbbāsids and the growth of provincial dynasties, 945–1258
    The Būyids
    The Sāmānids
    The Fāṭimids
    The Seljuq Turks
    The last ʿAbbāsids
  Economic and social life under the ʿAbbāsids
    The economy
    ʿAbbāsid society
  Cultural life under the ʿAbbāsids
    Religion
    Greek and Iranian influences
    Arab literature

I. The rise of the Arab empire, 622–750

THE CONSOLIDATION OF ISLAM AND ARAB EXPANSION

The foundation of the Muslim community (622–632). The political and moral climate of Arabia at the time of Muḥammad's mission was propitious for the rise of a firm, nationalistically Arab faith (see ARABIA, HISTORY OF). The civilization of the Himyarites in South Arabia was in full decay, and outside powers (*e.g.*, Ethiopia and Persia) were contending for control there. The region to the north of Arabia had been for several centuries a battleground between Persia on the one side and Rome and its successor Byzantium on the other. Shortly before Muḥammad died, in 632, the Byzantines, by a great military effort, secured the upper hand, but both these world empires were now exhausted and could no longer ward off the nomads of the Arabian Peninsula, who for centuries had been pressing on the fringes of the Fertile Crescent but who were now fired by the dynamic religion of Islām. Within the peninsula, ancient paganism was moribund, mourned by few but leaving a certain spiritual void. The ethos of the old Bedouin society of Arabia was based on a nexus of kin obligations, but the growth of city life in the western region of the peninsula (the Hejaz), with an incipient commercial economy in Mecca flourishing on the Yemen–Syria caravan trade, may have created some tensions in society, for the resolution of which the traditional ways offered no guidance. All in all, conditions favoured the appearance of a new religious system; and the catalyst for this was to be a religious figure of genius, the Prophet Muḥammad.

Arabia before Islām

Muḥammad began the public proclamation of his belief that God had chosen him to be a prophet and "warner" to his fellow Meccans in 613 or shortly thereafter. But, though there was some response to his preaching from members in the second rank of Meccan society, there were few converts from the leading clans, such as ʿAbd Shams (or Banū Umayyah). This was to have important consequences after Muḥammad's death, when that clan achieved supreme political power in Islām, forming the dynasty of Umayyad caliphs (see below *The Umayyad Caliphate, 661–750*); the Umayyads were never able to shake off the stigma of having been late and lukewarm converts to Islām. When Muḥammad began to attack the pagan gods of Quraysh, the tribe inhabiting Mecca, the Qurayshite chiefs became openly hostile to Muḥammad and his followers.

In September 622 Muḥammad and some 70 of his supporters slipped away from Mecca to the agricultural centre of Yathrib, or Medina, 200 miles (300 kilometres) to the north. This event is known among Muslims as the *hijrah*, or "migration," and the Muslims taking part in it are called *muhājirūn*, or "emigrants"; under the second caliph, ʿUmar I, the beginning of the Arab year in which the *hijrah* took place (*i.e.*, July 15 or 16, 622, in the Julian calendar) was adopted as the beginning of the Muslim era. Muḥammad had prepared the way by meetings with the representatives of the Medinans. It may be that the Medinans, through contact with their local Jewish community, were familiar with the idea of an inspired, messianic leader, but it is more likely that they hoped that Muḥammad, because of the superior wisdom that went with prophetal status, would act as an impartial arbiter in the internecine feuds rife within Medina; moreover, Muḥammad had connections with Medina through his mother.

The *hijrah*

The exact definition of Muḥammad's status in Medina soon became important, for there was some conservative opposition there to him, political rather than religious in inspiration. He was certainly not an unchallenged ruler in Medina but only an invitee, with no authority over the internal affairs of the Medinan clans. There has been preserved in early Islāmic sources a document commonly referred to as the "Constitution of Medina." In its present form it is patently a compilation, but it is undoubtedly based on two agreements made between the Prophet and the Medinans soon after the *hijrah*. This "constitution" is mainly political. It establishes the *muhājirūn* as a tribal group at the side of the eight clans of the Medinans (henceforth often called the *anṣār*, or "Helpers"), but all nine tribes are described as forming an *ummah* or community of Muslims; thus, the term seems to have a religious and theocratic connotation also. The Jews of Medina are described as a separate, protected group. Muḥammad is simply the head of one of the component groups of the Muslim *ummah*, with no coercive powers outside that group; but there is the religiopolitical provision that disputes are to be referred "to God and to Muḥammad." The implication here is that guidance will come either from a Qur'ānic revelation (*i.e.*, from the Qur'ān, or sacred writing) or from Muḥammad's own special wisdom and insight. Though restricted in its scope at the time, this provision was to have great consequences later: by the later Medinan period, Muḥammad was to demand obedience not only to God but also to himself as God's Prophet, a demand buttressed by his added prestige as a successful war leader and skillful negotiator with outlying Bedouin tribes.

As Muḥammad's position grew stronger in Medina, he was able to deal with internal opposition there and elevate his position beyond that of a first among equals. Muḥammad had expected that the Medinan Jews would recognize him as the prophet promised in their own scriptures, but, when the Jews failed to respond, he became openly hostile to them. Certain originally Jewish features in early Islāmic practice were abandoned, and, in the years after 624, the three main Jewish tribes in Medina either were expelled and much of their property confiscated or, in the case of the third tribe, their males slaughtered and the women and children enslaved. The conservative opposition in Medina, the so-called Hypocrites, had been allies of the Jews, and its prestige now suffered a decisive blow.

Muḥammad was accordingly free to deal with external opposition, particularly the pagan Meccans. The *muhājirūn* in Medina contrived to live by plundering Meccan caravans travelling between the Hejaz and Syria. The Meccans retaliated by organizing coalitions of Bedouins against Medina in 625 and 627. These attacks failed, and, with the damage being done to their commercial interests, the more farsighted of the Meccan leaders began to think about coming to terms with the Prophet. Muḥammad had no desire utterly to humiliate the Meccans, for he wished to make the Meccan shrine of the Kaʿbah the centre of his faith, the restored pure religion of Abraham. When at the opening of 630 he led an army against Mecca, opposition to him was negligible, and the Meccan chief Abū Sufyān, head of the clan of Umayyah, speedily made peace.

Absorption of Mecca

The last years of Muḥammad's life were devoted to consolidating the nascent Muslim community in the Hejaz and then to extending his personal links with tribes in the more distant parts of Arabia. These were the years in which the Islāmic cult was systematized, and institutions such as the poor tax, fasting, the veiling of women, and the performance of the pilgrimage to Mecca were given the sanction of Qur'ānic revelation. Thus, the Muslim community acquired a certain ideological infrastructure, the basic features of which were to endure under the caliphate, when the faith and law of Islām became vastly more complex. The conquest of Mecca gave Muḥammad an access of prestige. Delegations of tribesmen began to make their way to Medina, where they received Islām and recognized the dual obligation of obedience to God and his Prophet. From being a mere city-state in Medina, the Muslim community became what has been called a supertribe, a confederation of Arab tribes cemented together by adherence to the Islāmic faith rather than by the old basis of blood kinship.

A noteworthy feature of these last years of Muḥammad is the organization of raids and reconnaissances to the northern frontiers of Arabia, especially against the territories of the Byzantines and their Arab allies. The doctrine that Muḥammad had brought the pure, uncorrupted version of God's scripture meant that his revelation was potentially valid for all mankind and not a narrow, nationalistically Arab one. Hence arises the obligation of *jihād*, or holy war, against idolaters and polytheists, un-

Beginning of external expansion

til they are either exterminated or submit to Islām; and this impulse, compounded of religious enthusiasm and a love of plunder, became the driving force behind the expansion of the Arabs outside their peninsula and the formation of the empire of the caliphate. Herein lay Muḥammad's genius: he strove for internal peace within Arabia and unified the Arabs under the banner of their own religion and their own sacred book; at the same time, he provided an outlet for the energies thus aroused with a policy of external expansion.

The four "Patriarchal Caliphs," 632–661. *Abū Bakr, 632–634.* Muḥammad's death at Medina in 632 caused considerable dismay and confusion. A successor as military and political head of the community was urgently required, but there could be no question of a second religious leader like Muḥammad, for Muḥammad had been the Seal of the Prophets, the culmination of the line. The *muhājirūn* leaders hurriedly imposed Abū Bakr, an early Muslim and the Prophet's father-in-law, as head of the whole Muslim community, thus forestalling the *anṣār*, or Medinans, from choosing a separate head of their own and thereby splitting the community of the faithful. The fact that Abū Bakr, the first caliph (632–634), was from the Prophet's tribe of Quraysh established a precedent in the eyes of future generations, excepting the adherents of certain minority sects, that the head of the community had to be from Quraysh. The caliphate remained in the hands of persons of Qurayshite descent down to 1517, and descent from Muḥammad's clan of Hāshim was the basis of a claim to the caliphate put forward by the Hāshimite *amīr*s of Mecca in 1924 after the abolition of the Ottoman caliphate in Turkey. The actual title caliph (*khalīfah*) came from Qur'ānic usage, and Abū Bakr used the title *khalīfat Rasūl Allāh* ("successor of the Messenger of God"). The second caliph, 'Umar, first styled himself "successor of the successor of the Messenger of God," but the clumsiness of this title led to adoption of the simple title of caliph, or successor. 'Umar further styled himself *amīr al-mu'minīn*, "commander of the faithful" (or, possibly, "counsellor of the faithful"). The preservation of the caliphate within Quraysh during this period and subsequently reflected customary Arab practice, in which leadership of a tribe remained within the leading family; that is, the family possessing the requisite leadership qualities. But within that family any senior, capable male member might be chosen. Abū Bakr's nomination also preserved to some extent the idea of election by the whole community, in that the leaders of the Muslim community could claim to be acting on behalf of the masses. Later, some show of election and acclamation by the great men and religious scholars was usually sought at the succession of a new caliph; in this way, a certain sop to democracy could be offered.

Abū Bakr and his three successors are called by the Muslims the *rāshidūn*, literally "rightly guided" or "orthodox" caliphs, but a better term is that of patriarchal caliphs. Later generations of Muslims looked back on them and the first generation of Muslims, the Prophet's Companions, as the founding fathers of the community and regarded their age as a golden one in which a pristine Islām flourished, undefiled by later corruptions and luxury; modern reform movements in Islām have often tried nostalgically to go back to this period of "classical" Islām.

Abū Bakr's prime tasks were to uphold the religious heritage of the Prophet and to maintain the political hegemony of the capital, Medina. At this time, the supporters of Muḥammad may be divided into three groups: a devoted nucleus of Muslim enthusiasts, without whose support Muḥammad could not have persevered in the face of so much indifference and opposition; a larger group, composed of those who were religiously lukewarm but who had joined the Muslim *ummah* because of the advantages that it offered; and the Bedouins, who were only nominally Muslim but who were attracted to the war leader Muḥammad by the prospects of plunder outside Arabia. When Muḥammad died, this latter group saw little reason to keep up an allegiance that had been purely personal. Hence follows the period of the *riddah*, or "apostasy" (though this term, with its theological overtones, is unsuitable for a movement that was mainly one of political renunciation), in which the outlying parts of Arabia refused taxes to Medina. In the east and south, local prophets did arise; apparently, there was a feeling that Islām could be countered only by another faith. But the only serious contenders here were the followers of the veiled prophet of Yemen, al-Aswad (the Black One), and, above all, Musaylimah in the Yamāmah region of eastern Arabia, who seems to have had a genuine religious mission contemporaneous with Muḥammad's in western Arabia. Musaylimah, however, was killed at the Battle of 'Aqrabā' or the Yamāmah in 633. Abū Bakr sent out commanders to suppress the *riddah* outbreaks; the tribes of western Arabia were less actively hostile to Medina and generally remained faithful, if without much enthusiasm, to the Muslim connection. The result of the successful campaigns of Abū Bakr's generals against the rebels was that, for the first time, Islām became a military and political force throughout Arabia. Abū Bakr died in 634 and on his deathbed nominated as his successor 'Umar, another Qurayshite and father-in-law of the Prophet.

The period of the *Riddah*

'Umar I, 634–644. The caliph 'Umar I (634–644) was the great consolidator of the Islāmic empire as it expanded during his reign. Far from being the pious conservative of Muslim tradition, 'Umar I was a bold innovator in the fields of administration and military organization; he was a puritanical, iron ruler who tried to prevent the Muslim community, now being presented with riches beyond its wildest dreams, from being too embroiled in materialism. During 'Umar's caliphate, the momentum of conquest outside Arabia increased severalfold. As soon as the *riddah* outbreaks had been quelled, the Arab generals and the tribesmen under their command directed their attention to the settled lands to the north. Thus, the chief of the tribe of Bakr, al-Muthannā ibn Ḥārithah, and the Qurayshite aristocrat Khālid ibn al-Walīd, later known as "the Sword of God," operated in the northeast against Iraq. In 633, Ḥīrah, the capital of the old Lakhmid Arab dynasty, former allies of the Persians, was attacked. Iraq, or Mesopotamia, was at this time part of the Persian Empire, and the Sāsānid dynasty actually had its capital at Ctesiphon, near the site of the later Baghdad; but the population of Iraq was ethnically Semitic (rather than Persian), Syriac speaking, and largely Christian. There was certainly no cordial attachment to the Sāsānids, and, after the decisive battle of al-Qādisīyah, in 636 or 637, all Iraq fell to the Arabs. Subsequently, control of Iraq was ensured by the foundation of military centres at Kūfah and Basra; these served as concentration points for Bedouins from Arabia, and from these were organized expeditions into Armenia, the Caucasus, and Persia proper. The Iranian plateaus and mountains, topographically broken and climatically harsh, were unfavourable terrain for the Arab cavalrymen, and the Persians, proud possessors of an ancient imperial heritage, resisted strongly. Gradually, however, the last Sāsānid emperor Yazdegerd III was driven back, until he was finally killed at Merv, in Khorāsān, in 651; his son Fīrūz fled to China but was never able to organize a successful revanche. The Persian state religion of Zoroastrianism was deprived of support from the secular arm, and, through the Persian land-owning class of *dehqān*s, the Islāmization of Persia began.

Conquest of Iraq and Persia

The overrunning of Jordan, Palestine, and Syria took place at the same time as that of Iraq, under commanders such as the Qurayshite 'Amr ibn al-'Āṣ and Khālid, now transferred by Abū Bakr from Iraq. The enemy in these places was Byzantium, recently triumphant over the Persians but exhausted and overstretched in resources. The Muslims defeated Theodorus, the brother of the Byzantine emperor Heraclius, at Ajnādayn, in Palestine, but were temporarily halted by the siege of Damascus. The city, however, fell to Khālid in 635, and, after a final unsuccessful effort in 636 by Heraclius at the Battle of the Yarmūk, a tributary of the Jordan, all Syria and Palestine lay open to the Muslims. They spread northward to Antioch and into al-Jāzirah, the steppeland of what is

Conquest of Syria–Palestine

now northeastern Syria and northern Iraq, but the natural barrier of the Taurus Mountains prevented further advance into Anatolia, and the frontier there with the Greeks remained stable for more than two centuries. As in Iraq, the Arabs were operating in an ethnically Semitic region into whose fringes Arab settlers had long been infiltrating. The Arabs were undoubtedly helped in Syria and Palestine by indigenous opposition to the Greek ruling class of officials and clergy and to the attempts of the Greek Church to impose their orthodoxy on the Christian churches of the East. The Samaritans in Palestine are reported to have made themselves so useful to the Arabs that they gained in return certain tax exemptions.

The way into Egypt was now open, and ʿAmr marched into the land, defeating a Byzantine army at Heliopolis in 640. The Arabs took advantage of the confused internal state of the country, for the Byzantines had been trying to force a formula of theological reconciliation on the unwilling Coptic Church. ʿAmr negotiated with Cyrus, patriarch of Alexandria, for peace. Alexandria fell in 642 and again, after a Byzantine reoccupation, in 645. Soon after the first fall of Alexandria, ʿAmr made his capital in Egypt at the new army camp of Fusṭāṭ, the later Old Cairo. As elsewhere, the Muslims benefitted from local hostility to Hellenism and an outside imperial power, and they were wise enough to leave local administration and tax collecting in native hands. Possession of Egypt gave the Muslims access to a rich supply of grain, and, to facilitate the export of grain to Arabia, ʿAmr had the pharaonic canal between the Nile and Suez cleaned out and brought into use again. The Muslims also gained the dockyards of Alexandria and soon became a naval power in the eastern Mediterranean, harassing the Byzantine coasts and islands there. From the Nile Delta, Muslim columns moved along the Libyan coast and overran Barqah (modern Cyrenaica). In 647 they defeated an army under the Byzantine governor, or exilarch, Gregory at Subayṭilah (Sbeitla), in Tunisia, but internal divisions within the caliphate necessitated a withdrawal, and the real conquest of North Africa belongs to the succeeding Umayyad period.

ʿUthmān, 644–656. ʿUmar was assassinated by a Persian slave in 644 and was succeeded by ʿUthmān ibn ʿAffān, an early Muslim from the Umayyad clan and a son-in-law of the Prophet; he was actually chosen by the *shūrā*, a committee of six appointed by the dying ʿUmar.

Internal dissension

ʿUthmān incurred much obloquy from the pietists in Medina, from the non-Umayyad aristocracy of Quraysh, and from the Bedouin tribesmen of the army. This unpopularity resulted from defects in the state and society that were none of ʿUthmān's creation but that were rather the outcome of policies initiated by his predecessor; hence, much of the opposition to ʿUthmān was opposition to ʿUmar's system, now given a religious colouring.

The rate of external conquest was beginning to slow, although, to occupy the tribesmen and keep up the inflow of plunder, ʿUthmān organized fresh expeditions into North Africa, Armenia, and Persia. Much of the fighting was now in difficult regions in the Caucasus and in the mountain fringes of eastern Persia and Afghanistan, where plunder came in only slowly and where troops were separated for long periods from their families in Iraq. One of ʿUmar's most brilliant innovations had been the institution of the *dīwān*, or pensions list. Since fixed plunder from the conquered lands, such as landed property, could not easily be divided among the Arab warriors, the state left the original owners and cultivators in possession in return for a rent or property tax. Out of this, the state paid fixed pensions to the free Arab warriors registered on the *dīwān*, these pensions being hereditary. But by ʿUthmān's time the soldiers realized that the state was paying back to them only a part of the moneys collected and keeping back the rest, and this became a source of resentment. There was also jealousy of the wealth and ostentation displayed by certain of the Quraysh aristocracy who had done well out of the wars by exploiting opportunities for trading and slave dealing in the conquered lands. There was also opposition to ʿUthmān's appointment of relatives to high offices such as provincial governorships. Ostensibly religious grievances included those over ʿUthmān's collection of the Qur'ān and production of an authoritative text (see below), but these were really a cloak for political opposition.

Egypt and Iraq were the main centres of discontent, and in 656 Egyptian troops entered Medina, besieged the Caliph in his house, and then murdered him as he was reading the Qur'ān. This tragedy had momentous consequences. For the first time, Muslims had laid hands on the head of their own community and had disregarded the Qur'ānic injunction not to shed believers' blood. ʿUthmān's murder originated an age of *fitnah*, or civil strife; hence, he is termed in Arabic sources "the opened door" (*i.e.*, to civil violence).

ʿAlī, 656–661. Already at Muḥammad's death, his cousin ʿAlī ibn Abī Ṭālib had hoped to secure the caliphate for himself, as a member of the Prophet's clan of Hāshim and husband of his daughter Fāṭimah. These hopes were disappointed, and, during the subsequent three caliphates, ʿAlī played no significant part in public life. During the killing of ʿUthmān he remained passive and was then hailed as caliph (656–661). His supporters were the notables and pietistic elements of Medina, plus the Iraqi tribesmen, who hoped to make ʿAlī their creature; ʿAlī did in fact move his capital to al-Kūfah, and the caliphate never returned to Arabia. But conservative elements of Quraysh, who feared an upsurge of tribal anarchy in the caliphate, rose against ʿAlī at the so-called Battle of the Camel near Basra (656); but the ringleaders were killed and the Prophet's widow ʿĀ'ishah exiled to Medina.

Yet the cry of vengeance for ʿUthmān proved disastrous for ʿAlī, who was, with justice, accused of implicit agreement to the assassination. The avenger proved to be another member of the Umayyad family, Muʿāwiyah, son of Abū Sufyān, who for some 20 years had served as an energetic and successful governor of Syria; he accordingly represented the interests of Syria against ʿAlī and Iraq. Muʿāwiyah refused homage to ʿAlī, and the forces of the two sides clashed at Ṣiffīn, on the upper Euphrates, in 657. The confrontation was drawn out and indecisive, but Muʿāwiyah's supporter ʿAmr ibn al-ʿĀṣ managed to secure arbitration over the question of who had the superior right to the caliphate. This in itself was a blow to ʿAlī's prestige, for he was the incumbent caliph, whereas Muʿāwiyah had nothing to lose. Indeed, a section of ʿAlī's more intransigent supporters withdrew from his army and formed the violently hostile group of the Khārijites, or Seceders. These Khārijites later evolved into a radical, egalitarian sect that denied the intrinsic right of Quraysh to the caliphate and insisted that piety, not birth, was the sole qualification of leadership of the Muslim world. Militarily, they came to be a thorn in the flesh of the Umayyads and early ʿAbbāsids in Iraq and Persia for almost two centuries. A Khārijite sympathizer assassinated ʿAlī himself in 661. Before this, ʿAlī's prestige had dwindled, his sphere of authority confined mainly to Arabia and Iraq, while Muʿāwiyah consolidated his position in Syria and Egypt, backed by a disciplined military force tested in warfare with Byzantium. ʿAlī's lightweight son al-Ḥasan was raised to the caliphate in Iraq on his father's death—the first appearance in the caliphate of the principle of hereditary succession—but was quickly bought out by Muʿāwiyah, who thus in 661 became generally recognized as caliph, the first of the Umayyad line.

The Khārijites

THE UMAYYAD CALIPHATE, 661–750

The consolidation of the caliphate, 661–684. *Muʿāwiyah I, 661–680.* Muʿāwiyah and his two successors form the Sufyānid line of Umayyads. The rule of the Umayyads cemented the grip of the Qurayshite aristocracy on the caliphate. Indeed, the Umayyads' rivals, such as the partisans of ʿAlī's family and the Zubayrids, were equally from this social group, as was the succeeding dynasty of the ʿAbbāsids. During the period of the Patriarchal Caliphs, succession had been by nomination or election, accompanied, however, by dissent and, latterly, by violence. The Umayyads held the caliphate for 90 years,

with the succession only occasionally passing from father to eldest son; often it passed to brothers or to cousins of collateral lines. Nevertheless, a greater continuity in policy was now achieved, and under the Umayyads the Arab empire reached almost to its farthest extent, so that by the early 8th century Arab warriors stood on the Atlantic shores in Morocco and Portugal and the Indus banks in Sind.

The deep impression Muʿāwiyah made on contemporaries is shown by the prominent part he plays in Arabic lore and literature. A skillful organizer of warfare against the Byzantines, he was also a consummate statesman, famed for his shrewdness and his *ḥilm*—a compound of firmness, magnanimity, and conciliatoriness. After persuading al-Ḥasan to abdicate, he arranged to secure Iraq and despatched his general ʿAmr ibn al-ʿĀṣ to govern Egypt again; hence, 661 is celebrated as the "year of reunion," when a measure of peace and unity was restored to the empire. Syria and its capital, Damascus, became the centre of Umayyad power until almost the end of the dynasty. There the caliphs could command the loyalty of Syrian tribesmen long familiar with settled life in the region. In Syria, too, relations with the *dhimmī*s, or "protected peoples" (*i.e.*, Christians and Jews), were more relaxed than in other parts of the caliphate. The family of Muʿāwiyah's wife Maysūn was Christian, as was his favourite court poet, al-Akhṭal. Iraq, on the other hand, was deeply divided confessionally, ethnically, and politically, while, within Arabia, Mecca and Medina no longer commanded the wealth and manpower to aspire to a political role comparable with that of the lands farther north.

Restoration of Muslim unity

The westward orientation of the caliphate enabled the war with Byzantium to be prosecuted with fresh vigour, the conquest of Constantinople being the perpetual goal. There was raiding in the Taurus region, where a string of frontier fortresses was established between Tarsus and Malatya; naval operations were pursued in the Mediterranean and Aegean, and as early as 665, while Muʿāwiyah was still governor of Syria, a Muslim fleet had won the "Battle of the Masts" off the Lycian coast. In 669 Constantinople itself was besieged by Muʿāwiyah's son Yazīd, the future caliph, and further attacks were made during the protracted war of 674–680, when Constantinople is said to have been saved by the use of Greek fire, or naphthalene, hurled at the Arabs. Rhodes and Crete were temporarily occupied (672, 674); the Arabs had already carried off the famous Colossus of Rhodes and sold its bronze as scrap.

Internally, Muʿāwiyah faced the task of securing peace in the east; *i.e.*, Iraq and its administrative dependency of Persia. Here he showed his skill in choosing capable subordinates and delegating his authority to them. He appointed al-Mughīrah ibn Shuʿbah as governor of turbulent al-Kūfah, and it was the latter who in 662 reconciled to Muʿāwiyah the capable Ziyād ibn Abīhi (literally, "son of his father"; *i.e.*, bastard), formerly one of ʿAlī's partisans. Ziyād had a certain claim on the Umayyads in that Abū Sufyān was his reputed father. Muʿāwiyah came to value his talents so highly that in 665 he publicly adopted Ziyād as his half brother. Ziyād now became governor of Basra and, on al-Mughīrah's death, of al-Kūfah also, becoming the dominant figure in the eastern caliphate. He governed with exemplary firmness, suppressing sedition in Iraq and reorganizing the financial system among the tribesmen there, until his death in 673. In particular, he harried the Khārijites and kept careful watch over the partisans of ʿAlī, who were especially strong in al-Kūfah. Noteworthy is the fact that al-Mughīrah and Ziyād, and slightly later, al-Ḥajjāj were from the town of aṭ-Ṭāʾif near Mecca; the Thaqīf, or people of aṭ-Ṭāʾif, had an urban tradition and could produce administrators of this calibre. The *anṣār*, with their Medinan peasant background, generally fade as a distinctive group from public life after ʿAlī's caliphate, largely merging with the "pious opposition" inimical to the Umayyads and all their works.

Muʿāwiyah recognized that, besides threats from the tribesmen and schismatics of the east, there was a threat to his dynasty from the ambitious and disappointed non-Umayyad aristocracy. He therefore endeavoured to safeguard the transition of power after his death by nominating Yazīd as heir apparent. About 676 he solicited provincial centres for their agreement, though it required some effort by his governor in the Hejaz, Marwān ibn al-Ḥakam, to secure assent in Mecca and Medina. The precedent was thus established by which a caliph named his successor, whether a son or brother or other kinsman, during his own lifetime, securing an oath of allegiance to him. The practice certainly minimized the risk of succession strife, but it ran counter to the old democratic instincts of the Arab tribesmen and smacked of Byzantine and Persian autocracy. Hence, the Umayyads' enemies held it against them; pietist circles and later historians (most of these last with a pro-ʿAbbāsid or pro-ʿAlid bias) stigmatize the Umayyads as *malik*s, or "kings," not true caliphs, and their rule as *mulk*, "temporal kingship," and not a *khilāfah nabawīyah* ("caliphate in succession to the Prophet").

Safeguarding the succession

Yazīd I, 680–683. When Muʿāwiyah died, at an advanced age, his son succeeded as Yazīd I (680–683). The expected storm was not long in breaking out, with opposition coming from the Khārijites, the ʿAlids, and the Qurayshite aristocracy in Medina. All these had ostensibly religious grievances, aimed at the restoration of a true *khilāfah* in accordance with the Qurʾān and the Prophet's *sunnah*, or "example"; but they all also expressed a hatred of strong, centralized government, a desire for provincial autonomy, and a dislike of the privileged position of Syria. ʿAlī's son al-Ḥasan had retired to a life of luxury, and it was probably from his excesses that he eventually died. Headship of the legitimate progeny of ʿAlī now devolved on al-Ḥasan's brother al-Ḥusayn. The latter refused to acknowledge Yazīd as caliph and was persuaded to rebel against him by emissaries from the anti-Umayyad stronghold of al-Kūfah; Ziyād's son ʿUbayd Allāh, governor of Basra, easily suppressed the outbreak, and al-Ḥusayn was killed as the rebel he undoubtedly was at the Battle of Karbalāʾ, in central Iraq (680). The symbolic importance of this event was later to prove out of all proportion to its significance at the time. Al-Ḥusayn was considered a martyr, and, under this emotional stimulus, political support for the claims of the ʿAlid family to the caliphate began to take on a more definitely religious flavour. Thus, it came to be held that ʿAlī had been the only possible successor to Muḥammad, for the Prophet had specifically designated ʿAlī as his spiritual as well as his temporal heir. According to this view, the first three Patriarchal Caliphs had actually been usurpers. Furthermore, the divine light dwelling in ʿAlī was transmissible to his descendants; hence, they alone were the true *imām*s ("exemplars," "religious leaders") as well as the true caliphs, or temporal leaders. In this way there evolved the Shīʿah, or Party, of ʿAlī, who set this authoritarian theory of government, the guidance of an infallible *imām*, against the majority, Sunnite theory that the caliphate was a temporal benefit and convenience for the Muslims and that the consensus of the Muslim community was the ultimate authority in religious disputes unresolvable by resort to the Qurʾān or *sunnah*. Though the ʿAlids were frequently to rise in revolt against the Umayyads and early ʿAbbāsids, the Shīʿites did not achieve widespread political power until the decline of the caliphate in the 10th century.

The Shīʿah minority

Another strand of opposition to Yazīd was that eventually led by the Qurayshite ʿAbd Allāh ibn az-Zubayr, son of one of the leaders against ʿAlī at the Battle of the Camel. Stories were circulated in the Hejaz of Yazīd's dissolute life, his love of hunting and wine, of music and poetry—all of these anathema to the pious. Mecca and Medina rose and expelled the Umayyad representatives. A Syrian army marched southward, defeated the Medinans outside their city at the Battle of the al-Ḥarrah, and plundered Medina; it then marched on Mecca and besieged it, destroying the shrine of the Kaʿbah (683). But the news arrived of Yazīd's death in Syria, and, since it was uncertain who would succeed him, the army lifted the siege. The Syrian general al-Ḥuṣayn ibn Numayr, in-

deed, offered to recognize Ibn az-Zubayr as caliph if he would go to Syria and establish his authority there; but the latter was uncertain of his reception and preferred a safer if more circumscribed power in Arabia. Hence, Ibn az-Zubayr remained as an anticaliph in Arabia, with his authority recognized not only in Arabia but also in Egypt, Iraq, and the east and even in parts of Syria. The Umayyads did not dislodge him for nine years.

Muʿāwiyah II, 683–684. Back in Syria, Yazīd's eldest son, the youthful Muʿāwiyah II, succeeded briefly as caliph (683–684) but died within a few months; as one chronicler says, "none of his deeds merit record." Yazīd's reputation was inevitably blackened by later authors, for he had not only slain ʿAlī's son, al-Ḥusayn, but also had attacked the sacred cities of the Hejaz; hence the epithet frequently given to him, "the accursed." In reality, Yazīd seems to have had a good share of his father's famed quality of *ḥilm*. He had distinguished himself against the Byzantines, and but for his premature death the ensuing crisis of 684 would have been avoided.

The zenith of Umayyad power, 684–715. *The advent of the Marwānids.* The year 684 was one of deep crisis. The childless Muʿāwiyah II had refused to name an heir. He had a brother, but the army leaders in Syria preferred a stronger and more experienced leader, if necessary outside the direct line of Abū Sufyān. Some Syrians favoured Ibn az-Zubayr, but the choice finally fell on Marwān ibn al-Ḥakam, of a collateral branch of the Umayyads, formerly secretary and adviser to ʿUthmān. Under the Marwānids, ʿUthmānid sentiment seems to have been deliberately cultivated to the detriment of the Sufyānids' memory, though the attachment of the Syrian populace to the Sufyānids was enduring; in early ʿAbbāsid days, when Syria had lost its position of primacy in the empire, many Syrians looked for the appearance of a Sufyānid political messiah.

The short reign of the aged Marwān (684–685) was filled with violence. Much of Muʿāwiyah's diplomatic skill had gone into stilling tribal rivalries in Syria and al-Jazīrah. The older established Arab immigrants, mainly of the Kalb group and accounted South Arabian in genealogy, had different interests and attitudes from the North Arabs of the Qays group, more recently arrived from Arabia and controlling al-Jazīrah; these last, in turn, feared that the Umayyads would allow further emigration into the lands that they considered their own special ones. As Qurayshites, the Umayyads themselves were technically North Arabs, but Muʿāwiyah had largely depended on the Kalbites who settled in southern Syria and Palmyra; through his wife Maysūn he had become allied with the influential family of Ibn Baḥdal, so that the Baḥdalites were reckoned as the supporters *par excellence* of the Umayyads. The end of the Sufyānids saw now a recrudescence of tribal warfare, the bane of the ancient Arabs before the unifying bond of Islām and the distraction of external expansion had come along.

The position of Marwān and his supporters was perilous, for the leader of the Qaysites in Syria, aḍ-Ḍaḥḥāk ibn Qays, finally threw in his lot with Ibn az-Zubayr, and was crushed by Marwān only after a fierce battle at Marj Rāhiṭ, near Damascus (684). After this, all Syria and Egypt returned to Umayyad allegiance, and Marwān was firmly established there. Yet the tribal divisions engendered at this time continued later to erupt sporadically into violence all over the empire, from Spain to Khorāsān; and the watchwords of Qays and Yemen have been used by factions in such parts of the Arab world as Syria, Palestine, and Arabia almost to modern times.

ʿAbd al-Malik, 685–705. Marwān died shortly afterward, and the caliphate passed to his son ʿAbd al-Malik (685–705), thus cementing the succession in the Marwānid line. Four of ʿAbd al-Malik's sons eventually became caliph, so that he became known as Abū al-Mulūk, Father of Kings. His 20-year reign was comparable to that of Muʿāwiyah in importance and splendour, once the multiplicity of rebels in various parts of the empire had been mastered; and in this work of pacification and unification the role of the Caliph's right-hand man, al-Ḥajjāj ibn Yūsuf, was decisive. For several years, Ibn az-Zubayr's brother Muṣʿab nominally controlled Iraq on behalf of the anticaliph, but from 684 to 687 Iraqi politics were dominated by an adventurer from aṭ-Ṭāʾif, al-Mukhtār ibn Abū ʿUbayd, who had begun his career as a Shīʿite, attempting to secure support for al-Ḥusayn's son ʿAlī and then for ʿAlī's son by a slave wife, Muḥammad ibn al-Ḥanafīyah, and had then for a time been a supporter of Ibn az-Zubayr. In 685 al-Mukhtār took advantage of simmering discontent in al-Kūfah to raise the standard of revolt. He appealed primarily to pro-Shīʿite sentiments among the Arab tribesmen, to messianic hopes circulating in Iraq at the time, and, to a lesser extent, to the social grievances of the clients, or *mawālī*, non-Arab converts who had become affiliated with Arab tribes but who were nevertheless regarded with contempt by the genuine Arabs. Not until 687 did Muṣʿab manage to kill al-Mukhtār.

Al-Mukhtār's revolt

ʿAbd al-Malik himself could not move against his opponents—the rival caliph Ibn az-Zubayr and various Khārijite movements in Iraq and al-Jazīrah—until he had secured his rear by making peace with the Byzantines, agreeing to pay a tribute of 1,000 dinars a week. In 691 he invaded Iraq, and his forces defeated and killed Muṣʿab at the Battle of Dayr al-Jāthalīq (Monastery of the Catholicos). Ibn az-Zubayr's power was now on the wane. He had remained supinely in the Hejaz, devoting his energies to the rebuilding and enlarging of the Kaʿbah and its enclosure. In 692 al-Ḥajjāj appeared at Mecca with an army, and after a siege of several months, in which the Kaʿbah was again bombarded with catapults, the city was stormed and Ibn az-Zubayr killed. Because of the ending of the rival caliphate, the year 692 is famed as a second "year of reunion."

Al-Ḥajjāj campaigned in other parts of Arabia against Khārijite rebels until in 694 he arrived in al-Kūfah and took over the governorship of Iraq, which he proceeded to rule with a firm hand, suppressing a revolt of the Zanj, or black agricultural slaves, in Lower Iraq. He sent his general al-Muhallab ibn Abī Ṣufrah into Persia to combat the extremist Khārijites of the Azraqite sect; he also was confronted with the serious rebellion of the "Peacock Army." This last was really a revolt of the old Arab tribal aristocracy under the leadership of Ibn al-Ashʿath of the noble tribe of Kindah, but it expressed many of the grievances of the Iraqi tribesmen against the Umayyads and their privileged Syrian troops, for the Peacock Army (so called because of the splendour of its original array) had been sent to restore the Arab position in the remote region of southeastern Afghanistan, where the Arab advance had been halted by the resistance of a powerful local ruler, the Zunbīl (Rutbīl). Rejecting al-Ḥajjāj's attempts to station them there permanently, the troops rebelled and marched back to Iraq until they were crushed in 701 and Ibn al-Ashʿath later himself killed. Seeing that both Basra and al-Kūfah had supported the insurgents and regarding the Iraqis as chronically rebellious, al-Ḥajjāj in 702 founded a new fortified camp, Wāsiṭ, midway between the two earlier camps, and garrisoned it with Syrian troops. Thereafter, he kept Iraq substantially quiet until the end of his governorship and death, in 714. Al-Ḥajjāj's draconian measures against rebellion and schism should not obscure the vigorous positive measures that he took for the restoration of agriculture and irrigation in Iraq and his enlightened patronage of poets and scholars, aspects of his policy insufficiently stressed by later, anti-Umayyad historians.

The "Peacock Army"

ʿAbd al-Malik's power was thus firmly grounded, and he devoted the latter part of his reign to a renewal of the war with Byzantium and to matters of administrative and financial reorganization, all aimed at increasing the Arabization and centralization of the empire and at ensuring within it the dominance of the Arabs. Syria flourished under his rule, and in 691 he erected the magnificent Dome of the Rock in Jerusalem, the third holiest city of Islām, being generally accepted as the goal of the Prophet's "night journey," or miraculous ascent to heaven; some sources state that the caliph hoped to divert pilgrims to Jerusalem because Ibn az-Zubayr barred the

way to the Hejaz, but this seems improbable. In his youth in Medina, ʿAbd al-Malik had been famed for his piety, and this interest in religious and cultural affairs was not abandoned when he became caliph.

Al-Walīd, 705–715. ʿAbd al-Malik's eldest son, al-Walīd, succeeded him as caliph (705–715). ʿAbd al-Malik had in fact planned to exclude from the succession his brother ʿAbd al-ʿAzīz, whom Marwān had designated as next in line, but ʿAbd al-ʿAzīz died before ʿAbd al-Malik himself did. Al-Walīd had the advantage of a full treasury left by his father, and the prosperity of the empire was further assured by a great rise in the inflow of plunder and revenue from the new conquests, which outbalanced the decline in revenue from the older conquered lands, such as Iraq. Internally, the empire enjoyed peace. Al-Ḥajjāj continued to secure order in the east, and al-Walīd recovered some popularity for his house by appointing his cousin, the pious and pacific ʿUmar ibn ʿAbd al-ʿAzīz (the future caliph), as governor of the Hejaz (705–712). The holy cities there were beautified with new buildings, and the pilgrimage routes across Arabia were policed and supplied with wells and rest houses. In Damascus, al-Walīd indulged his love of building by erecting the splendid Umayyad Mosque (on the site of the former Christian Cathedral of St. John), which must have been at that time the supreme wonder of the Islāmic world.

But it is the fresh surge in the movement of external conquest, beginning in ʿAbd al-Malik's reign with the restoration of internal peace and reaching its climax under al-Walīd, that especially marks these years.

Conquest of North Africa

The raids along the coast of North Africa into what came to be called by the Arabs the Maghrib (Western Land) were renewed only when Muʿāwiyah had restored peace after the civil wars. The dominating figure in this adventure was the Qurayshite warrior ʿUqbah ibn Nāfiʿ, who later became a semilegendary figure and was almost regarded as the patron saint of Islām in the Maghrib. In 670 or perhaps a few years previously, he penetrated into Ifrīqīyah (present Tunisia) and founded the military settlement of al-Qayrawān (Kairouan), which became the bastion of Muslim arms in the west. The Byzantines were still in the coastal towns, while the indigenous Berber tribes of the interior resisted fiercely; in 683 their leader Kusaylah defeated and killed ʿUqbah near Biskra, and the Arabs were hurled out of Ifrīqīyah. It was not until ʿAbd al-Malik's caliphate that they were able to return, and, with the help of a Muslim fleet, Ḥassān ibn Nuʿmān captured Carthage from the Byzantines in 698 and overcame the Berbers' resistance under their woman leader Kāhinah ("Soothsayer," "Priestess"). In the following year, Mūsā ibn Nuṣayr extended Muslim power as far as Tangier, and the Maghrib was now administratively separated from Egypt and made a separate province directly dependent on Damascus. The Islāmization of the indigenous Berbers, attracted by the superior Arabic culture, now proceeded apace.

Muslim Spain

It was Mūsā who in 711 allowed his freedman Ṭāriq ibn Ziyād to raid across the Strait of Gibraltar into Spain. The Muslims took advantage of a local revolt against the Visigothic king Roderick, and within three years the Visigothic state collapsed. The Muslims overran the peninsula as far as Galicia and the Cantabrian Mountains (modern Cordillera Cantábrica), whither the Visigothic remnant retreated, forming a defensive redoubt that over the following centuries was to be the launching pad for the Christian reconquest of Spain from the Moors (see SPAIN, HISTORY OF). Berber settlers temporarily colonized Galicia, and the Muslims crossed the Pyrenees and occupied the region of Narbonne, in southern France. Raiding parties penetrated into Aquitaine, attracted by the rich abbeys and monasteries of France, but an expedition directed at the shrine of St. Martin at Tours was halted near Poitiers in 732 by the Carolingian Charles Martel, and the Muslims made no further serious attempts to occupy territory beyond the Pyrenees. In any case, it is dubious whether any permanent annexations in France were contemplated; even the conquest of Spain itself seems to have been unplanned, though it was helped by the fact that climatically and topographically the Iberian Peninsula is an extension of North Africa. The utter collapse of the Visigothic ruling class was probably facilitated by the passivity of the Hispano-Roman populace in the face of the Arabs, while the much-persecuted Jewish minority may have welcomed the invaders. Yet unlike North Africa, where Christianity eventually disappeared totally, and unlike Egypt, Syria, and Iraq, where it was reduced to a minority faith, many of the Christians of the Iberian Peninsula held fast to their Latin cultural heritage and Christian religion, forming the so-called Mozarab community; perhaps a half or two-thirds of the former Hispano-Roman population refused to succumb to the blandishments of Islām and its civilization.

In the east the impelling urge for plunder and, above all, for slaves led the Arabs across the Caucasus and beyond the Iranian plateau. Control of the Caucasus region was disputed with the Khazars, a powerful Turkish people who occupied the South Russian and Ciscaucasian steppes and who raided into Georgia and Armenia during the caliphates of Yazīd I and ʿAbd al-Malik. At this period all the Arabs could do was to hold on to their footholds in Armenia. On the far eastern fringes of the Arab empire, however, the frontier was more open and the opportunities for potential expansion greater, although the Arabs faced tenacious opponents there also, including the Hephtalites, or White Huns, in Afghanistan, the West Turkish Khans of Central Asia, and, beyond them, the might of the T'ang emperors of China, who claimed a vague suzerainty over Central Asia and the Iranian frontier lands.

Central Asian campaigns

Soon after the collapse of the Sāsānid monarchy during ʿUthmān's caliphate, Arab troops raided across the Oxus into Transoxania (modern Uzbek S.S.R.), attracted by the agricultural and commercial richness of such centres as Bukhara and Samarkand. Yet for many decades to come these were only summer raids, after which the Arabs returned to their camps at Merv and elsewhere in Khorāsān. In the earliest period there seems to have been no intention to colonize Khorāsān itself with Arab settlers, for the tribesmen disliked long periods of service away from their families in Iraq, and discontent over these absences contributed, as noted above, to the rising of Ibn al-Ashʿath and the Peacock Army of Seistan (Sīstān). It was Muʿāwiyah's governor in the east, Ziyād, who first began the planting of Arab families in Khorāsān on a large scale (671). The governorship of Khorāsān also included that of Seistan, but the Arabs were unable to push farther because of the resistance of the local Hephtalite ruler of Zābulistān (the region of modern Qandahār and Ghaznī). More successful was an expedition from Shīrāz in Persia through the barren region of Makrān (*i.e.*, southern Baluchistan) into Sind by al-Ḥajjāj's son-in-law Muḥammad ibn al-Qāsim, who in 711 captured the port of Daybul at the mouth of the Indus. Within two years he had advanced up the Indus valley to Multān and laid the foundations of an Arab colonization of the province of Sind, which for three centuries remained the Muslim foothold in the Indian subcontinent.

Progress in Central Asia was slow, for the local Iranian and Turkish rulers there were redoubtable foes. The conquests there are especially associated with Qutaybah ibn Muslim, an appointee of al-Ḥajjāj and governor of the east (704–715). Tukharistan, or Bactria, in northern Afghanistan, submitted, Samarkand and Bukhara were occupied, the ancient kingdom of Khwārezm on the lower Oxus was reduced to obedience, and an advance was made through Farghāna (modern Fergana) to the borders of what later became Chinese Turkistan. Yet in these regions the Islāmic faith made only slow progress in the face of indigenous religions such as Buddhism, Zoroastrianism, and Christianity. Transoxania was very remote from Syria and communication lines inordinately long. Above all, progress was hampered by the internal divisions of the Arabs in Khorāsān, for the tribal enmities of Syria and Iraq had been imported to the east. It was not at all surprising that, just before his death in

720, the caliph ʿUmar II ordered a general withdrawal of the Arabs from Transoxania.

The later Umayyads, 715–750. *Sulaymān, 715–717.* Al-Walīd was followed by his brother Sulaymān (715–717). Some sources stress his gluttony and lasciviousness. Others, however, praise him for his reversal of the stern policies of al-Ḥajjāj (who had died just before al-Walīd himself): he released political prisoners, recalled troops from distant garrisons, and, above all, appointed his cousin ʿUmar ibn ʿAbd al-ʿAzīz as his successor. Certainly, Sulaymān instituted a general change of governors, a move aimed at ending the general domination of North Arabs or Qaysites in high office (al-Ḥajjāj's own tribe of Thaqīf was accounted North Arab). Qutaybah, governor of the east, foresaw that al-Walīd's demise would mean a change of direction in the state and tried unsuccessfully to raise a rebellion (715). Muḥammad ibn al-Qāsim was recalled from Sind and executed. Iraq and then Khorāsān were given to Yazīd ibn al-Muhallab of the Yemenite tribe of Azd. It is possible that the shadowy but influential figure of Rajāʾ ibn Ḥaywah was behind Sulaymān's "new order," as he undoubtedly was behind that of ʿUmar II. Rajāʾ had been active under ʿAbd al-Malik as head of the chancery, and he may have had a direct hand in ʿUmar's financial reforms (see below *ʿUmar II, 717–720*). The outstanding military event of Sulaymān's reign was the great effort made against Constantinople, the culmination of early Islāmic attacks on the second Rome. For a whole year (716–717) an enormous army and fleet under the Umayyad prince Maslamah ibn ʿAbd al-Malik (who would certainly have made an outstanding caliph had his mother not been a slave, which had the effect at this time of excluding him from the succession) invested the city. The Byzantine emperor Leo III the Isaurian, however, vigorously defended it. Sulaymān died, and ʿUmar called off the siege. Not until 1453 did the Muslims return to the attack, this time with lasting success, under the Ottoman sultan Mehmed I the Conqueror.

The role of Rajāʾ ibn Ḥaywah

ʿUmar II, 717–720. Against the wishes of his family, Sulaymān designated ʿUmar ibn ʿAbd al-ʿAzīz as the next caliph (717–720). Possibly Sulaymān realized that the empire was heading for an economic and social crisis that could be averted only by a decisive change of leadership and attitudes. ʿUmar II's caliphate became famed as an interval of pious and ascetic rule amid the general frivolity and godlessness of the Umayyads. The Hungarian Orientalist Ignác Goldziher called him "the Hezekiah of the Umayyads," and, in the exhumation and burning of the Umayyads' corpses by the vengeful ʿAbbāsids, ʿUmar's corpse escaped. In fact, ʿUmar was a realist and also a true Umayyad who wished to preserve his family's rule and the domination of the Arabs by making timely concessions and adjustments. Influenced by his Medinan upbringing and the general deepening of religious feeling in the caliphate, he saw the urgent need for a politico-religious reform that would reverse his predecessors' policy of putting state interests first; that would reconcile the claims of piety with political realities; and that would divert the rising tide of grievances against the state by removing the disabilities and complaints of a large element of the empire's population, the converts.

The problem of converts

In order to comprehend ʿUmar's policy, it is necessary to go back several decades. In the first days of the Patriarchal Caliphs, the terms Muslim and Arab had been almost coterminous. The state did not go out of its way to encourage conversions, despite the universality of Muḥammad's message, and the comparatively small number of converts were absorbed into the Muslim *ummah* and admitted to some of the Arabs' financial privileges. But, once the advantages of membership of the *ummah* became apparent, the trickle of conversions swelled to a torrent. Peasants fled from the countryside, where they had been bound to the soil in a serflike condition (the change of masters after the coming of Islām often making little difference there), to the anonymity of the towns and garrisons, contributing to the socially turbulent populations of the latter. It was a major source of chagrin to the converts, or *mawālī* ("clients"), that, though they had adopted a faith in which all men were supposed to be equal through piety, they were regarded by the Arabs with contempt, discriminated against socially, and, above all, still held liable for such burdens as the poll tax, or *jizyah*, supposedly due from non-Muslims only. In defense of the attitude of the state, one must note that the volume of conversions and the loss of taxes badly affected a province such as Iraq; the revenue of Iraq declined sharply toward the end of the 7th century, and this was only partly counterbalanced by the inflow of plunder from the new conquests. The state therefore continued, as far as it could, to exact the poll tax from converted non-Arabs, but it could do little to prevent the exodus from the countryside to the towns, where taxes could be less easily collected.

Hence ʿUmar's dilemma: how to balance the claims of religion and justice with state policy. He tried first of all to still faction and schism by continuing Sulaymān's policy of reducing the ascendancy of one particular party in the state and by refusing to take sides. He tried to conciliate the Shīʿah by ending the public cursing of ʿAlī from the pulpits. Most important, however, was his financial policy, known from a fiscal proclamation circulated to his governors. In this he asserts, among other things, that the prime duty of the state is to extend the faith—"God sent Muḥammad to preach the faith, not to act as a tax-collector." Also, he asserts the obligatory nature of the poor tax, or *zakāt;* the state's duty to put its statutory fifth of all captured plunder for the benefit of the Muslim community; the prohibition of land liable to land tax being diverted into private, tax-exempt land grants for the Muslims; and the right of peasants to migrate to the towns and not be sent back, though they were still to be liable to the *jizyah* on their land. The absence of a categorical provision against exacting the poll tax from converts is probably explicable by the multiplicity of financial practices and systems prevailing in the empire: no general principle could be enunciated. The basic principle, however, was reasserted that converts were liable only to the taxes leviable on Muslims in like occupations, and ʿUmar's encouragement of converts to migrate to the towns, where they could be free of the *jizyah* when it was part of the global land tax, did remove a fertile source of grievance from al-Ḥajjāj's time.

Yazīd II, 720–724. With the end of ʿUmar's short reign, the caliphate returned to the sons of ʿAbd al-Malik in the person of Yazīd II (720–724), famed as a lover of the arts and music. The reforms of ʿUmar were quietly dropped. There was now a return to the policies associated with al-Ḥajjāj and the Qaysite ascendancy, for Yazīd was related by marriage to al-Ḥajjāj's family. One aspect of this was the overthrow of Yazīd ibn al-Muhallab and Yemenite power in the east. Yazīd rose in rebellion at the beginning of the new reign but was defeated and killed by the caliph's half brother Maslamah, and the power of his tribe, the Azd, was severely curtailed in Khorāsān.

Hishām, 724–743. On Yazīd II's death—allegedly of grief at the death of his favourite slave girl—Hishām succeeded smoothly, the fourth son of ʿAbd al-Malik to achieve the caliphate (724–743). Hishām's 20-year reign was comparable in prosperity to those of his father and of Muʿāwiyah. Yet the position of the Umayyad caliphate and the Arab ascendancy was now perceptibly altered. Over the preceding decades the Arab empire had expanded enormously and had virtually reached its limits; the basic difficulty now was to transform this dynamism into a stable, permanent regime; that is, to provide what had hitherto been an essentially military organization with the administrative institutions of a settled state. In order to achieve this, the Umayyad caliphs, from Muʿāwiyah onward, had developed the power of the state, their own personal rule, against centrifugal tribalism and the ambitions of rival Arab families such as the Zubayrids. ʿUmar II had tried to reverse the process of secularization and modify that of centralization but had failed.

Hishām, accordingly, had to follow the traditional Umayyad pattern of rule but at the same time endeavour to make it more palatable, especially as the bases of Umayyad power were narrowing, and Hishām could only depend militarily on the numerically limited Syrian army and the new professional troops being organized by his cousin Marwān ibn Muḥammad, the future caliph Marwān II.

Hishām was clearly aware of all these trends and of the dangers to the Arab ascendancy. Personally frugal, hardworking, and devoted to the orderly conduct of affairs, Hishām kept a balance between Qaysites and Yemenites in the allocation of offices and favours. He is said to have been interested in introducing Sāsānid Persian administrative techniques into his government, though this could hardly endear him to the religious classes. In fact, Hishām was strongly orthodox in religion; he enjoyed the company of the *ʿulamāʾ*, or religious scholars, and it was during his reign that the state intervened directly in religious affairs and the first executions for heresy took place. It seems probable that he followed ʿUmar II's example of reorganizing the fiscal system in response to the grievances of the *mawālī*, though few details are known.

Internal quiet under Hishām

Internally, the empire enjoyed much peace under Hishām. For the greater part of his reign Iraq was ruled by Khālid al-Qasrī, a governor of the calibre of Ziyād and al-Ḥajjāj; it was only in 738 that Qaysite intrigues brought about his downfall and eventual death. Under Khālid, security in Iraq was re-established, and many valuable irrigation and land reclamation projects were carried out. The Khārijites were put down, and a rising of the ʿAlid Zayd ibn ʿAlī at al-Kūfah was later suppressed (740). In the east it was realized that the process whereby the Arab troops in Khorāsān were becoming assimilated to the Persians around them could not be halted. Hishām's policy was to disperse these Arab settlers in various parts of the province and to reinforce them by fresh, unassimilated tribesmen from Iraq plus a Syrian force. Even so, in 734 discontented Arab tribesmen rebelled in Gūzgān in northern Afghanistan under al-Ḥārith ibn Surayj, who held out on these eastern fringes for over ten years with help from the Khan of the Türgesh, or western Turks. The prime task of Hishām's governors in the east was, indeed, to maintain and consolidate the conquests of Qutaybah in the face of strong counterattacks by the Turks from beyond the Jaxartes in the years up to 737.

There was similar pressure from the Turkish Khazars in the Caucasus region, where Maslamah and Marwān ibn Muḥammad campaigned vigorously. The Khazars invaded Armenia and Azerbaijan in 730, reaching al-Jazīrah, before Maslamah hurled them back and himself raided as far as the Khazar capital on the lower Volga or possibly to the lower Don. The Arabs left garrisons at strategic points such as Derbend on the western Caspian shore; but, although agreements for peace and the payment of tribute were frequently made with the local Caucasian rulers, no enduring political control was possible.

In the Muslim west, it soon became difficult to exert control from Damascus. Arab financial exploitation and arrogance sparked off a Berber revolt all over the west (740–742). In the Maghrib, the Arabs were reduced to control of the area round al-Qayrawān. The driving force behind this revolt was anti-Umayyad egalitarianism, which the sources equate with Khārijism. Whatever its connection with the Khārijism of the east, this feeling became a strong current in Berber North Africa down to the 10th century and has left traces today in the shape of the Ibāḍite Khārijite communities of southern Algeria, Jarbah, and Tripolitania. Muslim Spain, or al-Andalus, was in these years ruled by a succession of Arab governors. In 741 a fresh wave of Syrian troops arrived to suppress Berber unrest, and it was the presence of large numbers of Umayyad clients that in 756 enabled the fugitive Umayyad prince ʿAbd ar-Raḥmān I, grandson of Hishām, to achieve power in Spain and set up a revived Umayyad kingdom in rivalry to the ʿAbbāsids.

The last Umayyads. After the passing of Hishām's strong hand, the Umayyad Caliphate began to show signs of disintegration. In the years 743 and 744 there were three ephemeral caliphs. The principle of the caliph being of pure, free Arab stock was breached by the accession in 744 of Yazīd III, a son of al-Walīd I by a Persian slave mother. The financial crisis apparently deepened at this time. On accession, Yazīd III promised to reduce government expenditure; not to spend money on palaces and irrigation works; not to divert funds from the provinces, where they were to be spent on local defense and development; and not to drive the non-Muslims to desperation by overharsh taxation. Such a program, if put into execution, might have stayed the tide of discontent, but Yazīd died after a six-month reign, amid such chaos and civil strife as would have "turned a baby's hair white," as one chronicler puts it.

Disintegration of the Umayyad Caliphate

The last Umayyad caliph, Marwān II (744–750), a grandson of Marwān I, was a resolute commander, nicknamed "the Wild Ass" from that animal's proverbial hardiness, but he faced appalling difficulties. The mainstay of his power was that of the Qaysites of al-Jazīrah, and it was to Ḥarrān in that region that Marwān transferred his capital and administration, the better to watch the storm centre of Iraq. At this time the Khārijites controlled much of Iraq, while in Arabia the Khārijite leader Abū Hamza at one point occupied Medina. Khorāsān had since 739 been governed by the capable Naṣr ibn Sayyār, who restored Arab authority in Transoxania. Yet the internecine tribal feuds of the Arabs continued in Khorāsān, and, because of the region's remoteness from Syria, Naṣr had difficulties in getting reinforcements sent out. When Abū Muslim's revolution started in Merv, Naṣr addressed a last despairing appeal to Marwān (747), but the Caliph was at that point involved with a rising in Syria itself.

The ʿAbbāsid revolt. The movement that toppled the Umayyads was that of the ʿAbbāsid *daʿwah*, or underground propaganda campaign. Al-ʿAbbās had been the Prophet's uncle, but the family had played no significant role in politics during the earlier Umayyad period. From *c.* 718 onward, however, the ʿAbbāsids, from their centre at Ḥumaymah, in southern Jordan, organized a network of secret agents in al-Kūfah and thence in the Merv oasis of Khorāsān, which, unlike Iraq, was remote from Umayyad surveillance. It seems that the ʿAbbāsid head, Muḥammad ibn ʿAlī, secured the transfer to his line of the claim to the imamate of one of the various ʿAlid groups active in Iraq, that of Muḥammad ibn al-Ḥanafīyah and his son Abū Hāshim, and with this took over an extremist sectarian group, the Hāshimiyah (*i.e.*, partisans of Abū Hāshim). The whole movement was working for the overthrow of the Umayyads and the establishment of a caliph-*imām* who was unspecified but who would obviously be from the Hāshimite clan, comprising descendants of both al-ʿAbbās and ʿAlī.

During Hishām's caliphate, his governors successfully repressed overt activity by ʿAbbāsid agents, but propaganda intensified after 743, with the Umayyads' enforced neglect of Khorāsānian affairs, under the direction of two political organizers of genius—Abū Salamah of al-Kūfah and the Persian Abū Muslim al-Khorāsānī. Abū Muslim arrived at Merv in 746 and skillfully took advantage of the factions of the Arabs. Abū Muslim himself represented the extremist wing of the Hāshimīyah, and he appealed to messianic hopes current among both the Shīʿites and the Persian *mawālī*, resentful of Arab social dominance, hopes symbolized perhaps by the adoption of black flags as the emblems of revolution. Nevertheless, it seems that his main support came originally from assimilated Arab settlers in the Merv oasis who had lost many of the financial privileges of the Arab warriors and had come under the control of the Persian landowning class, the *dehqāns*; traditions of Persian support for the movement appear only later. The moderate Shīʿite groups had erupted in Iraq in 744 under the ʿAlid ʿAbd Allāh ibn Muʿāwiyah, but, when this claimant fled to Khorāsān, Abū Muslim had him executed and thus eliminated a possible rival.

Open revolt by the ʿAbbāsids

In 747 came open revolt. Merv fell, and ʿAbbāsid forces drove Naṣr ibn Sayyār into western Persia, where he died. In 749 ʿAbbāsid troops entered al-Kūfah, where Abū Salamah became provisional head of the political movement. Abū Salamah invited various members of the house of ʿAlī to become commander of the faithful (*i.e.*, caliph) with secular authority only, but this limitation of power was unacceptable to them, for they wanted the imamate, religious primacy, as well as the caliphate. Hence, in a *fait accompli*, the agents in al-Kūfah of the Khorāsānian wing of the revolution under Abū Muslim proclaimed the ʿAbbāsid Abū al-ʿAbbās as-Saffāḥ as caliph (749). Thus it was the ʿAbbāsid family and not the ʿAlids who gained the fruits of revolution. The latter realized that they had been cheated, and the familiar pattern of ʿAlid risings resumed under the early ʿAbbāsids. Marwān II's forces rallied in al-Jazīrah but were defeated at the Battle of the Great Zāb near Mosul in 750. Marwān himself fled to Egypt, where he was killed, and the majority of the Umayyad family were massacred in Syria by the ʿAbbāsids.

Thus ended the Umayyads and the purely Arab ascendency in the empire. Except for their later years, the Umayyads had not lacked capable and far-sighted rulers. Yet the evolution of the Islāmic community, with the growth of the religious institution and the yearning for a return to the virtues of primitive Islām, real or imaginary, and the demands of the growing numbers of non-Arab converts for an equal share in power and status, had worked against them. It was the achievement of the ʿAbbāsids to gather up diverse strands of discontent, and the resulting momentum of opposition overwhelmed the Umayyads.

GOVERNMENT AND SOCIETY, 632–750

Administration of the Arab lands. The Arabs in the conquered lands formed a military aristocracy, a thinly spread minority over the subject population. Accordingly, there could be no question of their taking over direct administration of the territories, except that Qurayshites and other Arabs with a comparatively sophisticated urban background filled provincial governorships, with ultimate responsibility for the collection of taxes. Day-to-day administration remained in the hands of the existing officials—Greek, Coptic, Persian, and Nabataean—so that the economic prosperity of the conquered lands was substantially preserved. In the decades after 632, the bellicosity of the Bedouins, to whom the concept of settled government and, above all, the payment of taxes were anathema and who would have turned the rich lands of the Fertile Crescent into pasture for their herds if left unchecked, was diverted against the unbelievers in the "land of war." The Qur'ān laid down that Muḥammad (hence, after his death, the state) was entitled to one-fifth of all captured booty; this provision was in fact merely the modified continuation of pre-Islāmic practice. The state utilized its fifth to fill the public treasury and to finance the increasingly complex work of administration; it also took over the old Byzantine and Sāsānid state domains and those lands vacated by the flight of their owners. The Arab warriors' share was physically divided out, for example, in the case of movables and captives (the *ghanīmah*), but this was clearly not feasible in the case of landed property. The state therefore drew the rents from this property (the *fay'*), compensating the warriors by a system of pensions listed in a register, or *dīwān*, beginning with the Prophet's widows and family, the earliest Muslims, and so on down to the ordinary warriors (see above). The *dīwān* was ʿUmar's invention, and he further showed his administrative wisdom by appointing, in certain provinces, governors with experience of civil affairs instead of pure soldiers. He also founded the two great garrison cities of Iraq, Basra and al-Kūfah, into which Bedouins poured from the desert and were then diverted to the northern and eastern fronts. Within the Arab warrior class, the tribe remained the basic organization now and throughout the Umayyad period, with the tribal chiefs leading their contingents into battle.

ʿUmar's achievements

The system was nationalistically Arab and, in effect, one of military exploitation. This did not necessarily mean that the non-Arabs were worse off than under their old masters; indeed, ʿUmar's interposition of the state between the masses and the Arab warriors over the *fay'* probably protected them to some extent. Nor did the state encourage wholesale conversions to Islām. The only way for non-Muslims to secure admittance to the Muslim *ummah* was by conversion and enrollment as clients (*mawālī;* singular, *mawlā*) of Arab tribes, a lowly status. This process presented few problems in the early years, when clients might find a place on the *dīwān*, or pensions list. But in the Umayyad period the rate of conversions accelerated, while the state's revenue from taxes on the non-Muslims decreased.

Treatment of non-Muslim peoples

The point here was that Islāmic law, based here on the Qur'ān, allowed the "people of the Book" (*i.e.*, those possessing written scriptures, essentially comprising the Jews and Christians, though peoples such as the Zoroastrians and Hindus later claimed this status) to retain their faith and accept a subordinate role in society provided that they paid the *jizyah*, or poll tax, supposedly in lieu of the military service to which all free Arabs were liable. When these "protected peoples," or *dhimmīs*, became Muslim, they naturally expected to become free of the poll tax and to be liable only for the property tax, or *kharāj* (the technical terminology of these taxes is actually vague and shifting in this early period), that Muslims paid on lands acquired by them. The Umayyad caliphs had to resist this process, at its most acute in Iraq, al-Jazīrah, and Egypt. A further aspect was that peasants abandoned their lands, where they had often been liable for corvées, or forced labour, for the shelter of the towns, leaving the remaining, reduced rural population to find the same global amount of tax. The governor of Iraq and Persia, al-Ḥajjāj (see above), therefore adopted a policy of sending back runaways to their villages. There was a counterfeeling among religious circles that conversion to Islām ought not to be discouraged, but it was only ʿUmar II, imbued with a sense of both his governmental and religious responsibilities, who tried to resolve the dilemma by his fiscal reforms. Nevertheless, although he reversed the policy of compulsory resettlement of runaways for a time, the old policies were revived by his successor, and there was still no clear ruling that conversion to Islām meant exemption from the *jizyah*. The grievances of the converts therefore continued to contribute to anti-Umayyad feeling, especially as many converts and their descendants were becoming as learned in the faith as the original Arabs and were entering the ranks of the influential religious scholars and canon lawyers. A typical figure here is Ḥasan al-Baṣrī (died 728), of Persian *mawlā* stock, famed for his sermons and moralistic sayings.

Growth of responsibilities of the caliph

The Umayyad caliphs at first ruled like desert tribal chiefs, *sayyids*. Muʿāwiyah allowed free access to himself for the weak and oppressed and acted as a conciliator and arbiter of disputes; indeed, he owed his position to his role of avenger of ʿUthmān in accordance with pre-Islāmic obligations of blood revenge. But the ruler was bound to have new responsibilities as caliph and commander of the faithful. The trend gradually began whereby the caliph withdrew himself from unfettered public access, protected by his chamberlain. Court ceremonial developed, though to nothing like the degree it was to attain under the ʿAbbāsids, who were to become despots enthroned far above the masses. On the other hand, the office of vizier, the caliph's chief executive minister, did not develop until ʿAbbāsid times. The complexity of government required to control the far-flung empire, to finance external war, and to curb internal sectarian or factional violence, all compelled the Umayyads into centralizing policies that exalted the position of their own family, the only reliable force in the state for continuity and stability. Both ʿAbd al-Malik and Hishām showed an interest in Persian administrative procedures, and the caliphate of the latter, in particular, saw a trend toward Persianizing ways that anticipated the Orientalization of the empire under the ʿAbbāsids. Muʿāwiyah is credited

with the establishment of a chancery for correspondence, the "department of the seal," and ʿAbd al-Malik with that of a government postal and intelligence service, the *barīd*, clearly a development from a similar Byzantine and Persian institution. The need for stability after the first civil war (656–661) explains the Sufyānids' care to regulate the succession. As one historian says, "fearing to leave the community of Muḥammad like sheep without a shepherd," Muʿāwiyah vested the succession in his son Yazīd (see above). Thereafter, one finds the Umayyads vacillating between the principles of the seniorate, succession among the capable elder members of the family, and straight father–son succession, the latter becoming more normal under the ʿAbbāsids.

All these tendencies contributed to the accusation that the Umayyads were mere kings, *malik*s, and not true caliphs; but in reality the Umayyads were by no means unaffected by the general penetration of society by the Islāmic religious ethos. They considered their rule as God-given, and they presided at the Friday mosque worship and delivered the sermon there. ʿUmar II's famed piety was not an isolated phenomenon, for both he and ʿAbd al-Malik consulted Ḥasan al-Baṣrī for spiritual advice. Hishām gave the education of his son to the traditionist az-Zuhrī. Hishām himself inclined to the determinist current of thought in Islām and executed a member of the opposing sect of Qadarites, the partisans of free will.

The two processes of Islāmization and Arabization continued throughout the Umayyad period, the latter more slowly than the former. Conversions to Islām grew once the social and financial advantages of this became apparent. But many peoples retained their ancestral faith. The Christians, Jews, and Zoroastrians were necessary to the caliphs as officials, tax collectors, physicians, and technicians. Zoroastrians persisted in the more mountainous and remote parts of Persia, such as Fars, Azerbaijan, and the Caspian region. The Copts in Egypt and especially the Hispano-Romans in Spain were tenacious of their faith. In these areas, as well as in Syria and Palestine, the Muslims in this period undoubtedly remained a minority. Since Syria was the seat of the Umayyads' power, the caliphs were conciliatory toward the large Christian population there. ʿUthmān's wife Nāʾilah had been a Christian, as was Muʿāwiyah's wife Maysūn, mother of Yazīd I. Under Muʿāwiyah the Damascus Melkite Christian family of Sarjūn (Sergius) filled some of the highest financial offices in the land; one of this family, St. John of Damascus (died 748), was originally a financial official and, in his unregenerate days, a drinking companion of Yazīd I. Certain Arab tribes in Syria and al-Jazīrah, such as the Banū Taghlib, had become Christian in pre-Islāmic times, and some retained their faith until early ʿAbbāsid times, even producing martyrs from among their number. Iraq, in particular, was a melting pot of races and faiths, with relics of ancient beliefs such as Gnosticism and Manichaeism surviving among the generally Christian and Muslim population; it is not surprising that it was so turbulent a region in the early centuries of Islām.

Arabization was slower, though ʿUmar I had shown the way by his expulsion to Iraq of the Christians of Najrān in Yemen, in defiance of the agreement they had made with the Prophet. Toward the end of the 7th century a tendency toward Arabization in the administration is visible, connected with ʿAbd al-Malik's renewed warfare with the Byzantines. The story of the Arabization of the coinage is traditionally linked with a series of Byzantine and Muslim threats and counterthreats over the official headings guaranteeing the authenticity of papyrus exported from Egypt to Byzantium, which had Christian inscriptions, and over the coinage, which the Arabs had in the past continued to mint on the pattern of the Greek gold solidus. Around 697–699 a change was made to the so-called Reform coinage, which still followed Byzantine gold and Sāsānid silver patterns but with the divine name and Qurʾānic inscriptions on it (in fact, Muʿāwiyah seems to have made an abortive attempt to introduce such a coinage nearly 40 years before). ʿAbd al-Malik also changed the language of the government offices and registers from Greek and Persian to Arabic, though the Coptic, Greek, and Persian officials remained unchanged; these adopted Arabic and came to excel the Arabs themselves in knowledge of the language and its literature.

Social classes

The main elements of social classes in Umayyad times have already been delineated: the rentier class of Arab warriors; the converts, increasingly clamorous for a greater say in affairs; and the numerically still important body of *dhimmī*s, or "people of the Book," useful to the Arabs as a reservoir of taxable wealth and as a professional class. In the 8th century the Bedouins were no longer the backbone of the Umayyads' troops, for there was a trend toward professionalism there, supplementing the caliphs' Syrian troops. This process is especially associated with Marwān ibn Muḥammad, the future caliph, during Hishām's reign, and it is said that he introduced the battle tactic of compact bodies of troops instead of the old unbroken line. It is difficult to discern as yet a clearly defined urban bourgeoisie and merchant class, but the bases for this class, prosperous and influential in ʿAbbāsid society, must have been laid. Many of the early conquerors benefited from the opportunities for slave dealing, and the demand for domestic slaves continued to be brisk throughout the empire. But it is also probable that external trade with East Africa, India, and the Far East was already providing a livelihood for the merchants of places such as Basra and its port, Ubulla, for very mixed populations, including colonies of Indians and Malays, were to be found at the head of the Persian Gulf by early ʿAbbāsid times.

Cultural life under the Umayyads. One aspect of the Arabization of the empire was the spread of the Arabic language, though this made only slow progress in the first century or so of Islām. Adoption of Arabic was easiest in regions such as Syria, Palestine, and Iraq, where the indigenous populations spoke Syriac, a Semitic language akin to Arabic. Coptic in Egypt was more resistant and Spanish in al-Andalus even more so. In North Africa, Berber was a nonliterary language; hence, the Berbers quickly adopted Arabic as the language of culture and religion, while retaining Berber as a spoken tongue. Pahlavi, or Middle Persian, went underground, as it were, during this period, as a language of culture, only reappearing two or three centuries later in its New Persian form. In all parts of the empire, Arabic acquired an unassailable prestige as the language of the victors and of the Qurʾān, even where local populations retained their vernaculars, and Arabic culture often became as attractive to non-Muslims as to Muslims. The bursting forth of the Arabs from their peninsula and their mingling with non-Arabic speakers started immediately the transition from the earliest, classical stage of Arabic, that of the desert, to a somewhat simpler, more flexible, spoken version of the tongue, which probably served as a lingua franca in the socially and ethnically mixed garrison cities (the beginnings of that stage of the language known as Middle Arabic). Nevertheless, the classical tongue, in all its richness of vocabulary and expression, remained for centuries the normal vehicle of literary expression, buttressed by the fact that God's own word, the Qurʾān, had been revealed in it.

Spread of Arabic

The period of the initial conquests, that of the Patriarchal Caliphs, was unfavourable to artistic and cultural expression of any kind; the overpowering example of the Qurʾān seems to have inhibited literary production, but, above all, Arab energies were being expended on carving out an empire, though it is strange that no epic emerged on this eminently suitable subject. The culture of the pre-Islāmic Arabs had been pre-eminently a literary one (as might be expected from a largely nomadic race, for whom cultivation of the visual and plastic arts was difficult), centred on their fluent and expressive poetry, of which a fair amount has come down to the present via later generations of Muslim scholars. Under the Umayyads, literature retained this primacy, above all, poetry, although prose tales of the tribal battles of the old Arabs and scraps of Hellenistic and Persian romances from the common Near Eastern heritage also circulated. The civil

wars of 656 onward and the growth of sectarian religious strife and political faction, all contributed to the rebirth of poetry, which became the favoured mode of expression for these divergent views. The Khārijites were famed for their poets and orators, such as ʿImrān ibn Ḥiṭṭān (died 703); some poets had Shīʿite sympathies, such as Kuthayyir (died *c.* 723) and al-Kumayt (died after 743) and were moved to eloquence by the martyrdoms and tribulations of the ʿAlids. Political motivation is equally apparent in the work of the three greatest poets of the Umayyad period: al-Akhṭal (died toward 710), Jarīr (died *c.* 729), and al-Farazdaq (died *c.* 728 or 730). These poets were active at the courts of the caliphs and their governors and served as mouthpieces and defenders of the regime. Al-Akhṭal was a Christian and a strenuous defender of the policies of Muʿāwiyah, Yazīd, and ʿAbd al-Malik; because al-Akhṭal's faith put him outside the sectarian conflicts of the Muslim community, Yazīd could, for instance, use him to satirize the *anṣār* of Medina. Jarīr and al-Farazdaq were enemies, though both from the same tribe, and their satires against each other provide brilliant examples of this genre. Indeed, the ethos of these poets was still basically that of the *jāhilīyah*, or pre-Islāmic, period, only partly tinged with Islāmic influences in that they emphasized in their poems praising the Umayyad caliphs the religious nature of their rule as successors to the Prophet.

Rebirth of poetry

Arabia itself became a backwater during the Umayyad period, and Bedouin poets lament the desertedness of once-populous encampments, now that the most vital elements had migrated northward. But the former capital, Medina, in spite of its subordinate political importance, became, on the one hand, a centre for luxury and dissolute living and, on the other, the headquarters of the pietistic party and especially of the scholars of law and tradition (Ḥadīth). It was in Medina that a new school of romantic love poetry, revolving round ʿUmar ibn Abī Rabīʿah (died 712 or 721), arose, and Medina and Damascus were the homes of singing and dancing, where slave girls were trained in these accomplishments. The encouragement of the caliphs was as notable here as in regard to poetry. Yazīd I and al-Walīd II were good poets, and most of the caliphs had their courts thronged with singers and musicians as well as poets, for singers, too, could have a propagandist role, spreading verses and messages favourable to the Umayyad cause.

Islāmic religion was little formalized and institutionalized in the Umayyad period, this being a process that came to fruition in the succeeding ʿAbbāsid period. Under the Umayyads did occur, however, the development of sectarianism, the legacy of the first civil wars, as has been shown above in the delineation of political events. During this period of personal uncertainty and separation from the tribal past, the Shīʿites came to look for an inspired charismatic leader from the house of ʿAlī. The Khārijites, however, saw salvation only within the holy community of Khārijite believers and cut themselves off, physically and intellectually, from the main body of Muslims; they evolved into a politically radical, socially egalitarian sect, emphasizing the brotherhood of all Khārijite faithful, whether from the noblest Arab tribe or a Negro slave. Between these extremes, the mainstream community of orthodox, or Sunnite, Islām contained within itself currents of opinion rather than distinct sects—such informal groups as the Qadarites, or partisans of free will, and the Murji'ites, those who postponed judgment on the status in the next life of those guilty of great sins.

Rise of sectarianism

A body of Qur'ān readers, the *qurrā'*, arose soon after Muḥammad's death to spread knowledge of the sacred book. There was therefore an acute need for a definitive text of the Qur'ān. This was produced between 650 and 656 for the caliph ʿUthmān by a group of experts under Zayd ibn Thābit and variant texts that had circulated in the provinces were destroyed. There now began the intensive study and interpretation of the Qur'ān text, including such questions as the investigation of the occasion for specific revelations, once the generation of the Prophet's Companions, with their firsthand memories, had died out. The science of Ḥadīth, the collection of traditions from the Prophet and early Muslims, on which much of Islāmic law came to be based, was still in its formative stage, but to the Umayyad period belong such important collectors of traditions as ʿUrwah ibn az-Zubayr (died 712 or 717) and az-Zuhrī (died *c.* 741). Nevertheless, Islāmic religion as an institution and as the motivating force behind individual lives of piety did begin slowly to permeate society, despite the strength of pre-Islāmic attitudes; hence, the change to the ostentatious religiosity of the ʿAbbāsids was by no means as abrupt as some of the later historians indicated.

The establishment of the Arabs in the conquered lands made them heirs of the settled civilizations of the Fertile Crescent and Persia. They now had an opportunity to cultivate the arts of peace and enjoy the comforts of sedentary life. At first, everything was strange, and the historians tell amusing stories of the Bedouins' behaviour when first they entered the Persian capital of Ctesiphon in 637; they mistook camphor for salt, thought that the familiar silver was more precious than the unfamiliar gold, and cut up among themselves a jewel-encrusted carpet. After a generation or so, however, such aspects of settled life as permanent settlements and residences appear. The first buildings of the Arabs in Iraq and Egypt were quite primitive, utilizing only such materials as palm trunks and sun-dried brick; it was Ziyād who first built mosques in Basra (665) and al-Kūfah (670) worthy of the name, probably with the help of Persian craftsmen. Conditions, however, were more advantageous in Syria and Jordan, where there remained fine buildings from the Hellenistic and Roman periods and where there was an abundance of building stone. It is not, therefore, surprising that the oldest surviving monument of Islāmic architecture is ʿAbd al-Malik's Dome of the Rock in Jerusalem (completed in 691); this was followed in al-Walīd I's reign by the Umayyad Mosque of Damascus, on a site that had gone through the successive stages of accommodating a pagan temple, a Christian church, and then a church and mosque side by side.

Architecture

The Umayyad caliphs were, indeed, enthusiastic builders and developers of large estates in the Syro-Jordanian region. The remains of their fortified palaces and settlements are dotted all over there, some in fertile, naturally well-watered districts (*e.g.*, Khirbat al-Mafjar, near Jericho; Khirbat al-Minyah, near Tiberias in Palestine; and ʿAnjar, in the Biqāʿ Valley, between the Lebanon and Anti-Lebanon mountains) but the majority on the desert fringes, where complex irrigation systems were necessary (*e.g.*, the two Qaṣr al-Ḥayrs, in south central Syria; Mshattā and Qaṣr ʿAmrah, in Transjordan). Nevertheless, this last group did not comprise exclusively desert hunting palaces, as was once believed, though some of them had extensive enclosures for game (*ḥayrs*); for one thing, they were not in the deep desert and, for another, they clearly formed the centre of rich agricultural estates, producing such things as olives and vines, and with a continuity of occupation and agricultural exploitation from Roman and Greek times. Indeed, the Umayyads were probably continuing some of the traditions of the pre-Islāmic Arab kings of Ghassān in this same area. Many of these palaces can be associated fairly certainly with specific caliphs, such as al-Walīd I with Minyah and al-Walīd II with Qaṣr aṭ-Ṭūbah in eastern Transjordan and the unfinished Mshattā. Above all, Hishām was a great builder, preferring to live outside Damascus, where plague was endemic. Associated with him are al-Mafjar and the two Qaṣr al-Ḥayrs; the eastern one of these last is probably to be identified with Hishām's capital of Ruṣāfah. The massive, fortified architectural style of these buildings is impressive, and the decorations are often splendid, if not quite comparable to the unique glass mosaics of the Umayyad Mosque. Mafjar includes a remarkable floor mosaic, while the bath at Qaṣr ʿAmrah is outstanding for its mural paintings, depicting hunting scenes, the signs of the zodiac, and, above all, the figures of the enemies of Islām, including the Byzantine and Persian emperors, the Negus of Abyssinia, and the Visigothic king Roderick—a striking demonstration of the fact that in earliest Islām there was no religious bar

to representing the human form, as arose later. Yet, despite the Umayyads' special attachment to Syria, the provinces of Egypt, the Hejaz, al-Jazīrah, and Iraq were by no means neglected by their governors. The efforts to improve irrigation and agriculture by governors such as Ziyād and al-Ḥajjāj have been noted, and Maslamah ibn ʿAbd al-Malik and Hishām undertook extensive works in al-Jazīrah, adjacent to Hishām's own palace of Ruṣāfah, and in Iraq.

II. The ʿAbbāsid Empire

THE ʿABBASID CALIPHATE 750–945

The establishment of the new dynasty, 750–786. The movement in the eastern provinces of the caliphate that swept the ʿAbbāsids to power is often characterized as a revolution, more exactly in the Arabic terminology of the time, "a turn of fortune, a change in the ruling authority." It is indeed true that after 750 there is discernible a new climate of thought and opinion in the Islāmic empire. The Umayyads had in many ways continued the patriarchal traditions of the "orthodox," or "rightly-guided," caliphs who had immediately succeeded the Prophet; their outlook had remained that of Arab tribal leaders presiding over an Arab military aristocracy geared to the financial and social exploitation of the empire's subject populations. Geographically, the Umayyad caliphate had been oriented toward the Mediterranean, with Byzantium as its supreme enemy. The ʿAbbāsids moved the capital of the empire from Syria to Iraq, because their victory had been essentially that of the Arab tribesmen settled in the east and of the non-Arab clients (*mawālī*), Nabataean and Persian, in Iraq and Persia. Their empire was in some ways a reconstitution of the pre-Islāmic Persian empires that had united the plains of Iraq with the plateaus and mountains of Iran, so that one recent authority has called the Umayyad caliphate "neo-Byzantine" and the ʿAbbāsid one "neo-Sāsānid." The political and military power of the old Arab ruling class was now inevitably reduced; from the caliphate of al-Muʿtaṣim, the old feudal forces of Arab cavalrymen were no longer kept up but replaced by slave troops and mercenaries, prominent among whom were the Turks. The Arabs, however, retained their unassailable social and cultural prestige as the people who had given birth to the Prophet and as speakers of the language in which the Qur'ān, God's own word, had been revealed to men.

ʿAbbāsid shift to the east

There was a further difference in the general ethos of the caliphate and the caliphs' life style after 750. Their actual behaviour did not differ all that much. Yet they and their propagandists adroitly projected a new and changed image of the Commanders of the Faithful as being not only caliphs, secular heads of the Muslim community, but also *imām*s, religiously buttressed figures who were responsible for guiding aright their subjects and ensuring their souls' salvation. The old idea of the Muslim community electing the caliphs still had some validity in men's minds, but in practice the ʿAbbāsids derived their authority from their self-perpetuating momentum and from the concept of responsibility for power to God alone, since Islāmic law was never able to define, much less enforce, explicit limits to the caliph's power.

Religious aura of the caliphs

To bolster the idea that they were the shadows of God on earth, the power of the ʿAbbāsids was given a religious aura. The caliphs frequented the company of the scholars, or *ʿulamāʾ*, and the men of religion and were deferential to them. Even so, these religious leaders rarely had the moral prestige, let alone the practical power, to oppose the caliphs, and on the rare occasions when they did, the caliphs could usually quietly ignore them. One manifestation of the ʿAbbāsids' new religiosity was the innovation of throne names expressing reliance on God or the assurance of his support, such as al-Manṣūr, al-Muntaṣir ("He who is made victorious by God"), al-Mutawakkil ("He who depends on God"), and al-Mustaʿīn ("He who seeks help from God"). This role of the ʿAbbāsids as theocratic rulers seems today a somewhat hypocritical pose. Undoubtedly, there was some disillusionment among people at the time, who grumbled that the "justice" of the ʿAbbāsids was worse than the "tyranny" of the Umayyads; but one should not imagine that contemporaries as a whole saw here elements of conscious dissimulation. Official publicists and scholars dependent on the regime proclaimed in the early ʿAbbāsid period that a new era of justice and piety had dawned, and this undoubtedly secured general assent. The way of life and the social customs of the ʿAbbāsid court reflected the increased influence of the easterners, Persian and Iraqi soldiers and officials. There was, moreover, a hierarchy of courtiers and ministers, with an elaborate ceremonial, and with the caliph screened from the gaze of the vulgar and only approachable in audience through his chamberlain. The caliph's favour or disapproval could make or break a man instantly; hence there was a gradual evolution of the caliph into something resembling the capricious oriental despot familiar from the pages of *The Arabian Nights*.

As-Saffāḥ, 749–754. When Abū al-ʿAbbās as-Saffāḥ ("the lavisher"; whether of largesse or of blood is uncertain) was hailed as caliph in Kūfah at the end of 749, he owed his throne to a political conspiracy and a military rising that had embraced many diverse expectations and hopes, but that had been made in the deliberately vague name of "one who shall be chosen from the House of the Prophet." These different elements of support nevertheless agreed generally upon a belief in the claims of Muḥammad's cousin and son-in-law ʿAlī and his offspring to the temporal caliphate and the imamate, or spiritual direction of the community. The supporters of the ʿAbbāsid revolution, however, had included both an extremist wing that attached itself to the ʿAbbāsid family, as being the ultimate spiritual heirs of one of ʿAlī's children by a slave wife, and also a more moderate wing that expected that the legitimate and direct descendants of ʿAlī would now assume the caliphal office. These last were the nucleus of the so-called Shīʿah, or "party" of ʿAlī. The skillful manoeuvres of the ʿAbbāsids and their partisans now meant that the expectations of these adherents of the claims of ʿAlī's direct progeny were bitterly dashed. The caliphate fell to the ʿAbbāsids, relatives of the Prophet through their ancestor al-ʿAbbās, Muḥammad's uncle, hence more distantly connected than the ʿAlids proper. The mood of frustration and anger engendered among the numerous ʿAlids and their followers was to persist for centuries to come; it was to cause periodic ʿAlid risings and martyrdoms of ʿAlid claimants. More important in the long run was that it brought about the crystallization of vague, emotional feelings for the ʿAlids into a distinct sect, the Shīʿah, with its own separate theology and body of law and hostile to the orthodox majority of Sunnīs (adherents of the *sunnah*, or example of the Prophet). The existence of these irreconciliable elements was to be a source of political and religious weakness in the ʿAbbāsid caliphate. Various caliphs were to abandon persecution for attempts at reconciliation or at least an understanding with the Shīʿah, but this deep-rooted division within the community of Islām has lasted down to modern times.

The ʿAlids

As-Saffāḥ speedily removed various of the men who had aided his rise to power but who might now come forward as rivals for power or focuses for discontent; thus in 750 his vizier (*wazīr*, "helper") Abū Salamah was murdered. Meanwhile, the surviving members of the Umayyad family were mercilessly hunted down and exterminated and the graves of almost all their past caliphs desecrated. Only one Umayyad of consequence escaped, Hishām's grandson ʿAbd ar-Raḥmān. He made his way through North Africa to Spain, where he was hailed as *amīr* by the Arab troops. He thereby became the first ruler of an Umayyad line in Spain, which was to rival the ʿAbbāsids in splendour and which was to endure till 1031.

Al-Manṣūr, 754–775. As-Saffāḥ's brother and successor, al-Manṣūr, had to consolidate the shaky authority of the new dynasty, for too many of the former participants in the ʿAbbāsid revolution had by now become alienated from the ʿAbbāsids. Thus the Persian Abū Muslim, the leader to victory in Khorāsān and a political organizer of genius, was killed by him in 755. ʿAlid revolts in Arabia

and Iraq began almost immediately, and extremist Shīʿites and former partisans of Abū Muslim, now inspired by messianic beliefs in his return from the dead, caused further trouble. Security considerations must have influenced al-Manṣūr in his decision to move from the region of turbulent Kūfah to a new capital on the west bank of the Tigris at the ancient settlement of Baghdad, which lay in a fertile and relatively healthy part of central Iraq and which was a centre for communications with both Syria and Persia. By 763 the caliph was able to take up residence in the "City of Peace," more specifically in the "Round City," a circular, walled, and fortified compound comprising a palace, a mosque, residences, barracks, and markets. This garrison compound was soon outgrown; flourishing commercial quarters grew up outside its walls, the right bank was settled, and a bridge of boats linked the two halves of the new capital of the Islāmic world. Until the rise of Cairo under the rival Fāṭimid caliphs of Egypt and Syria (969–1171), Baghdad retained a commercial, social, and cultural primacy among the cities of Islām.

Movement of the capital to Baghdad

Thanks to al-Manṣūr's policies, the stability and continuance of the ʿAbbāsid caliphate were assured. Within his own lifetime he had settled the succession on his son, the future caliph al-Mahdī, ensuring that the caliphate remained within the ʿAbbāsid family. There was never, however, any formal enunciation of the principle of primogeniture. Any suitable male adult member of the family might be designated as heir; hence, as had been the case among the later Umayyads, struggles for the succession within the ʿAbbāsid house were on occasion to lead to civil war and strife. Al-Manṣūr acquired a reputation for meanness, with the nickname of Father of Farthings, but the result of this carefulness was that he had a treasury of several million dinars to leave to his successor.

Al-Mahdī, 775–785. Al-Mahdī attempted a rapprochement with the moderate Shīʿah, but his attempts to win acceptance for the idea that the ʿAbbāsids' ancestor al-ʿAbbās had been specifically designated by Muḥammad as leader of the Muslim community after his death not surprisingly failed. Shīʿite unrest continued, and a rising in Transoxania (Central Asia) and eastern Persia under al-Muqannaʿ ("the Veiled One") combined extremist Shīʿite messianic ideas with older Iranian currents of thought and social protest at the domination of the Arab and Persian landowning class. After the brief reign of al-Mahdī's son al-Hādī (785–786), there succeeded to the caliphate another son, Hārūn, called ar-Rashīd ("the Rightly-Guided one").

The Shīʿite revolt

The ʿAbbāsids at their zenith, 786–861. *Hārūn, 786–809.* Hārūn's reign has gained a somewhat spurious glamour as the one in which the apogee of caliphal splendour and might was reached. In fact, the empire was racked by unrest and revolt in many regions, notably in Syria, where loyalty to the Umayyads' memory was still strong; in Egypt, where harsh financial measures led to periodic rebellions of the indigenous Christians, or Copts; in the Persian province of Daylam, to the south of the Caspian Sea, where ʿAlid claimants had taken refuge; and in eastern Persia, the provinces of Khorāsān and Seistan, where a radical, egalitarian Muslim sect, the Khārijites, took advantage of local grievances against caliphal tax collectors and mounted a revolt that lasted for over two decades. The remote North African province of Ifrīqīyah (modern Tunisia) was in 800 given to Ibrāhīm I ibn al-Aghlab to govern in return for annual tribute. Ibrāhīm subsequently obtained the right to nominate his son as governor after himself and in this fashion set up an autonomous line that endured for over a century (800–909). A precedent was thereby established for the falling away from caliphal allegiance of peripheral provinces, a process that began in earnest toward the end of the 9th century (the Muslim far west, which later became Morocco, had already become fully independent under a descendant of ʿAlī, who had escaped the various massacres of ʿAlids and had in 789 formed the Idrīsid principality, based on Fez). Where Hārūn did distinguish himself personally was in *jihād* (holy war) against Byzantium, leadership in *jihād* being considered in orthodox eyes as one of the key duties of the caliph. Hārūn clearly took this responsibility seriously; in his youth he had already led an expedition that had penetrated through Anatolia and reached the shores of the Bosporus (781–782). It was also in Hārūn's reign that certain obscure diplomatic exchanges took place between the caliph and the Frankish emperor Charlemagne, the latter apparently aiming at securing some privileges for the Latin clergy in Jerusalem; these events are documented, however, exclusively from the Christian side.

Closely associated with the early ʿAbbāsid caliphs were the fortunes of the Barmakid, or Barmecide, family of secretaries and ministers, a family of eastern Iranian Buddhist origin who had come to the fore in the times of as-Saffāḥ and al-Manṣūr and who typified the "new men" raised to high official positions by the ʿAbbāsids. Distrusting the old Arab aristocracy and the ambitious members of their own family, the caliphs preferred to bring up their servants from obscurity, some of these officials becoming officially designated as vizier or chief executive minister. The dominance of this secretarial class, largely Persian in origin and imbued with Persian conceptions of kingship and official procedure, contributed markedly to the orientalization of the caliphate, even though the Barmakids themselves fell from power in 803, when Hārūn decided to assert his personal authority. One aspect of the continued vitality of non-Islāmic beliefs in Iraq and the east is the prevalence among certain circles at this time of dualist beliefs, survivals of Manichaeism, and of messianic expectations combined with advanced social ideas, continuing the doctrines of the pre-Islāmic Persian heresiarch Mazdak; inquisitory tribunals had to be set up in Iraq to ferret out these dissidents, the *zindīqs*.

The Barmakid family

In two measures promulgated in 802, the so-called Meccan documents, Hārūn made arrangements for the future of the empire. Briefly, his son by a noble Arab wife of ʿAbbāsid lineage, the later caliph al-Amīn, was to have the caliphate and the western lands; while another son by a Persian slave mother, the later caliph al-Maʾmūn, was to govern the eastern half of the empire under his brother's general overlordship and be next in line for the succession. Hārūn died in 809, but his carefully laid plans soon went awry. Al-Amīn, although clearly the less capable of the two, determined to assert his direct authority over his half-brother and further decided to vest the succession in his own son and thus exclude al-Maʾmūn. Civil war resulted; Baghdad underwent a fearful siege by al-Maʾmūn's Persian army (812–813), and al-Amīn was deposed and murdered, so that al-Maʾmūn became caliph of a united empire.

Civil war over succession

Al-Maʾmūn, 813–833. If any caliphate deserves to rank as the golden age of Arab civilization, it is that of al-Maʾmūn. Personally brave, he led further expeditions against the Byzantines and coped with rebellions in Egypt, Syria, Armenia, and Khorāsān. Al-Maʾmūn's triumph over al-Amīn has often been viewed as a victory of the Iranian east against the Arab interests represented by the deposed caliph, and this is in large measure true; al-Maʾmūn brought with him Persian troops and ministers, and the Persianizing tendencies in administrative practice discernible in previous reigns were now intensified. Al-Maʾmūn also had a questing intellect; he took an interest in disputations between the adherents of various faiths; he built observatories and encouraged the study of astronomy and geometry; and he founded a "House of Wisdom" (Bayt al-Ḥikmah) in Baghdad devoted to the translation of scientific and philosophical works from the original Greek.

The Caliph seems further to have had in mind a great design, the vision of a united Islām, with the deep rift between the Sunnīs and the Shīʿah healed; in this way, the political unity of the caliphate would be assured and internal peace and prosperity favoured. His sympathies with the Muʿtazilite group of theologians, who were concerned with the defense of Islām by rational arguments against heresy and infidelity (see below), also led to an irenical approach to the Shīʿah, who shared certain attitudes with the Muʿtazilah. The middle portion of al-Maʾmūn's reign is accordingly marked by the adoption in

Attempts at religious unity

817 of the Shīʿite 8th *imām*, ʿAlī ar-Riḍā, as his heir. In the event, the *imām* himself died shortly afterwards, and the episode does not necessarily mean that the caliph planned permanently to divert the succession to the ʿAlids; he may have intended to enlarge the field of capable candidates, ʿAbbāsid and ʿAlid alike, who might then succeed according to personal merit. Attempts like this to win over the Shīʿah were to be followed by other caliphs of the 9th century (notably, al-Muntaṣir and al-Muʿtaḍid), but the breach between the two wings of Islāmic belief was unbridgeably wide. A predictable result of al-Maʾmūn's policies of favouring the Muʿtazilah and Shīʿah was a sharp reaction among the orthodox Sunnī *ʿulamāʾ* and lawyers, led by Aḥmad ibn Ḥanbal, founder of one of the more conservative law schools of Sunnī Islām (see below). He and others stood firm against the inquisitorial methods of the tribunal set up by al-Maʾmūn to compel agreement to certain theological ideas of the Muʿtazilah, even though these methods were continued with increased vigour under al-Maʾmūn's two successors.

Al-Muʿtaṣim, 833–842. The caliphate of another son of Hārūn ar-Rashīd, al-Muʿtaṣim, was notable for a renewal of the war with the Byzantines, culminating in a famous victory at Amorium (Ammūrīyah; 838), the last serious campaign into Anatolia undertaken by the Arabs; over the next two centuries, it was the Byzantines who were generally to assume the offensive. A 20-year-old rebellion by the heretic Bābak was also crushed in Armenia and Azerbaijan. But the significance of al-Muʿtaṣim's reign lies more in the general military and political trends of the time. The ʿAbbāsids still gloried in their Arab descent, but the percentage of Arab blood in their veins was by now decreasing rapidly. After Hārūn's time, the caliphs ceased to contract formal marriages with free wives, and all the caliphs from al-Maʾmūn onward were born of non-Arab slave mothers—Persian, Turkish, Armenian, Greek, etc. The caliphs soon became physically as well as intellectually removed from the masses of their Arab subjects in Iraq. Already in al-Maʾmūn's caliphate, the Khorāsānian troops were being supplemented by Turkish slave soldiers from Central Asia. Al-Muʿtaṣim turned this unsystematic practice into deliberate policy, purchasing large numbers of Turks, and even Berbers and Slavs, for his palace guard. The violence and unpopularity of these troops in Baghdad made the caliph determine in 836 to move to a new capital at Sāmarrāʾ, 60 miles north of Baghdad. He and subsequent caliphs laid out over several miles of the east bank of the Tigris a vast complex of palaces, barracks, and other buildings. Though only occupied for some 60 years, the ruins of these buildings remain impressive, attesting to advanced ideas of city planning, bold architectural techniques, and a high level of material culture and comfort.

Decline of Arab heritage in the caliphate

Al-Wāthiq, 842–847, and al-Mutawakkil, 847–861. The policies of al-Muʿtaṣim were continued by his son al-Wāthiq, and in particular the *miḥnah*, or tribunal for enforcing Muʿtazilite doctrines, was continued in full vigour. But there was a decisive change of attitude under the energetic al-Mutawakkil. He determined to take full personal charge of affairs, ruling for some time without a vizier, and endeavoured to reduce the influence in the state of the Turkish praetorian guards and the officials who were unscrupulously manipulating them. This entailed a conscious return to pro-Arab, orthodox Sunnī policies. The pro-Muʿtazilite measures of his predecessors were permanently reversed, as were the attempts at conciliating the Shīʿah. The orthodox *ʿulamāʾ* came to the fore, and discriminatory laws against the "People of the Book," primarily Jews and Christians, were revived, including the requirement of distinctive dress. The standard ʿAbbāsid execration of the defeated Umayyads was relaxed, and in 858 al-Mutawakkil temporarily moved his court to the old Umayyad capital of Damascus. But a conspiracy to murder him, successfully hatched by his son al-Muntaṣir, the next caliph, and the Turkish guards, removed these last hopes of reviving the caliphate and of turning its orientation back toward the Arab lands rather than toward the Persian ones.

Sunnī revival

Increasing difficulties and decline, 861–945. A period of anarchy followed al-Mutawakkil's death, with the Turkish generals making and unmaking caliphs, so that four of them, al-Muntaṣir, al-Mustaʿīn, al-Muʿtazz and al-Muhtadī, succeeded in rapid succession (861–870). Civil strife grew in Iraq, including a second siege of Baghdad by rivals for power. This paralysis and lack of continuity at the centre inevitably tempted governors and military leaders in the provinces to rule without reference to the caliphs. From 869 onward, southern Iraq was racked by a great rebellion of Negro agricultural slaves, the Zanj, who, under a leader claiming ʿAlid descent, held ʿAbbāsid armies at bay for some 14 years, seriously disrupting agriculture and commerce in lower Iraq and in the adjacent regions of Khuzistan, in southwestern Persia, and of eastern Arabia. Not long after the suppression in 883 of the Zanj revolt, much of the Syrian Desert and Arabian Peninsula fell under the control of the bitterly anti-ʿAbbāsid Qarmaṭians, a body of radical, egalitarian sectaries connected with the extremist Shīʿah; by 930

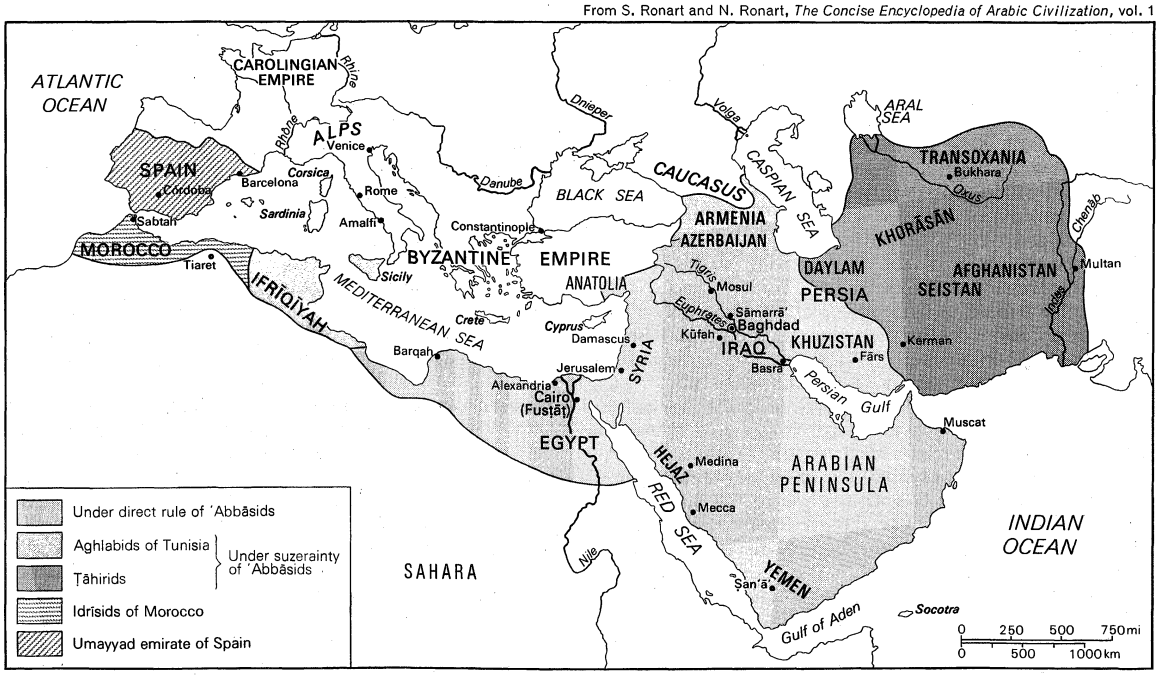
From S. Ronart and N. Ronart, *The Concise Encyclopedia of Arabic Civilization*, vol. 1



The ʿAbbāsid caliphate in the 9th century.

these Qarmaṭians were bold enough to raid the holy city of Mecca itself and carry off the Black Stone from the Kaʿbah.

Growth of provincial autonomy. The assumption of autonomous powers, if not full independence, by provincial governors was a growing trend of the later 9th century. The problem of holding together such disparate and scattered regions as those making up the Islāmic empire had long been a problem for the strongest monarchs. Control had usually been maintained through the awe and terror inspired by the caliphs themselves and the retributive power of the armies at their command, and through a communications network organized by local intelligence officers (the *barīd* system). As the century progressed, the coercive ability of the caliphs decreased, although they still retained their religious and moral aura as heads of the community of the faithful.

Arabized governors in Persia

In the eastern parts of Persia, a line of Arabized Persian governors, the Ṭāhirids, succeeded each other hereditarily (821–873), while other members of the family held important military and administrative posts in Iraq until the 10th century. In the remote province of Transoxania, the land beyond the Oxus (modern Soviet Central Asia), a local Iranian family, the Sāmānids, governed first as subordinates of the Ṭāhirids, but after 875 and the end of Ṭāhirid rule in Persia, they became directly responsible for Transoxania to the Baghdad caliphs; in the 10th century, they built up a prosperous and powerful amirate, in practice independent, in Transoxania and Khorāsān. Similarly, in Azerbaijan and Armenia, a short line of Arabized Persian governors, the Sājids, exercised power (879–930) in a region that had a long history of heretical and sectarian outbreaks and that presented special problems through the independent aspirations of the local Armenian princes.

A similar process is discernible in the Muslim west. It has been noted that an Umayyad survivor had assumed power in Muslim Spain as far back as 756. The amirate grew in strength under capable rulers until, in the 10th century, the *amīr* ʿAbd ar-Raḥmān III (912–961) actually declared himself caliph in rivalry to the enfeebled representative of the ʿAbbāsids in Baghdad. North Africa was hardly less remote from Iraq than Spain, and local dynasties such as the Idrīsids, Rustamids, and Aghlabids controlled it until the early 10th century and the rise of the Fāṭimids (see below); it was the Aghlabids who in 827 began the conquest of Sicily, turning it into a Muslim province for over two centuries. The lands immediately to the west of Iraq—*i.e.*, Syria, Palestine, and Egypt—were not immune from this process. In 868 the Turkish general Aḥmad ibn Ṭūlūn became governor in Egypt and, aided by the ʿAbbāsids' preoccupation with the Zanj rising, built up a large army and fleet there of his own; he governed so wisely that later Egyptian historians looked back on the period of the Ṭūlūnids (868–905) as a golden age. Not until 905, when less capable members of the Ṭūlūnid family had succeeded Aḥmad, was direct caliphal control reimposed in Egypt.

Yet such lines of governors as the Ṭāhirids and Ṭūlūnids should not be thought of as being rebels against the ʿAbbāsids or as being overtly hostile to them. On the contrary, they regarded themselves as faithful vassals, sending regular tribute to Iraq, giving the caliphs precedence on such occasions as the preaching of the formal Friday sermon, or *khuṭbah*, and maintaining the names of the caliphs on the coinage. A respectful autonomy, rather than independence, best describes their constitutional position. It was otherwise in regard to certain adventurers who achieved power in Persia. In the inaccessible Caspian provinces, ʿAlid claimants of the line of ʿAlī's grandson Zayd took refuge toward the end of the 8th century, and after 864 they established there the first of a series of local dynasties, the first independent Shīʿite state in the east; a second Zaydī Shīʿite state was set up in the Yemen in 901. The rule of the Ṭāhirid governors in eastern Persia was shattered in 873 by the meteoric rise of Yaʿqūb ebn Leyṣ, a soldier of fortune and a former coppersmith (*ṣaffār*, whence the name of the dynasty he founded). He and his brother ʿAmr assembled a vast, if transient, military empire in southern and eastern Persia and in what is now Afghanistan, based on their native province of Seistan. The plebeian Ṣaffārids hated the aristocratic ʿAbbāsids and did not disguise their contempt for them. Yaʿqūb planned to march on Baghdad, and in 876 his army came within 50 miles of this goal before being defeated. The Ṣaffārids were only reduced to the role of purely local princes in Seistan by the efforts of the pro-ʿAbbāsid Sāmānids of Transoxania (910).

Rise of the Ṣaffārids

The Baghdad caliphs, 861–945. The ʿAbbāsid caliphate in Baghdad survived the decade of chaos after al-Mutawakkil's death, but with impaired prestige and seriously diminished resources. The falling away of outlying provinces decreased the inflow of revenue from them, and the upkeep of a sumptuous court and a large but undisciplined army were drains on what money could be collected. During the nominal caliphate of al-Muʿtamid (870–892), effective power was exercised by his much more capable brother al-Muwaffaq (died 891), who mastered the Zanj rebels by 883 and repulsed the Ṣaffārids from Iraq, although he had to leave Aḥmad ibn Ṭūlūn in control of Egypt. Al-Muwaffaq's son al-Muʿtaḍid (892–902) and grandson al-Muktafī (902–908) were the last ʿAbbāsid caliphs to wield real power until the caliphal revival of the later 11th and 12th centuries. One Muslim author calls al-Muʿtaḍid "the closing point of the dynasty," and the reigns of both these capable caliphs were regrettably brief. Al-Muʿtaḍid aimed at securing internal peace through a program of religious conciliation, and he also had to stave off attacks from the Byzantines, now ruled by the vigorous dynasty of Macedonian emperors (867–1057); al-Muktafī in 905 regained control of Egypt.

Shīʿah terrorism

The twelfth and last "open" *imām* (*i.e.*, successor to ʿAlī) of the Shīʿites disappeared in mysterious circumstances in al-Muʿtamid's time. Certain strands of the extremist Shīʿah now began to adopt conspiratorial and revolutionary methods that made them greatly feared and were a further menace to the stability of the caliphate and to the fabric of Sunnī orthodoxy. Among these groups were the Qarmaṭians of Syria and Arabia, already mentioned, and the Fāṭimids in North Africa, who claimed descent from ʿAlī and his wife Fāṭimah and who drew support from the "Sevener," or Ismāʿīlī, Shīʿah group, the partisans of the seventh *imām*, Isṃāʿīl. Within the very caliphate itself, certain Shīʿite elements were at work, for in an effort to restore financial and administrative stability, al-Muʿtaḍid had recruited a group of Shīʿite secretaries and treasury officials; this group, notable among whom were the Furātī and Nawbakhtī families, were later to achieve particular prominence in the caliphate of the weakling al-Muqtadir.

The death of al-Muktafī opened a new period of crisis and instability for the caliphate, presaging the complete eclipse of its political authority in 945. Al-Muqtadir (908–932) lost his throne on two occasions because of conspiracies, and during his reign there were no less than 14 separate vizierates. It was the expertise of the viziers and their fellow officials, and not the efforts of the increasingly impotent caliphs, that kept the caliphate going in this period. The court became a centre of faction and intrigue, military conspiracies, and succession plots. Three of the caliphs of this period, al-Qāhir, al-Muttaqī, and al-Mustakfī, ended up deposed and blinded, a barbarous innovation that had, however, Byzantine precedents.

The caliph ar-Rāḍī (934–940) was hampered at all turns. Western Persia was in the hands of Daylamī military adventurers; northern Iraq and northern Syria, in those of an Arab family of Bedouin origin, the Ḥamdānids; Egypt and southern Syria, in those of a Turkish military governor, the Ikhshīdid Muḥammad ibn Tughj; and lower Iraq and Khuzistan, in those of local leaders. Surveying a bankrupt treasury, ar-Rāḍī was obliged in 936 to hand over supreme military and financial power to the Turkish governor of Basra, Muḥammad ibn Rāʾiq. The latter now assumed the title of "*amīr* of *amīr*s"; *i.e.*, supreme commander. This action was probably intended to demonstrate Muḥammad ibn Rāʾiq's primacy over other local military leaders, but at the same time it symbolized the

The "*amīr* of *amīr*s"

existence of a dual system, with the *amīr* exercising political and military power and leaving to the caliph only his moral authority as spiritual head of Sunnī Islām. A few years later, the Daylamī Aḥmad ebn Būyeh (Buwayh), later to receive the honorific title of Muʿizz ad-Dawlah from the caliph, entered Baghdad and himself assumed Muḥammad ibn Rāʾiq's old title of "*amīr* of *amīr*s" (945). Thus, effective control in the capital and in Iraq passed to a non-Arab, Shīʿite potentate, and for over a century the ʿAbbāsids were little more than puppets.

THE ECLIPSE OF THE ʿABBASIDS AND THE GROWTH OF PROVINCIAL DYNASTIES, 945–1258

The Būyids. The family of Muʿizz ad-Dawlah, that of the Būyids, or Buwayhids, was comprised of soldiers of fortune from the backward region of Daylam in northwestern Persia who took advantage of the disorders in the caliphate to set up a loose confederation of three amirates in southern and western Persia and Iraq. Their rise to power is only one aspect of a wider phenomenon in the eastern Islāmic world at this time, the appearance on the stage of Middle Eastern history of hitherto submerged Iranian peoples, notably the Daylamīs and the Kurds. Hence the period 900–1050 has been termed by the noted historian of Persia, Vladimir Minorsky, "the Daylamī interlude," a period in which Persia threw off rule by Arab or Arabized governors and was actually ruled by native Iranians, until the general triumph of Turkish generals and soldiers in the central and eastern lands of the caliphate again placed Persia under outside domination.

The "Daylamī interlude"

The installation of the Būyids in Baghdad in 945 presented the ʿAbbāsids with a potentially grave threat to their continued existence. The Būyids were rough tribesmen, not long converted to Islām and likely to be contemptuous of Arabic culture and the position of the ʿAbbāsids as heirs to much of this culture. Moreover, they had come to adopt the Shīʿite form of Islām, thanks to the earlier efforts of ʿAlid missionaries in the Caspian provinces. It was not improbable, therefore, that the Būyids might fulfill the dreams of generations of martyred ʿAlids and sweep away the ʿAbbāsid oppressors, regarded by convinced Shīʿites as usurpers of the rightful throne of the Shīʿite *imām*s. In fact, the Būyids were political realists. The Shīʿah were certainly favoured, and this is the period in which their distinctive theology and law, previously somewhat vague and unsystematic, began to take formal shape. But the Būyids made no move to abolish the ʿAbbāsid caliphate, for the latter, now deprived of independent political power and control over revenue, existed only as pensioners of the Būyids. Deposition of the ʿAbbāsids would have provoked a violent Sunnī reaction, and the Shīʿah, in any case, were a small minority compared with the Sunnīs.

Nor did ideological considerations affect the Būyids' external policy. Their main enemies in the west were both Shīʿite powers, the Ḥamdānids of Mosul and the Fāṭimids of Egypt and Syria—the latter, it is true, of the extremist Ismāʿīlī persuasion, whereas the Būyids adhered to the moderate Twelver variety of Shīʿism. Culturally, the attractions of Arabic civilization proved irresistible to the Būyids, and in their time Arabic literature and culture reached new heights; thus the great *amīr* ʿAḍud ad-Dawlah was the patron of al-Mutanabbī, commonly considered by the Arabs as their greatest poet. Hence the ʿAbbāsids continued to live modestly in Baghdad on the revenues that the Būyids allowed them and on the proceeds from the granting of honours and titles. They still retained their moral and spiritual prestige as heads of Sunnī Islām, and in this regard the Būyids had to tread circumspectly. One of the original triumvirate of the Būyid brothers, Rukn ad-Dawlah (ruler of the northern Persian amirate of Jibāl, 947–977), had employed on his coins the ancient Iranian title *shāhanshāh* ("emperor of emperors"), which to orthodox Muslim ears sounded blasphemous, as applicable to God alone. When the Būyid *amīr* of Iraq Jalāl ad-Dawlah (1025–44) wanted the title *shāhanshāh* to be included among all his other ones read out publicly by the official preachers in Baghdad, the populace was outraged at this presumption in the very capital of Islām. It was the caliph al-Qāʾim who quieted uneasy consciences over the title's legitimacy, thereby implicitly upholding the principle that it was the caliph who had the sole right to grant to secular rulers their titles and honours. Also, the Būyids used the prestige of the caliphate and the orthodox Sunnī *ʿulamāʾ* in their rivalry with the Fāṭimids, encouraging denunciations of the Fāṭimids' claim to genuine ʿAlid descent.

The Būyids reached their peak under ʿAḍud ad-Dawlah (949–983), who toward the end of his reign united under his sole rule all the Būyid lands in Persia and Iraq, conquering Kerman and even Oman in eastern Arabia, and pursuing an aggressive policy against the Ḥamdānids and the Daylamī Ziyārids of Ṭabaristān in the Caspian region. After his death there was much strife within the family, and the unitary rule hard won by ʿAḍud ad-Dawlah was lost, with separate Būyid lines emerging in Fārs and Khuzistan; in Kerman; in Jibāl, or northwestern Persia; and in Iraq. In the time of ʿAḍud ad-Dawlah, the ʿAbbāsids had been necessarily quiescent, and one of them, the caliph al-Ṭāʾiʿ (974–991), was deposed by ʿAḍud ad-Dawlah's son Bahāʾ ad-Dawlah (989–1012). But subsequent caliphs held office for unprecedentedly long periods, notably al-Qādir (991–1031) and al-Qāʾim (1031–75), indicative of the later Būyid relaxation of control over the ʿAbbāsids; Muslim historians praise these two caliphs both for their piety and for their gradual reassertion of the prerogatives of office.

Zenith of Būyid strength

The Sāmānids. Meanwhile, the northeastern fringes of the Islāmic world were ruled until 999 by the Sāmānid *amīr*s, faithful Sunnīs who were deferential to the ʿAbbāsids. Their provinces of Khorāsān and Transoxania enjoyed a remarkable material prosperity, and their court of Bukhara was a centre for Arabic scholarship and for the renascent New Persian language and literature alike. Much of this prosperity derived from the Sāmānids' control of the trade in Turkish slaves from the Central Asian steppes. Turks were highly prized for their fighting qualities and their hardiness, and by the 10th century it had become accepted dogma over much of the Islāmic world, outside of the extreme west, that mercenary troops and slave guards were more reliable supports for a ruler than feudal levies or tribal forces. With the aid of loyal troops, a ruler could place himself high above his subjects, centralize his power, and rule despotically. Turkish commanders and governors thereby acquired positions of high influence within the state, and these positions left them well placed for seizing full executive power. This largely explains how from the 11th century much of the Islāmic world was transformed by the installation of Turkish potentates and a Turkish military ruling class.

Use of Turkish troops

The founder of the powerful Ghaznavid empire, which dominated the eastern fringes of the Islāmic world in the first half of the 11th century, arose from the Turkish slave guard of the Sāmānids. The slave's son, the famous Sultan Maḥmūd of Ghazna (998–1030), assembled the most powerful military empire known in the East since the palmiest days of the Arab caliphate, with territories extending from northern Persia and Central Asia to the Ganges basin in India; one of Maḥmūd's great claims to fame as a Muslim hero was his role as "hammer" of the infidel Hindus. Almost all the Turkish dynasties that arose in the Islāmic world were strongly Sunnī; hence the Ghaznavids were hostile to a Shīʿite power like the Būyids on grounds both of political rivalry and religion. The sultans often spoke of mounting a great crusade in the west that would liberate the ʿAbbāsids from the tutelage of the Iraq Būyids and then go on to attack the Fāṭimids of Syria and Egypt; and Maḥmūd did succeed in overthrowing (1029) the Būyid amirate of Jibāl. The Ghaznavids assiduously cultivated links with the caliphs, sending rich presents from the Indian plunder and persecuting Muslim heretics, receiving in exchange the legitimation of their power as heirs of the Sāmānids and grandiloquent titles emphasising their support for and dependence on the ʿAbbāsids. In this way, the caliphal fiction that all secular rulers in the provinces derived their authority from an act of delegation by the caliph was preserved.

The rise of the Ghaznavid empire

Sunnī dynasties like the Ghaznavids, and shortly after them, the Seljuqs, maintained this deference to the caliphs as the ultimate legitimizers of temporal authority, even though the Seljuqs were to follow Būyid precedent in trying to exclude the ʿAbbāsids from exercising practical power. And, as noted earlier, the moderate Shīʿite Būyids found it expedient to leave the ʿAbbāsids as the focus of orthodox moral and spiritual aspirations rather than risk difficulties that would certainly have arisen had the caliphate been abolished or transferred to the ʿAlids.

The Fāṭimids. There arose in the 10th century, however, an impressive power in the west that not only opposed the ʿAbbāsids politically but also denied the religious and moral validity of their claim to the caliphate. It is uncertain whether the Fāṭimids really were of ʿAlid descent, connected in some still-unelucidated way with the seventh *imām*, Ismāʿīl; their Sunnī opponents generally denied the claim. At the beginning of the 10th century, Ismāʿīlī Shīʿite agents were spreading their propaganda in North Africa. With the support of Berber troops, the Fāṭimids speedily overthrew such local dynasties as the Aghlabids and Rustamids and reduced the Idrīsids to vassal status. A great new capital was built in 920 at al-Mahdīyah in Ifrīqīyah, and this was later to be the base for the Fāṭimids' eastward drive against Egypt.

Assumption of the title of caliph by the Fāṭimids

The Fāṭimids styled themselves caliphs of the true line of ʿAlī and openly stigmatized the ʿAbbāsids as usurpers who must be extirpated. They thus marked themselves off decisively from other dynasties that had acquired independence in practice but that continued to acknowledge the nominal suzerainty of the ʿAbbāsids.

In fact, the Fāṭimids were not the only ones in the Muslim west to assume the title of caliph at this time. The Spanish Umayyad ʿAbd ar-Raḥmān III adopted the designations of caliph and Commander of the Faithful in 928, partly as a counterblast to Fāṭimid pretensions, partly to show that the Spanish Umayyads were now strong enough to take up once more the caliphal dignity that had anciently belonged to their house. Soon after this, even the petty Midrārid ruler of Sijilmāssah, on the Saharan fringes of Morocco, styled himself caliph. The extreme Muslim west was so remote from Iraq that not even the fiction, let alone the reality, of a united caliphate could be maintained; later Muslim political theorists were compelled reluctantly to admit that there might be more than one caliph of the Faithful, provided that they were widely separated geographically.

The family of the Ikhshīdid Muḥammad ibn Ṭughj had continued to govern Egypt as vassals of the ʿAbbāsids, latterly under the skillful regency of the black eunuch Kāfūr, until in 969 they were swept away by the Fāṭimid invasion of Egypt. The Fāṭimid caliph al-Muʿizz was proclaimed there, and a new capital, that of New Cairo, was begun. It has already been noted that the Fāṭimids were more than unruly governors with independent aspirations. They were heads of a great religious movement, that of extremist Shīʿite Ismāʿīlism, whose agents were active in widely scattered regions of the Islāmic world and which was dedicated to the subversion of the ʿAbbāsid caliphate and its replacement by an Ismāʿīlī one. For over a century, the Fāṭimid caliphs pursued this aim vigorously, by secret propaganda and by force of arms. The organization of their army followed prevalent trends in that its personnel were multinational, with mercenaries and slave guards from several races. Palestine and southern Syria were occupied and the Syrian territories of the Ḥamdānids then taken over, so that the Fāṭimid frontier reached the southern boundary of the Byzantine Empire. Attempts were made to extend Fāṭimid rule into Iraq, and in 1059 a rebellious Turkish general for a while proclaimed the Fāṭimid caliph al-Mustanṣir (1036–94) in Baghdad itself. Ismāʿīlī missionaries worked in, among other places, Syria and Persia, where, toward the end of the 11th century, several inaccessible strongholds were seized and held against the ruling powers there. It was these Ismāʿīlīs who became known to the Frankish crusaders as the Assassins, or "hashish eaters," and who, by their policy of political assassination, spread a terror disproportionately greater than their actual numbers.

The Assassins

The Fāṭimid caliphate flourished culturally and economically, and the caliphs' commercial policy aimed at diverting the Indian and Far Eastern maritime trade from the Persian Gulf and Iraq to South Arabia and the Red Sea route. The splendour of the Fāṭimid court in Cairo far overshadowed that of the poverty-stricken ʿAbbāsids in Baghdad, and Cairo assumed the position of cultural leadership in the Arab world that it still holds today. But the Fāṭimids could not escape the path of decline already trodden by their ʿAbbāsid rivals. Ambitious generals rebelled; there were succession disputes; the Ismāʿīlī movement lost impetus and was rent by various schisms (the Druze sect of southern Syria grew out of the extravagant policies of the caliph al-Ḥākim, 996–1021); and the Fāṭimids' eastern flank was potentially jeopardized after 1099 by the injection of a new element, that of the crusaders. It did not prove difficult in 1171 for the Kurdish general Saladin to end the now feeble Fāṭimid caliphate. Sunnī orthodoxy was restored in Egypt; it returned to the spiritual overlordship of the ʿAbbāsids, and the traces of Fāṭimid rule there were speedily obliterated.

The Seljuq Turks. In 1055, the ʿAbbāsids were released from the tutelage of the Būyids by the Seljuq Turks, whose nomadic bands had been raiding for several years through Persia into Anatolia (where they eventually overlaid Byzantine rule) and into Iraq. The Seljuqs were enthusiastic Sunnīs and at an early point in their career had styled themselves by the stereotyped formula of Clients of the Commander of the Faithful. Orthodox opinion, to some extent, favoured them in their struggle with the Būyids, and eventually their leader, Toghrïl Beg, entered Baghdad and had his title of sultan (*i.e.*, "temporal ruler," a title already well-known in the eastern Islāmic world) confirmed by the caliph al-Qāʾim. Very soon al-Qāʾim married a Seljuq princess, although he held out as long as possible against the idea of the barbarian Toghrïl marrying one of his own daughters. The enfeeblement of the last Būyids had already allowed the caliph tentatively to reassert his authority. For long, the Būyids' close control had deprived the caliphs of the necessity for viziers. In 1045, al-Qāʾim felt strong enough to appoint a vizier who was strongly Sunnī and anti-Būyid, Ibn al-Muslimah. The spread of the Seljuqs over the greater part of the Middle East finally crystallized the new division of power in the central Islāmic lands, a division that had already taken shape in the Būyid period, between the caliph-*imām*s as spiritual heads and the Seljuq sultans as temporal rulers; this duality ultimately had to be recognized in Islāmic constitutional theory. Even so, the ʿAbbāsids were by no means freed from all outside constraint. The Seljuqs controlled much of the caliphal income, and it was through financial pressure that Toghrïl was finally able to compel al-Qāʾim to grant his daughter's hand.

Division between spiritual and temporal rule

The great Seljuq Empire reached its zenith under Malik-Shāh (1072–92) and his famous vizier Niẓām al-Mulk. The latter played a leading role in furthering the general revival of Sunnī orthodoxy in the Islāmic world, a revival favoured by the triumph of the Seljuqs and the decline of the Fāṭimids after 1094. The education and training of a specifically orthodox class of scholars and officials was promoted by the spread of *madrasah*s, or colleges, in conscious rivalry to the Shīʿite centres of learning founded by the Fāṭimids for training Ismāʿīlī missionaries. Despite this broadly Sunnī policy of the Seljuqs, specific contacts between the sultans and caliphs were by no means always harmonious. The ʿAbbāsids and their viziers were beginning to chafe at restrictions that they had previously endured in enforced silence. Malik-Shāh married the caliph al-Muqtadī's daughter in 1087, but relations so deteriorated that, just before his death, Malik-Shāh was contemplating making Baghdad his own winter capital and expelling the ʿAbbāsids from it.

The last ʿAbbāsids. After Malik-Shāh's death, the unity of the great Seljuq sultanate began to crack, and the last century of its life was marked by frequent succession disputes and the rivalries of ambitious Turkish generals. The real power of the ʿAbbāsids now increased

proportionately to the weakening of the Seljuqs. They had the services of several capable viziers, such as Ibn Hubayrah, vizier for 16 unbroken years to al-Muqtafī (1136–60) and al-Mustanjid (1160–70). Ibn Hubayrah also threw his weight behind the revived influence within Baghdad of the strictly orthodox Ḥanbalī law school, whose resurgence parallels that of the caliphate itself. The energetic al-Muqtafī built up a professional army of his own and fortified Baghdad, so that he was able to extend his political influence over central and southern Iraq to a degree unknown since the early 10th century; and he intervened on various occasions in the internal quarrels of the Seljuq family as legitimizer of one or another claimant's power.

The caliph an-Nāṣir (1180–1225) became a central figure in the diplomacy and politics of his age. The ʿAbbāsids had paid little attention to events in Syria and the Levant coastlands, where the crusaders had been entrenched since the opening of the 12th century, beyond giving moral encouragement to Muslim princes fighting there; outside of the eastern Mediterranean itself, the crusaders had attracted little interest in the Islāmic world at large. An-Nāṣir's main preoccupation was with the east, where an aggressive Turkish dynasty from Central Asia, that of the Khwārezm-Shāhs, was moving through Persia and threatening Iraq; at one point, the Khwārezm-Shāh Moḥammad seems to have toyed with the idea of putting an ʿAlid on the caliphal throne. The danger was such that the appearance of Genghis Khan's Mongols in Central Asia in 1217 was not unwelcome news to the caliph, relieved that Khwārezmian pressure in the west would now be relaxed; certain later Muslim historians allege that he deliberately incited the Mongols against the Shāh. An-Nāṣir sought to buttress his personal authority by becoming patron of the *futūwah*, or chivalric orders of Islām, using these organizations as a basis for bringing both Sunnī and moderate Shīʿite princes together in an informal union under his own leadership; in this regard, a striking success of his was the return to the orthodox fold in 1211–12 of the Ismāʿīlī Grand Master of the Assassins of Alamūt in northern Persia.

Mongol invasion

An-Nāsir weathered the storm of the first wave of Mongol invasions, but the last ʿAbbāsid of Baghdad, al-Mustaʿṣim (1242–58), was less fortunate. He was unable to ward off, by diplomacy or any other means, the second wave of Mongol onslaughts under Hülegü Khan, and in 1258 the Mongols sacked Baghdad and murdered the Caliph, thus extinguishing the ʿAbbāsid line there. A few years later, the Mamlūk Turkish sultan in Egypt invited a scion of the ʿAbbāsid family to establish himself in Cairo as spiritual head of Islām, but members of this new line of Cairo ʿAbbāsids were puppets and complete nonentities, and the dynasty was ended for all time when the Ottomans invaded Egypt in 1517. The Ottomans eventually styled themselves caliphs as well as sultans, but there is no truth in the story that became current in the 19th century that the last ʿAbbāsid had formally transferred his office to Sultan Selim in 1517.

ECONOMIC AND SOCIAL LIFE UNDER THE ʿABBASIDS

The medieval Islāmic world had an almost closed economy, producing for itself all the essentials for nourishment and comfort of life, with the exception of certain luxury articles imported from outside, such as slaves from Central Asia, Europe, and black Africa; furs from Siberia; and some spices and other tropical products from farther east. The strength of the Islāmic economy is attested by the vigour of city life, with large concentrations of people in Cairo, Baghdad, and Damascus and a network of smaller urban centres, and by the flourishing agricultural lands of the Fertile Crescent, the Nile Valley, Syria, and Mesopotamia, together with the oases of North Africa, Persia, and Central Asia. Only this richness, in the face of frequent natural disasters, such as floods and earthquakes, and in the face of such human interference as the tramplings of armies and the excessive mulcting of people for taxes, explains the resilience and continuity in Islāmic life. It also provides a key to the paradox that, in the ʿAbbāsid Caliphate, economic and cultural progress were not necessarily correlated with political expansion or integration of the state. It was the 10th century, the age of caliphal decline and disintegration, that was characterized by the Swiss orientalist Adam Mez as that which witnessed the social and cultural "renaissance of Islām." In this period, provincial centres for cultural activity and economic production came to replace the more centralized pattern of early ʿAbbāsid times, but without any overall deterioration in the quality of life and the level of achievement.

10th-century "renaissance"

The economy. It was not that this economic florescence of the caliphate was based on the exploitation of slave labour. With the advent of the ʿAbbāsids, the great conquests slowed down and finally ceased. Since Muslims could not in theory be enslaved, slaves had to be imported from outside the Islāmic world and, consequently, commanded high prices. Moreover, their main use was as domestic slaves and, from the 9th century onward, as elite troops. The only place where large-scale agricultural slavery was known was in lower Iraq, where Negro slaves were employed to remove the topsoil and desalinate and denitrify the earth. This region was the epicentre of the Zanj revolt of 869–883 (see above). Yet this was not a rebellion against the institution of slavery as such; the Zanj themselves had their own slaves, as had the egalitarian Qarmaṭians of eastern Arabia.

Among the regions of the caliphate, the fertile and densely populated Nile Valley and the Euphrates–Tigris basin stand out as the most intensely cultivated ones. Egypt had the advantages of reliable harvests from the Nile floods, a centralized bureaucratic tradition to direct agricultural operations, and excellent river and sea transport. Hence, the Egyptian farmers (*fellahin*) produced the sinews of war for dynasties such as the Ṭūlūnids and Fāṭimids, together with a normal surplus for export. But it was the richness of Mesopotamia, what was known as the Sawād, or "black region" (of dark-coloured vegetation, contrasted with the dazzling whiteness of the desert), that for long gave the caliphate such a firm financial base and supplied the populous capital, Baghdad, with its produce. Here, as everywhere in the Islāmic world, the availability of water was the key to life, and a highly complex system of irrigation canals and hydraulic machinery underlay the prosperity of the Sawād. "Bringing land to life" by irrigating and populating it was a traditional duty of caliphs and governors. Unfortunately, from the 10th century onward, the Fertile Crescent suffered from the incursions of nomads (Bedouins and, later, Turkmen) who cared nothing for agriculture or irrigation systems; and the political decline of the caliphate, with a drying up of its financial resources, must have adversely affected agriculture in Iraq. But it was probably long-term economic and cultural change in the Levant that accounted for the reversion to desert, during the early ʿAbbāsid period, of certain formerly flourishing oases in the Syrian and Iraq deserts (settlements whose surviving buildings were for long erroneously believed to be "hunting palaces" of the caliphs).

The wealth of Mesopotamia

The products of Islāmic agriculture were as diverse as the topographical and climatic divisions of the Islāmic world. On the whole, the staples of Muslim diet were bread made from wheat or barley and milk, rather than the rice eaten by peoples further east, and cereals were grown in such regions as the plains of North Africa, Egypt, Syria, and northern Iraq. Rice, however, could be grown in damp and low-lying places, such as the Jordan Valley, lower Iraq, and the Caspian coastlands. Lower Iraq and eastern Arabia were also noted for their dates, of which hundreds of varieties were enumerated, and Syria for its olives and its fruits. Sugarcane had been introduced to the Persian Gulf region from India; Khuzistan, the Jordan Valley, and the Syrian littoral were the main centres where this highly prized plant was grown (it was, of course, to be passed on to Europe at the time of the Crusades). A wide range of vegetables and fruit was grown almost everywhere. Fish was less a staple of life than a delicacy, but the coasts of Arabia and the great rivers did provide fish extensively, although no

curing and preserving industry on the northern European scale arose. The existence of easy communications by land and, especially, by sea and river and the needs of urban centres of consumption favoured trade in products that were especially desirable and not immediately perishable. In al-Wāthiq's caliphate, melons were exported from Khwārezm (Khwārazm) in Central Asia all the way to Baghdad in leaden containers packed with snow. Coveted varieties of dates were exported from the Persian Gulf coastlands to more temperate parts of the Middle East, where dates would not grow, while North African dates were sent across the Sahara to pay for slaves and gold from the Niger basin.

The industrial raw materials of the Islāmic world, such as metals, minerals, timber, and building stone, were distributed unevenly and were to be found mainly in the mountainous fringes. As in ancient times, the lack of iron and shortage of timber for fuel and building continued to be the two great bottlenecks hampering technological advance, but the converse of this was the stimulation of internal trade in these commodities. The metal-rich Iranian and Armenian highlands and the Atlas Mountain region of North Africa provided valuable metals, such as silver and mercury, as well as iron and copper; but it was still worthwhile in 964 for the metal-hungry Qarmaṭians of Arabia to carry back with them iron from ar-Raqqah on the upper Euphrates, including the town gates and the shopkeepers' weights.

The availability through trade of these raw materials and the fact that cotton, flax, wool, and silk were produced in abundance in several parts of the Islāmic world favoured small-scale industrial production in the towns and villages, above all of textiles, cloth, and carpets. Almost every town of note had its own specialty here, as the English names of certain types of cloth bear witness; *e.g.*, damask from Damascus, muslin from Mosul, dimity conceivably from Damietta, in northern Egypt. The manufacturer or artisan was often a petty trader also, the markets being centres for both production and retailing. Manufacturing was thus essentially small-scale. The state intervened to organize large-scale production only in cases such as that of the *ṭirāz*, gold-embroidered cloth for ceremonial and official usage. Groups of merchants trading on a larger scale, with ample capital resources, did, however, exist from middle ʿAbbāsid times onward, when the high level of consumption and luxury could support long-distance trading operations. Islām had begun in the mercantile centre of Mecca, and the merchant was an honoured figure in Islāmic society. In addition to extensive internal caravan traffic converging on cities like Baghdad, there were routes into the little-known pagan lands of Siberia, northern India, and sub-Saharan Africa. The volume of Islāmic coins of the 9th and 10th centuries, amounting to hundreds of thousands, found in Russia, the Baltic regions, and even Iceland testifies to the existence of steady trade connections between the northern fringes of the Islāmic world and inner Eurasia and eastern Europe; here, the most prized products were furs, hides, honey, wax, and, above all, slaves.

Absence of large-scale production

If available, sea transport was in many ways less hazardous than land travel, where brigandage, tolls, and other vexations were frequent. The products of the Far East were tapped by Arab and Persian sailors in the earliest Islāmic period, for in the 8th century there was a flourishing Muslim colony in Canton, although, thereafter, Malaysia tended to be the limit of Muslim navigation. But the products of China continued to arrive; much Chinese porcelain of the T'ang dynasty (618–907) has been found in the ruins of Sāmarrā', which was occupied for only five or six decades in the 9th century. Commerce in the Mediterranean came to be shared with the Christians, especially the traders of Venice and Amalfi. The Cairo Geniza records, those of one of the local Jewish communities, covering essentially the Fāṭimid period and just beyond, show much of the trade between Egypt and Tunisia in the hands of Jewish merchants. As well as being entrepreneurs, Jews were at this time acting as something like central bankers to certain Islāmic rulers. In the financial crisis of the ʿAbbāsids in the early 10th century, the caliph's ministers had recourse to Iraqi Jewish financiers; and the Fāṭimid caliphate owed some of its financial stability to the availability of capital and skilled financial advice from Jewish and Christian sources.

ʿAbbāsid society. Social life and organization under the caliphate was in one respect controlled by the state but in others remarkably uncircumscribed. The state or ruling institution was the chief corporate body in Islāmic society; there was no formally constituted church, as in medieval Europe, and the existence of lesser corporate bodies within the state was discouraged. Hence, in the economic field, although practitioners of a particular skill or craft might have their own quarter or market and a loose association for common interests, they had—at least in the first four or five centuries of Islām—no corporative organization comparable to the European trade guilds, with their initiation ceremonies and hierarchies of membership. On the wider plane, this meant that the Islāmic cities, despite a populousness and richness far exceeding that of Dark Age European towns, never evolved corporate identities of their own. Accordingly, there is nothing in the history of the caliphate corresponding to the evolution of the Italian trading republics or the Flemish communes; the state could brook no rivals.

On the other hand, the ordinary Muslim was left very much to himself, provided that he paid the requisite taxes and avoided heretical or seditious activities; the caliph or provincial ruler might be a despot, but his regime was not totalitarian. The non-Muslim communities, Jews, Christians, and Zoroastrians, normally subsisted in peace, provided that they made themselves as unobtrusive as possible and obeyed the official heads of their communities, who were normally confirmed in office by the Muslim ruler. Furthermore, despite the disapproval of pious Muslims, Christians and Jews continued to fill high financial and secretarial offices in the bureaucracy of the ʿAbbāsids and of such dynasties as the Fāṭimids, because of their expertise and probity.

Treatment of non-Muslims

The Bedouins of the Arabian, Syrian, and North African deserts performed certain functions for society, such as escorting caravans and supplying the products of their pastoral way of life, but they were rightly regarded by the sedentaries as predatory nuisances, outside the mainstream of Islāmic civilization and life. After the Arab conquests, the most active elements among the Arabs migrated to the garrison cities of the occupied territories, and the Arabian peninsula became a backwater. Now, with the general conversion of the indigenous peoples in the conquered lands, a population evolved in the ʿAbbāsid period that was culturally and religiously homogeneous, if not ethnically so. It was in the social field that Arabic racial superiority lasted longest, as shown by the *shuʿūbīyah* movement among the non-Arabs (see below).

Primacy of urban life

Islāmic civilization came to be based essentially on the towns, which flourished, as has been noted, during the ʿAbbāsid period; indeed, it came to be tacitly assumed that the good Muslim life could be properly lived only in a town. The villager lived in a very closed world, at little above subsistence level and hence at the mercy of many natural catastrophes. Rural prosperity depended on a strong government for maintaining irrigation and other essential services, for suppressing banditry, and for protecting the peasantry from exploitation by local landlords. The decay of ʿAbbāsid power in the 10th century had a deleterious effect on the agriculture of Iraq. The financial straits of the caliphs and of their successors the Būyids and Seljuqs compelled them to pay their servants in grants of land (*iqṭāʿs*), so that the central government lost its rights of supervision over the land, and the grantee was left free to exploit his estates to the hilt. The town dwellers were somewhat more secure; hence, urban populations were always being swollen by runaway peasants. In the towns there resided the ruling class of soldiers and officials and the religious classes of *ʿulamāʾ* and lawyers. Below these were the merchants and then the artisans and proletariat, a socially unstable group that, in many Islāmic towns, was likely to erupt periodically under the banners of social or religious faction: the frequent riots

of Sunnīs and Shīʿites in Baghdad are a typical instance of this. Islāmic society was, thus, a rich mosaic of ethnic and social groupings whose positions in life and whose characteristic skills were often handed down hereditarily. All this tended to perpetuate the status quo and to freeze existing patterns of behaviour. Yet in some ways there was less class consciousness and more social mobility than in feudal Europe. A slave guard in a ruler's service might enjoy a high rank in society, independent of his technically servile status. In any case, Muslims were always very conscious of the transience of worldly things: the vizier or even caliph of today might be a pauper tomorrow, while the humble coppersmith might rise to become head of a great military empire, as happened with Yaʿqūb ebn Leyṡ in Seistan (see above).

CULTURAL LIFE UNDER THE ʿABBASIDS

It was under the ʿAbbāsids that Islāmic civilization achieved its full flowering. The Umayyad period had been one of external conquest and of internal sectarian and tribal strife; while the religious institution was beginning to take shape, and the first steps in the systematization of the Sharīʿah, the body of Islāmic theological doctrines and legal practices, were made during that time, it was only under the ʿAbbāsids that these processes came to maturity. After 750 there was, broadly speaking, external peace, and, though sectarian violence continued to erupt in various parts of the caliphate, a general consensus of thought and belief emerged among Muslims, at least among those of the Sunnī majority. The racial arrogance of the Arabs was now less of an obstacle to the assimilation of non-Arab ideas and practices, for the victory of the ʿAbbāsids had ended the Arabs' monopoly of political and military power, if not of social privilege. The characteristic ʿAbbāsid culture was to be an amalgam of Arab, Persian, and Greek elements. On the material plane, the economic buoyancy of the caliphate produced a leisured class of courtiers and urban bourgeoisie who could patronize and enjoy literature and music. The political decay of the later 9th century and after did not affect adversely this cultural florescence. The republic of science and letters was unhindered by political boundaries and probably benefitted from the existence of a welter of rival courts. It is in this period that are found two familiar figures, the sectarian missionary, or propagandist, and the wandering scholar obeying the Prophet's injunction, "Seek knowledge, even as far as China."

Religion. In Umayyad times, there had been signs of increasing religiosity among the caliphs and of a growing influence of the religious classes; the first executions for heresy took place in the early 8th century. Under the ʿAbbāsids, the religious institution became an influential body, comprising theologians, canon lawyers, and traditionists (*i.e.*, those concerned with the handing down and evaluation of the traditions or sayings of the Prophet and the early Muslims), although it never became strong enough to challenge the caliphs for secular power, as did the papacy in medieval Europe in regard to the emperors; respect for the vicegerents of the Prophet and the fear of anarchy were always uppermost. The founders of the four great rites of Islāmic law, which survive today, all flourished in the later 8th and 9th centuries; namely, Abū Ḥanīfah (died 767), founder of the Ḥanafī rite; Mālik ibn Anas (died 795), founder of the Mālikī rite; Muḥammad ash-Shāfiʿī (died 820), founder of the Shāfiʿī rite; and Aḥmad ibn Ḥanbal (died 855), founder of the Ḥanbalī rite. Generally speaking, the Mālikī and Ḥanbalī rites represented a more conservative interpretation of the bases of Islāmic law, the Qur'ān and the *sunnah*, or example of the Prophet; but the differences among the rites were at the outset geographical rather than ideological. Thus, the Mālikī rite represented the custom of Medina and the rugged simplicity of life in the Arabian peninsula; the Ḥanafī rite represented the more flexible practice of Iraq, where society and institutions were more complex and of greater antiquity than those of the Hejaz. In any case, there was no unified, agreed system of basic legal principles; the different rites evolved piecemeal according to the needs of the time and place.

The four great rites of Islāmic law

Islāmic religion in the earliest period was more a body of rituals and practices than one of set beliefs and creeds. But questions of faith had already evoked discussion and dissension in the Umayyad period, as seen in the birth of such sectarian movements as Khārijism. By the end of the 9th century, the Khārijites had ceased to be a vital force, but the Shīʿite schism was more lasting and shows how persistent has been the interweaving in Islām of religion with political and social questions. The split with the Sunnī majority revolved round the question of the caliph-*imām*, with the Shīʿah representing the authoritarian view. For them, the imamate was a necessity for the community, not a matter of convenience, and the imamate resided in the pure and immaculate descendants of ʿAlī, who had been designated by Muḥammad himself. It may be that the emotions engendered around the person of ʿAlī and his martyred progeny provided an element of faith for some Muslims lacking in the rather matter-of-fact Sunnī form of Islām. The revolts of the ʿAlids and their persecution by the ʿAbbāsids have been noted above; but it is worth mentioning that the moderate Shīʿites often managed to live at peace with the orthodox majority and that many of the Shīʿite *imāms* themselves, down to the disappearance of the 12th one, lived respected and unmolested lives. It was the extremists, like the Ismāʿīlīs (from whom sprang the later Assassins) and the Qarmaṭians, who abandoned the apolitical stance of the *imāms* in favour of direct political action, who inevitably brought down upon themselves the full wrath of the Sunnī state. The mainstream of moderate Shīʿism also produced such a commanding figure as the Aristotelian and Neoplatonist philosopher-theologian al-Fārābī (died 950), called "the second teacher" (Aristotle being the first), who ended his days among the Shīʿite Ḥamdānids of Aleppo in northern Syria.

Growth of theology

With the consolidation and elaboration of the Sunnī, the majority form of Islām, this last now acquired a formidable body of theological doctrine. The challenge of other faiths, such as Christianity, had some part in this process, but most significant was the influence of Greek philosophy and logical methods, leading to the enunciation of a systematic Islāmic theology (*kalām*). These stimuli are all seen at work in the theological movement of the Muʿtazilah, which arose in Basra and flourished in early and middle ʿAbbāsid times, although its attitudes remained influential for several centuries afterward. The Muʿtazilah originally may have had some affiliations with the ʿAbbāsid revolution. They soon showed themselves zealous in defense of the faith against outside religions, such as Christianity and Manichaean Dualism, and, in constructing this defense, they defined Islāmic dogmas in Greek theological terms. Politically, they seemed to have aimed at organizing moderate support for the ʿAbbāsid caliphate by broadening its bases of support and compromising on certain details; hence, they favoured an accommodation with the Shīʿah. The caliphs of the period from al-Maʾmūn to al-Wāthiq (813–847) were all enthusiastic patrons of the Muʿtazilah, and they endeavoured to make Muʿtazilite views generally accepted. This provoked a reaction of the orthodox, disturbed by the introduction of Hellenistic methods into sacred theology, and this reaction was symbolized by Aḥmad ibn Ḥanbal's stand in defense of the orthodox doctrine of the uncreated Qur'ān. Al-Mutawakkil restored the primacy of orthodoxy, and the Muʿtazilah henceforth played no significant role in practical affairs.

The orthodox reaction showed the strength of traditional Islām among the masses in Baghdad and other cities. Ḥanbalism was not mere obscurantism: it simply refused to admit the validity of rational arguments in matters of faith, views so dogmatically asserted by the Muʿtazilah. Other groups in orthodox Islām, such as the Ḥanafīs, were also anti-Muʿtazilite, and the 9th and early 10th centuries saw the composition of several Ḥanafī creeds. The noted theologian as-Ashʿarī (died 935/936) adhered to Ḥanbalism, combatted the arguments of the Muʿtazilah, and was, above all, concerned to uphold the sovereignty of God, but he did admit the use, with due care, of rational methods; his great service, it has been

said, was to utilize the basic elements of Greek thought without compromising the central dogmas of Sunnī Islām. The outstanding figure in medieval Islāmic thought —according to some judges, the greatest Muslim after Muḥammad—was al-Ghazālī (died 1111), who lived at a time when the ʿAbbāsid caliphate was beginning to throw off Seljuq control and who was, above all, concerned to show that the ecstasies of the Ṣūfī mystics (whose movement was to evolve into definite orders in the course of the 12th century) could be harmonized with faithful observance of the external practices of the Sharīʿah. Finally, the raising of the study of the traditions of the Prophet and early Muslims (the *ḥadīths*) to the level of a science should be noted as an important aspect of the consolidation of orthodoxy in the middle ʿAbbāsid period. Such figures as al-Bukhārī (died 870) and Muslim (died 875) used critical methods to sift the vast corpus of traditions that had accumulated since early times and to eliminate the patently spurious.

Greek and Iranian influences. The branches of knowledge mentioned above made up some of the native "Arab sciences"; paralleling their development was the growth of *adab* literature and what were termed the "foreign sciences," in effect, the Greco-Persian elements in Islāmic culture. The ʿAbbāsids' dependence on Persian soldiers and on a class of Persian officials and secretaries (the *kuttāb*) led to the adoption of many Persian administrative practices and literary modes into Islām. A pioneer figure in this movement was the Persian Ibn Muqaffaʿ (died *c.* 756), who produced his *Kalīlah wa-Dimnah* from a Middle Persian text going back to the Indian *Panchatantra* collection of animal fables and who also made an Arabic version of the Persian royal chronicle, the *Book of Kings*. Gradually there grew up a body of polite learning, called *adab*, cultivated by persianizing officials and the leisured classes, and this speedily became recognized as a necessary part of a polished education. Virtually nothing was alien to *adab;* the writings of the polygraph al-Jāḥiẓ of Basra (died 869) show him to have been interested in almost every aspect of life, from psychology and anthropology to politics and natural history. It was the Persians who were in the forefront of the Shuʿūbīyah, the "movement of the nations," in the 9th century, in protest against the cultural and social pretensions of the Arabs, especially now that their political and military dominance was a thing of the past. This battle of the books was certainly not, on the Shuʿūbī side, anti-Islāmic. But the Persian and Greek Shuʿūbīs did quote the glories of their past civilizations, compared with the miserable desert origins of the Arabs, and thus, from a claim to equality with the Arabs, they soon passed to a claim of superiority. The defenders of the Arabs stemmed in considerable measure from the scholars of Arabic grammar and lexicography, with their great schools of Basra, Kūfah, and Baghdad, for the Arabic language was regarded as the foundation stone of Arab ideals. Yet surprisingly enough, some of the staunchest defenders of the Arab cause were themselves descendants of Persian clients, or *mawālī*, among them the writer Ibn Qutaybah (died 889). The echoes of the Shuʿūbīyah controversy lingered on long after this; in the later 11th century, a Spanish Muslim Shuʿūbī, Ibn Garcia, wrote against Arab pretensions.

Arab-Persian debate

The Greek heritage showed itself primarily in the fields of philosophy and science and was introduced to the Islāmic world through the activities of schools of translators in Syria, Iraq, and Alexandria, many of whom were Christian; indeed, many Greek texts came into Arabic thirdhand via Syriac. Alone among the infidel countries, Byzantium was profoundly respected by the Muslims as the inheritor of ancient Greek civilization. But it was Greek philosophy, science, and mathematics, and not imaginative literature and history, that interested the Arabs; in these latter fields, Persian influence remained paramount. The translation movement received an impetus from the caliph al-Maʾmūn when he founded his "House of Wisdom," undoubtedly in imitation of the old medical academy of Gondēshapūr (Jundīshāpūr) in Khuzistan. Notable among Nestorian Christian translators was Ḥunayn ibn Isḥāq al-ʿIbādī (died 873), at one time the private physician to al-Mutawakkil and reputedly the translator of the medical works of Galen, Dioscorides, and Hippocrates, as well as of several works of Aristotle and of the Old Testament. The pagan community of Ḥarrān in northern Syria carried on the traditions of Greek astronomy and mathematics, and Thābit ibn Qurrah (died 901) and his family provided, among much else, translations of Archimedes and Apollonius of Perga. Eventually, a considerable body of Aristotle's works, including, however, many apocryphal ones, was available to the Muslims, and Aristotle became a dominant influence in Islāmic philosophy. This was to prove of incalculable significance in the 12th and 13th centuries, when knowledge of Aristotle and other Greek authors was to be passed to medieval Europe through Arabic intermediacy.

Translations of Greek texts

On the basis of translations such as these, Muslim scholars worked on the harmonization of Greek philosophy with Islāmic ideas and began to make their own original contributions to knowledge, above all in the fields of astronomy, mathematics, alchemy, and medicine. Al-Maʾmūn, again, was interested in problems of astronomy and mensuration, and, from a base on the plains of northern Syria, his scholars achieved a surprisingly accurate figure for the circumference of the earth. Al-Kindī of Baghdad (died *c.* 870) won for himself the title "philosopher of the Arabs," and it was he who began the assimilation of Aristotelian and Neoplatonist philosophical ideas, but he was equally brilliant as an astronomer and theoretician of music. This tradition of the scientific polymath was continued by such figures as ar-Rāzī, or Rhazes (died in the 920s or 930s), outstanding as a medical clinician, whose medical encyclopaedia, the *Kitāb al-ḥāwī*, was translated into Latin in the 13th century; and Ibn Sīnā, or Avicenna (died 1037), who produced two great encyclopaedias, one on science and philosophy, the *Kitāb al-shifāʾ* ("Book of Healing"), with a basically Neoplatonist standpoint, and his *Qānūn fi al-ṭibb* (*Canon of Medicine*), the standard medical textbook in later medieval Europe. The views of men like Avicenna easily made them suspected of heresy or even infidelity by the pious; and the only attempt to make an encyclopedic survey of all branches of knowledge was undertaken in the collection of epistles by an Ismāʿīlī group in 10th-century Basra, the Brethren of Purity.

Interaction of Greek and Islāmic thought

Arab literature. The ʿAbbāsid period is generally considered to be the golden age of Arabic literature. By 750, the desert ideals that had inspired the work of the pre-Islāmic and Umayyad poets were becoming anachronistic; the audience for literature was now largely one of city dwellers, who lived far from the harshnesses of desert life and did not particularly want to be reminded of the early Arab past. Only for antiquarian-minded grammarians and lexicographers did poetry cast in the ancient mold still have attraction. A "new wave" in poetry is clearly discernible in the late 8th and 9th centuries. The penetration of Islāmic religious ideals is apparent in the religiously inspired verse of Abū al-ʿAtāhiya (died 825 or 826). The libertine Abū Nuwās, drinking companion of Hārūn ar-Rashīd, developed the earlier erotic poetry that had sprung up in the pleasure haunts of Medina and the Hejaz into a more refined but equally lascivious verse, much of it being homosexual in tone. Abū Tammām (died 845 or 846), compiler of, among other things, a famous anthology of Arabic verse, the *Ḥamāsa*, consciously proclaimed his poetic superiority to the ancients, as did Ibn ar-Rūmī (died 896) shortly afterward.

In the following century appeared al-Mutanabbī, perhaps the greatest of all Arab poets, whose panache, lauding of the heroic virtues and sententiousness alike, have commended him to all succeeding generations of Arabs. Poets such as these could not have flourished without the patronage and favour of contemporary rulers and governors, yet their verse had an appeal beyond that of this limited class of great men and officials and of the scholars; the verses of al-Mutanabbī, for example, spread, within his own lifetime, through popular acclaim to all

The work of the poet al-Mutanabbī

corners of the Islāmic world, and many of their phrases quickly became proverbial.

With the stimulus of the ideal of the *adīb*, the man with an all-round education, Arabic prose takes shape during the ʿAbbāsid period, beginning with the translations and epistles of Ibn al-Muqaffaʿ but best exemplified in the many-sided work of al-Jāḥiẓ, with his acute observation of the quirks of human nature. The danger of the *adab* style lay in its being pushed too far into preciousness and artificiality. Signs of this trend are observable in the spread of rhymed prose instead of the straightforward, almost conversational style of a writer like al-Jāḥiẓ; and, toward the end of the 10th century, there appeared the highly artificial and stylized dramatic sketch, the *maqāmah*, popularized by Badīʿ az-Zamān al-Hamadhānī (died 1008) and perfected by al-Ḥarīrī (died 1122).

Literature, rather than painting and sculpture, has always been the typical expression of the Arab creative spirit. It was not that Islām absolutely forbade representation of living forms, as is clearly demonstrated by some of the murals in the Umayyad hunting palaces and the ʿAbbāsid palaces at Sāmarrāʾ and by the representations of rulers on coins and medals; it was only later that a hostility to figural art developed, especially in the Arab parts of Islām. The desire to give concrete expression to the creative impulse expressed itself rather in such forms as ceramics and metalwork; in calligraphy as a work of art, not merely as a writing technique; and, of course, in architecture, where abstract decorative motifs in stucco, glass mosaic, etc., were widely used in mosques, madrasas, and palaces. In ʿAbbāsid architecture—as seen in a typical selection from its surviving monuments, such as the Sāmarrāʾ ruins (9th century), the mosque of Aḥmad ibn Ṭūlūn in Cairo (late 9th century), and the recently reconstructed Mustanṣirīyah *madrasah* in Baghdad (early 13th century)—there was a basic functional severity much more emphatic than in contemporary Byzantine architecture or that of medieval Europe a little later, yet a severity at the same time relieved by this tasteful decoration. The eastward orientation of the ʿAbbāsid caliphate after 750 had its echoes in architecture also, in that indigenous traditions of Iraqi and Sāsānid Persian architecture came to the fore; but there was an artistic regression in the use of building materials, as compared with the solid-stone Syrian Umayyad structures: ʿAbbāsid buildings of a site such as Sāmarrāʾ were run up hastily from fired and even from stucco-covered, sun-dried brick.

BECKER, "The Expansion of the Saracens," in *The Cambridge Mediaeval History*, vol. 2 (1913), a lucid and informative account of the Arab conquests, carrying the story down to the campaigns against Sicily and Italy in the 10th and 11th centuries; ADAM MEZ, *Die Renaissance des Islams* (1922; Eng. trans., *The Renaissance of Islam*, 1937), a classic on the cultural and social life of the caliphate in the 10th century, abounds in curious and recondite items of information from the Muslim sources; W. MONTGOMERY WATT, *A History of Islamic Spain* (1965), a general account of the eight centuries of independent Arab rule in Spain—contains several good plates of Spanish Islāmic art and architecture; R.A. NICHOLSON, *A Literary History of the Arabs*, 2nd ed. (1930, reprinted 1962), weaves the development of Arabic literature into the political events affecting it; W. MONTGOMERY WATT, *Islamic Philosophy and Theology* (1962) and *Islamic Political Thought* (1968); and N.J. COULSON, *A History of Islamic Law* (1964), three concise guides to these subjects; HENRY G. FARMER, *A History of Arabian Music to the XIIIth Century* (1929, reprinted 1967), technical information on music, and also much on the role of music and dancing in social life under the caliphs; D. TALBOT RICE, *Islamic Art* (1965), a general treatment of the subject, well illustrated; K.A.C. CRESWELL, *A Short Account of Early Muslim Architecture* (1958), deals with Umayyad and with ʿAbbāsid architecture.

(C.E.B.)

Calligraphy

Calligraphy is writing as an art. The term derives from the Greek words for "good" or "beautiful" and for "writing" or "drawing" and refers to what writing masters called the art of fair writing. It implies a sure knowledge of the correct forms of letters—*i.e.*, the conventional signs by which language can be communicated—and the skill to inscribe them with such ordering of the various parts and harmony of proportions that the cultivated, knowing eye will recognize the composition as a work of art. In East Asia, calligraphy by long and exacting tradition is considered a major art, equal to painting. In Western culture the simpler Greek and Latin-derived alphabets and the spread of literacy tend to make handwriting theoretically "everybody's art," though in a few instances, especially since the Renaissance, it either has aspired to or attained the status of calligraphy. For the study of ancient Greek and Latin handwriting as a discipline of historical research, see PALEOGRAPHY. (Ra.N.)

GREEK HANDWRITING

Origins to the 8th century AD. The oldest Greek writing, syllabic signs scratched with a stylus on sun-dried clay, is that of the Linear B tablets found in Knossos, Pylos, and Mycenae (1400–1200 BC). Alphabetic writing, in use before the end of the 8th century BC, is first found in a scratched inscription on a jug awarded as a prize in Athens. The consensus is that the Homeric poems were written down not later than this time; certainly from the time of the first known lyric poet of ancient Greece, Archilochus (7th century BC), individuals committed their works to writing. But the vehicles of literary writing have perished. Scratchings on pottery or metal and then texts deliberately cut in

bronze or marble or painted on vases are, until *c.* 350 BC, the only immediate evidence for the way the Greeks wrote, and their study is normally treated as the province of epigraphy. A find in 1962 at Dervéni, in Macedonia, of a carbonized roll of papyrus (Archaeological Museum, Thessaloníki, Greece) offers the oldest and only example of Greek handwriting preserved in the Greek peninsula (end of the 4th century BC). From then until the 4th century AD, there are countless texts, especially on papyrus. Found in Egypt, and, with a few exceptions, written there, these texts have given a firm foundation for knowledge. From outside Egypt there is a Greek library buried in Herculaneum, AD 79; and papyri and parchments from Owrāmān, Kurdistan, 1st century BC; from Doura-Europus on the Euphrates, 3rd century BC to 3rd century AD; from Nessana, 6th century AD; and from the Dead Sea area (Qumrān, 1st centuries BC and AD; Murabba'at and 'En Gedi, 2nd century AD). A number of original vellum manuscripts have survived from the 4th century AD onward, preserved in libraries such as the monastery of St. Catherine at Mt. Sinai. These materials of diverse origin suggest that the forms and shape of Greek handwriting were remarkably constant throughout the Greek world, wherever writing was practiced and whatever the material used; within this consistent framework it is occasionally possible to distinguish local variations (as between the contract hands of 1st-century-AD Doura and of Egypt).

Oldest Greek handwriting

Writing materials

The principal vehicles for writing were wax tablets incised with a stylus or a prepared surface of skin, such as leather and vellum, or of papyrus written on with a pen. Other surfaces—*e.g.*, broken pieces of pottery, lead, wood, and even cloth—were also used. To some extent the forms of letters were affected by the resistance of the material to the writing instrument. It is likely that the use as a pen of a hard reed, split at the tip and cut into a nib (which must be constantly sharpened), is an invention of the Greeks. Egyptian scribes used a soft reed, with which ink was brushed on.

Until about AD 300, ink was normally made of a carbon such as lampblack, mixed with gum and water, which even today retains its black lustre. After that time, because of the increasing popularity of vellum, iron inks (*e.g.*, of oak galls), better suited to vellum, tended to replace carbon. The iron inks have faded with age and often have eaten by chemical action into the vellum. Erasures could be made on wax with the blunt end of the stylus, on papyrus by wiping with a sponge; but, on vellum written in iron ink, erasures could be made only by rubbing with pumice or scraping with a knife. Texts from which a previous writing was deliberately erased to provide writing material are termed palimpsests.

Papyrus was normally sold in rolls (*volumina*) made up of 20 or 50 glued sheets: the horizontal fibres of the papyrus are placed on the inside of the roll, on which side (the recto) each gummed sheet overlaps the next when the roll is held horizontally. Leather, similarly, was for long made into rolls (the Dead Sea Scrolls). Shortly after the beginning of the Christian Era, the custom began of folding a single sheet (or several superposed sheets, a quarternion or quire) down the middle and stitching the quires into a binding case to give a book of modern form (codex, originally a set of wax tablets coupled with a thong). Tradition associated this invention with Pergamum.

Development of the book

The decisive impetus to the use of this form came from the early Christians, who deliberately chose the commercial vellum notebook (*membranae*) in which to circulate the Christian Gospels in preference to the traditional Jewish roll. Almost without exception the earliest texts of the New Testament are in codex form, even though written on papyrus, which is less able than vellum to bear repeated bending. In the 2nd century AD pagan works of literature also appeared in this format, which gained ground in the 3rd century, often in small or utility sizes. By the 4th century it became the predominant form, and codices with handsome margins, of dazzling white vellum, and of sufficient size to contain the whole Bible (*e.g.*, the Codex Sinaiticus) were being produced.

Codex Sinaiticus (British Museum, London; Add. MS. 43725, fol. 260).

The fundamental distinction in types of handwriting is that between book hands and documentary hands. The former, used especially for the copying of literature, aimed at clarity, regularity, and impersonality and often made an effect of beauty by their deliberate stylization. Usually they were the work of professionals, who may have multiplied copies to dictation, though ancient evidence on this subject is unreliable, and the evidence of scribal errors is equivocal (since the ancients invariably read out loud, a scribe copying by eye in solitude is likely to have pronounced the words of his exemplar). Outstanding calligraphy is not common among papyrus finds, perhaps because they are mainly provincial work. But the British Museum Bacchylides or the Bodleian

Book hands

Greek book hand. Bodleian Library Homer, passage from the *Iliad*, copied in the 2nd century AD (Bodleian Library, Oxford; MS. Gr. class A.1 (P)).

Library Homer can stand comparison with any later vellum manuscript from outside Egypt. Book texts are written in separately made capitals (often called uncials, but in Greek paleography, except for the time-hallowed class of biblical uncials, the term is better avoided) in columns of writing, with ample spaces between columns and good margins at head and foot. Punctuation (usually by high dot) is minimal or completely absent; accents are inserted only in difficult poetic texts or as practice by

schoolboys; and letters are not grouped into separate words.

Documentary hands

Documentary hands show a considerable range: stylized official "chancery" hands; the workaday writing of government clerks or of the street scribes who drew up wills or wrote letters to order; the idiosyncratic or nearly illiterate writing of private individuals. The scribe's aim was to write quickly, lifting his pen very little and consequently often combining several letters in a continuous stroke (a ligature); from the running action of the pen, this writing is often termed cursive. He also made frequent use of abbreviations. When the scribe was skillful in reconciling clarity and speed, such writing may have much character, even beauty; but it often degenerates into a formless, sometimes indecipherable, scrawl.

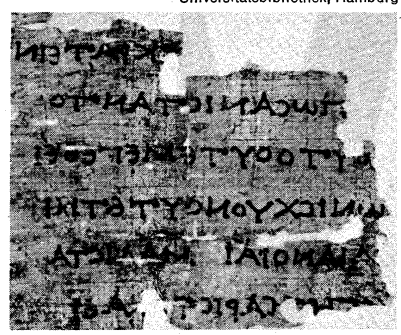
Both types of hands, in spite of the different styles they assume at different periods, show remarkable uniformity and continuity in the shapes of letters. Behind both lies an unvarying basic alphabetic form taught in the schools. The more skillful a book-hand scribe was, the harder it is to date his work. Documents in the ancient world carried a precise date; books never did. To assign dates to the latter, the paleographer takes account of their content, the archaeological context of their discovery, and technical points of book construction (*e.g.*, quires, rulings) or modes of abbreviation. But he finds of great service: (1) a stylistic comparison with those dated documentary hands that show resemblances to book hands; and (2) those cases where a roll was reused —*i.e.*, has a literary text on its recto and a dated document on its verso (in which case there is a *terminus ante quem* for the literary text, often estimated at 50 years before the date of the verso) or has a dated document on the recto and a book hand on the verso (which gives a *terminus post quem* for the literary text, not more than 25 years after the document). The number of illustrated manuscripts of this period is small; their quality is varied; and there is no agreement between specialists about the sources from which illustrations were taken.

Any historical sketch is bound to be a simplification. At certain epochs several different styles of handwriting existed simultaneously, so that there is no straight line of development. Moreover, owing to the arbitrariness of finds, generalizations are based mainly on provincial work; and, even in that, examples of book hand belonging to the 2nd century BC and the 5th century AD are still relatively rare.

Ptolemaic period. In the roll from Dervéni, Macedonia, dated on archaeological grounds to the 4th century BC, lines and letters are well spaced, and the letters carefully made in an epigraphic, or inscription, style, especially the square E, four-barred Σ, and arched Ω; the whole layout gives the effect of an inscription. In the Timotheus roll in Berlin (dated 350–330 BC on archaeological grounds) or in the curse of Artemisia in Vienna (4th century BC), the writing is cruder, and ω is in transition to the form that is afterward the invariable written form. Similar features can be seen in the earliest precisely dated document, a marriage contract of 311 BC. It has indeed been argued that a documentary hand of cursive type had not yet been developed and that it was a creation of the Alexandrian library. Plato, however (*Laws* 810), speaks of Athenian writing whose aim was speed; and later on, when a cursive hand had certainly been developed, documentary scribes often chose to use separate capitals.

Characteristic of its period is the contrast of size between long letters (*e.g.*, Μ) and narrow letters (Ε Ϲ Θ or Θ, Ο, or Ο). And characteristic forms are to be seen in the letters Τ (with its long crossbar, often with initial stroke); Υ (upsilon) with long shallow bowl; Μ or Μ in three or four strokes; Π in three strokes; α (alpha) raised off the line and its last vertical not finished; small round ε (with internal dot or tiny stroke); and broad epigraphic Δ and Η. These same features, written with more regularity, appear in the contemporary book hand of a fragment of a Thucydides manuscript (Staats- und Universitätsbibliothek, Hamburg). In documentary cursive hands of this

By courtesy of Staats- und Universitätsbibliothek, Hamburg



Thucydides manuscript, 3rd century BC (Staats- und Universitätsbibliothek, Hamburg; P. Hamburg 163).

period, letters seem to hang from an upper line: Ρ (alpha) often turns into a mere wedge, and Ν (nu) lifts its second vertical above the line. In the 2nd century BC the contrast between long letters and narrow letters disappears, the writing grows rounder, and letters are often linked by ligatures at the top of their last vertical (*e.g.*, Τ Μ Ν). In a loan contract of 99 BC (The John Rylands University Library of Manchester), in which capitals and cursive are mixed, this irregular

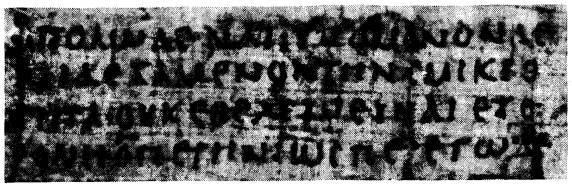
roundness is clearly seen. Note the ε with detached crossbar and the exaggerated serifs (Τ Κ Υ Ρ) which have been elevated by some paleographers into a criterion of a special style, though in fact they are always apt to occur.

Roman period. Half a century or so passes after 30 BC before a definitely Roman manner is established. In documentary hands the tendency to roundness continues. Documentary cursive may be influenced in various ways (*e.g.*, by Latin forms such as those of *e* and *d*, or by the exaggeration of verticals practiced by chancery scribes), may lean over in either direction, or may be reduced to tiny proportions. In the 2nd century the cursive hand tends to be round and sprawling, in the 3rd century

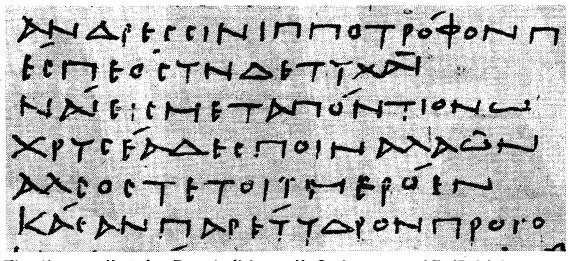


Phaedo, by Plato, copied in AD 100 (Egypt Exploration Society, London; P. Oxy. 1809).
By courtesy of the Egypt Exploration Society, London

to become more angular, and in the 4th century to become characterless and to combine letters into ligatures that distort the forms of the letters concerned. The book hand of a manuscript of Plato's *Phaedo* (*c.* AD 100; Egypt Exploration Society, London) shares its informality but regularizes the letter forms. Written on a larger scale and with more formality, this round hand can be very beautiful. In an example found at Hawara (2nd century AD), almost every letter (even ρ, τ, ι) would go into an identical square; only φ and ψ cross it above and below, μ, ω, and π horizontally.

If this writing is made to lean to the right, and to revive the 3rd-century-BC distinction between narrow and broad letters, it takes on the aspect of the "severe" style of the Bacchylides roll in the British Museum (2nd century AD).

By courtesy of the trustees of the British Museum



The "severe" style. Bacchylides roll, 2nd century AD (British Museum, London; P. 733).

Biblical uncial

If, however, the scribe makes his verticals or obliques thicker and his horizontals thinner, the hand is called biblical uncial, so named because this type is used in the three great early vellum codices of the Bible: Codex Vaticanus and Codex Sinaiticus of the 4th century and Codex Alexandrinus of the 5th century. It is now certain that this style goes back to the 2nd century AD. In the Dioscorides herbal in Vienna, written in AD 512, the writing is rigid and lumbering; the thick strokes are overdone; and blobs of ink terminate the horizontals of, for example, δ, ε, σ, τ. Such heavy decoration is also a feature of the Coptic style, of which there are examples as early as the 2nd century AD. This hand may be thought of as constituting a special case of biblical uncial.

Byzantine period. For the paleographer the significant division is not the founding of Constantinople in 330 but the 5th century, from which a few firmly dated texts survive. At its close a large-sized, exuberant, and florid cursive is found fully established for documents; in the 7th and 8th centuries, it slopes to the right, becomes congested, and adopts some forms of letters that anticipate the minuscule hand (*e.g.*, the π and λ in an 8th-century list of names preserved in the Aberdeen University Library). No new book hand was invented. A favourite informal type of the 6th century is shown in an acrostic poem by Dioscorus of Aphrodito, in the British Museum; it bears a clear relationship to the Menander *Dyskolos* hand, which was probably written in the later 3rd century AD. Similar pairs could be found to illustrate the continuity in transformation of the biblical uncial and Coptic styles. The latest Greek papyrus from Egypt is not later than the 8th century. There is a considerable lapse of time before the history of Greek writing resumes at Byzantium. (E.G.T.)

8th to 16th centuries AD. To judge when and where a Greek manuscript was written is as difficult in this as in the earlier period, but for different reasons. The material for study is admittedly more extensive; manuscripts produced in the Middle Ages and Renaissance have been preserved in very large numbers (more than 50,000 whole volumes survive, of which probably 4,000 or 5,000 are explicitly dated); and they include work from most parts of the Byzantine Empire as well as from Italy. The difficulty of the paleographer lies in the essential homogeneity of the material, which is largely the result of the conditions in which the manuscripts were produced.

The fully developed Byzantine Empire of the 8th to the mid-15th centuries was extraordinarily uniform in its culture. Its contraction in space after the Arab conquests of the 7th century, which cut off the more distant and ethnically differentiated provinces of Syria, Palestine, and Egypt, made it a relatively compact geographical entity. The continuity and comparative stability of a single empire not divided into distinct national states such as evolved in the West resulted in a strength and unity of tradition of which the Byzantines were always conscious and that shows in their habits of writing no less than in their literature and art. Distinct local styles and sharp breaks in ways of writing in different periods cannot, therefore, be looked for; characteristics that may be spe-

cially typical of one period come in gradually and disappear equally slowly. A more potent factor than date or place in producing divergencies in the style of writing is the purpose for which a manuscript was designed and what type of scribe wrote it.

Late uncial, 9th to 12th centuries. There is a gap in the evidence covering the 7th and 8th centuries, because of the Arab conquest of Egypt, the perpetual wars on all fronts in the 7th century, and the iconoclastic struggle among Eastern Christians during the 8th and early 9th centuries, so that no literary texts (and very few others) have survived that can actually be dated to this period.

During this time the evolution of writing in capitals (not very aptly named uncial) probably continued toward a greater formality and artificiality. But this natural tendency was hastened by the introduction and spread of minuscule as the normal way of writing, after which the purpose of uncial changed completely. From an everyday hand in which all books were naturally written, it became a ceremonial hand used only for special copies and therefore grew increasingly stylized and artificial. In the 9th century a still elegant style was used for both patristic and classical works in splendid volumes destined for the imperial library or for presentation copies, such as the copy of Gregory of Nazianzus (Bibliothèque Nationale, Paris) made for the emperor Basil I between 879 and 883. By the 11th and 12th centuries, capitals were used only for liturgical books, mainly lectionaries, which had to be read in dimly lit churches; but the increasing tortuousness of the style must in the end have reduced its usefulness, and, by about 1200, uncial was dead.

Change of purpose of uncial

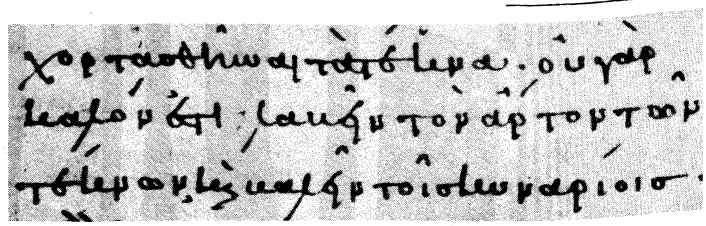
Late uncial. Copy of Gregory of Nazianzus, AD 879–883 (Bibliothèque Nationale, Paris; Grec. 510, fol. 61ᵛ).

Earliest minuscule, 8th to 10th centuries. By far the most important development that took place during the 7th–8th-century gap was the introduction of minuscule. There is no incontrovertible evidence of how this came about, or where. What scraps of evidence there are (a few documents from the gap, a few sentences in lives of the abbots of Stoudion of that time, and the first dated manuscript written in true minuscule) point to its development from a certain type of documentary hand used in the 8th century and to the likelihood that the monastery of the Stoudion in Constantinople had a leading part in its early development. Though its origins are obscure, the reasons that led to its introduction and rapid spread are obvious: poverty induced by wars and persecutions coincided with a shortage of papyrus after the Arab conquest of Egypt in the middle of the 7th century to induce a search for a more economical use of the relatively expensive vellum; the polemics of the iconoclastic controversy demanded a speedy, informal style of writing; and, finally, when peace was restored in the middle of the 9th century, the revival of learning, with the reorganization of the university, brought the need for multiplying plain workmanlike texts for scholarly purposes.

Reasons for the rapid spread of minuscule

The earliest dated example of true minuscule (and it is probably one of the oldest extant examples altogether) is a copy of the Gospels written in 835 (Leningrad Library), probably in the monastery of the Stoudion. Here are found all the characteristics of the earliest minuscule, which is called pure minuscule because there is as yet no admixture of uncial forms, except occasionally at line



Earliest dated true minuscule. Copy of the Gospels supposedly done at the monastery of Stoudion, AD 835 (Leningrad, Bibl. Publ. 219, fol. 124).

ends. The letters are even and of a uniform size; letters are joined or not joined to each other according to strict rules, sometimes by ligatures in which part of each letter is merged in the other, but not to the extent of distorting the shape of either letter. There is no division between words, for the divisions are only those that arise from the rules for joining or otherwise of individual letters, and at this stage any letter that can be joined to the next one nearly always is joined to it. Breathings are square, either ⊢ ⊣ or ⌊ ⌋, and accents are small and neat; abbreviations are very few, usually confined to the established contractions for *nomina sacra* (the names and descriptions of the Trinity and certain derivatives), omitted *ν* at line ends, a few of the conventional signs for omitted case endings, and ⸌S⸍ sometimes for *καί*. The writing either stands on the ruled lines or is merely guided by them.

First changes in minuscule

Absolutely pure minuscule did not last long. Gradually, uncial forms of those letters that had specifically minuscule forms began to be used alongside the minuscule forms: λ was the first to appear, followed by ξ and then κ, all by the end of the 9th century. Then from about 900 onward, γ, ζ, ν, π, and σ were used regularly, while α, δ, ε, and η were used sometimes. Not before about 950 were β, μ, υ, ψ, and ω used, and still comparatively rarely. But by the end of the 10th century, the interchangeability of all uncial and minuscule forms was complete, though all the alternative forms are not necessarily found in any one manuscript. Perhaps the earliest dated manuscript with any uncial form in it is of 892/893 (Sinai, St. Catherine, MS. 375 + Leningrad, Bibl. Publ. MS. 343, Chrysostom), but pure minuscule continued to be used, in probably the majority of manuscripts, up to 900, and thereafter mainly in provincial manuscripts until the last dated example in 969 (Meteora, Metamorph. MS. 565, John Climacus). Besides the intrusion of uncial letters, some other characteristics of the earliest minuscule were modified during the 10th century. Rounded breathings, ", are first found in manuscripts of the last half of the century, interspersed with square ones. From about 925 the practice of making the writing hang from the ruled lines began to prevail. Although in most manuscripts abbreviations were confined to a few forms used at line ends only, a few copies dated in the last part of the century used nearly all the conventional signs.

In spite of these developments—the gradual disappearance of pure minuscule and the other changes that accompanied it—the same general styles of writing persisted until about the end of the 10th century. Broadly considered, three styles can be distinguished. There is a rather primitive-looking, angular, cramped style that may perhaps be associated with the Stoudion monastery, in which a certain number of mainly patristic texts were written *c.* 880–*c.* 980 (*e.g.*, Paris, Bibliothèque Nationale, MS. grec 1470, a menologion of 890). Secondly, there is a plain, neat, workmanlike style (seen in a commentary on Gregory of Nazianzus copied in 986 that is preserved in the Bibliothèque Nationale at Paris), which continued in use at least until the end of the 10th century. In it were written several of the important classical manuscripts that are now the oldest texts of some ancient Greek authors (*e.g.*, Aeschylus, Sophocles, Aristophanes) but are unfortunately not explicitly dated. Thirdly, a consciously elegant, even mannered, style was used in books made for the imperial library or for wealthy dig-

nitaries, but it is not found before the early years of the 10th century (seen in a copy of Basil on Isaiah in the Bodleian Library that is dated 953). All these styles, which have many variations and are by no means always distinct from each other, are found at least until the end of the 10th century. Their one common characteristic is a crispness and individuality that distinguishes them from writing of the next period.

Formal minuscule, 10th to 14th centuries. From about the middle of the 10th century, a smoother, almost mechanical appearance can be noticed in an increasing number of manuscripts; the hands seem more stereotyped, less individual. They are not immediately distinguishable from the plainer styles of the earlier part of the century, and their evolution during the next four centuries was very gradual. A few distinct types can be singled out from time to time. A bold, round, heavy liturgical style, fully established in the 11th century, was one of the most enduring types (*e.g.*, London, British Museum Add. MS. 19,352, a psalter of 1066); it became more and more stereotyped and mechanical until, in the 15th century, a branch of it was transplanted to Italy.

Auct. E.2.12, fol. 80).

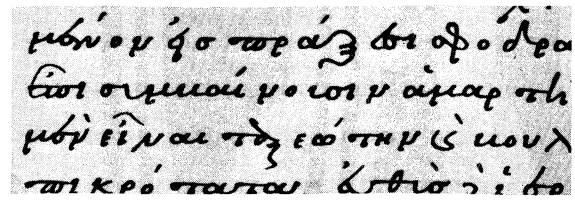
The style most widely used for biblical and patristic texts from the end of the 10th century, probably mainly in monastic houses in Constantinople, was one with plain, neat, rounded letters; this style became known as *Perlschrift* from its likeness to small, round beads strung together. A very plain, businesslike, rather staccato style was used in manuscripts with musical notation, most commonly in the 12th and 13th centuries (*e.g.*, Leningrad, Bibl. Publ. MS. 789, a sticherarion of 1106).

Manuscripts written outside Constantinople are recognizable, if at all, usually by a rougher, provincial appearance. Only two styles can be assigned to a specific provincial centre. One, a small unpretentious hand used by St. Nilus, the founder of many monasteries in south Italy at the end of the 9th century, was used for a time by others in that part of the world (*e.g.*, a copy of the works of Dorotheus made by Nilus in 965). Later, in the heyday of the reorganized Greek monasteries there in the 12th century, another elegant, rather mannered style, which almost certainly had its origin in Constantinople, is nevertheless often found in manuscripts known to have been written in south Italy and Sicily (*e.g.*, Paris, Bibliothèque Nationale MS. grec 83; Gospels copied in Sicily in 1167).

These particular styles, however, are not really as typical of the period as the less distinctive plain hands in which the majority of the manuscripts are written, at least in the 11th and 12th centuries (*e.g.*, a collection of canon law copied in 1042 in the Bodleian Library).



11th and 12th century plain hand. Collection of canon law, 1042 (Bodleian Library, Oxford; MS. Barocci 196, fol. 253).

The comparatively uniform type of writing of which all these were minor variations was remarkably enduring and widely dispersed, but, from the 11th century onward, certain changes may be observed that help to date manuscripts written in all types of formal minuscule. One change in its general appearance may be noticed as the 12th century advances: an increasing lightness of touch and a lessening of the closely knit, rather thick appearance that is characteristic of the 11th century. But the most noticeable change in this period is the breakdown in the evenness and regularity of the writing, which is partly attributable to the influence of documentary and the later personal hands. It is not, however, entirely so attributable, for a tendency to enlarge some letters out of proportion to the size of the rest is seen in a small way in some of the more personal hands of the earliest period. But it is rare in formally written manuscripts, only gradually becoming more general until, in the 12th and 13th centuries, it is the most noticeable feature of even the most formal hands (*e.g.*, a synaxarion, or a short narrative of a saint's life, copied probably in 1329). In the 14th century and later, there was a return to less flamboyant ways with the tendency to imitate earlier models more closely, but the habit of enlarging some and diminishing the size of other letters never died out.

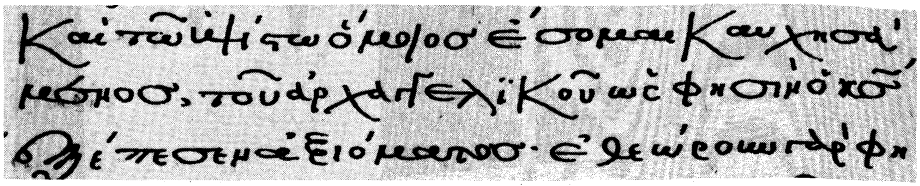
Changes dating from the 11th century

In the actual forms of letters used in these formal styles, there was practically no change; very occasionally, from the end of the 10th century onward, one of the "modern" forms of letter normally confined to personal hands found its way into a formal manuscript. Much the same is true of ligatures. The tendency from the 11th century onward is to use ligatures and to join letters less automatically than in earlier times. The permissive rules and most of the forms remain unchanged, for, already in the 10th century, most of the distorting forms (notably those in which the ε is represented only by a C-shaped stroke; e.g., for σε) were well established, and in formal manuscripts these, with the earlier forms, continued in use until they were illogically taken over by the first printers of Greek. Time did, however, gradually increase the tendency to join letters by insetting them in or superimposing them upon each other. Abbreviations were even more conservatively used, only the oldest conventional forms being admitted, and often only a very few and those only at line ends.

The rule that the writing should hang from the ruled lines, already applied in most manuscripts by the mid-10th century, became invariable by the middle of the 11th. Square breathings (used indiscriminately among the round ones) were gradually eliminated, though they did not completely disappear from formal manuscripts until the middle of the 12th century. The practice of joining accents with breathings and also with the letters to which they belonged spread from personal hands to formal writing in the 13th century, but it was far more often avoided altogether.

Apart from the actual writing, one development is common to all manuscripts written in this period: the use of paper instead of vellum, which occurred first perhaps in the late 11th century and was common by the 13th century whenever economy was a major consideration.

These are the main criteria by which a formally written manuscript can be assigned to an earlier or a later part of this period. But the problem of distinguishing different styles and their dates, and their places of origin, remains most difficult for these Greek manuscripts.



12th and 13th century formal hand. A synaxarion, probably AD 1329 (Bodleian Library, Oxford; MS. Auct. E.5.10, fol. 73v).

Personal hands, 12th to 14th centuries. From the beginning of minuscule, there were obviously educated individuals who occasionally copied texts for their own use in a formal hand that nevertheless had a distinctive personal flavour; indeed, professional scribes occasionally used a less formal style than usual. Several dated examples of this type of hand survive from the 10th, 11th, and early 12th centuries, but they are rarities. Toward the end of the 12th century, however, the prosperity and comparative stability of the Comnenan age (named from the dynasty of Byzantine emperors bearing the name Comnenus), with its brilliant literary and artistic achievements, gave way to increasing internal chaos and the hostile encirclement of Byzantium that was a prelude to the Fourth Crusade and the sack of Constantinople by the Western powers in 1204. Scholars perhaps already felt the pinch of poverty, which naturally grew greater during the exile of the Byzantium court (1204–61) and culminated in the economic crises of the 14th century.

Copying by scholars

Certainly, a change in writing habits began slowly to take place. Instead of commissioning professional scribes to copy manuscripts, some scholars began to make copies for themselves, and, in place of the smooth, mechanical styles of the professionals, they used the sort of writing that they presumably already used for personal notes. This was an adaptation (for greater clarity) of the type of writing that had been standardized in official documents from the beginning of the Byzantine period. Its chief characteristic was the greatly exaggerated size of certain letters or parts of letters, particularly letters with rounded bows such as β, ε, ζ, θ, κ, ξ, ο, υ, φ, and ω, and the excessive size of these letters is made to look even more unbalanced by some exceptionally small forms of, for example, η, ι, ν, or ρ. This essentially unbalanced, "wild" look was transplanted to literary manuscripts written by scholars for their own use.

Along with this exaggerated contrast in size between letters, they took from the documentary hands several new forms of letters that had gradually evolved from the originally common forms of both hands. In the 12th century the new scholarly hands began to use with separate small bows; , with a broken back; , which had lost its high first stroke; and , which had dropped its first long downstroke; and, by the end of the 13th century, , with a short embryonic tail. The old forms of ligature were kept basically the same but, in some cases, were reduced to a barely recognizable minimum (*e.g.*, or for ει) and, in others, distorted by the general flourishing tendency of the script (*e.g.*, for επ).

Use of abbreviations

Abbreviations were naturally used with great frequency in all positions; the ancient conventional signs for suppressed syllables, which had acquired rounded and more flourished shapes, were used alongside a certain amount of "arbitrary" abbreviation in which a large part of a word was omitted and replaced simply by a general sign that some abbreviation had taken place.

Accents and breathings joined with each other, with letters, and with abbreviation marks are found earlier and more frequently in scholarly than in formal manuscripts. The only exception to the rule of round breathings in this type of manuscript is in cases of deliberate archaism such as practiced by Demetrius Triclinius (died *c.* 1340).

One of the earliest datable examples of these scholarly productions is the copy of his commentary on the *Odyssey* (Biblioteca Nazionale Marciana, Venice) written *c.* 1150–70 by Eustathius, the scholar-archbishop of Thessalonica. In the 13th century, the exaggeration of specially round features reached its height (*e.g.*, in a copy of Euthymius Zigabenus on the Psalms, of 1279 [Bodleian Library, Oxford; MS. Roe 7]), while, in the 14th century, the tendency, as in the formal styles of writing, was toward less ebullience and exaggeration, and the writing of scholars such as Triclinius is compact and sober (*e.g.*,

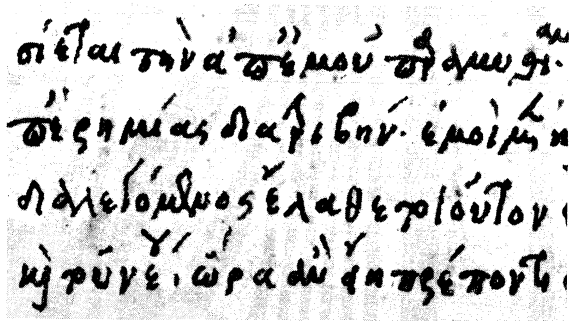
his copy of Aphthonius and other grammatical works, of 1308). For these hands the problem is not to discover centres of writing or styles for different uses but to identify the hands of individual scholars.

The Italian Renaissance. By the end of the 14th century, Italian scholars were learning Greek, and they were bringing back Greek manuscripts from Constantinople. At this time Greek scholars had also begun to teach in Italy. The Greek that the earliest Italians learned to write was a clear, simple style taught originally by Manuel Chrysoloras (died 1415). But, although they copied a number of manuscripts for themselves in this hand, the style had no influence beyond their small circle. Before long, Greek scribes began to go to Italy, and both scholars and scribes arrived in increasing numbers as the Turks pressed in round the Byzantine capital until it finally fell in 1453. They brought with them, naturally, the two styles of writing that had persisted throughout the history of the empire. On the one hand, professional scribes such as Joannes Rhosus (died *c.* 1500), the majority of them from Crete, copied an astonishing number of manuscripts in the formal, now glib and stereotyped "liturgical" style of writing (*e.g.*, London, British Mu-

Copies in "liturgical" style

seum Harl. 5658, an *Odyssey* copied by Rhosus in Rome in 1479). On the other hand, scholars such as Janus Lascaris continued to write in a mannered personal style (*e.g.*, a letter of Demetrius Chalcondyles of 1488 in the Vatican Library).

By courtesy of the Biblioteca Apostolica Vaticana



Renaissance personal hand. Letter by Demetrius Chalcondyles (autograph), 1488 (Vatican Library; Lat. 5641, fol. 2).

It was on the scholarly hands that Aldus Manutius and other early Italian printers of Greek based their types. But perhaps the most enduring of all styles was that of a group of Cretan scribes who made their way to France and were employed by Francis I in his library at Fontainebleau. The writing of one in particular, Angelus Vergecius (*e.g.*, his copy of Manuel Philes made in 1564

in the Bodleian Library), was used as a model for the French Royal Greek type, which has influenced the form of Greek printing down to the present day. (R.Ba.)

LATIN HANDWRITING

Ancient Roman styles. *Rustic capitals.* The Latin and vernacular handwriting of western Europe descends in an unbroken line to the present day from the point at which it is first observed, in the 1st century AD. The script used throughout the Roman Empire at that time for books and occasionally for formal documents is known as rustic capitals. The pen was cut with a broad end and held so that its thickest strokes fell at an oblique angle to the line of writing, and it was lifted several times in the formation of a single letter. The rustic capital alphabet is "majuscule," in that all the letters are contained between a single pair of horizontal lines. The use of this elaborate script, whose letter forms were the natural outcome of using a broad pen held obliquely, was extended to certain sorts of inscription on stone and other materials, and it is called rustic only by comparison with the magnificent square capitals characteristic of Roman imperial inscriptions, whose forms were governed by the use of the chisel. Square capitals were seldom used in manuscripts except for titles. Rustic capitals continued in use for literary manuscripts until the 6th century, especially for texts of Virgil, but thereafter they appear only in titles, down to the 12th century.

Roman book hand

Cursive capitals. The business hand of the 1st century, used for correspondence and for most documents, private and official alike, is known as cursive capitals. Here the pen, cut to a sharp point, was held at the same oblique angle but was lifted less often, and this "cursive" handling automatically produced new and simpler letter forms such as ∂ (two strokes) for D (three strokes) and ϵ (two strokes) for E (four strokes). Some of these new letter forms are "minuscule," in that parts of them ascend or descend beyond the body of the letter (h,q) instead of being confined between a pair of lines, as in the majuscule rustic capitals (H,Q).

Roman business hand

From the 2nd to the early 4th century, parchment was replacing papyrus as the standard writing material for books, and the codex was replacing the roll as their standard form. The evidence that survives from this period, during which biblical and other Christian literature was beginning to be copied extensively, is fragmentary, and its interpretation is still controversial. The main line of development, however, is clear enough. The elaborate letter forms of rustic capitals, with their numerous pen lifts, began to be abandoned, and experiments were made with new book hands in which the simplified letter forms of cursive capitals were written with a broad pen, sometimes held obliquely in the traditional way and sometimes held "straight," so that its thickest strokes fell at right angles to the line of writing. It was probably the use of a straight pen that produced, for example, the conversion of cursive capital ∂ (axis oblique) into the fully minuscule d (axis vertical).

Uncials, half uncials, and cursive minuscule. At the end of this period of transition, in the 4th and 5th centuries, when the evidence becomes more abundant, two new book hands and a new business hand are found in use. The older of the book hands, called uncials (the name dates only from the 18th century), was originally written with a slightly oblique pen; but, from the 6th century onward, a straight pen was used, and the hand began to look rounder and more contrived. Although it incorporates several of the cursive letter forms (𝒹, ℰ, h) of cursive capitals and has two forms peculiar to itself (𝒶, 𝓂), it also preserves certain forms, such as B, N, R, S, which differ only a little from the forms of rustic capitals; and all three kinds of letters are treated as majuscules, being confined as far as possible between one pair of lines.

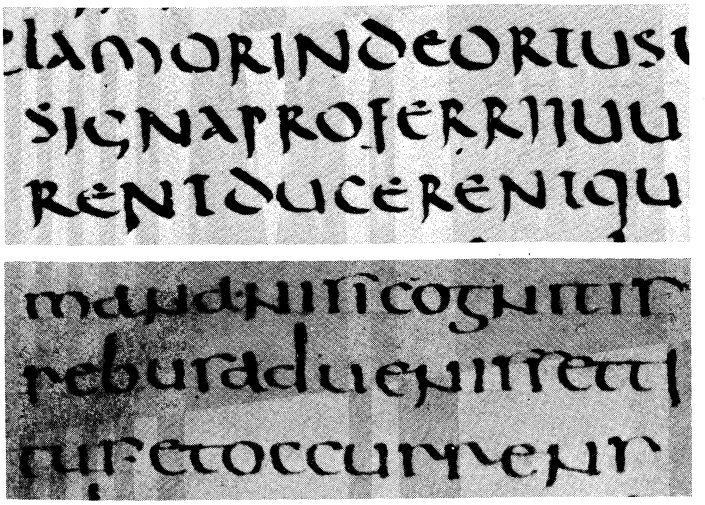
From the 4th to the early 7th century, most Christian books—biblical, patristic, and liturgical—were written in the uncial script, and even for pagan literature it almost entirely superseded rustic capitals. It survived the collapse of the Roman book trade. And, after the 6th century, when the production of all books, pagan as well as Christian, was taken over by the church—notably by the monasteries, such as the Vivarium founded in southern Italy by Cassiodorus, a scholar whose aim was to perpetuate Roman culture, and the houses that observed the Rule of St. Benedict—uncial script survived in many centres, especially for biblical and liturgical texts, down to the 9th century. Thereafter, like rustic capitals, uncials



4th–5th century Roman book hands.

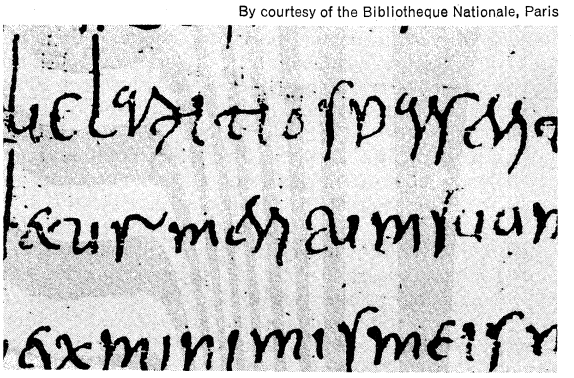
were used only for titles, and they, too, disappeared in the 12th century.

The younger of the two new book hands is called half uncial. This script was less popular than uncials and never broke their monopoly of biblical and liturgical texts, although like them it was still being written in the 8th century and even, as a display script for certain purposes, in the 9th. The artificial name half uncial tells nothing about the origin or nature of the script. It differs from early uncials in being written with a perfectly straight pen. One letter (N) remains more or less unchanged from the capital form, but the rest of the alphabet is cursive in origin. The letter forms that differ most from uncials are *a, b, d, g, m, r, s;* and the alphabet as a whole is frankly minuscule, since no attempt is made to confine it between a single pair of lines.

Cursive minuscule as a business hand

The new business hand of the 4th century and after is known as cursive minuscule. Like cursive capitals it was written with a pointed pen, but the pen was held more or less straight. It, too, is a frankly minuscule alphabet and uses basically the same letter forms as half uncials, although the frequency in cursive minuscule of ligatures between letters tends to conceal the fundamental likeness between the two hands.

By courtesy of the Bibliotheque Nationale, Paris



Cursive minuscule. Avitus of Vienne, 6th century AD (Bibliothèque Nationale, Paris; Lat. 8913 and 8914).

The letter forms that distinguish cursive minuscule and half uncials from rustic and cursive capitals and from uncials were evolved during the obscure period between the 1st and 4th centuries. The question of whether these forms were evolved in the sphere of the book hands or of the business hands is still undecided, but, whatever their origin, their importance for the subsequent history of European handwriting is paramount. They provided the material on which the Caroline (Carolingian) minuscule, first developed in the late 8th century, was based; and that script dominated Europe, in spite of severe modifications, until the end of the Middle Ages. Only in one other period were new letter forms evolved, between the 13th and the 15th centuries, in the group of scripts known as Gothic cursives; and the influence of these late innovations was ultimately cancelled out, thanks to the revival of Caroline minuscule in a pure form by the Italian Humanists at the beginning of the 15th century.

(T.J.Br.)

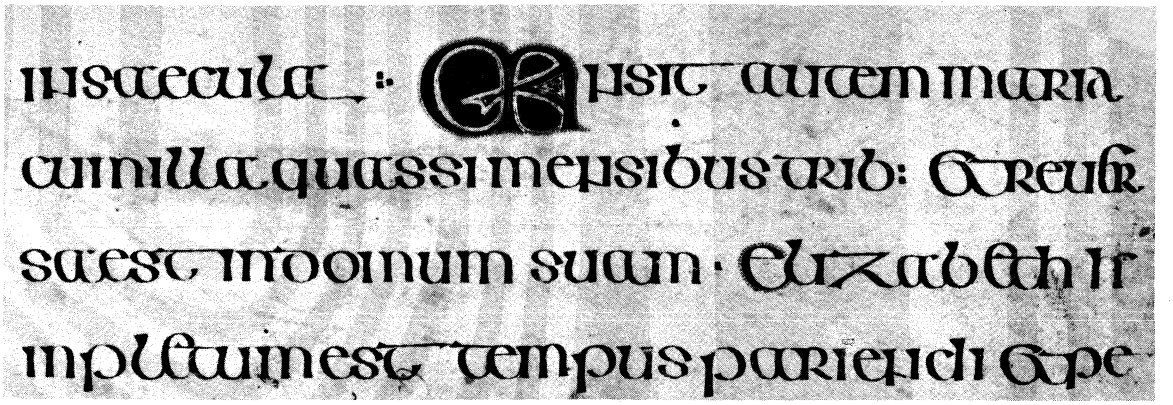
The Anglo-Celtic, or Insular, and other "national" styles (5th to 13th centuries). From the 5th century the relaxation of imperial Roman authority brought on a reassertion and growth of native cultures—that is, wherever the people were not wholly occupied in a savage struggle against barbarians for mere existence. The most isolated places such as the province of Britain responded strongly to this opportunity and at the same time were able to conserve important elements of the Roman civilization. With Ireland, which was never under occupation by the legions, it offered during Europe's darkest age comparative peace and shelter for the development of the richest and most original of book styles.

The Insular manuscripts were produced at monasteries that were often on a barren rock in the sea or at an equally inaccessible site. According to tradition, the earliest centre of Christian learning in Ireland was established by the Romano-British apostle St. Patrick (flourished 5th century AD). A great successor, St. Columba, or Columcille (*c.* 521–597), whom legend credits with divine scribal powers, founded monastic houses at Derry and Durrow and then journeyed to the Inner Hebrides to found one on the lonely island of Iona in 563. St. Columban, another Irish missionary, in much the same period was founding monasteries on the Continent: *c.* 590 in Gaul (modern France) the Burgundian centre Luxeuil, from which Corbie in Picardy was organized, and St. Gall in Switzerland and Bobbio in Italy about the years 612 to 614. From Iona a daughter house was founded in 635 on St. Cuthbert's holy isle of Lindisfarne just off the Northumbrian coast of England. To the south the Northumbrian monk, later abbot and saint, Benedict Biscop (*c.* 628–690) established the twin monasteries of St. Peter at Wearmouth in 674 and St. Paul at Jarrow in 682. He endowed them with splendid collections of books and pictures gathered during repeated visits to Rome, so that, in the late 7th and early 8th centuries, they comprised the most flourishing centre of Christian scholarship in western Europe and the meeting place of Hiberno-British and continental influences.

Anglo-Celtic monastic centres of manuscript copying and illumination

For the fine books made in the Anglo-Celtic centres, the majuscular script called Insular half uncial was deemed suitable rather than the pointed, more cursive Irish minuscule used for documents and vernacular texts. There is a high degree of conformity, attesting to their stylistic maturity, among such manuscripts as the Book of Kells (Trinity College, Dublin) and the Lindisfarne Gospels (British Museum, London) individual as they are in detail and ornament. After all, there is room for infinite variation where, in one-quarter of a square inch, 158 interlacements have been traced unerringly—by angels, it is said. The Book of Kells, Codex Cenannensis to paleographers, was probably produced at Iona around 800. It has 339 leaves, 13 by ten inches (33 by 25 centimetres) of noble script in single column, jet black on well-made parchment, through which runs the most spirited and colourful of ornamentation, ranging from the red-dotted outlining of letters, which is as much a feature of the style as the wedge-topped ascenders, to the wildly extravagant full-page initials at the opening of Gospels. The other masterpiece of Anglo-Celtic calligraphy and illumination, the Codex Lindisfarnensis, was written in honour of St. Cuthbert shortly after his death in 687. It displays the same lively inventiveness, the love of fantastic animal and bird forms (zoomorphs), intricate interlacing, and even, rhythmic script, set off by generous margins.

The earliest of all extant manuscripts of the Insular style is the *Cathach* ("Battler") of St. Columba (Royal



Insular Half Uncial. The Book of Kells, *c.* AD 800. In the collection of Trinity College, Dublin.
By courtesy of The Board of Trinity College, Dublin

Irish Academy, Dublin), who, according to legend, wrote it himself and, in the judgment of scholars, may actually have done so. Housed in its *cumhdach* (a sort of ark), it was carried into battle to ensure victory.

Besides the proud witness of such books as these to the Anglo-Celtic contribution, there were also the productions of continental centres influenced by St. Columban and his disciples, as well as books mainly in the Roman tradition but carrying the unmistakable sign of Insular influence. For instance, there are three that scholars believe were written in the 7th century at Bobbio, in the monastery of St. Columban. They are Codex Usserianus Primus, now a treasure of Trinity College, Dublin, and two manuscripts preserved in the Biblioteca Ambrosiana, Milan, known as Codex Ambrosianus C.26 sup. and Codex Ambrosianus D.23 sup. There is another, Codex Amiatinus (Biblioteca Medicea-Laurenziana, Florence), of 1,030 leaves measuring 20 by 13½ inches (51 by 34 centimetres), made in Northumbria in the 8th century. It is continental Roman in style with no concession to the Insular habit of ornamentation. This is understandable, for it was designed for presentation to the pope.

Though the Insular minuscule was ready to hand, the majuscular half uncial as the senior script was always given the place of honour and the preference for the fine Latin books of the Anglo-Celtic monasteries. Nevertheless, by the 8th century the minuscule was developing into a disciplined book hand, as seen in the copy of Bede's *Historia Ecclesiastica* (*c.* 731; Cambridge University Library). The spiky, ligatured, compactly written style migrated early to the Continent and, by the beginning of the 8th century, was at home in the Anglo-Saxon foundation of Echternach, in Luxembourg. Fulda and Würzburg, in Germany, were other important centres abroad of Insular culture and book production in this style.

Insular minuscule. *Historia Ecclesiastica*, by Bede, 8th century AD (British Museum, London; Cotton Tiberius C.11).

Merovingian and Visigothic scripts

The Merovingian, in France, and the Visigothic, in Spain, are two more varieties of minuscular script that grew out of Latin cursive after the withdrawal of the Roman authority. In the Luxeuil monastery, in Burgundy, the minuscule attained in the 7th century the characteristics of a fine book hand, but for only a short period, when the reforms under Charlemagne took effect. In the Iberian Peninsula, the Visigothic style was in use from at least the 8th to the 12th century. It has the verticality of emphasis that is common to the other hands out of the same cursive background, when deliberately written, with weighted ascenders carefully topped by flat serifs.

The South Italian script of the style called Beneventan, nurtured in the motherhouse of the Benedictine Order at Monte Cassino, was the "national" hand that rose to the status of calligraphy and held its position well into the 13th century, an active literary life of more than 500 years. It has a peculiar jerky rhythm and retains individual cursive forms, which, together with the abundance of abbreviations and ligatures, make reading difficult.

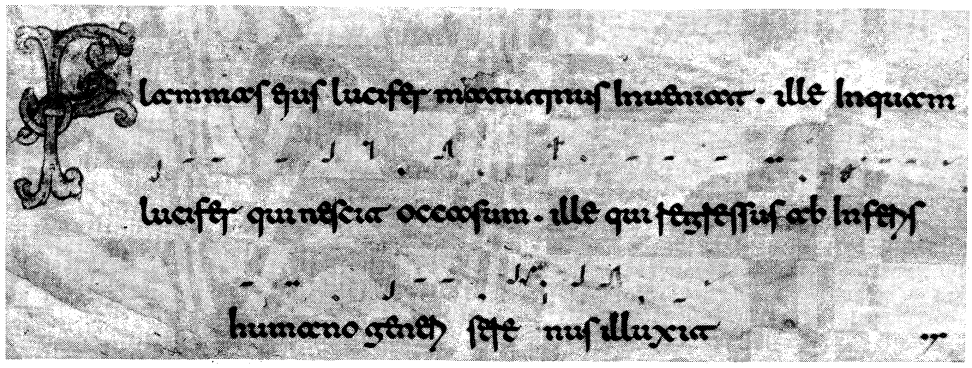
Visigothic minuscule. "Passionale," AD 919 (British Museum, London; Add. 25,600).

Carolingian reforms in the scriptorium (8th and 9th centuries). The literary reforms carried on in the latter part of the 8th century and early 9th century by order of the Holy Roman emperor Charlemagne set the highest of standards for the making of books throughout his Western Empire. The extensive educational program, looking forward to new authorized versions of the Vulgate, the missal, and other liturgical works, he placed in charge of the learned English cleric Alcuin of York. The Emperor persuaded Alcuin to leave his position at the head of the cathedral school of York and the excellent library he had gathered there, first to become master of the palace school at Aachen, then at Tours as abbot of St. Martin's to conduct the literary activities centred at the well-established scriptorium (writing room) there.

Contributions of Alcuin

Before taking up the abbacy in 796, Alcuin was responsible for, or at least inspirer of, the most precious of Carolingian codices, the so-called Golden Gospels. These were a series of illuminated masterpieces mainly written in gold and often on purple-stained vellum. The most famous is the Godescalc Evangeliarium (Bibliothèque Nationale, Paris), written before 783 for Charlemagne, the body of the text in uncials and the dedication in Carolingian minuscule. The most luxurious is the Saint-Médard Gospel Book (Bibliothèque Nationale, Paris), written entirely in gold uncials and illuminated with full miniatures, initials, etc. in gold and silver on purple ground.

Alcuin carried forward the work of the St. Martin scriptorium in the spirit of a true classical renascence. Each variety of traditional letter form was studied with a view to finding its norm by careful comparison with



Beneventan script. Exultet Roll from Monte Cassino, Italy, late 11th or early 12th century AD (British Museum, London; MS. 30377).

archetypes in ancient monuments and books. Thus, the square capitals, at the top of the hierarchy of scripts, were modelled on Augustan inscriptions. For rustic capitals (*capitales rusticae*), the reformers adopted the style of those used for the text of such fine old codices as the Virgil fragment now in the Vatican. The roman uncial was restored to its simple dignity, as in well-made books of the 6th century, and the minor, or half, uncial was likewise restored to the plain elegance of that earlier period, after the degeneracy of the 7th century.

The model for the most valuable and characteristic of all the Alcuinian contributions, the Carolingian minuscule, has never been precisely determined. It may well have been a local variety of cursive or, more probably, a mixture of half uncial and cursive, in which Alcuin discerned the possibilities of his clear, round, flexible but disciplined script, comfortable to both scribe and reader. For, as regularized at the scriptorium of St. Martin, the minuscule was written with the shaft of the pen pointing somewhat to the right instead of straight back over the shoulder; though the letters were formed deliberately, even and round, stroke by stroke the same way every time by rule, the writing brought relative ease for the hand and eye. With the years some cursive features became more prominent—*e.g.*, a tendency nearly to join certain letters and an occasional hint of "italic" in the slightly sloping, even, well-spaced lines. The incipits (the opening words of the text) were celebrated by means of display letters and a decorative initial that might come from any one of a number of sources, including Insular, Byzantine, and Merovingian scripts. Otherwise, the classic calm was maintained, supported by the superb ar-

Gospels of Lothair, *c.* AD 850 (Bibliothèque Nationale, Paris; MS. Lat. 266, fol. 19).

rangement of material on the pages and the excellence of the craftsmanship in carrying through every detail from the manufacture of the skins to the restrained illumination. The crowning achievement of the Tours school of scholars, scribes, and artists was reached in the mid-9th century, under Alcuin's successors, in the Gospels of Lothair (Bibliothèque Nationale, Paris).

There are observable variations among the different Carolingian schools, but these are generally in small details. The most surprising departure is the Utrecht Psalter (University Library, Utrecht), written at Rheims, in rustic capitals and illustrated with fluent pen drawings in the Hellenistic fashion. Apparently, the whole work was devotedly copied in the 9th century from an old model.

The black-letter, or "Gothic," style (9th to 15th centuries). Carolingian minuscule remained the unrivalled book hand of western Europe through the 9th century, or nearly so. Then a trend away from the official imperial standards set in. It can be observed progressing in the manuscripts written at St. Gall, in Switzerland, near the end of the 9th century and during the 10th. There is a tendency toward lateral compression of the letters. This begins as the natural result of an easier motion of the pen held in a slanting position—*i.e.*, with the shaft out to the side rather than pointing back over the right shoulder. At such an angle of holding the pen, a nib cut straight across does not deliver body strokes of full thickness to the letters. But the scribes learned to adjust this matter by cutting the pen's writing edge obliquely so that it would be parallel to the top of the page anyway; even though the shaft was held in the slanting position, the nib so cut would yield a perpendicular stroke of maximum width. They were led on by the attractive novelty of bolder and bolder contrasts that eventually were to appear to the eyes of the Italian Humanists in the Renaissance so brutal as to deserve the bad name of Gothic. Nevertheless, the more condensed, compact writing allowed significant economies in the amount of time taken in writing the books and the quantity of materials used and, therefore, in the cost of finished manuscripts.

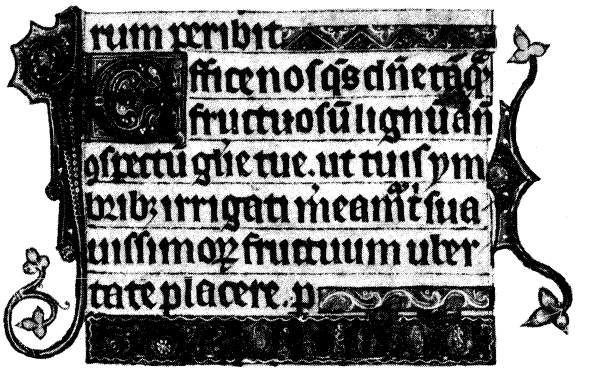
Gothic book hand. *Legenda aurea* by Jacobus de Voragine, 1312 (British Museum, London; Add. 11,882).

Lettre de forme

Black-letter style of increasing density deepened the "colour" of the page and imparted to the northern, advanced, formal variety of book hand a matted aspect, or fanciful likeness to woven fabric, that gave rise to the name Textura. It is called by paleographers *littera textualis formata* or *lettre de forme*. As the script developed through the 11th and 12th centuries in Germany, France, and England, its curves broke into angles. During the 13th and 14th centuries, the size of writing was generally reduced. It became stiffer, and though in the following century (its last of undisputed sway) the script regained size, the proportions were disagreeably narrowed, and the letters, in lines as rigid and mechanically perfect as a picket fence, have angles sprouting hairlines apparently added with a crow quill afterward. Of this species of formal black-letter book hand, two kinds are distinguished by paleographers. One stands flat and unseriffed on the base line and is known as *textus prescissus*. The other is completed with square or diamond-shaped feet and is called *textus quadratus*. Though the former, and earlier, has superior claims for the calligrapher, the latter is the variety that was carried into printing types and hence into much wider use.



Textus prescissus by Brother Tickhill. "Beatus" page from the Tickhill Psalter, *c.* 1310. In the collection of the New York Public Library.

By courtesy of the New York Public Library, the Spencer Collection, Astor, Lenox and Tilden Foundations

In Italy the writing during the same period took on weight, but the curves of comparable book script never became angles. The senior script there was the Rotunda, heavy but not pointed. The form persisted for liturgical work both as writing and printing type until late in the Renaissance.

Lettre bâtarde

The north and the south had, of course, their other kinds of writing for court and business or personal uses. A cursive hand that literally flourished in France, Flanders, and England rose to favour in the 15th century as a vernacular book script. This *littera bastarda*, or *lettre bâtarde* as it is termed in the vexed nomenclature of paleography, for all its high style as attained in fashionable books, was close kin to the epistolary "running secretary" commonly written by northern Europeans and early American settlers until it grudgingly yielded in the 17th century to italic script.

The scripts of Humanism (14th to 16th centuries). Under the inspiration of the 14th-century Italian poet Petrarch, who started the collecting of ancient manuscripts, coins, medals, and other "antiques," the essentially literary movement called Humanism engaged a group of scholars at Florence in the latter part of the 14th century and opening decades of the 15th. Their growing enthusiasm for antiquity led them on an ever-widening search for Latin books and ancient monuments, in order that they might restore the lost heritage of Rome. Classical authors written in the clear Carolingian minuscule with display lines in lapidary style (*i.e.*, in the style of ancient inscriptions cut on stone) appealed to them as though straight from the time of Cicero instead of from the 10th to 12th centuries. Reverently, Coluccio Salutati, the late-14th-century chancellor of Florence who followed Petrarch as leader of the movement, and his fellow Humanists imitated the old script, which they spoke of as the *lettera antica* to distinguish it from the ordinary *moderna* that belonged to the black-letter style.

Lettera antica and *moderna*

Lettre bâtarde by Henri de Ferrieres. *Livre du Roy Modus et de la Reine Ratio*, *c.* 1435 (Pierpont Morgan Library, New York City, M.820, fol. 16ᵛ).

Two protégés of Salutati are credited with developing, on the basis of these studies and experiments among old manuscripts, the two fundamental scripts of Humanism. Poggio, at the very beginning of the 15th century, produced the round, formal writing that, after further polishing by a generation of scribes, served the new art of printing as prototype of "roman" fonts. He promptly followed up this achievement by introducing into his manuscripts the square capital letters as used on ancient monuments. Later in the century, the rage for epigraphic inscriptions brought such enthusiasts as Cyriacus of Ancona, Felice Feliciano of Verona, and his fellow townsman Giovanni Giocondo into the field and, from Padua, Giovanni Marcanova, Bartolomeo Sanvito, and Andrea Mantegna. They compiled the fruit of their researches in great *sillogi*, or anthologies, which, among other uses, served calligraphers with precious authoritative patterns for letter forms, ornament, and the correct spacing and placing of all display elements in their books. Feliciano, a calligrapher fond of ornament and fertile in invention, about 1460 demonstrated for the first time how to construct the monumental roman capitals according to geometrical rules.

Humanistic scripts.
(Top) *De oratore*, by Cicero, calligraphy by Poggio, *c.* 1425 Laurentian Library Florence; Ms. Laur, Plut. 50.31. C. 166).
(Bottom) *Cicero*, calligraphy by Niccolò Niccoli, *c.* 1423 (Biblioteca Nazionale Centrale, Florence; Soppr., 1.1.14).

The second style of Humanistic script appears earliest in the writings of Poggio's friend Niccolò Niccoli, who was also an accomplished scribe. His slightly inclined cursive, written with a fairly narrow rounded nib at a good rate of speed, was to be to the printers' "italic" what the Poggian hand became to their "roman." Niccoli's innovation employed movements and rhythms close to those of the ordinary black-letter cursive familiar in everyday affairs. Indeed the script contains a sprinkling of current black-letter mannerisms and lends itself similarly to the joining or tying together of letters. The special character of this *antica corsiva* results from the narrowing of the bodies of letters due to the rapid up and down movement of the pen, facilitated by its being held with the shaft pointing at an angle away from the shoulder instead of straight back, producing this ✕, not +. As in italic fonts to this day, the form of *a* is distinctive; and *f*, *g*, *k*, and *ſ* (long *s*) are all more or less reminiscent of black-letter current habits. For his headings Niccoli preferred roman capitals "italicized" by a slight inclination to the right.

Antica corsiva

Both scripts were at once taken up and spread by other able scribes working at Florence in the first half of the 15th century, of whom the work of Giovanni Aretino, Giacomo Curlo, and Antonio di Mario, among others, is well recognized.

Poggio himself in 1403 had promptly carried his new script to Rome, where he later became papal secretary. Both scripts were devoted exclusively to the service of Latin literature, but there was a difference. Poggio used his hand as a calligrapher, while Niccoli used his as a copyist. The manuscripts of the former are set forth on fine parchment with meticulous care to formal details, such as even lines at the right-hand margin, and with handsome embellishment. Those of the latter are on paper, compactly and rapidly written, with attention to legibility and textual accuracy above all. There is an interesting parallel in the printed books of the following century. Ambitious Renaissance folios are set in fine roman types, while the well-edited but cheap little student books are just as naturally set in italic.

Typographic printing displaced the copyists. At the same time it gave impetus and new significance to the work of calligraphers. They accepted the challenge of mechanized writing and for a while responded by turning out the finest of Humanistic masterpieces. In the late 15th and early 16th centuries, the Paduan Sanvito and Pierantonio Sallando of Mantua, for instance, not only wrote the round Humanistic script in a fashion worthy of the richest miniatures and illumination, but they also honoured the slender proportioned "italic" script by promoting it to a place in some of their most proud and precious manuscripts.

Influence of printing

Sanvito's folio and octavo classics in the Humanistic cursive are also celebrated for vellum pages stained purple, yellow, green, or salmon pink and for lines of inscriptional capitals alternating gold, blue, lake, purple, violet, and green. The *antica corsiva* perfected by 15th-century papal scriptors for rapidly inditing briefs issued by the chancery also won its way as the chosen medium of polite correspondence. Thus, in the 16th century, the versatile *lettera da brevi*, or *cancellaresca* (chancery cursive), lively yet disciplined, responsive to wide variety in cut of nib and speed of movement, attainable by the novice and gratifying to the adept either as book or epistolary hand, became a vehicle of the new learning throughout Christendom.

Cancellaresca, or chancery cursive

As written by the early-16th-century calligrapher and printer Lodovico degli Arrighi of Vicenza, the *cancellaresca* can range from eye-arresting contrasts of almost

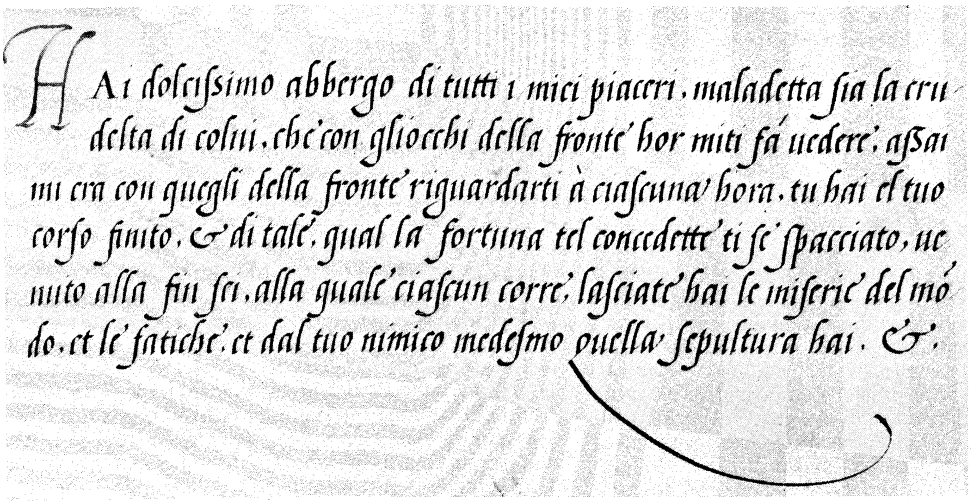
Littera cancellaresca. Brief of Pope Leo X, ascribed to Lodovico degli Arrighi, 1519 (Public Record Office, London; S.P. 1/19).

Gothic thick and thin strokes to a delicate, supple monotone tracery. The ascending letters, instead of terminating in serifs as with Sanvito or Sallando, now wave plumelike to the right, and the descenders are tending to balance them with a swing to the left. In 1522 Arrighi published at Rome his modest though revolutionary work *operina da imparare di scrivere littera cancellaresca*. This, the earliest of printed writing manuals, or copybooks, held out to the public clear, simple directions with woodcut examples and invited everyone to learn in a few days how to write this fashionable hand for themselves. In effect, it announced the end of the era of the scriptorium and the beginning of the era of the writing master. Dependence upon attracting pupils and gaining a reputation with the public was thereafter reflected in the tendency to exploit novel or flashy scripts and extravagant ornament.

Writing manuals and copybooks (16th to 18th centuries). The Arrighi *Operina's* devotion to the chancery cursive is matched in single-mindedness only by Gerardus Mercator's *Literarum Latinarum* (1540). Arrighi's second publication, *Il modo de temperare le penne* (1523), is a more normal performance for the calligrapher, notary, printer, and erstwhile scriptor of apostolic briefs in the role of writing master. Here the scripts described are as follows: *littera a merchanti*, cursive black-letter mercantile hand; *littera per notari*, small cursive semi-black-letter style, slightly inclined; *littera da bolle*, large carefully formed black-letter cursive; *littera da brevi*, chancery cursive; roman capitals, large Humanistic round hand; round black-letter interlaced initials; ribbon initials; large inscriptional roman capitals; large decorated formal Gothic minuscule; large round outline Gothic; *littera formata*, black-letter in two sizes. The specimens are completed with another page of smaller interlaced Gothic initials and two pages of type speci-



Cancellaresca formata by Giovanni Battista Palatino. Manuscript specimen book, *c.* 1550 (Bodleian Library, Oxford; MS. Canon. Ital. 196, fol. 44r).

mens, including the cramped italic as seen in books produced by the Aldine Press in Venice and the free calligraphic style first shown here. This book redresses the balance in favour of the popular scripts.

Arrighi's elder contemporary and possible mentor, Giovanni Antonio Tagliente, writing master to the Venetian chancery, published his *Presente libro* in 1524, two years after the *Operina;* and Giovanni Battista Palatino published in 1540 at Rome his *Libro nuovo d'imparare a scrivere.* Though Tagliente was master of an elegant *cancellaresca*—his "living hand" is displayed in a holograph supplication to the Doge and council of Venice, 1491—as well as of the black-letter hands, he was out of date and prey to the vices of the old professional; *e.g.,* his chancery specimens include a page of script leaning excessively to the right, and facing it is a page of similar script leaning away to the left, almost equally hard to read and useless. Unlike the author's own hand in his 1491 supplication, the woodcut models here are acutely pointed. Palatino at the same time exhibits a rigid, sharp-angled *cancellaresca formata* in his excellent manuscript specimen (Bodleian Library, Canon. Ital. 196 fol. 44r), while his popular manuals offer relatively easygoing models for learners. In particular, the Palatino *cancellaresca romana* is a normal even-toned script, modest as to bulbed ascenders (*testegiatta*) and angle of inclination, displaying in its forms hospitality for *bastarda* variations (*i.e.,* Gothicizing *g, h, k, r*). The fact that Palatino's *Libro nuovo,* besides being the most complete, was the most widely disseminated of mid-16th-century books on writing, bespeaks certain latitudinarian qualities along with marvellous virtuosity. The summit of absurdity in 16th-century writing manuals was reserved for Ferdinando Ruano, a Spanish scribe working in the Vatican Library, whose *Sette alphabeti* (1553) demonstrated by means of diagrams how to construct the chancery letters geometrically.

Chancery cursive attributed to Pierre Hamon. *Navigation,* title page from the Harleyian manuscript, *c.* 1560 (British Museum, London; MS. 3996, fol. 1).

Spread of chancery cursive

The propagation of the chancery cursive abroad was furthered by native manuals too. The Latin letters called italics were introduced into Germany by Casper Neff's *Thesaurium artis scriptoriae* (1549); into Spain by a disciple of Palatino, Juan de Yciar, in his *Recopilacion subtilissima* (1548); into France by Pierre Hamon's *Alphabet de l'invention des lettres en diverses escritures* (1561); and into England by means of *A Booke Containing Divers Sortes of Hands* (1570) by Jean de Beauchesne and John Baildon. This last was a translation of the French senior author's *Thrésor d'escripture,* believed to have been published at Lyons 20 years earlier; since no copy has been found, first place goes by default to the Hamon book.

The pure Italian chancery hand was the favourite of court circles and Humanist scholars through the second half of the 16th century. In England Roger Ascham, mid-16th-century schoolmaster to kings and queens, wrote and taught an exemplary *cancellaresca,* as did the late-16th-century Cambridge don Bartholomew Doding-

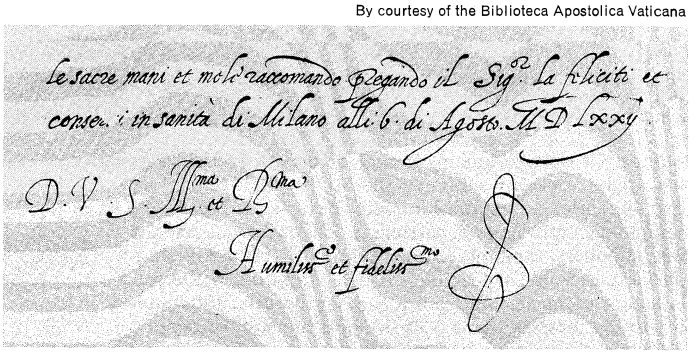
ton. These and other educated Europeans generally wrote the black-letter "running secretary," too, the script of Shakespeare, who gave voice to no more than a sturdy nationalism when he poked fun at the newfangled "sweet Roman hand." For their part, the writing masters, in striving to reach an ever larger public, increasingly emphasized the compromise script intended to bring learners already indoctrinated in the common Gothic cursive to command more readily the fashionable italic style. The *Opera nella quale si insegna a scrivere*, of Vespasiano Amphiareo (Albertacci), had already offered at Venice in 1554 models that combined the overdisciplined strokes of Palatino with elements of black-letter mercantile hands (*e.g.*, loops and running ligatures); to this hybrid *cancellaresca* that he claimed as his own invention, Amphiareo gave the accurate name of *bastarda*. Then Gianfrancesco Cresci of Milan, a Vatican scriptor, published his *Essemplare* (1560), to herald the oncoming Baroque and to reject vehemently the works and ways of Palatino and all his academic sort. He replaced their most stylish broad, chisel-bevelled nib and meticulous building up of disjoined strokes with a narrow, rounded-off pen flexible enough to respond to pressure and fluent in dashing off his much-inclined italic *bastarda* topped off dramatically with bulbous *testegiatta*. It is not too much to say that Cresci's script, with the handsome set of swash capitals (to borrow the typographic term for these free-swinging forms), not only established a revolutionary front for 17th-century calligraphy but also contained the germs of 18th-century "copperplate" and even Spencerian scripts. Cresci, by the way, was the first in Italy to take advantage of the sleek allurements of copperplate engraving, though Giuliantonio Hercolani's *Lo Scrittor Utile* (1574; plates engraved in 1571) was a close rival.

Importance of Cresci

By courtesy of the Biblioteca Apostolica Vaticana



Italic *bastarda*. Letter by Gianfrancesco Cresci, 1572 (Vatican Library; Lat. 6185, fol. 135 R).

The principal French hands of the period were the national black-letter cursive called *lettre françois* or *financière*, used in ordinary affairs, and the aristocratic *italienne bastarde*. In the Low Countries, examples of excellence are provided by Clement Perret in his *Exercitatio alphabetica* (1569), and by Jan van de Velde in his work *Spieghel der Schriftkonste* (1605), the fame of which was carried down through generations of English penmen.

It was the period of elaborate and bold "striking" of decorative figures and fanciful shapes by "command of hand." The writing masters did not regard such ornamental work as mere vain show or necessary proof of

prowess, though it was important in promoting a reputation; they prescribed full-arm flourishing for loosening-up exercises, as teachers later would have pupils perform on mammoth letters or banal push-pulls and oval tunnels.

In Britain and its empire, the *italienne bastarde* was largely disseminated through Edward Cocker's engraved copybooks and manuals. Known variously as the "new mixt current" or the "speedy à la mode," its concessions to the black-letter running secretary include the *e* looped at the top like a latter-day Palmer Method *o* and what has been termed the upside-down *r*, which is easily misread as *u* by Humanistic eyes. The *d* with a backswept stem and the *h* formed of a loop terminating in a wiggle below the line are other black-letter vestiges that gave up slowly. Nevertheless, in the second half of the 17th century, italic writing won decisively. By the opening of the 18th century, a chastened, businesslike version was developed in London by John Ayres and his younger contemporary writing masters eager to serve commercial demands. The small, narrow variety of Italian-French script was relegated to ladies' use as something suited to frail capacities, while the robust strain was considered fit to dominate an epoch of trade supremacy. The former came to be known as the Italian hand simply, while the latter took charge of affairs throughout the world as English round hand or "copperplate."

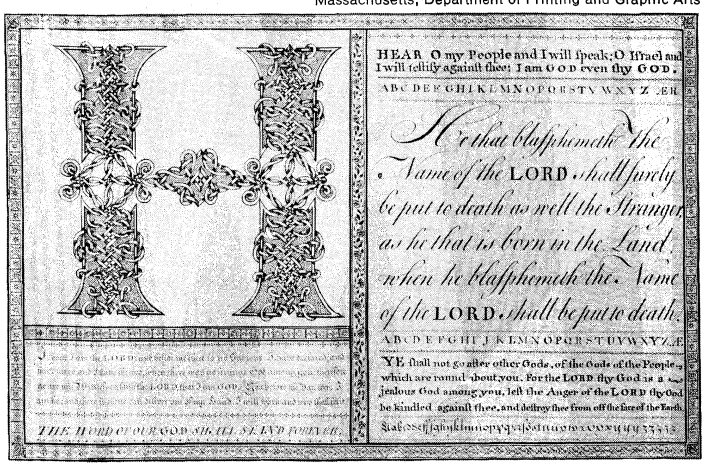
Copperplate, or English round hand. From *The Universal Penman*, Philip Hofer (ed.), engraved by George Bickham, 1743. Facsimile edition, Dover Publications, Inc., 1941.

Penmanship in colonial America

Though the transition from black-letter had been even more accelerated in the American colonies, Boston in New England was one of the last bastions of calligraphy in the trend toward countinghouse and commercial-college penmanship. The traditional foundations were laid solidly by the 18th-century writing master Abiah Holbrook, who raised a group of young Bostonian proficients at the South Writing School and left a fine manuscript, *The Writing Master's Amusement* (1767), in personal testimony.

By permission of the Harvard College Library, Cambridge, Massachusetts, Department of Printing and Graphic Arts



The Writing Master's Amusement, by Abiah Holbrook, 1767. In the Harvard College Library, Cambridge, Massachusetts.

As the 19th century advanced, the competition constantly mounted among systematists emphasizing the plain, practical business hand and decrying the "ornamental branches." Those who loved to flourish quill pictures of bounding deer or calligraphic portraits of national heroes were increasingly placed on the defensive. Gifted penmen like Nathaniel Duren Gould or Platt Rogers Spencer were almost apologetic when they let their hand go in a moment of professional ebullience. Certain religious sects clung to their heritage of individual styles of writing as an art. The Shakers under the influence of visions wrote and drew elaborate spiritual manuscripts. Most of these pieces remaining are in the round hand and Spencerian scripts of their contemporary world. Others, such as the Moravians and Mennonites settled in Pennsylvania, produced out of their background old-country culture bold and handsomely coloured decorative pieces generally called Frakturs because of the script in which their so-called "Pennsylvania Dutch" is presented.

Revival of calligraphy (19th and 20th centuries). The revival of calligraphy at the end of the 19th century was part of an artistic revolt against the mechanization of life. A nostalgic sense of the social losses resulting from industrialization was expressed in social-reformist and arts and crafts movements. About 1870 the English writer and artist William Morris had begun to concentrate attention on the ancient practice of scribes and to study with pen on parchment the means of achieving similar results. In this fashion he wrote out and illuminated a number of texts, Humanistic and medieval, in the years before he took up similarly the study of 15th-century printing prior to establishing the Kelmscott Press. His searching inquiries and patronage led papermakers and ink suppliers, among others, back to forgotten standards. His Socialist teaching turned attention to the satisfaction of mastering traditional handicrafts, thus adding to the ideal enjoyment of life and the sum of beauty.

"Praise of Venus," from *A Book of Verse*, calligraphy by William Morris, 1870. In the Victoria and Albert Museum, London.

Among those who heeded the message was Edward Johnston. He abandoned studies for an intended medical career for those of a scribe. On the basis of the Morris investigations and guided particularly by Sydney Cockerell, Morris' secretary, he rediscovered how to cut and sharpen reeds and quills, how to hold the chisel-nibbed pen so as to produce the kinds of writing that had become familiar in his study of old manuscripts, and every detail of how to make manuscripts. In 1899 he began teaching in London, first at the Central School of Arts and Crafts and, two years later, at the Royal College of Art. His early pupils soon became esteemed designers of lettering and influential calligraphers—*e.g.*, Anna Simons, Eric Gill, Noel Rooke, Graily Hewitt, and Percy

Influence of Edward Johnston

Manuscript copy sheet by Edward Johnston, 1918. In the Newberry Library, Chicago.

Smith. In 1906 he published the basic manual *Writing and Illuminating, and Lettering*, 500 pages profusely illustrated with his own and Rooke's drawings and with reproductions from historic manuscripts. It contains, among other things, a chapter by Gill on cutting inscriptions in stone and material on gilding by the specialist Hewitt. In 1910 the book was published in Germany, where it supported the work independently begun by Rudolf von Larisch in Vienna and carried on by Rudolf Koch and Anna Simons. Under the Nazi regime, the Gothic exponents enjoyed a resurgence, but, after the war, such skilled young German calligraphers as Hermann Zapf led the way back to roman and italic script styles. Jan Tschichold's work has been influential in the appreciation of classical letters for present-day uses.

Art schools everywhere gradually followed the Royal College of Art in offering courses in lettering and writing; these, along with sound forms, instilled a sense of responsibility to a rich heritage. Type design passed from the control of engineers into the hands of artists and calligraphical scholars, such as Stanley Morison, Jan van Krimpen, Akke Kumlien, Bruce Rogers, Frederic W. Goudy, Victor Hammer, Berthold Wolpe, and Warren Chappell. The "freezing" of fine alphabets as font material stabilizes them and multiplies their influence. The effects were not limited to the printed or manuscript page or to book covers and jackets; all kinds of private and public markers and memorials, addresses, diplomas, and even the politicians' ubiquitous testimonial "scrolls" were touched by reform or at least by some consciousness of shortcoming. The stylish lapidary capitals, italics, and sloped letters engraved on boxwood by Reynolds Stone for printing or cut on tablets of wood or stone by John Howard Benson, Will Carter, or David Kindersley are at once distinctively contemporary and lambent with tradition.

Revival of calligraphy in the United States

Though the United States was a decade behind Britain in organizing an arts and crafts movement, four years before the Johnston Bible a Boston architect, Frank Chouteau Brown, brought out a surprisingly sophisticated book, *Letters and Lettering: A Treatise with 200 Examples* (1902). He praised Morris' initiative but wished for more classical balance; he pointed to the neglect of italics and gave them generous space, including specimens from the Lucas 1577 *Arte de escrivir*, "letra del Grifo," *bastarda*, and others. In 1905 *The Parable of the Prodigal Son*, fashioned like a Humanistic manuscript by William Addison Dwiggins and printed from photoengraved plates, was offered for sale. Dwiggins, as illustration for a talk on early writing books, copied a page out of the 1542 Tagliente he had picked up in Europe and passed out prints of it at the December 29, 1913, meeting of the Society of Printers—thereby leading the revival of *cancellaresca*. Other graphic artists concerned in the movement included Thomas Maitland Cleland and Rudolph Ruzicka.

Edward Johnston's pupils, and their pupils, organized in 1921 the Society of Scribes and Illuminators, "zealously directed toward the production of books and documents" by hand and the advancement of the crafts of member scribes, gilders, and illuminators. The program of this professional group based in London is conducted by means of lectures, publications, and exhibitions. In the 1930s exhibits travelled to five American centres, as well as to Paris and Copenhagen. Members representing the several crafts have collaborated in the making of the rolls of honour for the Royal Air Force and United States Air Force, at St. Clement Danes Church, London. The society has served as a model for similar activities abroad, notably the organization in The Netherlands under the leadership of Jan van Krimpen. In 1952 the British society, with Alfred Fairbank as president, recognized the rising popular interest in italic handwriting by instituting the Society for Italic Handwriting, which soon attracted a large international membership of teachers and amateurs.

In the United States individual enthusiasts and informal groups fostered calligraphy outside the art schools. Ernst F. Detterer in Chicago, who had lessons from Johnston in 1913, headed such a group at the Newberry Library for many years and, when he died in 1947, was succeeded by James Hayes. In Portland, Oregon, the instruction and copybooks of Lloyd J. Reynolds, a professor of art in Reed College, had significant influence. For decades Paul Standard in New York practiced and preached *cancellaresca corsiva* and saw the italic reform gain.

20th-century writing manuals and copybooks

Since Johnston a series of manuals and copybooks centring attention on handwriting improvement have proceeded from the espousal of the rather heavy Humanistic hand he admired to an italic that at least implies more speed. Stanley Morison presciently picked out a model for his own hand from Johnston's *Writing and Illuminating, and Lettering* as early as 1913, and a scholar of calligraphy, James Wardrop, called that manuscript "the fons et origo" of his paleographical studies; it is, as Johnston says, a semiformal 16th-century Italian cursive, skillful but a bit colourless to the eye. The fullest and most practical work on the italic is by Alfred John Fairbank, *A Handwriting Manual* (1932). The author places before his book as frontispiece a page of the *bastarda* of Lucas, *Arte de escrivir*, 1577. J.H. Benson's work *The First Writing Book* (1955) consists of the text and examples of the Arrighi *Operina* translated and admirably written out by the editor and furnished with practical clarifications and notes for the learner. Since Johnston calligraphical research and publishing activities have also produced a handsome and scholarly shelfful of books on related forms, most notably the Renaissance capitals. (Ra.N.)

II. Aramaic, Hebrew, and Arabic handwriting and calligraphy

EARLY SEMITIC AND HEBREW WRITING

During the 2nd millennium BC, various Semitic peoples at the eastern end of the Mediterranean were experimenting with alphabetic writing. Between 1500 and 1000 BC, alphabetic signs found in scattered sites showed a correspondence of form and provided material for sound translations. Bodies of writing from this period are fragmented: a few signs scratched on sherds or cut in stone. Few of these are celebrated in terms of aesthetic value.

One interesting set of Semitic inscriptions was discovered in 1905 at an ancient mining site on the Sinai Peninsula. A sphinx from that discovery yields the taw, nun, taw, or t, n, t, meaning "gift." It is evident that the nun, or n, sign is a rendering of a serpent. Most of the early Semitic alphabetic signs were similarly derived from word signs of more ancient vintage. Early Semitic inscription letters are somewhat stiff in visual quality.

The several Semitic peoples in the Near East area spoke languages that were closely related, and this enabled them to use the same set of alphabetic signs. After some experimentation the alphabet was reduced to 22 signs for consonants. There were no vowel signs. The tribes of Canaan (Hebrews, Phoenicians, and Aramaeans) were important in the development of alphabetic writing, and all seemed to be employing the alphabet by 1000 BC.

Phoenician contributions

The Phoenicians, living along a 20-mile (30-kilometre) strip on the Mediterranean, made the great sea their second home, giving the alphabet to Greeks in the mutual trading area and leaving inscriptions in many sites. One of the finest Phoenician inscriptions exists on a bronze

cup from Cyprus called the Baal of Lebanon (Louvre, Paris) dating from *c.* 800 BC. The so-called Moabite Stone (Louvre, Paris), *c.* 850 BC, has an inscription that is also a famous example of early Semitic writing.

Old Hebrew existed in inscription form in the early centuries of the 1st millennium BC. The pen-written forms of the Old Hebrew alphabet are best preserved in the 13th century AD documents of the Samaritan sects.

The period of exile suffered by the Israelites (586–538 BC) dealt a heavy blow to the Hebrew language, since, after their return from exile, Aramaic was the dominant language of the area, and Hebrew existed as a second and scholarly language. Aramaic pen-written documents begin to appear in the 5th century BC and are vigorous interpretations of inscription letters. As may be observed in the Aramaic document (MS. Pell. Aram. XIV) in the Bodleian Library at Oxford, the penman has cut the pen wide at the tip to produce a pronounced thick and thin structure to the line of letters. The penman's hand was rotated counterclockwise more than 45 degrees relative to vertical, so that vertical strokes were thinner than the horizontal strokes. Then, too, there is a tendency to hold these strong horizontals on the top line, with trailing descenders finding a typical length, long or short on the basis of ancient habits. The *lamed* form, which has the same derivation as the Western L, resembles the latter and can be picked out in early Aramaic pen hands through its long ascender.

Merubba' script

The traditional square Hebrew, or *merubba'*, pen hand was developed in the centuries preceding the Christian Era. This early script may be seen in the famed Dead Sea Scrolls discovered in 1947. These scrolls are associated with a group of dissident Jews who founded a religious commune on the northwestern shore of the Dead Sea about 180 BC. The commune had an extensive library. Pens were the instruments of writing, and, as in earlier Aramaic documents, leather provided the surface. Again the *lamed* form is visually prominent.

Merubba' pen hand. The *Thanksgiving Psalms*, portion of the Dead Sea Scrolls, *c.* 1st century AD (the Shrine of the Book, Jerusalem; vol. 10).

There are no Hebrew manuscripts from the first half millennium of the Christian Era. Most of the development in the square Hebrew script occurred between AD 1000 and 1500. The earliest script to emerge from the Dead Sea writing was the Early Sefardic (Spharadic), with examples dating between AD 600 and 1200. The Classic Sefardic hand appears between the years AD 1100 and 1600. The Ashkenazic style of Hebrew writing exhibits French and German Gothic overtones of the so-called black-letter styles (see above) developed to write western European languages in the late Middle Ages. German black-letter with its double-stroked heads and feet was difficult for the scribe. Hebrew scripts from this period exhibit some of the same complicated pen stroking and change of pen slant within individual characters. Some of the decorative qualities of medieval French writing are seen embodied in this Hebrew script.

The Sefardic and Ashkenazic styles

It is generally recognized that Hebrew typefaces have in large measure been imitations of various hand scripts and are more slavish in this imitation than those occurring in other language cultures. One of the finest of the early Hebrew types is credited to the Frenchman Guillaume Le Bé, the excellent 16th-century punch cutter.

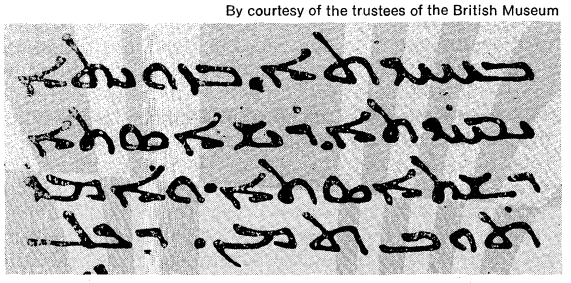
SPREAD OF ARAMAIC TO THE NEAR EAST AND ASIA

Aramaic was the mother of many languages in the Near East and Asia. Generally, the Canaanite-Phoenician influence went west from Palestine, while Aramaic became an international language spreading east, south, and north from the eastern end of the Mediterranean Sea. Never sponsored by great political power, the Aramaic script and language succeeded through inherent efficiency and because the Aramaeans were vigorous traders and extensive travellers in the millennium preceding the birth of Christ.

Syriac. One of the important languages to derive from Aramaic was Syriac. It was spoken over large areas to the north and east of Palestine, but the literature emerged from a strong national church of Syria centred in the city of Edessa. The development of Syriac scripts occurred from the 4th to the 7th century AD, and its most important script is called Estrangela.

By courtesy of the trustees of the British Museum



Estrangela script, *c.* AD 474 (British Museum, London; Add. 17,182, Aphraatis demonstrationes Edessa exar.).

Eastern Christendom was riddled with sects and heretical movements. After 431 the Syriac language and script split into eastern and western branches. The western branch was called Serta and developed into two varieties, Jacobite and Melkite. Vigorous in pen graphics, Serta

Serta and Nestorian writing

writing shows that, unlike the early Aramaic and Hebrew scripts, characters are fastened to a bottom horizontal. Modern typefaces used to print Syriac, which has survived as a language, have the same characteristic. Eastern Syriac script was called Nestorian after Nestorius, who led a secession movement from the Orthodox Church of Byzantium. The Nestorian church flourished in Persia and spread along trade routes deep into Asia, a fact observed by Marco Polo. (D.An.)

Arabic calligraphy. In the 7th and 8th centuries AD, the Arab armies conquered for Islām territories stretching from the shores of the Atlantic to Sind (Now in Pakistan). Besides a religion, they brought to the conquered peoples a language both written and spoken. The Arabic language was a principal factor in uniting peoples who differed widely in race, language, and culture. In the early centures of Islām, Arabic was not only the official language of administration, but also was and has remained the language of religion and learning. The Arabic alphabet has been adopted by the Islāmic peoples' vernaculars just as the Latin alphabet by the Christian West.

The Muslim believes that God (Allāh) revealed the Qur'ān to the prophet Muḥammad through the Archangel Gabriel as intermediary. For him, not only the sense but also the very words of the sacred text are inspired; and that is why in the Islāmic world the Qur'ān is recited not in the vernacular but in the original Arabic. The apparent great respect for the written word of God clearly explains the reason why calligraphy was accorded a high rank among the arts and why copying the Qur'ān was esteemed a most meritorious act. The names recorded of those who excelled in the art of writing far outnumber those of architects, painters, and craftsmen.

The Arabic script was evolved probably during the 6th century AD from Nabataean, a dialect of Aramaic current in northern Arabia. The earliest surviving examples of Arabic before Islām are inscriptions on stone.

Arabic is written from right to left and consists of 17 characters, or outlines, certain of which by the addition of dots placed above or below the character provide the 28 letters of the Arabic alphabet. Short vowels are not included in the alphabet, being indicated by signs placed above or below the consonant or long vowel that they follow. Certain characters may be joined to their neighbours, others to the preceding one only, and others to the succeeding one only. When coupled to another, the form of the character undergoes certain changes.

These features, as well as the fact that there are no capital forms of letters, give the Arabic script its particular character. A line of Arabic suggests an urgent progress of the characters from right to left. The nice balance between the vertical shafts above and the open curves below the middle register induces a sense of harmony. The peculiarity that certain letters cannot be joined to their neighbours provides articulation. For writing, the Islāmic calligrapher uses a reed pen (*qalam*) with the working point cut on an angle. This produces a thick downstroke and a thin upstroke with an infinity of gradation in between. The line traced by a skilled calligrapher is a marvel of fluidity and sensitive inflection, communicating the very action of the master's hand. Even in monumental inscriptions, whether on stone or some other intractable material, the craftsman still tries to retain this sense of the guiding hand by graduating the thickness of his line.

Broadly speaking, there are two distinct scripts in the early centuries of Islām: cursive script and Kūfic script. For everyday purposes a cursive script was employed: typical examples are to be seen in the Arabic papyri from Egypt. Rapidly executed, the script does not appear to have been subject to formal and rigorous rules; and not all the surviving examples are the work of professional scribes. Kūfic script, however, seems to have been developed for religious and official purposes. The term Kūfic means the script of Kūfah, an Islāmic city founded in Mesopotamia in AD 638; but the actual connection between the city and the script is not clear. Kūfic is a more or less square and angular script. In monumental and funerary inscriptions in stone, the angular forms may be partly dictated by the material. Professional copyists employed a particular form for reproducing the earliest copies of the Qur'ān that have survived. These are written on parchment and date from the 8th to the 10th century. They are mostly of an oblong as opposed to codex format. The writing is often large, especially in the early examples, so that there may be as few as three lines to a single page. The script can hardly be described as stiff and angular; rather, the pace is majestic and mea-

sured. Arab scholars writing in this early period record numerous scripts. Unfortunately, their descriptions do not allow us to determine the precise nature of these.

Kūfic went out of general use about the 11th century, although it continued to be used as a decorative element contrasting with those scripts that superseded it. About AD 1000 a new script was established and came to be used for copying the Qur'ān. This is the so-called *naskhī* script, which has remained perhaps the most popular script in the Arab world. It is a cursive script based on certain laws governing the proportions between the letters. The two names associated with its development are Ibn Muqlah and Ibn al-Bawwāb, both of whom lived and worked in Mesopotamia. Of the latter's work a single authentic example survives, a manuscript of the Qur'ān in the Chester Beatty Library, Dublin. *Naskhī* was used for copying the Qur'ān from the 11th century onward.

Establishment of *naskhī* script

The conception of proportional relationships between the letters gave rise to other scripts, more or less variants on *naskhī;* these include the large and majestic *thuluth* script, which came to be adopted for many of the large copies of the Qur'ān produced from the 13th century. In Mamlūk Egypt of the 14th and 15th centuries, the *ṭūmār* script was also used for large Qur'āns.

Distinctive scripts were developed in particular regions. In Spain, the *maghribī* ("western") script was evolved and became the standard script for Qur'āns

in North Africa. Derived ultimately from Kūfic, it is characterized by the exaggerated extension of horizontal elements and of the final open curves below the middle register, as well as by certain orthographic peculiarities.

Both Persia and Turkey made important contributions

to calligraphy. In these countries the Arabic script was adopted for the vernacular. The Persian scribes invented the *taʿlīq* script in the 13th century. The term *taʿlīq* means "suspension" and aptly describes the tendency of each word to drop down from its preceding one. At the close of the same century, a famous calligrapher, Mīr ʿAlī of Tabriz, evolved *nastaʿlīq*, which, according to its name, is a combination of *naskhī* and *taʿlīq*. Like *taʿlīq* this is a fluid and elegant script, and both were popularly used for copying Persian literary works.

Development of *taʿlīq* and *nastaʿlīq* in Persia

A characteristic script developed in Ottoman Turkey was that used in the chancellery and known as *divani*. It is highly mannered and difficult to read. Peculiar to Turkish calligraphy is the *tuğra* (*ṭughrā*), a kind of royal cipher based on the names and titles of the reigning sultan and worked into an intricate and beautiful design. A distinctive *tuğra* was created for each sultan and affixed to imperial decrees by a skilled calligrapher, the *neshani*.

There has always existed in the Islāmic world a keen appreciation of fine handwriting, and, from the 16th century, it became a practice to assemble in albums specimens of penmanship. Many of these assembled in Turkey, Persia, and India are preserved in museums and libraries. Calligraphy, too, has given rise to quite a considerable literature such as manuals for professional scribes employed in chancelleries.

In its broadest sense, calligraphy also includes the Arabic scripts employed in materials other than parchment, papyrus, and paper. In religious buildings, verses from the Qur'ān were inscribed on the walls for the edification of the faithful, whether carved in stone or stucco or executed in faience tiles. Religious invocations, dedications, and benedictory phrases were also introduced into the decoration of portable objects. Generally speaking, there is a close relationship between these and the scripts properly used on the conventional writing

materials. It was often the practice for a skilled penman to design monumental inscriptions. (R.H.P.-W.)

Indic calligraphy. The most important examples of calligraphy to develop from Aramaic writing in its dissemination through southern and Central Asia were the scripts of India, especially of Sanskrit, the ancient Indo-European language of the subcontinent. Indic writing first appeared in the 3rd century BC during the reign of Aśoka (*c.* 273–232 BC). Leader of a great empire, Aśoka turned from military success to embrace the arts and religion. Aśoka's edicts were committed to stone. These inscriptions are stiff and angular in form. Following the Aśoka style of Indic writing, two new calligraphic types appear: Kharoṣṭī and Brāhmī. Kharoṣṭī was used in the northwestern regions of India from the 3rd century BC to the 4th century of the Christian Era, and it was used in Central Asia until the 8th century. It is characterized by a vigorous pen letter, reflecting the influence of Near East calligraphy.

Kharoṣṭī and Brāhmī scripts

Copper was a favoured material for Indic inscriptions. In the north of India, birch bark was used as a writing surface as early as the 2nd century AD. Many Indic manuscripts are written on palm leaves, even after the Indian languages were put on paper in the 13th century. Both sides of the leaves were used for writing. Long rectangular strips were gathered on top of one another, holes were drilled through all the leaves, and the book was held together by string. Books of this manufacture were common to Southeast Asia. The palm leaf was an excellent surface for penwriting, making possible the delicate lettering used in many of the scripts of southern Asia.

Devanāgarī script

Visually, Sanskrit is associated most closely with the alphabetic form named Devanāgarī. In a 15th-century pen-written manuscript in the Freer Gallery at Washington, D.C., it can be observed that the pen's nib is cut wide, giving a considerable difference in thick and thin

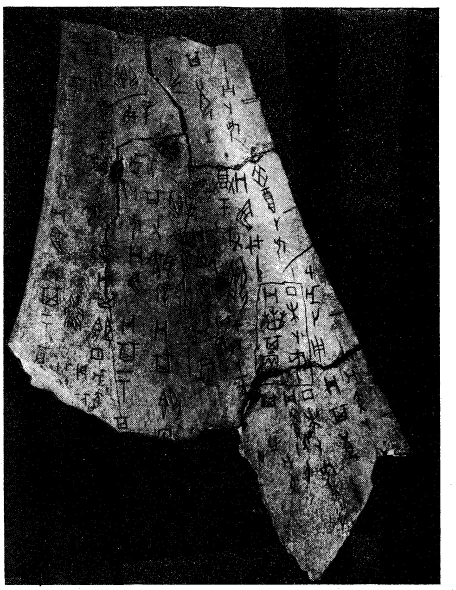
Sanskrit pen-written document, 15th century AD (Freer Gallery, Washington, D.C.; MS. 23.3).

strokes. The alphabetic signs hang down from a strong horizontal top line that may become connected. Through the years the strong horizontal and vertical emphasis of inscription writing has been preserved in the Devanāgarī script, and modern typefaces and teaching manuals stress this stiffness of execution. In informal documents this historical script can have more warmth and grace.

(D.An.)

III. East Asian handwriting and calligraphy

In China, Korea, and Japan, calligraphy is a form of pure art. Chinese, Korean, and Japanese calligraphy derive from the written form of the Chinese language. Chinese is not an alphabetical language; each character is composed of a number of differently shaped lines within an imaginary square. The early Chinese written words, like the Egyptian hieroglyphs, were pictorial images, though not so close to the objects they represented as in the ancient Egyptian writing. Rather, they were simplified images, indicating meaning through suggestion or imagination. These simple images were flexible in composition, capable of developing with changing conditions by means of slight variations.



Chinese bone script, Shang dynasty (*c.* 1766–*c.* 1122 BC). In the East Asian Library, Columbia University, New York.

CHINESE CALLIGRAPHY

Bone-and-shell script

The earliest known Chinese ideographs are engraved on the shoulder bones of large animals and on tortoise shells. The piece illustrated contains a number of the early ideographs; each seems to have been carefully composed before being engraved on the bones or shells. Although they are not entirely uniform in size, the variations are not great. The figures must have evolved from rough and careless scratches in the still more distant past. This *chia-ku-wen*, or bone-and-shell script (dated *c.* 1766–*c.* 1123 BC), is the earliest stage of development in Chinese calligraphy.

It was said that Ts'ang Chieh, the legendary inventor of Chinese writing, got his ideas from observing animals' footprints and birds' claw marks on the sand as well as other natural phenomena. He then started to work out simple images from what he conceived as representing different objects such as those that are given below:

Surely, the first images the inventor drew of these few objects could not have been quite so stylized but must have undergone some modifications to reach the above stage. Each image is composed of a minimum number of lines and yet is easily recognizable. Nouns no doubt came first. Later, new ideographs had to be invented to record actions, feelings, and differences in size, colour, taste, etc. Something was added to the already existing ideograph to give a new meaning. The ideograph for deer, for instance, is , not a realistic image but a very much simplified structure of lines suggesting a deer by its horns, big eye, and small body, which distinguish it from other animals. When two such simple images are put side by side, the meaning is "pretty," "prettiness," "beautiful," "beauty," etc., which is obvious if one has seen two such elegant creatures walking together. But, if a third image is added above

the other two, as , it means "rough," "coarse," and even "haughty." This interesting point is the change in meaning through the arrangement of the images. If the three stags were not standing in an orderly manner, they could become rough and aggressive to anyone approaching them. From the aesthetic point of view, three such images could not be arranged side by side within an imaginary square without cramping one another, and in the end none would look like a deer at all.

Bronze script

After the bone-and-shell script came writing on bronze vessels, known as bronze script. In the early days of divination, when the kings of the Shang dynasty (*c.* 1766–*c.* 1122 BC) tried to solve their problems by consulting their ancestors and deities, the latter's answers were engraved on bones and on tortoise shells for perpetual preservation. Later, bronze was used to make cooking utensils and wine vessels for the special ceremonies of ancestral worship, raw or cooked food being offered up in them. So sacred were these ancestor-worshipping ceremonies that the best types of bronze utensil were specially designed and cast for such purposes, and, in addition, inscriptions, from a few words up to several hundred, were incised inside the bronzes. The words of the engravings could not be roughly formed or even just simple images; they had to be well worked out to go with the decorative ornaments outside the bronzes, and in some instances they almost became the chief decorative design in themselves. Though they preserved the general structure of the bone-and-shell script, they were considerably elaborated and beautified. Each bronze or set of them may bear a different type of inscription, not only in the wording but also in the manner of writing. Hundreds of them were created by different artists. The bronze script represents another stage of development in Chinese calligraphy, known as *chin-wen* or *ta chuan*, or the big-seal style.

Before long a unification of all types of the bronze script was enforced when China was united for the first time in the 3rd century BC. The first emperor of Ch'in, Ch'in Shih Huang Ti, could be regarded as one of the most terrible dictators in the history of mankind, for he burned Confucian books, buried Confucian scholars alive, and sacrificed thousands and thousands of lives to build the Great Wall to protect himself and his empire; but he did one great thing for the Chinese in unifying their writing, and by this they have been bound together ever since. The First Emperor's prime minister, Li Ssu, was given the task of working out the new script, and no other type was allowed to be used. Here are some common words that can be compared with similar words in bone-and-shell script mentioned above:

sun moon mountain water rain wood dog cattle horse

This was the third step forward in the development of Chinese calligraphy, known as *hsiao chuan*, or the small-seal style.

The *hsiao chuan*, or small-seal style

In the small-seal style of writing, all lines are drawn of even thickness, and more curves and circles are employed. Each word tends to fill up an imaginary square, and a passage written in small-seal style has the appearance of a series of equal squares neatly arranged in columns and rows, each of them balanced and well-spaced. The Chinese practice the small-seal style when aiming at future attainments in calligraphy. They use only the tip of a long-haired brush, which is almost suspended in the air; no light pencil sketches can be drawn first. It is a hard task and good training.

The uniformity of writing in China was established chiefly for the purpose of meeting the growing demands for documented records. Unfortunately, the small-seal style could not be written speedily and was therefore not entirely suitable. Another stage of development was needed—the fourth stage, which is called *li shu*, or official style. The Chinese word *li* here means "a petty official" or "a clerk"; *li shu* means a style specially devised for the use of clerks. If examined carefully, *li shu* is found to contain no circles and very few curved lines. In other words, all the circles became squares, and the curved parts of the lines became angular. Short straight lines, vertical and horizontal, are chiefly used. Because of the speed needed for writing, the brush in the hand tends to move up and down, and an even thickness of line cannot be enforced. As the thickness varied, artist-writers could concentrate more on the artistic shaping of the lines. Thus, a door opened for developments in Chinese calligraphy.

The *li shu*, or official style

Li shu is thought to have been invented by Ch'eng Miao (240–207 BC), who had offended the First Emperor of Ch'in and was serving a ten-year sentence in prison. He spent his time in prison working out this new development, which not only facilitated speed in writing but opened up seemingly endless possibilities for later calligraphers. According to their own artistic insight, they evolved new variations in the shape of lines and also in construction. The words in *li shu* style tend to be square or slightly rectangular horizontally. Though the even thickness of lines is relaxed, the rigidity in the shaping of them is still there; for instance, the vertical lines had to be shorter, and the horizontal ones longer. As this curtailed the freedom of hand for individual artistic taste, another stage of development came into being—the fifth stage, which is called *chen shu* (*k'ai shu*), or regular style. There is no record of who invented this style, but it must have been in evolution for a long time, at least since the 1st century AD if not earlier. The Chinese still use this regular style of writing today; in fact, what is known as modern Chinese writing is almost 2,000 years old, and the written words of China have not changed since the first century of the Christian Era.

Development of the *chen shu*, or regular style

Since about 1950, it has been claimed that the formation of the Chinese written language has changed. This is a serious misunderstanding; the only change is that a certain number of words can now be written and printed with a simplified construction. Most of those simplifica-

Chen shu ("regular style") written by Emperor Hui Tsung (1082–1135), Sung dynasty. In the National Palace Museum, Taipei.
By courtesy of the National Palace Museum, Taipei

tions had long been in use in the grass style of writing dating back as far as the regular style, but they were not permitted in documents and records, in books, and in making type for printing. Only those who had never been familiar with the grass style of writing mistook them for newly invented forms.

Before coming to the grass style, the regular style, or *chen shu*, must be explained. "Regular" here means "proper"—"the proper style of Chinese writing" used by all Chinese for government documents, printed books, public and private dealings in important matters ever since its establishment. Since the regulations for the civil-service examination enforced in the T'ang period (AD 618–907), each candidate had to be able to write a good hand in regular style. This Imperial decree deeply influenced all Chinese who wanted to become scholars and enter the civil service. This examination was abolished in 1905, but most Chinese still try to acquire a hand in regular style even to the present day.

In *chen shu* each line, each square or angle, and even each dot can be shaped according to the will and taste of the calligrapher. Indeed, a Chinese word in regular style presents an almost infinite variety of problems of structure and composition, and, when executed, it presents to the onlooker a design whose abstract beauty can draw the mind away from the literal meaning of the word itself.

The greatest exponents of Chinese calligraphy were Wang Hsi-chih (died 379) and his son Wang Hsien-chih in the 4th century. Few of their original works have survived, but a good number of their writings were engraved on stone tablets, and rubbings were made from them. Many great calligraphers imitated their styles, but none ever surpassed them. Since the 7th century there have been many master calligraphers such as Ouyang Hsün (557–641), Sun Kuo-t'ing (died 688), Ch'u Sui-liang (596–658), Yen Chen-ch'ing (709–785), Liu Kung-ch'üan (778–865), Su Tung-p'o (1036–1101), Huang T'ing-chien (1045–1105), Mi Fei (1051–1107), the Sung emperor Hui Tsung (1082–1135), and Chao Meng-fu (1254–1322). A noted modern calligrapher was Yü Yu-jen (1878–1964).

Wang Hsi-chih not only provided the greatest example in the regular style of writing but also relaxed the tension somewhat in the arrangement of the strokes in the regular style by giving easy movement to the brush to trail from one word to another. This is called *hsing shu*, or running style, as if the hand were walking fast while writing. This, in turn, led to the creation of *ts'ao shu*, or grass style, which takes its name from its appearance—as if the wind had blown over the grass in a manner disorderly yet orderly. The English term cursive writing cannot describe the Chinese grass style, for even a cursive hand can be deciphered without very much difficulty.

The *hsing shu*, or running style, and the *ts'ao shu*, or grass style

But Chinese words in grass style are greatly simplified forms of the regular style and can be deciphered only by those who have practiced calligraphy for years. It is not a style for general use but for the calligrapher who wishes to produce a work of abstract art.

Technically speaking, there is no mystery in Chinese calligraphy. It depends on the skill and imagination of the writer to give interesting shapes to his strokes and to compose beautiful structures from them without any retouching or shading and, most important of all, with well-balanced spaces between the strokes. This balance needs years of practice and training.

The tools for Chinese calligraphy are very few—good ink, ink stone, a good brush, and good paper (some prefer silk). Even a child can fill up a squarish space with lines—straight or curved or circular—but to fill it so as to liberate the visual beauty of the linear shapes and composition depends on artistic insight and the training of a master.

Hsing shu ("running style") and *ts'ao shu* ("grass style") by Wang Hsien-chih (AD 344–388), Six Dynasties period. In the National Palace Museum, Taipei.

The fundamental inspiration of Chinese calligraphy, as of all arts in China, is nature. In *chen shu*, or regular style, each stroke, even each dot, suggests the form of a natural object. As every twig of a living tree is alive, so every tiny stroke of a piece of fine calligraphy has the energy of a living thing. This is very different from the strokes in a printed word. Printing does not admit the slightest variation in the shapes and structures, but strict regularity is not tolerated by Chinese calligraphers, especially those who are masters of the *ts'ao shu*. A finished piece of fine calligraphy is not a symmetrical

arrangement of conventional shape but, rather, something like the coordinated movements of a skillfully composed dance—impulse, momentum, momentary poise, and the interplay of active forces combining to form a balanced whole.

The study of Chinese calligraphy is the study of a highly advanced form of art with two keynotes—a simulation in every stroke and a dynamic equilibrium in the structure. (C.Y.)

KOREAN CALLIGRAPHY

Koreans have used Chinese characters probably since the 2nd or 3rd century AD. Even after the invention of the Korean alphabet in 1447, Chinese was used as the official script until the 19th century. Thus, traditional Korean calligraphy was in Chinese rather than in Korean.

A few inscribed stone monuments remain from the Three Kingdoms period (*c.* 57 BC–AD 668). Ancient Koreans, eager to adopt Chinese culture, developed a calligraphy reflecting contemporary Chinese styles. In the following Unified Silla dynasty (668–935), a devotion and adherence to the T'ang culture of China gave birth to such great masters of calligraphy in Korea as Kim Saing and Choi Ch'i-wŏn, whose styles of writing basically followed those of the Chinese calligraphers Ou-yang Hsün and Yü Shih-nan.

The angular, squarish style of Ou-yang Hsün, Shih-nan, and Yen Chen-ching, inherited from the Silla dynasty, continued in the Koryŏ period (918–1392) until around 1350, when the rounded, fluent style of the Chinese calligrapher Ch'ao Meng-fu, of the Yüan dynasty, was introduced and became the vogue. Since that time the *chao* style has remained the basic undercurrent in Korean calligraphy.

The *chao* style

At first the calligraphy of the Yi dynasty (1392–1910) followed the *chao* style, but, early in the 16th century,

Rubbing of stone engraving by Kim Saing (711–791), Unified Silla period.

a mannered, vulgar style began to be evident. Responsible for the Yi style were such noted calligraphers as Han Ho and Yi Kwangsa.

The 19th century saw, however, the emergence of individual styles related to those of the Chinese calligraphers Su Shih and Mi Fei of the 11th century, Wen Cheng-ming of the 16th century, and Tung Ch'i-ch'ang of the late 16th and early 17th century. The new trend was due to Korea's close cultural contacts with Ch'ing China.

The greatest master of the Yi period was Kim Chŏng hi, who established the so-called *ch'usa* style. His calligraphy is derived from the *li shu* script of China, but his sense of pictorial composition, harmony within asymmetry, and animation by unmatched, forceful strokes gave him a style completely his own.

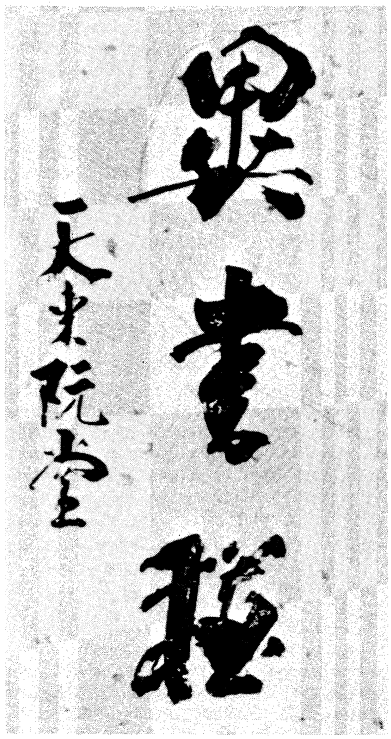
Chao style. *Hs'ing-tsu* written by Chao Meng-fu (1254–1322). In the National Palace Museum, Taipei.

A few calligraphers survived from the Yi dynasty into the early decades of the present century. One distraction was the influence of Japanese calligraphy, which began to be felt about 1920.

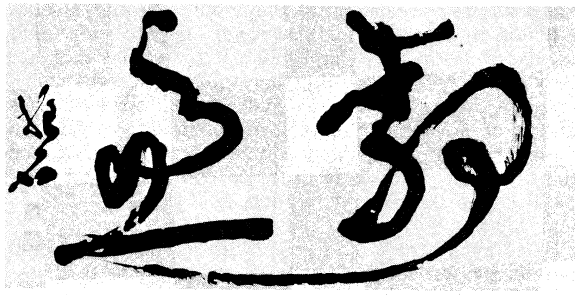
Since World War II, traditional calligraphy has survived only as a minor art. A new trend since the 1960s is an effort to exploit calligraphy in the Korean alphabet, a result of the government policy of eliminating Chinese characters from the Korean language. (W.-Y.K.)

JAPANESE CALLIGRAPHY

The art of calligraphy has long been highly esteemed in Japan as in China. There is no definite record of when the Japanese began to use Chinese words—called *kanji* in Japanese. It is known that a Korean scribe named Wani brought some Chinese books of Confucian classics, such as the *Analects*, *Great Learning*, and *Book of Mencius*, to Japan near the end of the 4th century AD.



Ch'usa style written by Kim Chong hi (1786–1856), Yi period.



Modern calligraphy by Hisamatsu Shinichi. In the collection of Masao Abe, Kyōto.

From the 7th century onward, many Japanese scholars, particularly Buddhist monks, went to China, and some Chinese came to Japan. As Indian Buddhism reached Japan via Korea and China and took root there, the use of *kanji* in Japan gradually grew. Eventually, *kanji* became the official system of writing in Japan, because it was the instrument for the transmission of Chinese Buddhism.

Kanji script

Most of the Chinese Buddhist monks who went to live in Japan were scholars and good calligraphers; their writings on the Buddhist scriptures and other subjects were highly admired and esteemed not only for their aesthetic value as calligraphy but also because they were the work of devout personalities and induced a sense of religious awe in the onlookers.

Many of the early Japanese emperors were ardent Buddhists and also acquired a masterly hand in *kanji* writings. So did many Japanese Zen priests, whose calligraphy tended to exercise a religious effect upon the Japanese mind. Theirs became a special type of calligraphy in Japan, namely, Japanese Zen calligraphy, or *bokuseki*.

Naturally, it was unsuitable for Japan to adopt an entire foreign language like Chinese, and Japanese thinkers began to devise a new, native script known as *hira-gana*, which was often referred to as "women's hand," or *onna-e* in Japanese. It was used particularly in the writing of Japanese poetry and had an elegant and graceful appearance. Thus, in Japanese calligraphy there are two different and distinctive types of writing, one in *kanji* and the other in *hira-gana*. Among the best known Japanese calligraphers are Kūkai (Kōbō Daishi), Emperor Saga, Michikaze, Fujiwara Yukinari, the Zen priest Daitō, and Ryōkan. The modern living Zen authority Hisamatsu Shinichi has been the unique calligrapher of the present age in Japan.

There are many outstanding pieces of Japanese calligraphy in *kanji*, but they are not distinctive when compared with their Chinese counterparts. Japanese *hira-gana* calligraphy, however, stands out prominently and proudly, especially in the style of *remmen-tai*, in which the *hira-gana* are written continuously and connected together without break, and in *chōwa-tai*, in which some *kanji* words join hands with the *hira-gana*. Japanese calligraphy in *remmen-tai* or in *chōwa-tai* has some resemblance to the Chinese grass style, but the two are easily distinguishable. In Chinese grass style, although the words are greatly simplified and several words can be joined together with trailing strokes, each separate word normally still retains its regular spacing within an imaginary square, big or small. But Japanese *hira-gana* cannot be spaced so separately and evenly. Therefore, a whole piece of *remmen-tai* calligraphy looks like a big bundle of beautiful silk strings hanging down confusedly yet artistically, as if the calligrapher had arranged them quite unconsciously. They were arranged consciously of course, but the calligrapher seems to have let his hand move swiftly of its own accord. The separate strokes

Hira-gana calligraphy

Types of Japanese Zen Calligraphy

kanji	*hira-gana*	transliteration	description
印可状	いんかじょう	*inkajō*	document of permit approval
字號	じごう	*jigō*	name or title given a monk by his master
法語	ほうご	*hōgo*	words of the law or words of admonition
偈頌	げじゅ	*geju*	gatha or hymn or short moral poem
遺偈	ゆいげ	*yuige*	a will in the form of a gatha or hymn
進道語	しんどうご	*shindōgo*	instruction or words leading disciples to practice the dharma or law
詩	し	*shi*	poetry
額字	がくじ	*gakuji*	tablet with a few words inscribed horizontally
書簡	しょかん	*shokan*	letter or written communication

and dots have no distinctive shape but join other strokes and dots in the following *hira-gana*. The strokes or lines in *hira-gana* are not shaped like living things, nor are they of even thickness; but there must be good spacing between the strokes or lines and between one *hira-gana* and another, so that there is no confusion or blur in the completed piece. This is a highly demanding art, and the whole piece has to be executed with speed and without hesitation. *Hira-gana* requires solid training and artistic insight.

To complete the whole piece with its strokes or lines not too varied in shape yet not too even in thickness needs a special training; to keep the tip of the brush at an even distance from the paper, the writer must cultivate a steady hand. It is said that some Japanese calligraphers trained themselves by supporting the arm with a cord hanging from the ceiling, so that the hand would remain at a fixed distance from the paper. (C.Y.)

Calvin, John

John Calvin, a French theologian and ecclesiastical statesman, was one of the most important leaders of the Protestant Reformation of the 16th century. Theological, ecclesiastical, and political ideas that he advanced in many publications, a model church that he created and directed in the city of Geneva, and the assistance he provided to the political and intellectual leaders of several countries profoundly influenced the development of Protestantism in many parts of Europe and in North America.

By courtesy of the Museum Boymans-van Beuningen, Rotterdam

Calvin, oil painting by an anonymous master of the French school, *c.* 1550. In the Museum Boymans-van Beuningen, Rotterdam.

Early life and education. Calvin was born in Noyon, in Picardy, France, on July 10, 1509, the fourth son of Gérard Cauvin and Jeanne Lefranc, the daughter of a successful innkeeper. His father was a member of the town bourgeoisie and worked for the episcopal establishment as secretary to the bishop, procurator for the cathedral chapter, and in other capacities. Calvin began his education with young noblemen of the de Hangest family, relatives of the reigning bishop. He was destined for a career in the church, and two benefices (ecclesiastical foundation endowments) were assigned to him as a boy to finance his education. After he finished his elementary studies in Noyon, in 1523, he went with the de Hangest boys to Paris, where he studied the liberal arts at both the Collège de la Marche and the Collège de Montaigu, an austere and demanding institution at which the famed Dutch Humanist Erasmus, the French author Rabelais, and, at a later time, Ignatius of Loyola, founder of the Jesuit religious order, also studied. After Calvin received the master of arts degree, his father sent him on to the University of Orléans for advanced study in law under the renowned jurist Pierre de L'Estoile, and he went briefly to Bourges to follow the lectures of the famous Italian legal scholar Alciati. Calvin then returned to Paris, after his father's death in 1531. There he studied with some of the great Humanists who had recently been appointed royal lecturers, notably Guillaume Budé.

Early scholarly activities

A significant product of this second stay in Paris was Calvin's first book, a learned study of *De clementia* ("Concerning Clemency") by the Roman Stoic philosopher Seneca. Calvin's work appeared in 1532. It contained a carefully established text of Seneca's treatise of advice to the emperor Nero, together with a copious and erudite commentary. It revealed Calvin to be an accomplished Humanist on the model of Erasmus and Budé, proved that he could write Latin with elegance and force, showed that he was beginning to read and use Greek, and that he had a wide-ranging and precise command of ancient literature and history. The study also showed that Calvin had acquired a great interest in rhetorical analysis and suggested that he sided with the rhetoricians against the dialecticians in an important contemporary quarrel. He probably believed, with the rhetoricians, that the essential test of the truth of a proposition is its clarity and its ability to move men; he probably rejected the belief of the dialecticians, who held that the best measure of a proposition's truth is the ease with which it can be fitted into a coherent logical system. These skills and attitudes were to have important results in Calvin's later career as a Reformer, and they created a solid basis for friendship with other Protestant Humanist activists, including Luther's disciple Philipp Melanchthon and Theodore Beza, who was to become Calvin's successor at Geneva.

Conversion to Protestantism. Apparently a short time after the publication of the study of *De clementia*, Calvin was converted to Protestantism. He later said that the conversion was sudden but added nothing about when, where, and how it happened. It may well have been induced by Humanist friends in the circle of religious Reformers led by Jacques Lefèvre d'Étaples of France. These men were increasingly frustrated by the government's growing persecution of any religious deviations. Most of them remained Catholic, but some became Protestant. After a split among university faculty and a royal proscription of the Protestant group, Calvin left Paris, resigned his benefices (1534), and, after travel in France, settled in Basel, Switzerland, a Protestant centre, where he lived under the pseudonym Martianus Lucanius. There he devoted himself to intense study of theology, concentrating above all on the Bible, but he also studied the writings of the early Church Fathers and such contemporary Protestant theologians as Luther and Martin Bucer. Most of his knowledge of Catholic theology had been gained from two elementary medieval textbooks, Peter Lombard's *Sentences* (on theology) and Gratian's *Decretum* (on canon law). The principal result of this study was Calvin's master work, the *Institutes of the Christian Religion*, published in 1536. In its initial form it was an extended catechism, in Latin, organized in the traditional way and neatly summarizing essential Protestant doctrines. It also contained some supplementary material attacking sacraments that he viewed as false, and it outlined organizational ideas. The work quickly won a reputation for Calvin as an authoritative spokesman of Protestantism. He revised, translated, and substantially expanded the book in a number of subsequent editions. The definitive Latin edition appeared in 1559, the French in 1560. The *Institutes* became a comprehensive and systematic manual of dogmatic theology, the most influential single manual, in fact, produced during the Reformation. In its later editions it developed positions quite distinct on a number of issues not only from ideas held by radical Anabaptist (*e.g.*, Menno Simons) and Spiritualist thinkers (*e.g.*, Kaspar Schwenckfeld) but also from the teachings of many Lutheran theologians. It thus laid an ideological base for a significant new version of Protestantism.

Institutes of the Christian Religion

Even before the *Institutes* was published, Calvin left Basel for Italy. There he visited Renée de France, daughter of a former king of France and at that time duchess of Ferrara, who had Protestant sympathies and had sheltered a number of Protestant refugees at her court. She was the first of many powerful aristocrats to whom Calvin appealed personally for material support of the Reformation. In a society in which the high nobility still monopolized most military power and much of the wealth, such support was essential for the success of any reform. In tapping this source of support, Calvin displayed a political acumen that was to increase over the years. He soon resumed his travels, however, returning to Basel, then going back to France, and then finally stopping in Geneva, in the fall of 1536, on his way to Strassburg.

Participation in the Genevan reform. The stop in Geneva proved to be fateful. That city-state had just turned

Protestant. It had defied the prince-bishop who possessed both temporal and spiritual sovereignty over the city and had ousted the cathedral canons and other officials who ruled on his behalf. An elected council of local bourgeois, which had previously managed the internal affairs of the city, had assumed complete control. The bishop appealed to the powerful neighbouring duchy of Savoy, to which Genevan bishops had been allied for centuries, for help in regaining his power. The city council appealed to the powerful neighbouring republic of Bern, a source of the Swiss mercenary infantrymen who were among the best fighters in 16th-century Europe, for help in maintaining its independence. In 1528 Bern had adopted the form of Protestantism preached by Huldrych Zwingli, and it was encouraging its neighbours to follow its lead. Inflammatory preachers, notably Guillaume Farel, a former student of Lefèvre, and Pierre Viret, had stirred the Genevan population to many forms of anti-Catholic demonstration, climaxing in image-destroying riots. Consequently, Geneva turned Protestant when it revolted from its bishop. Its government proclaimed the preaching of the gospel, barred the administration of Roman Catholic sacraments, and expelled all priests and members of religious orders who were not willing to conform. But the city had still not consolidated its revolution when Calvin arrived. No settled Protestant rituals had been developed, no new ecclesiastical institutions had been founded, and little provision had been made for the ancillary social services, such as education, that 16th-century communities expected the church to provide. With no previous experience in dealing with practical problems of this kind, Calvin stepped into a considerable vacuum. He did not intend to settle in Geneva, but Farel, in a dramatic interview, persuaded him to stay, threatening him with divine vengeance if he did not use his talents where they were so desperately needed.

Early reforming activities in Geneva and Strassburg

Calvin began his career in Geneva as a public lecturer on the Bible, charged with justifying to the educated citizenry the momentous changes they had witnessed. To educate the Genevans in the Reformed faith, he wrote *Instruction in Faith* (1537). Before long he was also asked to preach sermons; and soon he was using his literary and legal skills to prepare with Farel a series of liturgical and disciplinary regulations, which many of the less austere Genevans cared for not a bit. In fact, the introduction of these regulations by Calvin and Farel proved to be premature, arousing a fear of exchanging one form of clericalism for another. The problem was not so much a cataloging of regulations on morality, which had been in the city's codes from medieval times, but rather a fear that such regulations would be enforced. In an abrupt showdown in 1538, both Farel and Calvin were forced by a newly elected city council to leave the city within three days. Farel moved on to Neuchâtel, where he spent the rest of his life directing that city's Reformation. Calvin, after some hesitation, went to Strassburg, where he became minister to a church of French refugees for a period of three years.

In Strassburg, an imperial German city whose religious establishment was now directed by the liberal Lutheran Martin Bucer, Calvin gained some very useful practical experience. He worked out a Protestant liturgy in French for his congregation, developed a workable set of institutions for running a parish, and was invited to participate in pan-German negotiations at the highest level, which were designed to reconcile Protestants and Catholics and thus reunite Christianity. He participated in religious colloquies called for this purpose in Frankfurt, Hagenau, Worms, and Regensburg (Ratisbon) during 1539–41. This gave him the opportunity to become personally acquainted with prominent Lutheran theologians, above all with Philipp Melanchthon, the chief Protestant negotiator at most of these conferences. It also gave him the opportunity to observe such irenic Catholic theologians as Cardinal Gasparo Contarini, who led the Roman delegation at Regensburg. The failure of these conferences, however, left Calvin convinced of the futility of negotiation with Catholics as an avenue to reform and reunion. During this period he published biblical (*Commentary on Romans*, 1539) and theological works (*e.g.*, *Short Treatise on the Lord's Supper*). He also married Idelette de Bure, a widow of one of his converts from Anabaptism, in 1540.

Triumphal return to Geneva. Meanwhile, Geneva was threatened with chaos. The Protestant ministers who had replaced Farel and Calvin were not able to command the respect of the citizens. Increasing pressure—coming primarily from neighbouring Savoy and from such Catholic intellectuals as Cardinal Jacopo Sadoleto, then bishop of Carpentras in southern France—was brought upon the city to return to the Church of Rome. In countering these pressures, certain Genevans appealed to Calvin in Strassburg. He prepared a *Reply to Sadoleto*, which is one of the best summaries of his theological position. A majority of Geneva's elite finally became convinced that only with Calvin's personal leadership could a Protestant establishment be maintained. Following lengthy negotiations, in which Calvin was promised considerable freedom to build a Protestant regime of the kind he wanted, he agreed to come back to Geneva. Late in 1541 Calvin returned in triumph, was installed with his new wife in a fine canon's house containing an impressive wine cellar, and was awarded a substantial salary.

The first step that Calvin took toward building a Reformed Church for Geneva, following his return, was to draft a set of ecclesiastical ordinances. They were adopted by the city council, after a number of slight amendments, and in 1561 they were redrafted by Calvin and readopted by the city. The ordinances have served as the constitution for the Church of Geneva down to the present, with only a few modifications, and have provided a model for Reformed Churches in many other communities. These ordinances established four orders of ministry for Geneva: (1) teaching doctors, (2) preaching pastors, (3) disciplining elders, and (4) deacons charged with the administration of charity. The doctors were expected to discover the true intention of God for the Christian community by scholarly study of the Bible in its original languages, Greek and Hebrew, using all the best resources of contemporary philology and theology. The pastors were expected to proclaim the Word of God from the pulpits of the city's parish churches and to administer the sacraments. The elders were expected to see to it that the general population accepted this gospel proclamation and used it as a guide for both belief and behaviour. The deacons were expected to meet the social obligations of the community by collecting and safeguarding funds earmarked for charity and by spending them to care for orphans, widows, the aged, and others who could not support themselves.

The four orders of ministry

In the beginning of Calvin's Genevan reform, he was in actuality the only doctor. Once more he delivered the regular public lectures that he had begun under Farel. The lectures were in the form of sustained commentaries on the Bible. One biblical book after another was examined verse by verse in a leisurely way, so that it took several months to gloss each book. Many of these lectures Calvin later turned into published commentaries on books of the Bible. Some were copied down by public secretaries but remained in manuscript, and only in recent times are they being prepared for publication. These lectures proved to be a considerable attraction. They interested a number of Genevans and they attracted an increasing number of religious refugees from other countries—primarily from France, but also from Italy, Germany, England, the Netherlands, Spain, and central Europe.

For some time Calvin made no attempt to institutionalize this teaching. He did assist in the revitalization of a secondary school, however, which prepared students for the theological education that he had been providing for informally. A French Humanist named Sébastien Castellion had been invited to direct the school at about the same time that Calvin was invited to return to Geneva. But when Castellion applied for the additional position of pastor, Calvin blocked the appointment, disagreeing sharply with him on the interpretation of certain biblical passages and creedal statements that Castellion explained

literally and that Calvin insisted must be understood figuratively. Castellion was soon dismissed and moved to Basel, where he continued to create trouble for Calvin by attacking his intolerance in print and by criticizing his views in other ways. It was some time before Calvin could find a man of equivalent qualifications to take Castellion's place.

The spread of Calvinist doctrine

Ecclesiastical reforms. A first attempt to teach Calvinist doctrine in a systematic way was made in Lausanne, a city not far from Geneva under direct control of the Bernese state. There an academy, which had been established in 1537, began to offer linguistic and theological training on the university level for prospective Calvinist pastors. Theological controversy with the Bernese government, however, forced most of its faculty to leave in 1558 and 1559. Calvin promptly persuaded the Genevan government to fill the vacuum by creating in 1559 a new academy, which evolved into the present University of Geneva. Its first rector was Theodore Beza, a brilliant French Humanist who had studied with some of Calvin's own teachers in Orléans and in Paris and who had begun teaching in Lausanne after his conversion to Protestantism. Beza became Calvin's successor as the principal leader of non-Lutheran, or Reformed, Protestantism.

From the beginning Calvin was also a pastor. He assumed the leadership in 1542 of a corps of nine pastors, some of whom had rather dubious qualifications. In the ensuing 22 years the corps grew to 19, and almost all of its members were highly qualified. They were distributed among city parishes, the number of which varied depending on the population and the supply of pastors, and among several rural parishes belonging to Geneva. Calvin himself lived in the parish near the old cathedral church of St. Pierre and normally preached from its pulpit. Occasionally, he used the nearby parish church of the Madeleine.

The Company of Pastors

Once a week the pastors met as a body, in what came to be known as the Company of Pastors. Calvin served as its moderator, or presiding officer, until his death. This was the only official position he held in Geneva. Entrance to the Company of Pastors was basically by co-optation. When a vacancy occurred or when the city government authorized a new appointment, the company would conduct a search. A likely candidate would be assigned some Bible verses and asked to present an expository sermon on them before the company and then would be examined on the sermon and on his basic beliefs. He would be judged on the basis of competence in biblical exegesis, soundness of theological belief, and skill in speaking. Successful candidates were presented to the city council for approval. Often one or more members of the council attended the meeting of the company at which the examination was conducted. Candidates approved by both company and council were then presented to members of the parish that they were to serve, but this was only a formality.

In addition to screening candidates for the pastorate, the company, under the guidance of Calvin, made parish assignments and established the regular routine of services. It also held occasional sessions for mutual correction in which a kind of self-criticism was encouraged. Toward the end of Calvin's life the Company of Pastors handled an increasing volume of correspondence with Protestants in other countries. As moderator, Calvin often acted as spokesman for the company, particularly in its dealings with the city government. This meant that he frequently attended meetings of the city council and had an important voice in many political decisions—as a consultant rather than as an officeholder, for important offices in the Genevan government were limited to native-born citizens.

The work of the elders and Consistory

Calvin was personally involved in the work of the elders. These "policemen" of the Reformation were chosen in much the same way as all the other officials of the Genevan state, including the men who kept the accounts, maintained the city grain supply, guarded the fortifications, and sat on the municipal courts. Once a year the governing council would prepare a slate of nominees as elders, normally in consultation with Calvin and perhaps other pastors. This slate would then be presented to a general council of all voting citizens for acceptance or rejection. The same men could be elected year after year as elders, but normally there was some turnover. The elders were chosen so that they represented all of the geographic divisions into which the city was divided. Most were native-born Genevans, but toward the end of Calvin's life it became possible to elect to this position a few prominent refugees who had recently settled in the city.

Once a week the elders met with the pastors in a body called the Consistory. Its presiding officer was known as a syndic, one of the four magistrates elected to be chief executives in Geneva for the year. This body acted much like a court. To it were referred hundreds of cases of residents accused of idolatrous or heretical beliefs, of Catholic religious practices, and of misbehaviour ranging from public complaints about Calvin to serious sexual crimes. If the accused seemed penitent and if the lapse was minor, he might be merely reprimanded with a sharp scolding, often administered with considerable vehemence by Calvin. If the accused was not penitent or if the lapse was serious, he could be handed over to the city government for further investigation and punishment. The only punishment that the Consistory itself could administer was excommunication, and this was a real threat in an age when the sacraments were taken very seriously. The Consistory, however, had to fight even for this power. Few Protestant governments of the period were prepared to grant the right of excommunication to an ecclesiastical institution, and many Genevans were less than enthusiastic about the idea. It is not clear that the 1541 ecclesiastical ordinances, as amended by the city government, did in fact give the Consistory that right. Calvin insisted upon it, however, and made it an issue of confidence, threatening to leave the city again if he were forced to administer communion to any excommunicated sinner who had not been pardoned by the Consistory. After a series of sharp internal political fights on this issue, Calvin finally won his way in 1555. From then on the role of the Consistory and Calvin's power in the city were free of any effective challenge. A kind of moral "reign of terror" followed, remarkably reforming the city and creating the kind of moral austerity that later came to be labelled "Puritan."

The deacons and social work

Calvin was less personally involved in the work of the deacons. They were all associated with an institution called the Hospital-General, which coordinated all the charitable activities previously handled by a variety of Catholic foundations. This institution was not a hospital in the modern sense but rather a combination orphanage, home for the elderly, and asylum for the physically and mentally disabled, which also served as headquarters for the distribution of free bread and other forms of assistance to poor families temporally unable to support themselves. It was directed by a deacon (called the "hospitallier"), who lived in the hospital with his family and acted as its full-time administrator. He was selected by the city council whenever the position became vacant. To assist and superintend the hospitallier, the city government elected four or five more deacons, also called procurators of the hospital. They were elected once a year, in exactly the same way as the elders.

The Hospital-General had been established in 1535, before Calvin arrived in Geneva. By providing for it in his ecclesiastical ordinances he was really consecrating an existing institution. He and the other pastors were supposed to be consulted annually in the selection of nominees for procurators of the hospital, but only toward the end of his life was this legal requirement taken seriously. Calvin did, however, become quite involved in the administration of relief to the poor among the religious refugees to Geneva. He sometimes invited them into his own home upon their initial arrival in the city and helped organize, with a number of wealthy French refugees, a fund for the relief of their poor compatriots called the Bourse Française.

Theological disputes and the expansion of Reformed Protestantism. Between 1541 and 1555 much of Calvin's energy was devoted to making this ecclesiastical sys-

tem work, both by winning acceptance for it from the Genevan population and by superintending its daily operation. During these same years he also faced challenges to his doctrinal authority. The most formidable of these came from Jérôme Bolsec and Michael Servetus. Bolsec was a former Catholic theologian who, in 1551, publicly attacked Calvin's doctrine of predestination, claiming that it viewed God as the author of evil. Calvin indignantly rebutted the charge, with some assistance from theologians in other cities, and Bolsec was expelled from Geneva. Servetus was a Spanish doctor who published books attacking the central Christian doctrine of the Trinity—the belief that the one God is revealed as Father, Son, and Holy Spirit. When Servetus came to Geneva in 1553, Calvin saw to it that he was arrested and convicted, with the emphatic assistance of foreign theologians, of heresy. Servetus was subsequently burned to death at the stake. In both of these cases, and in others like them, the city government strongly supported Calvin.

Calvin's final victory in Geneva over his theological opponents left him free after 1555 to devote more of his energy to the spread of Reformed Protestantism in other countries. He had already forged an alliance for this purpose with Zwinglian Protestantism, now led by Heinrich Bullinger of Zürich. That alliance had been sealed by a common confession of faith, the Consensus Tigurinus, adopted in 1549. It was further supported from 1552 on by virulent polemical exchanges on points of sacramental theology between Calvin and certain of the conservative Lutheran opponents of Zwinglianism, notably Joachim Westphal of Hamburg and Tileman Hesshusius of Heidelberg.

Attempts to win France to Reformed Protestantism

Between 1555 and 1564 most of Calvin's concern for the spread of Protestantism was directed to his native France. Under his supervision dozens of French refugees were trained as Reformed pastors, and many were given some practical training as teachers or village pastors in French Switzerland. They were then smuggled back into their native country, where their very presence was illegal until a royal edict in 1562 granted Calvinism a measure of toleration. To bind their activities together, Calvin encouraged the creation of a network of underground ecclesiastical institutions covering much of France. On the local level, congregations were established on the model of Geneva. On a regional level, representative bodies called colloquies were established, including the pastors and elders of a number of churches. Analogues to these bodies later created in other countries were the presbyteries of Scotland and America and the classes of England and the Netherlands. They constitute one of the most characteristic institutions of Calvinist Protestantism. Above the colloquies, on the provincial level, representative synods were established. To unite the entire system a national synod was created that was scheduled to meet about once a year. Its first meeting was held in 1559 in Paris, under the noses of the persecuting royal government, and it there adopted a national confession of faith and code of discipline. During Calvin's lifetime the Geneva Company of Pastors tended to act as a supreme court over this entire system, providing assistance and resolving disputes that could not be handled by the colloquies and synods.

To provide material support for this rapidly growing Reformed Church, Calvin plunged into politics. He got in touch with a number of powerful French aristocrats and urged them to patronize the burgeoning Protestant movement. The most important of these were members of the House of Bourbon, allied by blood to the French royal house, notably the head of the house, Antoine de Bourbon, king of Navarre; his wife, Jeanne d'Albret; his younger brother, Louis, first prince de Condé. Also important were the three Coligny brothers (Odet, Gaspard, and François d'Andelot) of the powerful and wealthy House of Châtillon. Though the assistance of these aristocrats provided French Calvinism with essential protection, it also involved the movement in an open challenge to the French government. That challenge led to religious war. Calvin discouraged the first steps toward war, notably the 1560 Conspiracy of Amboise, in which a group of zealous young nobles from Condé's suite tried to kidnap the young king and kill his conservative Catholic advisers. But when Condé himself mustered an army in 1562 to fight the royal government, Calvin supported him in many effective ways. He even permitted Beza to serve Condé as a consultant, propagandist, and diplomat.

Religious war

Similar kinds of support, on a more modest scale, were provided by Calvin and his colleagues in Geneva to Reformed movements in other countries. Groups of Italian, English, and Spanish refugees were welcomed to the city and permitted to establish their own local churches. Individuals from the Netherlands, many German states, Poland, and still other countries were also welcomed. When these men returned to their native countries as missionaries for Protestantism, Calvin kept in touch with them by correspondence. He also got in touch with officials in their home governments who he thought might be inclined to support Protestant evangelization, writing letters and dedicating books to them. And he did what he could to help the new Reformed Churches organize and defend themselves against attacks from other Protestant and Catholic groups. Altogether, these activities made of Geneva an important international headquarters of Reformed Protestantism. It is with some justice that the city was sometimes called a "Protestant Rome."

In the 1560s Calvin began to have serious problems with his health. More and more of his duties in both Geneva and the international Reformed movement were shared with Beza, his heir apparent, and others. He maintained a reasonably active schedule of preaching, teaching, and writing until early in 1564, the year in which he died, on May 27.

Assessment. Calvin was a rather reticent man, and consequently little is known of the more personal or relaxed sides of his character. His wife died (1549) after a relatively short marriage. He never married again, and their only child died at birth (1542). A man of great intellectual talents, with a prodigious memory, a quick mind, and a rare gift for clear and forceful expression, he became a charismatic leader who inspired hundreds of men to change their lives and run appalling risks to advance his cause. During his entire career he was sustained by the conviction that he had been called by God to reform his church. These qualities help explain the enormous impact Calvin made on Western religious history.

BIBLIOGRAPHY. A nearly definitive biography is that by EMILE DOUMERGUE, *Jean Calvin, les hommes et les choses de son temps*, 7 vol. (1899–1927); it is extremely detailed and factually precise but dubious on some points of interpretation and generally too hagiographic in tone. Another classic biography, FRANZ WILHELM KAMPSCHULTE, *Johann Calvin, seine Kirche und sein Staat in Genf*, 2 vol. (1869–99), is somewhat more critical in tone but less detailed. The most useful recent English account of Calvin's life is JOHN T. MCNEILL, *The History and Character of Calvinism* (1954). For a skillful and authoritative introduction to Calvin's thought, see FRANCOIS WENDEL, *Calvin, sources et évolution de sa pensée religieuse* (1950; Eng. trans., *Calvin: The Origin and Development of His Religious Thought*, 1963). E. WILLIAM MONTER, *Calvin's Geneva* (1967), presents a thoughtful description of the milieu in which Calvin worked. ROBERT M. KINGDON, *Geneva and the Coming of the Wars of Religion in France, 1555–1563* (1956), provides an analysis of the methods Calvin used to extend his influence to other countries. The total number of studies on Calvin is very large. ALFRED ERICHSON, *Bibliographia Calviniana* (1900, reprinted 1960); and WILHELM NIESEL, *Calvin-Bibliographie, 1901–1959* (1961), provide guides to this vast literature. Supplements to these compilations may be found in a number of surveys published in periodicals, such as PIERRE FRAENKEL *et al.*, "Petit supplément aux bibliographies calviniennes, 1901–1963," *Bibliothèque d'Humanisme et Renaissance*, 33:385–413 (1971). The best and most complete edition of Calvin's works is the *Ioannis Calvini Opera quae supersunt omnia*, 59 vol., ed. by G. BAUM, E. CUNITZ, and E. REUSS for the *Corpus Reformatorum* (1863–1900, reprinted 1964). Supplementary material may be found in the *Supplementa Calviniana* (1961–), a series of hitherto unpublished Calvin sermons; and the *Registres de la Compagnie des Pasteurs de Genève au temps de Calvin*, 2 vol., ed. by ROBERT M. KINGDON and JEAN-FRANCOIS BERGIER (1962–64), a partial record of the deliberations of

the Geneva Company of Pastors from 1546 to 1564. Much of this material has been translated into English. Good recent examples include the JOHN T. MCNEILL and FORD LEWIS BATTLES edition of the *Institutes of the Christian Religion* (1960); the FORD LEWIS BATTLES and ANDRE MALAN HUGO edition of *Calvin's Commentary on Seneca's De Clementia* (1969); and the PHILIP E. HUGHES translation of *The Register of the Company of Pastors of Geneva in the Time of Calvin* (1966).

(R.M.K.)

Cambodia

Cambodia, or the Khmer Republic, is a country located in Southeast Asia in the southwest part of the Indochinese Peninsula. Together with Laos and North and South Vietnam, Cambodia is part of what formerly was known as Indochina. Covering a land area of 69,898 square miles (181,035 square kilometres), it is bordered on the west and northwest by Thailand, on the northeast by Laos, on the east and southeast by South Vietnam, and on the southwest by the Gulf of Thailand (Gulf of Siam). With a population of about 7,000,000 people, Cambodia is an underpopulated, predominantly agricultural country with a largely underdeveloped economy.

After United States and South Vietnamese forces intervened in Cambodia in 1970, the country became increasingly involved in the enlarged war in Indochina. Control over the country's territory is now contested on the one hand by the government of the Khmer Republic, and on the other by Vietnamese Communist forces who are assisting Prince Norodom Sihanouk's Royal Government of National Union, with headquarters in Peking. (For an associated physical feature, see MEKONG RIVER; for historical aspects, see CAMBODIA, HISTORY OF.)

THE LANDSCAPE

Physiography. *Relief.* Cambodia's maximum extent is about 280 miles from north to south and 360 miles from east to west. The central region is a low-lying, densely populated alluvial plain surrounding the Tonle Sap (Great Lake) and the Mekong River Delta. Extending outward from this region are transitional plains, thinly forested and with prevailing elevations no higher than several hundred feet above sea level. On the north, along the border with Thailand, the Cambodian plain abuts a steep sandstone escarpment that marks the southern limit of a mountain range, the Chuŏr Phnum Dângrêk. A southward-facing cliff, stretching for more than 200 miles in a west to east direction, rises abruptly from the plain to heights ranging from 600 to 1,800 feet, forming a natural frontier boundary. East of the Mekong the transitional plains gradually merge with the eastern highlands, a region of densely forested mountains and high plateaus that extended northward and eastward into Laos and South Vietnam. In southwestern Cambodia, two distinct upland blocks, comprising the Chuŏr Phnum Krâvanh (Cardamomes) and the Chuŏr Phnum Dâmrei (Éléphant), form another highland region that covers much of the land area between the Tonle Sap and the Gulf of Thailand. In this remote and largely uninhabited area is found Phnum Aôral (5,949 feet), Cambodia's highest peak. The southern coastal region adjoining the Gulf of Thailand is a narrow lowland strip, heavily wooded and moderately populated. It is effectively isolated from the central plain by the southwestern highlands.

Drainage. The two most dominant topographical features of Cambodia are the Mekong River and Tonle Sap. Rising in Tibet and emptying into the South China Sea, the Mekong enters Cambodia from Laos and flows broadly southward to the border with South Vietnam, covering a distance of approximately 315 miles. Its annual flooding during the rainy season deposits a rich alluvial sediment that accounts for the fertility of the central plain region.

Tonle Sap (the Great Lake)

The Tonle Sap, joined to the Mekong by the Tônlé (river) Sab, serves as a reservoir for the Mekong. During the rainy season, from mid-May to early October, the Mekong's enormous volume of water backs up the Tônlé Sab for a distance of 65 miles and flows into the Tonle Sap lake, expanding its surface area from the dry season minimum of 1,200 square miles to a rainy season maximum of more than 3,000 square miles and increasing its maximum depth from seven feet to 35 feet. As the water level of the Mekong falls during the dry season, the process is reversed. Water drains from the Tonle Sap lake back into the Mekong, thereby reversing the directional flow of the Tônlé Sab. As a result of this annual phenomenon, the Tonle Sap lake is one of the richest sources in the world of freshwater fish.

Climate. Cambodia has a climate governed by monsoonal (rainbearing) winds and characterized by two major seasons. From mid-May to early October, strong prevailing winds blow out of the southwest, bringing heavy rains and high humidity. From early November to mid-March, winds are from the northeast and are light in velocity. Cloudiness is variable, precipitation is infrequent, and humidity is low. Between these two seasons the weather is transitional. Maximum temperatures are high throughout the year, ranging from the mid-90s (° F, about 35° C) in April, the warmest month, to the low 80s in January, the coldest month. Daily minimums are usually 15° to 20° F lower than maximums.

Annual rainfall varies considerably throughout the country, from more than 200 inches on the seaward slopes of the southwestern highlands to 55 inches in the central lowland region. Between 70 and 80 percent of the annual rainfall occurs during the months of the southwest monsoon wind.

Vegetation and animal life. About 75 percent of Cambodia's land area is forested. The central lowland region is covered with rice paddies, fields of dry crops (such as corn [maize] or tobacco), tracts of tall grass and reeds, and thinly wooded areas. Savanna (grassy parkland) is the prevailing vegetation of the transitional plains, with grass growing to a height of five feet. In the eastern highlands the high plateaus are covered with deciduous forest and grassland. Broadleaf evergreen forests grow in the mountainous areas to the north, with trees 100 feet high emerging from impenetrable undergrowths of vines, rattans, palms, bamboos, and assorted woody and herbaceous ground plants. In the southwestern highlands open forests of pines are found at the higher elevations, while the rain-drenched seaward slopes are blanketed with virgin rain forest growing to heights of 150 feet or more. Vegetation along the coastal strip ranges from evergreen forests to nearly impenetrable mangrove forests.

Fruit, growing wild or cultivated, includes breadfruit, jackfruit, durian (a fruit with a prickly rind and a highly flavoured pulpy flesh), mango, mangosteen (a species of juicy fruit), papaya, rambutan (a bright red, oval fruit), and bananas.

Animal life includes elephants, wild oxen, tigers, panthers, leopards, bears, and innumerable small game. Among the more common birds are herons, cranes, grouse, pheasant, peacocks, pelicans, cormorants, egrets, and wild ducks. Four varieties of snakes are especially dangerous: the cobra, the king cobra, the banded krait (an extremely venomous, grooved-fanged snake of nocturnal habits), and Russell's viper.

The landscape under human settlement. Cambodia is a country of villages. Only about 10 percent of the total population lives in urban areas of 10,000 or more inhabitants; the major part of the urban population is concentrated in Phnom Penh, Cambodia's capital city, which is situated at the confluence of the Mekong, Basăk (Bassac), and Sab rivers.

Village life

About 90 percent of the country's total population inhabits the central lowland region, the economic heartland of Cambodia. The rural village is second only to the family as the basic societal unit. To most Cambodians it is a miniature world in which they spend their lives, and within which most of their material and physical needs are satisfied. The typical Cambodian village is largely autonomous and self-sufficient, made up of ethnically homogeneous people numbering fewer than 300 persons. It is part of a hamlet or commune—the smallest officially recognized administrative unit—with which it invariably shares one or more Buddhist temples, an elementary school, several small shops, and a marketplace.

Cambodian villages develop in a linear pattern along the waterways and roads. Many represent multiplications of paternal households. Most houses are built on high wooden pilings and have thatch roofs, walls of palm matting, and floors of woven bamboo strips resting on bamboo joists. Partitions separate the living, sleeping, and cooking quarters. Farm implements are stored under the house. Each house is usually surrounded by fruit trees cultivated by the family. The village is bordered by rice paddies and farmland.

There are few large landowners in Cambodia. The typical villager owns and works only enough land to support his family. Any Cambodian can become a landowner by settling on public land belonging to the government and working it for a period of five years. The tribal people residing in the eastern highland region follow migrant settlement patterns determined by their "slash-and-burn" agricultural practices. After the fertility of the land has been exhausted, the village is moved to a new locality.

Unlike the Cambodians of the lowland region, the tribal groups frequently build longhouses in which several families live. Throughout rural Cambodia the life-style of the population is closely geared to the agricultural cycle. Family members are awake before the first light of dawn, and the major portion of the day's work is accomplished before high noon, when the sun's heat discourages further labour in the fields. Following a light meal and a long rest, minor agricultural tasks are performed in the late afternoon. Since electricity is rare in the village areas, the average family is asleep soon after sunset. During the rice-growing season, all family members work together in the paddies (rice fields); even the young children have assigned duties to carry out. Festivals and marriages usually take place during the dry season.

Urban areas

The urban areas of Cambodia developed as administrative, communications, and commercial centres serving the surrounding rural regions. The majority are located at the intersection of river or land routes and are relatively accessible to the communities they serve. Phnom Penh (*phnom* means "hill"; Penh is a woman's name) is Cambodia's single metropolis (1971 population: 479,000 (excluding refugees). Only ten other localities have populations exceeding 10,000.

The typical city consists of a centrally located commercial and administrative area bordered by private dwellings. Government buildings, Chinese stores, the central market, and commercial buildings are usually two or three stories high and are of masonry construction. Buddhist temples and shrines are found throughout the city and represent well-known landmarks. Urban architecture is predominantly French, reflecting the influence of France's 90-year protectorate over Cambodia.

In the larger cities, Cambodians, Chinese, and Vietnamese reside in their own ethnic neighbourhoods; in the smaller towns the inhabitants are racially more homogeneous. The traditional role of the Chinese as the middlemen in the Cambodian economy—the buyers, processors, and sellers of the agricultural commodities produced by the rural Cambodian population—has had a strong urbanizing effect upon this ethnic minority group; few Chinese are found in the countryside. The Vietnamese, who serve primarily as technicians and mechanics, also gravitate toward the urban areas. As a consequence the rural areas are populated principally by Cambodians, while the towns and cities are racially mixed.

In addition to Phnom Penh, other principal cities include Bătdâmbâng (39,000), Kâmpóng Cham (35,000), Krâchéh (15,000), and Siĕmréab (13,000). Located in the

rich rice-producing region of western Cambodia, Bătdâmbâng is Cambodia's second largest city. Kâmpóng Cham, situated on the Mekong north of Phnom Penh, is the hub of the rubber plantation region. Krâchéh, further north, is in an important lumber-producing area. Siĕmréab, north of the Tonle Sap in west central Cambodia, is one of the most popular tourist sites in Southeast Asia. Here are located Angkor Wat and the extensive complex of ruins belonging to the Khmer Empire (802–1432).

Following North Vietnam's invasion of Cambodia in 1970 and the enlargement of the conflict in Indochina, Vietnamese Communist forces, aided by small elements of Cambodian dissidents, occupied approximately 50 percent of the country's national territory, containing about 20 percent of the total population. At an early stage, Cambodian government troops were forced to abandon most of the land area north of a line drawn from Siĕm réab to Kâmpóng Cham. This included the provinces of Rôtânôkiri, Stæng Trêng, Môndól Kiri, Krâchéh, Preăh Vihéar, and large parts of Kâmpóng Cham, Kâmpóng Thom, Siêmréab, and Ŏtdar Méanchey. In addition to seriously affecting the country's economy, the war produced a substantial flow of migration as refugees from the occupied areas sought protection and shelter in those controlled by the Cambodian government. By the end of 1970 it was estimated that Phnom Penh's population had increased to 1,100,000—nearly double the preinvasion figure. Other urban areas south of the Tonle Sap also increased rapidly in population as villagers sought to escape insecurity prevailing in the rural regions.

Effect of the war on population distribution

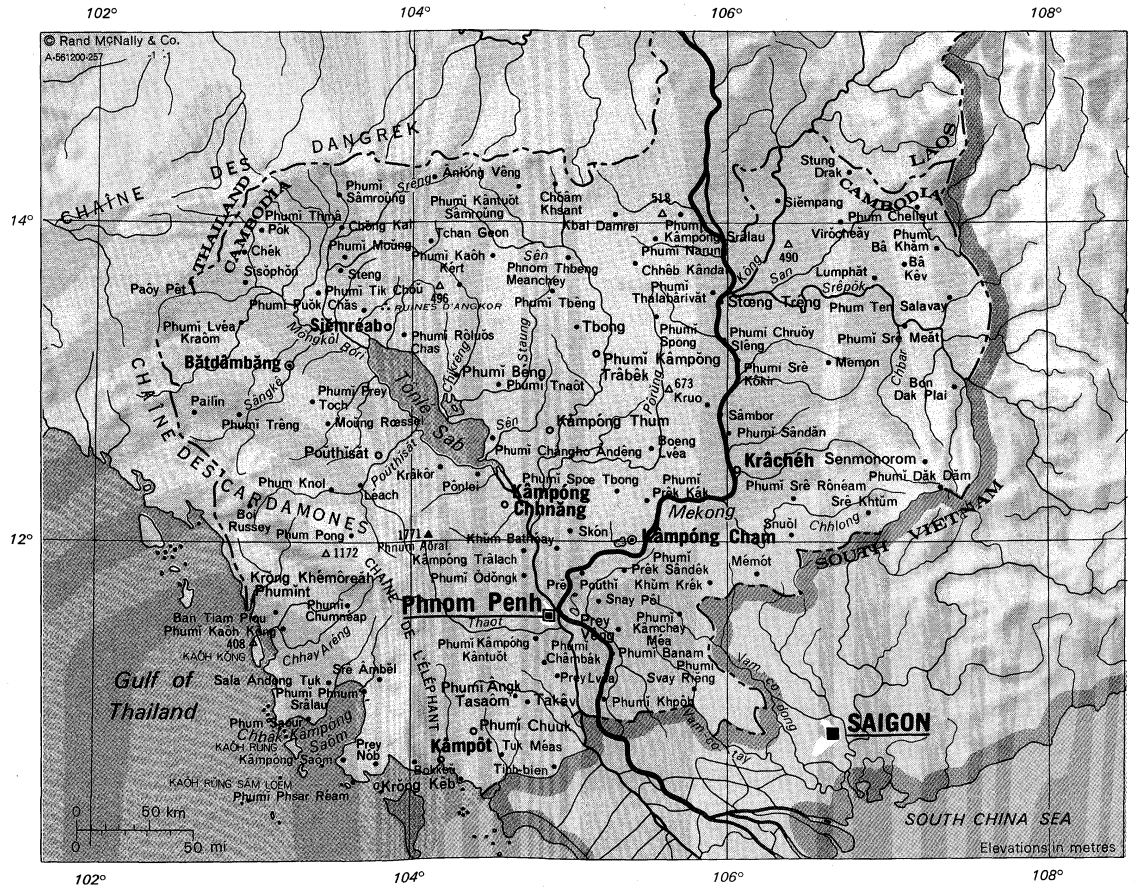
PEOPLE AND POPULATION

Cambodia's first national census as an independent nation was taken in 1962. The results showed that the population totalled about 5,700,000. By mid-1971 it was estimated to have increased to about 6,968,200, representing an average annual growth rate of 2.4 percent. Cambodia's population is about one-fifth that of Thailand, less than half that of South Vietnam, and less than a third that of North Vietnam. In Southeast Asia, only Laos and Singapore have smaller populations than Cambodia. Overall population density is 100 persons per square mile; it is high in the south, moderate in the west central area, and low in the north and northeast.

Ethnic and linguistic groups. Khmer (Cambodian) stock accounts for about 90 percent of the total population. This has produced a homogeneity that is unique among the nations of Southeast Asia and has brought about a strong sense of nationalism. Other major ethnic groups include the Chinese (350,000) Vietnamese Cham-Malays (90,000), various Malayo-Polynesian and Austro-Asian hill tribes (50,000), some Tai (300,000), and Europeans, mainly French (5,000).

The Khmer

The Khmer are concentrated principally in the lowland regions surrounding the Mekong and Tonle Sap, on the transitional plains, and in the coastal area. They belong to the Mon-Khmer ethnolinguistic group. An end product of centuries of intricate cultural and racial blending, the Khmer descended before 200 BC into the fertile Mekong Delta from the Khorat Plateau of what is now Thailand. They were Indianized by successive waves of Indian immigration at the beginning of the Christian Era, and in the 8th century AD were exposed to an Indo-Malayan migration from Java. This was followed by Tai migrations from the 10th to 15th centuries, by a Vietnamese migration beginning in the 17th century, and by Chinese migrations in the 17th and 19th centuries. As a result of this racial admixture, the Khmer are generally classified as Austroasiatics linked to the Veddoid, Indo-Australoid, and Mongoloid peoples. Their physical characteristics reflect their mixed background. Despite wide variations, they tend to be of short stature (the average height of a male is about five feet, three inches), robust, and muscular. Skin colour is light to brown, and hair is black. Less than 50 percent show the epicanthic fold (a fold of skin extending from the eyelid over the inner corner of the



CAMBODIA

eye; it is sometimes called the mongolian fold). The typical Khmer family is a five-member nuclear unit consisting of a married couple and their unmarried children. Both sons and daughters usually leave the parental home after marriage to establish their own households.

The ethnic minorities

Among the ethnic minorities, the Chinese are the most important, for they control the country's economic life, serving as moneylenders, entrepreneurs, merchants, and transporters. The Chinese retain a high degree of cultural distinctiveness, but many have been assimilated into Khmer society through intermarriage. The Vietnamese minority occupies a lower status. Before 1970 they numbered about 400,000, but following the outbreak of war in Cambodia, about half the Vietnamese either fled to Communist areas or were repatriated to South Vietnam. Centuries of mutual dislike and distrust characterize Vietnamese-Khmer relations, and intermarriage is infrequent. The Cham-Malay group, known in Cambodia as Khmer Islām, maintains a rigorous Muslim orthodoxy that discourages assimilation into the Buddhist Khmer ethnic majority. They live in their own villages, principally along the banks of the Mekong and Sab rivers, and like the Khmer engage in farming and fishing. The primitive tribal groups, designated Upland Khmer (Khmer Loeu) and Upland Cham are found mainly in small settlements in the sparsely populated eastern highlands. More than a dozen different linguistic groups may be distinguished.

Religious groups. The Khmer are almost universally Theravāda (Hīnāyana) Buddhists (*i.e.*, belonging to the earlier of the two great schools of Buddhism, the later school being represented by the Mahāyāna), and Buddhism is officially recognized as the state religion. Buddhist precepts permeate all levels of Khmer society. The social and psychological characteristics usually ascribed to the Khmer—individualism, conservatism, patience, gentleness, and unconcern for material wealth and possessions—are largely traceable to Buddhism. The Chinese and Vietnamese are eclectic in their religious beliefs, practicing various forms of Mahāyāna Buddhism, Confucianism, Taoism, and ancestor worship. The Cham-Malay group are strict Muslims and follow Qur'ānic law. The primitive tribal groups are mostly animists and spirit worshippers.

Demography. In common with many developing countries, Cambodia has a large proportion of children in its population. The median age group is 18 years old, as contrasted, for example, to 29 years old in the United States. Children under 15 comprise about 46 percent of the population. There are 874 persons in the dependent age groups (usually considered to take in those persons 14 years and under and those 65 and over) for every 1,000 persons of working age. Life expectancy in Cambodia is about 50 years. Corresponding values in the United States are 66 for males and 73 years for females. The birthrate is estimated at 45 per 1,000 population, while the deathrate is about 16 per 1,000. Since there is no accurate system for registering births and deaths among the population outside the urban areas, vital statistical data must in most cases be derived from estimates.

*The area and population of the new province of Preăh Vihéar are included in Kâmpóng Thum. †Area and population of the new province of Ŏtdar Méanchey are included in Siĕmréab. ‡Areas were published before the latest reorganization and include 1,158.3 sq mi (3,000 sq km) of inland water. §Final census figure. Population figures for individual municipalities and provinces are preliminary. ||Figures do not add to total because of rounding. Source: Official government figures.

THE NATIONAL ECONOMY

Cambodia's economy is one of the least developed of the Southeast Asia region. It is heavily dependent upon two major products—rice and rubber—and consequently is vulnerable to profound annual fluctuations caused by vagaries in rainfall and world market prices. Agriculture dominates the economy, employing about 80 percent of the population and providing more than a third of the total gross national product. Of 800,000 families residing in the rural areas, 670,000 are engaged in rice cultivation. The tradition of land ownership is strong. Approximately 84 percent of the rural population are owner-cultivators, 6 percent are tenants or contractual farmers, and 7 percent belong to unspecified categories. Family landholdings are relatively small: 55 percent own less than one hectare (2.5 acres), 25 percent own less than two hectares (five acres), and 12 percent own less than five hectares (12 acres). In 1969 Cambodia's gross national product (GNP) amounted to $578,000,000 U.S., representing a per capita income of $120 U.S. This figure, however, must be interpreted with the knowledge that the rural mass of the population is largely self-sufficient. One hectare of rice paddy provides for the needs of a family of five persons, and supplementary requirements are satisfied by fishing, cultivating fruit and vegetables, and raising livestock. Famine is extremely rare in Cambodia, but the self-sufficiency factor characterizing the rural family, coupled with the fertility of the soil and warm climate, have produced a conservatism that has proved resistant to government efforts to modernize Cambodia's primitive agricultural methods.

Sources of national income. *Agriculture.* Rice is Cambodia's principal food, its major crop, and its most important export commodity. Rice is grown on approximately 85 percent of the country's total cultivated land area. The principal rice regions surround the Mekong and Tonle Sap, with cultivation particularly intensive in Bătdâmbâng, Kâmpóng Cham, Takêv, and Prey Vêng provinces. Lacking sufficient irrigation systems, Cambodia produces one rice crop per year. Planting begins in July and August and the harvest period extends from November to January. The amount of rainfall determines the size and quality of the crop. During the 1960s, total annual production ranged from a low of about 2,200,000 tons of paddy (1,200,000 tons of milled rice) to a high of 3,580,000 tons (about 2,000,000 tons of milled rice). In a typical year approximately 50 percent of the crop is consumed by the rural population, 34 percent goes to the domestic market, and the balance is exported. Average paddy (unhusked rice) yield per hectare (2.5 acres) is 1.6 tons—one of the lowest in Asia.

Rice

Other food products include corn, beans, soybeans, and sweet potatoes. The principal fruit crops, all of which are consumed locally, include oranges, bananas, and pineapple.

Commercial crops such as cotton, tobacco, kapok, sugarcane, and oilseeds are grown in limited quantities. The red-coloured basaltic plateaus of Kâmpóng Cham, Krâchéh, and Rôtânôkiri provinces are especially suitable for rubber trees. Rubber exports account for 30 to 40 percent of Cambodia's total foreign-exchange earnings. By the end of the 1960s, rubber plantations covered 70,000 hectares (173,000 acres), of which 48,000 hectares (119,-

Rubber

000 acres) were in production. Total annual latex production is about 55,000 tons. The average latex yield per hectare in Cambodia is among the highest in the world.

Fisheries and livestock. Fisheries and livestock are important components of the domestic economy. Fish in its various forms—fresh, dried, smoked, and salted—constitutes the single most important source of protein in the Cambodian diet, and subsistence fishing is part of every farmer's activity. The annual freshwater catch, which includes perch, carp, lungfish, and smelts, is estimated to be from 110,000 to 130,000 tons. Cattle, particularly water buffalo, are used principally as draft animals in the rice paddies and fields. Hog production amounts to 1,000,000 head per year.

Mineral resources. Cambodia has few known mineral resources. Some limestone and phosphate deposits are found in Kâmpôt province, and precious stones in limited quantities are mined in Bătdâmbâng. Iron and coal traces have not justified commercial exploitation. No petroleum resources have yet been discovered. Electrical power sources are mainly dependent upon imported oil. The construction of modest hydroelectric dams at Kirirôm and Kâmchay has been halted by the war. A dam at Prek Inaut is to be built with United Nations help.

Industrial development. Although Cambodia's industrial development remains at a low level, the government has made strong efforts to build a modest industrial base suitable to the needs of the country. By the end of 1969 there were some 3,700 small plants and factories in Cambodia, the major portion of which were devoted to agricultural processing.

Management of the economy. In seeking rapid economic development, Cambodia in 1963 adopted a socialistic policy characterized by nationalization of the private banking system, establishment of a government monopoly over imports and exports, and extensive state participation in building and managing industrial enterprises. This policy proved to be unsuccessful, mainly because of defective economic planning, insufficient labour and managerial skills, and rigidly fixed agricultural prices that discouraged production incentive. Faced with a growing economic crisis in 1969, the government returned to more liberal practices. There are no trade unions. The tax system, centrally controlled by the Ministry of Finance in Phnom Penh, derives most of its revenue from property and sales taxes, and from service taxes.

Foreign trade. Throughout the 1960s and early 1970s Cambodia experienced a chronic foreign trade deficit. In a typical year (1970) exports totalled $39,000,000 U.S. and imports totalled $54,000,000 U.S. The bulk of Cambodia's exports, consisting almost entirely of rice, rubber, and agricultural products, go to Asian nations. European nations and Japan provide the major portion of imports, which cover an extensive range of manufactured goods, industrial products, and raw materials. Exports go to Hong Kong, Singapore, Japan, and France; and before 1970, mainland China and North Vietnam.

Trading partners

The effect of war on the economy. In 1970 the North Vietnamese invasion of Cambodia and the subsequent occupation of large areas of the country by Vietnamese Communist forces severely crippled the Cambodian economy, ending any immediate prospect of further economic development while the country remained engulfed in the enlarged Vietnam war. Within several months rubber production had completely ceased and all of the plantations were occupied by enemy forces; many of the trees were destroyed by the fighting. Rice cultivation decreased by 30 percent as a result of the war and general insecurity. Much of the road network and the two railroad lines were intermittently cut, isolating the agricultural areas from Phnom Penh and from the port at Kâmpóng Saôm. Under these circumstances Cambodia found itself dependent upon foreign aid, principally from the United States, as it struggled for both military and economic survival.

Transportation. Cambodia's inland waterways and road systems constitute the main transportation routes. Each is invariably affected by the floods of the rainy season, which result in heavy silting and washouts (flash floods). Railroads rank third in significance. Domestic shipping and civil air facilities are limited. Maritime commerce is carried out almost exclusively by foreign vessels.

The road system, which in recent years has surpassed the country's inland waterways as the principal means for moving cargo and passengers, has an overall extent of 9,300 miles. The network was originally designed by the French during the protectorate period to link the agricultural hinterland with the port of Saigon in South Vietnam. Consequently the system does not serve Cambodia as a whole. Extensive land tracts in the northern, northeastern, and southwestern parts of the country are roadless. Of the total road network, about 1,600 miles are paved; other roads are surfaced with crushed stone, gravel, or laterite or are simply graded without being paved. The network contains more than 1,800 bridges of more than 20 feet in length, with average load capacities of five tons. The country's longest bridge is a ten-span structure, more than 2,300 feet in length, traversing the Tônlé Sab at Phnom Penh.

The inland waterways have a collective extent of 1,200 miles, of which more than 90 percent are part of the Mekong and Tonle Sap systems. Phnom Penh, located about 200 miles from the mouth of the Mekong, can be reached by oceangoing vessels of less than 13-foot draft. North of Phnom Penh, the Mekong is navigable to Krâchéh for rivercraft, but rapids and winding channels in the 117-mile section between Krâchéh and the Laos border generally preclude commercial navigation.

Port at Kâmpóng Saôm

Cambodia's single maritime port is located at Kâmpóng Saôm (formerly Sihanoukville) on the Gulf of Thailand. Completed in 1960, Kâmpóng Saôm can provide unlimited anchorage for oceangoing ships, and its main pier can accommodate four vessels of up to 15,000 tons. The port is of strategic importance to Cambodia, and considerable industrial development has taken place in the area. A modern four-lane highway links Kâmpóng Saôm with Phnom Penh.

The railroad system comprises about 400 miles of single-track, metre-gauge line and is owned and operated by the Cambodian government. One line, completed prior to World War II, connects Phnom Penh with Paôy Pêt on the Thai frontier—a distance of 239 miles—and facilitates the movement of milled rice from the western provinces of Bătdâmbâng, Poŭthĭsăt, and Kâmpóng Chhnăng. The second line, completed in 1969, connects Phnom Penh with Kâmpóng Saôm, covering a distance of 168 miles through the provinces of Kândal, Takêv, and Kâmpôt.

International air service is available from Phnom Penh to Bangkok, Saigon, Hong Kong, and Singapore via Air Cambodge, the country's national airline. Domestic flights connect Phnom Penh with Siĕmréab, Bătdâmbâng, Kâmpóng Saôm, and Kâmpôt.

Since the outbreak of war in Cambodia in 1970 much of the country's transportation system has either been lost to Vietnamese Communist forces or has been severely crippled. Control over the system is an important military objective for both sides in the conflict.

ADMINISTRATION AND SOCIAL CONDITIONS

Administration. *Political developments.* In October 1970 Cambodia abolished its centuries-old monarchy and officially proclaimed itself the Khmer Republic. This development followed in the aftermath of the deposition of Prince Norodom Sihanouk as chief of state. The deposed leader has since settled in Peking for the purpose of forming a government in exile. The outbreak of war in 1970 severely disrupted all aspects of government administration.

The structure of government. Under the constitution adopted by referendum in 1972, executive power is exercised by the president, who is elected by direct universal suffrage. He promulgates the laws, designates a prime minister and a 15-member Cabinet (Conseil des Ministres), signs foreign treaties, and is the commander in chief of the armed forces. He presides over the Cabi-

net, which names ambassadors, provincial governors, and other civil and military officials. Legislative responsibility is vested in a Parliament, which is comprised of a National Assembly of 80 or fewer members, elected for periods of four years, and a Senate of 28 to 40 members, elected for periods of six years. Financial legislation must originate in the assembly.

Local government. Cambodia is divided administratively into 19 provinces (*khêt*) and four independent municipalities (*krung*). Each province is subdivided into districts (*srŏk*), hamlets (*khum*), and village groups (*phum*). Provincial governors serve as direct representatives of the central government and are appointed by the Cabinet. The various provincial services—public works, agriculture, education, police, health, finance—fall under the governor's overall supervision. The chief administrative officers of the districts and hamlets are responsible to the provincial governor. They execute the laws at the local level, collect taxes, serve as mediators between litigants, and maintain records and statistics. In time of peace they are elected by the residents of the localities in which they serve.

Justice. The judiciary is composed of the Magistracy, the Supreme Court, and the Superior Council of the Magistracy. In addition, there exist a separate Constitutional Court and a High Court of Justice, which have the authority to judge members of the government, the Parliament, and the Constitutional and Supreme courts.

The armed forces. From a pre-1970 level of 35,000, the Cambodian armed forces were subsequently rapidly expanded by volunteers to 200,000, resulting in a heavy drain upon the country's financial resources. The army was ill-trained, ill-equipped, and unprepared for the movement of Vietnamese Communist forces out of their sanctuary bases along the border and their rapid occupation of large areas of Cambodia. The government adopted a defensive strategy to retain the regions under its control until the armed forces could be adequately equipped and trained.

The airforce, with an inventory of some 120 aircraft of various types, has an approximate strength of 1,750 men. It is capable of providing only minimal transport and tactical ground support. The navy is responsible for river and lake patrol as well as limited coastal patrol; in 1970 it had almost 90 vessels and a total complement of almost 4,000.

Social conditions and services. *Education.* The government has made intensive efforts to expand education, health, and welfare services. Planning has concentrated chiefly on providing schooling in order to create a body of skilled and semiskilled manpower. Between the mid-1950s and 1969, total school enrollment nearly quadrupled, rising from about 300,000 to about 1,000,000 at the elementary level, from 6,000 to 120,000 at the secondary level, from 400 to 7,000 at the technical and professional level, and from more than 100 to 9,000 at the university level. More than 91 percent of all students are enrolled in public schools under the jurisdiction of the Ministry of Education, and during 1970 education expenditures averaged approximately 20 percent of the annual national budget.

The literacy level

Literacy levels in Cambodia have been rising slowly as a result of increased opportunities for schooling, but they remain below those of other Southeast Asian nations, with the exception of Laos and South Vietnam. It is estimated that 54 percent of the population aged ten years and older is literate.

Health. An acute shortage of medical personnel has been a major obstacle in implementing an effective public health program. In 1969 there were only 440 fully qualified physicians. There were less than 300 health officers in Cambodia in the middle 1960s. Medical services function under the jurisdiction of the Ministry of Health. By the end of the 1960s the country had 1,400 hospitals, infirmaries, dispensaries, clinics, and maternity centres, although a disproportionate share of them was located in Phnom Penh. The most prevalent diseases are malaria, venereal disease, yaws, leprosy, trachoma, and parasitic infections. In 1966 it was estimated that 20 percent of the population was affected by tuberculosis. No comprehensive system of social insurance has been established. Primary responsibility for care of the aged, infirm, and needy lies within the family circle, with supplementary assistance occasionally provided by the village.

Cultural life and institutions. Contemporary Cambodian culture and artistic expression are overshadowed by the greatness of the past. Although owing much to Indian influence, the achievements of the Khmer Empire represented original contributions to Asian civilization. The magnificent architecture and sculpture of the Angkorean period (802–1432), as seen today in the restored temple complexes at Angkor Wat and Angkor Thom, marked the apex of Khmer creativity. Following the capture of Angkor by the Thai (15th century) and the crumbling of the empire, Cambodia underwent four centuries of foreign invasions, civil war, and widespread depopulation. It was not until the establishment of the French protectorate in 1863 that internal security was restored, the country's borders stabilized, and efforts undertaken to revive traditional Khmer art forms. After gaining independence from France in 1953, the Cambodian government placed particular emphasis upon accelerating revival by establishing a national school of music, a national school of ballet and theatre, and a fine arts university. This coincided with the rapid expansion of elementary and secondary school facilities throughout the country, and the emergence of education as the most important social mobility factor in Cambodian society.

Khmer architecture

Music and dance forms. Music occupies a dominant place in Cambodian culture. It is sung and played everywhere—by children at play, adults at work, by young men and women while courting—and invariably is part of the many celebrations and festivals that take place throughout the year at Buddhist temples in the rural countryside. An especially popular pastime is to improvise lyrics for traditional tunes in order to tell a story or comment upon some aspect of the local contemporary scene. Instruments used in full orchestras include xylophones with wooden or metal bars, one- and two-stringed violins, wooden flutes, oboes, and drums of different sizes. The Cambodian scale has five tones, compared with seven in the Western scale. Orchestral music has no harmony, in the technical musical sense. The players follow the lead of one instrument, usually the xylophone, and improvise as much as they wish.

Dancing and drama

Dancing and drama are also popular forms of artistic expression. The Royal Ballet in Phnom Penh exemplifies the classic, highly stylized dance form adapted by the Cambodians and Thai from the ancient dances of Angkor. Accompanied by an orchestra and choral narration, the dancers act out stories and legends taken principally from Hindu epics such as the *Rāmāyaṇa*. In the countryside, folk drama and folk dances are performed at festivals and weddings by wandering troupes. The actors invariably depict stereotyped characterizations familiar to all: the country yokel, the clumsy lover, the beautiful princess, the cruel father, and the greedy merchant. The visual arts reveal the essential conservatism of the Cambodians. Ancient themes are preferred and rarely is there an effort to improve or adapt. The principal crafts are weaving, working silver and gold, making jewelry, and the sculpture of wood and stone. Traditional Khmer literature consists largely of old stories and legends in poetic form. Modern literature, dating from World War II, is beginning to reflect new social values as a result of the influence of young intellectuals sent abroad for university training.

Newspapers, radio, and television. The status of newspapers and of book publishing reflects the essentially rural nature of Cambodia. There are approximately 60 newspapers and periodicals in the country, with a total maximum circulation of over 300,000. Most are published in Phnom Penh. Books are available only in the urban areas. Approximately 350 new titles are published each year, but a typical edition consists of only 500 copies. Radio exerts the greatest influence on public opinion. Operated by the Ministry of Information, the Cam-

bodian National Radio broadcasts in Cambodian, French, English, Vietnamese, Laotian, and Thai. It is estimated that there are 1,000,000 radio receivers in the country. Television programming was initiated in 1960. There are 50,000 sets, owned mainly by wealthy people.

Prospects for the future. As a small and relatively weak country surrounded by more powerful neighbours, Cambodia's prospects for survival as an independent nation will largely be determined by the outcome of the enlarged Vietnam War, in which it has become involved, and by the effectiveness of any postwar settlement designed to prevent recurrent hostilities in the Indochina region. Historically, Cambodia has traditionally sought the protection of a larger foreign nation exerting authority in the area or has attempted to negate inimical external influence through a balance-of-power arrangement. The arrival of the French in the 19th century saved Cambodia from partition and possible extinction, while the neutralist policy of the postindependence period proved to be remarkably effective until the Sihanouk regime deviated from the neutralist line it had originally traced. These basic options are once again likely to influence the country's leaders. Future prospects must also take into account the substantial damage done to the economy by the war and the consequent need for large-scale foreign assistance if Cambodia is to reconstruct and resume the modernization program of the postindependence period. This in turn will require stable and effective government carried out within a political system ensuring national unity and social progress.

Cambodia, History of

The importance of Cambodia's cultural and historical contributions to the development of mainland Southeast Asia is out of proportion to its present reduced territory and limited political power. At the height of its power (11th–13th centuries), the Khmer (Cambodian) state stretched across a vast area of the Indochinese peninsula and incorporated much of modern South Vietnam, Laos, and Thailand, and the cultural influence of Cambodia on the other peoples of Southeast Asia has been enormous.

CAMBODIA BEFORE THE 9TH CENTURY AD

Knowledge of Cambodian prehistory is extremely limited. Excavations at three prehistoric sites—Samrong Sen and Longprao, in central Cambodia, and Melouprei, in northeastern Cambodia—have yielded remains from the Neolithic Age sufficient to permit only the barest reconstruction of life in the region before the Christian Era. Nor is it possible to make any certain link between the makers of the various artifacts that have been discovered and the succession of ethnic groups that moved through the Indochinese region as a whole in the prehistoric period, peopling both that region and the maritime areas of Southeast Asia as well.

Early inhabitants

Moving by both land and sea routes from areas to the north of Indochina, successive waves of migrants passed through the area. The original Australoid inhabitants were succeeded by Melanesians and then by Indonesians probably moving southward in two distinct phases, one by land and the other by sea. The languages spoken by these various migratory groups are increasingly seen by linguists as having had a distant common origin, whatever the later differentiations established among them. In the area of modern Cambodia, a language of the Mon-Khmer eventually became the dominant tongue after the Khmers, relative latecomers to the scene, had asserted themselves as political leaders, first in the state of Funan —centred in present southern Cambodia and the southernmost part of Vietnam—and later in the north-central Cambodian kingdom of Chenla.

The story of human activity in the area before the establishment of Funan, which Cambodian tradition ascribes to the 1st century AD, is not known in any detail. Settlements were close to lakes and rivers; the inhabitants engaged in agriculture and maintained cattle and pigs as domestic animals. They hunted with weapons that included the bow and arrow, for which arrowheads of polished stone, bone, and iron have been found. Metal cultures reached the Cambodian region well before the 1st century AD, and a site at Melouprei has revealed traces of iron and bronze casting. Close to the modern capital of Phnom Penh, the discovery of a bronze urn having close links with the Dong Son style of northern Vietnam (5th to 1st centuries BC) suggests that highly developed metalworking may have been taking place in pockets of Cambodian territory as early as the 4th century BC. Despite this evidence of growing technical capabilities, excavations at Oc Eo, Funan's major port on the southern coast of modern South Vietnam along the Gulf of Siam, suggest that the Neolithic culture characterized by polished stone implements survived alongside the more advanced metal culture.

Funan. While future archaeological work may lead to a better understanding of Cambodian prehistory, true historical knowledge begins with the rise of Funan. From its claimed mythical beginnings in the 1st century AD until its incorporation into the successor state of Chenla in the 6th century, Funan was vitally important as a recipient of Indian culture, which shaped the political institutions, art, and general culture of later Khmer states. Always regarded by later Khmer dynasties as the state from which they sprang, Funan owed its prosperity to its position on the great east–west trade route between India and China. The name of the state is generally believed to come from a Chinese transliteration of a Khmer word *bnam* (*phnom* in modern Cambodian) meaning hill. If correct, such a derivation is important as evidence of substantial Khmer influence over a state in which there was also a strong Indonesian ethnic and cultural presence.

Legendary origins

The national birth legend of the Funanese state tells of the arrival of a foreign Brahmin, Kaundinya, who overcame and subsequently married a local woman named Willow Leaf and set Funan upon its path to greatness. The legend is suggestive of the early influence of Indian thought and culture in the Indochinese area. Rejecting an earlier belief that large colonies of Indians settled in Southeast Asia, modern scholarship increasingly holds to a view that a relatively limited number of Indians, sometimes Buddhist traders, at other times Brahmins (high-caste Hindus), established themselves in positions of influence and propagated their more advanced knowledge of statecraft, religion, and art. A part of this view is the assumption that the existing populations of such areas as Funan were far from primitive savages and may have mastered the intricacies of wet rice cultivation.

The extent of implanted Indian influence in Funan be-

fore the middle of the 3rd century is uncertain, but a clearer picture of that period emerges from records left by two Chinese ambassadors who visited the country, *c.* AD 245. By that time Funan had extended its political power over the lower reaches of the Mekong and Tônlé Sab rivers and as far west as a section of the Malay Peninsula where trade passed from the Indian Ocean into the Gulf of Siam. This advance had taken place under the direction of King Fan Shih-man (*c.* 205–*c.* 225) and his nephew, Fan Chan (*c.* 225–*c.* 240), who took the throne as a usurper. Their successor, Fan Hsun (*c.* 240–*c.* 287), another usurper, was ruling at the time of the Chinese ambassadors' visit. The account of one of these ambassadors, K'ang T'ai, speaks of Funan as a land of walled cities whose inhabitants went unclothed through the streets but whose rulers gathered taxes in the form of precious metals, jewels, and perfumes. An Indian-based script was in use, and there were libraries and archives. The reference to the use of an Indian script is a clear indication of Indian influence, but it was not until the end of the 4th century that the full impact of Indian culture was felt in Funan.

This second "Indianization" of Funan came after a period about which there is little if any knowledge of developments within the state. Fan Chan's and Fan Hsun's reigns had seen the growth of official relationships between Funan and China and India. Relatively little is known, however, of the extent to which these official contacts were matched by a significant spread of Indian culture among the population at large. The appearance of a foreigner, Chandan, on the throne of Funan in 357 has been seen by some historians as a reinforcement of Indian influence and by others as reflecting a link with the Iranian world. Whatever may be the case, under Chandan's successors in the latter part of the 4th century and particularly in the 5th, there is a sense of Indian influence at a much wider level. Sanskrit inscriptions provide a more precise chronology of the reign of Funanese rulers and reveal that Hinduism and Mahāyāna Buddhism coexisted within the state.

Chandan's successor, according to the Chinese *History of the Liang*, was another Brahmin called Kaundinya, whose arrival in Funan was received with popular rejoicing and who instituted many reforms based on Indian models of law and administration. However mythical this Kaundinya may have been, the account of his arrival appears to capture correctly the importance of a new infusion of Indian culture. This cultural influence is abundantly apparent in the records that have survived describing the reigns of Funanese rulers during the 6th century. Funan was at the height of its power under the rule of King Kaundinya Jayavarman (d. 514).

Funan's greatest period

Excavations at the port city of Oc Eo have indicated the extent to which Funan prospered as a trading kingdom with links, indirectly, even with countries of the Mediterranean. Aerial photography has revealed a complex series of irrigation and communication canals that were established in the hinterland away from the coast. While Oc Eo may have been the most important port city, the royal capital was inland from the sea, at one time near the modern Cambodian town of Banam in Prêy Veng province and bearing the name Vyadhapura, "the city of the hunters."

From passages preserved in Chinese dynastic histories there is considerable information on the material culture of Funan in its heyday as well as insights into the state's religious life. It was a slave-owning society in which the rich decked themselves with gold and silver jewelry and wore rich brocades. The king lived in a richly constructed palace and travelled on the back of an elephant. The common people amused themselves with cock fights and contests between fighting pigs. Justice was administered through trial by ordeal. Since most buildings were constructed of wood, little is known of the style of Funanese building. A few architectural remnants at Oc Eo reinforce the evidence of Indian influence. The same initial source of inspiration was present in Funanese statuary. Sculpture from the 4th century has very obvious links with Gupta art in India. In the 6th century a distinctively Funanese art emerged in which Indian iconography was given a Cambodian form.

Hinduism was the religion of the rulers of Funan in the 5th and 6th centuries, but Buddhism was widely diffused in the kingdom also. There is evidence that Buddhism also enjoyed a measure of royal patronage. The importance of Buddhism in Funan in the 6th century was so great that a Chinese embassy visited the country between 535 and 545 to ask the ruler, Rudravarman (514–539), for Buddhist texts and teachers who could give Buddhist instruction in China.

Rudravarman was the last king of Funan to reign over an independent state. The subjugation of Funan by the rulers of the emerging state of Chenla marks a major division in Cambodian history. Although there are gaps in the history of Funan, the importance of the state is clearly apparent. It was through Funan that the initial process of Indianization took place, and it was this state which was always regarded by later Cambodians as the origin of their dynasties. Though this view was propounded in part to enhance legitimacy, it also reflected an awareness of the vital links that Funan had with its Angkorian successor state (9th–15th centuries). While the details are unclear, Funan before its absorption into Chenla already had links with the Khmers, whose base area was well to the north in the middle Mekong or Champassak area of modern Laos. There is clear evidence that Khmer princes were already associated with the Funanese ruling house and that some areas under the control of the Funanese state in the north of the kingdom were settled by Khmers.

Chenla. The first ruler claiming sovereignty over both Chenla and Funan was Bhavavarman (reigning 598), the grandson of Rudravarman of Funan, a fact which, along with his claim to power over both kingdoms, has led some authorities to suggest that the Chenla and Funan kings originally belonged to two branches of the same dynasty. Since Funan continued to send embassies to China until the beginning of the 7th century, the southern state apparently retained a degree of autonomy under Bhavavarman, whose capital was probably on the northern shore of the Cambodian Great Lake (Tonle Sap). Bhavavarman's brother, who succeeded him as Mahendravarman (*c.* 600–*c.* 611), left inscriptions that reveal considerable activity in the northeastern region of modern Cambodia around Krâchéh and Stœng Trêng. With Mahendravarman's son, Iśanavarman (*c.* 611–635), the power of the Chenla rulers over the declining state of Funan became absolute. Under Iśanavarman the power of Chenla was extended to the west as well as to the south, and good relations with the state of Champa (in present South Vietnam) were sealed by Iśanavarman's marriage to a Cham princess. Iśanavarman's capital, Iśanapura, at the modern site of Sambor Prei Kuk, near Kâmpóng Thum, is the most impressive group of pre-9th-century remains in Cambodia. A series of brick towers prefigure a number of later developments in Khmer art, and the site remained important as a centre of scholarship during the Angkorian period.

Chenla–Funan relationship

Under Iśanavarman's successors, Bhavavarman II (whose reign dates are unknown) and Jayavarman I (who reigned through most of the latter half of the 7th century), Khmer power extended throughout the Indochinese region. Yet, despite the description of Jayavarman as "glorious lion of kings" on one of his many inscriptions, the later division of the Chenla dominions into two separate regions probably began during his reign. Having expanded their power rapidly, the Chenla rulers were unable to maintain strict control over the various territories that they claimed the right to rule. Nevertheless, whatever political difficulties later sprang from the period, the 7th century was a time of continuing artistic development. Chinese accounts of court life under Iśanavarman give a picture of a rich material culture probably little different from that which had existed in Funan. Indian influence continued to be important in the art of the 7th century, and the two great Indian religions of Hinduism and Buddhism continued their coexistence. Of great significance for the future was the fact that the

Khmers, when they established their settlements in lowland Cambodia, used hydraulic techniques for agriculture that they had developed in lands further to the north. Their "captive water" technique, which damned water to be distributed by canals to less elevated regions, was later to be exploited to its full in the complex systems of Angkor.

Chenla's decline

Following Jayavarman I's death, the state of Chenla split into rival petty principalities. The history of the 8th century is obscure, but certain broad trends may be recorded. Land Chenla, the name given by the Chinese to the northern of the two divisions, apparently enjoyed a fairly stable existence with the centre of the state probably to the north of Angkor. By contrast, Water Chenla, the southern division, was an unsettled state beset by dynastic rivalries. As heir to Funan's position as an entrepot on the great east–west trade route, Water Chenla was grievously affected in the 6th and 7th centuries when traders began to bypass the Malay Peninsula, travelling to China by way of the Indonesian state of Śrivijaya in southern Sumatra. Along with the interruption of the trading link with the West, there was a sharp decline in direct cultural contact with India during the 7th century. Despite the diminution, and even elimination, of direct Indian influence, Khmer artistic achievements remained impressive until the latter half of the 8th century. And even this period of relative decline was rapidly followed by a dramatic efflorescence of Khmer artistic output, inspired by local genius rather than foreign models. This resurgence was the cultural accompaniment to the emergence of the Angkorian dynasty under the great Khmer ruler Jayavarman II (reigned *c.* 802–850), a man only distantly related to the ruling dynasties of pre-9th-century Cambodia.

THE ANGKOR PERIOD

Jayavarman II and his successors. In the latter part of the 8th century the Śailendra rulers of Java appear to have created a sphere of influence in Cambodia, and it was from Java that Jayavarman II returned to establish his kingdom about the year 800. Not the least remarkable aspect of his reign is the fact that since he left no inscriptions his achievements must be reconstructed from 11th-century inscriptions that give a clear picture of the vital importance of Jayavarman's reign. The concept of a unified Cambodian state was established, never to be forgotten by his successors, and a new state religion which established the Khmer ruler as a *devarāja* (god-king) was introduced during his reign.

On his return to Cambodia from Java, Jayavarman first established a capital at Indrapura, in modern Kâmpóng Cham province. But his subsequent three capitals were all in the region further north, close to but not actually in the area of the later Angkor complex. Strategically, the area on the east of the Great Lake was distant from the threat of external attack. The lake was a source of fish, and the plains about it were, with the application of hydraulic engineering, a great source for rice. Once Jayavarman had chosen this region as the centre for Khmer power, it remained so for most of the Angkorian era.

At his last capital of Mahendraparvata, in the Kulén hills to the east of Angkor, he took part in a Śaivite Hindu ceremony consecrating him as a *devarāja* and establishing both him and his kingdom as independent of any other power, especially that which the Javanese had claimed to exert over Cambodia. In this ceremony—perpetuated by Jayavarman's Angkorian successors—the king's sacred personality, the very essence of the kingdom, was enshrined in a sacred *liṅga* (a ritual phallic symbol) that was housed in a pyramidal structure called a temple mountain. This temple mountain was both the centre of the earthly kingdom over which the king ruled and the symbolic centre of the universe within which the kingdom existed. The details of this highly complex concept are possibly less important than the recognition that through participation in it Jayavarman and his successors saw themselves as universal rulers, subservient to no other state. The same symbolic purpose led to the establishment of the great Angkor temples, which were prefigured by those of Jayavarman's reign. In sculpture and the plastic arts, generally, the 9th century witnessed a revival and development of styles and techniques that blended Khmer traditions with those of Java and Champa.

Khmer kingship

After Jayavarman's death in 850 he was succeeded by a son, Jayavarman III (reigned 850–877), who left no significant mark upon Khmer history. The next ruler, Indravarman I, a cousin of Jayavarman III and possibly a usurper, played an important role in the development of the Angkorian state. Although his capital was not yet located on the site of the later Angkorian kings, it was at Roluos, not far distant, where Jayavarman II had founded one of his four capitals. At Roluos, Indravarman built two great stone temple mountains, Bakong and Preah Ko, which mark the beginning of Khmer classical art, the form from which the later temples developed. Even more important, however, was Indravarman's construction of a vast irrigation system that, by means of an artificial reservoir, permitted the assured exploitation of rice lands that otherwise would have remained unproductive. The later elaboration of artificial irrigation systems allowed the Khmers at Angkor to maintain a densely populated and highly centralized state in a relatively limited area. Only with such an irrigation system was it possible to feed the immense labour force necessary for the construction of the Aṅgkor temples.

Indravarman's successor, Yaśovarman I (reigned 889–900), inherited a kingdom from his father that was at peace, and he proceeded to build solidly upon Indravarman's achievements. His new capital of Yaśodharapura, the first Khmer city in the Angkor area proper, centred on the hill Phnom Bakheng, which Yaśovarman crowned with a temple. The city complex occupied some 16 square miles; the irrigation of this area depended upon a new system, fed from a great reservoir east of the city, the so-called *baray oriental*, or eastern *baray* of modern times, which was fed from the Siĕmréab River. The power which Yaśovarman accumulated at Angkor enabled him to extend Cambodian domination over a territory as large as Funan's at that empire's height. It is uncertain whether this extension of power was the result of armed conquest or the readiness of other states to acknowledge the suzerainty of the leading power in the region. Some authorities believe that achievements attributed to Yaśovarman rightly belong to later reigns, but he was certainly a figure of great importance. He built monasteries throughout his kingdom for both Śaivites and Buddhists, and the remains of his temples, particularly that of Phnom Bakheng, show a continuing development of the Khmer genius of blending architectural construction with religious symbolism.

The 8th-century empire

The century following Yaśovarman's presumed death in 900 was one for which political records are now at a minimum. External commentary from Chinese sources vanished with the internal division of China after the fall of the T'ang dynasty. Within Cambodia itself the progress of the state must be charted through inscriptions, which provide a highly selective view of developments, and through the material evidence of temples, both royal and nonroyal in foundation. Nevertheless, close study of the extant inscriptions does permit some insight into the life of Cambodian rulers, the narrow oligarchy of priests and advisers who supervised the complex bureaucracy that presided over the daily business of the state, and even, occasionally, the activities of less elevated members of the population. Six Khmer kings ruled during the 10th century. Probably the most significant political developments of their reigns were the temporary abandonment of the Angkor capital under the usurper Jayavarman IV (reigned 928–942) and its subsequent re-establishment by Rajendravarman II (reigned 944–968). Rajendravarman's successor, Jayavarman V (968–1001), is known chiefly for his continuation of Rajendravarman's efforts to control Champa and for his promotion of scholarship and learning. In religious matters the 10th century continues to provide a record of Hindu cults coexisting with Buddhism. Although Saivism (worship of

the Hindu god Śiva) was the principal royal cult, Buddhism also received its share of patronage.

Angkorian government and society. Though the Khmer monarchs were absolute rulers in theory, their power was often limited by the complex bureaucracy of the Angkorian state. The king was the final arbiter in legal matters and sometimes led his troops in battle, but much of his time was taken up with ceremonial and religious functions deemed necessary to insure the well-being of the state. If he was not a forceful personality, he might be reduced to a figurehead.

The bureaucracy

The bureaucracy was composed of learned Brahmins (members of hereditary priestly families) and military leaders who were sometimes members of the royal family. These men formed a class separate from the population at large; there is considerable evidence that their separate identity was reinforced through intermarriage. They were particularly influential in regions more distant from the capital. Although the construction of a temple mountain was the prerogative of the king alone, the great officials founded their own shrines, each supported by surrounding villages, which met the high cost of maintaining the temple and its priests. None of these shrines rivals the great royal foundations in size, but the temple of Banteay Srei, a little to the northeast of the Angkor complex, is considered by many to be the most perfect of all Khmer temples. It was built in 967 by a Brahmin, Yajñavarāha, a man of royal descent who had supervised the education of both Rajendravarman II and Jayavarman V.

Between the great officials, on the one hand, and the peasants and slaves (about whom little is known), on the other hand, there was another group, whose existence is recorded in inscriptions but whose role in the Khmer state has yet to be studied in any detail. This was a group of land-owning men who held no official position and who, unlike the priestly officials of the great foundations in provincial regions, appear to have had little contact with the capital. Their existence, and the existence of "castes" of teachers and priests who were recruited from provincial areas but who were clearly not of the elevated status of the great officials, provided some qualification to the narrow classifications into which Khmer society has frequently been divided in modern historical accounts. While the size of these intermediate groups is unknown, their existence suggests a more complex society than that which envisages a single, sharp division between the king and his officials, and the peasantry and slaves.

The 11th century. At the beginning of the 11th century one of the most energetic of the Khmer monarchs, Suryavarman I (reigned *c.* 1002–50), challenged the position of Jayavarman's legitimate successor, Udayadityavarman I, to hold the throne.

A new dynasty

A Cambodian prince, but with scant direct claim to the throne, Suryavarman had defeated Udayadityavarman by 1002, but a long civil war dragged on until he finally gained control over the whole kingdom about 1011. Although the evidence comes from chronicles of a considerably later period, Suryavarman appears to be correctly credited with the extension of Khmer power over much of modern southern Thailand and over Mekong valley regions as far north as Luang Prabang. In contrast to this activity in the west, his relations with Champa and Vietnam, to the east, seem to have been calm and stable. His long reign enabled the restoration of many of his predecessors' foundations both at Angkor itself and in other parts of the country, and the completion, notably, of the Phimeanakas and Ta Keo temples begun by Jayavarman V.

Suryavarman's son, Udayadityavarman II (reigned 1050–66), carried on his father's expansionist policies. While some historians judge that this led to the Khmer state reaching its furthest limits, these policies also provide part of the explanation for the record of revolts that marked Udayadityavarman II's reign. Cham encouragement appears to have been behind a revolt in the southeast of the kingdom. And in the west the Khmers found themselves in confrontation with the newly victorious Burmese, who had conquered the Mon capital of Thaton. Other revolts within Cambodia itself are believed by some historians to have reflected resentment at the favour which the ruler showed toward Buddhism, a religion that his father had done much to promote. Despite the record of warfare and revolt during his reign, Udayadityavarman II found time to build another great *baray*, or reservoir, the western *baray*, which greatly increased the cultivable area of the region around Angkor. Udayadityavarman's successor was his brother, Harshavarman III (reigned 1066–80), who was unable to prevent a major incursion into Cambodia by a Cham army that marched to Sambhupura, a city on the Mekong near the modern town of Krâchéh, and sacked it. Harshavarman was overthrown by a usurper, who reigned as Jayavarman VI (1080–1107), but possibly never occupied the capital at Angkor. He and his successor, Dharanindravarman I (1107–13), had to contend with the opposition of members of Harshavarman's family.

From Suryavarman II to Jayavarman VII. *Suryavarman II.* This opposition was finally and forcefully crushed by Suryavarman II, one of the greatest figures in Cambodian history, who came to the throne in 1113. Reducing the kingdom of Champa to vassal status, he annexed it completely when the Cham king would not cooperate in his campaigns against the Vietnamese state further north. Suryavarman's expeditions against the Vietnamese took his armies as far north as Thanh Hoa in modern North Vietnam. The extent of his success in the Mae Nam Chao Phraya Valley is open to some doubt, but the substantial Khmer influence found in the architecture of the Thai state of Lopburi suggests an important impact on that region (present Thailand). Khmer influence also reached well down into the Malay Peninsula.

Suryavarman's empire

Suryavarman's military and political conquests are matched by the magnificence of his achievements in building the great temple complex of Angkor Wat. Completed at about the time of his death in 1150, Angkor Wat was only one of the outstanding architectural achievements of his reign. Beng Mealea, some 25 miles to the east of Angkor, and Banteay Samre on its outskirts are other magnificent examples of Khmer art and architecture.

Suryavarman blended Śaivism and Vaiṣṇavism (the cult of Viṣṇu) in his state religion. Within the inner sanctuary of Angkor Wat was a gold statue of Viṣṇu (Vishnu) mounted on the fabled winged Garuḍa, representing the deified Suryavarman as Viṣṇu. Yet once again, there was no religious exclusiveness within the Khmer state. Buddhism, even if overshadowed by the Hindu cults, continued nonetheless to have its adherents.

The first period of decline. Suryavarman's successes rested on uncertain foundations, and by the end of his reign the combined effects of an overambitious external policy and the demands that his building program placed upon the resources of the state entailed heavy costs. His repeated expeditions against the Vietnamese failed to achieve his goal of subjugating that energetic neighbouring state. A year before his death (*c.* 1150), the Chams freed themselves from Khmer domination and their strength in the immediately succeeding decades was directed toward wiping out the stigma of Khmer overlordship by attacking the Cambodian heartland. Indeed, between 1050 and the accession of Jayavarman VII in 1181, the fragility of the Khmer state after a period of greatness was demonstrated time and again. Internal rebellion was added to the challenge of the Chams to further weaken the power of the ruler. Suryavarman's immediate successor, Dharanindravarman II (1150–60), had an apparently uneventful reign, notable largely for the fact that the new king was a devotee of Buddhism rather than of Hinduism. But at his death the rightful successor, Jayavarman, was passed over and the throne was occupied by his younger brother Yaśovarman II (reigned 1160–*c.* 1166). In the space of six years Yaśovarman faced a peasant or slave revolt, which was successfully subdued, and the rebellion of an ambitious official, Tribhuvanadityavarman, which caused the king's dethronement and death. Although Jayavarman came out of exile in Champa to defend the king, he arrived after the

usurpation had taken place and again retired from the scene. In Tribhuvanadityavarman's reign the resurgent Chams began their long campaign of attrition against the Khmers. Border skirmishes begun in 1167 finally culminated in the humiliating and successful Cham attack against the capital at Angkor in 1177. The capture of the

Cham attacks

Khmer Empire, c. 1200.

capital and the death of the ruler left Cambodia in chaos.

Jayavarman VII. The accession of Jayavarman VII brought a change. This ruler ranks with Suryavarman II among the greatest of all Angkorian rulers. His energy was phenomenal: in both the success of his campaigns against the Chams and his devotion to temple construction he revivified the Khmer empire. As was the case with Suryavarman II, however, this massive outpouring of energy exacted a heavy cost. Jayavarman's policies so exhausted the state that, once his leadership had gone, no other ruler was able to maintain it in the same manner. The most active builder of all the Angkorian monarchs, he left a large number of inscriptions. To his reign belongs the great complex of Angkor Thom, which rivals Angkor Wat in magnificence.

Jayavarman was nearly 60 when, following a period of almost constant campaigning, he achieved sufficient control to assume the kingship in 1181. He repaid in full the injuries his country had suffered at the hands of the Chams. The Khmer armies laid waste to their kingdom and sacked the Cham capital of Vijaya. Through skillful use of Cham allies opposed to their own ruling family, Jayavarman prepared a campaign that finally led to the annexation of Champa, which remained under Khmer control from 1203 to 1220. Within Cambodia itself Jayavarman was unchallenged after the first year of his reign. To the west and south of Cambodia, the Chao Phraya Valley and parts of the Malay Peninsula recognized Cambodian suzerainty. An inscription near modern Vientiane, Laos, records his domination of that area.

Though Jayavarman's Buddhist adherence was to the Mahāyāna scholl, which had long been dominant in Cambodia, during his reign Theravāda Buddhism was introduced into Burma by the Mon monk Chapata. Among Chapata's companions was a Khmer prince who has been identified as one of Jayavarman's sons. This link with the Theravāda school foreshadowed its later patronage by the Khmer kings, which led to its supplanting the Mahāyāna school and so to a major change in the state's religion. Although modern scholarship rejects the view that the conversion of the Cambodian state to Theravāda Buddhism provides a single convincing explanation for the decline of Angkorian power, the change when it came was a profound one, not least because the Theravāda cult did not call for the construction of great temples as did both Hinduism and Mahāyāna Buddhism.

Jayavarman VII's greatest energies during his reign, as far as external policies were concerned, had been directed toward the conquest and subjugation of the Chams. Before the end of his life, however, the most formidable threat to Khmer power was developing to the west.

The Thais had been filtering into the Chao Phraya Valley from well before the beginning of the 12th century. In a famous section of the Angkor Wat bas-relief, Thai mercenaries are depicted as ill-disciplined and strangely dressed men of little civilization. Thai chieftains living under Khmer rule in what was the northwestern extension of the Cambodian empire were, however, growing in power and absorbing much of the civilization of their overlords. Only 20 years after Jayavarman's death the Thais of the state of Sukhothai were powerful enough to break the shackles of foreign rule. That this should have been so emphasizes the rapid reversals that followed the end of Jayavarman's rule (*c.* 1215, possibly as late as 1219). He was the last of the great kings. Yet even if the 13th and 14th centuries were centuries of decline, they were by no means a period of eclipse, despite the repeated incursions of the Thais, which forced a temporary abandonment of Angkor before the end of the 14th century.

The Thai threat

The final decline. After Jayavarman's death, no significant building took place at Angkor, and the Khmer empire began to contract. Control over Champa ended in 1220. In 1238 a Thai chieftain—son-in-law of Jayavarman VII—mounted a successful coup d'etat against the Khmer governor of the upper Chao Phraya region and founded the Thai state of Sukhothai. Khmer overlordship in the Malay Peninsula also disappeared after Jayavarman's death. For the greater part of the 13th century, however, Angkor remained a glittering and wealthy city, one which inspired wonder in the eyes of the Chinese traveller Chou Ta-kuan when he visited the city in 1296. The account that Chou Ta-kuan provides of Angkor at this time is both the longest and most detailed description of the Khmer capital, and despite its inaccuracies and reliance on legend it gives a remarkably vivid picture of the rich court society that continued to exist, even though the Chinese writer records the fact that Cambodia had been under attack from the Thais shortly before. Chou Ta-kuan left a picture of a bustling city in which the king still went forth in great pomp and ceremony. Whatever weakness now characterized the Khmers, Chou Ta-kuan still judged Cambodia to be the strongest of the states to the south of China. Notable among his observations was the presence in the Khmer capital of Buddhist monks of the Theravāda school. Thus, by the end of the 13th century the Cambodian state had abandoned its adherence to Hinduism and, at the court and in the capital at least, adopted Theravāda Buddhism.

This change took place during the long reign of Jayavarman VIII (reigned 1243–95), probably about the middle of the century. Its causes remain a matter for some debate. The view of some of the earliest scholars of Cambodian history, that Theravāda Buddhism was a "democratic" religion that appealed to the Cambodian masses bowed down before the overwhelming exactions of their kings, has been severely qualified. The adoption and propagation of a particular religion within Angkorian society is much more likely to have been a matter for royal patronage. One intriguing suggestion is that the rulers and their advisers at Angkor were aware of the political success of the increasingly powerful Thai states to the west and attributed this to the form of Buddhism, the Theravāda school, which the Thai rulers followed. Adherence to Theravāda Buddhism was never incompatible with the pursuit of power for Thai rulers and would not

Theravāda Buddhism

have been viewed so by those in power at Angkor. Moreover, placing importance on the population's acceptance of Buddhism seems illogical in view of the fact that their most fundamental religious adherence was to animistic cults. Viewed from a slightly different perspective, however, there may be value in considering the permeation of Theravāda Buddhism into the ranks of the general population as reflecting some readiness on the part of the people to accept a new religion that made few demands upon them—in contrast to Hinduism and Mahāyāna Buddhism, which had sapped their material and physical resources. Not only did the introduction of the new religion mean the end of temple building on the old scale, it also led to the disappearance of the use of Sanskrit; the latest Cambodian Sanskrit inscription dates from 1327. Henceforth Pāli was the sacred language.

For a short period at the beginning of the 14th century the Khmers enjoyed a respite from external threat. The great Thai ruler of Sukhothai, Ramkhamhaeng, died *c.* 1317 and his death removed the motive force that had brought Sukhothai to a position of considerable power, posing a threat to Angkor. The respite, however, was a brief one. Whereas the selection of the Angkorian region as a site for the Khmer capital in the 9th century had ensured its isolation from external threats, the ever-growing presence of the Thais in the Chao Phraya Valley meant that Angkor was in an increasingly exposed position. The king at Angkor when Chou Ta-kuan visited the city in 1296 was Indravarman III (1296–1308). His successors, the last to leave inscriptions, were Indrajayavarman (1308–27) and Jayavarman Paramesvara, who acceded to the throne in 1327 but for whom no date of death is recorded. With an absence of inscriptions and the unreliability of other records, there has been a measure of historical disagreement over developments during the 14th and 15th centuries. Recent research has challenged the previous assumption that the Thais captured Angkor in 1431, from which date the Khmers abandoned their capital. According to this new view, based on both Cambodian and Chinese sources, Angkor fell to Thai attacks in 1369 and 1389 and was on each occasion occupied by Thai forces. It was not, however, until 1444 that the final (third) great attack against Angkor took place that did, indeed, lead to its ultimate abandonment.

The fall of Angkor

The proposed new chronology, which is accompanied by evidence of considerable Thai involvement in the family rivalries of the Khmer royal house, is helpful for an assessment of why it was that Angkor was finally abandoned in such a dramatic fashion. Emphasis on the political significance of the change to Theravāda Buddhism remains important, with its overtones of a sense of crisis in Khmer national confidence. But other, more obvious, material factors were clearly involved. The record of Thai attacks against Angkor highlights the extreme fragility of the Angkorian economic system. Under pressure from the Thais, and on occasion from the Chams also, the Khmer rulers at Angkor had the greatest difficulty in maintaining the intricate hydraulic system upon which Angkor's survival depended. The reservoirs and canals needed constant attention, which was impossible under conditions of war. Damage to the system during actual attacks on the city, and the shipping off of thousands of prisoners of war, further weakened the economic base of the state. Recent analysis now discounts the view that malaria, spreading from the shattered hydraulic system, played a part in Angkor's decline. When, in a manner that became so characteristic in the years of decline after the fall of Angkor, squabbles between members of the royal family further weakened the Khmers, the stage was set for the collapse of the Angkorian empire. After the abandonment of the former imperial city in 1444, the Khmer court moved south to a site near modern Phnom Penh, and thence to Phnom Penh itself. For the remainder of Cambodian history to the present, this region was to be the centre of a contracting Khmer world.

The artistic traditions of Angkor did not immediately disappear. The expression of these traditions was no longer the mighty temples in stone but rather the more intimate art of the religious statue, and even this art form declined as political power waned more rapidly during the 17th and 18th centuries before the ever greater power of the Thais and the Vietnamese. When a French colonial presence was established in Cambodia shortly after the middle of the 19th century, it was common for the European newcomers to speak of Cambodia as having "fallen from its antique splendour." This comment accurately assessed the manner in which the once singularly powerful Khmer empire had, in the years after the fall of Angkor, gradually ceased to play any major role in the Indochina region.

THAI AND VIETNAMESE HEGEMONY

In the century and a half following the abandonment of Angkor, much of Khmer history is a confusing mixture of uncertain dates and complex dynastic rivalries within the Khmer royal family. Dominating the years up to the Thai conquest of Lovek (a later Khmer capital a little to the north of Phnom Penh) in 1594 is the record of almost incessant warfare between the Khmers and the Thais, now based in their capital of Ayutthaya. The contest was not entirely uneven. During the reign of Ang Chan (1516–66) the Khmers carried their campaign deep into Thai territory on one occasion, in 1564, but reached the city of Ayutthaya only to find it occupied by Burmese invaders. Yet despite the temporary success of his son Barom Reachea I (1566–76), which enabled the Cambodian court to reoccupy the city at Angkor temporarily, the tide was flowing against the Khmers. Once the Thais had successfully resisted the challenge posed by repeated Burmese invasions, they were able under the leadership of King Naresuen to plan and deliver a crushing blow against the Cambodian state. This was the capture of the capital at Lovek in 1594.

The "Spanish interlude." Before Lovek fell to the Thais the Cambodian king Satha (1576–*c.* 1594) had sought to gain assistance from the Portuguese and Spaniards, who were now established in Southeast Asia. Satha's efforts to enlist their support and the ambitions of both missionaries and soldiers of fortune led to one of the more curious episodes in Cambodian history. For a brief period, after the fall of Lovek, Spanish soldiers became arbiters of power within the Khmer state. A Spanish expedition arrived in Cambodia in 1596 with the intention of giving aid to King Satha. By then, however, Satha had been deposed and a usurper, Chung Prei, occupied the throne. After a series of disagreements and the sacking of the Chinese quarter of Phnom Penh by the Spanish forces, the Spaniards attacked the king in his palace at Srei Sânthôr, killing him and his son. Deciding to return to Manila after this affair, the Spaniards later changed their minds while sailing along the Vietnamese coast and marched overland to Laos, where they found one of Satha's sons and successfully installed him upon the Cambodian throne in 1597 as Barom Reachea II (1597–99). The great officials within the Cambodian court were by this time deeply resentful of the power wielded by the foreigners and were anxious to depose Barom Reachea in favour of Satha's brother, Soryopor. An incident involving one of the Spanish leaders in Phnom Penh led to a massacre of the Spanish garrison in mid-1599 and, after a period in which three princes occupied the throne, Soryopor returned to gain the throne as Barom Reachea IV (1603–18), with the assistance of a Thai army. The Spanish interlude was the last significant contact the Cambodian court had with Europeans until the onset of French colonialism in the mid-19th century. It was an exotic interregnum that had no lasting political effect but did, however, provide later historians with one of the few accounts of the Angkorian irrigation system, written by an observer who visited Angkor at a time when it had been reoccupied toward the end of the 16th century.

First European contact

Cambodia as a vassal state. Cambodian history from the accession of Barom Reachea IV until the establishment of the French Protectorate in 1863 is a sorry record of weak kings, almost always under challenge from dissident members of the royal family and forced to seek

the protection of either of their stronger neighbours, Siam (Thailand) and Vietnam. Between 1603 and 1848, the date of the last Cambodian ruler to assume the throne free from French political control, no fewer than 22 monarchs uneasily occupied the throne. Several of these rulers had more than one reign, as they gave up their position either through choice or under duress, only to return when their successors either proved incapable or were themselves deposed. The details of this unstable period are less important than the record that is available of the manner in which Cambodia slowly slipped under the dual suzerainty of Siam and Vietnam. Early in the 17th century, Chey Chetta II (1618–28) successfully, if rather temporarily, declared his country's independence from Siam. In order to strengthen his position, the King sought assistance from the Nguyen lords of southern Vietnam. This fatal decision, which had involved Chey Chetta's marrying a Vietnamese princess, brought a Vietnamese demand for the right to settle Vietnamese colonists in areas of southern Vietnam, near Saigon, which until this time had been Cambodian territory. From this point onward, rival claimants for the Khmer throne sought to advance their interests through the respective support of either the Thais or the Vietnamese, at the ever-increasing cost of loss of territory or loss of power. For the Vietnamese, assistance given to Cambodian princes was followed by the extension of Vietnamese settlement into former Cambodian territories. For the Thais, the provision of aid was joined to an insistence upon Cambodia's assuming vassal status, but it did not involve the colonization of Cambodian lands.

Vietnamese expansion

That Cambodia survived at all during this bitter period was attributable in large part to the other preoccupations that weighed upon the Thais and the Vietnamese. In the middle years of the 18th century, Thai energies were largely taken up with wars against the Burmese, which led, in 1767, to the Burmese capture of Ayutthaya. Later in the same century, the Nguyen rulers of southern Vietnam were engaged in a prolonged campaign to regain power from the usurping Tay Son rebels. Yet if these facts had slowed the pace of Cambodia's decline, the situation by the end of the 18th century was nonetheless grim. Over the course of the century, all of what was to become the French colony of Cochinchina had fallen under Vietnamese control. In the west, Thai suzerainty had been firmly established over the great provinces of Bătdâmbâng and Siĕmréab. As the century drew to a close, and as the Vietnamese leader Nguyen Anh, later to reign as Gia Long, still fought to unify his country, the Thai court at Bangkok was firmly in control of the Cambodian royal family. King Ang Eng (reigned 1779–96) was actually crowned in Bangkok and was placed on the throne at the Khmer capital, Oudong, north of Phnom Penh, through the support of a Thai army. Following Ang Eng's death, Ang Chan, a minor, succeeded to the throne. He was crowned in 1806 and ruled uncertainly until 1835.

Ang Chan's reign

The reign of Ang Chan II confirmed Cambodia's dual vassalage to Siam and Vietnam. Faced with his rebellious brothers, Ang Chan gained assistance from Vietnam, while the Thais supported his brothers. The uneasy calm that was finally established, as Cambodia acknowledged both Thai and Vietnamese suzerainty, ended with Ang Chan's death. Vietnamese pressure was strong enough to ensure that a weak and powerless princess was then placed on the throne while almost total Vietnamese control was exercised over the country. Not until 1841, when Ang Duong (reigned 1848–60) returned from exile in Bangkok supported by Thai troops, were the Cambodians able to exercise even a minimal degree of independence. Because Thai support had helped him to the throne, Siam exercised a preponderant influence over Ang Duong, but he remained in tributary relations with Vietnam. As the last king to rule free from French control, Ang Duong has often been idealized in modern Cambodia. He was devoted to revitalizing the state, but his resources were desperately limited. Cambodia survived essentially because of the restraint of its neighbours, and before the end of his reign, Ang Duong's rule was troubled by internal rebellions.

FRENCH RULE

The protectorate. French control over Cambodia developed as an adjunct to French colonial involvement in Vietnam. Before his death, Ang Duong, on the urging of a French missionary, had sought to gain French assistance to regain former Cambodian lands held by the Vietnamese. He did not seek a French protectorate over his country, as many French accounts have suggested. There was no response to Ang Duong's call for help, and the French decision to advance into Cambodia came only when, with a colony implanted in Cochinchina, the French began to fear that British and Thai expansion might lead to hostile control of the Mekong River. In an almost classic use of gunboat diplomacy, the French in 1863 intimidated the Cambodian king Norodom (acceded 1860) into signing a protectorate treaty that gave France control of Cambodia's foreign affairs. When Norodom was crowned at Oudong in 1864, the French stood by as new suzerains of the weak Cambodian state.

Reign of Norodom

In the early years of the French protectorate, the European newcomers interfered little in the affairs of the Cambodian state. Indeed, French protection had distinct similarities to the part played by Cambodia's Asian suzerains in the past. At odds with his half brothers and faced with rebellion, Norodom gained rather than lost as the result of the French presence. Although he bitterly resented the French recognition of Thai control over Bătdâmbâng and Siĕmréab provinces, he might well have lost the throne if it had not been for French support. By the mid-1870s, however, French officials in Cambodia were pressing for greater control over internal affairs. Shocked by what they regarded as the profligacy and barbarity of Norodom's court and methods of government, they sought to introduce reforms. In pursuing their goals they acted with the knowledge that Norodom's half brother Prince Sisowath was ready to cooperate with them and was most ambitious to replace Norodom on the throne. Yet, despite the power that the French could exercise, their repeated efforts to change the methods of Cambodian administration foundered on the rock of Norodom's stubborn opposition to change. Exasperated by the King's intransigence, Gov. Charles Thomson of Cochinchina, who also held responsibility for the French position in Cambodia, forced Norodom in June 1884 to sign a convention virtually transforming Cambodia into a colony. The result of this action was a Cambodian rising that broke out in January 1885 and lasted for two years.

Anti-French rebellion

This rebellion was the only major anti-French movement to occur in Cambodia until after World War II. It gravely threatened the French position in the country and was finally put down only when French officials were able to persuade the King to call upon his countrymen to lay down their arms in return for some French concessions to the King's position. This was, basically, a hollow victory for Norodom. What the French had been unable to achieve in a single sweep by the convention of 1884 they proceeded to gain through piecemeal action. As Norodom's health declined and as senior Cambodian officials began to see their interests linked as much with French power as with their monarch, the way was opened for greater and greater French control over the actual business of government. In 1897 the French representative in Phnom Penh assumed the chairmanship of the Cambodian Council of Ministers, and the King's influence in government was reduced to a bare minimum. Norodom died a bitter man in 1904.

Yet Norodom's reign was not entirely one of constant loss for the Cambodian monarchy. Although the French gained political ascendancy, they ensured the survival of the Cambodian state, and, by maintaining the king in a splendour that had probably not been equalled since Angkorian times, they greatly enhanced his symbolic position within the kingdom. This fact was to be of considerable importance in the post-independence period following World War II.

King Norodom's ambitious half brother Sisowath finally did succeed to the Cambodian throne in 1904. Already in his 60s, he nonetheless continued to reign until 1927. While Sisowath held the throne, no difficulties arose between the Cambodian king and the French, nor was there any growth of nationalist activity comparable to that in Vietnam. By preserving the Cambodian monarchy, the French administration successfully prevented the development of any alternative focus for national identification. The one significant event that occurred during Sisowath's reign involved a mass peasant protest against tax and corvée (forced labour) requirements in 1916. Yet even this peasant protest was essentially peaceful, and the protesters disbanded once the King had given his assurance that royal consideration would be given to ameliorating conditions. During Sisowath's reign and that of his son and successor, Monivong (1927–41), the first notable economic developments derived from French rule took place. Red-earth lands in the east were brought under rubber cultivation, and, for the first time, there was a realization that Cambodia's economic opportunities went beyond the export of rice.

Rubber cultivation

World War II and the First Indochina War. When Monivong died in 1941, the Japanese had occupied Indochina while leaving the French administration in nominal control. In these difficult circumstances, the French governor general of Indochina, Adm. Jean Decoux, placed Prince Norodom Sihanouk on the Cambodian throne. Although some uncertainties remain about the reasons for Sihanouk's elevation, Decoux seems to have been guided by the expectation that, as a young man of 18, Sihanouk, unlike the late King Monivong's son, Prince Monireth, would be readily controlled by the French. The error of the French estimation of Sihanouk's pliability became apparent in the years after the end of the war.

The effect of the Japanese occupation on Cambodia was less profound than it was in many other Southeast Asian countries. The overthrow of the French administration throughout Indochina in March 1945 brought the opportunity for political development to Cambodia. Although Sihanouk declared his country's independence from France, he and his advisers looked forward to cooperation with the former protecting power. Others, led by Son Ngoc Thanh, who had urged opposition to the French in the 1930s and been forced into exile in 1942, urged a sharp break with France.

Re-establishment of French control

The end of World War II brought the re-establishment of French control over Cambodia. Despite abolition of Cambodia's protectorate relationship, as it became an "autonomous state within the French Union," real power remained in French hands. Yet between 1945 and Cambodia's final achievement of independence in 1953, important political developments occurred. There were more demands for full independence, and a contest developed between the King and his supporters, who wished to uphold the supremacy of the crown, and those who sought to make Parliament the predominant power.

Cambodia was ill prepared for parliamentary democracy, and the years between 1945 and 1953 were marked by factional strife. The dominant Democratic Party was frequently at odds with the King and suffered from internal dissension. The death in 1947 of its able leader, Prince Youtevong, was a blow to the party and to those who hoped for a constitutional monarchy. Outside Parliament, Son Ngoc Thanh, now a bitter opponent of Sihanouk's policies, led the dissident Khmer Issarak (Independent Cambodians), who opposed both the King and the French. With this internal disunity and with the French fighting the Vietnamese revolutionaries, the Viet Minh, throughout Indochina, Sihanouk acted. In January 1953 he dissolved Parliament, declared martial law, and left Cambodia to seek the support of world opinion for his country's independence.

INDEPENDENCE

Sihanouk finally succeeded in his personal campaign, known as the Royal Crusade, when the French granted independence on November 9, 1953. At the Geneva Conference in May of the following year, Sihanouk's representatives achieved a further triumph when his government was recognized as the sole legitimate authority within the country. This decision prevented the Viet Minh forces and the limited number of left-wing Khmers who were their allies from gaining any regional authority within the country, as happened in Laos. The King's achievements left him in a momentarily unchallengeable position; even Son Ngoc Thanh appeared ready to cooperate with Sihanouk.

Independence and the end of the First Indochina War did not, however, bring an end to political factionalism. Finding himself once again in conflict with his domestic opponents, Sihanouk took a dramatic new step. In March 1955 he abdicated in favour of his father, Norodom Suramarit, and formed a new mass political movement, the Sangkum Reastr Niyum (People's Socialist Community). Loyalty to Sihanouk and the country were the guiding principles of the Sangkum. In the elections of September 1955 it won every seat in the National Assembly. From then until his fall in March 1970, Sihanouk was the central figure in Cambodian politics, sometimes as prime minister and, after his father's death in 1960, when no new monarch was named, as chief of state. Overt political life was carefully controlled by the Prince and his advisers.

Founding of Sangkum

Before the mid-1960s, external crises posed the greatest threat to Cambodia's stability. Conscious of historical precedent, Sihanouk saw South Vietnam and Thailand as the greatest threats to Cambodia's survival, particularly as these two neighbouring states were allied with the United States, which Sihanouk distrusted. At the same time Sihanouk feared the eventual success of the Vietnamese Communists and the danger he saw in a unified Vietnam. In these circumstances he proclaimed a policy of neutrality in international affairs. Convinced, however, of U.S. involvement in plots against his state and his family in 1959 and 1960, Sihanouk finally broke relations with Washington in May 1965 and aligned Cambodia more closely with China, North Vietnam, and the National Liberation Front in South Vietnam. From 1965, in an attempt to anticipate the future, he agreed clandestinely to the use of Cambodian territory by the Vietnamese Communists.

This decision further alienated right-wing elements in Cambodian society, particularly the army officer corps. The conservative urban elite already resented the economic policies introduced in 1963 and 1964, and they saw the closer alignment with the Vietnamese Communists as potentially ruinous to their interests.

From 1966 Cambodia's internal politics developed in a complex fashion. Although Prince Sihanouk remained a revered, even semi-divine figure for most of the peasantry, he was increasingly seen as a threat by both the right and the left. Young left-wing Cambodians, many of them educated abroad, resented Sihanouk's internal policies, which did not tolerate radical dissent. The outbreak of a rural rebellion in 1967 convinced Sihanouk that the greatest danger to his regime came from the left. He increasingly bowed to pressure from the army and other conservatives to follow a policy of harsh repression against left-wing elements.

By 1969 Sihanouk's personal position had deteriorated, and conflict between the army and left-wing opponents of the Prince's regime had increased. Right-wing politicians, most notably Gen. Lon Nol and Prince Sisowath Sirik Matak, plotted to depose Sihanouk, whom they saw as the root cause of their country's problems. They enlisted the support of Sihanouk's long-time enemy Son Ngoc Thanh, who had remained a dissident throughout the 1960s at the head of the Khmer Serei (Free Cambodians), a group receiving clandestine United States assistance. The extent of U.S. involvement in this plotting against Sihanouk is a matter of controversy. There seems little doubt, however, that U.S. intelligence services were aware of developments.

Matters came to a head in March 1970 when, with Sihanouk absent in France, Lon Nol and Sirik Matak called for the evacuation of all Vietnamese Communist forces from Cambodian soil and instigated demonstra-

tions against the North Vietnamese and National Liberation Front embassies in Phnom Penh. At the same time, Sihanouk's conservative opponents called on him to renounce his international and domestic policies. Within a week it was clear that neither the Vietnamese Communists nor Sihanouk would negotiate under threat, and on March 18, 1970, Lon Nol's faction deposed the Prince. Sihanouk took up residence in Peking, where he became the head of both a government in exile and a National United Front of Cambodia (NUFC) dedicated to overthrowing the Lon Nol regime.

Deposition of Sihanouk

Second Indochina War. Sihanouk's overthrow brought Cambodia's full involvement in the Second Indochina War, particularly after the U.S. and South Vietnamese invasion of the country on May 1, 1970. At first the Lon Nol regime confronted a largely Vietnamese military threat, but a Khmer revolutionary force slowly emerged as the principal opponent. The leaders of this newly important group included men such as Khieu Samphan, Hou Yuon, and Hu Nim, who had opposed Sihanouk's policies in the past and who had fled into the countryside before his overthrow to escape the summary justice of the Prince's security forces.

As these and other left-wing leaders emerged into prominence, Sihanouk's importance declined. Although he remained a symbol of the legitimacy of those who opposed the Lon Nol regime, Sihanouk was clearly not in charge of either the daily tactics or the long-term strategy of those fighting against the Phnom Penh forces. By 1973 he spoke publicly of his difficulties with the Cambodian revolutionaries.

Despite proclaimed policies of reform and United States military and economic aid, the Lon Nol regime never succeeded in gaining the initiative against its opponents. Gestures such as declaring Cambodia the Khmer Republic in 1970 were of little account, as the revolutionary forces pursued a strategy of attrition, choking off provincial capitals from the countryside. Following the end of the U.S. bombing of Cambodia in August 1973, the balance tilted toward the eventual success of the NUFC forces despite continuing strong U.S. aid to the Lon Nol regime. This success was finally achieved when Phnom Penh fell to the revolutionary forces on April 17, 1975.

Postwar uncertainty. Great secrecy surrounded developments after April 1975. Sihanouk returned to Phnom Penh in September 1975 as titular chief of state but resigned three months after a new constitution of Democratic Kampuchea was instituted on January 5, 1976. Amid reports by refugees of mass executions and death from disease, major political and social changes took place. Phnom Penh was forcibly evacuated and programs were instituted to reorient the country toward agricultural self-sufficiency and to remove the economic and social patterns of the prerevolutionary period. Elections for the 250-member People's Representative Assembly were held in March 1976, and in April Khieu Samphan was named head of state and Pol Pot was named premier. In 1977 the Communist Party of Kampuchea was first officially recognized as the country's governing body.

Pol Pot as premier

For a period after 1953 Cambodia appeared to occupy a unique position in Southeast Asia as Sihanouk successfully confronted both external and internal challenges. The pressures of the late 1960s ended this situation as external developments passed beyond Sihanouk's control and as political division within his country grew sharper. The onset of a savage war in 1970 brought widespread suffering and the collapse of Cambodia's economy. Those who gained control of Cambodia in April 1975 faced daunting internal problems and border clashes with Thailand and Vietnam.

BIBLIOGRAPHY

Cambodia to the end of Angkor: Much of the important material concerning Cambodian history until the fall of Angkor is in journal articles, mostly in French. Cambrian Period

The Cambrian Period, oldest division of the Paleozoic Era, includes a time interval of about 70,000,000 years that began about 570,000,000 years ago. Precise numerical dating of events during this time is rarely possible because very few Cambrian rocks have the minerals that can be analyzed to produce such dates. The stratigraphic boundaries for the Cambrian and all younger periods are determined by the use of a relative time scale that is based on evolutionary changes in the fossil record of the common animals or plants.

The Cambrian Period is particularly important for biologists as well as geologists. It is the time of the earliest record of abundant animal life on Earth and therefore contributes valuable information to studies of evolution. The Cambrian record provides the earliest reasonably detailed data about physical and animal geography that geologists can use to build the story of the changing face of the Earth.

The name Cambrian was introduced into geologic literature in 1835 by the English geologist Adam Sedgwick. In the early 1800s, when the modern stratigraphic framework was in its formative stages, Sedgwick and Roderick Murchison undertook a study of the thick, complexly folded series of sandstones, slates, and quartzites known as the Graywacke Series that lay beneath the Devonian Old Red Sandstone in Great Britain. Sedgwick, working with the oldest rocks of this series in northern Wales, and Murchison, working with the younger rocks in southern Wales, recognized distinctive sedimentary sequences within the Graywacke Series that they proposed to call the Cambrian and Silurian systems. The times during which these systems were deposited were referred to as the Cambrian and Silurian periods. Sedgwick chose the name Cambrian because "Cambria," a latinization of the Welsh word *Cymry,* meaning "people," was popular among English writers as an ancient name for Wales. The name first appeared in its latinized form in about the 12th century in a compilation of historical and quasi-historical records of the Welsh people called *Annales Cambriae.*

Work of Sedgwick and Murchison

Shortly after 1835 the upper boundary of the Cambrian

became the subject of a bitter geological debate between Sedgwick and Murchison and their friends when further geological work established that the upper beds of Sedgwick's Cambrian and the lower beds of Murchison's Silurian were contemporaneous. The difficulty was resolved by compromise in 1879, a few years after the deaths of the principal protagonists, by introduction of the term Ordovician Period for the time of deposition of the overlapping parts of the systems.

The reference region for a system is normally the region in which the name was first applied. Because northern Wales is a region of poorly fossiliferous rocks and complex geology, it never has been a satisfactory reference for global correlation of the Cambrian System. Because of geographic proximity and similar sedimentary facies, the more richly fossiliferous and relatively undisturbed Cambrian succession of southern Scandinavia therefore has served as a reference section. The lower part of this section, however, is incomplete, and the entire section is only about 600 feet (180 metres) thick. The most complete records of Cambrian sedimentation and faunal development are in Siberia and western North America, where fossiliferous Cambrian sections exceed 6,000 feet (1,800 metres) in thickness; but neither area has become clearly established as the principal Cambrian reference area.

Cambrian rocks are important sources of many economic minerals. Ores of lead, zinc, silver, gold, and tungsten have been mined from Cambrian rocks in the Cordilleran region of western North America, the southern and central Appalachian regions of eastern United States, Sardinia, North Africa, southeastern Australia, and Tasmania. Upper Cambrian rocks of Sweden are important sources of uranium and vanadium as well as potential producers of oil from oil shales. Oil has been produced from Cambrian rocks in southern Siberia, where extensive Cambrian salt deposits also are known and from the midcontinent region of the United States. Sandstones of Cambrian age in many parts of the world are quarried as sources of silica for the glass and steel industries. Cambrian limestones are extensively quarried in many places and burned to produce agricultural lime or cement. They also are crushed for use as flux in ore smelters or quarried as slabs and blocks for use in the building industry. In many parts of the northcentral United States, Cambrian sandstones are increasingly important sources of groundwater as younger beds become exhausted through increased industrial and population demands. For additional information on the Cambrian Period, its boundaries, and its relation to other geological periods, see PRECAMBRIAN TIME; ORDOVICIAN PERIOD; and PALEOZOIC ERA, LOWER. See FOSSIL RECORD for a further discussion of life forms during Cambrian time.

CAMBRIAN ROCKS

Occurrence and distribution

Cambrian rocks occur on all continents. The most extensive and best studied areas are North America and the U.S.S.R. east of the Ural Mountains. The outcrop areas of western Europe and North Africa also have been well studied, but they are widely scattered. Cambrian rocks are known from many areas of China, but information about them is meagre. Australia is an important Cambrian area, but much of the Australian Cambrian is unstudied. Very little is known about details of the Cambrian rocks and faunas of South America, Antarctica, and New Zealand.

Most Cambrian rocks are now found in present or former mountainous regions where they have been subjected to varying degrees of folding, faulting, and in some cases metamorphism since Cambrian time. Parts of the midcontinent region of the United States, the Baltic region of northern Europe, the central Siberian plateau, and northeastern Australia are areas where Cambrian rocks have been little disturbed since they were deposited. Most of the rocks in all regions contain fossils of marine organisms or other evidence of marine origin, indicating that much of the world's surface was covered by Cambrian seas.

Sedimentary facies

The marine sediments can be grouped into three major types or facies: terrigenous (land derived), carbonate bank (shallow calcareous sediments), and deepwater deposits. Near the Cambrian land areas, the sediments were predominantly sands, silts, and clays. Many contain the distinctive marine mineral glauconite. This region of terrigenous sediments was often many tens of miles wide. Local patches of muddy carbonate sediments developed toward the seaward margins. The second principal facies is represented by limestones and dolomites, some quite pure, that accumulated to great thicknesses beyond the seaward margins of the terrigenous belt. These carbonate sediments have abundant layered structures formed by algae and many textural evidences for shallow and agitated water, such as oolites and cross-bedding, which indicate that they accumulated in areas analogous to the present-day Bahama Banks. Many Cambrian banks were more than 200 miles (320 kilometres) wide and many hundreds of miles long. The third principal facies includes thin-bedded limestones and shales, usually gray or black and containing the iron sulfide mineral pyrite. These sediments show little evidence of water agitation. In many areas, they accumulated on the seaward side of the carbonate banks and are interpreted as relatively deepwater sediments. In some restricted areas they include conglomerate beds formed of pure limestone or dolomite fragments derived from the banks. This facies is associated with marine volcanic rocks and sediments derived from local volcanic islands in some parts of the world.

In the volcanic areas Cambrian sediments are many thousands of feet thick; limestone and dolomite accumulations to thicknesses of several thousand feet are common in the regions of the carbonate banks. Similar thicknesses are also known for many areas of terrigenous sediments. Regions that, since the Cambrian, have been relatively undisturbed were subject to slow or frequently interrupted Cambrian sedimentation and thus may be represented by less than 1,000 feet (300 metres) of sediments.

CAMBRIAN LIFE

There is no Cambrian record of terrestrial or freshwater animal or plant life, and no vertebrate fossils have been found in Cambrian beds. The distribution and abundance of Cambrian organisms are related to the major marine environments represented by the principal sedimentary facies. The greatest variety of organisms lived on the margins of the carbonate banks and in the protected regions behind the banks. Most marine invertebrate phyla whose modern members have mineralized skeletons were represented in the earliest Cambrian. However, the relative abundance of these representative groups has changed significantly since Cambrian time. Only three major groups, Bryozoa, Foraminifera, and corals, each of which have well established post-Cambrian histories, are not present in Cambrian age rocks.

Invertebrate life forms

The dominant Cambrian marine invertebrates were trilobites, a major subgroup of the Arthropods that has been extinct since the end of the Paleozoic Era. Trilobites are distantly related to modern horseshoe crabs and had a similar dorsal exoskeleton divided into a head region and a tail region separated by a variable number of articulated segments. Most trilobites averaged about three inches in length, but they ranged in size from one-fourth inch (agnostids) to almost two feet (*Paradoxides*). They fed on microscopic organisms in the sea or on bottom detritus. Trilobites were abundant in all marine environments from the muddy sea floor to the sea surface. Almost 75 percent of all fossils found in Cambrian rocks are trilobites, preserved as numerous molts or parts of the dead animals.

Many other arthropod groups existed in the Cambrian seas, but they either lacked mineralized skeletons and thus were rarely preserved or they were minor elements of the Cambrian faunas. Small bivalved ostracods and the merostomes, which are close relatives of the modern horseshoe crab, are the principal nontrilobite arthropods found as fossils.

The Mollusca, the group to which modern snails and clams belong, was represented by a variety of Cambrian forms. The commonest shells of these organisms were slender, conical, and generally less than two inches long with circular or triangular cross-sections; these represented the hyolithids that became extinct at the end of the Paleozoic Era. Small, laterally compressed, cap-shaped univalve shells of the Helcionellida are also found in many Cambrian deposits. Snails with coiled shells are rare in Cambrian faunas, occurring only in younger Cambrian beds. Cephalopods with straight, chambered, conical shells, relatives of the modern *Nautilus*, are found only rarely in Late Cambrian faunas. Bivalves, with the exception of a peculiar unsymmetrical group, the Stenothecoida, that became extinct in the Middle Cambrian, are absent in Cambrian faunas. Shells of several other shapes have been assigned to the Mollusca and attest to the variety of Cambrian representatives of this phylum. Few of these groups survived the Cambrian, which seems to have been a time of unsuccessful experimentation for the Mollusca.

The Echinodermata, to which modern sea urchins and starfish belong, were represented by a variety of free-living and attached groups. Some (eocrinoids) had a cylindrical or spherical body with a stem at one end and a cluster of slender arms at the other. Others (edrioasteroids) had spherical or disk-shaped bodies without stems or arms. Most of these were relatively unsuccessful, and few survived the Cambrian. Representatives of this phylum, however, were much more abundant than the record of well-preserved specimens would suggest. They characteristically lived in areas of agitated water, and their skeletons, which are composed of many individual loosely attached plates, rarely remained intact. A large part of the calcareous sediment in many Cambrian areas is composed of disarticulated echinoderm debris.

The brachiopods, a group of bivalved animals that is very rare in modern oceans, is second in abundance and stratigraphic value to the trilobites in the Cambrian. The commonest forms were the Acrotretida—brachiopods less than three millimetres in diameter with one saucer-shaped and one conical shell composed of calcium phosphate. These are obtained, often in great numbers, from the insoluble residues of Cambrian limestones digested by dilute acetic or formic acid. They are largely unstudied but have considerable potential for stratigraphic work. Two other groups of phosphatic brachiopods occur with the Acrotretida, but they are less varied and have limited stratigraphic value. One of these, the Lingulida, is still found in modern oceans and has changed very little since the Cambrian. Calcareous shelled brachiopods are abundant in some restricted areas but generally are rare in Cambrian rocks.

During the early part of the Cambrian, a group of spongelike organisms called archaeocyathids formed crudely cylindrical or cone-shaped calcareous skeletons made up of porous inner and outer walls separated by radial partitions. The structural details were often quite elaborate. This group flourished on the carbonate banks and other areas with good water circulation, but for unknown reasons it became extinct at the end of the Early Cambrian even though the habitats remained apparently unchanged. Porifera or sponges were common in the Cambrian seas, but, like the echinoderms, they are rarely found completely preserved. Calcareous or siliceous rods that served as stiffeners within the sponge bodies are found in most Cambrian deposits.

The marine annelids were probably also abundant, as evidenced by many thoroughly burrowed Cambrian sediments. Except for rare species that formed phosphatic tubes and others that made distinctive straight or curved burrows in Cambrian sands, there is little record of their existence.

Graptolites, fragile colonial hemichordates, were rare elements of the Late Cambrian faunas and were preserved only in areas of quiet sedimentation where there were few burrowing bottom dwellers. Conodonts, small phosphatic fossils of uncertain biologic affinities, are found principally as rare elements in faunas from the areas of unrestricted access to open ocean conditions in Middle and Late Cambrian rocks.

In addition to the animal groups with mineralized skeletons that are usually found as fossils, the Cambrian seas supported a great variety of other organisms that formed important parts of the animal communities but were rarely preserved. The discovery in 1910 of a rich fauna of soft-bodied organisms in Middle Cambrian shales at Burgess Pass in the Rocky Mountains near Field, British Columbia, provided ample proof of the diversity of these Cambrian marine organisms.

The principal marine plants were algae. Blue-green algae grew in sheetlike layers that trapped fine calcareous sediment and formed laminated beds, domes, columns, or golf-ball sized spheres termed stromatolites in many of the shallow marine environments on and adjacent to the carbonate banks. Some massive calcareous structures attributed to green or red algae are also moderately common.

The origin of the Cambrian faunas

The origin and appearance of the Cambrian faunas in the geologic record constitutes a major biologic problem. The earliest Cambrian beds with skeletal remains contain several distantly related trilobite, brachiopod, mollusk, and echinoderm groups and representatives of other phyla that total about 20 distinct kinds of invertebrates. There is no indication of convergence toward a common ancestor. Slightly older sediments in Australia (Ediacara fauna) and western United States have yielded impressions of soft-bodied animals or tracks and trails indicating that a variety of invertebrates without mineralized skeletons were present at least a few million years earlier, in Precambrian time. The biologic problem is thus concerned with two major events that occurred in sequence: first, the origin of the invertebrates; and second, the origin of the conditions under which they could secrete mineralized skeletons.

An early explanation of the contrast between the Precambrian rocks that were almost barren of animal life and the Cambrian rocks bearing the rich and diversified faunas invoked a period of time called the Lipalian Interval, during which all the present land areas of the world were above sea level. Life evolved in the restricted oceans, and the record was thus not available on the present continents. When the seas inundated the continents, the already diversified Cambrian faunas came with them. The Cambrian System was believed to begin everywhere above an erosional unconformity. As knowledge increased and marine sedimentary sequences many thousands of feet thick and barren of fossils were found in continuous succession below marine beds bearing abundant Cambrian fossils, the explanation for the abrupt appearance of the Cambrian fauna based on the "lost" Lipalian Interval became untenable.

The origin of the invertebrates may have been dependent on the evolution of the earth's atmosphere. The oxygen of the atmosphere serves as a shield against ultraviolet radiation from the sun that would be lethal to life on land and in the shallow seas. Several lines of evidence indicate that the Early Precambrian atmosphere lacked oxygen and that its appearance is related to photosynthesis by marine algae, which have a geologic record almost 2,000,000,000 years older than the oldest invertebrates. The buildup of oxygen took many millions of years because much of it was consumed in the beginning by oxidation of inorganic materials in the oceans and on the land. As photosynthetic oxygen production exceeded inorganic needs, a surplus developed in the atmosphere. When this surplus reached a level sufficient to provide a shielding from solar ultraviolet radiation, conditions necessary for the evolution of the invertebrates were achieved.

Several explanations have been given for the origin of conditions permitting mineralization of invertebrate tissues, but none has been supported by convincing evidence. Two of the most plausible possibilities are that skeletons evolved as protection against some unknown predator or predators, or that skeletons became possible

only after some subtle chemical change in the evolving environment created conditions in which inorganic compounds could be retained in animal tissues.

BOUNDARIES AND SUBDIVISIONS OF THE CAMBRIAN

Both biological problems discussed in the preceding section have a direct bearing on the geological problem of the lower boundary of the Cambrian System. The environmental change permitting rapid evolution and diversification of the invertebrates has been considered the significant temporal event marking the beginning of the Cambrian. It may be argued, however, that the ancient soft-bodied organisms are so unlike any Cambrian forms that they are a true Precambrian fauna; thus, the significant temporal event marking the beginning of the Cambrian would be the nearly simultaneous appearance of mineralized skeletons in many different invertebrate groups. Until a criterion for time determination is agreed upon by convention and finds general acceptance among paleontologists, the problem of worldwide identification of the beginning of the Cambrian will remain.

Within the Cambrian System, correlation of events from one region to another requires reasonably precise time criteria (see STRATIGRAPHIC BOUNDARIES). Trilobites, which were abundant, evolved rapidly throughout the period, and had preservable exoskeletons, are the principal tools used for this purpose.

Trilobite successions

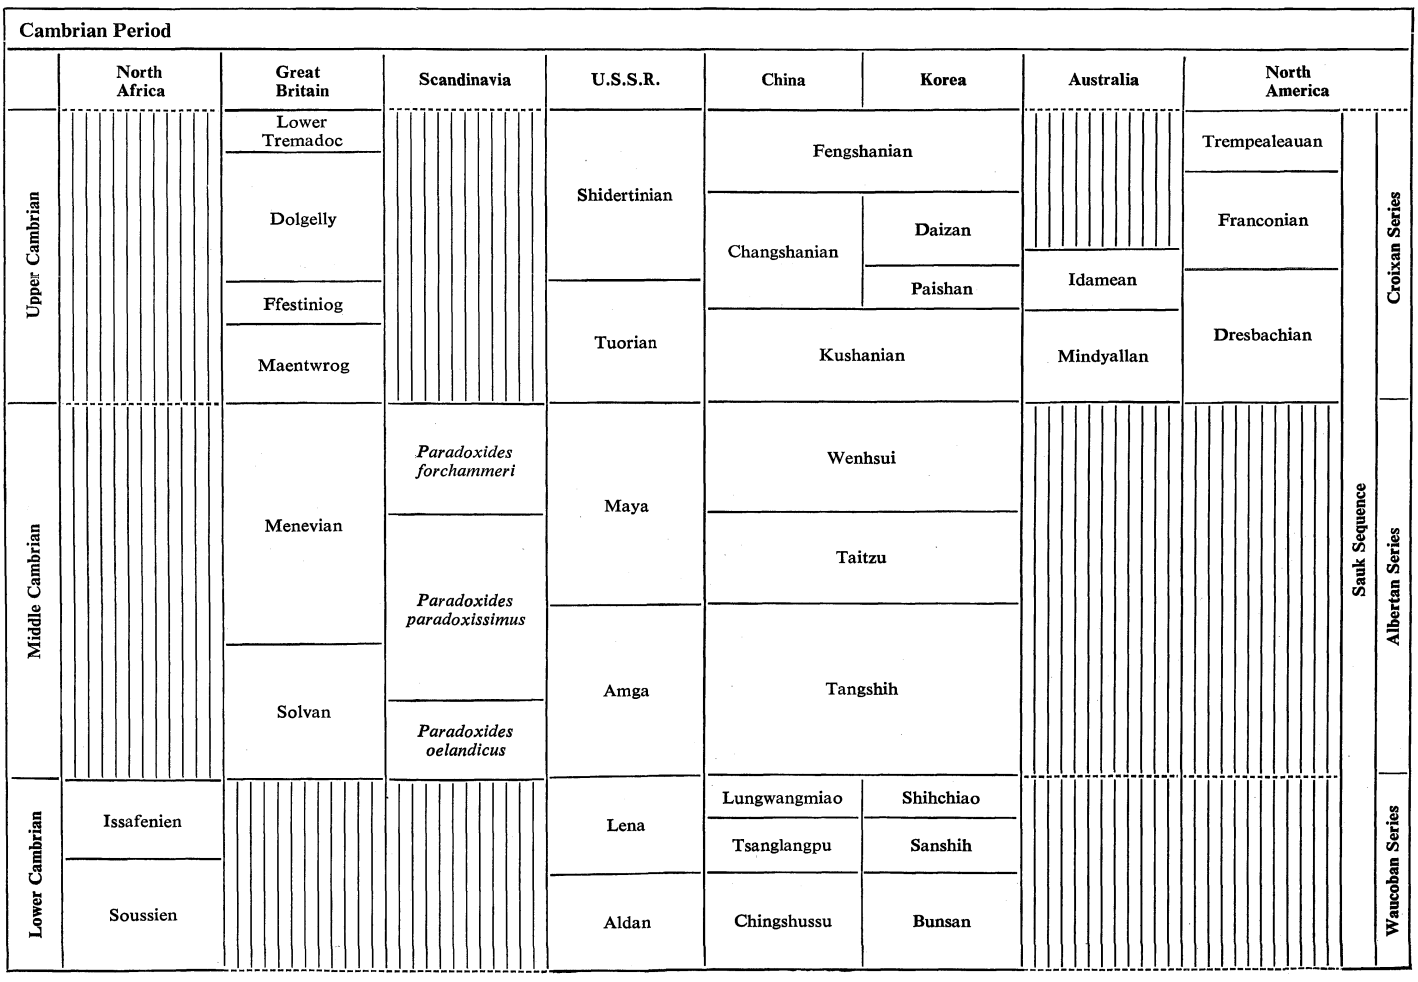
In many regions of the world, empirical successions of changing trilobites have been described and subdivided into zones with characteristic assemblages of genera and species. The zones have been grouped into stages. Ideally, the stages should be worldwide subdivisions of the Cambrian System, but the major Cambrian areas have different stage sequences, and for most areas only parts of the Cambrian System have been formally divided into stages (see Table). The reason for this lack of global uniformity is that the trilobite sequences of even the major areas are not yet completely studied. In addition, as discussed below, neither the contrasts between the trilobite successions in regions of restricted environments with those in regions with unrestricted access to the open ocean nor the significance of the annihilations in the restricted regions have yet been fully appreciated.

These factors contribute to the correlation problem involving the upper boundary of the Cambrian System. When the Ordovician System was proposed, the Cambrian-Ordovician boundary was placed at the base of the Arenig Series that overlies the Tremadoc Series in northern Wales (see Table). Because of a 19th-century miscorrelation, however, upper Tremadoc beds were designated as Ordovician. Soon, the Tremadoc was regularly included in the Ordovician by almost all geologists outside Great Britain. C.D. Walcott identified the boundary between the Cambrian and Ordovician by means of the faunas in North America and correlated this with the boundary in Great Britain.

The American boundary was established in a region of restricted access to open ocean conditions and has been used as a standard in other similar regions. The British boundary was established in a region of unrestricted access to the open ocean and has been used as a standard elsewhere in those regions. Refined correlations indicated that the American boundary falls within the Tremadoc of Great Britain. The resolution of this correlation problem is still being debated.

PALEOGEOGRAPHY

The Cambrian Period was generally quiet. A few uplifts of marine areas produced short periods of erosion in small parts of the continents. Significant regions of active volcanism are recorded only in Tasmania and southeastern Australia, northwestern China, and adjacent regions



of the U.S.S.R., Spain, and the extreme eastern parts of the United States. Except for these, the Cambrian Period records a slow, progressive inundation of most continental regions by the sea. By the end of the period, most of North America, Europe, and Asia and the east half of Australia were submerged beneath shallow seas. Too little is yet known about South America and Antarctica to assess the amount of submergence of these continents. Africa seems to have remained mostly above sea level.

By using organism-sediment relationships of the trilobites, a very crude picture of the major aspects of paleogeography during the Cambrian can be obtained. Among the trilobites, the Agnostida are most abundant in the areas of sedimentation farthest from the Cambrian shields, and most genera and many species have a worldwide distribution. They are most common on the seaward margins of the carbonate banks and in the sediments beyond. In some deeper water sediments beyond the banks, they are the only trilobites found. For these reasons the agnostids are believed to have lived in the surface waters of the open oceans, and the regions where they are abundant are interpreted as regions that had clear access to open ocean conditions. The regions where agnostids are rare or absent, and other trilobites with limited geographic distribution are abundant, are interpreted as regions with restricted access to open ocean conditions. These contrasting regions and their relations to major Cambrian land areas are shown in Figure 1. The boundaries between adjacent regions fluctuated during Cambrian time, but the general distribution of the regions was apparently stable. All questions of faunal provinces, migration routes, and evolutionary trends must be viewed within this context of restricted or nonrestricted access to open ocean conditions.

Faunal provinces

Throughout most of the Cambrian, four faunal provinces can be recognized in the regions of restricted environments: one included North America and perhaps South America: a second included central and southern Europe; a third included most of Siberia; and a fourth included southeastern Asia and perhaps Australia. Each of these provinces, particularly in the Middle and Late Cambrian, was characterized by its own rich variety of trilobite genera and species. In surrounding areas with apparent access to open ocean conditions, there is less differentiation into faunal provinces because the most common trilobites in these areas were the globally distributed agnostids. Associated nonagnostid trilobites indicate some differentiation into faunas typical of the Atlantic and Arctic regions on the one hand, and the Pacific and central Asiatic regions on the other.

Several times during the Cambrian, the trilobite faunas of one or more of the provinces in the restricted regions were virtually annihilated by some abrupt change in the marine environment that did not affect the sediments. Following each annihilation, the varied environmental areas within the provinces were occupied by immigrants from the surrounding open oceans. These immigrants quickly became adapted to the diverse new environments available in the restricted regions and evolved specialized forms. These forms, however, could not adapt to the next environmental crisis. The effect of these environmental crises on nontrilobite organisms is not yet clear; but abrupt changes in the sequences of brachiopods, which are second to the trilobites in abundance as Cambrian fossils, are also known and occur close to the times of the trilobite annihilations.

Most knowledge of Cambrian faunal successions has been obtained from study of the records of the restricted regions. The regions of apparent access to the open oceans are mostly in disturbed areas of complex geology and are only slowly yielding their store of Cambrian knowledge. The evidence presently available suggests that the evolutionary history of the Cambrian faunas may reflect the results of repeated attempts by most phyla to colonize the shallow regions of the seas of the world. These attempts were largely frustrated, perhaps by hostile changes in environmental factors such as temperature or solar radiation or biologic interactions that left no imprint on the sediments but which produced discontinuities in the record of shallow marine life. This conflict between colonization and environment could explain the lack of persistence during or after Cambrian time of many mollusk and echinoderm groups, as well as some Porifera and Brachiopoda and the archaeocyathids. Only toward the end of the Cambrian did many of the groups develop sufficient adaptability to become relatively persistent members of the shallow-water communities.

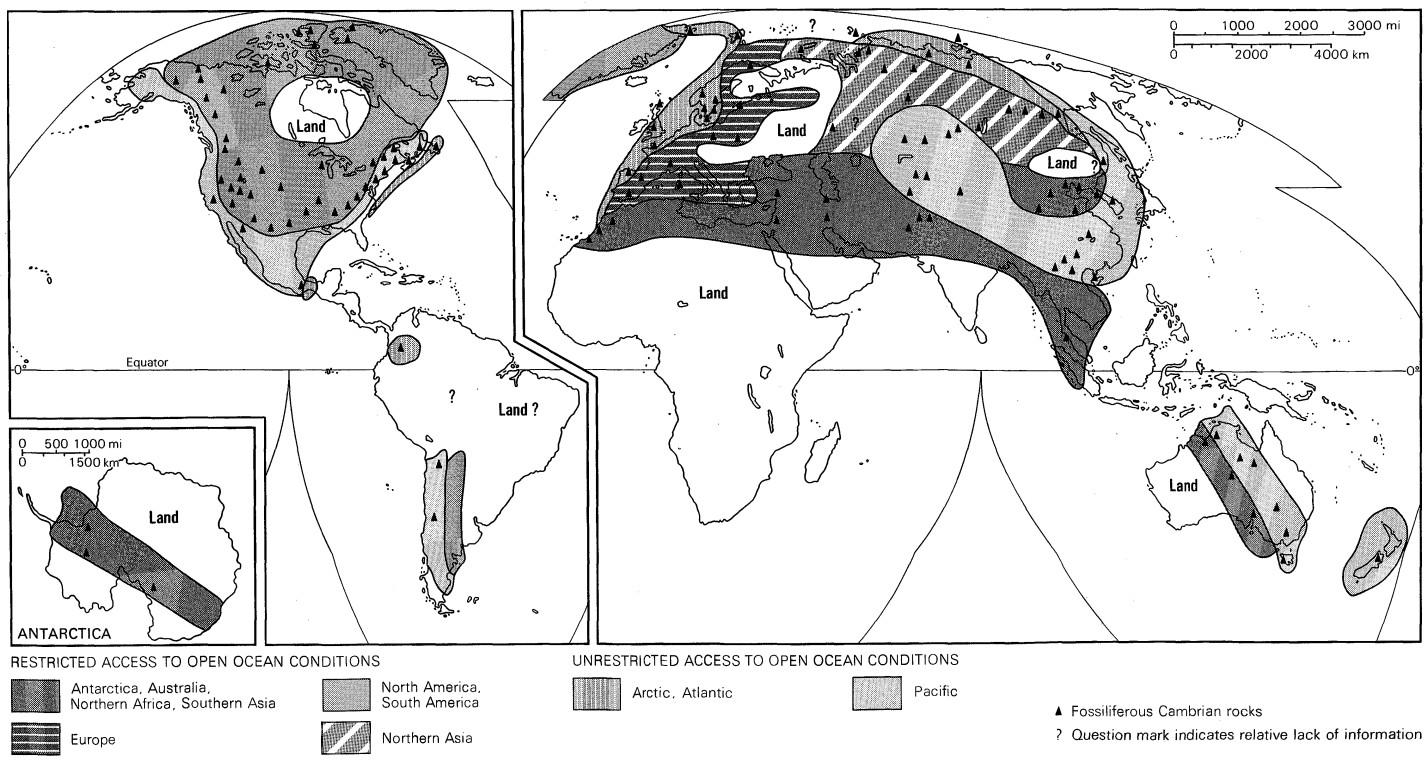


Figure 1: General paleogeography and regions of restricted and unrestricted access to open ocean conditions during Cambrian time.

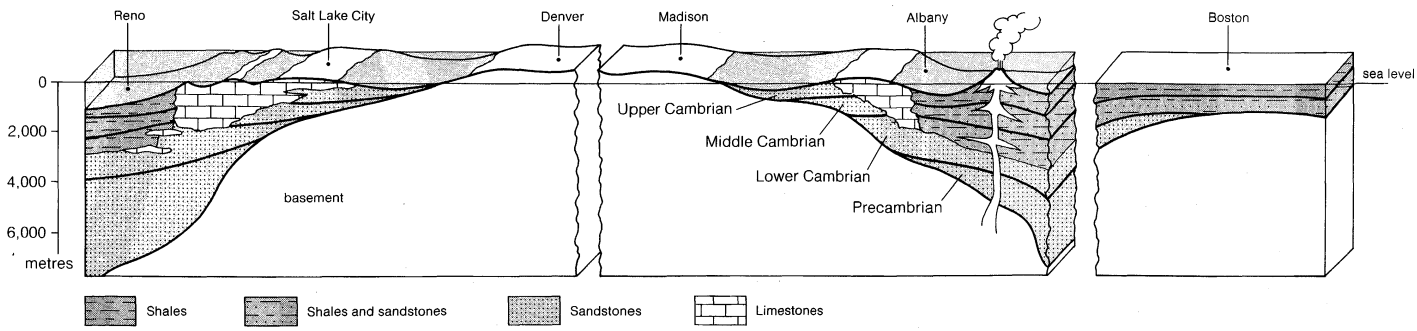

Figure 2: General relations of the principal lithofacies and biofacies regions and the problem of regional relations of Cambrian deposits of extreme eastern United States.

One additional factor complicates the Cambrian story. Increasingly strong evidence indicates that the present distribution of continents and oceans has developed during the last 100,000,000 years and that at earlier times global geography was quite different. Because this geography for the Cambrian has not yet been worked out satisfactorily, the data (Figure 1) are shown on the present geographic base. Cambrian data from the Atlantic margins of Europe and North America provide important support for the idea that the present Atlantic Ocean configuration is unlike that of the Cambrian.

Continental Drift

Along the east coast of North America near Boston, eastern New Brunswick, Nova Scotia, and eastern Newfoundland, the Lower Cambrian beds are characteristically red and include distinctive red, muddy limestones. The Middle and Upper Cambrian beds in this region are typically gray or black shales. Near the Lower-Middle Cambrian boundary is a sedimentary interval that has a very high content of manganese. This lithologic succession and almost all of the trilobites for the whole of the Cambrian can be duplicated in Great Britain exclusive of northwestern Scotland. The faunas are also typical of northwestern Europe. In Scotland, the Cambrian section includes Lower Cambrian quartzites and shales overlain by a thick succession of dolomites. The few Lower Cambrian fossils and almost all of the lithologies can be duplicated in western Newfoundland and the Appalachian region of the United States but are not known elsewhere in Europe.

If the Atlantic margins of the present continental shelves are joined not only the Cambrian facies trends but also later Paleozoic facies and structural trends form a simple pattern in which northwestern Scotland is aligned with areas of similar rocks and faunas in North America, and the areas from eastern Newfoundland to Boston are aligned with similar areas of western Europe. Furthermore, within the Cambrian rocks, the facies patterns indicate that the region now occupied by a belt of metamorphic rocks that separates the fossiliferous Cambrian rocks with European affinities from those with American affinities was the site of a Cambrian seaway (Figure 2). The breadth of the seaway during the Cambrian is not known, but if there was a Cambrian Atlantic, it lay to the west rather than to the east of Boston.

Not only were the relations of the Cambrian continents to each other probably different than at present, but their relationships to the magnetic poles and thus probably to the polar regions were also different. By analyzing iron-rich or volcanic Cambrian rocks for evidence showing the position of the earth's magnetic field at the time they were formed and assuming that there is a causal relationship between the earth's rotational axis and the magnetic poles, an estimate of the position of the Cambrian magnetic poles and thus perhaps the polar regions can be made. Although data for Cambrian poles are limited, findings consistently suggest that the central Pacific Ocean was in one polar region during Cambrian time and the bulge of western Africa was near the other.

Climatic extremes may have been considerably less in the Cambrian than they are at present. With the exception of western Europe, most Cambrian regions have significant accumulations of carbonates, which today form extensively only in the warm-temperate and tropical regions of the world. Accumulation of evaporite sequences in the Lower Cambrian of southern Siberia and parts of eastern United States is further evidence of warm to hot conditions. Although there is abundant evidence for late Precambrian glaciation, evidence for unusual cold during the Cambrian is lacking.

BIBLIOGRAPHY. Most textbooks in historical geology have chapters about the Cambrian Period. The reader who wishes more substantial summary information may turn to one or more of the following books. The references in these books will lead the serious researcher to the majority of the primary references. J. RODGERS (ed.), *El sistema Cámbrico, su paleogeografía y el problema de su base*, 20th International Geological Congress, Mexico City, is a three-volume symposium that summarizes world knowledge of the Cambrian to about 1955. Most papers in the first two volumes (1956) are in English. The third volume (1961) comprises papers in several languages. C.H. HOLLAND (ed.), *Cambrian of the New World* (1970), contains a comprehensive summary of knowledge of the Cambrian of North and South America, including the Arctic regions, through 1968. Н.Е. ЧЕРНЫШЕВА (ed.), *Кембрийская система* (1965), entirely in Russian, contains a comprehensive summary of knowledge of the Cambrian of the U.S.S.R., through 1961. T. KOBAYASHI, "The Cambrian of Eastern Asia and Other Parts of the Continent," *J. Fac. Sci. Tokyo Univ.*, sec. 2, vol. 16, pt. 3, pp. 381–534 (1967), presents an English summary of the Cambrian of southeastern Asia, through 1966. R.C. MOORE (ed.), *Treatise on Invertebrate Paleontology*, a multivolume set, includes the most recent data in English on most Cambrian fossil groups. Those parts that include Cambrian information are: pt. E, *Archaeocyatha, Porifera* (1955); pt. H, *Brachiopoda* (1965); pt. I, *Mollusca 1* (1960); pt. K, *Mollusca 3* (1964); pt. O, *Arthropoda* (1960); pt. P, *Arthropoda 2* (1955); pt. Q, *Arthropoda 3* (1961); pt. R, *Arthropoda 4* (1969); pt. S, *Echinodermata 1* (1967); pt. U, *Echinodermata 3* (1966); pt. V, *Graptolithina* (1955); and pt. W, *Miscellanea* (1962). See also "Premetazoan Evolution and the Origins of the Metazoa," in *Evolution and Environment*, ed. by E.T. DRAKE (1968).

(A.R.P.)

Cameroon

The United Republic of Cameroon (République Unie du Cameroun) is a triangle-shaped state wedged between West and Central Africa. It covers an area of 179,557 square miles (465,054 square kilometres) and is bordered by the Atlantic Ocean to the southwest, Nigeria to the northwest, Chad to the northeast, the Central African Republic to the east, Congo (Brazzaville) to the southeast, and Gabon and Equatorial Guinea to the south. Its ethnically diverse population totalled more than 5,800,000 at the start of the 1970s. The federal capital of Cameroon is at Yaoundé.

The country's name is derived from Rio dos Camaroēs (River of Prawns)—the name given to the Wouri River estuary by Portuguese explorers of the 15th and 16th centuries. Camaroēs was also used to designate the river's neighbouring mountains. Until the late 19th century, English usage confined the term the Cameroons to the mountains, and the estuary was called the Cameroons River or, locally, the Bay. In 1884 the Germans extended the word Kamerun to their entire protectorate, which largely corresponded to the present state.

The republic is a federation consisting of the former United Nations Trust Territory of Cameroun under

Establishment of the united republic

French administration in the east, which became independent in 1960, and the southern half of the former Trust Territory of Cameroon under British administration in the southwest, which voted to join Cameroon in 1961. (The northern half of British-administered Cameroon joined the Republic of Nigeria.)

Since unification, the Cameroonian economy has continued to display steady growth. More important, perhaps, the success of the federation has demonstrated that regions of varied colonial background can unite into larger political units. For historical aspects, see WEST AFRICA, HISTORY OF. For a related physical feature see CHAD, LAKE.

THE LANDSCAPE

The natural environment. *Relief features.* Cameroon can be divided into the four geographic regions of the south, the central, the north, and the west. The southern region extends from the Sanaga River to the southern border and from the coast eastward to the Central African Republic and Congo (Brazzaville). It consists of coastal plains that are about 25 miles wide and a densely forested plateau with an average elevation of a little less than 1,000 feet (about 300 metres).

The central region extends from the Sanaga River north to the Bénoué River. The land rises progressively to the north and includes the Adamaoua (or Adamawa, a plateau region), with elevations between 2,500 feet and 4,500 feet.

Upland areas

In the extreme north, the savanna plain slopes downward as it approaches the Lake Chad Basin. To the west, the relief is mountainous, the result of a volcanic rift that extends northward from the island of Fernando Po. Near the coast, the peak of volcanic Cameroon Mountain rises to the highest elevation in West Africa—13,353 feet (4,070 metres). The Monts Gotel of the Adamaoua trend from south to north, culminating in the Monts Mandara of the northwest.

Drainage. The rivers of Cameroon form four large drainage systems. In the south, the Sanaga, Wouri, Nyong, and Ntem rivers drain into the Atlantic Ocean. The Bénoué River and its tributary, the Mayo Kébi, flow into the Niger River Basin of Nigeria. The Logone and Chari rivers—which form part of the eastern border with Chad—drain into Lake Chad, whereas the Ngoko River joins the Sangha River and flows into the Congo River Basin.

Climate. The major factors that influence Cameroon's climate are its latitudinal extent and its relief. Lying wholly within the tropics, the country has a hot climate throughout the year; average temperatures range between 70° and 82° F (21° and 28° C), although they are lower in areas of high elevation.

The incidence of rainfall depends largely on the seasonal movements of two dominant air masses; the warm and dry tropical continental air mass is associated with dusty weather, whereas the warm and humid tropical maritime air mass brings rain-bearing winds. Rainfall decreases from south to north. Along the coast, the rainy season lasts from April to November, and the relatively dry season lasts from December to March; a transition period from March to April is marked by violent winds. The mean annual rainfall of 98 inches occurs in 150 days. In the central plateau region, rainfall decreases to 59 inches. There are four seasons—a light rainy season from May to June, a short dry season from July to October, a heavy rainy season from October to November, and a long dry season from December to May. The north, however, has only a dry season from October to May and a rainy season from June to September, with a mean annual rainfall as low as 15 inches. The wettest part of the country lies in the western highlands. Debundscha Point on Cameroon Mountain has a mean annual rainfall of about 400 inches, most of which falls from May to October.

Vegetation and animal life. The major vegetation types of West Africa are represented in Cameroon. The hot and humid south supports dense, tropical rain forests, in which hardwood evergreen trees including mahogany, ebony, obeche, dibetu, and sapelli may grow to more than 200 feet high. There are large numbers of orchids and ferns.

Plants of the tropical rain forest

Mangroves grow along the coasts and the mouths of rivers. The rain forest gives place to the semi-deciduous forest of the central region, where a number of tree species shed their leaves during the dry season. North of the semi-deciduous forest, the vegetation is composed of wooded savanna with trees 10 to 60 feet high. The density of trees decreases toward the Chad Basin, where they are sparse and mainly of *Acacia* species.

Between 4,000 and 8,000 feet, the tropical rain forest differs from that of the lowlands; the trees are smaller, are of different species, and are festooned with mosses, lichens, and other epiphytes (plants that derive their moisture and nutriments from the air and rain). Above the forest zone are drier woodland, tall grassland, or patches of mountain bamboo. Above about 7,800 feet in the interior and above about 10,000 feet on Cameroon Mountain, short grasses predominate.

The country is rich in animal life. Its dense forests are inhabited by screaming red and green monkeys, chimpanzees, and mandrills, as well as rodents, bats, and numerous birds—from tiny sunbirds to giant hawks and eagles. A few elephants survive in the forest and in the grassy woodlands where baboons and several types of antelope are the most common animals. The 656-square-mile (1,700-square-kilometre) Réserve de Waza in the north, which was originally created for the protection of giraffes and antelope, abounds in both forest and savanna animals including monkeys, baboons, lions, leopards, and birds ranging from white and gray pelicans to spotted waders.

Traditional regions and settlement. In general there is a cultural division between the north and the south. The northern savanna plateau is inhabited by Sudanic and Arab pastoralists who migrate seasonally in search of grazing land and occupy temporary dwellings, whereas the forested and hilly south is peopled by Bantu agriculturalists in permanent villages. The north is predominantly Muslim, whereas the southern peoples adhere to animism and Christianity.

Most of the large urban centres are in the south. Douala, the largest city, has a population of 250,000 and is the country's main port. The federal capital of Yaoundé, with 178,000 inhabitants, is an important communication centre. Buea, the capital of West Cameroon state, has a population of only 13,000. In the north, Garoua is a port on the Bénoué River with a population of 28,000.

PEOPLE AND POPULATION

Ethno-linguistic groups. The country has been described as a "racial crossroads" because of its more than 100 different ethnic groups. There are three main linguistic groups—the Bantu-speaking people of the south, the Sudanic-speaking people of the north, and those who speak the Bantu languages of the west.

The principal linguistic groups

The Bantus settled in the Cameroons from Equatorial Africa. The first group that invaded the country included the Makas, Ndjems, and Dualas. They were followed at the beginning of the 19th century by the Fang (Pangwe) and Bete peoples.

The Sudanic-speaking peoples in the north include the Sao, who live on the Adamaoua plateau; the Fulani; and the Kanuri. The Fulani came from the Niger Basin in two waves—in the 11th and 19th centuries; they were Muslims who converted and subjugated the Logone valley and the Mayo Kebbi and Faro areas. The third ethnic group consists mainly of small tribes, except for the 1,500,000 Bamilekes who live between the lower slopes of the Adamaoua mountains and Cameroon Mountain. Other western Bantu-speaking tribes include the Tikar who live in the Bamenda region, the Bali, the Bamum, and the Keaka.

The oldest inhabitants of the country are the pygmies, locally known as the Baguielli and Babinga, who are found within the southern forests. They have been hunters and food-gatherers for thousands of years and live in small hunting bands.

The work of European missionaries and the colonization of the country by European powers led to the intro-

duction of European languages. During the colonial era German was the official language; it was later replaced by English and French, which have retained their official status in the unitary republic established in 1972.

Religious affiliations. More than half of the population continues to adhere to traditional beliefs. European Christian missionaries first came to Cameroon in the 19th century, and in the mid-1970s there were estimated to be about 1,500,000 Roman Catholics; older estimates indicated more than 750,000 Protestants and members of independent Christian churches. There were also about 600,000 Muslims.

Demography. In 1975 the population was estimated to number more than 6,398,000. The birth rate was about 41 per 1,000 population and the death rate about 20 per 1,000, with an annual growth rate of a little more than 2 percent. Life expectancy at birth was about 43.5 years.

The average population density for the country in 1975 was 36 persons per square mile (14 per square kilometre), but densities vary from region to region. The highest densities occur in the western mountains, where they may reach more than 700 persons per square mile (270 per square kilometre). The southeast and Adamawa (Adamaoua) Plateau are the most sparsely populated regions.

THE NATIONAL ECONOMY

Like most African countries, Cameroon has a basically agricultural economy. The economy—which is dominated by French financial institutions and banking houses—has maintained steady growth since independence in 1960. During the period of the Second (1966/67–1970/71) Plan, gross domestic product rose by 7.7 percent per year in real terms, and a remarkable 5.7 percent annually per capita; this substantial growth rate was made possible by the rapid expansion of investments and output in private industry. One of the major goals of the Third (1971/72–1975/76) Plan, however, was gradual Cameroonization of the economy. Cameroon does not suffer from a chronic trade deficit, since imports and exports are usually in reasonably good balance. The government was able to dispense with external support for its budgetary needs after 1969. Cameroon is an associate member of the European Economic Community (EEC, or Common Market) and a member of the Union Douanière et Économique de l'Afrique Central (UDEAC; Central African Customs and Economic Union) to which the Central African Republic, Gabon, and Congo (Brazzaville) also belong.

The extent and distribution of resources. In the mid-1970s there were few indications of abundant mineral wealth. The largest reserves were those of kyanite (an aluminum silicate) and bauxite at Minim-Martap and Ngaoundere on the Adamawa Plateau; the deposits, amounting to more than 1,000,000,000 tons, have a 44 percent alumina content. Another 40,000,000,000 tons

of bauxite reserves are situated at Fonga-Tongo. There is some gold in eastern Cameroon and cassiterite (a tin dioxide) occurs at Mayo Darlé in the northeast.

About 41,000,000 acres (16,000,000 hectares), or one-third of eastern Cameroon, and about 2,500,000 acres in western Cameroon are forested and yield valuable hardwood timber. The rivers and offshore ocean waters are a rich source of fish, and the grasslands support valuable herds of cattle. The wild animal life provides a firm basis for tourism.

Water-power resources

The main developed source of hydroelectric power is the Sanaga River; the power station at Edéa on the Sanaga Falls is the country's largest. The Akam-Wouri River in the west also provides hydroelectric power as it drops from the central plateau to the coastal region. Thermal power is expensive because diesel fuel and coal must be imported.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture accounts for about 80 percent of the country's export earnings and employs 90 percent of the adult population. The main subsistence crops include plantains, yams, manioc, and palm oil in the south and peanuts, millet, and manioc in the north. Most cultivation is carried out on small farms by crude methods. Some cash crops, however, are grown on large plantations owned by French interests in the east and a government agency—the Cameroon Development Corporation—in the west.

Cocoa and coffee production

Cameroon is one of the world's leading cocoa-producing countries. Cocoa is grown on small farms throughout the Centre-South (Centre-Sud) province, in parts of the coastal and western areas, and in western Cameroon. Much attention was given to the improvement of cocoa production under the second five-year plan; under "Operation 100,000 Tons," agricultural extension workers helped farmers to tend their cocoa trees and to fight pests and diseases.

Among the French-speaking African countries, Cameroon is the second largest coffee exporter, after the Ivory Coast. Eastern Cameroon produces 90 percent of the coffee crop, which is grown on an estimated total of 400,000 acres. About 64 percent of the coffee exported is robusta, the rest arabica.

Bananas are an important export product by value, but production and exports declined in the 1960s because of the lack of new markets and the loss of imperial preference in the United Kingdom in 1967. The government launched a campaign in 1965 to produce a hardier, disease-resistant banana variety. Bananas are grown on plantations in the southwest and on small farms; both production and export levels recovered in the 1970s.

Cotton was introduced in 1952 by the Compagnie Française pour le Développement des Fibres Textiles, in which the government owns the controlling interest. It is grown largely in the grasslands by private farmers.

Rubber is produced on government and domestic company plantations; the Société Africaine Forestière et Agricole owns 25,000 acres of plantations at Dizangué in the southern area of eastern Cameroon. Rubber plantations in western Cameroon are owned by the Cameroon Development Corporation and Palmol Cameroon, Ltd. Rubber is produced mainly for export, but a small quantity of rubber produced at Dizangué is used domestically.

Except for pigs, which are prohibited in areas where Islām is predominant, livestock is concentrated on the northern Adamawa Plateau. In the mid-1970s, there were about 2,500,000 cattle, 3,500,000 sheep and goats, 370,000 pigs, 96,000 donkeys, 58,000 horses, and 8,600,000 of various kinds of poultry. Domestic consumption of meat is low; livestock is exported to Nigeria, meat to Equatorial Guinea and to the Congo, and hides and skins to Nigeria and Equatorial Guinea.

Forestry

Forestry is limited to the most accessible areas along the Douala–Yaoundé railway and along the main roads. The logs are transported by water, road, and rail. Timber and palm kernels are produced for export, whereas wood for construction purposes, firewood, charcoal, kola nuts, and palm oil and kernels are produced for domestic use.

Marine fishing is carried out by individual fishermen using traditional methods as well as by large companies. The fishermen go to sea in dugout canoes and use nylon nets, whereas the companies employ trawlers based in Douala. The combined annual deep-sea catch is more than 21,000 tons. Some prawns are caught for export. Fishing in the rivers yields 50,000 tons of fish annually.

Mining and quarrying. Mining has contributed little to the economy. Gold production in 1973 was a mere 6.6 pounds (3 kilograms) and that of tin was about 40 metric tons. Small amounts of bauxite are mined to supply the aluminum smelter at Edéa; most bauxite, however, is imported from France and Equatorial Guinea. Several foreign petroleum companies have been prospecting for oil, and indications of small deposits of petroleum and natural gas have been found.

Manufacturing. The manufacturing industry of Cameroon employs about 2 percent of the working population and accounts for 25 percent of total exports. The industrial sector consists of one major heavy industrial complex—the Edéa aluminum smelter—and about 500 small and medium-sized enterprises engaged in processing, various manufacturing procedures, and the assembly of radios.

Apart from a few establishments, such as the aluminum smelter, the industrial enterprises have been operating only since the 1960s. The largest development has been in textiles, with the establishment of two factories in Douala for spinning, weaving, bleaching, dyeing, and printing cotton. In the year 1966–67 about half of the total industrial investment went into processing industries. Food-processing plants include a sugar factory at Mbandjock; palm-oil plants in Bota, Lober, Dibambari, and Edéa; a chocolate factory at Yaoundé; and flour mills at Douala.

Energy. The two power stations on the Sanaga River at Edéa have a hydroelectric capacity of 159,760 kilowatts. On the completion of a third plant, the total capacity will rise to 180,000 kilowatts.

Financial services. Cameroon is linked together with the Central African Republic, Gabon, and Congo (Brazzaville) in a monetary union (UDEAC) with a common currency, the CFA (Communauté Financière Africaine, or African Financial Community) franc. The CFA franc is convertible into any currency, but France must approve direct investment by citizens within the franc area in countries outside it, the issue and sale of foreign stocks and shares in the area, and borrowings from outside the area. France is also represented on the board of directors of the Central Bank in Yaoundé; its notes and coins are legal tender in each member state of the monetary union. Each member state has its own monetary committee, on which France is represented, and a National Credit Council. The latter body advises the respective governments on credit policy and banking organization and methods. There are seven commercial banks in Cameroon, four of which are French, two British, and one owned by the Cameroonians. Most insurance companies are French owned. There is no stock exchange.

Monetary relations with France

Foreign trade. The main exports are agricultural products and aluminum. Coffee and cocoa together accounted for almost 50 percent of the total value of exports in 1970. Aluminum accounted for 9 percent, timber 9 percent, and cotton 8 percent. There has been increasing emphasis on the importation of capital equipment and semifinished products for the growing industrial sector. Other imports include aluminum oxide, pharmaceuticals, beverages, rubber, and synthetic fabrics.

Most trade is carried on with the EEC countries, which purchased almost 70 percent of Cameroon's exports in 1970. France is the largest individual trading partner; it supplies about 50 percent of Cameroon's imports and takes about one-third of the country's exports. Trade outside the Common Market is carried out primarily with the United States and Japan.

Management of the economy. *The public and private sectors.* The government sets the guidelines in its five-year plans and attracts private capital for the development of certain sectors of the economy.

The five-year plans

The First Five Year Plan (from 1960 to 1965) laid emphasis on the expansion of educational facilities, the diversification of farm production, and selective industrialization. The objectives of the second development plan, the so-called Peasants Plan, of 1965 to 1970 emphasized rural development. It included the introduction of cooperatives as a basis for rural organization, the processing of raw materials, the choice of certain areas for integrated rural development, and the extension of the Trans-Cameroon Railway northward to Ngaoundéré. These projects were to be financed about equally from public and private funds.

The Third Five Year Plan of 1971 to 1976 is an extension of the two previous plans. The processing of local raw materials is encouraged in order to diversify the economy, to reduce urban unemployment, and to improve foreign trade.

In order to encourage private investment, the Cameroon National Federal Assembly has adopted an investment code; its objectives include stabilization of company taxes, provision of security to large businesses, and the protection of local industries from foreign competition.

Taxation. There are four different company tax systems, which offer various benefits to developing industries. Most tax revenues are derived from import and export duties.

Trade unions. There are more than 80,000 members of trade unions in the federation. Four large trade unions are recognized by the government: the Cameroon Federation of Unions (*Féderation des Syndicats du Cameroun;* FSC); the Union of Denominational Workers Organizations (*Union des Syndicats Croyants du Cameroun*); the National Teachers Union (*Syndicat National des Enseignants du Cameroun;* SNEC), and the National Federation of Private School Teachers (*Fédération Nationale des Enseignants privés du Cameroun;* FNEPCAM).

There has been industrial peace in the country since 1960. The International Labour Office (ILO) established an Inter-African Centre at Yaoundé in 1965 that provides courses for labour administration officials. Employers' associations include chambers of commerce in Douala and Yaoundé and associations for those engaged in industry and the import—export trade.

Contemporary economic problems. The main problem that Cameroon has in common with the other developing countries of Africa is the acquisition of capital to finance resource development. When foreign investment capital is scarce, the country must depend largely on moneys acquired through the sale of its products on the world market. The fluctuations in world prices of raw materials such as cocoa and coffee, however, make the future unpredictable.

TRANSPORTATION

The difficult terrain and heavy rainfall in the south have been contributory factors to the absence of an adequate transportation network linking the different regions of the country. The north has traditionally been virtually isolated from the south. Until the construction of the railway line between Mbanga and Kumba in 1965, it was difficult for products from West Cameroon to be transported to the port of Douala in East Cameroon. Transportation is more developed in some regions than in others; the best roads are in the coastal region, whereas the roads in West Cameroon are few and are often in bad condition.

Problems of transport development

The road network. There are more than 8,500 miles of roads, only about 765 miles of which are paved and most of which can be travelled only during the dry season. Douala is linked to the large population centres by roads that run through the central region, Yaoundé and Yoke Yokon, and the Adamaoua district. Two subsidiary roads from Garoua lead to Maroua and Makole. Douala is also linked by road through Bertoua and Batouri to Bangui in the Central African Republic and to Gabon via Edéa and Kribi.

Railways. The more than 500 miles of railways will increase to more than 800 miles when the Trans-Cameroon line reaches Ngaoundere from Yaoundé. The two short railway lines of metre gauge in the southwest were constructed by the Germans before World War I; they remained separated until 1955 when the Wouri Bridge made it possible for them to use a common terminus and to gain access to workshops at Bassa, just outside Douala. A 107-mile-long northern line runs from Douala to Nkongsamba and serves the coffee and banana region of East Cameroon; a line from Mbanga to Rumba was completed in the late 1960s. The Central Line runs for 191 miles between Douala and Yaoundé; it has a 24-mile branch line to Mbalmayo on the Nyong River, which serves Edéa and the cocoa-producing area.

Facilities at Douala

Port facilities. The main port is Douala, on the estuary of the Wouri River. One of the best equipped ports in West Africa, it has 11 docks for cargo ships, including a wood-loading dock and a tanker dock with adjacent facilities for the unloading and storing of minerals. The fishing port above the wood-loading dock is equipped with refrigeration facilities.

The minor ports include Kribi at the mouth of the Kienké River, which is used primarily for the shipment of logs and cocoa from the Boulon district; the ocean port of Victoria in West Cameroon, which handles only a modest amount of traffic; and the port of Tiko, on a creek

leading to the Wouri estuary, which handles bananas, wood, and rubber. In the north, the river port of Garoua on the banks of the Bénoué transports goods to Nigeria; the Upper Bénoué, however, is navigable only from seven to 10 weeks in a year.

Air transport. Douala is the main international port of entry, and Yaoundé and Tiko also handle international flights. There are domestic airports at Garoua, Ngaoundéré, and Batouri, as well as numerous airfields. Air-Cameroun has scheduled domestic flights and flights to Chad.

ADMINISTRATION AND SOCIAL CONDITIONS

The structure of government. By the constitution of 1961, the states of West Cameroon and East Cameroon were linked together into a federation. Executive powers are conferred on the president, who is the head of the federal government and chief of the armed forces. The president is assisted by a vice president, who may not come from the same state as the president. They are both elected for a period of five years by direct and secret universal suffrage granted to all citizens over 21 years of age. The president appoints the federal ministers and parliamentary secretaries and may dissolve the federal legislature.

The federation of the two states

Legislative power is held by a unicameral National Federal Assembly whose members are also directly elected for five-year terms. One deputy is elected for every 80,000 inhabitants. The National Assembly shares with the president the initiative for proposing federal bills, which it adopts on a simple-majority basis.

Each of the two federal states can in law establish any institutions of its choice except those listed in the constitution as being subject to federal law; institutions restricted to the federal level include those dealing with personal liberty, law, the electoral system, national finance, and education. The head of each state government is the prime minister, who is named by the president of the republic and invested by his respective legislative assembly. In East Cameroon the legislative assembly consists of 100 representatives who are directly elected for five-year terms. The 37-member legislative assembly of West Cameroon shares its power with the 20-member Assembly of Traditional Chiefs. The prime minister of a state can be removed by a vote of nonconfidence. The president has the power to dissolve a state legislative assembly in the event of persistent disagreement between the assembly and the federal government.

The federal republic was divided into six administrative regions in 1962, and each region was placed under the authority of a federal inspector. The six units are the South Central (Centre Sud), West Cameroon (both a federal state and a regional unit), Coastal (Littoral), Northern (Nord), West (Ouest), and East (Est) regions. Each region is further divided into *départements*.

Evolution of the one-party state

In the 1950s there were no fewer than 84 political parties in East Cameroon. With the exceptions of the Union des Populations du Cameroun (UPC; Union of the Populations of Cameroon) and the Action Nationale (National Action), both of which were broadly based, the rest of the parties existed only at the tribal or regional level. In 1955 the UPC was banned by the French government; as a result a wave of terrorism broke out, especially in the Bassa Mungo, Wuri, and Bamileke districts. Political rights were restored to the party in 1960. The arrest, conviction, and imprisonment of the four principal opposition leaders in East Cameroon during 1962 left the ruling party, L'Union Camerounaise (The Cameroonian Union) as virtually the only party in the state. In 1966 the Union merged with the governing party of West Cameroon, the Kamerun National Democratic Party (KNDP), creating the Union Nationale Camerounaise (UNC; Cameroon National Union). The country is now a de facto one-party state.

Justice. A federal magistrates council, which is responsible for guaranteeing the independence of the judiciary, advises the president on the nomination of magistrates and judges and acts as a disciplinary body. The Federal High Court decides whether a bill is receivable by the National Assembly in the event of a dispute between the president and the legislature. It also settles questions of competence among the highest jurisdictions of the federated states; passes judgment on appeals with respect to the administrative actions of the federal authorities; decides whether laws passed by the states are in conformity with federal law; and settles all disputes between the states or between one of the states and the federal government.

The special High Court of Justice passes judgment on the president in case of high treason and on the vice president, the ministers of the federated states, and the state secretaries in the event of a plot against the government.

The dual system of justice

The legal system of East Cameroon consists of a supreme court, four courts of appeal, and first-instance, labour, and conciliation tribunals. It is closely modelled on the French court system. In West Cameroon, the legal system displays British influence and includes a judicial system for customary law. There is a High Court and a Magistrates' Court for state law and 70 native courts with traditional jurisdiction.

The armed forces. The armed forces include a 2,700-man army, an air force, a navy, and a civil guard. Army officers are initially trained at the École Militaire Interarmes (EMIAC) in Yaoundé and then in specialized schools in France. The first Cameroonian commander in chief of the army took office in 1965.

Apart from guaranteeing national territorial integrity, the army aids the police in the maintenance of law and order and is actively involved in the construction of roads. The navy was created in 1960 and is responsible for guarding the coasts, maritime communications, maintaining law and order in regions that are accessible to its units, and preventing illegal entry and smuggling.

The Cameroon Air Squadron was created in 1961 and is gradually being developed with the return of Cameroonians who have completed their training in France and other European countries. The National Civil Guard is an auxiliary force composed of volunteers who initially sign up for a period of one year. It was created in 1960.

Educational services. Educational services have been expanding since 1960, and the curriculum in secondary schools has been modified to make it relevant to the country's needs. About 67 percent of the children of primary school age are enrolled either in government or in Catholic or Protestant mission schools.

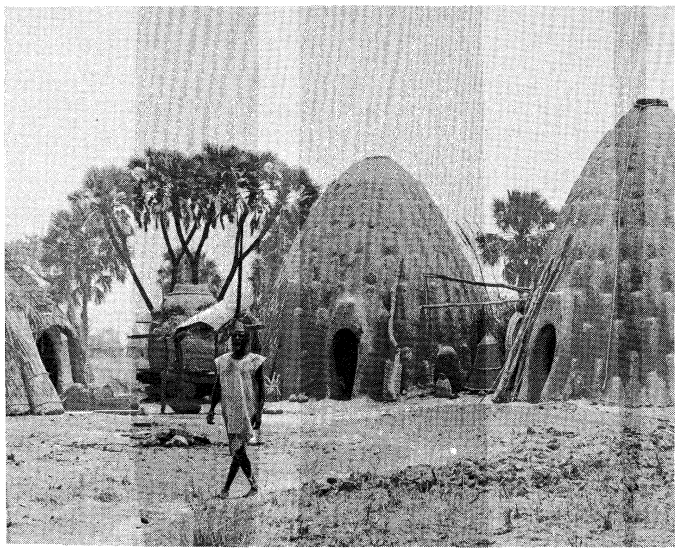
There were more than 150 general education secondary schools, 73 vocational schools, and 15 teacher-training schools in the early 1970s. In 1969, manual labour was made compulsory in secondary and technical schools as a means of encouraging students to take up farming on the completion of their courses instead of seeking white-collar jobs in the cities.

The Federal University of Cameroon at Yaoundé was established in 1962. There were over 2,000 students during the 1970–71 academic year, 20 percent of whom were in the schools of law and economic science. About 8 percent of the registered students were women.

Health and welfare services. The government emphasized the improvement of the nation's health facilities in the first and second five-year development plans. In 1958 there were only 12 hospitals, about 25 dispensaries, and 40 subsidiary centres; by 1967 there were approximately 85 hospitals, 340 dispensaries, and 50 elementary health centres. Between 1965 and 1970 hospitals in Yaoundé, Douala, Foumban, Garoua, and Ngaoundéré were modernized. Long-term plans call for a further expansion of dispensary and health-centre services.

In 1970, there was one doctor to every 26,000 inhabitants and one qualified male nurse for every 2,455. Nearly 70 percent of the doctors were foreign-born and were concentrated in the main cities. A Health Sciences University Centre was established at the Federal University in 1969 to train Cameroonian doctors and other medical personnel.

There is no government system of social security, and there are no pension plans or health insurance programs for workers. Most assistance is obtained through the



Housing of the Masa tribe in Mourla village, near Pouss, northern Cameroon.
Marc and Evelyne Bernheim—Rapho Guillumette

traditional kinship system. There are, however, indemnities for occupational diseases or accidents, and the Public Health Service provides free services to the poor.

Housing. The chronic housing shortage is being attacked by the government in both urban and rural areas. Housing loans may be obtained by workers through the state-owned Crédit du Cameroun. The Société de Prévoyance provides moderately priced building materials, and the Société Immobilière de Cameroun is engaged in the building of communal housing projects.

Police services. The police force consists of six regional legions, five squadrons, and a Republican Guard Legion. It is responsible for maintaining the government's authority throughout the country. It also ensures that price-control laws are enforced and traffic regulations are obeyed. The Republican Guard Legion is responsible for the safety of the president.

Social conditions. In 1970, about 2,400,000 persons were economically active, with approximately 75 percent of the labour force engaged in traditional activities such as agriculture and fishing. Unemployment was about 6 percent. In the cities, the cost of living has steadily risen since 1963. The average annual per capita income is equivalent to about $150 U.S.

Legal working hours are 48 hours per week in farming and forestry and 40 hours in industry, commerce, and the professions. Labour legislation provides for paid vacations, a minimum employment age of 14 years, the exemption of women and children from labour at night, and a minimum-wage scale.

Malaria is prevalent everywhere but in the mountainous regions, where respiratory and pulmonary diseases and dysentery are common. There are incidences of leprosy and schistosomiasis (a parasitic infestation of the bladder and intestines), as well as syphilis, sleeping sickness, and rheumatism.

Social and economic divisions in general follow ethnic lines. In the north, the Muslim pastoralists dominate, whereas the more urban south is dominated by those who have acquired Christianity and a Western education. Because of the multiplicity of tribes, precise divisions are difficult to draw.

CULTURAL LIFE

Each major ethnic group of the country has developed its own culture. The frenzied rhythms played on the drums by the people of the southern forest region contrast with the flute music of northern Cameroonians. Rich diversity is well represented in the country's art. In the Adamaoua area, the Muslim Fulani produce elaborately worked leather goods and ornate calabashes (gourds used as containers), and the Kirdi and the Matakani of the western mountains produce distinctive types of pottery. The powerful masks of the Bali, which represent elephants' heads, are used in ceremonies for the dead, and the statuettes of the Bamileke are carved in human and animal figures. The Tikar people are famous for beautifully decorated brass pipes, the Ngoutou people for two-faced masks, and the Bamum for smiling masks.

Cultural institutions and organizations

L'Institut Français d'Afrique Noir (French Institute of Black Africa) maintains a library in Douala that specializes in the sociology, ethnology, and history of Africa. Small libraries are also maintained by secondary and technical schools. Of the several museums, the Musée du Diamare et Maroua has anthropological collections relating to the Sudanese peoples and the Musée Camerounais de Douala exhibits objects of Cameroon's prehistory and natural history.

Cultural organizations include the Cameroun Cultural Association, the Cameroun Cultural Society, and the Centre Fédéral Linguistique et Culturel. There are also numerous women's associations, youth movements, and sporting associations.

French is the principal language of the press, although some periodicals are printed in English and Boulon. The French *La Presse du Cameroun* is the only daily newspaper, and there is a daily government gazette of limited circulation. *The Cameroon Express* is published twice weekly. All publications are censored by the government through the Agence Camerounaise de Presse. The government owns and operates four radio stations, located at Yaoundé, Douala, Garoua, and Buea. There is no television.

PROSPECTS FOR THE FUTURE

Development has been made possible by the political stability that the republic's diverse peoples have enjoyed since independence and by the sound fiscal and monetary policies pursued by the federal government. The main problem is the regional inequalities in levels of development between the relatively isolated north and the more economically developed south and between the less developed West Cameroon and the more advanced southern section of East Cameroon. Continued stability would seem to depend largely upon the determination with which the government attempts to bridge the gap between the better developed and the poorer regions.

BIBLIOGRAPHY. DAVID E. GARDINER, *Cameroon: United Nations Challenge to French Policy* (1963); and V.T. LEVINE, *The Cameroons, from Mandate to Independence* (1964), are the best accounts of the political history of the country up to the time of reunification. Gardiner's study is limited to the former French trusteeship territory of Cameroon; LeVine traces developments in both the former French and British trusteeship territories. The realities of reunification have been examined in W.R. JOHNSON, *The Cameroon Federation: Political Integration in a Fragmentary Society* (1970); NEVILLE RUBIN, *Cameroon: An African Federation* (1971); and V.T. LEVINE, *The Cameroon Federal Republic* (1971). The MINISTRY OF INFORMATION AND TOURISM OF THE CAMEROON FEDERAL REPUBLIC, *Cameroon* (1970), is an official account of the achievements of the country since independence. K. EWUSI, *West African Economies: Some Basic Economic Problems* (1971), is an introductory study of the economies of selected West African countries, including Cameroon. H.S. BEDERMAN, *The Cameroons Development Corporation: Partner in National Growth* (1968), examines this quasi-governmental organization that manages the plantations developed in the Victoria division of West Cameroon. W.A. HANCE, *The Geography of Modern Africa*, ch. 4 (1964), gives a brief account of the geography of the country and has useful maps.

(G.Be.)

Camões, Luís de

The poet Luís Vaz de Camões was one of the few Portuguese writers to overcome the language barrier and the modern confusion of Portugal with Spain and to have a widespread influence on Western literature. He had a permanent and unparalleled impact on Portuguese literature and Brazilian literature alike not only with his epic based on Portuguese encounters in the East, *Os Lusíadas* (*The Lusiads*) but also with his posthumously published lyric poetry.

Camões, portrait miniature painted in Goa, 1581. In a private collection.

Known biographical information. What little information there is about the man in a strict biographical sense falls into three categories: statements by his first biographers in the 17th century, a few documents unearthed in the 19th century and scant subsequent research, and very abstract allusions (some chronologically uncertain) to his own life in his works. From these rather fragile sources much irrelevant scholarship and romantic guesswork has sprung during the last four centuries.

One of Camões' countrymen and first biographers, Manuel Severim de Faria, provides a glimpse of Camões (some more-or-less authentic portraits also exist): "not too tall, strong of body and large of face, with something of a frown in his expression, long nose curved at the middle, a missing eye lost in his youth, and hair so blond as to have reddish tones; not too graceful in his manners but easygoing and witty in his conversation." Despite the lack of authentic knowledge of him, everything hints that Camões was in tune with his station in the social life of the time and with his age of imperial adventures. He never married or fathered any known children, in spite of the display of love pangs, burning eroticism, and even adolescent boasting in his works. Though the works reveal little about his life, they reveal much about his ideas, feelings, hopes, and despairs, however disguised they may be under the Petrarchan modes and tones of his time and however contrived by the dangerously repressive epoch in which he lived. Few great poets in world literature, in fact, have written so much or so obsessively about themselves as he did, even in his epic poem. Yet criticism of his work, particularly *Os Lusíadas*, has been biassed by Portuguese political pride and religious prejudice, which, stressing the national character of the epic, have served to reduce the range of Camões' thought.

Heritage and youth

It is supposed that Camões was born in Lisbon around 1524 or 1525, when Portuguese expansion in the East was at its peak. Recent research, expanding on statements of his first biographers and collating them with aristocratic genealogies, has shown him to be a member of the impoverished old aristocracy but well related to the grandees of Portugal and Spain. Vasco Pérez de Camoens, his great-great-grandfather, was a Galician gentleman who had migrated to Portugal for political reasons in the last quarter of the 14th century. A tradition that Camões studied at the University of Coimbra or that he followed any regular studies, for that matter, remains unproved, though few other European poets of that time achieved such a vast range of both classical and modern culture and philosophy. He is supposed to have been, in his youth, in territories held by the Portuguese in Morocco, but it is uncertain whether he had been exiled or whether he was there because it was simply the place for a young Portuguese aristocrat to start a military career and to qualify for royal favours. It is also assumed that his youth in Lisbon was less than subdued. King John III pardoned him in 1553, when he was under arrest for taking part in a street brawl in which a royal officer was assaulted. The pardon hints that Camões would go to India in the King's service, but none of his wanderings for nearly 17 years there has been documented. Certainly, he was there, judging from references in his works that reveal an intimate knowledge of the area's social conditions. He surely did not make his fortune there, since he complains many times about his bad luck or the injustices he met with. After his return to Portugal, in July 1572, he was granted a royal pension on account of his services in India and not merely to reward him for having published *The Lusiads*, as is commonly said. While in the East, he took part in one or two military naval expeditions and, as he alludes to it in his epic, underwent shipwreck in the Mekong Delta. His years in the East can be assumed to have been like those of thousands of Portuguese scattered at the time from Africa to Japan, whose survival and fortunes were, as he says, always hanging from Divine Providence's very thin thread. Diogo do Couto, a 16th-century historian of the Portuguese East, who never included Camões among the nobles he listed so carefully for every skirmish, did note, however, that he found "that great poet and old friend of mine" stranded in Mozambique and helped to pay his trip back to Lisbon, where Camões must have arrived in 1570. *The Lusiads* appeared in 1572, certainly in the first months of that year. It has been much debated whether his pension was enough for a decent retirement, but it seems that it was reasonable—though, according to his first biographers, Camões always spent whenever he had money in his purse. His mother, a widow, survived him and had the pension renewed in her name. Documents related to payments due and to the renewal are known, and through them the date of his death has been accepted as June 10, 1580. It is not certain that he died of anything more than premature old age brought on by illnesses and hardships; to connect his death, as some have done, with the loss of Portuguese independence in 1580, when the Portuguese and Castilian crowns became united for 60 years, is a patriotic and romantic assumption, like another legend of his faithful Javanese slave begging alms for him. Commentators have pointed out the injustice of his not having been appointed as one of the poets who, in 1578, went to North Africa to sing the praises of King Sebastian (whom Camões had promised, when dedicating the epic to him, another poem for his Moroccan deeds). But perhaps he was too ill by the time and, hence, spared the terrible fate of all the others who were caught in the military disaster in which most of the high aristocracy and the King himself lost their lives. His tombstone in the Lisbon church of Santa Ana disappeared in the great earthquake of 1755. The bones that were transferred with national and international pomp and circumstance to a glorious Gothic-revivalistic tomb at the monastery of Jerónimos in Lisbon (ordered by King Manuel I on the spot from which Vasco da Gama had sailed in 1497 on the voyage to India that Camões took as the axis of the narrative in his epic), on the occasion (1880) of the third centennial of Camões death, are certainly not his—an ironic commentary on a famous line in which Camões said that he had left his life scattered in shreds throughout the world.

Years in the East

Non-epic works. During his lifetime he did not publish any of his non-epic works, except for three complimentary pieces: an ode commending Garcia de Orta's *Colóquios dos Simples e Drogas e Coisas Medicinais da India* (1563) and a sonnet and an epistle in terza rima (an Italian form of iambic verse) offering Pero de Magalhães Gandavo's *História da Província de Santa Cruz a que vulgarmente chamamos Brazil* (1576) to a hero of the East whose family appears to have been connected with Camões in several ways. Two plays attributed to him were printed in Lisbon in 1587. His unpublished poems were first collected in 1595, though some of them had already been appearing in Spanish translations, two different versions of *The Lusiads* having been published in Spain in the year of his death. A new, expanded edition of the *Rimas*

Attribution of inauthentic works

appeared in 1598. These two first editions already included many poems not by Camões, and this process of attributing inauthentic works to him continued until the end of the 19th century, with almost any poet of some distinction in Portugal and Spain after the beginning of the 16th century to the middle of the next contributing unwittingly to the growing body. A second part of the *Rimas* (1616), one more play in 1645, a third part (1668), and an immense edition of the lyric poetry (1685–88) with commentaries by Manuel de Faria e Sousa, were milestones of that pious folly that saved for later readers many pieces but reached its peak at the end of the last century (when manuscript songbooks of the 16th and 17th centuries were ransacked for the purpose) in an edition prepared by Viscount Juromenha and others prepared by a literary historian, Teófilo Braga. In the meantime, all the apocrypha were used to substantiate increasingly erudite "biographies." In the 1880s Wilhelm Storck (a German translator of the "complete" works) and the Luso-German scholar Carolina Michaelis de Vasconcellos were the first to react critically against such procedures, but it was not before the 1930s that "complete" editions started to take notice of these criticisms of authorship, never methodically furthered except in the most recent years, not to speak of the readings of many lines never corrected according to first printings or the extant manuscripts. No autograph has been discovered nor did Camões' editors ever claim to have seen anything except copies such as those in extant 16th- and 17th-century manuscript collections, not all of them duly studied and published. It must be said, however, that hundreds of the most impressive or graceful poems, like the three plays and some of the attributed prose letters, have not been subject to any suggestion of doubtful authorship, even if the authenticity of many pieces is substantiated only by the fact that no other attribution appeared since they were first printed in Camões' name. It is notable that recent research has substantially reduced his already thin Spanish output. *The Lusiads* do not offer the same textual problems, in spite of two different "first editions," one of which is thought to be "authentic" and the other pirated—the reality being that there are several small differences among copies of either one, which point only to the books having been produced much like the Shakespearian First Folio, with sheets being newly revised and composed according to demand.

Evaluation by contemporaries

Most of Camões' illustrious contemporaries have been taken to task by biographers and critics for not mentioning him in their works. But, when Camões left for the East, he was only one young poet among many. Being absent from Portugal for 17 years, he was cut off from a literary life that, by the patterns of the time, depended upon very closely knit circles in Europe. And, when he returned, many of his great contemporaries had died, and the prevailing mood of the Counter-Reformation was no longer in tune with the daring of Camões paganism, which his first biographers and critics are clearly intent on defending. Nevertheless, there are references to him by some of his contemporaries (certainly dating from his last years in Lisbon), who held him in the highest regard (notably André Falcão de Resende, Gaspar Frutuoso, and Pero de Magalhães Gandavo), and even the censor's license for his epic shows a leniency that points to strong opinion in his favour. The Italian poet Torquato Tasso's sonnet to him and the admiring quotations by the Spanish writer Baltasar Gracián in his *Agudeza y arte de ingenio* (1648) are examples of his fame, which was also noted by the Spanish dramatist Lope de Vega and poets Góngora, Milton, Goethe, the German Romantics, Byron, the Brownings, and others among his admirers, the last, but not the least, being Herman Melville.

The Lusiads. Most of this celebrity rested for long much more on the epic than on the lyric poetry, which, very much admired through the centuries, has only in the last 40 years begun to be understood as the high intellectual achievement that his own times and the 17th century had seen it to be. At the end of the 19th century, Camões was thought to be the Renaissance poet and man *par excellence*, after having been, for the European Romantics, a paragon of the adventurous genius who lives unhappy in love and dies a miser ignored by society. Today, the notion of the Renaissance proper has shrunk, and it no longer covers with its legendary luminous skies the anguish of Camões, heir to the European High Renaissance, but rather the great Mannerist frustrated by a time "out of joint" (as he called it, anticipating Shakespeare). Neither does it cover his conception of the soul of man divided among opposites and always striving to overcome them in a synthesis as much made of oppositions as the previous one nor his hunger for an ultimate freedom that only an aesthetic order could give him—either in the creation of elegant and deeply moving lyric poems or in the majestic sweep of *The Lusiads*, where Jewish and Christian traditions, paganism and Christianity, Platonism and empiricism, intellectualism and sensuality, realism and fantasy, history and literary imagination, patriotism and a universal humanist love, sad frustrations and dazzling epiphanies, the Earth with its varied civilizations and the eternal primeval sea are harmoniously fused to celebrate, much more than da Gama's voyage or Portuguese history, the impossible dream. The ten cantos of *The Lusiads* are in *octava rima* (1,102 stanzas). After an introduction, an invocation, and a dedication to King Sebastian, the action, on both the historical and the mythological levels, begins. Da Gama's ships are seen already in the Indian Ocean, sailing up the coast of East Africa, and the Olympian gods gather to discuss the fate of the expedition (favoured by Venus and attacked by Bacchus). The conclusion is a huge epiphany in which history, the voyage, and mythology are fused together. Throughout *The Lusiads*, Camões develops splendid episodes that enliven the narrative: the murder of Inês de Castro, who becomes a symbol of death for love; an impressive condemnation of the adventurous spirit by an old man when the ships are leaving Portugal; Adamastor, the giant of Classical parentage who, as the Cape of Good Hope, tells da Gama he will lie in wait to destroy the fleets coming back from India. Realistic descriptions of sensual encounters, battles, and storms and other natural phenomena transcend the thrust of Classical allusions that permeate the work, all of which make for the high-flown yet fluent style of the poem. *The Lusiads*, as well as the enormous output of lyric poems, the three plays, and the prose letters reveal an astonishing command of language and variety of styles and provide a fascinating portrait of an extraordinary man and poet. Camões felt doomed by fate to take European history to its meeting with the East (*The Lusiads* is much less an imitation of Virgil than a poem intended to be for the West what the *Aeneid* was for Rome) and to embody the ultimate loss of all human aspirations.

Camões' conception of the soul of man

Camões' thought

Camões was a Neoplatonist who believed in God as a supreme idea of love and in the pagan gods as the figures for spiritual communication with that silent idea; he was a man obsessed with erotic tensions that evoke, with no sense of sin, all the dark sides of sex; a moralist craving for honesty and human dignity, who would excuse an absolutely free license in sensual love; a Christian who saw religion as tolerance and charity and considered man to be predestined in this world but to be saved in the next or, at least, wandering in a sort of pagan paradise under the sight of God; an esoteric mind intent on building his epic on cabalistic and Christian–Pythagorean calculations and his lyric poems on despair redeemed by the contemplation of the very process of the human intelligence consuming itself in endless dialectics. He was also a proud man who could not offer his great poem to anyone but King Sebastian himself and, never bowing to anyone in his works, put many of his family or friendly connections in his epic as heroes of Portuguese history and of the Eastern Empire (himself and his shipwreck being the last exploit in the list). An adventurer in the pattern of an aristocratic society with no outlet but that Eastern Empire, a spirit so intellectualized that his spiritual yearnings refuse mystical solutions, and an overpowering personality composed of lucid reason and passionate emotions, inflexibly analyzing himself in the capturing of his own *temps perdu*, always capable of ironically looking

into his own musings, and quite aware that no one would follow (in the decadent and strife-torn times that he was measuring by his chivalric ideals) his proposal of the conquest of the East as Paradise regained, Camões was all these.

MAJOR WORKS

POETRY: *Os Lusíadas* (1572; *The Lusiads*, trans. by Leonard Bacon, 1950; *The Lusiads in Sir Richard Fanshawe's Translation*, ed. and introd. by G. Bullough, 1963); *Rhythmas de Luís de Camões* (1595; *Camoens: The Lyricks*, trans. by Richard Burton, 2 vol., 1884).

PLAYS: *Anfitriões* and *Filodemo*, in *Primeira Parte dos Autos e Comedias Portuguesas Feitas por A. Prestes e por L. de C.* (1587); *El-Rei Seleuco* (first appeared in the 1644–45 ed. of Camões' works).

BIBLIOGRAPHY

Editions: The editions of Camões' works in Portuguese and other languages are in the hundreds, and his bibliography is immense. The best modern edition of *The Lusiads* is still by AUGUSTO EPIFANIO DA SILVA DIAS, *Os Lusiadas*, 2 vol. (1916–18). The best contemporary edition of the lyric works, if unsatisfactory, is ALVARO J. DA COSTA PIMPAO, *Rimas*, new ed. (1961). The first complete English translation of *The Lusiads* was by RICHARD FANSHAWE (1655), and the best modern one is by LEONARD BACON (1950). The lyric poems were often translated in the 19th century, from LORD STRANGFORD'S (1803) down to RICHARD BURTON'S (1884), the famous traveller and translator.

Biographies: A monumental modern biography is by FRIEDRICH WILHELM STORCK, *Luis' de Camoens leben* (1890; annotated Portuguese trans., *Vida e Obras de Luis de Camões*, by CAROLINA MICHAELIS DE VASCONCELLOS, 1897), in which everybody and everything in Portuguese life during the 16th century gets into the picture except Camões himself. The most prudent, shorter life (in English), though outdated, remains AUBREY F. BELL, *Luis de Camões* (1923); and the best debunking of all the biographical myths is ANTONIO SALGADO JR.'s introduction to his too eclectic edition of the *Obra Completa* (1963).

Critical studies: The numerous articles by CAROLINA MICHAELIS are still scattered in learned reviews from the 1880s to the 1920s, and with some of her other works remain the starting point of any Camonian scholarship. Other studies include: THEOPHILO BRAGA, *Camões: Época e Vida* (1907) and *Camões, a Obra Lírica e Épica* (1911); F. REBELO GONCALVES, *Dissertações Camonianas* (1937); HERNANI A. CIDADE, *Luís de Camões*, 2nd ed., 3 vol. (1952–56); CECIL M. BOWRA, *From Virgil to Milton* (1945); JORGE DE SENA, *A Poesia de Camões* (1951), *Uma Canção de Camões* (1966), *Os Sonetos de Camões* (1969), and *A Estrutura de "Os Lusíadas"* (1970); ANTONIO J. SARAIVA, *Luís de Camões* (1959); A. BARTLETT GIAMATTI, *The Earthly Paradise and the Renaissance Epic* (1966); and ROGER BISMUT, *La Lyrique de Camões* (1971).

(J.deS.)

Campanulales

Campanulales is the formal name of the bellflower order of flowering plants. The order derives its name from the diminutive of the Latin *campana*, which means "little bell," referring to the bell-shaped flowers of a number of species of the family Campanulaceae. The order includes seven families with a total of about 2,000 species. The largest and most attractive family, Campanulaceae, with about 900 species belonging to 40 genera, has received the most attention from botanists; yet the classification of the family, as well as of the order, is not quite satisfactory and many problems remain to be solved.

Scientific and horticultural importance

The main reasons for interest in the group are purely scientific, but much attention has also been paid to the great domestic importance of the large number of ornamentals in the group. Some genera—notably the best known one, *Campanula*—are very interesting with respect to problems of evolution; others show highly remarkable morphological characteristics and anatomical peculiarities. The geographical distribution of a number of groups (notably the genus *Donatia*) shows that a close affinity exists between the floras of New Zealand and South America.

GENERAL FEATURES

Most species are herbs, but shrubs and even trees up to nine metres high (*e.g.*, *Clermontia*) are also present in the order. *Campanula vidalii*, which originates from the Azores, has the growth habit of a shrubby *Sempervivum*; *i.e.*, it is adapted to dry environments and has fleshy leaves. Some giant *Lobelia* species, which may reach a height of six metres (20 feet), are characteristic of African alpine vegetation zones. They occur at altitudes between 6,500 and 14,100 feet.

The distribution of the family Campanulaceae is worldwide, but most species occur in mountainous areas of temperate regions in both hemispheres. The family Lobeliaceae inhabits tropical regions and many temperate areas of the Southern Hemisphere, with some species also distributed in temperate regions of the Northern Hemisphere. The representatives of the other families are mainly Australian. Some members of the Lobeliaceae that inhabit islands (notably the Hawaiian Islands) have a treelike or shrubby habit.

The order Campanulales is generally of slight economic importance, although one exception is the large number of ornamentals in the family Campanulaceae, particularly the genera *Wahlenbergia*, *Campanula*, and *Phyteuma*, and in the family Lobeliaceae, the genera *Lobelia* and *Downingia*.

Some members of the order, however, have a certain importance as medicinal plants. The roots of *Platycodon grandiflorum* (family Campanulaceae), known as kikyo-root, are used in China as expectorants and anti-asthmatics. The blue-flowering wild specimens, especially, contain large quantities of the active substance, platycodin (= kikyo saponin). *Scaevola koenigii* (family Goodeniaceae), a characteristic plant of the tropical beach jungle, furnishes a kind of rice paper, made by squeezing its pith flat. The fruits of *Canarina campanula*, *Clermontia macrocarpa*, and *Centropogon surinamensis* (all belonging to the family Campanulaceae) are locally eaten. *Lobelia inflata*, native to the eastern and central regions of the United States and Canada, is of medicinal importance. The plants are usually short-lived annuals with an inflated capsule. They were used by the North American Indians as an emetic and because of their tobacco-like taste were called Indian tobacco. Also known under the name Herba Lobeliae, these plants are characterized by an unusually high content of closely related alkaloids, which are derivatives of piperidine, especially of n-methyl-piperidine. The alkaloids are thought to occur only in the milky juice of the laticiferous vessels, a system of latex-bearing ducts in the stems and leaves. The best known and most active of them is lobeline, a substance characterized by its stimulating effect on respiration. Because of this property, lobeline is used to enhance the activity of certain centres of the central nervous system in cases of asphyxia in newborn infants. The action of lobeline also resembles that of nicotine to a certain extent, and based on the observation that both of these alkaloids have an additional effect, lobeline is used as a remedy against nicotine addiction. Other species of *Lobelia* also contain lobeline, especially representatives of the subgenus *Tupa*, such as *Lobelia tupa* and *Lobelia excelsa*, which occur in South America.

Medical uses of lobeline

NATURAL HISTORY

The flower. The natural history of the flowers of the family Campanulaceae is of interest, and the flowers of *Campanula* are the best known in this respect. They are provided with a nectar-secreting disk situated at the base of the style, the narrow upper part of the ovary. In most cases the disk is covered by the triangular bases of the male sex organs, or stamens, which fit closely together. The size of the flowers, their frequently blue colour, and their drooping position indicate that they are well adapted to the visit of bees. There are, however, many other insect visitors such as flies, butterflies, and moths. In nearly all species of Campanulaceae the flowers are proterandrous, which means that within an individual flower the mature pollen is always presented for dissemination before the female pollen-receiving structures, or stigmas, of the flower are receptive. The pollen is usually shed in the bud, in which the long, pollen-filled anthers form a column around the end of the style,

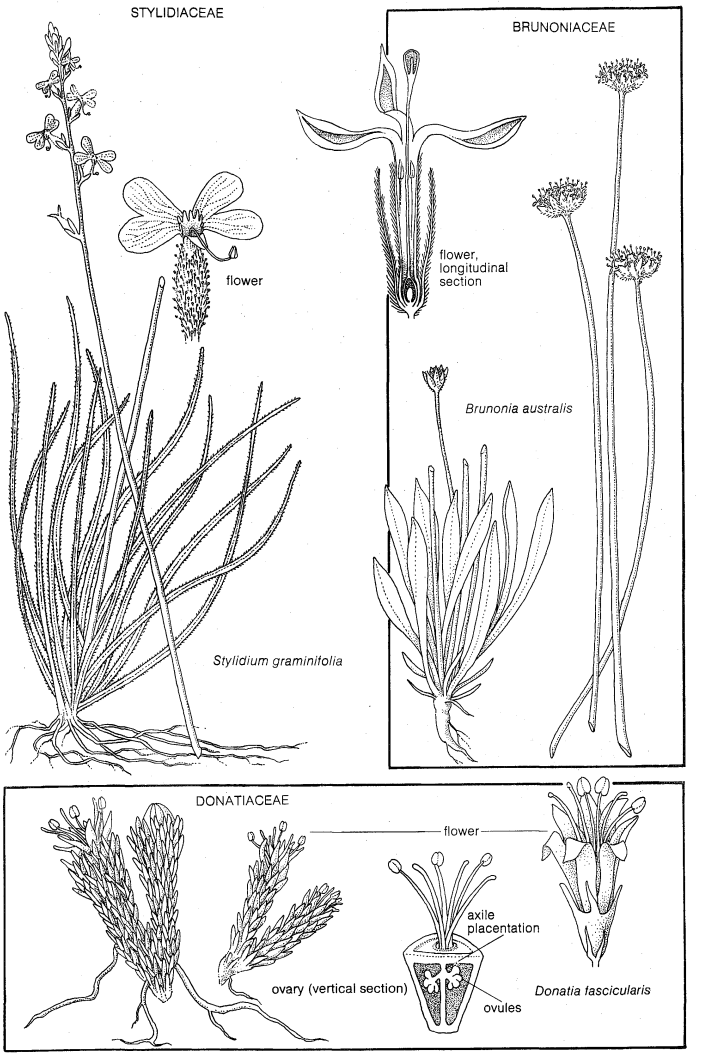

Figure 1: Representative vegetative and floral structures of three of the smaller families of the order Campanulales.
Drawing by M. Moran after Baillon from *Die naturlichen Pflanzenfamilien*

whose stigmas are closed up against one another. The style is densely covered with short, stiff hairs, which hold the pollen after it has been shed by the anthers. After the opening of the flower bud the anthers wither quickly and for some time the style acts as a pollen presenter to insects. Insects trying to get at the nectar contact the hairs of the style and carry away the pollen. The pollen-collecting hairs, each of which is formed from a single epidermal (surface) cell, invaginate at this stage into the style, which may possibly be caused by extraction of water. This implies that after some hours the style becomes denuded.

After a time the stigmas separate and expand. Usually this expansion occurs the second day after the opening of the flower, which signifies that the mature female stage has begun. The stigmas are receptive to pollen by the time they are spread. On the third or fourth day the stigmas curl back so far that they touch any pollen that may still be present on the style, thus effecting self-pollination. Self-pollination, followed by self-fertilization, does not seem to be very common, although there are self-fertile species, such as *Campanula colorata* and *C. canescens* of the Himalaya region, whose flowers may be cleistogamous—*i.e.*, they remain closed at maturity—and some populations of *Campanula rotundifolia*. In most species, however, if the pollen of a certain flower is transferred to its own receptive stigmas or those of another flower of the same plant, no fertilization is effected. The final conclusion is that, in most *Campanula* species, a considerable amount of outbreeding occurs.

In the genus *Phyteuma* the flowers are grouped together in dense heads. The tips of the long and very thin petals cohere and form a kind of tube within which the anthers are held. The style pushes up through this tube and drives the pollen gradually out at the end where it is exposed to insects. In the final stage the style itself emerges, the stigmas expand, and the petals separate and fall back.

Pollen presentation mechanism in *Phyteuma*

In the family Lobeliaceae the pollen-collecting hairs often take more or less the form of a ring, concentrated on the stigmatic branches. The anther walls and the closed stigmatic branches together form a structure that encloses the pollen. Agitation of the hairs on the top of the anthers causes the pollen grains to shake out. It is assumed that the pollen grains are no longer viable after the opening of the stigmatic branches. Some plants of the family Lobeliaceae are visited by birds for nectar. This is especially true for some species of *Clermontia*. So well adapted are both bird and flower that the birds' bills (*e.g.*, those of the Hawaiian honeycreepers) match the curvature of the tubular flowers.

The flowers of the family Goodeniaceae are also proterandrous. In *Leschenaultia formosa*, for example, before flower opening, the pollen is shed into a membranous cup surrounding the stigma. Insects rub against this cup and carry the pollen away with them, thus pollinating other flowers. The same process is also carried out in other species.

The flowers of the family Stylidiaceae are also proterandrous. The characteristic connection of the anthers and style again indicates that insect pollination is necessary. In all cases in this family, however, the pollen is presented to visiting insects while still contained within the anther lobes.

Ecology. The order Campanulales is distributed throughout the world and its members grow in very different habitats, ranging in elevation from sea level to 13,000 feet. For that reason it is impossible to give a survey of all the ecological diversity encountered in the order, but there are some general trends.

In the largest genus of the order, *Campanula*, the species show a great ecological diversity. Many, such as *C. cochleariifolia* and *C. medium*, grow on calcareous (lime-containing) soils, but some avoid such soils (viz., *C. excisa*). Some species prefer woods (*C. latifolia* and *C. trachelium*), others light woodland in more or less shady places (*C. persicifolia*), but the majority prefer sunny habitats. The Portuguese species *Campanula loeflingii* prefers sandy soils, whereas the North American *Campanula aparinoides* occurs in marshes, swamps, and bogs. Sometimes closely related species are very different in their ecological requirements: the alpine species pair *C. elatinoides* and *C. elatines* present a clear example; the first prefers dolomite, the second avoids it and all other calcareous soils as well. Most *Campanula* species, however, prefer calcareous soils.

It is remarkable that some species, such as *Campanula xylocarpa* of Czechoslovakia, which grows in rocky habitats on limestone and dolomite, never colonizes humus soils in natural habitats, even though plants growing on vertical rock walls often disseminate seeds there.

In the other large genus, *Lobelia*, many species grow in moist habitats such as ditches, marshes, and along streams. Some North American species, however, can tolerate much drier conditions; populations of *L. spicata* or *L. syphilitica*, for example, are sometimes found in open fields but mainly in areas where the soil is saturated with water.

Giant lobelias

Another very interesting group of the genus *Lobelia* consists of the giant forms, which are a characteristic element of the lower alpine and alpine mountainous regions of East Africa. They are characterized by tall, unbranched stems, numerous narrow leaves, terminal racemose (spikelike) flower clusters, large, blue or purple flowers, and large anthers, the three upper ones at the top, the two others bearded. Species of the same group occur not only in East Africa, but also in the West Indies, Brazil, and India. Five series of giant *Lobelia* species are distinguishable, conforming largely to altitudinal and precipitation zones.

In spite of the treelike habit of the giant lobelias, the

stems remain largely herbaceous (nonwoody). All giant species flower only once during their life-span. The group is thought to have evolved from some annual forest species with a branched habit and lax inflorescence (flower cluster). *Lobelia longisepala* and other species of its group are regarded as a relic of the ancestral forest forms from which the giant lobelias evolved. The dense inflorescence, the unbranched stem, and the thick, hairy leaves characteristic of the alpine species are explained as adaptations to the higher altitude and severe climate.

Seed dispersal. Knowledge concerning the seed dispersal of the various species of the order is rather limited. Usually the seeds are small. The fruits are generally capsules (only exceptionally drupes—stony-seeded fruits) and they open in various ways. The seeds are not adapted to wind dissemination and usually fall to the ground close to the mother plant. In some species, however, such as *Campanula rotundifolia*, the wind may carry the seeds up to crevices, cliffs, or walls, in which they lodge.

Wind-assisted release of seeds

In the genus *Campanula* the species have capsules that open laterally. The capsules have apical pores or basal valves. Species with apical capsule pores have erect fruits, whereas those with basal valves have pendent fruits. This implies that, from the biological point of view, the pores and valves are always situated at the top position. For that reason, the seeds are shed only if the stems are moved by the wind, thus enabling the seeds to spread over some distance. In the group including the genera *Campanula*, *Legousia*, *Phyteuma*, and *Adenophora* the fruits open laterally, whereas in the genera *Wahlenbergia*, *Jasione*, and *Lightfootia* the capsules open apically. In these genera the seeds are not adapted to wind dissemination, but the wind promotes the spread to a limited extent by moving the capsule-bearing stems.

The fruits of *Scaevola* (family Goodeniaceae) are stony-pitted fruits (drupes), their outer layers being more or less fleshy, the stone very hard, woody, or sometimes corky. Dispersal in most species is effected by fruit-eating birds. In the seashore species *Scaevola sericea* and *Scaevola plumieri*, however, the fruits float very well in seawater and retain their viability for some time. This means of dispersal accounts for their large area of distribution.

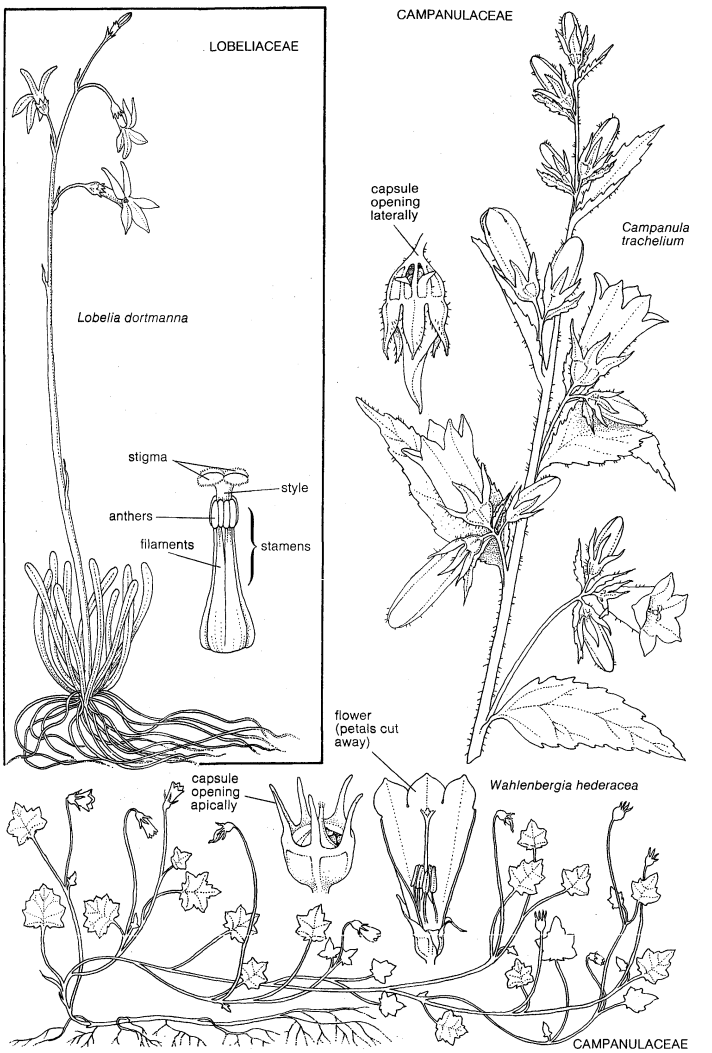

Figure 2: Representative plants and floral structures of the two largest families in the order Campanulales.
Drawing by M. Moran

FORM AND FUNCTION

Distinguishing anatomical characteristics. One of the most distinguishing anatomical characteristics of the families Campanulaceae and Lobeliaceae is the presence of laticiferous vessels, a system of ducts carrying latex and characterized by cross walls at intervals along their length. They are distributed throughout the plants. In the stems they are usually localized in the outermost portion of the vascular system (the phloem region). These laticiferous vessels are absent in the other families of the order. The family Goodeniaceae differs from the Campanulaceae and Lobeliaceae in the more complex anatomy of the cambial tissue—the region of cell division contributing to stem thickness. In the family Stylidiaceae growth in stem thickness is a result of the formation of new vascular bundles outside the primary cylinder, a situation also observed in some woody representatives of the flowering plant class Monocotyledoneae (*e.g.*, *Dracaena*, *Yucca*). The cell walls of some species of the Campanulaceae and Goodeniaceae are silicified.

With the exception of some shrubby species, most Campanulales plants are perennial herbs, surviving from year to year, but there are also some short-lived annual species that overwinter in seed form. Both of these types usually have a repeatedly branched stem. The biennial species, those that fruit and die in the second year, often have fleshy roots and a basal rosette of leaves. The leaves are always simple and lack stipules, which are small appendages at the base of the leafstalk. The leaves of the different species vary considerably in shape, from grasslike in the family Stylidiaceae to rather large in some *Campanula* species. Sometimes the basal leaves are different in form and size from those of the upper stem.

The flowers of the family Campanulaceae are sometimes solitary in the upper angles between leafstalks and the plant stem (the leaf axils) but are usually arranged in inflorescences of various shapes, including spikes, heads, and racemes, which all have a top flower. In the family Lobeliaceae the axis of the inflorescence may be branched, but the top flower is usually lacking. In both the Campanulaceae and Lobeliaceae solitary terminal flowers are sometimes found, which are thought to represent the last flower of a reduced inflorescence. The other families exhibit a variety of inflorescences ranging from solitary in Goodeniaceae to dense heads in Brunoniaceae, closely resembling those of the family Asteraceae (order Asterales).

Floral characteristics

The flowers are radially symmetrical or bilaterally symmetrical and consist in principle of five sepals, five petals, five stamens, and five carpels (ovary segments), the number of locules, or ovary chambers, varying. The number of sepals, however, may vary from three in some species of *Wahlenbergia*, to six in *Canarina*, or eight in *Michauxia*.

The corolla, or collection of petals, is bell-shaped in many species (*e.g.*, *Campanula*, *Adenophora*, *Platycodon*, and others) but in others it is deeply divided (*e.g.*, in *Phyteuma*, *Jasione*, and *Michauxia*). In *Phyteuma* the corolla lobes are united at the top but in the genus *Lobelia* the corolla is split down one side. The family Lobeliaceae has irregular corollas, but Campanulaceae has regular ones. The lips of the corolla are reversed (resupinate) in *Lobelia* by a twisting of the flower stalk. In the family Goodeniaceae the corolla is bilaterally symmetrical and usually two-lipped, whereas the irregular corolla of the family Stylidiaceae usually consists of four petals of

equal size, the fifth being much smaller (*Stylidium*, *Levenhookia*). The number of stamens is usually five in the families Campanulaceae (except for some species of *Wahlenbergia*, which have three), Lobeliaceae (in which three stamens are usually longer than the other two), Goodeniaceae, Sphenocleaceae, and Brunoniaceae. The stamens number only two or three in the family Donatiaceae, however, and finally only two in the Stylidiaceae, in which they are united with the style to form a structure known as the gynostemium. The anthers are free or variously closely associated, but not fused, as in *Symphyandra* and *Jasione* (Campanulaceae) or even joined as in the Lobeliaceae. The bases of the stamen filaments are triangular and form a dome-shaped chamber over the nectar-producing disk that surrounds the ovary. This disk may be very large and glandlike in the genus *Adenophora* (Campanulaceae).

The fruits of the family Campanulaceae are usually capsules that open by apical or lateral pores or valves. In some genera (*e.g. Canarina*) the fruits are berries.

The same is the case in the family Lobeliaceae, in which the majority of the species have capsular fruits but some (*Pratia*, *Clermontia*) have drupaceous ones. The number of locules, or ovary chambers, varies, sometimes within the same genus (*e.g.*, three or five in *Campanula*), but is very often three in the family Campanulaceae. In the other families of the order the number of locules is often less than three. In all families there are usually numerous ovules in the ovaries. As a rule the ovules are inverted, or anatropous, and have only one integument. The endosperm formation, the development of starchy nutrient tissue for the embryo, is cellular in all families.

Some chemical characteristics. In view of the fact that the families of the Campanulales order are of little economic importance, only a few chemical investigations have been carried out. There is some information with regard to saponins, polyphenols, latex, and carbohydrates. In many species of the Campanulaceae the occurrence of inulin has been demonstrated and this substance has been used as a test for kidney function. Fructan A and fructan B are quite common, not only in the perennial species but also in the annual ones. These compounds are also found in the family Asteraceae (order Asterales), but usually they are lacking in the annual species. The accumulation of the fructans tends to corroborate the opinion that the families Campanulaceae and Asteraceae are related. Polyfructans are also present in the Lobeliaceae, but at least some members of this family differ from the Campanulaceae in the presence of alkaloids. This is an argument for separating the Campanulaceae and Lobeliaceae, which are usually united in one family.

EVOLUTION

Some authorities are of the opinion that the orders Campanulales and Polemoniales are probably derived from the Gentianales. Others, however, derive the Campanulales from the order Rubiales. Chemical and morphological characters suggest that the order Campanulales is a rather natural one, but fossil evidence is lacking, and most opinions remain speculative.

Absence of fossil evidence

On the basis of cytological, taxonomical, geographical, and geological data some authorities believe that the principle genera of the family Goodeniaceae arose in the early Tertiary Period (about 60,000,000 years ago) in Australia, the present-day species originating subsequent to the formation of distinct eastern and western floristic regions in Australia.

In the family Campanulaceae the genus *Campanula* has been most extensively studied with regard to the number of chromosomes per cell, and such studies strongly suggest that the evolution of its species ran along two separate and independent lines. A few isolated species differ in form and structure rather markedly from the other species of the genus, and it is thought by some authorities that some of them should be transferred to a number of smaller, usually monotypic (single-species) genera. *Campanula vidalli* of the Azores, for example, should be placed in the genus *Azorina*, and the North American species *Campanula americana* should be placed in the monotypic genus *Campanulastrum*. At present the genus *Campanula* contains other groups of species that are only remotely related to each other, and some of its species and species groups are undoubtedly closely related to the genera *Adenophora* and *Symphyandra*. In the eastern Mediterranean Basin and in the Caucasus the genus *Campanula* shows the greatest morphological and cytological diversity. It is thought that the genus probably originated in that area.

Studies of the North American species of the family Lobeliaceae indicate that there are four lines of speciation in that group. The earliest populations of *Lobelia* in eastern North America are thought to have been established in Tertiary times or before.

CLASSIFICATION

Annotated classification. The following classification is a recent one of wide acceptance. The order Campanulales, as defined here, includes as a family the plant group sometimes treated as a separate order in other classification systems (order Goodeniales). The family Campanulaceae is to be understood here as including the sometimes separately recognized family Pentaphragmataceae, which is a group of about 30 species found in Southeast Asia and Malaysia.

ORDER CAMPANULALES

Plants usually herbaceous, often with septate laticiferous vessels. Leaves simple and without stipules. Inflorescence racemose with a tendency to form loose heads. Flowers actinomorphic (with radial symmetry) or zygomorphic (with bilateral symmetry), generally 5-merous (with parts numbering 5 each) with a fused corolla, usually with 5 stamens in a single whorl and 2-lobed anthers variously coherent to fused. Ovary 1- to 5-locular (chambered) with many (sometimes 1) ovules in each locule. Ovules with 1 integument. Endosperm cellular. Seven families, 105 genera, about 2,000 species. Distribution worldwide.

Family Stylidiaceae

Herbs or undershrubs without milky sap. Flowers irregular. Corolla with unequal lobes, one of which is smaller or larger than the others and called a labellum. Stamens 2, united with the stigma, together forming the gynostemium. Ovary bilocular with many ovules. Fruits usually capsular. Five genera and 125 species distributed in Australia and New Zealand.

Family Goodeniaceae

Perennial herbs or small shrubs without milky sap. Flowers irregular in capitate or paniculate inflorescences. Stamens 5 and free. Ovary with 2 carpels, 2- or 2-locular with many ovules. Stigma surrounded by an indusium-like cup. Fruits drupes, capsules, or nuts. Twelve genera and 300 species distributed mainly in Australia, but also in New Zealand, South Africa, Antarctic South America, and Asia.

Family Brunoniaceae

Small perennial herbs with spoon-shaped leaves in basal rosettes. Flowers in capitate inflorescences. Corolla with 5 lobes. Stamens 5, inserted near the corolla base with 5 fused anthers. Ovary superior, 1-locular, and with 1 ovule. Style with a cupulate indusium at the base of the stigma. Fruit an indehiscent capsule. One genus and species (*Brunonia australis*) distributed in Australia and Tasmania.

Family Donatiaceae

Small herbaceous plants with linear leathery-textured leaves, densely arranged in a spiral. Flowers without stalks and solitary at the end of the stem. Calyx with 5 to 7 lobes, corolla with 5 to 10 petals. Stamens 2 or 3, free, inserted within a disk. Filaments free. Ovary inferior, with 2 or 3 locules and 2 or 3 styles, which are usually free. Stigma globose. Ovules many, placed on hanging placentas. Fruits indehiscent. One genus (*Donatia*) with two species distributed in New Zealand, Tasmania, and subantarctic South America.

Family Lobeliaceae

Annual, biennial, or perennial herbs, rarely entirely woody, often with milky juice. Flowers zygomorphic. Corolla 1- or 2-lipped of fused petals. Stamens 5, filaments free, anthers cohering into a tube around the style. Ovary inferior with 2 or 3 locules and many axile ovules. Fruits capsular or drupaceous, with many seeds. Twenty-five genera and 750 species with worldwide distribution.

Family Sphenocleaceae

Herbaceous plants with radially symmetrical flowers arranged in dense spikes that have a thick axis. Corolla lobes overlapping in the bud. Stamens inserted at the base of the corolla. Style very short without hair collectors. Ovary 2-locu-

lar with thick placentas hanging from the wall separating the locules. Capsule opening by a transverse slit. One genus and one species (*Sphenoclea zeylanica*) distributed in tropical regions.

Family Campanulaceae

Herbs, rarely small shrubs to small trees, usually with watery or milky sap. Leaves usually alternate, simple, and without stipules. Inflorescences are spikes, racemes, or capitula. Flowers regular, bisexual, usually showy. Sepals usually 5. Corolla of fused petals; tubular or bell-shaped and usually 5-merous. Stamens as many as corolla lobes, alternate with them, and inserted near the base of the corolla or on a disk. Anthers not united nor cohering. Ovary generally inferior, 2- to 10-locular with axile placentas. Ovules usually very numerous. Fruit a capsule or rarely a drupe. Forty genera with 900 species. Distribution worldwide.

Critical appraisal. Three orders, Campanulales, Calycerales, and Asterales, are often considered as separate but closely related plant groups. Many authorities, however, regard the last two orders as families (Calyceraceae and Asteraceae or Compositae), which they placed in the order Campanulales. The family Calyceraceae, however, differs from the Campanulaceae in having an undivided style and a one-locular ovary that contains only one pendulous ovule. There are some arguments in favour of placing the Asteraceae in the Campanulales order, however. The accumulation of fructans and the occurrence of derivatives of caffeic acid and triterpene saponins is a characteristic shared by both the families Campanulaceae and Asteraceae. Also, the position of the anthers, which are frequently in contact with each other in the Campanulaceae, and the usually inferior ovary, are characteristics shared by both groups. Finally the septate laticiferous vessels of the subfamily Cichorioideae of the Asteraceae and of the family Campanulaceae point in the direction of a close affinity.

Disagreements over placement of the Lobeliaceae

The position of the family Lobeliaceae is a much disputed one. The dominant genus of the Campanulaceae, *Campanula*, and the dominant one of the Lobeliaceae, *Lobelia*, differ considerably from each other, but there are so many intermediate genera that the differences become less significant as these intermediates are considered. On the other hand, as far as is known, the family Campanulaceae seems to lack alkaloids and has a much more pronounced accumulation of caffeic acid.

The family Sphenocleaceae is often united with the Campanulaceae, but it is sometimes regarded as related to the Phytolaccaceae. The pollen grains resemble those of the family Lobeliaceae, however. Combined cytological and phytochemical studies must be undertaken in order to obtain a better insight with regard to the position of this family. The same holds true for the family Donatiaceae, which is placed by some authorities near the family Saxifragaceae. This, however, does not seem justified in view of the presence of inulin, a character that the Donatiaceae share with the other families of Campanulales. Moreover, the pollen grains of the Donatiaceae are slightly similar to those of *Cyphia* (Lobeliaceae), whereas the grains in the family Saxifragaceae (*Brexia* and other genera) are different. The only resemblance between the families Donatiaceae and Stylidiaceae is the habit of *Donatia* and the species of the genus *Phyllachne*, but otherwise these families seem to be very different. There is much agreement in the various systems with regard to the inclusion of both Stylidiaceae and Goodeniaceae in the order. Only the family Brunoniaceae is treated in different ways by various authors. Earlier botanists accepted the genus *Brunonia* as constituting a separate subfamily of the Goodeniaceae. It has been raised to family rank by most recent workers, both on the basis of morphological characters and on palynological (pollen) and cytological (chromosome count) evidence.

BIBLIOGRAPHY. H.C. CROOK, *Campanulas: Their Cultivation and Classification* (1951), a nicely illustrated book, containing descriptions of many *Campanula* species (especially of horticultural value); S. SCHONLAND, "Campanulales," in A. ENGLER and K. PRANTL (eds.), *Die Natürlichen Pflanzenfamilien IV*, 5:40–84 (1894), a classic in German, now in some respects outdated but still the most complete survey available to all the genera of the order; R.C. CAROLIN, "The Structures Involved in the Presentation of Pollen to Visiting Insects in the Order Campanulales," *Proc. Linn. Soc. N.S.W.*, 85:197–207 (1960), a very clearly illustrated treatment of the pollen presentation in the bellflower order; E.A. BRUCE, "The Giant Lobelias of East Africa," *Kew Bull.*, pp. 61–88 (1934), a treatment of the remarkable giant lobelias; L. HAUMAN, "Les 'Lobelia' géants des montagnes du Congo Belge," *Mem. Inst. R. Colon. Belge, Sect. Sci. Nat. Méd. 8°*, 2:3–50 (1933), a description, with photographs, of a number of giant lobelias occurring in the Congo; R. MCVAUGH, "Studies in the Taxonomy and Distribution of the Eastern North American Species of *Lobelia*," *Rhodora*, 38:241–298, 305–329, 346–362 (1936), a historical survey of the literature of North American *Lobelia* species with keys and descriptions to 22 species, distribution maps, and a literature survey; W.M. BOWDEN, "Phylogenetic Relationships of Twenty-One Species of *Lobelia L.*, Section Lobelia," *Bull. Torrey Bot. Club*, 86:94–108 (1959), a very nice example of modern research in a group of the genus *Lobelia;* T.W.J. GADELLA, "Some Notes on the Delimitation of Genera in the Campanulaceae," *Proc. K. Ned. Akad. Wet.*, sect. C, 69:502–521 (1966), a survey of the literature pertaining to difficulties in classifying the species in the family Campanulaceae.

Camping

Camping—living for a night, a weekend, a week, or more in the open with no more than a tent, motor caravan, or trailer caravan for shelter—has expanded enormously as a recreational pastime, especially since 1950, and in the 1970s counted some 60,000,000 enthusiasts, half of them in North America and most of the rest in Europe. The important difference between camping and the life of gypsies or nomads is that campers choose to camp for recreation and more and more as an escape from the pressures of a time-dominated urbanized life.

What was once regarded as a rough, back-to-nature pastime for hardy, slightly eccentric open-air lovers is now the standard holiday for vast numbers of ordinary families whose main common factor, apart from their enjoyment of camping, is the ownership of an automobile, which makes them mobile and is able to carry the modern, reasonably light but rather bulky equipment that ensures a remarkable degree of comfort in camp. The development of this fastest growing recreation in the world is, in fact, directly related to the development and growing private ownership of means of transport that are also capable of carrying camping equipment.

History of recreational camping. People camped from the earliest times, under tents of skins and leaves. The woven cloth tents of Old Testament biblical days were remarkably similar to the tents still used by the nomads of the desert areas of the Middle East. But the evolution of leisure camping is barely a hundred years old, and the great explosion of family camping began as recently as 1955.

The first *Campers Handbook*

The founder of modern camping for pleasure was Thomas Hiram Holding (1844–1930), who wrote the first book on the subject, the *Campers Handbook*, published in 1908. It is clear that, in part, his urge to camp derived from his youthful experiences in North America, for in the book he wrote:

> In the prerailway days of 1853, I crossed the prairies of America. My first experience of camping was above the wooden slope of the plateau behind Kaircock in the Mississippi when a lad of nine.
>
> There, 300 of us camped in tents and waggons . . . but it was only the beginning of a prolongation for, of course, it was a case of camping entirely across the prairies over a distance of 1,200 miles and it lasted from the Spring until August.
>
> The plains were then uninhabited save for a few wandering tribes of Indians, probably a million antelopes and possibly half a million of wary buffaloes. Soon afterwards, the gallant herd was swept away before the "railway hunger". . . .
>
> Spring and a wild and dangerous wagon trip and camp, back from Salt Lake City, up and through the Rockies, back to the States, closed the experience in that early stage. . . .
>
> In the Spring of 1877 I became the proud possessor of a canoe. The canoe led to camping and camping led to a canoe cruise in the Highlands of Scotland. . . . An account of this was published under the title, *The Cruise of the Osprey*. . . .

In 1878 another canoe and camp with several enthusiastic canoeists came off in Scotland, a full account of which, from my pen, was published by Waterlow and Co., *Watery Wanderings 'mid Western Lochs.*

Holding continued to camp throughout Great Britain and Ireland and wrote that in 1897 he was able to put into practice a long-felt urge to cycle-camp, something which only became possible when the old high-wheeled "ordinary" or penny-farthing bicycle, which, says Holding, "was practically an impossible machine with which to camp," was replaced by the safety bicycle, broadly similar to those in use today.

His trip through Ireland provided copy for another book, *Cycle and Camp* (1898), and in it he wrote of the advantages of camping:

> Who can question them? only those who have never tried it. All the horrors which outsiders fear and with which they threaten us, we neither meet nor find. In fact, they don't exist. Camping is nearly always delightful for a holiday at least, and if well managed, is pleasant and healthy, as well as cheap for a more protracted period.
>
> But it is not a lazy life—far from it.
>
> The question comes in here, perhaps, as to which kind of holiday is more beneficial—a loafing or an active one? He who would spend a holiday in sheer laziness should take luxurious lodgings or quarter himself at a fine hotel, and, next to the strain and exertion of eating, do literally nothing.
>
> To most men, however, young or middle-aged, who lead active lives and who are gifted with average energy, something less dormant is surely an advantage.
>
> The camp gives this—exercise without fatigue; fresh air night and day and sufficient excitement to create interest, and remind a man that he lives.
>
> That sounds well! Yes, and has been proved to answer when physic failed and tonics had lost their charm.

When Holding wrote of men, he should have included women, for there were women in his party in 1897. Campers use different words to describe their pastime today, but they would generally agree with the sentiments he expressed so long ago.

Camping clubs and the international federation

Holding founded the first camping club in the world, the Association of Cycle Campers, at a camping meet at Wantage, Berkshire, in August 1901. By 1907 it had merged with a number of other clubs to form the Camping Club of Great Britain and Ireland, of which it is still a flourishing part. The Camping Club published the first issue of its magazine in November 1907 and has done so continuously since that date (since 1957 under the editorship of Alan Ryalls).

Capt. Robert Falcon Scott, the famous Antarctic explorer, became the first president of the Camping Club, in 1909. On his last tragic trip to the Antarctic in 1912, he took with him a Camping Club pennon, which is presumed to have been with him when he died.

After World War I, Sir Robert Baden-Powell (founder of the Boy Scout movement) became president, and the Camping Club of Great Britain and Ireland fostered the establishment of camping organizations in a number of west European countries. In 1932, again on British initiative, steps were taken to establish the Fédération Internationale de Camping et de Caravanning (FICC), and the first international camp and congress were held in the Royal Paddocks at Hampton Court, near London, in 1933. Apart from World War II, this International Rally, as it is now called, has been held every year since, usually in different countries of western Europe, although it was held in Israel in 1964 and in Hungary in 1966, when 7,000 west European campers attended; at Woburn Abbey, England, in 1969, attendance exceeded 13,650.

Membership of the FICC includes organizations from all west European countries; from Czechoslovakia, Hungary, and Poland in eastern Europe; and from Turkey and Israel as well as from the United States, Canada, Morocco, Gibraltar, Brazil, and Japan. The FICC, through its affiliated organizations, issues an International Camping Carnet, which is a certificate that the holder is insured against third-party risks while camping anywhere in the world except mainland China. The carnet serves as an identity card, and it requires the holder to camp in a responsible way. In western Europe, except for Great Britain, it is usually presented on arrival at a campsite and may be retained until departure or until all fees are paid. On many sites a discount on fees is given to carnet holders. Lack of a carnet may lead to refusal of permission to camp, especially in the national forests of France. With a carnet, one may camp on any of the thousands of sites throughout western Europe. From 1970 onward, the FICC, in association with the Alliance International de Turismo (ATT) and the Fédération Internationale de l'Automobile (FIA), has issued a carnet common to all three organizations.

Camping and clubs in North America

In North America individuals were camping in the wilderness for recreational purposes from the early 1870s, travelling on foot, on horseback, or by canoe; but since they were, by definition, individualists, there is no record of camping organizations in the early days. A number of organizations, such as the Adirondack Mountain Club, the Appalachian Mountain Club, and the Sierra Club, have catered, in part, for campers for a very long time, but the organization of campers on a large scale is a post-World War II development.

Even now, the majority of organized campers belong to local clubs, but there are two large-scale national organizations, the National Campers and Hikers Association and the North American Family Campers Association. The NCHA has groups or chapters all over North America, and its biggest activity is its annual "campvention," a meeting of campers from all over North America, which has attracted as many as 30,000 people. The NCHA (founded 1954) affiliated to the FICC in 1960 and has been represented at every FICC International Rally and Congress since that date. The North American Family Campers Association is of more recent origin (founded 1957). It has over 50 chapters throughout the United States. The Camping Club of Canada, a national organization that affiliated to the FICC in 1953, took on a new title, the Canadian Federation of Camping and Caravanning, in 1965.

Individual camping is widely practiced in Australia and New Zealand, but organized camping facilities are relatively few. In South Africa there are several hundred campsites and a number of camping clubs. The most recently formed camping clubs are in Sri Lanka (formerly Ceylon) and the West Indies, further indications of the wide spread of recreational camping.

Organized camping. Organized camping started in the United States in 1861 with a boys camp run by Frederick William Gunn and his wife at Milford-on-the-Sound for students of the Gunnery School for Boys in Washington, D.C. Its success was immediate; it was repeated for 18 successive years and other similar camps began to develop. A private camp was established in 1876 by Joseph Trimble Rothrock and a church camp was started at Gardners Island, R.I., in 1880 by the Rev. George W. Hinckley. Camp Dudley, a YMCA camp still in existence, was founded in 1885 by Summer F. Dudley. The first girls camp was established by Luther Halsey Gulick and his wife on the Thames River, in Connecticut, in 1888.

Youth camps

The Boy Scouts of America was formed in 1910 by Ernest Thompson Seton, who had studied the movement in Great Britain and incorporated camping as a major part of the program, as emphasized by Gen. (later Sir) Robert Baden-Powell. Similar emphasis on camping was to be found in the Girl Guides (founded in Great Britain in 1910), the Campfire Girls (U.S., 1910), and the Girl Scouts (U.S., 1912; patterned after the Girl Guides). Most other organizations concerned with young people, such as the YMCA, the YWCA, the YMHA, the Boys Clubs of America, the Girls Clubs of America, and Four-H Clubs, also undertook camp development as an important part of their activity. Charles W. Eliot, former president of Harvard University, in 1912 stated that "the organized summer camp is the most significant contribution to education that America has given to the world," indicative of the importance attached to it at that time.

Camp directors had begun meeting to exchange experience and discuss common problems at the turn of the 20th century. The Camp Directors' Association was

formed in 1910 and developed into the American Camping Association, a professional body that was broadened to include all those associated with organized camps. Camping standards are laid down and leadership certification is provided by it. Colleges and universities provide camping courses, and many camp leaders are recruited from these sources and from the teaching profession.

Organized camps cover a very wide variety of activities whether run by churches, youth agencies, labour organizations, municipal authorities, or privately. Many are based on a nucleus of permanent buildings but with tented sleeping accommodations. All provide supervised camping with a purpose, which may be purely educational or concerned with such activities as nature study, mountaineering, canoeing. Many teach such subjects as woodcraft and campcraft. All are designed to help those participating to develop a greater self-sufficiency while learning to live harmoniously with others of a different background.

Extent of organized camping

In Canada, the Boy Scouts and Girl Guide organizations, together with the YMCA and many churches, have long operated similar camps. So have a number of community groups and several of the provinces.

The fact that the Boy Scout movement was founded in Great Britain ensured the development of organized camping early in the 20th century, and the practice was also developed by the Girl Guides, the Boys Brigade, YMCA, YWCA, Girl Scouts, and a multiplicity of youth organizations, churches, and individual schools. The Order of Woodcraft Chivalry has organized camps for almost 50 years, and the Woodcraft Folk, an offshoot of the co-operative movement, for almost 40 years.

One of the most interesting organizations is the Forest School Camps, founded by teachers before World War II, which continue to provide a wide variety of camping vacations for children from seven to 18, all of which are designed to teach a very high degree of self-assurance, self-sufficiency, and responsibility.

The Camping Club Youth is a body of many thousands of young members of the Camping Club of Great Britain and Ireland, all of whom learn, under leaders, how to camp competently and independently. They are tested and awarded a test pennon and certificate on attaining the necessary proficiency. The CCY certificate is accepted as denoting that the owner is competent to camp without supervision in his own or other countries. It is a necessary prerequisite to camping at the FICC's International Youth Camp, held at Easter-time each year in a different European country.

Vacation camps for young people are arranged in every western European country, and they are operated on a very considerable scale in all the countries of eastern Europe, including the U.S.S.R. So are camps of the Young Pioneers, the Eastern equivalent of the Boy Scouts and Girl Guides of the West. Youth camps, which are usually arranged by schools with some state subsidy, are operated in Australia, New Zealand, South Africa, India, and Japan and are to be found in such unlikely places as Iceland and Singapore. In Israel many kibbutzim organize international work camps each year, which attract young campers from the United States and Mexico as well as from most western European countries.

Individual or family camping. It is in the area of individual or family camping that the most phenomenal growth has taken place, particularly since 1955. More and more people from all walks of life and every income group have been drawn to it as a leisure-time and vacation activity. Some find their pleasure in camping for its own sake, but far more use camping as an adjunct to travel—in their own country or abroad—to their hobbies—which vary from sightseeing and meeting different peoples and experiencing the cultures of other nations and continents—to fishing, photography, hunting, and backwooding. This growth in individual or family camping was made possible by the rapid expansion of private ownership of automobiles but also because camping manufacturers developed more and more sophisticated equipment, designed to make camping easy, comfortable, and convenient. The key development in Europe was the frame tent, a canvas cottage-like edifice of considerable proportions (up to 20 feet [six metres] square) over a strong jointed tubular metal frame, often spring-linked so that it is easy to erect. The outer tent reaches almost to the ground and is pegged by many metal pegs attached to rubber guys that are self-adjusting. There are large picture windows, often partly mosquito netted and with protective awnings. Within, there is usually a kitchen area, sometimes flameproofed; a living and eating area; and up to three separate bedrooms or inner tents, each with sewn-in groundsheet, mosquito-netted ventilation, and zippered door. There are many shapes, sizes, and colour schemes, but all are functional as well as attractive. Surprisingy, this most sophisticated of tents has never really appealed to American campers, who continue to use heavier, external-framed tents on a considerable scale.

Improved equipment and the growth of camping

Most American campers use gasoline stoves for cooking, in addition to charcoal grills and, of course, wood fires in suitable places. In Europe, almost all camp cooking is on bottled butane or propane gas stoves, which usually have two or three burners and a grill. The bottled gas is available in all European countries, the Middle East, and North Africa.

It should be noted that kerosene (called paraffin in England) is not readily available in all European countries and that alcohol (called methylated spirit in England) is very expensive in some, so that gas stoves are the most suitable. Unleaded gas, required for some stoves, is often difficult to obtain, however.

Iceboxes are used extensively both in North America and in Europe. Ice is more readily obtainable in the U.S. and Canada but is gradually becoming more readily obtainable on European campsites. On some campsites in Israel, it is possible to rent a refrigerated locker.

Polythene food and water containers, plastic dishes, nonstick cooking utensils, folding tables and chairs, air beds (air mattresses) or folding camp beds or foam mattresses, lightweight sleeping bags, and a multitude of gadgets all combine to make camping easy.

Wheel campers

Because they eliminate much of the work of family camping, the number of wheel campers has grown enormously since 1960. Some 100,000 trailer caravans are sold each year in Europe to touring caravanners and about 50,000 trailer tents, trailers that open up into a large, comfortable fully furnished tent on wheels. There is growing interest in motor caravans, small but practical caravans built into the bodies of motor vans.

In North America, wheel camping is much more sophisticated and on a much larger scale, because of the larger automobiles and cheaper gas, the bigger state and interstate highways, and the vast distances to be covered. Travel trailers are usually much longer and wider than European trailer caravans. So are the motor homes, which can be up to 35 feet (10.7 metres) long, compared with an average 15 feet (4.6 metres) in Europe. They are equipped with the main services usually found in a house—electricity, running hot and cold water, flush toilets, and waste water disposal. To cater for them, more and more North American campsites are equipped with "complete hook-ups," or connections to all the main services. Such comprehensive facilities cannot be found anywhere in Europe.

In addition to motor homes, North American campers are offered a wide variety of truck campers, or turtle backs, caravan bodies in many shapes and sizes, made to rest on a truck body but capable of being lifted off and left freestanding on a campsite while the truck is used for travelling. There is, too, a considerable variety of camping trailers or tent trailers, similar in principle to their European counterparts but again much larger and more elaborately equipped.

Surprisingly, there is a steadily growing interest in really lightweight compact tents and equipment that can be carried in pack or rucksack by those in Europe and America who choose to camp off the beaten track where

they must be self-sufficient and able to carry all they need on their backs.

Pedestrian campers hitchhike their way through most countries of Europe, and cycle campers, scooter, and motorcycle campers are still to be found, but it is the large numbers of family campers that have led to the great development of campsites on a commercial basis.

Campsites for family campers

In Europe, particularly in France and in Scotland, there are many municipal campsites, usually transit sites adequately equipped but not suitable for long holidays. Spain is the most popular camping country, and there are vast campsites along the Costa Brava and the Mediterranean coast south of Barcelona, some capable of accommodating 15,000 campers and providing restaurants, nightclubs, supermarkets, hairdressers, doctors, and every type of amusement. The coastal areas of France and Italy have many good campsites, usually overcrowded in midsummer. Switzerland, Austria, Germany, and the Italian lakes all attract increasing numbers of campers every year.

So does Great Britain, which actually has more campsites than any other country in Europe, many of them with good facilities and many of which are farm sites offering minimal facilities, but peace and quiet and often a superb view.

Denmark, Norway, Sweden, Finland, The Netherlands, Belgium, and Luxembourg all continue to expand their camping facilities. So does Portugal, which has a limited number of quite good sites.

It is possible to camp in the tiny countries of Andorra in the Pyrenees, Liechtenstein on the Austrian-Swiss borders, or San Marino on the Adriatic.

Iceland has a few campsites but many dramatic camping possibilities, and Greece has a growing number of sites of varying standards.

In eastern Europe, Yugoslavia has many sites, those along the Adriatic coast being overcrowded in summer. Hungary has many good campsites, a number on the Danube River and most around the shores of Lake Balaton. Bulgaria has a countrywide network of sites, many along the Black Sea coast. Czechoslovakia, too, has many sites. Romania, Poland, and East Germany have some sites, and the Soviet Union makes a number of its sites available to foreign campers, who must travel along predetermined routes, however.

There is an excellent range of motor camps in Turkey, with a variety of facilities. Israel caters well for campers. Morocco has a number of sites, often with indifferent sanitation, and there are some camping facilities in all of the North African countries.

Campsites in the United States and Canada number many thousands, a considerable proportion of them in state and national parks, forests, and national recreation areas. Generally these sites have minimal facilities—drinking water, some sanitation, and rubbish disposal—but the beauty of their surroundings often compensates for the lack of facilities. The private campsites offer a very wide variety of standards, and although a growing number provide complete hookups, there are few North American sites to compare with the vast supersites in the popular holiday areas of Europe.

An interesting development is the franchise of a network of sites. The largest in this field organizes some 500 sites throughout the United States and Canada and guarantees a high standard of sanitation, free hot showers, laundry facilities, ice, grocery shop, lounge, and many other amenities, including free reservation at the next campsite required. Camping on a dude ranch in the Rockies is an interesting experience for most campers, American or European.

One of the most interesting developments of the 1970s has been intercontinental air camping, package holidays by air offered in North America, Europe, and South Africa, the package including a camping vehicle and equipment in the country chosen for the holiday.

BIBLIOGRAPHY. Examples of general manuals on camping in Europe include: A. RYALLS, *Enjoy Camping Holidays* (1963), *Camping with BP: How and Where to Camp in Great Britain and Ireland* (1968); F. TINGEY, *Tackle Caravanning This Way*, new ed. (1969); N. HUNT, *Camping* (1969); and P.F. WILLIAMS, *Camping and Hill Trekking* (1969). General manuals on camping in North America include: P. CARDWELL, *America's Camping Book* (1969); C. ORMOND, *Complete Book of Outdoor Lore* (1964); J.J. and J.L. KELLY, *Camping—Where and How* (1964); W.K. MERRILL, *All About Camping*, 2nd ed. (1964); L. MIRACLE and M.H. DECKER, *Complete Book of Camping* (1962); and F. STURGES (ed.), *The Camping Manual* (1967).

In addition to books, handbooks, and manuals on camp cooking, selection and use of equipment, first aid, and similar subjects, there are many specialized works on the techniques and various types of camping. Examples of these are: J.R. JOHNSON, *Advanced Camping Techniques* (1967); L.A. ANDERSON, *A Guide to Canoe Camping* (1969); R.C. RETHMEL, *Backpacking*, rev. ed. (1968); and C. RUTSTRUM, *Paradise Below Zero* (1968), a guide to Arctic or winter camping.

The publications most widely used by campers, however, are the guides that list the locations, facilities, fees, and other pertinent information about specific campsites. The Camping Club of Great Britain and Ireland publishes a list of over 2,500 campsites in the British Isles; its publication, *International Camping*, lists recommended sites throughout Europe, North Africa, and the Middle East. *Camping Führer*, published by the German Camping Club, and *Europa Camping* list sites in the same areas; the Michelin guide, *Camping et caravanning en France*, covers French sites in detail. Most of the national camping clubs list sites in their own countries, and the national tourist offices also provide site lists and maps showing their locations.

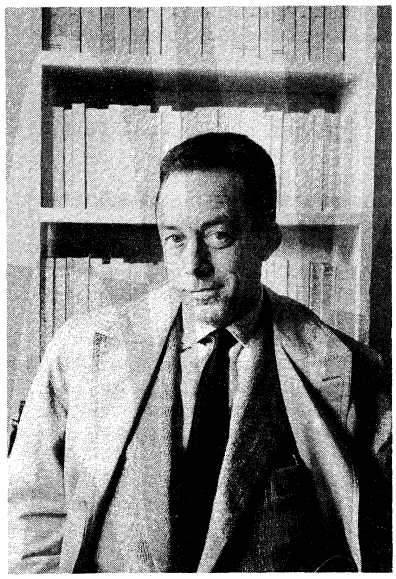
The most extensive campsite guides for North America are *Camping and Trailering*, eastern and western editions, published by the American Automobile Association; *Woodall's Trailering Parks and Campgrounds;* and *Rand McNally's Guidebook to Campgrounds*. Each state and province publishes its own list of sites, as do many of the parks, forests, and recreation areas.

(A.R.)

Camus, Albert

As novelist and playwright, moralist and political theorist, Albert Camus after World War II became the spokesman of his own generation and the mentor of the next, not only in France but in Europe and eventually the world. His writings, which addressed themselves mainly to the isolation of man in an alien universe, the estrangement of the individual from himself, the problem of evil, and the pressing finality of death, accurately reflected the alienation and disillusionment of the postwar intellectual. Though he understood the nihilism of many of his contemporaries, Camus also argued the necessity of defending such values as truth, moderation, and justice. In his last works, before his death at the age of 46, he sketched the outlines of a liberal humanism that rejected the dogmatic aspects of both Christianity and Marxism.

Henri Cartier-Bresson—Magnum



Camus, photograph by Henri Cartier-Bresson.

Early years. Camus was born at Mondovi in Algeria on Nov. 7, 1913. Less than a year later, his father, an impoverished worker of Alsatian origin, was killed in World War I during the first battle of the Marne. His mother, of Spanish descent, worked as a charwoman to support her family. Camus and his elder brother Lucien moved with their mother to a working class district of Algiers where all three lived, together with the maternal grandmother and a paralyzed uncle, in a two-room apartment. Camus's first published collection of essays, *L'Envers et l'endroit* (1937), describes the physical setting of these early years and includes portraits of his mother, grandmother, and uncle. A second collection of essays, *Noces* (1938), contains intensely lyrical meditations on the Algerian countryside and presents natural beauty as a form of wealth that even the very poor can enjoy. Both collections contrast the fragile mortality of human beings with the enduring nature of the physical world.

Education

In 1918 Camus entered primary school and was fortunate enough to be taught by an outstanding teacher, Louis Germain, who helped him to win a scholarship to the Algiers *lycée* (high school) in 1923 (it was typical of Camus's sense of loyalty that 34 years later his speech accepting the Nobel Prize for Literature was dedicated to Germain). A period of intellectual awakening followed, accompanied by great enthusiasm for sport, especially football, swimming, and boxing. In 1930, however, the first of several severe attacks of tuberculosis put an end to his sporting career and interrupted his studies. Camus had to leave the unhealthy apartment that had been his home for 15 years, and after a short period spent with an uncle—a butcher by trade and a Voltairean by conviction—Camus decided to live on his own, supporting himself by a variety of jobs while registered as a philosophy student at the University of Algiers.

At the university, Camus was particularly influenced by one of his teachers, Jean Grenier, who helped him to develop his literary and philosophical ideas and shared his enthusiasm for football. He obtained a *diplôme d'études supérieures* in 1936 for a thesis on the relationship between Greek and Christian thought in the philosophical writings of Plotinus and St. Augustine. His candidature for the *agrégation* (a qualification that would have enabled him to take up a university career) was cut short by another attack of tuberculosis. To regain his health he went to a resort in the French Alps—his first visit to Europe—and eventually returned to Algiers via Florence, Pisa, and Genoa.

Camus's literary career. Throughout the 1930s, Camus broadened his interests. He read the French classics as well as the writers of the day—among them Gide, Montherlant, Malraux—and was a prominent figure among the young left-wing intellectuals of Algiers. For a short period in 1934–35 he was also a member of the Algerian Communist Party. In addition, he wrote, produced, adapted, and acted for the Théâtre du Travail (Workers' Theatre), later named the Théâtre de l'Équipe, which aimed to bring outstanding plays to working class audiences. He maintained a deep love of the theatre until his death. Ironically, his plays are the least admired part of his literary output, although *Le Malentendu* (*Cross Purpose*) and *Caligula*, first produced in 1944 and 1945, respectively, remain landmarks in the so-called theatre of the absurd. Two of his most enduring contributions to the theatre may well turn out to be his stage adaptations of Faulkner's *Requiem for a Nun* (*Requiem pour une nonne;* 1956) and Dostoyevsky's *Possessed* (*Les Possédés;* 1959).

Plays

In the two years before the outbreak of World War II, Camus served his apprenticeship as a journalist with *Alger-Républicain*. He fulfilled a variety of functions, including those of leader-writer, subeditor, political reporter, and book reviewer. He reviewed some of Sartre's early literary work and wrote an important series of articles analyzing social conditions among the Muslims of the Kabylie region. These articles, reprinted in abridged form in *Actuelles III* (1958), drew attention (15 years in advance) to many of the injustices that led to the outbreak of the Algerian War in 1954. Camus took his stand on humanitarian rather than politico-ideological grounds and continued to see a future role for France in Algeria while not ignoring colonialist injustices.

He enjoyed most influence as a journalist during the final years of the occupation of France and the immediate post-Liberation period. As editor of the Parisian daily *Combat*, the successor of a Resistance news sheet run largely by Camus, he maintained an independent left-wing position based on the ideals of justice and truth and the belief that all political action must have a solid moral basis. Later, the old-style expediency of both Left and Right brought increasing disillusion, and in 1947 he severed his connection with *Combat*.

Novels and philosophical works

By now Camus had become a leading literary figure. *L'Étranger* (American *The Stranger;* British *The Outsider*), a brilliant first novel begun before the war and published in 1942, is a study of 20th-century alienation with a portrait of an "outsider" condemned to death less for shooting an Arab than for the fact that he never says more than he genuinely feels and refuses to conform to society's demands. The same year saw the publication of an influential philosophical essay, *Le Mythe de Sisyphe* (*The Myth of Sisyphus*), in which Camus, with considerable sympathy, analyzed contemporary nihilism and a sense of the "absurd." He was already seeking a way of overcoming nihilism, and his second novel, *La Peste* (*The Plague;* 1947), is a richly symbolical account of the fight against an epidemic in Oran by characters whose importance lies less in the (doubtful) success with which they oppose the epidemic than in their determined assertion of human dignity and fraternity. Camus had now moved from his first main concept of the absurd to his other major idea of moral and metaphysical "rebellion." He contrasted this latter ideal with politico-historical revolution in a second long essay, *L'Homme révolté* (*The Rebel;* 1951), which provoked bitter antagonism among Marxist critics and such near-Marxist theoreticians as Jean-Paul Sartre. His other major literary works are a technically brilliant novel, *La Chute* (*The Fall;* 1956), and a collection of short stories, *L'Exil et le royaume* (*Exile and the Kingdom;* 1957). *La Chute* reveals a preoccupation with Christian symbolism and contains an ironical and witty exposure of the more complacent forms of secular humanist morality.

In 1957, at the early age of 44, Camus received the Nobel Prize for Literature. With characteristic modesty he declared that had he been a member of the awarding committee his vote would certainly have gone to André Malraux. Less than three years later, on Jan. 4, 1960, he was killed in an automobile accident.

MAJOR WORKS

NOVELS AND SHORT STORIES: *L'Étranger* (1942; English title, *The Outsider*, 1946; U.S. title, *The Stranger*, 1946); *La Peste* (1947; *The Plague*, 1948); *La Chute* (1956; *The Fall*, trans. by Justin O'Brien, 1957). Short stories collected in *L'Exil et le royaume* (1957; *Exile and the Kingdom*, trans. by J. O'Brien, 1958).

PLAYS: *Le Malentendu* (performed 1944; pub. with *Caligula*, performed 1945, in *Le Malentendu, suivi de Caligula*, 1944; *Caligula and Cross Purpose*, 1947); *L'État de siège*, (performed and pub. in 1948; *State of Siege*, trans. in *Caligula and Three Other Plays*, 1958); *Les Justes* (performed 1949, pub. 1950; *The Just Assassins*, trans. in *Caligula and Three Other Plays*, 1958). (ADAPTATIONS): *La Dévotion à la Croix* (1953, from Calderón); *Un Cas intéressant* (1955, from Dino Buzatti); *Requiem pour une nonne*, (1956, from William Faulkner); *Les Possédés* (1959, from Dostoyevsky).

ESSAYS, JOURNALISM, AND NOTEBOOKS (COLLECTIONS): *L'Envers et l'endroit* (1937), recollections of childhood and travel sketches; *Noces* (1938), four Algerian essays; *Actuelles*, 3 vol. (1950, 1953, 1958), editorials and articles written for *Combat*, 1944–45; *L'Été* (1954). (OTHER ESSAYS): *Le Mythe de Sisyphe, essai sur l'absurde* (1942, enl. and rev. ed. reprinted 1945; *The Myth of Sisyphus*, trans. by J. O'Brien, 1955), a long philosophical essay; *Lettres à un ami allemand* (1945; trans. by J. O'Brien in *Resistance, Rebellion, and Death*, 1960), four linked essays, with preface, in the form of letters written during the Occupation, the first and second previously published in the "underground" reviews, *Le Revue Libre* (1943) and *Cahiers de la Libération* (1944); *Le Minotaure ou la halte d'Oran* (written 1939, pub. 1950), poetic and satirical description of Oran, the background for *La Peste;*

L'Homme révolté (1951; *The Rebel*, 1953), a long metaphysical, historical, and political essay. (NOTEBOOKS PUBLISHED POSTHUMOUSLY): *Carnets: Mai 1935–Février 1942* (1962; *Notebooks, 1935–42*, trans. by Philip Thody, 1963); *Carnets: Janvier 1942–Mars 1951* (1964; *Notebooks, 1942–51*, trans. by P. Thody, 1965); *Carnets: Avril 1951–Décembre 1959* (1966; *Notebooks, 1951–59*, trans. by P. Thody, 1969).

BIBLIOGRAPHY. The major bibliographies of works by and about Camus are: R.F. ROEMING (ed. and comp.), *Camus: A Bibliography* (1968); and B.T. FITCH and P.C. HOY, *Essai de bibliographie des études en langue française consacrées à Albert Camus (1937–1967)* (1969). His main works are published with much excellent editorial material by ROGER QUILLIOT in two "Bibliothèque de la Pléiade" volumes: *Théâtre, récits, nouvelles* (1962), and *Essais* (1965). Collections of the author's writings in English translation are *The Collected Fiction of Albert Camus* (1961); *Resistance, Rebellion and Death* (1961); and *Lyrical and Critical* (1967). Camus's main English translators are Stuart Gilbert, Justin O'Brien, and Philip Thody.

Good general studies in French include: ROGER QUILLIOT, *La Mer et les prisons*, rev. ed. (1970); J.C. BRISVILLE, *Camus* (1959); and MORVAN LEBESQUE, *Albert Camus par lui-même* (1963). Camus has been fortunate in his English and American critics. Major studies of his personality and writings are GERMAINE BREE, *Camus* (1959); JOHN CRUICKSHANK, *Albert Camus and the Literature of Revolt* (1959); and PHILIP THODY, *Albert Camus, 1913–1960* (1961). Two more recent studies offering clear expository summaries of his ideas are ADELE KING, *Camus* (1964); and P.H. RHEIN, *Albert Camus* (1969). See also EMMETT PARKER, *Albert Camus: The Artist in the Arena* (1965), an excellent analysis of Camus's political writings and ideas on artistic commitment.

(J.Cr.)

Canada

The second largest country in the world in area, after the Soviet Union, but one of the most sparsely populated, Canada occupies roughly two-fifths of the North American continent. Its 3,851,809 square miles (9,976,139 square kilometres) of land and freshwater include its adjacent islands, except Greenland, a part of the Danish kingdom, and St. Pierre and Miquelon, parts of the French Republic. Canada is bounded on the north by the Arctic Ocean, on the east by the Atlantic Ocean, on the south by 12 states of the United States, and on the west by the Pacific Ocean and the U.S. state of Alaska. The national capital for the ten provinces and two territories of Canada and for the almost 22,000,000 Canadians recorded at the start of the 1970s is Ottawa.

Because much of Canada's land is mountainous or rocky or located in an Arctic climate, the developed area is probably not more than one-third of the total. Occupied farmland comprises less than 8 percent; and the productive forestland, 25 percent. Yet, its geographical position and its shape place Canada in contact with the principal powers and some of the most populous areas in the world. It not only borders the United States for a distance of 5,527 miles (8,895 kilometres), but the peninsula of southern Ontario knifes into the heart of the United States. In the north, the Arctic archipelago penetrates far into the Polar Basin and brings Canada close to the Soviet Union and northern Europe. In the east, the island of Newfoundland commands the shortest crossings of the North Atlantic Ocean and the country's strong traditional ties with Great Britain and France, while in the west the arc of the coast provides departure points for routes between North America and the Far East.

For information on related topics, see especially the article CANADA, HISTORY OF and articles on each of the provinces and territories and on MONTREAL, OTTAWA, QUEBEC (CITY), and TORONTO. See also NORTHWEST PASSAGE. The relation of Canada's land to the continent as a whole appears in NORTH AMERICA, while articles on related specific physical features include ARCTIC ISLANDS; ARCTIC OCEAN; BAFFIN BAY; BARENTS SEA; BEAUFORT SEA; COLUMBIA ICEFIELD; COLUMBIA RIVER; FRASER RIVER; FUNDY, BAY OF; GREAT LAKES; GREAT PLAINS; HUDSON BAY; MACKENZIE RIVER; NIAGARA RIVER AND FALLS; PACIFIC COAST RANGES; ROCKY MOUNTAINS; SAINT LAWRENCE, GULF OF; SAINT LAWRENCE RIVER; SAINT LAWRENCE SEAWAY; and YUKON RIVER. The history of the arts in Canada is covered in LITERATURE, WESTERN; VISUAL ARTS, WESTERN; and THEATRE, WESTERN. See also ICE HOCKEY.

I. The natural and human landscape

Overview of the land and settlement

In very general terms, Canada can be considered as a vast basin almost 3,000 miles (4,800 kilometres) in diameter. The Cordillera in the west, the Appalachians in the southeast, the mountains of northern Labrador and of Baffin Island in the northeast, and the Innuitian Mountains in the north form its high rim, while Hudson Bay, set close to the centre of the enormous platform of the Canadian Shield, occupies the basin bottom. The western rim of the basin is higher and more massive than its eastern counterpart, and pieces of the rim, notably in the far northwest and in the south, are missing. The main lines of Canadian landforms continue well into the United States, intimately linking the geography north and south of the border. Although terrain and climate always impose conditions on human activity, in Canada their influence on the patterns of human settlement and on the nation's economic development has been critical and pervasive. As a consequence, the Canadian North remains one of the least settled and least exploited parts of the world, contributing significantly to the nation's underpopulation.

THE NATURAL ENVIRONMENT

Physical regions. In its broad features, the land comprises eight physical regions. Almost in the centre of the country is the vast Canadian Shield. Bordering the shield are the principal lowlands: in the west, from the United States border to the Beaufort Sea, the vast interior plains; in the east, from the Great Lakes to the Atlantic, the Great Lakes–St. Lawrence lowlands; in the north, the Arctic plains and plateaus. Adjoining the plains in the far west are the high mountains and plateaus of the Canadian Cordillera, part of the backbone of the continent that extends throughout the Americas. In the southeast are the lower mountains of the Appalachian system, and in the far north are the Innuitian ranges. Finally, where the shield is broken into by Hudson Bay and Hudson Strait, the waters are bordered by the Hudson Bay lowlands. Having recently emerged from below sea level, they are generally low, flat, and covered with ill-drained marshes, mossy (or muskeg) swamps, and bodies of standing water.

The Canadian Shield. By far the largest of Canada's physiographic regions, the Canadian Shield occupies about 49 percent of the total area of the country and is centred about Hudson Bay. It consists of ancient rocks folded by mountain-building movements and cut down by erosion until the area was reduced almost to a plain. It was warped and folded in places so that parts of it now stand much higher than others, especially around its outer edges. In the north the rim is about 7,000 feet (2,000 metres) above sea level, and fjords with walls from 2,000 to 3,000 feet (600 to 900 metres) high extend many miles into the mountain masses. South of Hudson Strait lie the Torngat, Kaumajet, and Kiglapait mountains, the heights of which sometimes exceed 5,000 feet. Along the north shore of the St. Lawrence River in Quebec, the shield rim is a 2,000-foot escarpment—the Laurentide Scarp. The rim is almost imperceptible in southern Ontario, but in northern Ontario it rises again to almost 1,500 feet above the north shore of Lake Superior. From Manitoba northwestward the shield edge is marked by a number of lakes, some of which, such as Lake Winnipeg, Lake Athabasca, Great Slave Lake, and Great Bear Lake, are very large.

Formation of the landscape

Most of the shield itself is less than 2,000 feet above sea level. Its lack of hills of any size produces a generally monotonous landscape, but geologically recent glaciations have had a striking effect on the surface. Much of their work was erosive. By stripping off the top, weathered material, they roughened the surface into a rock-knob type of landscape, or a grained landscape, with the hollows between the knobs or the troughs between the ridges occupied by enormous numbers of lakes. In other areas the glaciers deposited till or moraine on the surface and in still others left gigantic fields of erratics and boulders. Eskers—long, narrow ridges of earth deposits—

stretch across the shield sometimes for more than 100 miles (160 kilometres), marking the course of old, subglacial rivers. In still other places, deposits laid down by glacial lakes that have since drained away have given rise to extensive clay belts, which may be used for agriculture.

The interior plains. Taking in 18 percent of the total land area of Canada, the interior plains extend southward into the Great Plains of the United States. In the southeast is the Manitoba lowland, with an elevation of less than 1,000 feet (300 metres) above sea level. It includes a number of lakes, some of them very large; most of them are remnants of the huge glacial-age Lake Agassiz, which once occupied all of the lowland and adjacent areas. In the southern portion the Red River Valley is covered with clays and silts that accumulated on the floor of Lake Agassiz and today create a rich farmland. The Mackenzie lowland, in the northwest, is similar to the Manitoba lowland. It is not level throughout, but most sections of it are flat and covered with muskegs, swamps, and lakes sometimes interrupted by low limestone escarpments.

The Saskatchewan plain to the west of the Manitoba lowland varies in elevation from 1,500 to 2,100 feet above sea level. Its surface is varied with clay plains laid down by glacial lakes and materials deposited by the ice sheets, but its flatness makes it well suited to the use of large-scale farm machinery. Thick accumulations of moraine form occasional isolated ranges of low hills studded with kettle lakes. Undulating plains were formed by material known as glacial till spread over the bedrock by moving ice. Other common features are moraines resulting from the deposition of material, by melting glaciers, at the ice front while it was stagnant or stationary, and flat-bottomed, steep-banked stream channels, cut by the glacial meltwaters, some of which are up to four or five miles in width and 300 feet deep.

The Alberta upland, still farther to the west, is rougher and more elevated, much of it about 2,500 feet above sea level. Water and wind erosion has modified the landscape greatly since the retreat of the ice sheets. The land is deeply dissected by sharp valleys from 200 to 400 feet below the surrounding plain.

The Great Lakes–St. Lawrence lowlands. The four parts of the Great Lakes–St. Lawrence region, although much smaller than those described above, are important because of the large numbers of people living within them. The domelike Huron and Erie lowlands lie between the lakes of the same name and the Niagara Escarpment. As the ice receded from around this dome it halted periodically, and at each stage glacial meltwaters deposited sands and gravels around its edges. These deposits, known as recessional moraines, today ring the central portion of the dome. In this upland portion the glacial meltwaters also cut wide channels, or spillways. Today nearly all these spillways are occupied by streams, but they are much too small to have carved the main valley and are known as misfit streams. Beach deposits and sharp bluffs mark the former glacial shorelines of the present Great Lakes. Shallow, flat-bottomed valleys characterize the monotonously flat clay and silt plains that border the lakes in certain areas. The Ontario lowlands east of the Niagara Escarpment are made up mostly of a till plain traversed by the latitudinally extending Oak Ridges and Dummer moraines. They also include several thousand hills of glacial deposit, or drumlins.

Ottawa–St. Lawrence lowlands

The Ottawa–St. Lawrence lowlands extend east of the Ontario lowlands, from which they are separated by the Frontenac Axis, a narrow belt of ancient Precambrian rocks more than 570,000,000 years old that extends from the Canadian Shield to the Adirondack Mountains in the U.S. state of New York. These lowlands embrace the lower part of the Ottawa valley and extend to a point some 70 miles below Quebec. The area was inundated by the Champlain Sea when seawater invaded the region as far west as the Frontenac Axis during glacial times. In the west the widest and flattest section of the lowland is pierced by outlying islands of Precambrian rocks that form conspicuous hills, and the levelness of the plain is also broken by the eight Monteregian Hills, the remains of igneous intrusions. The westernmost of these is Mont-Royal in Montreal, 763 feet (262 metres) in altitude. Anticosti Island and the Mingan islands at the mouth of the St. Lawrence form the fourth natural division of the Great Lakes–St. Lawrence region.

The Canadian Cordillera. The Cordilleran region comprises a belt of mountains some 500 miles wide that flanks the Pacific coast of Canada. Its eastern section rises abruptly from the interior plains and trends in a generally north–south direction, except in the far north, where it curves, ultimately, to run almost east–west and into the peninsula of Alaska. Three groups of mountains make up this section: the Richardson and British mountains in the extreme north are separated by the Peel Plateau from the Mackenzie and Franklin mountains, which, in turn, are separated by the Liard Plateau from the Rockies. The Rockies have at least 30 peaks over 10,000 feet high, Mt. Robson, at 12,972 feet (3,954 metres) above sea level, being the highest.

Passes through the Rockies are not numerous. The Yellowhead Pass (3,717 feet; 1,133 metres) is used by the main line of the Canadian National Railway; the Kicking Horse Pass (5,338 feet; 1,627 metres) is used by the main line of the Canadian Pacific Railway as well as the Trans-Canada Highway; and the Crowsnest Pass (4,429 feet; 1,350 metres) is also used by the Canadian Pacific Railway. Snowfields and icefields add to the scenic attractions of the Rockies, which include five of Canada's national parks, the oldest of which, Banff, was established in 1885.

To the west the eastern ranges are bordered, for most of their length, by a sharp topographical break known as the Rocky Mountain Trench, up to 15 miles wide and several thousand feet deep. West of the trench the relief is generally lower, for plateau forms predominate; but they alternate with deep valleys and local mountain ranges.

Coast mountain scenery

Farther west still lies another belt of mountains some 50 miles wide. The mainland coast comprises the St. Elias and Coast mountains, which embrace some of the grandest and most awesome scenery in the country, including Mt. Logan—which, at 19,850 feet (6,050 metres), is the highest mountain in Canada—and several other peaks of over 15,000 feet. All along the coast there are spectacular fjords the steep-sided walls of which often rise over 7,000 feet. Off the coast is a lower chain of mountains that appear as a series of islands, the largest of which are Vancouver Island and the Queen Charlotte Islands. The trough that separates the insular mountains from the mainland has been drowned by the sea and forms an inside passage, an ocean-water route along the west coast.

Appalachian Canada. The Appalachian region extends from the eastern townships of Quebec province northeastward to embrace the Gaspé Peninsula, the Maritime Provinces, and the island of Newfoundland. It consists of very old folded rocks that have been eroded into low, rounded mountains that are dissected by valleys and broken by broader lowland areas developed on belts of weaker rocks. Three broad groups of highlands and uplands can be recognized. The westernmost and highest is made up of Sutton Mountains, Megantic Hills, Notre Dame Mountains, and the Shickshock Hills of Quebec. Elevations in places exceed 4,000 feet. Farther east are the Chaleur uplands and Miramichi highlands. The third and most easterly of the highland groups is made up of the St. Croix highlands, Caledonian highlands, and the Nova Scotia highlands and uplands. They merge into one on the island of Newfoundland to form the Long Range, Topsail Hills, Dunamagon Highlands, and Anguille Mountains. The few lowlands of the region—the lowlands of central New Brunswick, Prince Edward Island, the Cumberland lowland, and the Magdalen Islands—generally border the Gulf of St. Lawrence.

The Arctic islands. The Innuitian region flanks the Canadian Shield to the north, extending from northernmost Ellesmere Island to Prince Patrick Island. Much of it is covered with fields of permanent ice and snow through which mountain peaks often protrude. They reach 10,000 feet in the Grantland Mountains (formerly the United States Range).

Drainage. The waters of Hudson Bay and Hudson Strait receive almost one-half of the drainage from the

rivers and lakes of Canada. Not much smaller in area than the Hudson Bay Basin is the Arctic Basin, dominated by the Mackenzie, the longest river in Canada, which, with its tributaries, drains 711,000 square miles (1,840,000 square kilometres). The St. Lawrence is the largest river draining into the Atlantic Ocean. Its basin includes the Canadian portions of all of the Great Lakes, forming an inland waterway reaching 2,000 miles into the heart of the continent. The longest river that drains into the Pacific Ocean and is wholly within Canada is the Fraser, but large areas of Canada are drained by the headwaters of the Yukon and the Columbia, both of which have their lower courses in the United States.

Almost all Canadian rivers are characterized by rapids and falls, many of which have been developed for the generation of hydroelectricity. The most famous example is Niagara Falls, lying on the Niagara River between Lake Erie and Lake Ontario.

Climate. Because of its great latitudinal extent, Canada experiences a variety of climates, dominated by cold winters, hot summers, and sufficient but not over-abundant precipitation. Exceptions are to be found in small areas on the Pacific coast, where, due to the influence of warm ocean waters, the extremes of temperature are not great and where the presence of high mountains causes moderate to heavy precipitation on the western slopes. The same situation, though to a lesser extent, prevails on the Atlantic coast. In winter, average temperatures are below freezing everywhere but the extreme southwest.

Nearly three-quarters of Canada experiences continental climates, with very cold winters but adequate precipitation. These may be subdivided according to the warmth and length of the summer. The sub-Arctic, the coldest, covers 53 percent of Canada. Another subdivision with cool summers covers most of Canada's populous regions. The warm-summer phase, or "corn-belt" type of climate, covers only the southwestern peninsula of Ontario jutting among Lakes Huron, Erie, and Ontario; its climate is similar to that of the Middle West of the United States. The remaining climatic type, similar to that of western Europe, affects the Pacific coast and is characterized by its mild winters.

Temperatures. Those parts of the country farthest from open water are the coldest, so that in the interior plains and the north the winters are extremely cold. The lowest temperature ever recorded was −81° F (−63° C) at Snag in the Yukon. In July those parts of Canada farthest from open water are the warmest. Thus, west-coast Vancouver has an average January temperature of 37° F (3° C) and an average July temperature of 64° F (18° C), while on the prairies Regina's temperatures vary from 2° to 67° F (−17° to 19° C). The daily range of temperature is also less on the coasts than in interior locations. The highest temperature recorded was 115° F (46° C) at Gleichen in southern Alberta.

Rainfall. Humid air masses from the Pacific cause enormous quantities of orographic (mountain-caused) rain to fall on the coast and mountain areas—Henderson Lake, on Vancouver Island, receives an average annual of 262 inches (6,650 millimetres). But the orographic effect is not the whole explanation, since southern British Columbia receives much less rain in summer than in winter because low-pressure, rain-producing systems move in a more northerly track in summer and seldom cross the southern part of the coast. Vancouver has an annual average precipitation of 41 inches.

Impact of the Pacific and Rockies on precipitation

In the Prairies and the North, precipitation is low. Seldom more than 15 inches (380 millimetres) a year, it is as low as two inches (50 millimetres) at Eureka on Ellesmere Island. The west-coast mountains quite effectively keep marine air out, since the dominant movement of air in Canada is from west to east. Spring and summer are wetter than winter, however, because the air is warmer and can hold more water vapour and because the melting of accumulated snow provides moisture. Thunderstorms in the Prairies reprecipitate moisture that has evaporated, thus helping to prevent water vapour from being removed from the area.

Ontario and Quebec have more rainfall than the Prairies because the air masses can pick up water vapour from the Great Lakes, Hudson Bay, the Atlantic Ocean, and the Gulf of Mexico. The average annual precipitation for Toronto is 30 inches (760 millimetres); for Montreal, 41 inches (1,000 millimetres). Since the winters are not as cold as those in the Prairies, the air is less dry, and enough snow falls to make winter precipitation equal to that in summer. The Atlantic Provinces are wetter than those of Central Canada. Yearly rainfall, most of which is cyclonic in origin, is over 50 inches (1,300 millimetres) in many places and is fairly evenly distributed throughout the year. Because the weather in summer is usually cool, there are few thunderstorms, and the low Appalachian Mountains produce only a little orographic rainfall. In general, the rainfall on Canada's east coast is less than on the west coast because the prevailing wind is offshore.

Snowfall. Canada's snowfall does not follow the same pattern as rainfall. In the North and the Prairies, snowfall is light because cold air is very dry. The snow is hard and dry, falls in small amounts, and is packed down by the constant wind. The east and west coasts are areas of lighter snowfall because the ocean usually makes the air too warm for large quantities of snow to fall. The depth of snow increases inland from each coast, reaching maximums of about 240 inches (6,100 millimetres) in the Rocky Mountains and on the shores of the Gulf of St. Lawrence. Still farther inland, lack of moisture brings the depth of snow down again. Freezing precipitation may occur during the colder months in any part of the country, and it occasionally seriously disrupts transportation and communication in southeastern Canada.

Vegetation. The relief of the land and the climate are largely responsible for the distribution of plants. The chief plant associations are the forests, grasslands, and tundra. The forests under natural conditions once formed the cover of about 65 percent of Canada; tundra, about 20 percent; and grasslands, about 10 percent. The remaining 5 percent, either bare rock or permanent ice and snow, is devoid of vegetation. Much of the southern edge of the forests and most of the grasslands have been replaced by agriculture.

Forest zones. Three broad zones of forest occur in Canada: the eastern, the northern, and the western. The eastern forests, from the basin of the Great Lakes to the St. Lawrence Valley and the lowlands of the Maritimes, is the plant response to low plains, a relatively long growing season, and humid, temperate conditions. In the most southerly parts, the flat plains bordering Lake Erie, are remnants of a predominantly deciduous forest of oak, hickory, and chestnut, together with maple, elm, and walnut. Farther north, on the hillier morainic land of central and eastern Ontario and on the terraces overlooking the St. Lawrence, is a mixed deciduous–coniferous forest of sugar maple, beech, yellow birch, white and red pine, and hemlock. Between the hills of the Maritimes, a mixed deciduous–coniferous forest prevails.

The northern coniferous, or boreal, forest is one of the largest in the world, stretching from Newfoundland across Canada to the border of Alaska. The region has in common extensive glaciation, rather infertile and acid soils, severe winters, and a short growing season. Only a limited number of tree species do well under these circumstances. White and black spruce and white birch are common throughout the region, and balsam, poplar, and tamarack trees are also widely distributed. Species with more limited distribution are balsam fir, jack pine, and trembling aspen. Thus, the boreal forest is ideal for logging for pulpwood. Along its northern fringes the boreal forest merges with the tundra to produce a zone of forest–tundra transition. In the south, it similarly merges with the grasslands to produce a zone of aspen parkland, or forest–grassland transition—dotted with clumps of trees that are continuous only in the river valleys.

The western forests

The western forests of the Cordillera are very complex, as might be expected from the strong relief and the sudden change in climate within relatively short distances. The subalpine forest, of Engelmann and white spruce and lodgepole pine, is characteristic of the slopes of the Rockies from about 4,000 feet up to the timberline. The

forests of the Selkirk and Purcell mountains contain Engelmann spruce at higher elevations, merging with western red cedar and western hemlock on the lower slopes. On drier slopes Douglas fir is common. Typical of the ranges that traverse the rather arid interior plateau is a generally open forest of aspen and yellow pine interspersed with glades of grass. Douglas fir and lodgepole pine are found on higher slopes.

The forest of the Pacific coast, where steep slopes facing rain-bearing winds produce a very high rainfall, is Canada's densest tall-timber forest. This, with the long growing season, is conducive to the growth of evergreens with very hard wood, excellent for construction lumber. Douglas fir, western hemlock, and western red cedar are the outstanding trees; they grow to great height and thickness. Alder, cottonwood, and maple are subsidiary, along with western white pine. Dense stands of immense trees, their crowns almost touching, their trunks rising to considerable heights, give a grandeur to the forest.

Grasslands. The interior parts of the Prairies, cut off by mountains or by distance from moisture-laden winds, are too dry for forest and give rise to grasslands or natural prairies. Today, the area under grass is quite small, for crops have replaced grass in all but the driest or most hilly regions. Thus, while two broad belts once existed, the tallgrass prairies in the north and the shortgrass prairies in the south, now only about half the shortgrass country remains under grass, while nearly all the tallgrass land is plowed up and lies under crops.

Tundra. Tundra is the name given to the variety of low-growing plants found in areas of permanently cold climates. The rock deserts are almost devoid of vegetation, but relatively fast-growing mosses often surround large rocks. In rock crevices such plants as the purple saxifrage survive, and the rock surfaces themselves may support lichens, some of the orange and vermilion species adding colour to the landscape. Lichen tundra is found in the drier and better drained parts. Mosses are common, and some species may dominate the landscape to such an extent that it appears snow covered. The heath and alpine tundra support dwarf, often berry-bearing shrubs, while the ground between usually is covered with a thick carpet of lichens and mosses.

Animal life. The wildlife regions of Canada correspond closely with the climatic and vegetational zones. In the Arctic, the distinctive animals are the seals and the polar bear that feed on them; the musk-ox, Barren Ground caribou, and lemming, which graze on the tundra, and the Arctic wolf and white fox that prey on them. Many species of birds find summer nesting grounds in the Arctic. The forest–tundra transition zone supports the woodland caribou; while further south, the boreal forest proper supports nearly all the species of mammals and birds that are recognized as distinctively Canadian. These include the moose, beaver, the Canada lynx, the black bear, and the Canada jay. In the southern, more densely populated parts of Canada, the typical large mammal is the white-tailed deer, which prefers forest borders and partially cleared areas. Smaller mammals are the gray and red squirrels, mink, and skunk, with such birds as the cardinal and, in summer, the Baltimore oriole and the catbird. The western, prairie, section has a particular fauna in addition, which includes the sharp-tailed grouse, jack rabbit, and gopher. Under the early unrestricted hunting and settlement, such species of animals and birds as the passenger pigeon and wild turkey became extinct, while others, such as the buffalo and prong-horned antelope, almost so. Such animals as the Rocky Mountain sheep, the mountain goat, and the mountain caribou roam the southern part of the western mountains.

Soils. Geology and relief, climate and vegetation are linked together and find a common expression in the soil, which can be divided into regions.

The northern groups. The thin sub-Arctic and tundra soils lie over permanently frozen ground known as permafrost. They are characterized by patterned ground in which the soil materials are sorted by the alternate freezing and thawing of the ice between the rock fragments to form circles, polygons, and stripes. In some areas, especially near the mouth of Mackenzie Delta, pingos—conical hills with a core of ice—are prevalent. The soils are usually waterlogged in early summer because of the inability of the spring meltwaters to soak into the ground. Sometimes the soil is so saturated it creeps or flows down the slopes. These soils may be dismissed for all but very limited agricultural purposes.

Forest soils. Podzols are leached, grayish-coloured soils that extend through the forested part of the Canadian Shield and the Appalachian region. They are acid and rather infertile. Peat soils are common throughout this zone, especially in the northern part. Gray-wooded soils underlie the forested part of the interior lowlands in western Canada. They have developed under the boreal forest, where the climate is subhumid and cool. Generally, they are lower in natural fertility than the gray-brown soils but higher than the podzols.

Limitations on agriculture

Eastern agricultural soils. Agriculture is limited to the southerly parts of the shield and the Appalachian region, in which soil and climatic conditions are more favourable, but even in these parts much of the total area is unsuitable for agriculture because of rough topography, rock outcrops, or stony soils. Many more acres could be used for agriculture, however, if economic conditions and demand for land warranted such development. Gray-brown podzolic soils extend over the low plains of the Great Lakes–St. Lawrence region. These soils are fertile and, when properly managed, produce a wide range of crops. The combination of soil, climate, and markets has given rise to an intensive agriculture and produced the highest rural population density in Canada.

Prairie soils. Although a large part of the prairies is not suitable for agriculture, it contains greater reserves of potential agricultural land than any other zone. The black earths, thick surface soils rich in organic matter, are probably the most fertile soils in the country. Extending from Winnipeg to Edmonton, they lie along the subhumid margin of the prairies, on which a lush vegetation of tallgrass once flourished. Although grain growing is important, the soils also support mixed farming. Dark-brown soils, transitional between the black earths and the brown soils, have become the chief wheat-raising soils in Canada. Brown soils developed in the most arid parts of the prairies, where the grass was short and bunchy. These soils are lower in organic matter and more alkaline than the other prairie soils, although many of them are quite productive if there is sufficient rain or they are irrigated. Stock ranching as well as farming is of great importance in this zone.

Western mountain and coastal soils. In the Cordillera, relief predominates, and the soil belts follow altitudinal zones. In the great trenches, in which there is relative aridity, brown to dark-brown soils occur, with all the characteristics of the southern prairies. Higher slopes have podzolic soils. This accounts for the considerable variety in the agriculture of the interior valleys of British Columbia. Along the Pacific coast, humid brown types of soils have developed under heavy rainfall, in a long growing season under a forest of tall trees. The heavy rainfall leads to some leaching, especially on the windward slopes. The best soils are those on the alluvial deposits of the river deltas and river and coastal terraces.

TRADITIONAL REGIONS AND HUMAN SETTLEMENT

From this combination of physical elements coupled with the population distribution, popular regional terms have emerged. Thus, the Maritimes refers to the Appalachian region without the island of Newfoundland, and if Newfoundland is included, the area is referred to as the Atlantic region or the Atlantic Provinces; Quebec and Ontario are usually referred to alone but sometimes together as Central Canada; the West usually means all of the four provinces west of Ontario, but British Columbia may be referred to alone and the other three collectively as the Prairies, or Prairie Provinces; the Yukon and Northwest Territories are referred to as the North.

Patterns of habitation and land use. These terms often disguise the fact that the effectively occupied part of the country, the ecumene, covers only about 10 percent of

Canada and that this part is all in the south along the border with the U.S. Furthermore, the ecumene is not continuous but covers the southern lowlands only. Thus, it embraces a small area around St. John's, Newfoundland; the lowlands of the Maritimes; the Great Lakes–St. Lawrence lowlands; the southern Prairies, where its width increases from less than 100 miles (160 kilometres) on the eastern Manitoba border to 600 miles (1,000 kilometres) on the western Alberta border; and a small area around Vancouver and Victoria, British Columbia.

Rural settlement patterns

Within the ecumene, rural land use varies. The average farm size in the Atlantic region, Quebec, and Ontario is approximately 163 acres (66 hectares); in the Prairies, 685 acres (277 hectares); and in British Columbia, 277 acres (112 hectares). The pattern of rural settlement also differs. In the Maritimes, farms are spaced along the roads at irregular intervals wherever there is cultivable land. In Quebec the first settlers laid off long, narrow lots from the shores of the Gulf of St. Lawrence or the St. Lawrence River into the interior. As settlement moved further inland, roads were built parallel to the waterways, from which narrow lots extended on either side. The same pattern of land tenure is visible in many parts of the Red River Valley of Manitoba, where the early settlers were also of French origin.

In Ontario and the eastern townships of Quebec, land subdivision was made with reference to a much more definite plan. The townships were more or less square, but the grid became irregular because it was started from a number of different points, each of which used a differently oriented base. In the Prairies the grid is much more regular, partly as a result of the topography, partly because a plan for the subdivision of the whole region was laid out in advance of settlement.

The distribution of the nucleated rural settlements reflect these patterns. In the Maritimes they tend to be distributed around the coast or along river valleys; in the St. Lawrence lowlands they are strung along the banks of the river; in Ontario and the Prairies, however, they are much more evenly spaced, although many of the cities of the former have developed on the shores of the Great Lakes rather than from inland centres.

Urbanized and wilderness Canada. At the beginning of the 20th century, only one-third of the people of Canada lived in urban areas, but by the 1970s the situation had completely changed. About three-quarters of the population live in communities of more than 1,000 people. Almost two-thirds of these urban dwellers, or nearly one-half of the total population, are in cities of 100,000 or more. Canada has 22 such cities, easily led in size by Montreal (1,222,000), Toronto (713,000), and Vancouver (426,000). There is at least one large city in every province except Prince Edward Island, each of which functions as a major commercial centre for that province. Some are almost satellites of a larger metropolis, such as Kitchener and Hamilton with respect to Toronto.

Although rapid urbanization is a characteristic of the entire country, it is much more marked in the Great Lakes–St. Lawrence lowlands, in which more than two-thirds of Canada's urban dwellers are found. Consequently, this region's ways of life are closely related to an industrialized, sophisticated society. Yet, because the population distribution within the ecumene is far from even, no part of Canada is further than 60 miles from an almost deserted wilderness area, and one of the many results is an emphasis on the outdoors for recreation and relaxation. A cottage by the lakeshore or a summer home by the ocean is a tradition with many families. Camping with trailers and tents has enabled others to vary their summer locale. Winter activities have increased in recent years with improvements in transportation, and skiing especially has increased in popularity.

Proximity and impact of the outdoors

II. The people of Canada

Canadians do not form a compact, homogeneous people. They are, rather, a collection of diverse national and cultural groups. In the strictly legal sense, there was no such thing as a Canadian citizen until the Canadian Citizenship Act came into force on January 1, 1947.

MAKEUP OF THE POPULATION

National origins. The official Canadian census, which is taken decennially in years ending with the figure 1, continues to record individual origins according to the national group to which a citizen or his ancestor on the male side belonged on coming to North America. Statistics on national origins from the census of 1961 gave the following percentages for the nation as a whole: British Isles, 44; France, 30; other nations of Europe, 23; Asia, 1; Indian and Eskimo, 1; and other, 1.

Ethnic backgrounds

Breakdowns by province and territory, however, reveal that these proportions are far from constant across the breadth of the Canadian domain, and certain figures are striking. The most constant factor is the percentage of persons from the British Isles, though this varies from 94 in Newfoundland to 11 in Quebec; in Manitoba, Saskatchewan, and Alberta, these persons are exceeded in numbers by the "other-European" group. Canadians of French descent comprise 81 percent of Quebec's population but less than 5 percent of the populations of Newfoundland, of the western provinces, and of the territories. A major French cultural pattern is being created in New Brunswick, and, since early in the 20th century, French Canadians have crossed in significant numbers into Maine and other New England states of the United States. The greatest proportion of Asiatics lives in British Columbia, forming 3 percent of the population; and of "others," in the Yukon Territory, forming 3 percent. In the Yukon and Northwest territories, 15 and 58 percent, respectively, of the inhabitants are of Indian and Eskimo origin.

Assimilation. Historically, most foreign-born immigrants into Canada have felt the need to live near members of their own race, nationality, creed, or culture, but, in time, they have become assimilated into either the British-Canadian or the French-Canadian culture. Virtually all Canadians of non-British or non-French origin have chosen to identify with and become a part of the former, though by no means has this meant total abandonment of their Old World cultures, points of view, or ways of life. The rate of assimilation has varied with the national origin of the immigrant. Scandinavians and Netherlanders appear to melt quickly into Anglo-Saxon ways, Italians and Germans rather more slowly, and Poles and Ukrainians less slowly still.

Canada, Area and Population

The Indians and Eskimos. The earliest inhabitants of Canada came from Asia by way of Bering Strait more than 10,000 years ago. When the European colonists began their settlements, the Indian and Eskimo population of Canada was probably about 220,000. In the intervening years it declined considerably before improved living conditions and medical attention caused the numbers to increase to present levels, but today the Indians are the fastest growing ethnic group, numbering 244,000 in 1970. They are grouped into some 550 bands and occupy or have access to more than 2,200 reserves and settlements having a total area of nearly 6,000,000 acres.

The Eskimos were never as numerous as the Indians. Their numbers were estimated at 3,700 in 1910 but increased to about 6,000 in the 1920s and to about 11,050 in 1970. They live in scattered camps and settlements of 25 to 500 people. The resources of the far north have been too limited, however, to provide them with incomes on which they can survive except on marginal living standards. Education and training programs have been instituted to enable them to compete for employment, hopefully in the industrial south.

Canadians of U.S. origin. Canadian census figures do not account for the number of Canadians whose forebears immigrated from the United States, since only origins outside North America are recorded. Migration from the United States into Canada was considerable during and after the American Revolution (1776–83), when thousands of colonists who remained loyal to the British crown, now known as United Empire Loyalists, moved north into what remained of British North America, principally into the Maritime colonies; and after 1789 many other Americans migrated into the Great Lakes lowlands to take advantage of offers of free land. It is probable that the number of people arriving from the U.S. in the 1780s did not exceed 50,000, but since the total population of Canada in 1790 was just over 300,000, about one-sixth of that total was certainly of U.S. origin.

Patterns of U.S.-to-Canada migration

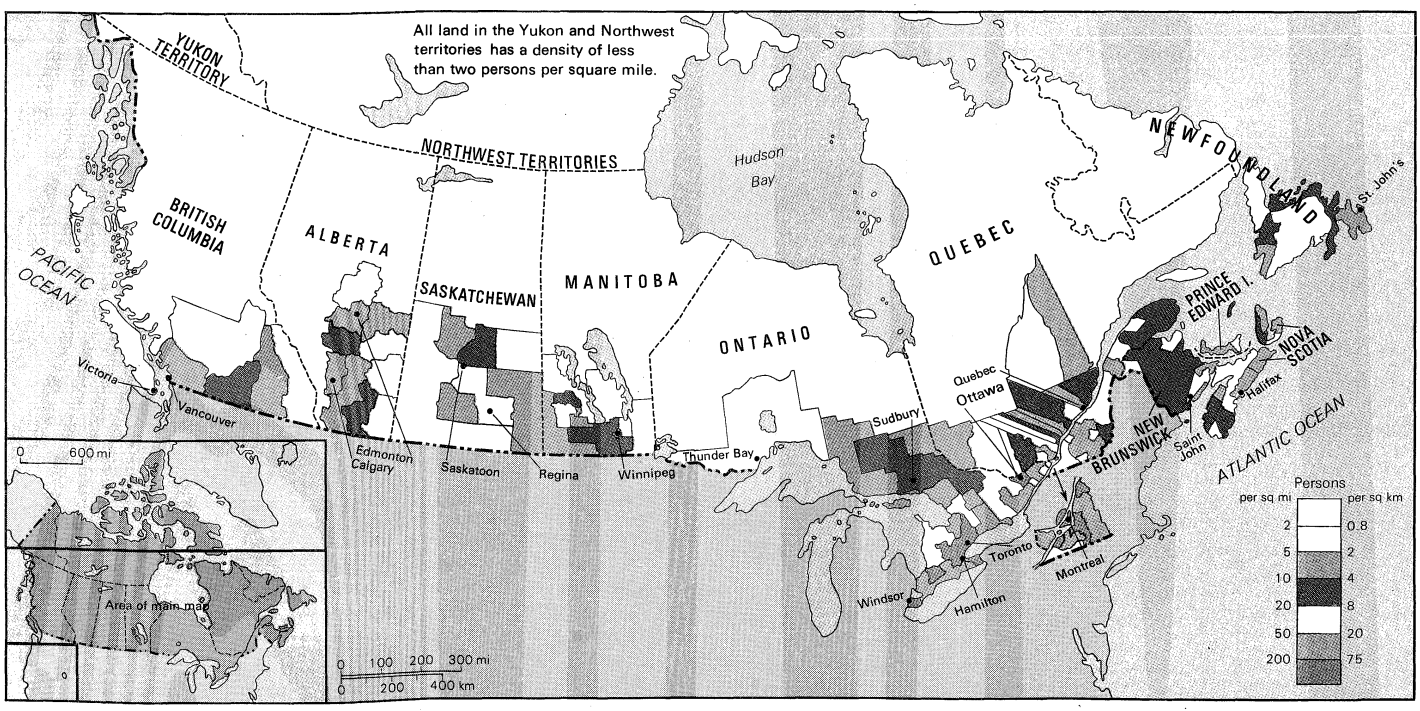
This immigration introduced a new element into the population complex of British North America, for, whether they arrived with strong Loyalist views or whether they developed such views to take advantage of the land offers (the so-called late Loyalists), these people had all been exposed to the ideas of popular government and democracy that had grown up along the Atlantic seaboard. Their impact on the development of Canada was different from that of those persons who came to Canada directly from Britain. They not only influenced the British North America of their time, but have implanted their ideas firmly within the Canada of today.

Linguistic and religious groups. The Canadian census defines mother tongue as the language first learned in childhood and still understood. For the entire nation, English was claimed by 59 percent in 1971, French by 28 percent, while German, Italian, and Indian and Eskimo accounted for 3, 3, and 1 percent, respectively.

The percentage of persons reporting English as the mother tongue is generally greater than that of persons with origins in the British Isles, largely reflecting the fact that most persons in the "other countries of Europe" category probably will have learned English first if they were born in Canada. In British Columbia, for example, in 1961, 59 percent of the population claimed origins in the British Isles, but 81 percent claimed English as their mother tongue. In addition, a decline in the percentage claiming English does not necessarily imply an increase in French, or vice versa: in 1954–63, more than 430,000 immigrants were from Italy, Germany, and The Netherlands, most of them diluting Ontario's largely English-speaking population. Few of the outstanding phenomena concerning linguistic distribution are unexpected. In Quebec, in 1971, 81 percent claimed French, but only 13 percent, English, while in neighbouring Ontario, the percentages were 78 English, 7 French. In the Prairie Provinces (Manitoba, Saskatchewan, and Alberta), German is the mother tongue for 8, 8, and 6 percent, and in the Northwest Territories, 45 percent claim Indian and Eskimo.

Although some relation exists between language and religion, the relation between national origin and religion is probably the greater. Almost half of all Canadians profess Roman Catholicism (46 percent), the United Church of Canada (20 percent), or Anglicanism (13 percent).

Much smaller percentages of other Protestant denominations and a number of Jewish, Greek Orthodox, and other faiths account for most of the remainder. Roman Catholicism is especially strong in Quebec (88 percent), New Brunswick (52), Prince Edward Island (46), Newfoundland (36), and the Northwest Territories (43). Lutheranism and the United Church are proportionally strong in the Prairie Provinces, Anglicanism in the territories, though where populations are relatively small, a high percentage may encompass fewer persons than a much lower figure in more densely populated regions.



Population density of Canada.

DEMOGRAPHIC TRENDS

Changes in population makeup. The population composition according to origin is by no means fixed. Sometimes these changes are due to direct recent migration into and out of the country, sometimes to differential birth rates among the national-origin groups. Between 1901 and 1971, the numbers of people of British Isles origin remained the largest but declined steadily as a percentage; the proportion of French origin remained constant.

The greatest change has occurred with the non-Franco-British group. In 1901 it made up 12 percent of the population, but by 1961 it was 26 percent. Within this group, other variations exist. Those of German origin have always been most numerous, but after 1951 their proportion increased slightly. Ukrainians, the eighth most numerous non-Franco-British group in 1921, were in fourth place in 1971, followed by persons of Italian origin.

Such changes have not occurred uniformly throughout the country, so that their regional or local impact is greater than national figures indicate. For example, though the Canadian average birth rate has changed little since the 1920s, the differentials are much less. Whereas Quebec at that time had a birth rate 50 percent higher than Ontario, the decline in Ontario (to 17.6 per thousand persons in 1970) has been less than that in Quebec (to 15.3 per thousand), making the two provinces nearly identical. Similar convergence has occurred elsewhere.

In the period 1941–68, life expectancy at birth for men rose from 63 to 69 years; for women, from 66 to 75.5 years. The infant-mortality rate fell from 61 per 1,000 live births to 21. Birth rates declined gradually but steadily from 29.3 in 1921 to a low of 20.1 in 1937, rose to a postwar high of 28.9 in 1947, remained relatively stable until 1959, but since then has been declining, to reach a record low of 17.1 in 1971. The rates in most provinces followed trends very similar to the national trends, though they were highest in Newfoundland and the territories, lowest in Quebec and British Columbia.

Decline in birth and death rates

Death rates have declined with improved sanitation and medical services. They were halved between 1851 and 1930, dropping from about 22 to 11. They declined further to a low of 7.3 in 1971, one of the lowest in the world. High death rates were recorded in Prince Edward Island, Nova Scotia, and British Columbia, lows in the Yukon and Newfoundland.

In 1971, 29.6 percent of the population was under 15 years of age, but the number in the 0–4 age range had decreased markedly in just a five-year period. Although only 8.1 percent were over 65, the figure promised to rise with the drop in birth and death rates.

As to sex distribution, the Canadian population has always been characterized by an excess of males. The peak sex ratio of 113 males to 100 females was reached during the period of heavy immigration prior to World War I; after that it declined to virtual parity in 1971: 100.2. In the Prairies a high of 146 was reported in 1911, again during a period of high immigration. In 1971 all provinces except Quebec and Ontario had rates between 100 and 104, though the territories were about 113, collectively. It was only between the censuses of 1966 and 1971 that female populations of Quebec and Ontario finally overtook the male (both provinces had rates of 99).

Patterns of migration. Traditionally, Canada has sought to increase its population through immigration in order to expand its domestic market, reduce per capita costs of administration, stimulate economic activity, and support a higher level of cultural development. The peak year in recent immigration was 1913, with 400,870 arrivals. Since World War II more than 3,000,000 immigrants have entered Canada. Of these, some 53 percent settled in Ontario, about 21 percent in Quebec, 11 percent in British Columbia, 13 percent in the Prairie Provinces, and the remaining 2 percent in the Atlantic Provinces.

Emigration from Canada has tended to offset to some extent present and past immigration. The major outward movement has always been to the United States, and that movement, both of native-born Canadians and of Europeans who originally migrated to Canada, has attained considerable proportions at certain periods. Between 1960 and 1969, these numbers varied between 35,000 and 51,000 annually. Of these, almost half were housewives and children. Of the productive males, professional and technical workers formed the largest group, followed by clerical workers and craftsmen and foremen.

During the first 20 years of the century, the notable feature of internal migration was the movement from eastern Canada to the Prairie Provinces. Although British Columbia has continued to gain from migration since 1931, much of this has been at the expense of the Prairie Provinces. Saskatchewan has had more emigration than immigration since 1941. Ontario consistently has received far more people since 1941 than the other provinces, but most of this growth has been from immigration rather than interprovincial movement. The Atlantic Provinces have lost about 275,000 persons since World War II.

Shape of internal migration

Distribution of the population. The proportion of the population living in rural areas has been declining since Confederation: from 80 percent in 1871 to 46 percent in 1941, 30 percent in 1961, and 23.9 percent in 1971. The sharp drop after World War II reflected the accelerated increase in urbanization during the postwar period, particularly the growth of the large cities. In 1971, 47.5 percent of the people lived in cities of over 100,000.

The relatively small total population is concentrated in the southern part of the country. This discontinuous ecumene covers about 463,000 square miles. In other words, 90 percent of the people live on 12 percent of the land. But the east–west belt of population along the international boundary is far from continuous. There is a marked contrast between the well-occupied humid East, with its predominance of lowlands supporting some 75 percent of the population, and the somewhat meagrely occupied drier and rougher West, which supports the remaining 25 percent. Furthermore, the major population centres of the Atlantic Provinces are separated from the St. Lawrence lowlands by the Appalachian Highlands; the densely populated Great Lakes lowlands are separated from the Ottawa–St. Lawrence plain by the Frontenac Axis; the Prairie Provinces are cut off from southern Ontario by the Canadian Shield; and the Prairie Provinces are separated from British Columbia by the Rocky Mountains. Thus, a number of population clusters are strung together like beads on a string.

This situation is increasing rather than decreasing as more and more people migrate from rural areas to the cities. Between 1966 and 1971 the urban population of Canada grew by 11.4 percent, and the cities of over 100,000 expanded even more rapidly. In 1966–71, Montreal's metropolitan area gained 306,000 people and Toronto's gained 470,000.

What is also significant about these population clusters is that each of them is nearer to a large centre in the United States than it is to a cluster within Canada. Thus, the metropolis for the Atlantic Provinces is Boston; for the Ottawa–St. Lawrence lowlands, New York City; for the Great Lakes lowlands, Buffalo, Detroit, and Chicago; for the Prairies, Minneapolis–St. Paul; and for the west coast, Seattle, Portland, and San Francisco. Thus, the influence of the United States is not simply derived from the physical presence of Americans and the descendants of Americans. It is also derived from their close proximity and the attraction of the developments within their large and nearby urban centres. (N.L.N.)

III. The national economy

With a gross national product, at market prices, of over $4,000 per capita in 1971, Canada placed fourth after Switzerland, Sweden, and the United States on the list of affluent countries. The total national output increased by an average of 5 percent in the 1960s, while the population grew by 1.8 percent annually and the output per capita by about 2.8 percent. The presence of a still more affluent society in the neighbouring United States is, nevertheless, a continual irritant in Canadian society, as is the control of a significant portion of Canada's economy, through ownership or heavy financial investment, by U.S. companies. A recurrent theme of Canadian labour union demands is parity with corresponding United

The general picture: income, output, and inflation

States wage rates. The practical conclusion that has tended to be drawn—at least under successive Liberal governments in the 1960s—is that, other things being equal, a relatively high growth rate of national income is more important in Canada than in most of its Western competitors. In the second half of the 1960s, other things were not equal, and growth potential was deliberately sacrificed in the fight against price inflation. In this struggle, Canada was fairly successful, for, although inflation continued to accelerate, that of major competitors was accelerating faster.

THE EXTENT AND DISTRIBUTION OF RESOURCES

Minerals. Canada is rich in mineral resources, and exploitation has grown rapidly since World War II. Much of Canada's mineral resources are difficult to tap because of their location within the Arctic Circle under the permafrost, soil that is frozen for much of the year. By the 1970s, however, much of the thrust of Canada's economic planning and activity was directed toward developing these resources.

Canada is a leading world producer of a number of minerals and metals, with first place in nickel and zinc and great importance in asbestos, uranium, and molybdenum. It is also a major producer of petroleum and natural gas, copper, iron ore, potash, sulfur, gypsum, silver, cadmium, cobalt, magnesium, and platinum. Between 1961 and 1970 the volume of production in the whole mining sector rose by 75 percent, while in petroleum products it rose by almost 150 percent.

Biological resources. In the first half of the 20th century, exploitation of Canada's abundant biological resources provided a major component of the national economy. Two elements were overwhelmingly important: agriculture and lumbering. The huge flat and fertile expanses of the prairies between the Great Lakes and the Rockies became one of the world's major grain producers, and, in spite of some diversification in the second half of the 1960s (in fact, primarily a substitution of coarse grains for wheat), farming in food grains remains the major land use for this enormous area.

In a rather small area (by Canadian standards) of southern Ontario between Lakes Erie and Huron, a markedly softer, almost tropical climate makes possible the extensive growing of tobacco and fruit. The tobacco, which is important in national terms, is mostly quite high quality Virginia varieties, and in good years Canada is a significant exporter, especially to the United Kingdom.

Just under 5 percent of Canada's surface, however, is fully suitable for farming. Most of the country lies too far north, with a climate that makes farming and livestock raising economically unfeasible. This land, however, contains one of the world's largest concentrations of coniferous forest: some 1,711,000 square miles, or nearly one-half of the total land area, is classified as forest. The forest belt stretches across most of northern Canada. Much of this area, well into the Arctic Circle, is relatively inaccessible most of the year, but the river systems are used wherever and whenever possible to move timber out for processing in economically more hospitable areas. Canadian timber production—for lumber, pulp and paper, and other products—is among the world's highest.

In contrast with forestry and farming, Canada's animal and fishery resources are not striking. Fishing remains significant, however, both in the rivers and lakes (salmon) and in the ocean (especially whitefish and tuna varieties). Most of Canada's seafish catch comes from offshore and deep waters, close to the national coast. Livestock populations are, in order, cattle, pigs, and sheep.

Energy resources. In terms of energy resources, Canada is in a real sense the world's most richly endowed country, endowed with great water resources, with petroleum and natural gas, and with uranium. A severely limiting factor in the development of energy sources, however, has tended to be the cost of transmission of these resources over vast distances to widely scattered points of consumption.

For 1970 the statistics of the Department of Energy, Mines and Resources showed installed hydrogenerating capacity of 28,300,000 kilowatts. By conservative assessments, Canada had a further 21,000,000 kilowatts of undeveloped waterpower, while by a relatively optimistic assessment the figure was almost 90,000,000 kilowatts, well over three times the existing capacity.

Vastness of hydroelectric installation and potentiality

The future development of hydropower in Canada, unlike other developed Western countries, is more constrained by considerations of system load requirements and transmission costs than by availability of water. Canada did not see, in the 1950s and 1960s, the shift from hydropower to thermal power that occurred in other developed countries. Hydropower has substantially retained its share, with more than two-thirds of the kilowatt-hours generated. During the 1970s, a number of technical developments may sustain the past rapid rate of hydropower development by making it economical to transport electricity many hundreds of miles from generating station to consuming areas.

The future for other primary energy sources is still more speculative. Canada is a net exporter of both petroleum and natural gas and natural uranium, and, in a geological sense, its proven resources are very large. But the development rate depends crucially on U.S. import policies; for petroleum and natural gas, where the major reserves lie north of the Arctic Circle, transport costs to the major markets are also a crucial factor.

SOURCES OF NATIONAL INCOME

Agriculture, forestry, and fishing. One of the more surprising features of the Canadian economy is the small contribution of agriculture to national income. In 1961 its share of the domestic product was under 5 percent, and during the decade its production rose by well under one-half that of the domestic production as a whole. This decline is evident also on the income side; in 1971 the income of farm operators represented less than 3 percent of net national income, while incomes of agricultural workers represented only under 1 percent of total labour income. Even in employment terms, only about 6 percent of the 1971 labour force was in agriculture, a lower share than in some other countries generally regarded as much less agriculturally based than Canada; *e.g.*, France, West Germany, The Netherlands, and Sweden.

Mining and quarrying. In 1961 just over 4 percent of Canada's domestic product, or about 13 percent of the whole industrial sector, was accounted for by mining and quarrying. During the 1960s, however, production rose at a greater rate than that of the economy as a whole, increasing the sector's contribution to national income and product. The sector is not a major source of employment and therefore not of labour income, and during that decade the growth of employment was remarkably small by comparison with the growth of the sector's output or with the growth of total industrial employment.

Mineral exploitation and foreign investment

The sector is now, however, the largest single contributor to Canadian exports, nearly 25 percent in 1971, and was a major contributor to the dynamism of total exports in the late 1960s and early 1970s. The principal items in 1971 were crude petroleum and natural gas; copper, nickel, and their products, as well as iron ore; primary iron and steel; and lead, zinc, and their products. The sector has been, however, a major cause of the massive capital inflow that has led to the domination of Canadian industry by foreign corporations and to the crucial dependence of Canadian economic policy on United States economic policy, for more than 80 percent of investment in the sector was from the United States.

Manufacturing. The manufacturing sector in 1971 had about a 25 percent share in Canada's domestic product and labour income. This proportion, however, did not altogether indicate the dynamic importance of manufacturing in national income in the 1960s, when its product outstripped that of the whole economy. Within the total of manufacturing, moreover, some large industries (particularly durable goods) had a very rapid growth, which set the pace for other sectors in the economy. For example, production of motor vehicles increased by more than 250 percent, while the production of other consumer durables more than doubled.

Energy. The generation and transmission of energy (excluding petroleum and natural-gas production) have a weight of just under 3 percent in domestic product. More than 80 percent of this is contributed by electricity, the output of which rose by an annual average of 8 percent in the 1961–70 period. The claim of electricity production, transmission, and distribution on investment resources has been relatively high, almost 9 percent in 1968.

Financial services. Canadian financial services have developed relatively flexibly in response to the monetary needs of the economy. To operate in Canada, a commercial bank must be individually chartered by Parliament. Most normal central-banking functions are fulfilled by the Bank of Canada, which has substantial autonomy in the determination of monetary policy. The Bank of Canada implements its monetary policies through its relations with the nine chartered banks, which are at the centre of the financial system and relatively highly developed. Although there are other financial institutions—credit unions, provincial savings banks, trust and mortgage-loan companies—the chartered banks remain the main financial institutions, even in some specialized activities. They are relatively free from controls on activities involving foreign exchange.

Canada has three stock exchanges, the Montreal, the Toronto, and the Canadian. In 1971 the value of shares traded was about $6,300,000,000, up 30 percent over 1970, a rather poor year. There is extensive interpenetration between Canadian and United States stock exchanges. In the bond market the role of government-sector borrowing traditionally has been dominant.

Foreign trade. Canada's economic development has been affected by foreign trade far more than that of most developed nations. Exports and imports represented, respectively, about 23 and 21 percent of Canada's gross national product in 1971. This foreign trade, moreover, has grown rapidly, exports rising over 20 percent, imports about 17 percent, as an annual average from 1961 to 1971—the export rate rising some 34 percent faster than the growth of national output. These rates were no higher than those experienced by the six countries of the European Economic Community (EEC); among the 20-nation Western alliance known as the Organization for Economic Cooperation and Development (OECD), only Italy had such a high relative growth rate over this period. More significant was that Canada's exports of manufactured goods over the same period rose by an average annual 9 percent, as against a corresponding average of less than 8 for the OECD countries.

The mid-1960s witnessed the most striking acceleration in this growth of foreign trade, both exports and imports. This dynamism was very much associated with the integration of the Canadian market into the United States market, particularly in automotive products. Over the five years to 1970, total Canadian exports rose by more than 90 percent, while exports to the United States rose by nearly 120 percent to make up some 65 percent of total Canadian exports. Dependence on the United States was greater still in imports, about 70 percent coming from south of the border.

Irony of trading dynamism and dependence

The dependence on trade with the United States is not just a technical matter of market shares in imports and exports. In an overall sense, the degree of export dependence means that business trends in the United States feed back directly and quickly into the Canadian business sector. Changes in consumer tastes in the United States and Canada may have disproportionate effects on Canadian producers because, to the North American consumer, it is a matter of almost no relevance whether, for example, his automobile is produced in the United States or Canada. In the second half of the 1960s, economic integration between the two countries worked very much to Canada's benefit, but there is little (in theory or practice) to suggest that this will continue. Canada probably will retain, at least through the early 1970s, a small labour-cost advantage over the United States, but over a considerable area of industry, higher productivity in the United States may offset the lower Canadian wage rates.

Canada's balance of payments remains the crucially uncertain variable in overall economic prospects. As well as the uncertain prospects for merchandise trade, there are large uncertainties about the service and capital items. One major item consists of tourist accounts, which, except for the period of Expo 67, have tended to deteriorate in recent years and seem likely to produce a widening deficit in the late 1970s and early 1980s. Two other items should also continue to deteriorate: interest and dividends, which represent the recurrent cost of encouraging foreign ownership of the economy.

MANAGEMENT OF THE ECONOMY

The private sector. Canada's economy is oriented aggressively to the private sector, and only a relatively small part of the goods-and-service-producing sector—postal services, some electricity utilities, and some but not all air and railroad services—is publicly owned. Most of industry is private, and agriculture is firmly private, although it is now as dependent on government protection as it is in other Western democracies. Considerable public involvement exists in the development of natural resources, but most of it is provincial rather than federal. In many cases public involvement is minor, and control rests with private investors.

The most striking feature of the Canadian goods-producing sectors is the extent of private foreign ownership, control, and influence—certainly well over 40 percent of manufacturing production in United States-controlled plants in the early 1970s. No other major developed economy exhibits such a degree of dependence on a neighbouring economy. Almost all major private-sector non-agricultural activities are dominated by United States influences: through United States corporate ownership of Canadian assets, through the growing dependence of Canadian producers on U.S. market trends, and through the extreme dependence of Canadian corporations on U.S. financial markets for their bond issues.

Domination of Canadian industry by U.S. capital, market

To a considerable extent and in various ways, national economic policy in the 1960s was conditioned by this growing dependence of the private sector on foreign influence. Broadly speaking, the overriding influence is a marked positive correlation between growth and foreign influence. The resumption of rapid economic growth in the first half of the 1960s, which stemmed directly from massive U.S. investment in resource-based industries (petroleum, minerals, pulp and paper) and manufacturing industries (especially automobiles), would have produced an unsustainable balance-of-payments deficit if United States capital had not been keen to move into Canada and if the United States government had not been willing to exempt Canada from successive restrictive programs to protect the United States balance of payments. The most striking example of this Canadian dilemma concerns the Auto Pact. In this characteristically North American deal between government and free enterprise, the Canadian authorities traded important tariff concessions to the United States, amounting to free trade, in return for undertakings from United States auto makers that they would increase the volume of work in their Canadian subsidiaries and associated component suppliers by more than the growth rate of the Canadian market. The results in the years 1965–70 were spectacular: Canadian exports of automotive products to the United States rose by nearly 200 percent. Although imports from the United States also rose rapidly, the trade balance in automotive products swung from a Canadian deficit in 1966 to a Canadian surplus in 1970. This growth in auto production and exports was one of the principal sources of economic dynamism in the second half of the 1960s, but the price for it was a sharply increased dependence on the United States. Governmental plans to develop a Canada Development Corporation that would help to channel public savings and, hopefully, private savings into key privately controlled Canadian investments seem unlikely to be able to substitute in volume for foreign private investment. Neither can the government's assumption of powers to prevent the sale of important national assets to foreigners provide a full solution to the problem of foreign dominance of Canadian private industry.

The public sector and the role of government. By comparison with some other developed Western economies, Canadian authorities are relatively inhibited in their role in the economy. As in the United States, there is a marked political inhibition about spending public money on many social and productive sectors, though, unlike the United States, Canada does not have major military and other commitments to foreign aid or an involvement in the space race to sustain public expenditure. Thus, through much of the 1960s, government revenues exceeded expenditures, and in 1971 the government accounts were overall in surplus by more than $2,400,000,000. This predominantly deflationary fiscal position, in fact, was deliberately pursued by the authorities in the period 1968–71 as part of a campaign against inflation.

Traditional and imposed constraints on governmental involvement

This example of classical demand management in the fight against inflation reflected the relatively limited possibilities for government intervention in the economy. First, Canadian authorities have little scope for using monetary policy: Canadian monetary developments cannot move much out of line with corresponding United States developments without provoking unacceptable movements of capital across the exchanges. Second, the system of federal–provincial relations reserves to the provinces such major potential areas of policy action as government procurement, public-sector wage negotiations, and price controls.

In the late 1960s and early 1970s the federal administration tried delicately but with some limited success to strengthen federal support for regions with chronic economic problems—principally the Maritime Provinces and Quebec. One thrust of this was on training and retraining programs for labour. Foreign observers judged that the policies were more successful than in most other Western countries. A second thrust was toward attracting new investment to economically backward areas by investment tax incentives and, to some extent, by governmental participation in financing. Both programs had to operate in the early 1970s within a very unpromising context of almost historically high unemployment rates.

Taxation. Like other tax systems, Canada's has developed with its own historical peculiarities. Its most striking constraint has been the federal structure, established by the British North America Act of 1867 and shaped since then by political tensions between Ottawa and certain provinces. Canada's federal structure gives large powers to the provinces in the area of direct taxation, although (by contrast with the United States) residual powers constitutionally lie much more clearly with the federal Parliament. Thus, federal authorities, on the one hand, developed a structure of indirect taxes, and, on the other hand, in the 1950s and 1960s they came to agreements with provincial governments that balance the collection of income and corporation taxes by the central government with agreed-upon transfers to the provinces. The system remains complicated because federal–provincial cooperation varies from province to province, but the tax regime is generally uniform throughout Canada.

Federal–provincial division of taxing powers

It is difficult to characterize the Canadian taxation system in terms of its incidence between different income and social groups: it can fairly be said that it is not a particularly progressive system in the European sense of redistributing wealth, although the progressive establishment of the medicare (national social security) system and recent public-pension increases went a considerable way toward bringing the welfare system into line with developments in other affluent societies. One major non-welfare preoccupation remains the taxation of foreign ownership of Canadian corporations, but, in spite of some tougher measures introduced in 1970, the fiscal regime for foreign investors remains relatively attractive.

Trade unions and employer associations. The most striking aspect of Canadian trade unionism is its international orientation, which has a crucial effect on the development of the economy. At the beginning of 1971, 2,211,000 workers, or about one-quarter of the labour force, belonged to trade unions. Of this total, two-thirds belonged to unions with international affiliations, mainly with unions in the United States. The two largest Canadian unions, the United Steelworkers of America and the United Auto Workers, have been closely integrated with the corresponding U.S. unions.

Whether or not particular Canadian unions are closely affiliated to United States unions, the concept of parity with the United States seems likely to continue to echo through union bargaining in the 1970s. The problem about parity has been, first, that productivity levels, even in directly corresponding industries, have remained lower in Canada than in the United States and, second, that these industries remain fairly untypically high in terms of Canadian labour productivity, which sets up tensions in other sectors of the Canadian economy where parity would raise labour costs rather sharply.

POLICIES, PROBLEMS, AND PROSPECTS

Contemporary economic policies. It has been a major Canadian policy preoccupation merely to keep the Canadian economy in some sort of equilibrium in the face of the constraining influence on short-term policy of developments in the United States economy. From the mid-1960s there was a considerable policy preoccupation with reversing growing and unsustainable current deficit on the balance of payments, through restrictive fiscal and monetary policies as well as special arrangements with the U.S. government. For reasons largely beyond the control of the Canadian authorities, the balance-of-payments problem disappeared in 1970, and the authorities became preoccupied with the indirect problems of a large surplus and a still more embarrassingly large short-term capital inflow. Monetary and fiscal policy was put in reverse gear. The Canadian dollar was floated in May 1970, not downward, as might have been expected, given the country's unemployment, but upward toward parity with the United States dollar.

Attitudes toward trade balance, inflation

The turnaround in 1970 and 1971 was welcome relief, for the policies of the second half of the 1960s had seemed to many observers to be almost doomed to failure, partly because of a growing inflation. Anti-inflationary policies after the mid-1960s remained undeveloped, reflecting traditional North American attitudes toward governmental intervention and the relative difficulties of operating in a federal system. Up until 1971 the main strategy of anti-inflationary policy was to appeal for voluntary cooperation from businessmen and unions in a deflationary fiscal and monetary environment. Unions refused to cooperate in the government scheme, as proposed in 1970, and the authorities made only temporary use of the limited voluntary cooperation of business in restricting price increases.

The turnaround in the balance of payments in 1970 leading to the upward floating of the dollar had a direct, if temporary, moderating influence on prices. The authorities announced that inflation was no longer the main preoccupation (nor the balance of payments) and that the time had come to think more about realizing the growth potential of the economy, taking up the slack in unemployment and accelerating programs for promoting the development of structurally backward regions.

Economic problems and prospects. Contrary to widespread impressions, Canada's geography is less a guarantee of prosperity than a continuing handicap. Recognition of its underpopulation lies behind its traditionally liberal immigration policy. With this low population density even in the south, where most of the people live, the unit cost of providing certain social and productive services—of transportation and communications—is necessarily higher than in most economically developed countries. The strategy of encouraging rapid growth in population and labour force appeared justified to many as a long-range goal, though it created short-range policy problems in terms of absorption and employment.

Disparity between potential and actual production

The rise that has taken place in the potential output of the Canadian economy, an output that would meet the demands of the growing population for goods and services and of the growing labour force for work, has not yet been matched by a comparable rise in actual productivity. This situation was, in large measure, responsible for massive unemployment in the early 1970s, in spite of

a continuing rise in gross national product. Various fiscal moves of the United States government in 1971 to curb its balance-of-payments deficit further upset Canada's attempts to close the gap between potential and real productivity and threatened the favourable trade balance that it had achieved so recently. No foreseeable political developments in Canada were likely to lose it its place as a deliberately preferred trading partner with the United States, but Ottawa's constant concern was to increase the economic advantage of its dependence on its more populous neighbour, while decreasing the attendant risks.

In aggregate economic terms Canada's performance in recent years has been good, though in per capita income and other measures of living standards it was little different from other developed countries. Continued growth and expansion through the 1970s seemed certain but at the price of continued trade with, and consequent dependence on, the United States. Canadian officials and public opinion have tended to accept this situation almost with enthusiasm. Whether this attitude would continue was questionable. (E.I.U.)

TRANSPORTATION

An economical transportation system is essential to a country that, like Canada, is so largely dependent on its ability to export its large surpluses of bulky primary and manufactured goods. But the obstacles raised by the topography, the long but narrow east–west line of its main cities, and the overall patchiness of the population distribution produce unusual transportation problems.

Roads and highways. The populated sections of Canada are well supplied with highways and roads, but vast areas of the larger provinces and the territories that are sparsely settled are virtually without roads of any kind. Access to outlying settlements often is provided by roads built by logging, pulp and paper, and mining companies, although these are not generally available for public travel. Trans-Canada Highway was opened officially in 1962, and it became possible to drive the entire length of the 4,860-mile route from St. John's, Newfoundland, to Victoria, British Columbia. Motor vehicles number more than one for every three inhabitants. Trucking as an industry has grown spectacularly since World War II.

Railways. Canada has one of the highest railway mileages per capita of any country in the world. The main railway networks, although connecting the Atlantic and Pacific coasts, are confined to the southern part of the country. Even in the West, where they extend farthest north, the transcontinental routes do not go farther north than Edmonton and Prince Rupert. North–south regional lines, however, reach Hudson Bay at Churchill, Manitoba; James Bay at Moosonee, Ontario; and central Labrador at Schefferville, Quebec.

Two great transcontinental systems operate almost all of the railway facilities in Canada. The Canadian National Railway system, a government-owned body, is the country's largest public utility. The Canadian Pacific Railway Company is a joint-stock corporation. These systems, though highly competitive, still cooperate in many fields in which duplication of service would not be profitable. They are supplemented by a major north–south line on the west coast, the Pacific Great Eastern Railway, and a number of regional independent railways.

Total track mileage has changed little since the 1920s. Since 1959, when the main-track mileage peak reached over 44,000 miles, there has been a gradual decline, new construction being more than offset by the abandonment of unprofitable lines. Canada also has two train subway systems, one in Toronto, with about 34 miles of track, and one in Montreal, with nearly 13 miles.

Waterways. A large proportion of goods carried in Canada, in both domestic and international trade, uses water facilities for some part of its journey. The inland shipping routes are dominated by the St. Lawrence–Great Lakes waterway, which provides navigation for vessels of 25-foot draft to the head of Lake Superior, 2,342 miles (3,769 kilometres) from saltwater. It includes the major canals of Canada. There are seven locks between Montreal and Lake Ontario; the Welland Ship Canal bypasses the Niagara River and Niagara Falls between Lake Ontario and Lake Erie with eight locks; and the Sault Ste. Marie Canal and lock link Lake Huron and Lake Superior. These 16 locks overcome a drop of 580 feet from the head of the lakes to Montreal. The St. Lawrence Seaway accommodates all but the largest oceangoing vessels, making the upper St. Lawrence and Great Lakes area open to 80 percent of the world's maritime fleet.

St. Lawrence–Great Lakes and canal systems

Subsidiary Canadian canals or branches include the St. Peters Canal between Bras d'Or Lakes and the Atlantic Ocean in Nova Scotia; the St. Ours and Chambly canals on the Richelieu River in Quebec; the Ste. Anne, Carillon, and Grenville canals on the Ottawa River; the Rideau Canal between the Ottawa River and Lake Ontario; and the Trent and Murray canals between Lake Ontario and Georgian Bay in Ontario. The commercial value of goods carried through these canals is not great, but they are maintained to control water levels and permit the passage of small vessels and pleasure craft. The Canso Canal, completed in 1957, permits shipping to pass through the causeway connecting Cape Breton Island with the Nova Scotia mainland.

Within most of the St. Lawrence–Great Lakes system, the carriage of goods or passengers from one Canadian port to another is restricted to ships registered in Canada. Elsewhere, it is open to all Commonwealth ships.

The interchange of cargo from land to water routes and vice versa is handled at many ports on the seacoasts and along the St. Lawrence–Great Lakes waterway. Nine of the principal harbours are administered by a National Harbours Board, 11 others by commissions that include municipal as well as federal appointees. In addition, there are about 300 public harbours, all of which are under the supervision of the Ministry of Transport. An overall construction program keeps Canadian harbour facilities in line with requirements. This includes aids for seaway channels, new and improved wharves and transit sheds, and additions and improvements to grain elevators and other facilities. The federal government owns and operates dry docks at Lauzon, Quebec, and Esquimalt, British Columbia, and leases one at Kingston, Ontario.

Airways. Vast distances, rugged terrain, and extreme variations in climate have shaped the development of civil aviation in Canada, and air transport is of tremendous importance. Two major airlines, Air Canada and Canadian Pacific Airlines, form the nucleus of Canada's domestic freight and passenger air service. Five major domestic air carriers operate other scheduled commercial services. Some 500 small airlines operate nonscheduled services, many of them to parts of Canada that are inaccessible by other means of transportation. More than 1,580 airports and landing facilities have been established, and a network of radio aids is maintained to facilitate en route navigation and landings under instrument conditions. Weather services are provided by the federal Department of Transport.

Domestic and international flight and pipeline services

Both Air Canada and Canadian Pacific Airlines operate international routes. In addition, in 1970 there were 32 Commonwealth and foreign air carriers licensed for internationally scheduled commercial services into Canada.

Pipelines. Pipelines are a major element in Canada's vast transportation network. Growth has been so rapid since 1950, when pipelines were a negligible factor in intercity freight traffic, that oil and gas pipelines now account for about one-fourth of intercity freight ton-miles. The world's longest oil and gas pipelines, nearly 2,000 miles in length, have been built to link the oilfields and gasfields of Alberta and Saskatchewan to major cities as far east as Montreal, and two major pipelines several hundred miles in length cross the Rocky Mountains and supply the lower mainland of British Columbia and the Pacific Northwest of the U.S. In 1961 a 1,100-mile pipeline was completed from Alberta to California, 400 miles of which were in Alberta and British Columbia. The oil pipeline transport industry moves crude oil through 18,000 miles of pipeline from the oilfields in Alberta, Saskatchewan, and Manitoba to the major refineries located across Canada, while the gas-pipeline transport industry has about another 6,800 miles of pipeline.

IV. Administration and social conditions

Canada is an independent federal parliamentary state, the ruler of which is the reigning monarch of the United Kingdom. The state was established by the British North America Act of 1867, which united the colonies of Nova Scotia, New Brunswick, and Canada into the provinces of Nova Scotia, New Brunswick, Quebec, and Ontario. Rupert's Land and the Northwest Territories were acquired from the Hudson's Bay Company in 1869, and from them Manitoba was created and admitted to the Confederation as a province in 1870; its extent was enlarged by adding further areas from the territories in 1881 and 1912. The colonies of British Columbia and Prince Edward Island were admitted as provinces in 1871 and 1873, respectively. In 1905 Saskatchewan and Alberta were created from what remained of the Northwest Territories and admitted to the Confederation as provinces. In 1912 the provinces of Quebec and Ontario were enlarged to their present limits by adding areas from the Northwest Territories. Finally, in 1949, Newfoundland and its dependency, Labrador, joined the Confederation following a popular referendum. Yukon Territory in 1898 was separated from the Northwest Territories, the remainder of which, in 1920, was divided into three provisional districts—Mackenzie, Keewatin, and Franklin. Thus, Canada now consists of ten provinces and two territories, all of which vary greatly in size.

STRUCTURE OF GOVERNMENT

Although the British North America Act is popularly regarded as the constitution of Canada, it is not an exhaustive statement of the laws and rules by which Canada is governed. The constitution of Canada in its broadest sense includes other statutes of the Parliament of the United Kingdom; statutes of the Parliament of Canada relating to such matters as the succession to the throne, the demise of the crown, the governor general, the Senate, the House of Commons, electoral districts, elections, and royal style and titles; and statutes of provincial legislatures relating to provincial legislative assemblies.

Preservation of bilingualism

The preservation of both the English and French languages was safeguarded by the provision that either language may be used in the debates of the Parliament of Canada and of the legislature of Quebec and in any federal court in Canada and that both languages shall be used in the respective records and journals and in the published acts of the Parliament of Canada and of the National Assembly of Quebec. It also guarantees to Quebec the right to a Roman Catholic school system under Roman Catholic control and to exclusive jurisdiction over property and civil rights, and safeguards preservation of the French system of civil law in the province.

Canada makes its own treaties; appoints its own ambassadors and other representatives abroad; levies its own taxes; makes its own laws, which are executed by a government dependent on the will of a majority of the people; maintains its own military forces; and is an independent member of the United Nations.

Federal legislative and executive authority. Federal legislative authority is vested in the Parliament of Canada, which consists of the sovereign of Canada (constitutionally not the same as the sovereign of the United Kingdom although physically perhaps the same person), the Senate, and the House of Commons. The Senate has 102 members, who are appointed on a provincial basis and may hold office until they are 75 years of age. The 264 members of the House of Commons are elected by the people of Canada for maximum terms of five years.

The British North America Act divided legislative and executive authority between Canada, on the one hand, and the several provinces, on the other. The Parliament of Canada was assigned authority over control of the armed forces, the regulation of trade and commerce, banking, credit, currency and bankruptcy, criminal law, postal services, fisheries, patents and copyrights, the census and national statistics, the raising of money by taxation, and, in the field of communication, such matters as navigation and shipping, railways, canals, and telegraphs. In addition, the federal government was endowed with a residual authority in matters beyond those specifically assigned to the provincial legislatures and including the power to make laws for the peace, order, and good government of Canada. Both the House of Commons and the Senate must pass all legislative bills before they can receive royal assent and become law. Both bodies may originate legislation, but only the House of Commons may introduce bills for the expenditure of public funds or the imposition of any tax.

The personal representative of the crown in Canada, the governor general, is appointed for a term of about five years. He exercises the executive authority of the monarch in relation to the federal government. On the recommendation of his responsible advisers, he summons, prorogues, and dissolves Parliament, assents to bills, and exercises other executive functions.

The leader of the party winning the most seats in a general election is called upon by the governor general to form a government. He becomes the prime minister and generally chooses party colleagues from among the elected members to form the Cabinet. If he wishes to have in his Cabinet someone who is not a member of the House of Commons, that person must secure a seat in the House within a short time through a by-election or receive appointment to the Senate by the governor general upon the nomination of the prime minister. Almost all Cabinet ministers are also heads of executive departments of the government, for the work of which they are responsible to the House of Commons. The Cabinet is responsible for determining all important policies of government and securing the passage of such legislation, financial measures, and administrative provisions as their supporters may approve.

Selection of ministers of the crown

The ministers of the crown, as members of the Cabinet are called, are chosen generally to represent all regions of the country and its principal cultural, religious, and social interests. Although they exercise executive power, they are collectively responsible to the House of Commons and can remain in office only so long as they retain the confidence of the House. The choice of the Canadian electorate not only determines who shall govern Canada but also, by deciding which party receives the second largest number of seats in the House, designates which of the major parties becomes the official opposition. The function of the opposition is to offer intelligent and constructive criticism of the existing government.

Provincial and territorial government. Similar political institutions and constitutional usages operate in the government of the ten provinces as in that of the nation as a whole. In each province the sovereign is represented by a lieutenant governor appointed by the governor general in council, usually for a term of five years. The powers of the lieutenant governor in the provincial sphere are essentially the same as those of the governor general in the federal sphere.

The legislature of each province is unicameral and comprises, in addition to the lieutenant governor, a legislative assembly elected for a term of five years. The conventions of Cabinet government operate as in the federal House of Commons. The provinces have powers embracing mainly matters of local or private concern such as property and civil rights, education, civil law, provincial company charters, municipal government, hospitals, licenses, management and sale of public lands, and direct taxation within the province for provincial purposes.

Territorial administration

The vast and sparsely populated regions of northern Canada lying outside the ten provinces—Yukon Territory and the Northwest Territories—are administered by the federal government, but they have both elected representation in the House of Commons and a measure of local self-government. The local government of Yukon Territory is composed of a commissioner appointed by the federal government, and a legislative council of seven members elected for a term of three years. The government of the Northwest Territories is vested in a commissioner assisted by a legislative council of 14, of whom ten are popularly elected and four are appointed by the federal government, all for four-year terms. General responsibility for the administration of the Northwest Terri-

tories, for Eskimo affairs, and for the resources of both territories rests with the federal Department of Indian Affairs and Northern Development.

Federal–provincial relations. A major part of Canada's constitutional development has occurred gradually through judicial interpretation and constitutional convention and through executive and administrative coordination at the federal and provincial levels of government. Through such devices, the national and provincial legislatures have been able to retain their separate jurisdiction over different aspects of the same matter. Only in such an approach can Canada achieve an accommodation that gives fair assurances to the aspirations of the provinces without disrupting the integrated national structure of the Canadian Confederation.

The French in Canada

Of the provinces, Quebec has the most pronounced aspirations. Only there are citizens of French origin in the majority. They have overflowed into Ontario, particularly in the north and the Ottawa valley, and into northern New Brunswick. Smaller concentrations in Nova Scotia and southern New Brunswick are descendants of those who formed the early French colony of Acadia. Elsewhere, people of French origin are scattered, although they form locally important minorities.

Their survival in Quebec as a distinctive and majority group is not hard to explain in light of the historical constitutional guarantees. They have therefore developed a culture of their own that differs in many respects from that of the rest of Canada—and, indeed, from the rest of North America. By instinct and design they have kept themselves French and Roman Catholic. The course of politics for them is not primarily material prosperity or liberty in the Anglo-Saxon sense but ethnic survival. The political consequences of this are that they tend to act as a unit in national matters and support whichever party is paying attention to their claims. It has also led, at times, to strong movements in favour of political secession of the province from the Confederation. At the national level it has also led to efforts to create a dual culture in Canada rather than simply preserve two cultures.

Thus, the Official Languages Act of 1969 declares that the English and French languages "enjoy equality of status and equal rights and privileges as to their use in all the institutions of the Parliament and Government of Canada." The significant addition is "the institutions of . . . Government of Canada," since this embraces all federal offices and organizations throughout the country. Pursuant to this act, a commissioner of official languages was appointed to ensure compliance with the intent of the act. Not only has this increased opportunities throughout the country for Canadians of French origin, but also it may increase the desire of other Canadians to speak French and interest themselves in French culture.

Local government. Since government at the municipal level falls under the jurisdiction of the provinces, there are ten distinct systems of municipal government in Canada, as well as many variations within each system. The variations are attributable to differences in historical development and in area and population density. Thus, the legislature of each province has divided its territory into geographical areas known generally as municipalities and, more particularly, as counties, cities, towns, villages, townships, rural municipalities, or municipal districts, although the county system as understood in Britain or the U.S. is present only in southern Ontario and southern Quebec. The nearly 4,600 incorporated municipalities in Canada have various powers and responsibilities suited to their classification. A municipality is governed by an elected council, the head of which may be called mayor, reeve, warden, or overseer; the other members may be known as controllers, aldermen, or councillors. The responsibilities of the municipalities are generally those most closely associated with the citizen's everyday life, his well-being, and his protection. The sparsely populated areas of the provinces are usually administered as territories by the provincial governments; only about one-fifth of 1 percent of Newfoundland is municipally organized, one-third of Quebec, one-tenth of Ontario, and the southern parts of the western provinces.

Justice. Canadian courts of law are independent bodies. Each province has its police, division, county, and Supreme courts, with right of appeal being available throughout provincial courts and to the federal Supreme Court of Canada. At the federal level there is also an Exchequer Court, in which proceedings instituted by or against the crown may be launched and from which appeals may be made to the Supreme Court. All judges, except police magistrates and judges of the courts of probate in Nova Scotia and New Brunswick, are appointed by the governor general in council, and their salaries, allowances, and pensions are fixed and paid by the Parliament of Canada. They cease to hold office at age 75.

Legislation concerning criminal law and the procedure in criminal matters is under the jurisdiction of the Parliament of Canada. The provinces administer justice within their own boundaries, including the organization of civil and criminal codes and the establishment of procedure in civil matters.

Police and the military. The police forces of Canada are organized in three groups, the federal force, called the Royal Canadian Mounted Police (RCMP), the provincial police, and the municipal police. The Royal Canadian Mounted Police—or Mounties, one of Canada's best-known organizations—was established in 1873 for service in the Northwest Territories of that time. It is still the sole police force in the Yukon and Northwest territories, but it also has complete jurisdiction of the enforcement of federal statutes throughout Canada, which includes the control of narcotics. The maintenance of peace, order, and public safety and the prevention and investigation of criminal offenses and of violation of provincial laws are provincial responsibilities. Ontario and Quebec have their own provincial police forces, but all other provinces engage the services of the Royal Canadian Mounted Police to perform these functions. Provincial legislation makes it mandatory for cities and towns and for villages and townships with sufficient population density and real property to furnish adequate policing for the maintenance of law and order in their communities. Most large municipalities maintain their own forces, but others engage the provincial police or the RCMP, under contract, to attend to police matters. In addition, the Canadian National Railways, the Canadian Pacific Company, and the National Harbours Board have their own police forces.

Royal Canadian Mounted Police

The control and management of all matters relating to national defense, including the armed forces, are the responsibility of the minister of national defense. The Canadian armed forces are organized on a functional basis to reflect the major commitments assigned by the government. They are formed into a Canadian Forces Headquarters, located in Ottawa, and eight major commands. Mobile Command provides military units suitably trained and equipped to support United Nations or other peacekeeping or peace-restoring operations; to provide ground forces, including tactical air support, for the protection of Canadian territory; and to maintain operational readiness of combat formations in Canada required for the support of overseas commitments. Maritime Command is to defend Canadian interests from assault by sea, to support NATO by assisting in conducting anti-submarine warfare, and to provide any sealift required by Mobile Command. Air Defence Command participates with the United States in the air defense of North America. Air Transport Command provides air transport support to Canadian forces everywhere and conducts search-and-rescue operations in Ontario and Quebec. Training Command conducts search-and-rescue operations in Manitoba, Saskatchewan, and Alberta and provides individual training for the forces. The Canadian Forces Communications Command provides fixed communications networks for the forces as well as a national communications system for survival operations. Canadian Forces Europe embraces the Canadian forces allocated to support NATO.

THE SOCIAL MILIEU

National attitudes in the social sphere are derived from the English poor law and of charity provided by religious institutions and voluntary agencies. These have been

modified, however, by the transformation of the population from a predominantly rural–agricultural to an urban–industrial society and the social stresses engendered by two world wars, influences that have brought about the need for intervention by government. The British North America Act assigns responsibility for charities and charitable institutions to the provinces, but it is not clear on other aspects of social welfare. The result has been a diversity of joint federal–provincial programs to meet social needs.

Standards of living. In 1972, average weekly wages and salaries were highest in construction and mining and lowest in clothing manufacture and the service occupations. The Canada Labour Code provides for a minimum hourly wage of $1.75 for an eight-hour day and 40-hour week, eight general holidays with pay, and an annual vacation of two weeks with pay. Women may not be paid at a rate less than males for identical or substantially identical work, and discrimination in employment because of race, colour, religion, or national origin is prohibited. The personal income per capita was one of the highest in the world; but families who spend more than 70 percent of their income for food, clothing, and shelter are considered "poor," in a relative sense, and on this basis at least one Canadian in five suffers from poverty.

The personal income per capita varies markedly from province to province. In Ontario and British Columbia it is higher than the national average, while the Atlantic Provinces lag behind the rest of the country. There, average incomes are only about 60 percent of those of Ontario, a disparity that has changed little in 40 years. The incidence of low incomes is also higher in the Atlantic region, but the problem of income disparity is not only a regional one but also an urban one.

Health and welfare. Provincial governments bear the main responsibility for health and welfare services, administering a broad range of activities either directly or in cooperation with the municipalities, to which considerable authority often is delegated. Such activities include health insurance; general public-health services, primarily of a preventive nature; services for specific diseases or disabilities, combining prevention, treatment, and rehabilitation services related to general medical and hospital care; and welfare services. The health professions and voluntary agencies and institutions supply services, initiate new activities, and stimulate better standards. The role of the federal government is primarily to provide consultant, coordinating, and financial assistance. A federal Medical Care Act (1968) provides for federal contributions to medical-care plans of participating provinces provided such plans are comprehensive with regard to medical services, have universal coverage, are administered by a public authority, and allow portability of benefits between provinces. The federal Hospital Insurance and Diagnostic Services Act (1957) allows for federal contributions to the costs of specified hospital services and now covers 99.5 percent of the insurable population of Canada. The federal government also has long-established responsibilities that include the administration of food-and-drug legislation (including narcotics control), quarantine, immigration and sick-mariners services, and the health and welfare of Indians, Eskimos, and past and present members of the Canadian armed forces.

Federal–provincial coordination of social activity

A number of social security and social assistance programs exist. The Canada Pension Plan provides retirement, disability, and survivors benefits. The Old Age Security Act provides a monthly pension to all persons 65 years of age or over, while the guaranteed-income supplement provides additional income for old-age pensioners. Financial aid is available under provincial or municipal auspices to persons in need and their dependents.

Housing. Although the government originally entered the field of housing in 1918, the present role of the federal government in housing stems from the National Housing Act (1954), an act to promote the construction of new houses, the repair and modernization of existing houses, and the improvement of housing and living conditions, as well as its subsequent amendments. Central Mortgage and Housing Corporation, a crown agency, administers the act and coordinates the activities of the federal government. These activities include such matters as insured mortgage loans, direct loans for homeownership and rental housing, financial assistance for the elimination or prevention of water and soil pollution, public housing, urban renewal, and research. All provinces have complementary legislation providing for joint federal–provincial housing and land-acquisition projects, and most have special legislation with respect to housing.

Education. Under the British North America Act, the organization and administration of public education are provincial responsibilities. The federal government is directly concerned only with the provision of education in the Yukon and Northwest territories, in Indian schools throughout Canada, for inmates of federal penitentiaries, for the families of members of the Canadian forces on military stations, and for the operation of three military colleges. In addition, it finances vocational training of adults and provides financial support to the provinces for the operating costs of postsecondary education.

Because each of the ten provinces has the authority and responsibility for organizing its education system as it sees fit, policies and practices vary from province to province, but each has a department of education headed by a minister who is a member of the provincial Cabinet. In addition, Ontario has a Department of Colleges and Universities with a minister of its own. Most Canadian children enter an eight-grade elementary school at age six. At about 14 years of age, nearly 90 percent of those who entered grade one enter a regular four- or five-year secondary school. Graduation from secondary school may lead to college or university.

Canada has over 70 institutions of higher education, excluding those in theology, with degree-granting powers. They range from institutions with a single faculty and enrollments of a few hundred to institutions with many faculties and research institutes and over 15,000 students, such as the Université de Montréal, the University of Toronto, and the University of British Columbia.

The oldest university in Canada, Laval, in Quebec, was founded during the French regime. Universities in English-speaking Canada were established after the American Revolution. King's College, Nova Scotia, and what is now the University of New Brunswick were patterned after King's College (now Columbia University) in pre-Revolutionary New York City. Most of the other universities in pioneer days were begun by churches, but almost all have since become secular and almost entirely financially dependent on the provincial governments. Others, particularly in the western provinces and Newfoundland, were established by provincial governments. There are no real private universities in Canada and none that are analogous to the land-grant institutions in the United States. A somewhat unusual characteristic has been the system of "affiliated colleges" linked to a "parent" degree-granting institution even though separated from it physically. English is the language of instruction at most places, French in several, and a few are bilingual.

V. Cultural life and institutions

THE ARTS AND RECREATIONS

The development of the arts in Canada today reflects a geographical and cultural pattern as well as the changes that have come to a rapidly growing and rapidly urbanizing country. The existence of two dominant cultural traditions has led to a certain diversification of artistic endeavour, a diversification encouraged further by groups of other national origins and a widely dispersed population. As there are several metropolitan centres, so there are several focal points for artistic activity.

Since 1950 economic growth has provided all Canadians with greater means for the practice and enjoyment of the arts, and the influx of immigrants from many countries has increased both the audience and the pool of available talent. Each new event in the artistic life of the country has aroused greater interest, and with it has come more substantial financial support from public and private sources. All provincial governments except New-

foundland, Prince Edward Island, and Manitoba provide some form of financial assistance for the arts, amateur and professional, and for cultural organizations within their borders. In 1968 New Brunswick established an office of cultural affairs; the British Columbia Cultural Fund was established in 1967; in 1962 the Ontario government set up the Council for the Arts; a similar agency was established in Quebec in 1961; and Saskatchewan has had its Arts Board since 1949. At the national level, the Canada Council was established in 1957 "to foster and promote the study and enjoyment of, and the production of works in the arts, humanities and social sciences." Its income is derived from a $50,000,000 fund with which it was endowed at its creation, an annual grant from the federal government, and private donations. Its assistance to the arts in 1969–70 amounted to nearly $17,800,000. The Canada Council also supports the Canadian National Commission for the United Nations Educational, Scientific, and Cultural Organization.

Literature. The first truly Canadian literary works were written in French by explorers, missionaries, and settlers, and many of them became the inspiration of subsequent writings. Some were notable literature, such as Marc Lescarbot's *Histoire de la Nouvelle France* (1609). The years following were also marked by some works that have become classics—William Kirby's *Golden Dog* (1877), Robert W. Service's *Trail of '98*, the humorous works of Stephen Leacock, and the long series of *Jalna* novels by Mazo de la Roche. Natural and vigorous French-Canadian writing was held back by a sense of isolation, strict Roman Catholicism, a small and relatively unsophisticated reader market, and a tendency to favour academic and formal literary styles and themes. The 1940s saw the emergence of Canadian writers of the first rank. Hugh MacLennan established himself as a writer of international importance with *Barometer Rising* (1941) and *Two Solitudes* (1945) and Thomas Raddall with *His Majesty's Yankees* (1942). Gabrielle Roy's novel *Bonheur d'Occasion* (1945) was an immediate success, and *Le Survenant* (1945), by Germaine Guèvremont, placed its author in the forefront of French-language novelists, both in Montreal and Paris. Still later came the novels of Robertson Davies and the satires of Mordecai Richler. The French-Canadian novel, long handicapped by sentimentality and stilted prose, went beyond even hard realism into the psychological realm with Marie-Clair Blais's *La Belle Bête* (1959) and *Tête blanche* (1960). Although the growth of competent novel writing was the main feature of Canada's literary scene after World War I, the period saw marked changes in the work of Canadian poets. John McCrae's *In Flanders Fields* (1919) was the only important Canadian verse related to the 1914–18 conflict, but since then E.J. Pratt, Earle Birney, James Reaney, Irving Layton, Anne Hebert, Pierre Perrault, and Gilles Vigneault, among others, have attracted widespread attention to their work.

Visual arts. The visual arts in Canada today present a scene of unprecedented activity. In some ways painting has been the most successful of all the arts in the expression of Canada's national identity in that some Canadian painting has a manner of portraying locale and atmosphere that sets it apart. Most of this specific content appeared from the first decade of the 20th century through the 1930s. Especially notable were the Group of Seven, who influenced the succeeding generation through their enthusiastic portrayals of the Canadian landscape. Today, 17 universities offer degree programs in fine art.

Although painting has received most of the attention in the art world of Canada, sculpture and the handicrafts have been in evidence since earliest times and only now are receiving adequate public attention. Prominent in contemporary sculpture exhibitions are stone carvings of the Eskimo people, while among the most interesting of museum-guarded sculptures are the totem-pole carvings of the Indians of the west coast.

Art collections and galleries

Along with these developments has come the establishment of art collections and art galleries. The National Gallery of Canada in Ottawa, dating from 1880, includes not only the most extensive and important collection of Canadian art in existence but also collections built up along international lines to give an indication of the origins from which Canadian tradition is developing. It also circulates exhibitions to several hundred centres in the country each year. In addition, 20 major cities have public art galleries, and some 25 arts councils and university galleries house important collections.

Music. Canadian music failed to reach beyond the borders before 1940, but the years before this prepared the way for the intense musical activity that followed World War II. Earlier developments included the music-festival movement that began in 1908 in Edmonton and now claims almost 100 units across the country. Many performers who began as amateurs in these festivals went on to achieve professional status. Some Canadian performers have become well-known internationally—among them pianist Glenn Gould and Metropolitan Opera performers George London and Jon Vickers.

Somewhat similarly, civic symphony orchestras have developed since 1902, when L'Orchestre Symphonique de Québec was founded. Today, most major cities have their own, particularly in the broadcast centres, where musicians can be sustained by radio and TV assignments. Those of Toronto and Montreal have become fully professional and internationally recognized. In 1962 the Montreal Symphony became the first professional symphony orchestra from Canada to play in Europe.

Canadian school of composers

The years since 1940 also have seen the development of a school of Canadian composers. Providing thematic material for the new composers were assiduous collectors of early Canadian folk songs. Paralleling these developments has been an expansion in music education in the schools and universities. Today 32 Canadian universities have departments, schools, or faculties of music.

Choral music and choral societies are to be found in many Canadian cities and towns. Opera in Canada has benefitted from these developments. Toronto, Montreal, and Vancouver enjoy brief but regular seasons. The Toronto-based Canadian Opera Company makes extensive tours, often to remote parts of the country.

The performing arts. Ballet has been a matter of public interest only since the 1930s, but today there are three top-ranking professional companies—the Royal Winnipeg Ballet, founded in 1939, the National Ballet of Canada, founded in 1951 with headquarters in Toronto, and Les Grands Ballets Canadiens, founded in 1957 in Montreal. Les Feux-Follets, also headquartered in Montreal, is essentially a folk ensemble reflecting the founding French heritage of Quebec. The National Ballet is the largest and the most widely travelled, touring not only Canada but the United States as well.

Canada long had no professional theatre in the accepted sense, and yet from coast to coast a continuous, successful theatre movement took place under amateur auspices and involved Canadian playwrights and performers. The Little Theatre movement spread during the 1920s, and by 1933 the Dominion Drama Festival had come into being. A national festival, the climax of a series of regional competitive festivals, is held each year in a different city. The movement has inspired a knowledgeable and appreciative theatre audience and provided the training ground for many actors now in professional ranks.

The professional theatre developed from several year-round repertory groups such as Les Compagnons du Saint Laurent (Montreal), the New Play Society (Toronto), and Totem Theatre (Vancouver) and by a long line of summer-theatre ventures in the 1935–65 period. Of these the John Holden Players (Winnipeg, Manitoba, and Bala, Ontario), Mountain Playhouse (Montreal), Straw Hat Players (Port Carling, Ontario), and the Theatre-Under-the-Stars (Vancouver) are noteworthy. In 1952 the Stratford Shakespearean Festival was launched in Stratford, Ontario. In 1957 a 2,200-seat theatre was completed, and by the mid-1960s three Shakespearean plays, two modern plays, one opera, one ballet, and numerous concerts were presented in repertory during the summer season. Another celebrated summer festival is the Shaw Festival at Niagara-on-the-Lake, founded in 1964.

Influence of the Stratford Shakespearean Festival

The enthusiasm and excitement engendered by the suc-

cess of these ventures set off a new Canadian determination to have professional theatre on a regular and nationwide scale. More than 12 spectacular new theatres have been built across the country since 1958, among them Confederation Centre in Charlottetown (Prince Edward Island), Place des Arts (Montreal), National Arts Centre (Ottawa), O'Keefe Centre and St. Lawrence Centre for the Performing Arts (Toronto), the Centennial buildings of Winnipeg and Saskatoon, the Jubilee theatres of Edmonton and Calgary, and the Queen Elizabeth Theatre in Vancouver.

Film making. The impact of television on the film-production industry can be readily assessed by the fact that about three-quarters of the films produced as features, advertising, trailers, newsclips, and newsreel stories by Canada's private and governmental film-making agencies were for television in 1970. About 40 percent were made in French and another 10 percent in languages other than English and French. The National Film Board was established by the federal government in 1939 to produce films, filmstrips, and still photographs that reflect the life and thought of Canada and to distribute them both internally and abroad. It has earned international acclaim for the imaginativeness as well as the artistic and technical excellence of its work. During the fiscal year 1968–69, it produced 730 works, over half of which were motion pictures, while at home and abroad its films were seen by audiences of several hundred million. It won 76 awards from film festivals around the world to bring the number of its awards to well over 500. In 1967 the federal government established a Canadian Film Development Corporation to foster and promote a feature-film industry through investment in productions, loans to producers, grants to film makers and film technicians, and advice and assistance in administrative matters.

Work of National Film Board

Sports. Several of the sports played in Canada are derived from those of the indigenous peoples or the early settlers. Lacrosse, adopted as Canada's national game at the time of Confederation, was played by Indians in all parts of the country and adopted by later immigrants. By 1867, definite rules had been established, and the game had become organized. Ice hockey is also Canadian in tradition, leadership, and playing ability. It remains Canada's most popular winter sport on outdoor and indoor rinks across the nation, and a large percentage of Canadian boys learn to skate almost as soon as they can walk. The sport, in its early organizational stages at the time of Confederation, originated in Nova Scotia in 1828. Curling is a popular indoor ice sport believed to have been introduced from Scotland in 1759.

Other sports have been more strongly influenced by the recreational interests of the U.S. and Europe. Baseball and U.S.-style football are two examples of this. Their development in Canada owes a great deal to the influence of both radio- and television-network broadcasting. The professional Canadian league plays a football only slightly different from that of the U.S., while Canadian cities have franchises in professional hockey and baseball.

PRESERVATION OF THE PAST

In 1919 the federal government established a Historic Sites and Monuments Board to advise on matters of national historic importance, with particular reference to commemoration or preservation. In the early 1970s most of the 36 national historic parks were military or fur-trading forts or historic buildings or reconstructions of historic buildings; most had museums. They ranged from the 13,000-acre site around the reconstructed Fortress of Louisbourg, Nova Scotia, to the boyhood home of former prime minister W.L. Mackenzie King, and a reconstructed theatre of the "Gold Rush" days in Dawson, Yukon Territory. Two were preserved Yukon river boats. Each province had a similar policy. In the West many of the marked sites, such as Head-Smashed-In Buffalo Jump in Alberta, recalled the Indian period. Several provinces had restored or reconstructed pioneer communities. British Columbia's first provincial historic park was the restored gold-mining town of Barkerville. In Ontario, Ft. Sainte-Marie, the headquarters of the Jesuit mission to the Huron Indians in the 17th century, was restored.

Historic sites and museums

But many of the national treasures were in museums and galleries that paid special, but not exclusive, attention to Canada. Four such institutions were maintained by the federal government: the National Museum of Natural Sciences, the National Museum of Man, the National Museum of Science and Technology, and the National Gallery of Canada, which included the most important and extensive collection of Canadian art in existence. All were in Ottawa, as was the Public Archives of Canada, whose purpose it was to assemble and make available source materials relating to the nation's history. Most of the provinces had similar institutions, and nearly all had a provincial museum. The Royal Ontario Museum in Toronto held international stature. Others, such as the Saskatchewan Museum of Natural History, were newer and more concerned with provincial traditions. Some of the art galleries were municipally or privately financed and operated.

BROADCASTING

Canada's broadcasting industry ranks among the world leaders in terms of broadcasting and receiving equipment and in coverage, quality, and variety of programs. The large number of transmitters is related to the numerous services provided and the fact that the main services must be broadcast in English and French. There are two national networks for both radio and television, one in English and one in French. In addition, five regional radio programs serve the Atlantic Provinces, Quebec, Ontario, the Prairie Provinces, and the west coast, while local radio broadcasts are designed for both rural and urban audiences. Programs in other languages are provided by a number of stations for Canadians recently arrived from other parts of the world, and some radio broadcasts originate in several Indian and Eskimo languages.

Thus, the complexity of the Canadian broadcasting system stems from the vast geography of the country as well as the diverse origins and interests of the people. The proximity of the population to the United States also has its effect. From the beginning, competition from United States stations has been a spur to Canadian radio broadcasting, and they claim a particularly important part of the audience in Canadian cities close to the border. The same is true of television, There is no doubt, for instance, that the introduction of colour television in Canada was accelerated to meet competition from across the border.

Radio. Since the opening program from Canada's first radio station was beamed into a few Montreal homes in 1919, radio service has grown to the point at which it is available, in some form, to 99 percent of all Canadians. This has been accomplished by a unique combination of private and public enterprise. The publicly owned Canadian Broadcasting Corporation (CBC), a federal crown agency, maintains 46 radio stations and 181 low-power relay transmitters; in addition, some 370 privately owned stations are in operation. Many of the latter are affiliated with the CBC and help to distribute national radio services over networks operated by the CBC. The CBC operates an international service to provide information abroad. Shortwave programs are transmitted daily to Europe, Latin America, Africa, the Caribbean area, and Australasia in 11 languages—English, French, German, Spanish, Portuguese, Czech, Slovak, Russian, Ukrainian, Polish, and Hungarian. The shortwave schedule includes news bulletins, news commentary, talks, interviews, press reviews, and various features on cultural and business activities in Canada. The international service also provides broadcasting organizations in other countries with music and spoken-word transcriptions and relays. Works by Canadian composers and performances by Canadian musicians are made available in a variety of categories, including classical, popular, jazz, and folk music. Dramas, talks, documentaries, and other features are included in a wide range of spoken-word transcriptions in English, French, Spanish, and Portuguese. News and special events programs are relayed upon request.

Combination of public–private TV

The CBC established a northern service in 1958 to meet

the needs of the widely scattered population of the North. Listeners in the more remote areas are able to hear daily shortwave broadcasts of the northern service. Regular broadcasts are made in Indian and Eskimo languages in addition to French and English.

Television. Canada has about 450 television stations, 138 operated by the CBC, the remainder privately operated. As in radio, many of the latter are affiliated with the CBC and help to distribute national programming over CBC networks. Over 77 private stations form the CTV Television Network Ltd. The two networks reach over 96 percent of the population. In 1971 there were 353 cable-television systems in operation.

The regulation and supervision of all aspects of the broadcasting system rest with the Canadian Radio–Television Commission. It comprises five full-time and ten part-time commissioners, representative of the various parts of Canada, and regulates the establishment and authorization of networks and stations, the activities of the CBC and the privately owned stations, and the relationship between them. CBC program policy serves a twofold purpose. Besides fulfilling audience wants and needs, the corporation develops talent in all fields. Actors, writers, and performers are given opportunities to expand their creative talents through media that offer audiences of a size not possible in Canada through other outlets. During one recent year, some 30,000 Canadian artists, musicians, commentators, and performers of all kinds appeared on CBC radio and television.

PUBLISHING

The Canadian press: extensive, multilingual

Every weekday, 120 daily newspapers are published in almost 4,600,000 copies. More than four-fifths appear in the afternoon. Over 100 are published in English, 12 in French, and six in other languages. The trend in daily-newspaper publication is toward chain ownership, mainly by three large chains, one of which owns 27 papers; editorial policy, however, is developed at the local level. Most newspapers have no competition in their own areas; only 14 cities have more than one paper. In addition to the dailies, 900 weekly papers are published, including about 170 in French and over 80 in foreign languages.

Behind the newspapers lie two great news-gathering organizations, the Canadian Press and the United Press International of Canada. The former, a cooperative venture formed in 1917, is owned and operated by the Canadian newspapers. It collects and delivers news and photographs of interest to newspapers and radio stations throughout the nation and transmits items of worldwide interest through reciprocal arrangements with Reuters, the British agency; the Associated Press, the United States cooperative; and Agence France-Presse, the French service. United Press International of Canada serves North America, South America, Europe, and Australia with news from Canada, as well as subscribers and private broadcasting stations in Canada. Agence France-Presse maintains offices in Montreal and Ottawa, and several foreign newspapers have agencies in Ottawa to interpret Canadian news for their readers.

Daily newspapers alone contribute about 60 percent of the revenue received from Canadian periodical publications. Over 850 magazines and related publications were published in 1970, of which over 200 were classed as trade, industry, and related publications and over 100 as educational. But most of the general magazines that circulate in Canada are from the United States. It is believed that this competition can be met only by providing protection to Canadian publications, though many argue that to do so on a large scale would interfere with the traditional freedom of the press. Canadian book publishing suffers from the same set of circumstances, and the number of wholly Canadian book-publishing companies has declined dramatically in recent years.

BIBLIOGRAPHY. PIERRE CAMU, E.P. WEEKS, and Z.W. SAMETZ, *Economic Geography of Canada* (1964), more economic than geographical at start, serving as an introduction for a 68-region system for Canadian regional analysis; CANADA, DEPARTMENT OF FORESTRY, *Native Trees of Canada*, 6th ed. (1961), invaluable for the study of the predominant vegetation of Canada (well illustrated); DOMINION BUREAU OF STATISTICS, *Canada: Official Handbook of Present Conditions and Recent Progress* (annual), many photographs and useful data for the geographer—essentially a popular summary of the *Canada Year Book*, which contains maps, graphs, useful statistical data, and special articles on various aspects of Canadian geography; W.E. GODFREY, *The Birds of Canada* (1966); DIAMOND JENNESS, *The Indians of Canada*, 7th ed. (1967), the standard authoritative work on part of Canada's aboriginal population; R. ST.J. MACDONALD (ed.), *The Arctic Frontier* (1966), a series of chapters by various authorities, several of them devoted exclusively to Canadian problems, particularly political geography; N.L. NICHOLSON, *Canada in the American Community* (1963), Canada in its New World setting, leading to a discussion of Canada and Pan-Americanism; *The Boundaries of Canada, Its Provinces and Territories* (1964), a monograph on the evolution of the political boundaries of present-day Canada and each of its provinces and territories, with a discussion of the general pattern of political boundary development and the direction it might take in the future; and (ed.), *Atlas of Canada* (1957), all aspects of the geography of Canada depicted on 110 large sheets containing several hundred maps; D.F. PUTNAM (ed.), *Canadian Regions* (1952), a comprehensive geographical treatment of the various regions of Canada, abundantly illustrated with sketch maps and diagrams; JOHN E. ROBBINS (ed.), *Encyclopedia Canadiana*, 10 vol. (1957–58, reprinted 1970), an invaluable reference work for all aspects of Canada except very recent developments; GUY SYLVESTRE, BRANDON CONRON, and C.F. KLINCK (eds.), *Canadian Writers* (1964), a biographical dictionary; D.W. THOMSON, *Men and Meridians*, 3 vol. (1966–69), a history of surveying and mapping in Canada; MASON WADE, *The French Canadians, 1760–1945* (1955), the standard work on the French Canadians from a historical point of view; JOHN WARKENTIN (ed.), *Canada: A Geographical Interpretation* (1968), chapters on most aspects of Canadian geography written mainly by Canadian geographers; J.W. WATSON, *Canada: Its Problems and Prospects* (1968), particularly useful for its analysis of historical relationships and aspects of urban geography.

(N.L.N.)

Canada, History of

The first inhabitants of the territories that now make up Canada were the Indians and Eskimo. The former came from northern Asia across the Bering Strait, while the latter were part of the circumpolar dispersion of a race that lived along the edge of the Arctic ice. For the prehistory of the North American Indians, see NORTH AMERICAN PEOPLES AND CULTURES.

I. Canada to 1867

The first Europeans to reach what is now Canadian soil were Norse explorers about AD 1000, as is recorded in the Icelandic sagas and recently confirmed by the archaeological discovery of a Norse site at L'Anse-aux-Meadows on the northern peninsula of Newfoundland. While the Norse made no lasting settlements, their voyages traditionally begin most general histories of Canada, largely because of their discovery of the northern route to North America. Only five years after the first voyage of Columbus, an Italian navigator, known to the English as John Cabot, sailed from Bristol in 1497 under the patronage of Henry VII of England by the northern route in an attempt to reach Cathay (China). He made a trip so expeditiously, to a landfall generally accepted as having been on the east coast of Newfoundland, that it is tempting to assume that he had the aid of local knowledge of the route and its winds, perhaps from Bristol fishermen accustomed to sailing in Iceland's waters. Cabot, however, perished in an unknown manner with a large expedition in the following year.

The voyage of John Cabot

THE SETTLEMENT OF NEW FRANCE

Jacques Cartier. The discoverer of the great entry to Canada, the St. Lawrence River, was the Frenchman Jacques Cartier. In 1534, in a voyage conducted with great competence, he explored the Gulf of St. Lawrence and claimed its shores for the French crown. In the following year, Cartier ascended the river itself and visited the sites of Stadacona (Quebec) and Hochelaga (Montreal). So favourable were his reports that the French king, anxious to challenge the claims of Spain in the New

World, decided to set up a fortified settlement. Internal and European politics delayed the enterprise until 1541, when, under the command of Sieur de Roberval, Cartier returned to Stadacona and founded Charlesbourg-Royal just above Quebec. Cartier had hoped to discover precious gems and minerals, as the Spaniards had done in Mexico and Peru. But the mineral speciments he sent home were worthless, and "false as a Canadian diamond" became a common French expression. Disappointed in his attempt to reach the mythical "Kingdom of Saguenay," the reputed source of precious metals, Cartier returned to France after a severe winter, deserting Roberval, who had arrived in Newfoundland with reinforcements. Roberval also failed, and during the century only two subsequent attempts were made at exploiting the French claim to the lands of the St. Lawrence. The French claim remained; it had only to be made good by actual occupation.

At that time overseas adventure and explorations had to earn their own expenses. The search for minerals in the St. Lawrence region having failed, there remained only two possibilities of immediate profit: the great maritime fisheries of Newfoundland and Nova Scotia and the fur trade of the adjoining lands. Indeed, the latter grew out of the former, beginning as barter between crews of fishing vessels and later becoming the object of separate trading voyages.

The monopoly of Chauvin

In 1600 the Norman entrepreneur Pierre Chauvin obtained from King Henry IV a ten years' monopoly of the fur trade in the Gulf of St. Lawrence, in return for which he was to settle 50 Frenchmen a year in the country. The monopoly was designed to exclude unauthorized traders, both foreign and French, from the area. Private traders might well garner, by being first on the spot, the furs brought down to the coast by the Indians and thus render a whole year's voyage unprofitable. But royal policy, concerned to confirm the French claim to the St. Lawrence and its approaches, knew that only permanent settlement would make good the French title against that of the Spanish, the English, and the Dutch.

Samuel de Champlain. Chauvin died in 1602 and was succeeded by the Sieur de Chaste. His geographical expert, Samuel de Champlain, was led by reports of the milder climate of Nova Scotia (Acadia) to urge that the enterprise turn to that region to form a settlement. In 1604 Champlain, under the Sieur de Monts, who had received a grant of the monopoly, led a group of settlers to Acadia. He chose as a site Dochet Island in the St. Croix River, on the present boundary between the United States and Canada. But the island proved unsuitable, and in 1605 the colony was moved across the Bay of Fundy to Port Royal (now Annapolis, Nova Scotia). The colony was to survive not only as a trading post but also as a centre of settlement. But the rugged, forested inlets of the Nova Scotian peninsula, the heavy forests of the St. John River, and the many bays and beaches of Cape Breton and Prince Edward islands made it impossible to enforce the monopoly of the fur trade against enterprising interlopers.

Foundation of Quebec

In 1608, therefore, de Monts and Champlain left Acadia and returned to the St. Lawrence. At "the place where the river narrowed" (Quebec), they built a "habitation" (*i.e.*, a fur-trading fort, or factory) to control the great river and to be the mart of its fur trade. Already in 1603 Champlain had noted that the Iroquois (or Huronian) Indians, whom Jacques Cartier had found there, had withdrawn from the St. Lawrence under pressure from the Algonkin (Algonquin) Indians of the north country and Acadia. The French now became the allies of the Algonkins in the fierce rivalry that began for control of the inland fur trade. In 1609, in accordance with this alliance, Champlain and three armed companions joined an Algonkin war party in a raid against the lands of the Mohawks, the easternmost tribe of the Iroquois Confederacy. The party ascended the Richelieu River to Lake Champlain. In an encounter with a Mohawk band, the fire arms of Champlain and his men killed some Iroquois and struck panic into the remainder. This skirmish signalled the commitment of New France to the side of the Algonkins and the Hurons (Iroquoian but hostile to the confederacy) in the century-long struggle for control of the output of furs from as far away as the western Great Lakes.

The company of de Monts and his frequent successors, to whom Champlain remained the lieutenant in New France, had the obligation to bring out settlers, as well as the exclusive right, seldom enforced, to trade in furs. Their efforts at settlement were even less successful, partly because settlement was not easy in a country of heavy forests and severe winters and partly because the fur trade had little need of settlers beyond its own employees. The company, moreover, had scant funds to bring out and establish colonists on the land. Champlain did the best he could, and he also encouraged missionaries (first the Recollects [Franciscans], then the Jesuits) to come to Quebec to convert the Indians. His greatest interest, however, lay in exploration. Already in Acadia, in 1606 and 1607, he had surveyed the coast southward and westward to Stage Harbor, only to be rebuffed by hostile Indians. Had he persisted, it is not impossible that the Hudson River, the mouth of which was discovered by the Florentine navigator Giovanni de Verrazano in French service, might have been the French entry to America rather than the St. Lawrence.

In 1613 Champlain set out from Quebec to explore the upper St. Lawrence Basin. He passed the Île de Montréal, not settled since Cartier's time but used by traders who bypassed Quebec. In order to avoid the heavy rapids of the St. Lawrence, he ascended its great tributary, the Ottawa, only to be turned back at the Île aux Allumettes by the Algonkin middlemen who were trading for the furs of the Hurons and other people further inland and who wished to retain that trade. There Champlain, however, heard of the "inland sea" (Hudson Bay), the existence of which he had divined before he could have heard of Henry Hudson's discovery of it in 1610. Undaunted, he ascended the Ottawa again in 1615, passed by the Mattawa River, Lake Nipissing, and the French River to Georgian Bay, and turned south to "Huronia" (the land of the Hurons). He wintered with the Indians and went with a Huron war party to raid an Onondaga village south of the St. Lawrence. He was slightly wounded and the party was repulsed, but Champlain had once more confirmed the alliance of the northern tribes and the Hurons against the Iroquois and, by the opening of the Ottawa route, had secured the midcontinent for the French fur trade.

Alliance against the Iroquois

The discovery of this inland, central region was perhaps Champlain's main achievement. He had no success, however, from 1616 to 1627 in maintaining the fur trade. The fault was not entirely his, for the enterprise in itself was very difficult. The coupling of trade and settlement was somewhat contradictory, and it was impossible to finance both out of annual profits, especially as the French government failed to uphold the monopoly.

The Company of New France. The French government was to supply more active support after the remarkable revival of royal power carried out by Cardinal de Richelieu in the 1620s. Richelieu sought to make French colonial policy comparable with that of England and the Netherlands, joint victors with France in the long struggle in Europe against Spain. These countries had found in the joint-stock company a means both of raising capital and enforcing trading rights. Richelieu used his power to create such a company to exploit the resources and settle the lands of New France. This was the Company of New France, commonly called the "Hundred Associates" from the number of its shareholders. It was given broad powers and wide responsibility: the monopoly of trade with all New France, Acadia as well as Canada; powers of government; the obligation to take out 400 settlers a year; and the task of keeping New France in the Roman Catholic faith.

The company was chartered, and its capital raised in 1627. The next year, however, war broke out with the English, who supported the French Protestants, or Huguenots, in their struggle against Richelieu. The war was mismanaged and inconclusive, but it gave a pretext for

the Kirke brothers, English adventurers who had connections in France with Huguenot competitors of the Hundred Associates, to blockade the St. Lawrence in 1628 and to capture Quebec in 1629. For three years the fur trade was to be in the hands of the Kirkes and their French associates the brothers de Caën. It was a stunning blow to the new company and to Champlain, who was taken prisoner to England. At the same time, Acadia, already raided from Virginia in 1613, was claimed by Scotland. An attempt at settlement there was made by Sir William Alexander, to whom Nova Scotia (New Scotland) had been granted by the Scottish king James VI (after 1603, James I of England).

The Scots in Nova Scotia

It is difficult to estimate the effect of the war on the policy of the Hundred Associates. Canada and Acadia were restored by the Treaty of Saint-Germain-en-Laye in 1632, and the company retook possession in 1633. On the surface all seemed to go smoothly. In 1633 Champlain returned as governor; the government and settlement of Acadia was farmed out to the vigorous Isaac de Razilly; the Society of Jesus assumed sole responsibility for the care of souls in Canada and for the conversion of the Indians. The fur trade was resumed, and the Trois Rivières settlement was founded in 1634 to control the Saint-Maurice River. Settlement began, but the company seemed unable to recoup the losses caused by the capture of Quebec and by the disruption of five years' trade and seemed unable to make profits that would both pay dividends and provide for the costs of settlement. The company remained the proprietor of New France until 1663, providing a succession of governors and other officials, but it never succeeded in meeting its obligations to colonize. Weary of its profitless task, the company leased the fur trade to private companies and then, in 1645, to a group of Canadian residents known as the Community of Habitants. The Company of New France became merely a sort of holding company or "sleeping partner." To strengthen the government of New France in the new circumstances, a council was set up in 1647 by the King's council in France.

The character of French settlement. The fur trade was not the sole enterprise of New France. By 1645 settlers in Canada and Acadia were producing provisions for the fur traders and the annual ships. The mode of landholding, known as the seigneurial system, a modified form of feudal land law and justice, was begun. But the great partner and sometime rival of the fur trade was the missionary endeavour of the Jesuits. They had two obligations: (1) to keep New France Catholic by ministering to its people and excluding Huguenots and (2) to convert the Indians. The missionaries made the conversion of the Hurons their principal concern. Huronia, on the southeast corner of Georgian Bay, was the seat of one of the most civilized and sedentary tribes in North America. It was also the hub of the inland fur trade. To make Huronia a Christian community would create a centre of Christianity and confirm the French commercial alliance with the Hurons and their Algonkin clients. French missionaries had already visited Huronia in the mid-1620s, and in 1634 the Jesuits resumed the mission, which thrived, at least outwardly, for ten years. Its success, however, menaced the trade of the Iroquois with the Dutch in New Amsterdam, and, in 1648 and 1649, the Confederation savagely and completely devastated Huronia. Thereafter, both missionaries and traders had to follow the trading Indians farther inland across the Great Lakes and, eventually, to the Mississippi and Saskatchewan rivers.

Missionary activity

These checks to both the fur trade and the missions, at least in terms of the intentions and hopes of 1627, were the result not only of bad luck and poor management but also of the economic conditions of New France, which depended almost entirely on the fur trade for profit. Settlement was unprofitable to both the company and the colonists. Population, therefore, grew quite slowly, rising from an estimated 200 residents (*habitants*) in 1642 to perhaps 2,500 by 1663; and by no means all of these were farmers. The fur trade, however, was booming, borne up by the fashion of the beaver felt hat in Europe. The traders at Quebec, and at what after 1642 became Montreal, brought French goods to trade with the flotillas of canoes that carried the furs of the Ottawa and Great Lakes countries, which before 1648 were usually manned by Huron middlemen. This was the sole commercial enterprise of New France. The few farmers supplied Quebec, Trois Rivières, and Montreal with grain, milk, and eggs; but as yet nothing from the lands or forests of New France moved down to sea and markets abroad.

Royal control. New France, though a proprietary colony, was governed by the company, which appointed governors for Canada and Acadia, and a few dependent officers. The kings of France remained interested in the colony, both because of the vast potential wealth of the area and because the crown might have to resume the powers of government given to the Hundred Associates. Government was, in fact, very much what it would have been if the colony had been directly under the rule of the crown. The council that had been established in 1647 included the governor, the chief religious authority, the superior of the Jesuits, and the governor of Montreal. During the brief rule of the Community of Habitants, representatives (syndics) of the people of Quebec, Trois Rivières, and Montreal were consulted on local matters. This, however, was the nearest approach to anything like representative government. Government in New France, as in old, was authoritarian and paternalistic, but it was not despotic, nor was it necessarily harsh.

Nor was it always efficient, and this, with the commercial lassitude of the Hundred Associates, but most of all the assumption of power by Louis XIV and the colonial ambitions of his great finance minister, Jean-Baptiste Colbert, led to a recasting of French colonial policy and of the government of New France. Colbert entrusted commercial policy to a new Company of the West Indies. Politically, he made New France a royal province, governed much like a province of France itself. The substance of power and the immediate direction of justice, economic policy, and the militia lay in an intendant, a powerful royal official hitherto unknown in New France. Because of distance and the long winter of no communication, the governor also had a council, at first called the Sovereign Council and, later, the Superior Council, to advise him. The governor was largely a titular officer, except in his power of presiding at the council and in the conduct of relations with the Indian tribes—the most important business in a fur-trade colony. The bishop (also a member of the council) and the intendant, great powers in virtue of their offices, often quarrelled with the governor, notably the famous Comte de Frontenac, in the conduct of the colony's affairs. New France's first bishop, François de Montmorency de Laval, was installed in 1659; from 1674, he was called bishop of Quebec.

Colbert's reorganization

The general effect of Colbert's reorganization, however, was to give New France firm and rational government thereafter, strongly centralized and efficient for the times. The exception was Acadia. Torn by feuds among French rivals, claimed by England, and occupied by New Englanders eager to exploit its fishery, Acadia did not again become an effective part of New France until 1667–70.

The strength of the royal government was in inverse proportion to the weakness of a small and scattered population. Great efforts made by the first intendant, Jean Talon, did indeed bring some thousands of settlers, hundreds of them women, to New France in the 1660s and early 1670s. The population in 1666 reached 3,215; in 1676, about 8,500; thereafter, however, the population grew largely by natural increase, fortunately at a prodigious rate. Most of the population lived in the three towns (Montreal, Quebec, and Trois Rivières) and in seigneuries along the banks of the St. Lawrence between Quebec and Montreal. Scores of the men, however, went inland with the trading canoes, and some of these voyageurs remained inland permanently, marrying Indian women and fathering the Métis, or people of mixed French and Indian blood.

Intendant Jean Talon

The frontier of New France was, in brief, not a broad

front of advance but, rather, a penetration of the wilderness by the rivers. The fur trade meant dispersion of effort and resources on the Indians, with whom harmonious relations were so necessary, rather than on colonization. In general, the French allied themselves with the northern tribes against the Iroquois Confederation. The Iroquois, after destroying the Huron towns in 1648 and 1649, later subordinated all the tribes as far as Lake Michigan. The French, however, managed by repeated wars with the Iroquois to maintain their alliance and to penetrate as far inland as the Mississippi, explored as far as Arkansas by Louis Jolliet in 1672. In relations with Indians the French missionaries also played an important role, for, in addition to their religious activities, they also served as ambassadors and agents of the colony in the fur trade.

The growth of Anglo-French rivalry. In the 1660s two voyageurs, Médard Chouart des Groseilliers and Pierre Esprit Radisson, exasperated by the high cost of the long haul back to Quebec and by the heavy tax on fur pelts, fled to New England. From there they were escorted to England, where in 1668 they persuaded a group of London merchants to attempt to gain the fur trade of the midcontinent by way of Hudson Bay. This led to the formation in 1670 of the Hudson's Bay Company, a late proprietary company that was given exclusive trading rights in all the territory draining into Hudson Bay. New France now found itself caught between the Iroquois, supported by the Dutch and English, to the south, and the Hudson's Bay Company to the north. In this juncture lay one cause of the great wars of the next century. At the time, however, the French were led by Governor Frontenac's ambitions merely to maintain their inland corridor, although the French under La Salle pushed to the mouth of the Mississippi in 1682. After Frontenac's recall, they tried repeatedly to eject the English from the bay, which they also claimed. In 1686 a French expedition from Canada destroyed the English posts in James Bay (at the south end of Hudson Bay), and in the 1690s the noted Canadian commander Pierre Le Moyne d'Iberville captured all English posts in the bay but one. The French held these posts throughout Queen Anne's War (1702–13), the American phase of the War of the Spanish Succession (1701–14) in Europe. At the same time, the French were able to reduce the Iroquois to neutrality and to keep the alliance of the inland tribes. But, defeated in Europe, the French were ejected from the bay and, more important, from Acadia and a foothold in Newfoundland by the Treaty of Utrecht in 1713. New France was still held in the vise of the English to the south and north and had lost all the approaches to the St. Lawrence except Cape Breton Island.

The Treaty of Utrecht

After Queen Anne's War there followed a generation of peace during which the governors of New France built a line of fortified posts: Louisbourg on Cape Breton Island, Chambly on the Richelieu River, Carillon (Ticonderoga) on the portage from Lake George to Lake Champlain; the trading posts of Niagara, Toronto, Detroit, and Michilimackinac extended the line to the west. At the same time, French priests and military emissaries kept the Acadians and the Indian allies of New France aware of their former ties with New France. The Acadians, claiming to be "neutral," obstinately refused to take the oath of allegiance to the British crown.

For New France the early 18th century was a period of steady growth in population, settlement, and industry. French *défrichements* ("clearings") spread along the St. Lawrence between Quebec and Montreal; the iron forges at Saint-Maurice produced iron for Quebec stoves and even cannons; shipbuilding flourished. The colony nevertheless remained largely dependent on the fur trade, which, in turn, depended on keeping the west open. Access to the far west was frustrated, however, by the three Fox wars (1714–42), in which that small but obstinate tribe strove with much success to close the Wisconsin portages to French traders. Then Pierre Gaultier de Varennes, sieur de La Vérendrye, turned the flanks of the Fox and Sioux by proceeding by way of Lake Superior and the Rainy River to the Lake of the Woods and the Red and Saskatchewan River country. There he found a new region for the French fur trade and also cut into the English trade in the area of Hudson Bay and the Hayes River.

The expansion of New France in these years was challenged, however, by the outbreak of the War of the Austrian Succession in Europe in 1740. In America the war became known as King George's War (1744–48). Fighting broke out again in Acadia, on Lake Champlain, and among the English and French Indian allies in the country of the Great Lakes and the Ohio Valley. It was a confused conflict of raids and reprisals marked by only one action of major significance—the capture of Louisbourg by an expedition from New England. But the conflict revealed the need for a final struggle for the mastery of the continent. Holding the St. Lawrence Valley, the Great Lakes, and the mouth of the Mississippi, the French commanded the better strategic position in America. But the English colonies, if lacking central direction, were far wealthier and more populous. England, moreover, enjoyed the advantage at sea. In consequence, the chief outcome of King George's War was that the supply of French trade goods was cut off and replaced by cheaper and better made English goods. The loyalty of the western tribes, on which the French positions largely depended, was undermined.

King George's War

All this was perceived by Roland Michel Barrin, marquis de La Galissonière, the exceptionally able governor of New France (1747–49). He declared in a memorandum to the French court that New France must restore its position by a bold advance into the Ohio Valley, which hitherto had not really been claimed by New France or its Indian allies. His policy was adopted by his successors, and in 1749 Céleron de Blainville led an expedition down the Ohio to claim the valley for France and thereby confine English colonists and their fur trade to the east of the Alleghenies. The British colonists, from New York to Virginia, immediately felt the threat to their trade, to their expansion, and to their settlement. In 1749 the Ohio Company was formed in London with English and American support, and the fortress of Halifax in Nova Scotia was built to counter the French fort at Louisbourg, which had been restored to New France by the peace of 1748 ending King George's War. In 1753 an American expedition under young George Washington was sent to the Forks of the Ohio—the site of present-day Pittsburgh, Pennsylvania—to make good the English claim.

The French and Indian War. The French had also been active on the Ohio and had opened a line of communication from Lake Erie to the Forks. The rivals clashed on the Monongahela, and Washington was forced to surrender and retreat. This clash marked the beginning of the Anglo-French war known in America as the French and Indian War (1754–63) and in Europe as the Seven Years' War (*q.v.*; 1756–63). England resolutely supported the colonies and sought to recover the Ohio Valley by an expedition under Gen. Edward Braddock in 1755. This, too, was bloodily repulsed on the Monongahela, and both sides then reinforced their colonies with regular troops. It was to be a war for empire; how sternly it was to be fought was made clear by the expulsion of the Acadians from Nova Scotia in 1755.

Defeat of Braddock

The French in America, cut off by British blockade, fought to hold the long line from the Ohio to the Bay of Fundy, counting on the results in Europe for a victory. Britain, however, while subsidizing and aiding Prussia, its only European ally, sought victory in America and sent across the Atlantic what was, for that century, an overwhelming body of regular troops in order to stiffen the militia of the American colonies. The first victories went to the French, who captured Ft. Oswego and Ft. William Henry in 1757 and sternly repulsed the British at Fort-Carillon (Ft. Ticonderoga) in 1758. Then numbers and more skillful British generalship began to tell. In 1758 the British captured and razed Louisbourg. In 1759 Sir Jeffrey Amherst began a cautious but irresistible advance from Ft. William Henry by way of Ft. Ticonderoga to Lake Champlain. In the same year an expedition un-

der Gen. James Wolfe sailed up the St. Lawrence and besieged Quebec, which fell to the British after the celebrated Battle of the Plains of Abraham. Sir William Johnson took Niagra, and John Bradstreet took the Forks of the Ohio. New France was caught in cruelly closing pincers. In 1760 Amherst closed in on Montreal, and New France capitulated. By the terms of the Treaty of Paris in 1763, all French North America east of the Mississippi was ceded to Britain. The Louisiana Territory, west of the river, was given to Spain. Britain and its colonies had thus eliminated France from North America.

The British victory produced three major results: (1) The danger from New France to the American colonies was ended, thus weakening their dependence on Britain. (2) The British (largely Scots with some Americans) took over and expanded the Canadian fur trade. (3) Britain now possessed a colony populated almost wholly by persons of alien descent.

CANADA UNDER BRITISH RULE, 1763–91

The Royal Proclamation of 1763

The Quebec Act. The governance of New France was a problem to the British government. The Royal Proclamation (October 7, 1763) made broad decisions on this and on the related matter of the territory between the Alleghenies and the Mississippi. The latter was declared to be Indian territory and was closed to settlement until the Indians there could be quieted. The French province of Canada now became the colony of Quebec, was cut off from the upper country, and provided with a royal governor with the authority to call an assembly. The assumption underlying the latter provision was that American settlers from New England and New York would move into the new colony and would outnumber the some 70,000 French habitants. Quebec, in short, was to become the traditional royal colony, with English institutions and a largely English population.

This assumption proved unfounded. Few American colonists moved to Quebec, and those who did sought trade rather than land. Moreover, the summoning of an assembly, in which the French, as Roman Catholics, would be unable to sit, would place taxation and representation of the colony in the control of a small body of Protestant newcomers (perhaps 500 in all). Gen. James Murray, who had served as military governor from 1760 to 1764, was now appointed civil governor. Murray sympathized with the condition and difficulties of the French and ignored the demands of the Protestant "old subjects" for an assembly, with the result that an agitation by the old subjects led to his recall. He was replaced in 1766 by Gen. Guy Carleton, who was expected in Quebec to carry out the policy of the proclamation. Carleton, however, soon came to see that the colony was certain to be permanently French. Fearful of renewed war with France, he also envisioned Canada as returning to the role of New France as a check on the growing independence and expansion of the English colonies along the Atlantic seaboard.

Carleton returned to England to 1770 to press his new policy for Quebec on the government of Lord North. The trouble the imperial government continued to have with the colonies, together with a certain nascent liberalism among English politicians, combined to bring success to Carleton's policy. The result was the Quebec Act of 1774, by which the province of Quebec was expanded to include all the inland territory to the Ohio and the Mississippi. The new colony was given a governor and an appointed council. Roman Catholics were allowed to hold office by providing a form of oath to which they could subscribe. French was made an official language, along with English, and French civil law was restored, but with English criminal law. The Roman Catholic faith was recognized, and the church was allowed to collect the tithes of the faithful.

Political and religious toleration for the French

Toward the French Canadians the act was liberal and conciliatory; toward the American colonies it was menacing, as their strong protests gave evidence, in that it re-established to the north and west a great military power, French and Indian, despotically governed as they saw it.

The impact of the American Revolution. In any case, the act assumed the predominance of the French in Quebec. Moreover, instead of intimidating the American colonies, the act helped push the Americans to open revolt. Indeed, the first act of the American Continental Congress in 1775 was not to declare independence but to invade Canada. And the failure of that invasion ensured that north of the Rio Grande the continent would, on the recognition of American independence, be divided between the Americans and the British.

Not all American colonists had supported the cause of independence, and many had resisted it in arms. At the conclusion of hostilities, these loyalists had to make their peace with the new republic, as by far the greater part did, or go into exile. The refugees, known as United Empire Loyalists, were the object of considerable concern to the British government, which sought to compensate them for their losses and to assist them in establishing new homes. Some went to the United Kingdom, others to the British West Indies, but the majority emigrated to Nova Scotia or Canada. Nova Scotia, which to a great extent had been recently settled by American colonists, had not, except for an ineffectual rising or two, joined the revolting colonies. Overawed by British sea power and by the fortress of Halifax, Nova Scotians at first kept quiet, and later many of them even made fortunes pri-

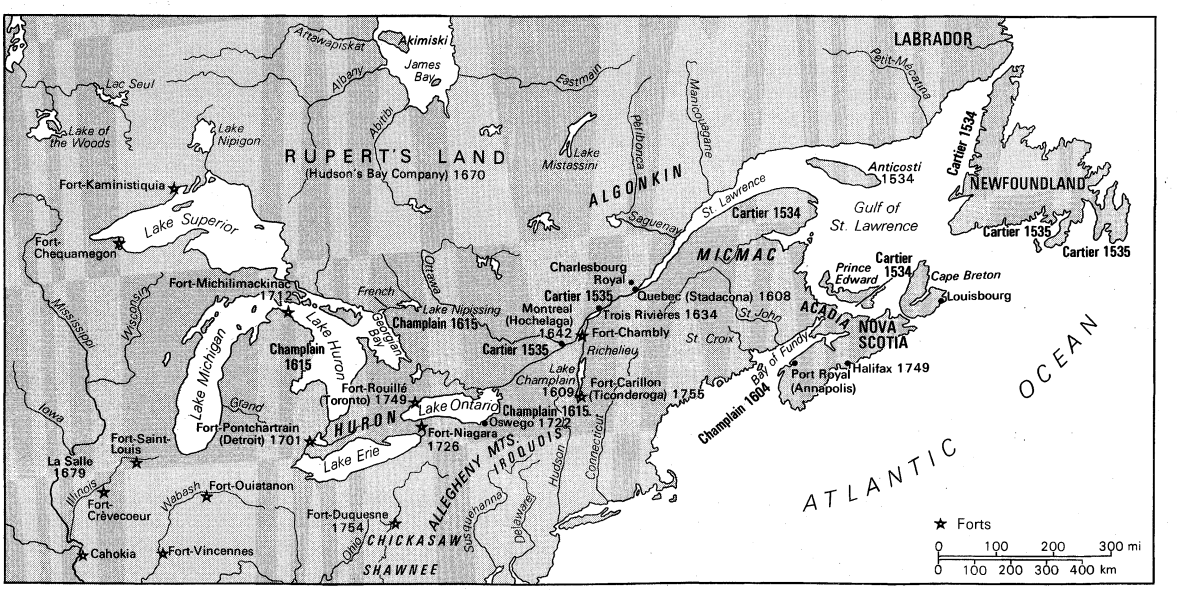


Figure 1: New France, 16th–18th centuries.

vateering against American commerce. Easily reached by sea from New York, Nova Scotia became the chief refuge of the Loyalists. Some settled in the peninsula itself, some in Cape Breton and in the separate colony of Prince Edward Island. A large number, however, settled along the St. John River, north of the Bay of Fundy. Dissatisfied with tardy government from Halifax, they promptly agitated for a government of their own, and equally promptly the new province of New Brunswick was erected for them in 1784, with its own governor and assembly.

The impact of the Loyalists on the province of Quebec was even greater, resulting also in a new province and, perhaps more important, the Constitutional Act of 1791.

The Loyalist population

The Loyalists who settled in Canada were for the most part quite different from those who went to what were soon to be called the Maritime Provinces. The latter had possessed an elite of government officials and professional men, often Loyalist regiments with their officers and men, from the long-settled seaboard areas. The Canadian Loyalists, however, were largely from upper New York, especially the Mohawk Valley country, and were almost wholly simple frontier folk and recent immigrants, driven from their homes by neighbours who often used the Revolution to dispossess them of their lands; hence, the bitter fighting along the frontier and the long Loyalist hatred in the new province for all things American.

Their coming transformed the character of the population of Quebec. That province had been given a government much like that of New France, except for the important office of intendant, and the province was in population almost wholly French, as it was in civil law. Most Loyalists simply crossed the new frontier and settled along the St. Lawrence River. They all had one desire, to hold the land granted them in simple ownership, something the civil law of Quebec did not allow. Some of them—how many is uncertain—also wanted representative government, denied by the Quebec Act. Their representations reached London and were listened to with respect, as they were, after all, from people who had lost everything fighting for the crown.

The Constitutional Act of 1791. Their appeals caused a great problem for the British government. The measures taken in the Quebec Act to conciliate the French could not in honour or policy be withdrawn. Yet the Loyalists could not be required to live under French civil and land law and without the representative assembly to which they were accustomed. One obvious answer was to divide Quebec into separate French and English provinces. The English province would have, of course, English common law and an assembly. The French province might have been left with the forms of government provided by the Quebec Act. But there had already been one revolution in America, and, by 1789, another had broken out in France. British statesmen felt that the former had occurred partly because Americans had not been granted the British constitution in its proper forms. The thing to do, therefore, was to give, not only the new province but Quebec as well, the British constitution in its entirety, or at least as far as the circumstances of small colonies might permit. The result would be, it was hoped, to assimilate the French population of Quebec to British institutions.

After a fiery debate in the British House of Commons, the Constitutional Act of 1791 gave the same constitution to the colonies of Upper and Lower Canada. Nothing that had been given the French in 1774 was revoked, but the form of government was changed to the familiar one of governor with his executive council, a legislative council, and an assembly elected on what was for the time a wide franchise. The result of this last provision was that the first assembly in 1792 had a majority of French members.

NATIONAL GROWTH IN THE EARLY 19TH CENTURY

Population trends. The coming of the Loyalists changed the composition of the population of the British North American colonies by adding elements at once American yet profoundly attached to British institutions; it also increased the population by some 6,000 in the old province of Quebec. To these were to be added the unknown numbers of "late Loyalists"—settlers, primarily land seekers, who arrived from the northern states as late as 1812. Some 80,000 came to Nova Scotia, although not all remained; of these, some 20,000 settled in what became New Brunswick, and a few hundred on Prince Edward Island.

The ethnic mixture

They added also to the growing diversity of the population of the colonies. In Newfoundland there were already the west country English and a growing number of Irish—a total of 26,505 in 1806. In Nova Scotia there were, in addition to New Englanders, Loyalists, and Yorkshiremen, the Germans of Lunenburg and the Highland Scots of Pictou county and of Cape Breton Island —in all, an estimated 65,000 in 1806, with 2,513 on Cape Breton Island. New Brunswick had a population of about 35,000 in 1806, mostly Loyalists or of Loyalist descent, but already the southern Irish, drawn by the timber trades, were beginning to appear on the rivers of the north shore. Prince Edward Island, with a population of 9,676 in 1806, had some Acadians, some Loyalists, some English, Scots, and Irish. In Upper Canada in 1806 the population numbered 70,718; in Lower it was estimated at 250,000 for the same year.

The first Canadian mosaic had taken shape as it was to remain for a century, a population of British, French, and German. The British element was to be steadily reinforced by northern English, coming by way of Liverpool, Highland and Lowland Scots, and southern and northern Irish. The result was the creation of a society in which religious liberty and a great measure of social equality were necessary for social cohesion and common effort.

Until 1815, however, the number of immigrants was small: Highlanders for Glengarry County in Upper Canada, disbanded soldiers in Lanark County south of the Ottawa River, and a straggle of Irish after the crushing of the rebellion of 1798. Nor did the numbers greatly increase after 1815; not until 1830 did the English, Scots, and Irish begin to come to the British North American colonies in great volume. Afterward, thousands came each year, until the population of Newfoundland reached 73,700 (1836); Prince Edward Island, 32,300 (1838); Nova Scotia, 202,575 (1838); New Brunswick, 156,162 (1840); Lower Canada, estimated at 716,600 (1840); and Upper Canada, 432,159 (1840). The British North American colonies had become predominantly British in population, except in Lower Canada, a fact that was to determine the course of Canadian history for the next 100 years.

The Montreal fur traders. To an important degree Canadians were becoming less American than they had been in 1783. The redivision of the continent begun by the American Revolution had been intensified by rivalry in the fur trade. As noted above, the French fur trade of Montreal had been taken over by British fur traders who conducted the trade with the aid of French experience and skill. The British supplied the capital, and the French voyageurs supplied the skill of canoemen and the knowledge of the country and the Indian. These "Montrealers" pushed the trade with great boldness southwest from Montreal, where they had persuaded the British government not to surrender the fur posts after 1783 on the ground that debts owing Loyalists had not been paid by the United States. Thus, the trade of the lands lost by France in 1763 and by Britain in 1783 was kept tributary to Montreal rather than to New York and Philadelphia. The Montrealers also pushed the trade into the far northeast. By 1784 most of the Montreal traders to that region had combined in the North West Company, which dominated the trade from Montreal and seriously challenged the trade and legal monopoly of the Hudson's Bay Company. In the southwest, however, they were slowly squeezed out by the American government and by John Jacob Astor's American Fur Company. So the British traders pushed ever harder into the farthest northwest. In 1787 one partner, Peter Pond, gathered information

The North West Company

about a great river that he was convinced flowed into the Pacific. In 1789 a young Scot, Alexander Mackenzie, followed that river, later named after him, to an outlet in the Arctic Ocean. It was a bitter disappointment, for Mackenzie had hoped to find a passage to the Pacific by which the high cost of bringing furs to Montreal could be avoided. In 1793 Mackenzie crossed what is now British Columbia to the Pacific at Bute Inlet. It was a great feat of exploration but did not lead to a route to the Pacific. That route was to be found years later, on the eve of the War of 1812 with the United States, on the Columbia River by the great geographer David Thompson, only to find that Astor's men had preceded him to the mouth of the Columbia.

The War of 1812. The War of 1812 was to a large degree caused by the Anglo-American rivalry in the fur trade. British traders and soldiers had supplied Indian tribes and afforded them moral support in their contest with the advancing American frontier. Britain had surrendered the western posts by the Jay Treaty of 1794, but the cause of the Canadian fur trade and of the Indians remained the same—the preservation of the wilderness. Certainly, apart from single ship actions and privateering, the war was fought for the conquest of Canada and its elimination as an ally of the Indian. In the end, the war was a stalemate and closed with no concession by either side. It did, however, push back the Indian frontier, increase the breach between the United States and the British North American colonies, and confirm the boundary line between Canada and the United States.

The U.S.–Canadian boundary

That boundary had been fixed in 1783, by a line running from the mouth of the St. Croix River to the "high lands" dividing Quebec from Maine; then by the mountains between the St. Lawrence and Connecticut River valleys to the 45th parallel; by that line to the St. Lawrence; then by centre line of the river and the Great Lakes and the Pigeon and Rainy rivers to the northwest angle of the Lake of the Woods. The Treaty of Ghent, 1814, confirmed this, although the location of the Maine–New Brunswick boundary remained in dispute until the Webster–Ashburton Treaty of 1842. The Rush–Bagot Agreement of 1817 limited naval armaments on the Great Lakes, while another convention in 1818 reduced the rights of American fishermen along the shores of the Atlantic colonies and made the 49th parallel the boundary from the Lake of the Woods to the Rocky Mountains. Beyond, the Oregon Territory was to be jointly occupied for a period of ten years, an occupation ended by the division of the territory, after some threat of war over the American claim to the whole, by extending the 49th parallel to the Strait of Georgia in the Oregon Treaty of 1846. Vancouver Island remained British.

The Rebellion of 1837. The colonies grew quietly but steadily after the War of 1812, aided by the development of the timber trade and shipbuilding and by increased immigration from the British Isles. The growth of population and social sophistication led to growth of a reform movement, stimulated by similar movements in Great Britain and the United States. The movement was essentially attempted to make the institutions of the colonies more popular and less the monopoly of the royal governors and the appointed and permanent councils. The rise of a middle class of professional men, especially lawyers and journalists, and the importance of religious liberty in a population so diverse in faith underlay this development. In the Maritimes, the movement proceeded peaceably and constitutionally under the leadership of forceful but moderate reformers, such as Joseph Howe of Nova Scotia. But Upper Canada, under the leadership of the irascible Scots democrat William Lyon Mackenzie, was more militant. In Lower Canada, matters became much more serious for two reasons: one was that the political division was to a great extent a national split between English and French; the other was that the wheat farming of the habitants was primitive and dependent on new lands and exhausted both the fertility and the extent of the good soils. An economic depression in 1837 intensified political grievances and burst into open rebellion. A hasty and unplanned republican rising in Lower Canada was crushed by the British regular garrison and the militia; and an even more scrambled rising in Upper Canada was put down by the militia alone.

The Union of Canada. The abortive rebellions, however, did dramatize the need to reform Canada's outmoded and constrictive constitution. The "Canadian question" became a leading issue in British politics. Lord Durham was sent out as governor general with a royal commission to enquire into the causes of the troubles. Durham's stay in Canada was brief, but his enquiry was sweeping and his recommendations trenchant. Durham perceived that the colonies had stagnated and that if they were to live side by side with the dynamic United States, they must be brought into the full stream of material progress. One political means to this end was union. Durham decided the time for the union of all the North American colonies had not yet come, but he did recommend the reunion of at least the two Canadas in order to realize the economic possibilities of the St. Lawrence Valley. In Durham's view, union would also bring the French, whom he saw as a backward people, into the progressive ways of English politics and business. Second, he adopted a proposal of certain Upper Canadian and Nova Scotian reformers for "responsible government." This would make the colonial executive responsible to the assembly and assure colonial self-government. Other than local matters would continue under imperial control.

The Durham Report (1839)

The British government did not share Durham's confidence that such a division between local and imperial affairs could be made and refused an explicit grant of responsible government. It did, however, take measures to end the permanent tenure of members of the executive councils and ordered the governors to govern in harmony with their assembly. The government did accept the proposal to unite the Canadas, and in 1841 the united province of Canada came into being under a new and dynamic governor, Charles Poulett Thomson (later Lord Sydenham). The Union was meant to incorporate the French much like any other group into the population, but the political capacity of Louis Hippolyte Lafontaine converted the Union into a quasi-federal government in which the French remained an almost insoluble bloc. At the same time, the attempt of Sydenham to modernize the administration of Canada and govern in harmony with the assembly prepared the way for the recognition of responsible government. That was finally recognized beyond question, first in Nova Scotia, next in Canada, in 1848.

Achievement of responsible government

The British North American colonies, then, had achieved self-government by 1848; the next decade saw their laws and institutions remodelled to fit the individual needs of each colony. But for Canada at least, the time was at hand for expansion. The British repeal of the Corn Laws in 1846 had deprived the colonies of imperial protective tariffs. The Grand Trunk Railway, begun in 1853, was an attempt to draw the trade of the American Middle West down the St. Lawrence. The Reciprocity Treaty of 1854 in part replaced imperial with continental trade, but close U.S.–Canadian trade relations were dangerous in that they might end in political union with the United States, especially if the Southern states were to secede from the American Union. The only Canadian solution to Canada's difficulties was to expand into the territory of the Hudson's Bay Company in the northwest.

From 1766 to 1821 the North West Territory had been the scene of competition between the traders from Montreal and the older English monopoly. This competition had been accelerated in 1811, when Lord Selkirk had bought a controlling interest in the Hudson's Bay Company. Selkirk persuaded the company that its title to the lands of the northwest and beyond would be confirmed by planting a colony on Red River of the North. The colony, begun in 1812, lay at the juncture of the plains country, which provided pemmican to supply preserved food for the canoe brigades of the North West Company, and the forest country, where the furs were taken. The

result was five years of warfare between the companies, marked by the skirmish of Seven Oaks on the Red River in 1816, in which the governor of the Red River Settlement, Robert Semple, and 20 of his men were killed by the Métis at the instigation of the North West Company. The British government had to intervene, resulting in the union of the two companies under the Hudson's Bay Company, which obtained exclusive trading rights in the northwest to the Pacific. The new company operated entirely independently of Canadian authority.

THE MOVEMENT FOR CONFEDERATION

By the 1840s, however, free trade from St. Paul on the Mississippi and renewed connection with Canada began to undermine the company's empire, and men began to ask if the fur-trade wilderness might not be capable of agricultural settlement. An affirmative answer was given by the American scientist Lorin Blodget in 1856 and by a British and a Canadian expedition in 1857–61. The northwest was worth taking, if Canada could take it, and so achieve a national destiny of its own. In 1858 an investigating committee recommended the annexation of the northwest, but the government failed either to challenge the validity of the Hudson's Bay Company's charter or to buy it out, largely because of the fears of the French Canadians. The addition of the northwest to Upper Canada was delayed until 1870, when confederation had made it possible.

Background of Confederation

That union, finally called Confederation, had been discussed for over a century and, by 1858, had become a practical possibility. A union of the Maritime colonies, with the exception of Newfoundland, was also urged by some. Nova Scotia and New Brunswick lacked both railways and a continental hinterland. An intercolonial railway from these colonies to Canada had been discussed since 1846 but was always frustrated. In Canada the great reforms necessary for self-government had been completed. Politics became sectional, and, from 1862 to 1864, a "deadlock" of parties ensued, preventing most of the necessary legislation. Even provision for an adequate militia was prevented until late 1863, despite the U.S. Civil War raging across the border. This deadlock in Canada, however, was ended by the formation of a coalition of the two main rival parties, Conservative (dependent on French support and led by George Etienne Cartier and Sir John Macdonald) and Reformer (dependent on English Upper Canada and led by George Brown). The coalition was based on a policy of Confederation.

The new government moved quickly, and, at the Charlottetown Conference (September 1, 1864), persuaded the Maritimes to postpone Maritime union and discuss Confederation. At a conference called at Quebec (October 10, 1864), an agreement was quickly reached on a general federal union; this agreement was immediately approved by the British government, which was anxious to set the colonies up on their own and to be rid of its obligation to defend them inland from Quebec. There were hitches and failures; New Brunswick voted against union in 1865, then reversed itself in 1866; Prince Edward Island refused to enter until 1873; Newfoundland also refused and did not join Canada until 1949. But the Canadas and the British government applied quiet but strong pressure on the reluctant colonies. In 1867 the four colonies of Nova Scotia, New Brunswick, and the Canadas (now the provinces of Quebec and Ontario) were united under the British North America Act as the Dominion of Canada.

That act has remained, with certain amendments, the "constitution" of Canada to the present day. The act provided constitutions, based on the British model, for the new provinces of Quebec and Ontario, confirmed the language and legal rights of the French, and above all provided for the division of power between the federal government and the provinces. The union was not, at its beginning, a truly federal one because the central government was given broad powers, not unlike those the British government had possessed over the colonies. In time, judicial interpretation and the growth of provincial rights made the union more truly federal. For the moment, however, a strong central government was needed in order to develop the northwest and the colony of British Columbia beyond and to build a railway to the Pacific that would bind the vast new territories to the original Dominion.

II. Canada from 1867 to 1920

THE DOMINION OF CANADA, 1867–1914

Section 146 of the British North America Act provided for the admission of Rupert's Land (the Hudson's Bay territory) to the new Dominion. The first action taken by the federal government was to buy out the title of the Hudson's Bay Company. The negotiations for this purpose, assisted by the British government, were completed in the winter of 1868–69. Canada was to pay the company £300,000 for its title, and the company was to retain 5 percent of the Fertile Belt (land fit for agricultural settlement) and designated areas around its various posts. The Canadian government passed a provisional act for the government of the Northwest Territories, sent out a survey party to begin a land survey before settlement began, and appointed as governor William McDougall of Ontario.

Purchase of Hudson's Bay Company territories

The first Riel rebellion. The government unwisely regarded the acquisition of the northwest as a transaction in real estate with the Hudson's Bay Company. But the company was not the only power in the territory. There was the colony of Red River, and also the Métis, who made up more than half the colony. The Métis were French in language and Catholic by faith, and they had a semimilitary, semipolitical organization of their own. They had long thought of themselves as a new nation, neither European nor Indian but both, sharing the rights of one and the title to the land of the other. And behind them were the powerful Plains tribes—Plains Cree and the Blackfoot confederacy, buffalo hunters not under the influence of the Hudson's Bay Company. Canada had taken no account of the Métis or Indians in effecting the transfer. It assumed it could take over from the company and then consider what should be done.

This policy was rendered impossible by Louis Riel, a Métis educated in Montreal, who organized resistance in Red River to a transfer to Canada without the people of the northwest having a voice in the transaction. Riel, with the support of armed Métis, seized control of Red River and forced Canada to postpone the transfer and to negotiate. The result was the creation in 1870 of the small province of Manitoba, with equality of the English and French languages and an educational system like Quebec's two systems of public, confessional schools, Roman Catholic and Protestant. The implication was that the northwest was to be open to French institutions and language, as well as English.

That assumption was to be thwarted, however, by the extreme smallness of the new province, which amounted to little more than the Red River Settlements, and by the Dominion's control of natural resources and of the still vast North West Territory. Riel's obstructionism did not block Canada's march to the west, and the Dominion at once opened negotiations with delegates from British Columbia. That colony consisted of Vancouver Island (organized as a colony in 1849) and the mainland to the watershed of the Rockies, the latter having first been made a separate colony in 1858, when the gold rush along the Fraser River began, and united with Vancouver Island in 1866. The chief needs of the new colony were responsible government and connection with the east. Union with Canada might afford both, and in the negotiations the chief Canadian representative, George Etienne Cartier, promised both and more—in fact, a railway was to be begun in two years and finished in ten (1881). Faced with such generosity, the Legislative Council of British Columbia could only accept. British Columbia became a Canadian province in 1871.

Addition of British Columbia

The transcontinental railroad. With the addition of British Columbia, Canada extended from Atlantic to Pacific. To maintain that area, however, and to ensure its independence from the United States, it was necessary

to build a railway to the west coast. The effort to organize a company to undertake this enterprise, much greater than any railway yet built, was made in 1872. But Sir John Macdonald's government, charged with corruption in its dealing with the head of the new company, fell on the eve of the great depression of 1873. The railway thereafter could only be built piecemeal until Macdonald returned to power in 1878. An economically revived Canada, fortified with a new National Policy of tariff protection, incorporated the Canadian Pacific Railway in 1881, and the line was pushed ahead rapidly with government grants of land and money.

The National Policy

Even so, the railroad came to need new loans from Parliament, and its funds ran out as depression returned. Had it not been for the Riel Rebellion of 1885, which showed the need for the railway in moving troops, the last loan needed might have been refused. Despite the victory in the creation of Manitoba, many of the Métis —finding life impossible with the influx of new settlers— sold their lands and trekked westward to the Saskatchewan River. Even there, they were followed by the government land survey. The buffalo herds were vanishing, and the railway would supersede transport by boat and cart, from which many of them earned their living. The Plains Indians, alarmed by the end of the buffalo and unhappy with the treaties made with them, were also restless. The Métis again organized to claim their rights as they saw them and sent for Louis Riel, living in exile in Montana. Riel returned and a new armed resistance was formed. Canada had to rush militia to the northwest. Here the new railway, though not quite completed, proved its worth. The troops were rushed out, the rebellion was suppressed, and the railway obtained the grant that enabled it to complete its track across the Canadian Shield and the Rockies. Riel, with several associates, was tried, and despite evidence that he was of unsound mind, convicted of treason, though with a recommendation for mercy. Macdonald, as minister of justice and prime minister, refused clemency. The last spike of the Pacific railway was driven on November 7, 1885, nine days before Riel was hanged at Regina.

Canada had united its new territories with its old, but there was a fierce reaction in the French province of Quebec. Riel, who had not gained much French sympathy in 1870, was now viewed by nationalist French Canadians as a martyr to the cause of French Canadian rights. The result was the election by a narrow majority of a clerical-nationalist government in Quebec. This produced a reaction in Protestant Ontario, which, in turn, led in 1890 to the abolition of the confessional schools in Manitoba, where the Roman Catholic schools were almost wholly French speaking. French Canadians thereafter fell back on the provincial rights of Quebec to maintain the rights of French Canadians—a reaction with serious consequences for the Canadian federation. The Conservative Party, which had lost Macdonald by death in 1891, fell from power in 1896 largely because of the Manitoba Schools Question. The Liberal Party, under the French Canadian Wilfrid Laurier, came to power by virtue of a large majority in Quebec. Canada, it seemed, was not to be governed without the support of Quebec, even though the west retained only traces (in the Northwest Territories) of French population and French rights.

Fall of the Conservative Party

The Klondike gold rush. These conflicts took place against the background of a long depression, which lasted from 1873 to 1896. With the advent of Laurier's government in 1896, prosperity returned, and with it political peace. The most exciting manifestation of the new prosperity was the Klondike gold rush of 1897. Canada had already had the great rush to the Fraser, largely made up of American miners from the mountain states. It had petered out by 1866, but prospectors continued to comb the mountains northward into British Columbia and the lands of the Yukon River beyond, both in Canada and Alaska, which the United States had purchased from Russia in 1867. In 1896 nuggets were found on Klondike Creek, a tributary of the Yukon. A rush began in 1897 and swelled in 1898, as miners and adventurers poured in, mainly from the United States. The Klondike was the last of the great placer rushes and excited a world weary of depression. The Klondike was, in fact, the most publicized of all the great rushes. Canadians, ready to exploit the newly acquired territory, and equipped with the Pacific railway, benefitted from the publicity in two ways. First, its vast, largely virgin wheatlands became known in the United States and Europe shortly after the availability of free land in the United States came to an end. Settlers from the United States and Europe as far as Russia poured into the Canadian west by the hundreds of thousands. Second, the new nation had to assert its sovereignty and institutions in far distant territories, suddenly occupied by a rush of Americans. It did so successfully, to the strengthening of its national confidence.

The Klondike, however, was not the only mineral find on the new Canadian frontiers. The beginning had been the discovery in 1883 of a great nickel bed on the route of the Pacific railway at Sudbury, Ontario. A second had occurred in the early 1890s in southern British Columbia, where great deposits of mixed base metals were found, most notably at Trail. Then, in 1903, the building of a provincially owned and operated railway northward from Toronto toward James Bay resulted in the rich silver strike at Cobalt, north of Lake Nipissing. A great wave of prospecting began that led to further silver strikes and then to the finding of gold on both sides of the Ontario–Quebec border. Suddenly, the north of those provinces, long ignored since the early days of the fur trade, became mineral empires, not to mention their resources of waterpower, wood pulp, and even agricultural land in the "clay belt" beyond the shield. The prospectors spread westward also in search of "cobalt bloom," to make the base metal stake at Flin Flon, Manitoba, in 1915, and the radium strike on Great Bear Lake in 1931. Canada had become a major mining country.

Other mineral finds

The land rush in the west. At the same time, the land rush to the prairies widened the country's agricultural base by the settlement of Manitoba and the Northwest Territories. Their population rose from 419,512 in 1901 to 1,322,709 in 1911. Manitoba had already been enlarged westward and northward in 1881. The territories, governed by a governor and appointed council since 1876, had had elected members added to the council, and began the traditional Canadian struggle, first for representative and then for responsible government. The latter, however, could only come with provincehood, and the demand arose for the creation of a province between Manitoba and the Rockies. The federal government responded after the election of 1904, and in 1905 not one but two provinces were created, Alberta and Saskatchewan. The territories were divided into roughly equal areas by the 60th parallel. A fierce political struggle arose over the question of French schools in the new provinces, and again the cause of French rights outside Quebec received a setback. Separate schools in the Canadian sense of denominational schools supported by the taxes of members of a denomination—Roman Catholics in this case—there were to be, but nothing like the dual confessional school system of Manitoba before 1890, or of Quebec. Once again the development of the west had disturbed the relations of English and French in Canada.

The Laurier era. For 15 years, Laurier's Liberal government reflected the acquiescent politics of prosperity and progress. Canada seemed at last to be entering on its own century, as the United States had done in the one just past. Nothing better exemplified the confident, easy mood of the Laurier years in Canada than the vast and extravagant railway expansion in response to the settlement of the west and the initial development of the mineral and forest wealth of the nearer, or middle, north. The Laurier government built one transcontinental railway from Quebec to a point east of Winnipeg; from there to Prince Rupert a well-subsidized Grand Trunk Railway of eastern Canada built a subsidiary line, the Grand Trunk Pacific. Not to be deterred by two transcontinental railways in a country that was yet little

Further railway construction

more than a narrow corridor from east to west, two Canadian private entrepreneurs, geniuses of their kind, William Mackenzie and D.D. Mann, built or bought the Canadian Northern bit by bit with lavish subsidies from provincial governments. By 1914 Canada had one long established coast-to-coast railway (the Canadian Pacific) and two railway lines from Montreal to the Pacific toiling to complete their tracks in the Rocky Mountains. In such a wealth of easy capital and easy prosperity, governments were not likely to be defeated.

Yet two factors—one as old as Canada, one relatively new—were to disturb the smooth current of prosperity. The former was the never quite settled place of the French in an English Canada. The question had flared up in the creation of the new provinces in the west; it now arose over participation in Britain's wars, first the South African War in 1899, then World War I. The result was the growth of a new nationalist movement among French Canadian clerics and intellectuals, who made their voices heard in a new paper, *Le Devoir*. Their spokesman, in so far as a man so independent could speak for anyone but himself, was Henri Bourassa. The second factor was the impingement of the world on a Canada intensely absorbed in its own development and its own troubles. The two were to combine to end the Laurier regime and bring Canada, still troubled, into the world at large.

Foreign relations. Canada's contacts with the world in 1900 were almost wholly through Great Britain and the United States. Indeed, Canada's formal relations with other countries were conducted only through the British Foreign Office because Canada, as a colony, had no diplomatic status.

Relations with Britain

The dependence on Great Britain raised, after 1895, the question whether Canada might be expected, on its own decision, to take some part in Britain's imperial wars. The British colonial secretary Joseph Chamberlain was anxious that the Dominion should at least be committed in principle to supporting the mother country. Laurier, at the colonial conference of 1897, remained silent on the issue; thereafter his stand was that the Canadian Parliament must decide whether or not Canada would take any action. When the South African War broke out in 1899, many English Canadians actively urged participation; but some French Canadians, led by Henri Bourassa, were actively opposed. A compromise was reached, by which Canada sent volunteers to serve under British command and with British pay. But a rift between French and English Canadians had opened over foreign policy—a rift exacerbated by trouble over schools in the northwest. Also, Britain's naval competition with Germany made Britain eager to have colonial help, preferably by contributions in money, or by the colonies' assuming their own naval defense. Again, Laurier sought a compromise. In 1910 he established a Canadian Navy, which in time of war, however, was to be placed under British command. The measure was bitterly opposed by the nationalists in Quebec, who argued that conscription in Britain's army would follow. Their clamorous opposition led to the defeat of the government candidate in a Quebec by-election, foreshadowing Laurier's fall from power in 1911. In fact, as the history of the organization of the Canadian militia reveals, Canada was preparing to fight at Britain's side.

In the last analysis, Great Britain was Canada's only ally. Relations with the United States were close and informed, but in the final analysis they were relations between states foreign to one another. There had been a long record of border disputes, the settlements of which were resented, rightly or wrongly, by Canadians. There were the perennial difficulties over fishing rights in the North Atlantic and the dispute in the 1890s over the sealing industry in the Pacific. The Fenian raids at the time of Confederation symbolized another cause of strain, the Irish-American hatred of England, and suspicion of Canada as a British colony. Matters were brought to a head in the dispute over the Alaskan Panhandle boundary. The line laid down by treaty between Great Britain and Russia had not since 1867 been marked on the ground by the United States and Canada. It became an urgent issue in 1897 with the Klondike gold rush, as the principal access to the gold fields was through the Panhandle, and the disputed territory might contain gold. Canada claimed a line that would have put the heads of major inlets in Canadian territory, and so have given it, especially the port of Vancouver, free access to the Yukon Territory. The United States claimed a boundary that would have excluded Canada from the sea. A joint commission of Americans, British, and Canadians found in favour of almost the whole of the American claim, the one British jurist voting with the three Americans. The decision was bitterly resented in Canada, the action of the British member Lord Alverstone even more than that of the Americans. In fact, Canada's case was exceedingly weak, but the combination against it of the two powers with which alone Canada dealt made the country realize it must be prepared to look out for itself. Canadian nationalism in a new sense came into being.

U.S.–Canadian friction

Two results followed. One, neither quick nor dramatic but significant, was the creation of the Department of External Affairs in 1909, in preparation for Canadian handling of its own foreign affairs. The other, encouraged by Lord Bryce, the British minister to the United States, was the cultivation of direct relations with the United States. From this followed the final settlement in 1909 of the long-vexed Atlantic fisheries issues and the creation of the Permanent Joint Commission on Boundary Waters in the same year.

Relations between Canada and the United States were assuming a new guise, and with reason. The United States was beginning to turn to Canada as an outlet for investment and as a source of raw materials, particularly minerals and newsprint. An exchange of ideas began on a new scale, particularly in the ideas of the Progressive movement, which advocated a wide range of reforms to combat the growing social evils caused by industrialism. These ideas were influential on both sides of the border, in Canada sometimes more than in the United States, as in the creation of the publicly owned and operated Ontario Hydro-Electric Power Commission in 1906. These developments, however, were abruptly upset by the Canadian election of 1911. An outburst of economic nationalism, fed to some degree at least by resentment at the Alaska boundary award, enabled the Conservative Party under Sir Robert Laird Borden to overturn the Laurier regime.

The new government was not a reactionary one—indeed, Borden had taken up some of the ideas of the Progressive movement—but it had early to deal with the heightening of diplomatic tensions in Europe. Borden did so by seeking to add monetary contributions to the Royal Navy to the maintenance of the new Canadian one, with the concurrent proposal that Canada should have a voice in Britain's imperial policy. Borden was defeated in the former by the Canadian Senate in 1913, still under Liberal control, but even so lost much of what little influence he had in French Quebec. The idea of a Canadian voice in imperial affairs was politely turned aside in England, but the idea was to survive. Thus, Canada came to the outbreak of World War I with national opinion divided and with little naval strength. Only the militia was to some degree organized and ready, by tactical training and equipment, to cooperate with the British Army.

CANADA IN WORLD WAR I

On the outbreak of World War I in August 1914, Canada might have been as divided as it had been over the South African War. But the German violation of Belgian neutrality brought instant union for participation by sending an expeditionary force of men who had volunteered for overseas service. (The Canadian Militia was for the defense of Canada only.) As a result of this unanimity, and the previous preparation of the militia, a force of 33,000 men was sent to England in October 1914. There it had to complete training, and not until the spring of 1915, at the Second Battle of Ypres, did Canadian units see action. At first they served as battalions in British formations, but the Canadian government and people were determined that Canadian units should be kept together

First Canadian mobilization

and formed into the largest formation their numbers and officers equipped for higher commands would permit. The First Division was formed in 1915, the Second in the same year, the Third and Fourth in 1916. A fifth was also organized, but it was broken up to provide reinforcements. In 1915 the Canadian Corps was formed, and its four divisions fought together in the taking of Vimy Ridge; in June 1917 Lieut. Gen. Sir Arthur Currie of Vancouver became its commander. This force not only earned an enviable record as a fighting force; it was the first authentic expression of Canada in the world. Its strength and reputation meant that Canada could not be disregarded or treated as a mere colony. The Canadian Corps won many battle honours, but its role in history was to ensure Canada that "voice" in imperial and international affairs for which Borden had asked in vain in 1912.

At home, the war effort was scarcely less impressive. Canadian foodstuffs and raw materials were of first importance in maintaining the western Allies. If the troops brought Canada into international politics, the war workers made it an industrial as well as a primary producer. But tragically, the cooperation of 1914 between English and French Canadians did not last, partly because it was not fostered, and partly because few French Canadians had the feeling for France that many English Canadians had for Britain. They were content with a limited, voluntary war effort, in which French-Canadian units had won distinction as fighting men. But the length of the war and of the casualty lists forced Canada, as it had the United Kingdom, to abandon the customary reliance on volunteers and to impose compulsory military service. French nationalist feeling had been reawakened by new troubles with respect to the use of the French language in schools in French districts in Ontario and Manitoba. French Canada, led by Laurier, opposed conscription, but was overridden by the formation of a Union government—almost wholly English in personnel—and in the wartime election of 1917. Canada had conscription, and its corps was kept up to strength; but the country was divided as it had not been since 1837.

French-Canadian opposition to war

Despite this rift at home, the entry of Canada into the world of nations went ahead. In 1917 the British government under Prime Minister Lloyd George formed an Imperial War Cabinet, of which the prime ministers of the dominions were members, to conduct the war and to plan the peace. In reality, if not yet in name, the British Commonwealth of Nations had come into being (see BRITISH EMPIRE AND COMMONWEALTH). This was recognized by Article IX of the Imperial War Cabinet in 1917, which stated that the British Empire was made up of self-governing nations as well as colonies, with India in a special position. Henceforth, it was hoped, a common policy would be worked out by government conferences in peace as well as war.

III. Canada since 1920

CANADA BETWEEN THE WARS

Commonwealth relations. Canada and the other dominion powers, however, were not content with their status within the empire. At the peace conference in 1919, they demanded separate signatures to the treaties with the defeated countries, and won at least the right to sign as members of a British Empire Panel. They also demanded and got, despite the doubts of the United States and France, membership in the newly organized League of Nations. Thus, Canada finally became a full-fledged member of the community of nations.

If independent of the United Kingdom, Canada's role was not a fortunate one, either for the League or for Canada. Membership in the League meant that Canada was now recognized in the world as an independent nation. Yet the country followed an isolationist policy. This was partly, if paradoxically, the result of its new national character. But it was mainly a consequence of its return to government by the Liberal Party, now more than ever dependent on French-Canadian support. French Canadians were themselves isolationist, and they strengthened the general disposition of Canadians to express their new national feelings by the completion of autonomy in the empire and by resuming their material development as a North American country. The idea of imperial policy made in conferences of governments had one success when Borden's successor, Prime Minister Arthur Meighen, persuaded the Imperial Conference of 1921 to accept American policy in the Pacific and allow the Anglo-Japanese Alliance, a source of some concern to the United States, to lapse. Meighen, however, was crushingly defeated in the general election late in that year by the Liberal Party, which swept Quebec and the Maritimes, and by the Progressive agrarian democrats who swept the prairies and made inroads in Ontario. The new prime minister, W.L. Mackenzie King, and his government were firmly nationalist and isolationist, as was made very clear by their prompt refusal to back the United Kingdom's policy in Turkey in 1922. This, in effect, ended the hope of a common imperial policy. Instead, there would be conference, consultation, and sharing of information, but freedom of action.

King's government had, in fact, determined on attaining complete autonomy within the Commonwealth—that is, an independent foreign policy reached in terms of Canada's interests. In this determination Canada found itself in alliance with the new Irish Free State and with the Union of South Africa. The Imperial Conference of 1923 firmly ended the hope of a common foreign policy for the Commonwealth. This was followed by Canada's signature, without that of the British Foreign Office, to the Halibut Treaty of 1923 with the United States.

A national foreign policy was not the only goal. Another was that of recognized and explicit equality of status of all members of the Commonwealth. In the Commonwealth Conference of 1926 the principle of equality of status was accepted, and a committee was set up to examine the vestiges of British sovereignty and dominion subordination and to suggest necessary changes. While the committee was at work, formal steps were taken to end the position of the governors general of the dominions as imperial officers and to make them the personal representatives of the king, appointed on the advice of dominion cabinets, not of the Imperial Cabinet. In 1931 the necessary changes to create legal equality were combined in the Statute of Westminster. This act ended all legislative supremacy of the Imperial Parliament over the dominion parliaments and made them, when they proclaimed the Act, sovereign states sharing a common crown. The Commonwealth had become a legal reality and Canada an independent nation.

The Commonwealth Conference of 1926

Canada's new independence was reflected by its establishment of its own foreign service. Canadian ministers were appointed to Washington in 1927 and to Paris and Tokyo in 1928 and 1929. (In the United Kingdom and Canada, officers called high commissioners played much the same role after 1928, although the office was to some degree political and not just diplomatic.)

Internal politics and the Great Depression. At the time, the completion of the quest for equality of status was to some degree obscured by the onset of the Great Depression, begun with the New York stock market crash in October 1929 and intensified into world depression by bank failures in Germany. Canada reacted early to the onset of depression. The Liberal Party, except for a brief interval in 1926, had been in power since 1921. In the general election of 1930, the Conservative Party, led by R.B. Bennett, succeeded in winning the election—partly because the King government had refused to give federal funds to the provinces to combat unemployment and give relief, and partly because Bennett promised to blunt the effects of the depression by protective tariffs. If the attitude of King was old-fashioned and not up to the needs of the times, so were the election promises of Bennett. The depression was so far-reaching in its effects that only drastic measures could lessen its impact and begin the process of recovery.

The Bennett government did little to increase the already high tariffs that had been in effect under the Liberals, but it did stiffen the application of customs regulations. The Conservatives also sought relief for Canadian

producers by reviving an old dream of Joseph Chamberlain that the empire should have a common tariff policy. The obstacle created by Britain's policy of free trade had ended with the modification of that policy in the 1920s. Political imperialism had ended, but perhaps commercial imperialism would be revived. Prime Minister Bennett arranged an Imperial Economic Conference at Ottawa in 1932. The national interests of the representatives made agreement difficult, but all countries were desperate. The dominions badly needed the British market for their foodstuffs and other primary products, and Britain itself could not afford to ignore protected markets in the dominions. The Ottawa Agreements were a series of preferences given by Commonwealth countries to one another, to some degree at the expense of producers in other countries, particularly the United States.

The Imperial Economic Conference

The depression, however, merely intensified. Canada had known widespread unemployment in the mid-1870s and in the immediate postwar years. But an economy still predominantly agricultural had largely, if painfully, absorbed the unemployed. In 1921, however, supremacy began to pass from agriculture to industry, and from countryside to city, and the trends thereafter were rapid. The cities had now to provide for mass unemployment, and Canadian municipalities were required by law yet unfitted in financial resources to furnish welfare and relief. The municipalities had therefore to turn to the provinces for aid; the weaker provinces had to turn to the federal treasury. Thus, not only was the economy being dragged down to unexampled levels of prices and production, but the very framework of government was threatened in the poorer provinces. What happened in Newfoundland, where responsible government was replaced by administration by a commission aided with British funds, came close to happening in the prairie provinces. The brighter side of the picture was that the mining industry of Ontario and Quebec kept the revenues of those provinces comparatively good, and so the greater part of the country remained in condition to maintain the federal revenues and make possible the support of the weaker provinces. Confederation had never been more important.

Prime Minister King might refuse to aid the provinces in 1930, before the second great slump of the depression, but his successor had no such choice. Prime Minister Bennett's own remedies—stiffened protection and imperial preference—could only act slowly at best. But conditions were drastic by 1931, aggravated by unprecedented drought on the prairies. Bennett began, on entering office, to advance federal funds to the provinces for relief works. The provinces had already come to the financial aid of their municipalities, and a relief system was worked out for the unemployed. But all the means of aid that were employed ended with the giving of relief; the government still looked for recovery from the depression. The rise of parties with more fundamental solutions than relief therefore began. One was the Co-operative Commonwealth Federation, a party socialist in theory if pragmatic in fact. Another was Social Credit, a movement urging the payment of social dividends to fill the gap between the costs of production and the cost of purchase. There was even a small Fascist Party in Quebec, and a splinter group led by Paul Gouin, a Liberal rebel, which in 1936 joined with Maurice Duplessis's Conservatives to make up the Union Nationale, which became a nationalist "Quebec First" party. Disquieting findings of a Price Spreads Commission and the growing desperation of the farmers led Bennett to listen favourably to praise of the New Deal in the United States. Perhaps personally convinced, certainly politically desperate, in 1935 he had his last Parliament enact a Canadian New Deal. It quite failed to remove the resentment his government had provoked during its years of office, and the Liberals returned to power easily.

Attempts to relieve the depression

King, despite some advanced ideas in his youth, was convinced that Bennett's New Deal was unconstitutional, as indeed the courts in 1937 found nearly all of it to be. King and his government believed that the way to end the depression was to stimulate international trade. The Ottawa Agreements, of course, remained in force. Canada, however, availed itself of the United States' policy of more liberal trade agreements, and the result was what was called the Reciprocity Treaty of 1936. Reciprocity and imperial preference were reconciled. In the long run, American–Canadian trade was to grow to enormous proportions, but for the time being the depression continued, as did the drought.

The Liberal government did concern itself with the devastation wrought by the depression on government finances. In 1936 an official inquiry made by the newly created central Bank of Canada revealed that the prairie Provinces were at the end of their economic rope. A distinguished Royal Commission was set up to inquire into the allocation of revenues between the federal and provincial governments. The resulting report in fact amounted to a comprehensive study of the constitutional and financial development of government in Canada, and of how the depression had revealed its weaknesses. The federal government, with unlimited power to tax, lacked the power to spend on needed issues; the provinces possessed the necessary constitutional power but, except for Ontario, their financial resources were inadequate. The commission in 1940 recommended the assumption by the federal government of provincial debts, a scheme of federal unemployment insurance, and a reallocation of revenues between the two levels of government, on the principle that all provinces have the means to maintain a national level of governmental and social services. The first two were done, relieving the credit of the provinces and strengthening the federal government, but on the latter there was no agreement, as it involved a redistribution of income between wealthier central Canada and the Maritimes and the Prairies. At that time both Ontario and Quebec were strongly provincialist and resisted redistribution.

Growing international tension. Even domestic distress was to some degree submerged in the second half of the 1930s by the worsening outlook in international affairs. The external interests of Canada shifted from the development of the Commonwealth to the fate of the League of Nations and the first shocks of aggression in Asia and Europe. Canada was too preoccupied with its own affairs up to 1935 to take great note of Japanese aggression in Manchuria or the rise of Hitler in Europe. By that date, however, the fate of the League of Nations, clearly threatened by unprovoked aggression, drew more and more attention. Much Canadian opinion deplored the failure to stop the Italian invasion of Ethiopia or to oppose the Fascist powers in the Spanish Civil War (1936–39). The government, however, refused to take a firm line and seemed to practice a rather uncertain isolation, which became, in fact, support of the policy of appeasement. But after visiting Hitler in 1937 to inform him of the continuing cohesion of the Commonwealth, Prime Minister King let the British government know that Canada might be expected to oppose aggression in Europe. For the first time since World War I, the government began to build up the exiguous defense forces of Canada. After Hitler's occupation of Czechoslovakia late in 1938, few members of the Canadian government or of the informed public thought that there was any realistic hope of peace. Canada would again be drawn into full involvement in world affairs.

Canada's policy toward Hitler

CANADA IN WORLD WAR II

When the Parliament of Canada voted on the declaration of war against Germany on September 9, 1939, only a very few members voted in opposition. This unanimity, however, rested on two assumptions. One was that Canada's role would be, in the main, to supply raw materials and furnish training facilities; the other was dependent on the former—that conscription for overseas service would not again be necessary, or attempted, as King actually pledged. It was in a more sophisticated form the illusion of 1914, that the war would be short, and it was again to be shattered. The expulsion of the British from Europe and the fall of France in May and June of 1940 totally changed the circumstances. Canada's defenses had

fallen, and it immediately concluded an agreement at Ogdensburg with the United States for the defense of North America. Moreover, Canada now stood in the forefront of the war. After England, it was for once the second most powerful of Germany's adversaries. The emphasis on supply had to give way to an emphasis on combat forces. Necessarily, the question of the allocation of manpower, including compulsory service overseas, came to the fore and was made more urgent by the Japanese attack on Pearl Harbor in December 1941. King, resolved at almost all costs to avoid a repetition of the Anglo-French cleavage, had to recognize the changed situation by holding a national plebiscite in 1942 to free him from his pledge and allow conscription if necessary. It was strongly carried in English Canada but heavily defeated in Quebec. Thereafter, compulsory service for home defense was enforced, while overseas service remained voluntary until the last year of the war. Then in 1944 unexpectedly great casualties in Normandy led to a "conscription crisis" and the ordering of 16,000 home defense men overseas. The gulf of 1917 between English and French, reopened in 1942, was deepened.

Increased Canadian involvement in the war

Even so, Canada played a greater, if less glorious, part in World War II than in World War I. This was done in three ways. The first remained supply. Canada furnished not only raw materials and foodstuffs but manufactured goods of a volume and sophistication unknown before in Canada. The industrialization of Canada was accelerated, both by investment and by increase of technology and also by government investment and control and the device of Crown corporations (autonomous government corporations). Second, the federal government of Canada developed the financial power of Canada to such an extent that Canada not only financed its own war effort without American help but even supplied money to Great Britain. Finally, Canada developed complete armed services of army, air force, and navy, through whose ranks and auxiliary services over 1,000,000 Canadians passed, not to mention those who served with the Royal Air Force.

POSTWAR CANADA

International commitments. The outcome of the war was uncertain for Canada. It had no national interest to serve except the survival of Britain and the restoration of France. The most significant outcome of the war for Canada was the relative decline of Britain and the emergence of the United States as the world's foremost economic and military power. Canada's relations with Britain remained unchanged; those with the United States became closer. The creation of the Permanent Joint Defence Board in 1940 was the greatest exercise in "continentalism" since the American invasion of 1775. Canada had moved far into the continental military system of the United States, as it had already done in the economic sphere.

Permanent Joint Defence Board

It was hoped and, indeed, assumed that this was a new continentalism, not isolationist as was the old, but international and devoted to collective security. Such was the purpose of America's wartime leaders. Canada's problem then, was not that it had fallen under the control of the United States. Its problem, rather, was to define its role in a postwar world governed by the great powers through the United Nations. Most informed Canadians welcomed the new organization, and the Canadian government took a vigorous part in its creation. But King, mindful of his own lifetime battle to remove Canada from the trammels of British imperialism, was dubious of a world to be dominated by the great powers. His advisers, for their part, wanted to find some way for Canada to play a significant role in the world. The government therefore advanced the concept of a status of "middle power," that is, a state strong economically if not militarily. Members of the United Nations should function appropriately, according to their capacities. The idea in practice meant that Canada should concern itself mainly with economic policy in world affairs and with aid to developing countries.

Similarly sensible was the Canadian decision to use its considerable knowledge of nuclear fission not for military purposes but exclusively for peaceful and economic ones. Canada, in short, wanted—as in 1918—to get back to its original peaceful character and to resume its own development, this time in the world at large.

Nevertheless, the country did not cut its armed forces to the bare bone as it had in 1919. There were two reasons for this. One was, that under the Ogdensburg Declaration it had assumed an obligation to the United States for the defense of North America. The second was that Canada planned to contribute to the peace-keeping capacity of the United Nations. Both concepts were to be tested in the Korean War of 1950.

Maintenance of armed forces

Even before that, however, a third and perhaps more powerful factor had come into play: the possibility of Soviet aggression in Europe. In 1948 this danger was felt in the Berlin crisis and in the coup d'etat in Prague that made Czechoslovakia a Communist state and brought it within the Soviet orbit. No one could be sure at that time that the Soviet move was limited and defensive. Nor was the United Nations any help, as it clearly could not coerce a power such as the Soviet Union into obedience to a collective will, if indeed such could be found. The idea of a regional agreement for the defense of western Europe against Soviet pressure or attack was therefore taken up. Devoted supporters of the United Nations in Canada as elsewhere were dismayed, for they felt that regional agreements militated against the global purposes of the general organization. The Canadian government, nevertheless, supported the United States' proposal for an alliance of North Atlantic powers. Yet Canada insisted that this alliance should not be purely military, but also political and economic. The minister of external affairs, Lester B. Pearson, pressed strongly for the adoption of that principle. It was accepted in Article 2 of the North Atlantic Treaty Organization (NATO) in 1949, sometimes referred to as the "Canadian article." The article, however, has never been made use of in any notable way. Whether that is a comment on a Canadian lack of realism, or the lack of percipience in others, it remains evidence of the outlook and intent of Canadian foreign policy, and of informed Canadian opinion at the time. Canada as a member of NATO also, for the first time in its history, assumed serious peacetime military commitments, maintaining out of its armed forces an infantry brigade and 12 air squadrons and contributing ships to the naval forces of NATO until 1969. Then a change of emphasis in foreign policy led to a reduction, much criticized by its NATO allies, of the Canadian contribution.

Just as NATO was a test of Canada's seriousness in entering world affairs, so, too, was the Korean War of 1950, which also tested the country's new relationship (since 1940) with the United States. When that country decided to assist South Korea in resisting invasion by the forces of North Korea, the question for Canadians was: Was this an endeavour to uphold the peace settlement that had divided Korea at the 38th parallel of latitude, or was it simply part of an American crusade against Communism? In the latter, few Canadians had any interest—not even French Canadians, for all their Catholic heritage. The government, as did the United Nations, decided that it was the former, and military and naval contingents from Canada served with the American forces. Canada had exerted itself to uphold a peace settlement against revision by force and was satisfied with the outcome.

The Korean War

More significant was the fact that informed Canadian opinion was already markedly diverging from the opinion of the majority of Americans on the subject of the new Communist regime in China and would have approved recognition of it as the government manifestly supported by the Chinese people. But the government, though sympathetic, thought it wise not to challenge American opinion on an issue in which no major Canadian interest was at stake. Most important, from a practical standpoint, was the economic outcome of the Korean War, which ended any possibility of a postwar depression—expected but not experienced from 1945 to 1950—and helped launch Canada on its extraordinary development in the 1950s.

U.S.–Canadian relations. The policy of the Liberal government (in power since 1935), wartime cooperation, and the close interconnections between the two economies had brought the two neighbours into a more intimate relationship than ever before. The United States, with British power and influence ended in Canada, no longer had intermittent designs on that country and had dropped the language of Manifest Destiny. Most Canadians were persuaded that the development of economic relations did not necessarily carry with them political relations that would end in annexation. The two nations, then, accepted and took one another for granted. In that development, however, there were certain dangers. Americans, including the American government, were accused by Canadians of taking Canada for granted in the sense of being unaware of and indifferent to Canadian sentiments and changes. Canadians, in turn, were apt to claim both a special standing with the United States and independence of it. None of this was ultimately of great importance, but two new trends were to prove significant. One was the growth of "continentalism," a special relationship not provided for in the theory of national independence—except perhaps in the joint commissions, such as the Permanent Joint Commission on Boundary Waters and the Ogdensburg Declaration, in which the parties met as legal equals and in which the fundamental assumption was that both, when in agreement, would contribute a proportionate share of their population and wealth to the common undertakings. The second was the unequal rate of economic and technological development, especially after 1950. The United States, leader of the world in industrial capacity and technology, was nearing the limits, subject to strategic reserves, of its national resources. Canada, within the inner defense orbit of the United States, had many such resources undeveloped and available. The interest of the United States was, therefore, to have assured access to these resources as they were developed, largely with American capital. This, however, tended to keep Canada a primary producer and a country of relatively low employment and low income. Its national development and its hope of educational and cultural development, called for the continued growth, under Canadian law and control, of its secondary industry. Yet its provinces—owners of the natural resources of the country, except for those controlled by the Northwest Territories—driven by the need for revenue and to satisfy the popular demand for development, were eager to alienate their resources to foreign, usually American, investors. This disparity of aim made American–Canadian relations, if much better diplomatically than in the days of territorial expansion and boundary settlements, much more subtle and complicated than ever before. Something of this lay behind Lester Pearson's warnings in the mid-1950s that henceforth those relations would be more difficult. It appeared also in the conclusion of a study prepared in 1965 by Livingstone Merchant, American ambassador to Canada, and A.D.P. Heeney, Canadian ambassador to the United

The United States and Canadian resources

States, that American–Canadian relations could best be handled by "the practice of quiet diplomacy"; that is, with a minimum of public discussion.

Canada's role in the United Nations

A third element of difficulty in American–Canadian relations, which became more apparent in the late 1960s and early 1970s, involved the fact that the main thrust of Canadian policy was to support the United Nations, in which Canada might evade subordination to the great powers. It did so by its peace-keeping efforts (Canadian troops served with the United Nations in Egypt after the Suez crisis of 1956 and some are still in Cyprus, and in cultivating the developing countries and those, like India, that attempted to play a neutral role between the United States and the Soviet Union in the Cold War. To do this, Canada had the advantage of being at once a materially advanced country and also a small nonimperialistic one. But Canada's special relations with the United States continued and expanded. One notable example of joint action was in the Early Warning System against surprise aerial attack, largely based in the Canadian Arctic. Another was the North American Defense Command (Norad) arrangement of 1958 for the defense of North America against aerial and missile attacks, in which elements of the Canadian Air Force were placed under American command. How could Canada be at once an influential, because uncommitted, power in the Third World, and an ally, even for limited purposes, of the United States? The opinion increased that it could not, and after the election of Pierre Elliott Trudeau as prime minister in 1968 this attitude began to affect Canadian foreign policy. Canada's contribution to NATO was reduced in 1969; Norad began to be whittled down in the Defence White Paper of 1970. At the same time, relations with the Soviet Union were improved, and in 1970 diplomatic recognition was extended to the People's Republic of China. Concurrently, however, the stress on aid to developing countries and the idea of Canada as an intermediary with the Third World were played down. The emphasis shifted to more domestic aspects of foreign policy: control of pollution in coastal waters, extension of Canadian fishing rights, and especially to confirming Canadian sovereignty in its Arctic islands and their icebound waters, a concern not much in evidence since the early years of the century. Yet in all these changes the special relationships with the United States remained unchanged, rooted in the facts of neighbourhood and common interest.

Canada and the Commonwealth. If the special ties with the United States waxed during these years, the historic ones with Great Britain waned. It cannot be said that this was willed or decided by either party. It was the outcome of the developing circumstances. The traditional ties remained—the common Crown; the parliamentary system of government; the desire for much the same kind of world; the same pragmatic, unideological temperament and outlook. Cordial relations between the two governments remained, consultation continued. Canada had, however, achieved the kind of world it wished to inhabit, with the creation of the Commonwealth; Britain, charged with the task of liquidating its empire, began to find the Commonwealth a burden and an embarrassment. Even imperial preference failed of its purpose; Canada exported more to Britain and imported more from the United States, while Britain exported less to Canada. Like relations who have moved apart, each knew it could call on the other at need, but each was going its own way with little to call them together. The British phase of Canadian history, which had begun with the great British immigration of the 1830s, seemed to have ended.

The reverse was true for the Commonwealth of Nations during the 1950s and 1960s. Canada as one of the principal creators of the Commonwealth, had a special if largely sentimental interest in it. But the Commonwealth had consisted of self-governing nations and, thus, those dependent parts of the British Empire, including India, that were not self-governing, or not wholly so, had not been members of the Commonwealth. With the rapid achievement of independence in most parts of the empire after World War II, a process of which Canadians in general approved, the new nations could choose to leave the empire entirely, or to apply for membership in the Commonwealth. Burma chose the former course, India the latter. But India had also become a republic in 1947. How could a republic be part of an association bound together by allegiance to a common Crown? Suddenly, the Commonwealth was seen as an association that might bridge the differences of race and culture in freedom as the empire had done by power. It was agreed among the members of the Commonwealth that republics could be members if they chose to accept the king as "Head" of the Commonwealth. Canadians, as members of a republican hemisphere, were perhaps particularly happy to agree, and certainly because the proposal fitted well with their desire to cultivate the widest possible associations, especially with the new and developing nations. Canada, perhaps somewhat smugly, saw a possible role for itself as an intermediary between the old and white members of the Commonwealth and the new and coloured.

Canada's relationship with the Third World

That it might, in some sense, play such a part was revealed by the Suez crisis of 1956, a great strain for the Commonwealth, as for world peace. Australia and New Zealand, for example, were disposed to sympathize with the strategic concern of the United Kingdom, while India was dismayed and angered by what it saw as an act of concerted aggression. Canada, led by Lester Pearson, was able to intervene between a wrathful and humiliated United Kingdom and a righteously angry India, and not only enable the contestants to withdraw with some saving of face but also to preserve the integrity of the Commonwealth.

The Canadian role of disinterested friend was also played in the crisis in Commonwealth affairs precipitated by the apartheid policy of the Union of South Africa. To a multiracial association such as the Commonwealth, South Africa was not only an anomaly but a reproach. Yet a basic rule of the Commonwealth was that of nonintervention in the domestic affairs of members. The issue of South Africa's racial policy came to a head in the Commonwealth Conference of 1960, at which certain members sought to have South Africa expelled. The United Kingdom, Australia, and New Zealand deplored this violation of the rule of nonintervention. Canada again tried to play the role of impartial intermediary, but when that failed, voted for expulsion. In short, Canada's Commonwealth policy was normally that of supporting the coloured members, as later in the matter of economic sanctions against the white regime in Rhodesia.

That was a defensible policy, if pursued realistically and for the purposes of mediation, and even if it led to some feeling against Canada in the United Kingdom. But in 1961 another issue was to arise at the Commonwealth Conference in Accra that raised some question of the whole future of the Commonwealth: the possible entry of the United Kingdom into the European Common Market. For it to do so would mean, if not the ending, at least the diminution of the imperial preferences, which since 1932 had given the Commonwealth a material as well as a sentimental basis. The Canadian delegates professed to be appalled by the prospect and spoke strongly against it as a betrayal of the Commonwealth. But in view of Canada's favourable economic position in trade with Britain, this attitude seemed to the British selfish and unacceptable. Britain was, in fact, not to join the market until 1971, by which time Canada, then under a Liberal government, chose merely to wish Britain well and to look out for Canadian trade with the market as best it could. But Britain's entry meant that the Commonwealth would be less and less a matter of material ties and more and more one of tradition and sentiment.

Britain and the Common Market

Ideally, perhaps, Britain might, like France, have sought to bring its Commonwealth partners into some form of economic association with the market, as it was to do with New Zealand and the African and West Indian members, heavily dependent on the British market for the sale of their primary produce. But industrialized members such as Australia and Canada, with their economic ties with the United States, had relatively little such dependency, and the members of the market were

firmly opposed to their becoming even associated members. There was no hope of a special relationship in that respect. Canada must stand on its own, economically as well as diplomatically.

Franco-Canadian affairs. That Canada was regarded in Europe as being at once on its own and also an economic, if not a military, dependency of the United States was revealed by the course of Franco-Canadian relations in the 1960s. France was, of course, as much as Britain a mother country of Canada. Yet practically nothing to reveal that fact had happened since the cession of New France in 1763. Relations between France and French Canadians had been strained by the Seven Years' War. The British regime was watchful against all but private correspondence. Then the French Revolution, particularly its attack on the Roman Catholic Church, caused further friction between France and French Canadians. What influence there was was private and literary. There had been readers of the *Philosophes* in New France, and in Quebec French books and ideas were always sure of at least a small audience. Nothing was done officially and formally, however, until the 1850s when the Second Empire of Napoleon III, Catholic and expansive, took note of French Canada. Not only did the frigate "La Capricieuse" visit Quebec in 1855; in 1859 the Emperor's cousin Prince Jérôme Napoleon visited the province incognito (under the watchful eye of the British government) and gave a sum of money for the statue on the monument to commemorate the Battle of Sainte-Foy (in which the French had defeated the British in 1760). Also in 1859, a French consul general was appointed to Quebec and a form of diplomatic relations began, and continued thereafter. But little more came of this rapprochement. French Canada's true ties abroad were with Rome, not with Paris.

The "Quiet Revolution"

All this changed in the 1950s and 1960s, particularly after the "Quiet Revolution" began in the province of Quebec with the election of a Liberal government led by Jean Lesage. All changed because French Quebec had wholly changed.

One result was to alter decisively relations between French Canada and France. The former suddenly found an interest in French history, French ideas, and the place of France and the French language in the world. French-Canadian students went to French universities, teachers were exchanged, some liaison developed between the press of the two countries. All this the Department of External Affairs both noted and welcomed. Canada and France had exchanged ministers in 1928, but as between foreign countries.

A warming of established relations proved to be by no means enough, however, either in Quebec or in France. Perhaps the main object of the Quiet Revolution was to arouse and make flourish French culture and the French spirit in Quebec. To do so was not a matter of diplomacy, as generally practiced, or of commerce, but of cultural affairs, for which Quebec had already set up a government ministry. The urgent spirit of the new Quebec was profoundly dissatisfied with the way Ottawa dealt with such matters in the Canadian embassy in France. Quebec began to establish what might be called quasi-diplomatic relations between France and Quebec, and had constitutional grounds for thinking it might do so. The federal government could not make treaties with foreign powers on subjects coming under the jurisdiction of the provinces. Cultural affairs, Quebec claimed, were educational, a provincial matter, and therefore Ottawa could not conclude treaties in cultural matters. It followed that Quebec ought to be free to develop its own cultural relations with France and, indeed, all French language countries. The matter was difficult, but one of concern in Quebec, and is not yet wholly resolved.

The second result arose from the personality of Pres. Charles de Gaulle of France. De Gaulle made it his particular role to restore French prestige in a world dominated by the "Anglo-Saxon" powers after World War II. De Gaulle encouraged the informal and then formal relations between the republic and Quebec. He, first of international statesmen, unless one counts the flurry of interest shown by Napoleon III, recognized Quebec for what it is, an island of French speech and culture in an Anglo-Saxon sea. His interest and those of the new nationalists of Quebec happily coincided. Moreover, de Gaulle had been rebuffed, largely because of United States influence, in two attempts to deal with Canada: first, in the attempt to sell French aircraft to Air Canada in 1964, and second, in an attempt to buy radium from Canada in 1965 without giving assurance that it would not be used for military purposes. De Gaulle therefore saw in Quebec an occasion to raise French prestige in the world, and in Canada a chance to separate that country from what he regarded as American domination. He visited Quebec in the summer of 1967 and received an extraordinarily emotional reception. There, in an apparently calculated move, he took the opportunity to encourage Quebec *separatisme*, and in a speech in Montreal he created a furor by repeating the slogan of the French separatists: "Vive le Québec Libre!"

De Gaulle's 1967 visit

De Gaulle was gently but directly rebuked on the spot by Mayor Jean Drapeau of Montreal, his official host, and firmly by the Canadian government, and returned to France in customary grandeur. His *bêtise* (foolishness), however, was possible because there was a separatist movement of growing strength in Quebec. The cause of the movement for a special status for Quebec within Confederation, or a new form of association on the basis of equality with English Canada, or complete independence as a sovereign nation, was the belief of a growing number of Quebec intellectuals and labour leaders that the economic difficulties of Quebec were caused by Confederation, and could only be ended by altering, or ending, the ties with the other provinces and the central government. In part it was the outcome of the perennial desire of Québecois to have their own state, as in a sense they had from 1791 to 1841. In part it was a continuation of the minority of French-Canadian opinion that had opposed Confederation in 1867. It was also a continuation of that sense of minority grievance stimulated by the execution of Riel, given substance by the Manitoba Schools Question, and given voice in the nationalism of Jules-Paul Tardivel and Henri Bourassa.

The origins of French separatism. Yet French nationalism was much more the outcome of profound economic and sociological changes that had taken place in Quebec since about 1890. Up until that time French Canadians had lived by agriculture and seasonal work in the timber trade. The middle class French of Quebec and Montreal acted as intermediary between their humbler countrymen and the English masters of commerce and industry. The coming of hydroelectric power and the wood-pulp industry as a result of the successful national policy of protection in creating Canadian manufacturing plants in Quebec and Ontario created a labour force that brought French Canadians as workers into the cities, particularly Montreal. The rate of growth of the French-Canadian population and the lack of good workable land outside the narrow St. Lawrence and Richelieu valleys contributed to the rush to low-paid jobs in urban industries and to the growth of slums, particularly in Montreal. By 1921 Quebec was the most urbanized and industrialized of all Canadian provinces, including Ontario, and also the most populous and the wealthiest. The Quebec government, devoted to the 19th-century policy of laissez-faire, recklessly encouraged industry and did little to check its worst excesses. With few exceptions the new enterprises were owned and directed, in the English language, by English Canadians or by Americans. It was a kind of second conquest of Quebec.

At the same time it destroyed the myths by which French Canada had survived: that of the Catholic mission to the New World, and the cult of agriculture as the basis of virtuous life. Ever more Québecois had to make their way as best they could in quite a different world, in which the old values were mockeries and the obstacles not to be overturned by the old powers of endurance.

This clash of old and new came to a head in the last years of the regime of Premier Maurice Duplessis. A Conservative who became leader of the new Union Na-

The regime of Maurice Duplessis

tionale Party formed in the depression, he came to power in 1936, was defeated in 1939, but returned in 1944, and remained in office until his death in 1959. Duplessis, after 1944, wielded unequalled power in Quebec, partly by fostering the nationalist sentiments of rural and conservative elements in Quebec, partly by a seasoned mastery of political corruption in a province realistic in its politics, but especially by preserving a close alliance with Anglo-Canadians and American big business in the province. They furnished him the money he needed for political purposes; he in return preserved a free enterprise system in the province that would have done credit to a government before 1850. In the political miasma he created, all possibility of reform, all political integrity, seemed to be stifled.

Yet they were not. The fight against conscription in 1944 lifted Quebec politics out of the rut of place and favour. In 1949 the prolonged and bitter fight of the asbestos workers gave young idealists, one of them Pierre Elliott Trudeau, a chance to combine with labour in a struggle for a free society of balanced interests. Over the decade more and more intellectuals in the universities, in the press, in law, and as independents, began a searching analysis of Quebec politics and society in modern terms, often French and American as well as English Canadian. A new outlook—historically, a modern version of the Rouges who had talked of republican virtue and opposed Confederation as no more than a railway job—was building up pressure in Quebec. For the time being, Duplessis smothered it, and English Canadians took little note. What reason was there to expect novelty in a province that had spent so much rejecting it?

The successors of Duplessis

When Duplessis died, it was a deliverance. Even his successors in office, Paul Sauvé and Antonio Barrette, seemed like reformers and to some degree were. But in the election of 1960 Jean Lesage and the Quebec Liberal Party made themselves the political vehicle of the new outlook and tried to carry out a Quiet Revolution; that is, to bring in much needed reforms before demands became revolutionary. They did much, both to assist the power of the province against the federal government, and to transform Quebec society from clerical to secular, and from 19th-century laissez-faire to positive, if not socialist, politics. Politically, indeed, they did too much for the taste of the rural areas of Quebec, which were still heavily over-represented in an antiquated electoral system, and the party was defeated by the Union Nationale in 1966. The revolution was not reversed, but it was slowed down.

In the years that followed, the extremes widened in Quebec, and the elements of opinion began to crystallize. The Liberal Party was federalist; it held that the reforms needed in Quebec could be obtained within the federal system. So, at bottom, did the Union Nationale, but, as a mainly conservative party, it had to stress the importance of remaining Québecois, and of obtaining greater provincial power. To the left of the traditional parties, however, opinion ranged from a demand for a special status for Quebec to the demand for separation and independence. The truth was that an active minority of Montrealers had passed far beyond the concept of constitutional reform, and in the process, of course, they broke with Trudeau and the Liberals. They saw Quebec society as one of exploiters and exploited, largely along racial lines. This, they fervently believed, must be ended as intolerable, and the first step to end it was to break the tie with Confederation. No social revolution (which, in their opinion, Quebec desperately needed) was possible, they believed, without independence. Organizations rose and fell trying to find a power basis for these ideas. From their efforts came the Parti Québecois with a platform of secession from Confederation. Under René Lévesque, a former Liberal, they won 24 percent of the popular vote in the election of 1970, but the Liberals, by reasons of the antiquated distribution of electoral districts, won 72 seats out of a total of 95. Constitutional reform was to be tried once more.

Still other social revolutionaries had given up thought of conventional political action, and inspired by refugees from Algeria and by the Cuban example, began to practice terrorism. Bombings began in 1963 and continued sporadically. This mode of action most French and English Canadians felt was "un-Canadian," but it illustrated both the social ills of Quebec and the ties of the French intellectuals with the world outside Canada. No overt special measures were taken, but in October 1970, with the kidnapping of James Cross of the United Kingdom consular service, and Pierre Laporte, minister of labour in Quebec, who was murdered, there was a sudden fear in the government of Quebec and of Montreal that the situation had become revolutionary. The government of Quebec called in the federal government for help, and the War Measures Act was proclaimed, allowing the federal government sweeping authority in time of war or imminent insurrection. The usual civil liberties were suspended, some 500 people arrested, and troops were moved into Quebec. Few convictions followed—except the accused of the murder of Laporte—and public opinion in Canada, including Quebec, which in the majority approved the invocation of the act, began to wonder if the action had been too drastic. The crisis did, however, reveal what no one at the time seemed to have considered, that while social revolution may well be a provincial matter in Canada, secession is not, since secession affects all members of the association.

The growth of terrorism

Postwar prosperity. The rest of Canada, and even Quebec to a lesser degree, had enjoyed in the 20 years after 1950 growth and prosperity such as it had never known before. Not only did its old primary industries thrive, even with setbacks as in the failure of export markets to absorb the large wheat crops of the mid-1950s, but Canada also entered on a new phase of industrial development: the development of a higher technology and a greater sophistication of production and management. In this Canada was only moving with the greater industrial powers, especially the United States; the significance lay in it now being able to move in such company. The result was the development of electronic, aeronautic, nuclear, and chemical engineering on a great scale, and the transformation of industrial Canada. Much of the growth, however, was also simple enlargement of earlier established industry, such as steel. Production of crude steel, which had risen sharply since 1941, almost doubled between 1959 and 1969 (from 5,900,000 net tons to 10,300,000), aided by the opening of the St. Lawrence Seaway in 1959 and the abundant supply of iron ore from the newly opened mines in Labrador.

Rise of steel production

New sources of minerals were, indeed, part of the boom of the 1950s. Not only Labrador iron but also radium and oil gave Canada resources it had hitherto had only in comparatively small supply. The iron deposits of Labrador had been known since the beginning of the century and were only awaiting development. Petroleum and gas had long been known to exist, and gas had been produced in southern Alberta since the end of World War I. Not until the Leduc strike of 1947, however, did Canada become an exporter of oil. Oil prospecting spread across the prairie provinces, with strikes in Saskatchewan and even Manitoba, but the main line of discovery was northward in Alberta and into the Mackenzie Valley. By the 1960s the prospecting of the Arctic islands was being planned, and in 1970 and 1971 gas was found on the islands and oil east of the Mackenzie Delta. More exciting and spectacular, however, was the rush to stake radium claims after 1945. The Great Bear Lake mine had furnished radium for the experiments in nuclear fission that led to the making of the atomic bomb. After the war the nuclear arms race and the possibility of the use of fission for the production of electricity led to widespread prospecting, which resulted in major finds in the Algoma District of Ontario and in northern Saskatchewan. For a while a great new industry seemed to be in the making, but the discovery of domestic supplies in the United States and the restrictive policy of the federal government diminished sales. The boom fell away.

In more conventional mining, the opening of the large nickel and base metals mine at Thompson, Manitoba, was the chief development (with the possible exception

of the gradual exhaustion of the gold mines of Ontario and Quebec and the restriction on output caused by the American fixed price for gold).

Thompson also provided an excellent example of two matters of primary importance: first, how much the greater part of Canadian economic growth had come to be financed by American capital, largely in the form of direct investment and American ownership of the plant and control of operations; and second, how foreign investment, largely American, aided by the American demand for Canadian materials, made the Canadian boom possible. Investment from abroad was, of course, eagerly sought, especially by the provincial governments, and Canada prospered both because of it and because of the resulting advanced technology and management. The direct investment took place extensively in secondary as well as in primary industry, although oil was the field of principal American interest. By 1965 direct investment by United States citizens in Canada totalled $13,940,000,000 and was growing rapidly; that from elsewhere abroad totalled only $3,268,000,000. In 1963 United States citizens controlled 46 percent of manufacturing in Canada, 62 percent of Canada's petroleum and natural gas industry, and 52 percent of its mining and smelting. It is believed that these percentages increased thereafter.

The increase of foreign investment

Thus by the mid-1960s there was growing concern over the degree of foreign control of Canadian economic life outside the "strategic" areas, such as banking and insurance, that were closed to foreign ownership. The concern was not over the amount of the investment but over the form it took of direct investment, which gave the foreigners perpetual ownership and control. By 1971 a strong movement of economic nationalism had emerged, caused by the shaping of Canadian economic life to fit the needs of foreign decisions taken in foreign rather than Canadian interest, the extra-territorial operation of foreign law and policy on foreign-owned plants in Canada, the acceleration of the process, and its perpetuity when accomplished. This new movement demanded the restoration of Canadian control of the Canadian economy, at least to a much greater degree.

The principal inspirer of the movement was Walter Gordon, Liberal minister of finance in 1963–65. The wave of economic nationalism that followed found a leading voice in the left wing of the New Democratic Party, successor to the CCF. But the formation of the popularly based Committee for Canadian Independence revealed that the concern was widespread.

Indian relations. Much of the new economic development took place in Canada's northlands and had some part in ending the nomadic hunting life of the forest Indians and the Eskimos of the Arctic shores and islands. This contact between the Canadian government and the Indians signallized a new dilemma that Canada faced in trying to deal equitably with its aboriginal peoples. Canada, as a fur-trade country, had had little warfare between Indians and Europeans as such until the Saskatchewan Rebellion. The fur trade had required the cooperation of hunter and trader. But agricultural settlement in the mid-1800s forced the application of the Indian policy the British Empire had developed by 1763—acknowledgement of the Indian title to the soil and the transfer of the title by treaty for indemnities, gifts, reserve lands, and hunting rights. From Ontario to the prairies and Northwest Territories treaties were negotiated. Although no treaties were signed in Quebec and British Columbia, the Indians as responsibilities of the federal government were treated as though they had formal treaty rights. Under the Indian Act, an Indian might so remain; or, on giving up his treaty rights, he might become a full citizen.

The system of administering Indian affairs had a fair measure of success; but that success rested not on an adaptation of Indians to the new society of Canada but on their ability, despite economic pressure and the general failure of formal schooling, to maintain their own way of life, modified somewhat by European contacts. After 1945 it was apparent that this was not enough and that the system was itself collapsing. The poverty and disease of many reserves were a reproach to Canadian policy and humanity. The health care provided was greatly improved, and in 1959 the Indian Act was amended to increase opportunities for Indian influence on decisions affecting them. The former greatly increased the survival rate of children; the latter allowed for an outspoken avowal of dissatisfaction. The Métis, equal to whites according to the law, while in fact often treated as treaty Indians, played an important part in the growing protest. The federal government took note by granting the franchise to all Indians in 1960, and several provinces followed suit. Indians were also allowed to purchase liquor and use beer parlours like other Canadians, privileges denied them in the past.

Growing voice of the Indians

These measures improved the condition of Indians, but they were only a beginning in a struggle to end the well-meant paternalism of the Indian Affairs administration, to solve the problem of educating Indian children to their best advantage, and to determine how the Indian could obtain capital for development and earn a living in Canadian society without ceasing to be an Indian or giving up his reserve or treaty rights. Some radical opinion developed, and there was talk of "Red Power" and an Indian society autonomous within Canadian society. No outcome could be foreseen; but the Canadian Indian seemed to be gaining self-confidence, winning a measure of economic security if only through the welfare system, and learning through the Indian Brotherhood to overcome the great differences between Canadian Indians and to arrive at a common policy. One thing was certain for Indian and Eskimo alike: the old ways of life were finished.

Indian agitation, like separatism in Quebec, was both a commentary on the change and diversity of Canadian life and a challenge to the flexibility of Canadian government and society. So also, if in somewhat other ways, was the great immigration that followed the ending of World War II. First displaced persons, then people leaving war-devastated Europe, then those coming to share the prosperity of Canada in the 1950s comprised the greatest immigration Canada had known. In 1951–60 more than 1,500,000 persons entered Canada as landed immigrants; in 1961–66 nearly 700,000 more arrived. A majority of the immigrants were from Europe, many from southern Europe, particularly Italy, Greece, and Portugal; and almost all went into industrial cities in the east. As a whole the movement marked a new phase in the development and character of Canadian society. By 1961 Canadians of British and Irish descent had fallen to 43.8 percent and those of French descent to 30 percent, while persons of other descents had risen to 26.4 percent. Moreover, the newcomers to Quebec chose to speak English and not French and to join the English instead of the French culture. This was a significant cause of the unrest over the future of French Canada, especially when seen in the light of the rapidly declining French birth-rate.

Internal politics since World War II. The internal politics of the years 1945–56 were quiet and complacent. Prime Minister King retired in 1948, having held that office longer than anyone in Canadian history. His successor, Louis St. Laurent, proved an admirable and amiable president during a period of confidence and prosperity. A conservative revival, however, led to a series of parliamentary struggles in which a government long in power was made to appear both arrogant and indifferent to public feeling and opinion, notably in a debate over the Trans-Canada Pipeline in 1956. A new leader, John G. Diefenbaker, an impassioned platform orator, defeated St. Laurent in 1957 to form a minority government, then in 1958 won the greatest electoral victory in Canadian history. Diefenbaker's term of office, however, saw a major recession. He had to face the strains of an unsuccessful British attempt to enter the European Common Market; of relations with the United States during its Cuban missile crisis, in which Canada was not consulted and yet was expected to take part in the air defense of North America; and of a domestic struggle over the installation of nuclear warheads in Canada and their

The Diefenbaker government

use by the Canadian NATO contingent. Internal dissension brought the Diefenbaker government down to a minority government in 1962 and to defeat in 1963. The Liberal government of Lester Pearson that followed, however, was also a minority government and had difficulty dealing effectively with the new demands of Quebec and retaining the confidence of the rest of the country. Pearson retired in 1967 and was succeeded by Pierre Elliott Trudeau, a strong federalist, who in 1968 won a decisive victory in Canada and in Quebec. Trudeau's terms of office saw a restoration of firm government at Ottawa and the election of the Quebec Liberals under Robert Bourassa. The intent of the two electorates seems to have been to give these two men and their governments a strong mandate to reduce the tension in Canada's rapidly changing society and rapidly evolving political consciousness.

At bottom, to do so would seem to ensure the coexistence of both English and French cultures in a liberal federal system. French culture in Canada is French not only in its sense of stress on form, logic, and manner and in its stress on good living above making money, but also in a nationalist sense, in that it is a close and intimate society of kinship, language, and manners. English-Canadian culture on the other hand, is open, tolerant, and informal, publicly at least, and has all the Anglo-American preoccupation with material aspects of life, money, position, and property; it is a culture of personal and private refinement rather than of social consensus. Roughly and broadly speaking, French-Canadian society is an ethnic one, English-Canadian society a cosmopolitan one. That the latter's language is English does not give it an English culture, for the language is to a great extent a mode of communication rather than a spiritual possession and a mold of ideas.

In terms of the usual content of culture, education and the arts, there may well be little to choose between the two societies, except that the French probably have done more proportionately with fewer resources than have the English. The great exception is literature, where in the mid-1900s French Canada displayed amazing vitality, while English Canada was only respectably active. The difference was not so much one of correctness of judgment as of the French Canadian's greater depth of passion; the French Canadian knows his society is in crisis, while the English Canadian feels his is in trouble. This difference underlines the differences between English and French Canada—differences expressed politically, but which are fundamentally cultural. Such differences may constitute a splendid practical partnership, as in the production of the exposition in Montreal of 1967, in which French Canada furnished ideas, ambience, and grace, and English Canada the managerial and engineering skills. In words and aspiration they may, however, constitute gulfs of separation.

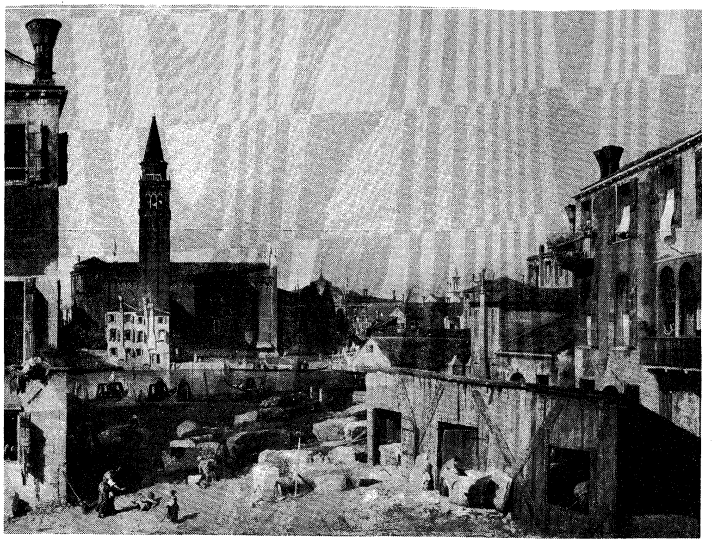
BIBLIOGRAPHY. W.L. MORTON, *The Kingdom of Canada*, 2nd ed. (1969), is the fullest one-volume history and the most traditional. A shorter, less conservative general history is K.W. MCNAUGHT, *The History of Canada* (1970). More intensive and interpretative are J.M.S. CARELESS (ed.), *Colonists and Canadiens, 1760–1867* (1971); and J.M.S. CARELESS and R. CRAIG BROWN (eds.), *The Canadians, 1867–1967* (1968). The development of government in Canada has received a definitive statement in J.R. MALLORY, *The Structure of Canadian Government* (1971). A comprehensive history of the French period is GUSTAVE LANCTOT, *Histoire du Canada*, 3 vol. (1960–64; Eng. trans., *A History of Canada*, 3 vol., 1963–65). Other studies are W.J. ECCLES, *The Canadian Frontier, 1534–1760* (1969); and MASON WADE, *The French Canadians, 1760–1967*, rev. ed., 2 vol. (1968). To understand the place of the colonies that became Canada in the British Empire, the following are most useful: H.A. INNIS, *The Fur Trade in Canada*, 2nd ed. (1956), and *The Cod Fisheries*, rev. ed. (1954); J.B. BREBNER, *New England's Outpost: Acadia Before the Conquest of Canada* (1927) and *The Neutral Yankees of Nova Scotia* (1937). HILDA M. NEATBY in *Quebec: The Revolutionary Age, 1760–1791* (1966), analyzes the factors that led to the renewed separation of Quebec from the former colonies to the south. The following works both introduce and analyze the development of the remaining British colonies to self-governing communities and their union in Confederation. W.S. MACNUTT combines in a single narrative the histories of the Atlantic provinces in *The Atlantic Provinces, the Emergence of Colonial Society, 1712–1857* (1965). FERNAND OUELLET in his *Histoire économique et sociale du Québec, 1760–1850* (1966; Eng. trans. in prep.), applies with great success the demographic method of French historiography to the little known domestic development of that province. HELEN TAFT MANNING in *The Revolt of French Canada, 1800–1835* (1962), details the political conflicts of those years. G.M. CRAIG, *Upper Canada: The Formative Years, 1784–1841* (1963), traces the origins of what is now Ontario. CHESTER NEW, *Lord Durham* (1929); and CHESTER MARTIN, *Foundations of Canadian Nationhood* (1955), are the leading authorities on the achievement of self-government. For a searching critique of colonial self-government, J.E. HODGETTS, *Pioneer Public Service* (1955), should be consulted. The story of Confederation has been told in various modes by D.G. CREIGHTON, *The Road to Confederation: The Emergence of Canada, 1863–1867* (1964); W.L. MORTON, *The Critical Years: The Union of British North America, 1857–1873* (1964); PETER B. WAITE, *The Life and Times of Confederation, 1864–1867* (1961); and ROBIN W. WINKS, *Canada and the United States: The Civil War Years* (1960). An overall view and realistic interpretation of those years may be found in KENNETH BOURNE, *Britain and the Balance of Power in North America, 1815–1908* (1967). Relations with the United Kingdom and the United States are a constant in Canadian history. J.B. BREBNER, *North Atlantic Triangle* (1945), is the definitive treatment to its date of publication. EDGAR MCINNIS, *The Unguarded Frontier* (1942), tells the story of American–Canadian relations as seen at their optimum. Changes in the last generation are reflected in JAMES EAYRS, *The Art of the Possible: Government and Foreign Policy in Canada* (1961) and *Northern Approaches* (1961); also in sombre tones in D.G. CREIGHTON, *Canada's First Century, 1867–1967* (1970). A sober and intensive study of the fundamentals of American-Canadian relations may be found in R. CRAIG BROWN, *Canada's National Policy, 1883–1900* (1964). Canadian historiography in recent years has been marked by pessimism, regionalism, and a greater concentration on mere scholarship as is to be noted in most of the more recent works cited above. More traditional, if not unaffected by the new climate is PETER B. WAITE, *Arduous Destiny: Canada, 1874–1896* (1970). The background of a new focus of interest in Canada may be found in MORRIS ZASLOW, *The Opening of the Canadian North, 1870–1914* (1971). The beginnings of a critique of the Canadian mind are present in CARL BERGER, *The Sense of Power* (1970). Events in French Canada since 1960 are too recent for historical treatment. A critical account of the background is found in RAMSAY COOK, *Canada and the French Canadian Question* (1966); a sensitive analysis in RICHARD JONES, *Community in Crisis: French Canadian Nationalism in Perspective* (1967); a reasoned statement of the case for separatism in MARCEL RIOUX, *La Question du Quebec* (1969; Eng. trans., *Quebec in Question*, 1971).

(W.L.M.)

Canaletto

In the 18th century, the age of the grand tour, the portraiture of places (topography) reached its height; and Venice, a city unique in character and splendid in ceremony, was the centre of topographical painting. The dominating figure of the Venetian school of skilled view (*vedute*) painters was Giovanni Antonio Canal, called Canaletto. Transcending the bounds of simple topographical accuracy, Canaletto expressed in his pictures a full feeling for art, and his understanding of cloud effects, flickering contours, colour-filled shadows, and the melting textures of full daylight made him a determining influence for the landscape artists of following generations who sought to capture the light and atmosphere, as well as the facts, of their scenes.

Canaletto was born in Venice on October 18, 1697, connected with a noble family whose coat of arms he occasionally used as a signature. How he came to be known as Canaletto is uncertain—perhaps the name was first used to distinguish him from his father, Bernardo Canal, a theatrical scene painter in whose studio Canaletto assisted. Canaletto is recorded as working with his father and brother in Venice from 1716 to 1719, and in Rome in 1719–20, painting scenes for Alessandro Scarlatti operas. It was in Rome that Canaletto left theatrical painting for the topographical career that was to bring him international fame so quickly, although a close connection to his theatrical work remained in his



"The Stonemason's Yard," oil on canvas by Canaletto, *c.* 1730. In the National Gallery, London. 1.238 × 1.629 m.
By courtesy of the trustees of the National Gallery, London

choice of subject matter, his use of line and wash drawings, and his theatrical perspective.

Works of the Venetian period

When he returned to Venice, he began his contact with the foreign patrons who would continue as his chief support throughout his career. Four large paintings were completed for the Prince of Liechtenstein, in or before 1723, and in 1725–26 he finished a series of pictures for Stefano Conti, a merchant from Lucca. Dated memoranda accompanying the Conti pictures suggest how busy and yet how exacting the artist was at this time. Canaletto indicates that delays in the delivery of the pictures had been due to the pressure of other commissions and his own insistence on obtaining reliable pigments and on working from nature. In his pictures of the late 1720s, such as "The Stonemason's Yard" (National Gallery, London) he combined a freedom and subtlety of manner that he was rarely to achieve again with an unrivalled imaginative and dramatic interpretation of Venetian architecture. His understanding of sunlight and shadow, cloud effects, and the play of light on buildings support the contention in his memoranda that he was working out-of-doors, which was a most unusual procedure for painters of that time.

Throughout the 1730s Canaletto was deeply absorbed in meeting foreign demands for souvenir views of Venice. Such was the pressure upon him that he ultimately was forced to work largely from drawings and even from other artists' engravings, rather than from nature. He also developed the use of the *camera ottica*, a device by which a lens threw onto a ground-glass screen the image of a view, which could be used as a basis for a drawing or painting. Finally, he developed a mechanical technique, in which ruler and compasses played a part, and architecture and figures were put into the picture according to a dexterous and effective formula. Such a vast number of views of Venice were produced during his lifetime that it is often thought that Canaletto was head of a large studio, but there is no evidence of this.

Canaletto had no serious rivals. The painter Luca Carlevaris, who may have been his initial inspiration in choosing to produce topographical pictures for a largely foreign audience, had been driven from the field; Bernardo Bellotto, Canaletto's nephew, was not yet a mature painter; and Michele Marieschi was a follower rather than a competitor. Because of this lack of rivals, Canaletto became increasingly difficult to deal with. Owen Mac Swinney, an English operatic figure and patron of Canaletto, wrote as early as 1727,

> The fellow is whimsical and varys his prices, every day: and he that has a mind to have any of his work, must not seem to be too fond of it, for he'l be y^e^ worse treated for it, both in the price and the painting too.

The outbreak of the War of the Austrian Succession in 1740, which cut down sharply the number of visitors to Venice, seriously affected Canaletto's commissions. At this point, an early acquaintance, Joseph Smith— publisher, merchant, and later British consul in Venice—stepped into the breach. As standardized views of Venice dropped from demand, Smith seems to have encouraged Canaletto to expand his range of subjects to include Roman monuments and the area of Padua and the River Brenta. Pictures composed of more or less recognizable elements rearranged (*capriccio*) and pictures composed of almost completely imaginary architectural and scenic elements (*veduta ideata*) now began to play an increasingly important part in Canaletto's work. In 1741–44 Canaletto also made a series of 30 etchings, exceptionally skillful and sensitive, showing a command of perspective and luminosity.

Later works in England

Canaletto's international reputation served him well as the tourists became more scarce. In 1746 he went to England, where he was welcomed and remained until 1755, despite an invitation to Dresden (now in East Germany), from the Elector of Saxony. He worked mainly in London, on English views. It is notable, when considering the works executed during this period, that Canaletto—an artist 50 years of age who had evolved various conventions based on Venetian experience—was dealing with an entirely different set of atmospheric conditions and different subject matter. Occasionally, by putting English material into a Venetian framework, he achieved a masterpiece, but for the most part he fell below his own standards, and his work was lifeless and mechanical.

On his return to Venice, however, his reputation had not diminished; and at last he received official recognition—election to the Venetian Academy in 1763 and, in the same year, appointment as prior of the Collegio dei Pittori.

Canaletto died in Venice on April 20, 1768.

MAJOR WORKS

Since Canaletto executed so many paintings of views of Venice and other real and imaginary scenes, the list given here is of representative works that may be seen in public collections.

VIEWS OF VENICE: "Piazza San Marco Looking East from South of the Central Line" (Fogg Art Museum, Harvard University); "Venice: Piazza S. Marco and the Colonnade of the Procurate Nuove" (National Gallery, London); "The Piazzetta Looking North West: The Fonteghetto della Farina" (*c.* 1735–40; Museum of Fine Arts, Boston); "Scene in Venice; The Piazzetta Entrance to the Grand Canal" (*c.* 1726–28; Metropolitan Museum of Art, New York); "View in Venice" (National Gallery of Art, Washington, D.C.).

VIEWS IN ENGLAND: "Greenwich Hospital from the North Bank of the Thames" (National Maritime Museum, Greenwich, London); "Old Somerset House from the River Thames" (Minneapolis Institute of Arts, Minneapolis, Minn.); "Old Walton Bridge" (1754; Dulwich College Picture Gallery, London).

CAPRICCI AND IMAGINARY COMPOSITIONS: "Capriccio, a Tomb by the Lagoon" (Uffizi, Florence); "Capriccio, a Domed Circular Church" (Worcester Art Museum, Massachusetts).

BIBLIOGRAPHY. The most complete collections of Canaletto's paintings and drawings are held in the Royal Collections at Windsor and Buckingham Palace; see MICHAEL LEVY, *Canaletto Paintings in the Collection of Her Majesty the Queen* (1964); and K.T. PARKER, *The Drawings of Antonio Canaletto in the Collection of His Majesty the King at Windsor Castle* (1948). Other works recommended include: W.G. CONSTABLE, *Canaletto*, 2 vol. (1962), the most comprehensive biography, with catalogue raisonné and full bibliography; F.J.B. WATSON, *Canaletto*, 2nd ed. (1950), an authoritative brief account, with bibliography; BARON VON HADELN DETLEV, *The Drawings of Antonio Canal, Called Canaletto*, trans. by CAMPBELL DODGSON (1929); VITTORIO MOSCHINI, *Canaletto* (1954; Eng. trans., *Drawings by Canaletto*, 1963 and 1969), the best collection with many plates; RODOFLO PALLUCCHINI and G.F. GUARNATI, *Le Acqueforti del Canaletto* (1945), a very good work (in Italian) on the watercolours; J.G. LINKS, *Views of Venice: The Engravings by Visentini* (1971), a readable account on the etchings; and *Canaletto: Giovanni Antonio Canal, 1697–1768* (1964), an exhibition catalog from the Art Gallery of Toronto (with text by W.G. CONSTABLE)—the best introductory work for the general reader.

(W.G.C.)

Canals and Inland Waterways

Despite modern technological advances in air and ground transportation, inland waterways continue to fill a vital role and, in many areas, to grow substantially. This article traces the history of canal building from the earliest times to the present day, describes both the constructional and operational engineering techniques used, and the major inland waterways and networks throughout the world.

Transport by inland waterways may be by navigable rivers or those made navigable by canalization (dredging and bank protection) or on artificial waterways called canals. Many inland waterways are multipurpose, providing drainage, irrigation, water supply, and generation of hydroelectric power as well as navigation. The lay of the land (topography) and particularly changes in water levels require that many rivers be regulated to make them fully navigable, thus enabling vessels to proceed from one water level to another. The chief regulating method is the lock, the development of which contributed significantly to the Industrial Revolution and the development of modern industrial society.

For many types of commodities, particularly such bulk commodities as grains, coal, and ore, inland-waterway transport is still more economical than any other kind of transport. Thus, it is hardly surprising that modernized inland waterways, using the latest navigational aids and traction methods and traversing the great land masses of North America, Europe, and Asia, play an increasingly important economic role.

History

Most of the improvement of rivers and construction of artificial waterways in antiquity was for irrigation purposes. In the 7th century BC the Assyrian king Sennacherib built an 80-kilometre (50-mile) stone-lined canal 20 metres (6.6 feet) wide to bring fresh water from Bavian to Nineveh. The work, which included a stone aqueduct 300 yards (330 metres) long, was constructed in one year and three months, according to a plaque that survives on the site. Surprisingly advanced techniques were used, including a dam with sluice gates allowing regulation of the flow of the water stored. The Phoenicians, Assyrians, Sumerians, and Egyptians all constructed elaborate canal systems. The most spectacular canal of this period was probably Nahrawān, 400 feet (120 metres) wide and 200 miles (335 kilometres) long, to provide a year-round navigation channel from near Samarra to al-Kūt, using water provided by damming the unevenly flowing Tigris. Many elaborate canals are known to have been built in Babylonia. In Egypt, the Nile was dammed to control its flood waters, and an extensive system of basin irrigation was established. The Persian king Darius in the 5th century BC cut a canal from the Nile to the Red Sea. The Romans were responsible for very extensive systems of river regulation and canals in France, Italy, The Netherlands, and Great Britain for military transport. The legions in Gaul canalized one of the mouths of the Rhône to protect their overseas supply route. In the 1st century AD, the Roman consul Marcus Livius Drusus dug a canal between the Rhine and Yssel to relieve the Rhine of surplus water, and the Roman general Corbulo linked the Rhine and Meuse with a canal 23 miles long to avoid the stormy North Sea passage from Germany to the coast. Attempting to reclaim the Fens in England, the Romans connected the River Cam with the Ouse by an eight-mile canal, the Nene with the Witham by one 25 miles long, and the Witham with the Trent by the Fosse Dyke (ditch), still in use.

Use of sluice gates

Outside Europe and the Middle East, between the 3rd century BC and the 1st century AD, the Chinese built impressive canals. Outstanding were the Ling Ch'ü in Kuangsi, 90 miles long from the Han capital; Ch'ang-an (Sian) to the Huang Ho (Yellow River); and the Pien Canal in Honan. Of later canals, the most spectacular was the Grand Canal, the first 600-mile section of which was opened to navigation in 610. This waterway enabled grain to be transported from the lower Yangtze and the Huai to K'ai-feng and Lo-yang. These canals had easy gradients (changes in water levels); and at about three-mile intervals there were single gates of stone or timber abutments with vertical grooves up or down which the log closure was manually hauled by ropes to hold or release the water, thus controlling the water level. A few more elaborate gates had to be raised by windlasses. Where water level changes were too great for such simple devices, double slipways were built and vessels were hauled up the inclines.

MEDIEVAL REVIVAL

In Europe, canal building, which appears to have lapsed after the fall of the Roman Empire, was revived by commercial expansion in the 12th century. River navigation was considerably improved and artificial waterways were developed with the construction of stanches, or flash locks, in the weirs (dams) of water mills and at intervals along the waterways. Such a lock could be opened suddenly, releasing a torrent that carried a vessel over a shallow place. The commercially advanced and level Low Countries developed a system of canals using the drainage of the marshland at the mouths of the Scheldt, Meuse, and Rhine; about 85 percent of medieval transport in the region went by inland waterway.

Use of stanches

Because shipping was handicapped where barges had to be towed over the weirs with windlasses or manually, the lock and lock basin were evolved to raise boats from one level to another. Although a primitive form of lock had been in operation at Damme, on the canal from Bruges to the sea, as early as 1180, the first example of the modern pound lock, which impounded water, was probably that built at Vreeswijk, The Netherlands, in 1373, at the junction of the canal from Utrecht with the River Lek. Outer and inner gates contained a basin, the water level of which was controlled by alternatively winding up and lowering the gates. This system became widespread in the 14th century. In the 15th century, the lock-gate system was much improved with the addition of paddles to control the flow of water in and out of the lock chamber through sluices in the gates or sides of the lock.

Commercial needs soon encouraged canal construction in less ideal locations. The Stecknitz Canal, built in Germany (1391–98), ran 21 miles from Lake Möllner down to Lübeck, with a fall of 40 feet (13 metres) controlled with four stanches; the canal was later extended south to Lauenburg on the Elbe to establish a link between the Baltic and the North Sea. To deal with a fall from the summit to Lauenburg of 42 feet (13.5 metres) in 15 miles (25 kilometres), two large locks were built, each capable of holding ten small barges.

Italy, the other principal commercial region of medieval Europe, also made important contributions to waterway technology. The Naviglio Grande Canal was constructed (1179–1209) with an intake on the River Ticino, a fall of 110 feet (33 metres) in 31 miles (52 kilometres) to Abbiategrasso and Milan, the water level being controlled by sluices. To facilitate transport of marble from the quarries for the building of the Milan cathedral, the canal was linked with an old moat, and in Italy the first pound lock with mitre instead of the earlier portcullis gates was constructed to overcome difference in water level.

China may have been ahead of Europe in canal building. Between 1280 and 1293 the 700-mile northern branch of the Grand Canal was built from Huai-an to Peking. One section, crossing the Shantung foothills, was in effect the first summit-level canal, one that rises then falls, as opposed to a lateral canal, which has a continuous fall only. The Yellow River was linked with a group of lakes about 100 miles south, where the land rose 50 feet higher; and to overcome water lost through operation of the lock gates, two small rivers were partially diverted to flow into the summit level.

16TH TO 18TH CENTURIES

The development of the mitre lock, a double-leaf gate the closure of which formed an angle pointing upstream, heralded a period of extensive canal construction during the 16th and 17th centuries. The canalized rivers and ca-

The mitre lock

nals of that period foreshadowed the European network to be developed over many years.

France. In France, the Briare and Languedoc canals were built, the former linking the Loire and Seine and the latter, also known as the Canal du Midi, linking Toulouse with the Mediterranean. Both were remarkable feats of engineering. The Briare Canal (completed 1642) rose 128 feet (39 metres) to a plateau with a summit level 3.75 miles (6.2 kilometres) long and then dropped 266 feet to the Loing at Montargis. It included 40 locks, of which a unique feature was a staircase of six locks to cope with the fall of 65 feet (20 metres) on the descent from the Loing to Rogny. Construction of the 150-mile (250-kilometre) Languedoc Canal joining the Bay of Biscay and the Mediterranean via the Garonne and the Aude ran through very rugged terrain. Begun in 1666 and finished in 1681, it rose 206 feet (61 metres) in 32 miles (54 kilometres) from the Garonne at Toulouse to the summit through 26 locks, and then descended 620 feet (185 metres) through 74 locks for 115 miles (190 kilometres). Near Béziers a staircase of eight locks was built, and six miles (ten kilometres) further upstream a tunnel 180 yards (165 metres) long was constructed; three major aqueducts carried it over rivers, and numerous streams were diverted beneath it in culverts. The most notable technical achievement was a complex summit water supply that included unique diversion of flows and storage provision.

Flanders. The canal system in Flanders included one from Brussels to Willebroeck on the Rupel to shorten navigation by half, an 18½-mile (30-kilometre) canal with four locks; another of 44 miles (70 kilometres) was constructed from Bruges to Passchendaele, Nieuport, and Dunkerque and was later extended to Ostend, while Dunkerque was linked with the River Aa, at the mouth of which a large tide lock was constructed at Graveslines. The outstanding achievement in Flanders was a lock at Boesinghe on the canal from Ypres to Boesinghe beside the River Yser. The fall of 20 feet (six metres) on this four-mile (6.5-kilometre) stretch was contained by a single large lock. Side ponds with ground sluices were provided for the first time to reduce the loss of water during the lock's operation. The ponds took one-third of the water when the lock was emptied and returned it for the filling.

Germany. In Germany, the 15-mile (25-kilometre) Friedrich Wilhelm Summit Canal, completed in 1669, rose from Neuhaus on the Spree for ten feet (three metres) in two locks and from west of the summit fell 65 feet (20 metres) to Brieskow on the Oder. An extensive system of waterways in this part of Germany was finally established with the opening of the Plaue Canal in 1746, which ran from the Elbe to the Havel. The 25-mile (42-kilometre) Finow Canal along the Havel to the Liepe, a tributary of the Oder, had been built earlier but fell into decay because of flooding and neglect and was not rebuilt until 1751. In the late 17th and early 18th centuries, under the Great Elector of Brandenburg and Frederick I of Prussia, the three great rivers, the Elbe, Oder and Weser, were linked by canal for commercial and political reasons, including the bypassing of tolls charged by the numerous states and petty principalities of the Holy Roman Empire. In the Low Countries, wars, political considerations, and the rivalry between the Dutch and Belgian ports handicapped canal building. The Dutch, for example, strongly opposed a Rhine–Meuse–Scheldt canal, fearing diversion of trade to Antwerp.

The linking of the Elbe, Oder, and Weser rivers

England. The first lock was not built on an English canal until the 16th century, and the canal era proper dates from the construction of the Bridgewater Canal to carry coal from Worsley to Manchester in the 18th century by the engineer James Brindley. Opened for navigation in 1761, it was extended to the Mersey in 1776. Its success promoted a period of intense canal construction that established a network of inland waterways serving the Industrial Revolution and contributing to Britain's prosperity in the half-century preceding the railway era, which began in the mid-19th century. The Grand Trunk Canal established a cross-England route by linking the Mersey to the Trent, opened up the Midlands, and provided water transport for exports to European markets. There followed the link between the Thames and the Bristol Channel provided by the Severn Canal and the Gloucester and Berkeley Ship Canal from Sharpness on the Severn to Gloucester. Birmingham's growth and industrial prosperity were stimulated because the city became the centre of a canal system that connected London, the Bristol Channel, the Mersey, and the Humber. The Caledonian Ship Canal across Scotland, joining the chain of freshwater lakes along the line of the Great Glen, was built between 1803 and 1822.

One of the few canals to be built after the canal era was the 36-mile- (60-kilometre-) long Manchester Ship Canal, which was opened in 1894 to give oceangoing vessels access from the Mersey estuary to Manchester.

Technological development. This spate of canal construction was accompanied by technological development both in construction methods and operation. Locks, inclined planes, and lifts were developed to cope with changes in water level. At Bingley, for example, on the Leeds and Liverpool Canal, a lock staircase was built; and on the hilly areas at Ketley in Shropshire, inclined planes were constructed in 1788 to haul tugboats from one level to another. The longest plane, about 225 feet (67 metres), was on the Hobbacott Down plane of the Bude Canal in Cornwall. Vertical lifts counterweighted by water were also used; a set of seven was built on the Grand Western Canal; while at Anderton in Cheshire, a lift was later converted to electrical power and was still operating in the 20th century. The most spectacular inclined plane was built in the United States on the Morris Canal, which linked the Hudson and Delaware rivers. For a rise of 900 feet (265 metres) to the Alleghenies watershed, 22 locks were installed at the head of an inclined plane, and descending on a gradient of 1 in 10 to 1 in 12, ran down to the pound below. Barges 79 feet (22 metres) long with loads up to 30 tons were hauled up by trolleys running on rails, on which they settled as the lock emptied; the barges descended under gravity into the lower pound to float on an even keel when the water levelled off. In the reverse direction, they were hauled up by drum and cable mechanism.

19TH CENTURY

Europe. In Europe, where the canal era had also started toward the end of the 17th century and continued well into the 18th, France took the lead, integrating its national waterway system further by forging the missing links. In the north, the St. Quentin Canal, with a 3½-mile tunnel, opened in 1810, linked the North Sea and the Scheldt and Lys systems with the English Channel via the Somme, and with Paris and Le Havre via the Oise and Seine. In the interior, the Canal du Centre connected the Loire at Digoin with the Sâone at Chalon and completed the first inland route from the English Channel to the Mediterranean; the Sâone and Seine were linked further north to give a more direct route from Paris to Lyon; and the Rhine–Rhône Canal (Canal du Rhône au Rhin), opened in 1834, provided a direct north-to-south route; while the Canal de la Sambre à L'Oise linked the French canal system with the Belgian network via the Meuse. Toward the end of the 19th century, France embarked on the standardization of its canal system to facilitate through communication without trans-shipment. The ultimate result was a doubling of traffic between the opening of the century and World War II.

Industrial development in the early 19th century prompted Belgium to extend its inland waterways, especially to carry coal from Mons and Charleroi to Paris and northern France. Among the new canals and extensions built were the Mons-Condé and the Pommeroeut-Antoing canals, which connected the Haine and the Scheldt; the Sambre was canalized; the Willebroek Canal was extended southward with the building of the Charleroi–Brussels Canal in 1827; and somewhat later the Campine routes were opened to serve Antwerp and connect the Meuse and Scheldt. When the growth of the textile trade in Ghent created a need for better water transport, the

Dutch canals

Ghent Ship Canal, cut through to Terneuzen, was opened in 1827, giving a shorter route to the sea. The Dutch extended their canals to serve the continental European industrial north. The Maastricht–Liège Canal was opened in 1850, enabling raw materials and steel to be transported from the Meuse and Sambre industrial areas by waterway throughout The Netherlands. In 1824 a long ship canal was built to bypass silting that obstructed navigation on the Ijsselmeer (Zuiderzee) and to enter the North Sea in the Texel Roads. Later, an even shorter ship canal was built to Ijmuiden.

In Scandinavia, new canals were built to facilitate transport of timber and mineral products. In 1832 the new Göta Canal was opened, crossing the country from the Baltic to the Skagerrak and incorporating 63 locks. The political climate was less favourable for canal building in central Europe, but the Ludwig Canal, forming part of the Rhine–Main–Danube route, was opened in 1840. At the same time, steps were taken to improve river navigation generally, to provide speedier transport, and to enable a greater volume of freight to be carried. The Danube was regulated for 144 miles from Ennsmundung to Theuben, and the Franz Canal was dug in Hungary to join the Danube and Tisza. A nationwide Russian canal system connecting the Baltic and Caspian seas via the Neva and Volga rivers became navigable in 1718. A more direct route was established in 1804 with a canal between the Beresina and Dvina rivers. In the 19th century, Russia concentrated on making connections between the heads of navigation of its great rivers, the Volga, Dnepr, Don, Dvina, and Ob.

The Corinth ship canal

An outstanding engineering achievement in Greece was the cutting of a deep ship canal at sea level through the Isthmus of Corinth to connect the Aegean and Ionian seas. The Roman emperor Nero had first attempted this linking in the 1st century AD; the shafts sunk by him were reopened and sunk to their full depth. The canal, 4.8 miles (6.3 kilometres) long, 81 feet (25 metres) wide, and 27 feet (eight metres) deep in its centre section, running 280 feet (86 metres) below almost vertical rock cliffs, was opened in 1893.

United States. In the U.S., canal building began slowly; only 100 miles of canals had been built at the beginning of the 19th century; but before the end of the century over 4,000 miles were open to navigation. With wagon haulage difficult, slow, and costly for bulk commodities, water transport was the key to the opening up of the interior, but the way was barred by the Allegheny Mountains. To overcome this obstacle, it was necessary to go north by sea via the St. Lawrence River and the Great Lakes or south to the Gulf of Mexico and the Mississippi. A third possibility was the linking of the Great Lakes with the Hudson via the Mohawk Valley. The Erie Canal, 363 miles (580 kilometres) long with 82 locks from Albany on the Hudson to Buffalo on Lake Erie, was built by the state of New York from 1817 to 1825. Highly successful from the start, it opened up the Midwest prairies, the produce of which could flow eastward to New York, with manufactured goods making the return journey westward, giving New York predominance over other Atlantic seaboard ports. The Champlain Canal was opened in 1823; but not until 1843, with the completion of the Chambly Canal, was access to the St. Lawrence made possible via the Richelieu River. Meanwhile, Canada had constructed the Welland Canal linking Lakes Ontario and Erie. Opened in 1829, it met the 326-foot (98-metre) rise of the Niagara River with 40 locks, making navigation possible to Lake Michigan and Chicago. Later, the St. Mary's Falls Canal connected Lake Huron and Lake Superior. To provide a southern route around the Allegheny Mountains, the Susquehanna and Ohio rivers were linked in 1834 by a 394-mile (630-kilometre) canal between Philadelphia and Pittsburgh. A unique feature of this route was the combination of water and rail transport with a 37-mile (59-kilometre) portage by rail by five inclined planes rising 1,399 feet (413 metres) to the summit station 2,334 feet (689 metres) above sea level and then falling 1,150 feet (340 metres) to Johnstown on the far side of the mountains, where a 105-mile (170-kilometre) canal with 68 locks ran to Pittsburgh. By 1856 a series of canals linked this canal system to the Erie Canal.

The Susquehanna-Ohio Canal

Meanwhile, the Louisiana Purchase of 1803 had given the United States control of the Mississippi River, and it became the main waterway route for the movement of Midwest produce via New Orleans and the Gulf of Mexico. Developments included the Illinois–Michigan Canal, connecting the two great water systems of the continent, the Great Lakes and the Mississippi. Entering Lake Michigan at Chicago, then a mere village, the canal triggered the city's explosive growth. Several canals were constructed subsequently to link up with the Erie and Welland canals and the St. Lawrence, and a comprehensive network of inland waterways was established.

Impact of the railways. With the development of rail transport in the 19th century, canals declined as the dominant carriers of freight, particularly in the U.S. and Britain. In continental Europe the impact was less marked because the great natural rivers already linked by artificial waterways constituted an international network providing transport economically without trans-shipment; the terrain was more favourable and the canals larger and less obstructed by locks. Elsewhere, canals could not compete with rail. They were limited both in the volume carried per unit and in speed; they were too small, too slow, and fragmented; and the railways, as they became integrated into national systems, provided a far more extensive service with greater flexibility. The canals were further handicapped because they were not, for the most part, common carriers themselves but were largely dependent on intermediate carrying companies. Although transport on the canals was for some time cheaper than rail, the railways gradually overcame this advantage. To modernize and extend the waterways to enable larger boats to ply them, to reduce the number of locks that slowed down movement, and to provide a more comprehensive service, all this required capital investment on a scale that made the return problematical. The railways exploited the difficulties of the canals by drastic rate cutting that forced many canal companies to sell out to them. In Britain, in the 1840s and 1850s a third of the canals had become railway owned and many were subsequently closed down. In the U.S., half the canals were abandoned. The railways thus succeeded in eliminating their competition and obtained a near-monopoly of transport that they held until the arrival of the motor age.

The Kiel Canal. The 19th century saw the construction of three of the world's most famous canals—the Kiel, Suez, and Panama canals. The Kiel Canal carries tonnage many times that of most other canals. Frequent attempts had been made to make a route from the Baltic to the North Sea and thus to bypass the Kattegat and the dangerous Skagerrak. The Vikings had portaged ships on rollers across the ten-mile Kiel watershed, but not until 1784 was the Eider Canal constructed between the Gulf of Kiel and the Eider Lakes. A little over 100 years later, to take the largest ships, including those of the new German navy, the Kiel Canal was widened, deepened, and straightened to cut the distance from the English Channel to the Baltic by several hundred miles. Running 59 miles (95 kilometres) from locks at Brunsbüttel on the North Sea to the Haltenau locks on the Gulf of Kiel, the canal crosses easy country but has one unique engineering feature. At Rendsburg, to give clearance to the largest ships, the railway was made to spiral over the city on an ascending viaduct that crosses over itself before running on to the main span above the water.

The Suez Canal. The Isthmus of Suez so obviously provided a short sea route from the Mediterranean to the Indian Ocean and beyond as against the sea voyage around Africa that a canal had been dug in antiquity, had fallen into disuse, had been frequently restored, and finally had been blocked about the 8th century. Later there were many projects and surveys, but nothing happened until 1854 when Ferdinand de Lesseps, who had served as a French diplomat in Egypt, persuaded Saʿīd Pasha, the viceroy of Egypt, to grant a preliminary concession for construction of a new canal across the isthmus. A later report recommended a sea-level lockless canal be-

tween Suez and the Gulf of Pelusium; and the original concession was superseded by one granted in 1856 to the Suez Canal Company, an international consortium. The concession was for 99 years from the canal's opening to navigation, after which it was to revert to the Egyptian government; the canal was to be an international waterway, open at all times to all ships without discrimination. In addition to the ship canal, the company undertook to excavate a freshwater canal from the Nile at Bûlâq to Ismailia, with a branch extending to the Suez, to be available for smaller ships. Work on the ship canal lasted ten years, during which political, financial, contractual, and physical difficulties were overcome, and the canal was opened on November 17, 1869. As ultimately constructed, it was a 105-mile (169-kilometre) lockless waterway connecting the Mediterranean and the Red Sea. From its northern terminal at Port Said, the canal passes through the salt marsh area of Lake Manzala, with the freshwater canal running parallel. About 30 miles (50 kilometres) from Port Said, a seven-mile (12-kilometre) bypass built between 1949 and 1951 enables convoys to pass. At about the halfway point the canal enters Lake Timsah and passes Ismailia. Thence the waterway proceeds through the Bitter Lakes and on to Port Tawfīq, the southern terminal on the Red Sea, a few miles from the town of Suez. Since its construction, the canal has been constantly improved; originally 200 feet (60 metres) wide with a maximum depth of 24 feet (7.5 metres), it was widened in 1954 to 500 feet (150 metres) at water level and 196 feet (58 metres) at a depth of 33 feet (ten metres) with the main channel 45 feet (13 metres) deep, enabling ships of a maximum draft of 37 feet (11.3 metres) to navigate the canal.

Improvements in the Suez Canal

The canal remained open despite much political controversy. Nationalized by Egypt in 1956, it was blocked in 1967 after the Arab-Israeli War and so remained in the early 1970s.

The Panama Canal. After his success with the Suez Canal, de Lesseps was attracted to the Isthmus of Panama, where many projects had been suggested for cutting a canal to join the Atlantic and Pacific oceans and thus make unnecessary the passage around South America. De Lesseps proposed a sea-level route via Lake Nicaragua, but construction difficulties forced him to abandon this project in favour of a high-level lock canal via Panama. Further problems, especially yellow fever among the work force, halted construction after about 78,000,000 cubic yards of material had been excavated. Meanwhile, United States interest had been actively maintained, but the situation was complicated by political difficulties and questions of sovereignty. A treaty between Britain and the U.S. recognized the exclusive U.S. right to construct, regulate, and manage a canal across the isthmus; but Panama was Colombian territory, and the Colombia Senate refused ratification of a treaty with the U.S. After a revolt, a treaty was signed with independent Panama that granted the U.S. in perpetuity exclusive use, occupation, and control of the Canal Zone. (See below *Waterway Systems: Administration* for later history.)

Although preliminary work started in 1904, little real progress was made because of disputes over the type of canal that should be built; not until 1906 was the high-level lock plan finally adopted, as opposed to the previously favoured sea-level plan. Largely responsible for this decision was John F. Stevens, who became chief engineer and architect of the canal. Completed in 1914, the canal is 51.2 miles (85 kilometres) long. At its start from the large harbour area in Limon Bay on the Caribbean Sea, it rises over 80 feet (22 metres) above sea level to the Gatun Lake through the Gatun Locks and is retained at the north by these locks and dam and at the south by the Pedro Miguel Locks and Dam. The waterway then runs through the Gaillard Cut, which channels it through the Continental Divide, then between the Pedro Miguel Locks and the Miraflores Lake at an elevation of 54 feet (16 metres), ships to the Pacific Ocean being lowered by them to the Balboa Harbor entrance. The Gatun Lake, with its area of 166 square miles (450 square kilometres), is an integral part of the waterway and the principal source of its water. The minimum channel depth throughout the length of the canal is 37 feet and its width 300 feet. There are 23 angles or changes of direction between the entrances. Ships normally travel through the canal under their own power except in the locks, through which they are towed by electric locomotives.

(E.A.J.D.)

Modern waterway engineering

Waterways are subject to definite geographical and physical restrictions that influence the engineering problems of construction, maintenance, and operation.

The geographical restriction is that, unlike roads, railways, or pipelines, which are adaptable to irregular natural features, waterways are confined to moderate gradients; and where these change direction, the summit pounds (ponds) require an adequate supply of water, while valley pounds need facilities for disposal of surplus.

The primary physical restriction is that vessels cannot travel through water at speeds possible for road vehicles or railway wagons. Because transport economics are based on the Transport Unit (x tons moved y miles in 1 manhour), waterways must provide larger tonnage units than those possible on road or rail in order to be competitive.

The Transport Unit

Modern waterway engineering, therefore, is directed toward providing channels suitable for larger vessels to travel faster by reducing delays at locks or from darkness and other natural hazards. While such channels and associated works are designed to minimize annual maintenance costs, the costs of operating vessels, locks, wharves, and other waterway works can be minimized by increased mechanization.

CHARACTERISTICS OF BASIC TYPES

Fundamentally, waterways fall into three categories, each with its particular problems: natural rivers, canalized rivers, and artificial canals.

On natural rivers navigation is subjected to seasonal stoppages from frost, drought, or floods, all of which lead to channel movements and to the formation of shoals. While minimizing natural hazards, attention is primarily directed to retaining the channel in a predetermined course by stabilization of banks and bed, by elimination of side channels, and by easing major bends to obtain a channel of uniform cross section that follows the natural valley.

On canalized rivers navigation is facilitated by constructing locks that create a series of steps, the length of which depends on the natural gradient of the valley and on the rise at each lock. Associated with the locks for passing vessels, weirs and sluices are required for passing surplus water; and in modern canalizations, such as the Rhône and the Rhine, hydroelectric generation has introduced deep locks with longer artificial approach channels, which require bank protection against erosion and, in some strata, bed protection against seepage losses.

On artificial canals navigation can depart from natural river valleys and pass through hills and watersheds, crossing over valleys and streams along an artificial channel, the banks and sometimes the bed of which need protection against erosion and seepage. The route of an artificial canal can be selected to provide faster travel on long level pounds (stretches between locks), with necessary locks grouped either as a staircase with one chamber leading directly to another or as a flight with short intervening pounds. Where substantial differences of level arise or can be introduced, vertical lifts or inclined planes can be constructed. Storage reservoirs must be provided to feed the summit pound with enough water to meet lockage and evaporation losses; other reservoirs can be introduced at lower levels to meet heavier traffic movements entailing more frequent lockage operation. If supplies are insufficient to offset the losses, pumps may be needed to return water from lower to upper levels.

CHANNELS

Channel design. Natural rivers and canalized rivers away from artificial cuts need no protection against seep-

age and only light protection of banks against erosion. The widening or cutting off of major bends assists navigation, but wholesale straightening is undesirable because the natural sinuosity of the river, though modified, should be retained. Local widening is effected by dragline excavators cutting into the channel and dumping the material ashore either direct to form levees or to be removed elsewhere. Deepening or widening beyond the reach of shore-based excavators requires a floating plant that discharges to hopper barges for transport to a disposal point or to pipelines for pumping ashore.

Cross section of artificial canals

Artificial canals should provide a waterway with a cross-sectional area at least five, and preferably seven, times the cross-sectional area of the loaded vessel. In rock cuttings, such as those of the Corinth Canal, the waterway cross section could be rectangular, but the normal cross section is trapezoidal, with bed width three to four times and surface width six to eight times the width of the vessel, while the depth must be enough to allow the water displaced by the moving vessel to flow back under the hull.

Channel construction. The physical construction of a canal has been facilitated by the development of very large mechanical excavators. Walking draglines with 20-ton buckets such as were used on the St. Lawrence Seaway are more suitable for quarry or opencut coal workings; for general channel construction the more versatile tracked machines are preferred. Scrapers and dumper trucks with oversize pneumatic tires for fast travel over rough ground readily dispose of excavated materials to form embankments or other fill.

Water losses by percolation through bed or banks must be prevented on embankments and wherever permeable strata are encountered. While the watertight skin was originally obtained by a layer of puddled clay with protective gravel covering, other materials later became available, such as fly ash from power stations, sometimes with a cement admixture; bentonite; bituminous materials; sheet polythene; or concrete.

Bridges, aqueducts, and tunnels for waterways. Canals must frequently cross over or under roads and railways, rivers, and other canals. These crossings are made by a variety of bridges, sometimes carrying the road or railroad, sometimes carrying the canal. Most are fixed, though movable bridges are also used. On the Weaver River in England, four movable bridges, carrying main roads across the waterway, swing on pontoons.

Canals originally crossed valleys on heavy masonry structures supporting the full formation, including puddled clay lining. Cast-iron flanged and bolted troughs later provided a lighter and watertight channel; current practice uses concrete with bituminous sealing.

Canals were originally carried through hills and watersheds in small bricked tunnels through which vessels were propelled by manual haulage, by poling, or by legging—that is, by crewmen lying on their backs on the cabin and pushing with their feet against the tunnel roof. Later, tunnels were provided with towpaths.

Bank protection. On natural or canalized rivers of relatively large cross section, bank erosion can be checked by rubble roughly tipped or by natural growth such as reeds or willows.

On artificial canals of smaller dimensions, where passing vessels create a serious wash, some revetment (bank protection) is essential. Sloping banks are readily protected by close laid stone pitching, by bundles formed of interwoven willow branches, or by bituminous carpet; more permanent protection is provided by steel or concrete piles, close driven, overlapping or interlocked, and protected against impact damage by horizontal fendering above the waterline and below the waterline by roughly tipped rubble. In cuttings, the slopes are stabilized by berms (level strips) six to ten feet wide at intervals determined by the nature of the soil. On long embankments safety stop gates can minimize water losses in the event of a breach.

Towpaths. Originally provided for animal haulage, towpaths were adapted on many French canals for mechanical and electrical haulage until the general use of powered craft terminated this service in 1969. But the towpaths are still useful; in addition to providing ways for some local haulage by mechanical tractor, they provide valuable access to the canals for inspection and maintenance.

LOCKS

On canalized rivers and artificial canals, the waterway consists of a series of level steps formed by impounding barriers through which vessels pass by a navigation lock. Basically, this device consists of a rectangular chamber with fixed sides, movable ends, and facilities for filling and emptying: when a lock is filled to the level of the upper pound, the upstream gates are opened for vessels to pass; after closing the upstream gates, water is drawn out until the lock level is again even with the lower pound, and the downstream gates are opened. Filling or emptying of the chamber is effected by manually or mechanically operated sluices. In small canals these may be on the gates, but on larger canals they are on culverts incorporated in the lock structure, with openings into the chamber through the sidewalls or floor. While the sizes of the culverts and openings govern the speed of filling or emptying the chamber, the number and location of the openings determine the extent of the water disturbance in the chamber: the design must be directed toward obtaining a maximum speed of operation with minimum turbulence. The dimensions of the chamber are determined by the size of vessels using, or likely to use, the waterway. Where the traffic is dense, duplicate or multiple chambers may be required; in long chambers intermediate gates allow individual vessels to be passed.

Lock dimensions

Lock dimensions vary from the small narrow canal locks of England with chambers 72 feet (21 metres) long and seven feet (two metres) wide to the 1,500-ton capacity waterways of Europe with chambers 650 by 40 feet (190 by 12 metres). On the St. Lawrence Seaway the dimensions are approximately 800 by 80 feet (240 by 24 metres); on the Mississippi and Ohio rivers, where push-towing units are operating, the dimensions rise to 1,200 by 110 feet (360 by 33 metres).

On canalized rivers the present trend is for locks to be deeper, particularly where they form an integral part of a hydroelectric dam. On the Rhône the lock at Donzère-Mondragon has a depth of 80 feet (24 metres); in Portugal, where the Douro was being developed in the early 1970s for power and navigation, the Carrapatelo Lock has a depth of 114 feet (35 metres).

On artificial canals, where conservation of water is essential, depths do not normally exceed 20 feet (six metres): water consumption can be reduced by the provision of side pounds either adjacent to the lock, as at Bamberg on the Rhine–Main–Danube waterway, or incorporated in the lock walls, as in the (1899) Henrichenburg Lock on the Dortmund-Ems Canal.

Locks are located to provide good approach channels free from restrictions on sight or movement. Where traffic is heavy or push tows operate, adequate approach walls are needed both to accommodate vessels awaiting entry and to provide shelter from river currents while vessels move slowly into or out of the lock.

Lock gates. Movable gates must be strong enough to withstand the water pressure arising from the level difference between adjacent pounds. The most generally used are mitre gates consisting of two leaves, the combined lengths of which exceed the lock width by about 10 percent. When opened, the leaves are housed in lock wall recesses; when closed, after turning through about 60°, they meet on the lock axis in a V-shape with its point upstream. Mitre gates can be operated only after water levels on each side have been equalized.

On small canals gates may be manually operated by a lever arm extending over the lock side; on large canals hydraulic, mechanical, or electrical power is used. On the Weaver Navigations Canal in England, the hydraulic power for operating the lock gates has for 100 years been derived from the ten-foot (three-metre) head difference between the pounds.

Vertical gates, counterweighted and lifted by winch or

other gearing mounted on an overhead gantry, can operate against water pressure; as the gate leaves the sill, water enters the chamber, supplementing or replacing the culvert supply. The turbulence is more difficult to control and the overhead gantries impose restrictions on masts and other superstructure of a vessel.

The use of sector gates, which turn into recesses in the wall, depends on the physical characteristics of the site and on the traffic using the waterway; falling gates lower into recesses in the forebay; and rolling gates run on rails into deep recesses in the lock walls.

Lock equipment. Ladders recessed into the walls provide access between vessels and the lockside and are vital in case of accidents.

Bollards (mooring posts) on the lockside are used for holding vessels steady by ropes against the turbulence during lock operation; mooring hooks set in recesses in the walls provide an alternative anchorage against surging. Floating bollards are provided in deep locks; retained in wall recesses, they rise or fall with the vessel, obviating the need for continuous adjustment of the ropes. Signals, physical or visual, erected at each end of the lock indicate to approaching craft whether the lock is free for them to enter and, in the multiple-chamber locks, which chamber they should use. Control cabins, centrally situated, enable all operations of the lock gates, sluices, and signals to be carried out by one man from a push-button control panel. Telephone or radio communication between adjacent locks gives the operator advance information enabling him to have a lock prepared in anticipation of the vessel's arrival. Experiments in France in the early 1970s were directed toward the automatic passage of a vessel through a flight of locks, the various operations at each lock, once initiated, continuing automatically until the vessel left.

Communications between locks

Lock bypasses. The passage of a small pleasure boat through a deep lock is an expensive operation if it is passed alone and can be hazardous if it is passed with large barges that might surge against it. Canoes are normally brought ashore and manually moved around a lock on a portable trolley; larger pleasure craft can be transported on a cradle mechanically towed on a lockside rail track.

Water chutes have been introduced in Germany for canoes and rowboats where there are rises of 30 to 80 feet (9 to 24 metres); although more costly to install than lockside rail track, they are more popular. The canoeist, entering the approach channel, pushes a button actuating the head gates, which rise to allow the water to carry the canoe into and down the chute, where it is kept in the centre of the chute by guide vanes. For upstream passage, canoes are kept afloat by descending water but require manual towage.

Boat lifts. Vessels can be transported floating in a steel tank or caisson between adjacent pounds by a vertical lift, replacing several locks. Vertical lifts can be operated by high-pressure hydraulic rams, by submersible floats, or by geared counterweights. Hydraulic lifts with twin caissons were constructed in 1875 at Anderton, England, with a 50-foot (15-metre) lift for 60-ton vessels; in 1888 lifts were constructed at Les Fontinettes, France, for 300-ton vessels and at La Louvière, Belgium, for 400-ton vessels; in 1905 similar lifts were constructed at Peterborough and Kirkfield in Canada. Float lifts were constructed in 1899 at Henrichenburg, Germany, with a 46-foot (14-metre) lift for 600-ton vessels; in 1938 at Magdeburg, Germany, with a 60-foot (18-metre) lift for 1,000-ton vessels; and in 1962 a new lift at Henrichenburg for 1,350-ton vessels.

Counterweighted lifts were introduced in 1908 when the Anderton lift was reconstructed. Each caisson was separately counterbalanced by a series of weights and ropes with electrically driven gearing. This method was used in 1932 at Niederfinow, Germany, with a 117-foot (35-metre) lift for 1,000-ton vessels.

Inclined planes. In the 18th century, inclined planes were constructed to transport small boats on trucks between adjacent pounds, using animal power and gravity and, later, steam. A series of planes was built in the U.S. on the canal between the Delaware and Hudson rivers to transport 80-ton vessels in caissons; a similar plane for 60-ton vessels was built at Foxton, England, to bypass ten locks.

Three planes have been constructed in Europe, at Ronquières, Belgium, for 1,350-ton vessels; at St. Louis Arzviller, France, for 300-ton vessels; and at Krasnoyarsk, Russia, for 1,500-ton vessels. At Ronquières and Krasnoyarsk, vessels are carried longitudinally up relatively gentle inclines with gradients of 1 in 21 and 1 in 12, respectively, while at Arzviller the site permitted only a steep gradient of 1 in 2½, necessitating vessels being moved transversely. At Ronquières the plane rises 220 feet (66 metres) and replaces 17 locks; at Arzviller the rise is 150 feet (45 metres), and here, too, 17 locks have been replaced. At Krasnoyarsk the plane rises 330 feet (98 metres) from the downstream water level of the River Yenisei to surmount the hydroelectric dam; on top of the dam the caisson moves on to a turntable, where it is rotated through 38° before passing to a second plane running down to the water level impounded upstream of the dam.

INLAND WATERWAY CRAFT

While early navigation of natural rivers was dependent on the use of sail for upstream operation, towpaths and animal haulage were provided when rivers were canalized and artificial canals constructed. Later, mechanical haulage was developed and is still used for local movement of unpowered craft.

Steam, and later diesel, tugs improved speed of travel, particularly where lakes or estuarial lengths were encountered. Powered barges, towing one or more unpowered (dumb) barges, were introduced on rivers with adequate lock chambers; but on artificial canals double (or treble) lockage operations made this method uneconomical; and, except for local lighterage (loading, transporting, and unloading) or maintenance duties, dumb barges are little used on artificial canals.

Tugs and barges

To meet competition from road haulage, with its greater flexibility and higher speeds, water transport must find its solution in larger units, thus necessitating the enlargement of channels and locks. Consequently, the 300-ton barges operating economically early in this century have been replaced by craft as large as 1,350 tons and more.

In North America, transport operators grouped dumb barges into assemblies, lashing them on either side or ahead of a power unit with similar barges secured in rows ahead. These assemblies of unpowered and individually unmanned barges are known, somewhat illogically, as push tows and the power unit as a push tug. While these assemblies operate most advantageously on natural rivers, their development has justified heavy capital expenditure for enlarging lock chambers on some canalized rivers to avoid delays and increased operational costs arising from multiple lockage. In Europe, push tows normally operate with fewer than six barges, but on the Mississipi, with its deep channel and 700 miles without a lock, a push tow may aggregate 40,000 tons, an assembly of 40 barges being controlled by one 9,000-horsepower push tug, with cabins and facilities for 24-hour operation. On the Ohio River, the original 600-feet lock chambers are being lengthened to 1,200 feet (355 metres) to obviate double lockage.

Push tows and push tugs

Movement of push tows around bends, as on the Moselle River, is facilitated by portable power units attached to the bows and operated as required. Similar units can be attached to individual barges for transfer from push tow to wharf or vice versa; they can also be used for handling dumb barges in docks and for moving hopper barges short distances from dredger to disposal site.

WATERWAY MAINTENANCE

Inspection vessels, self-propelled and equipped with echo-sounding appliances, are necessary for regular survey of the waterway. On natural and canalized rivers, which are subject to droughts and floods, attention is particularly directed to the location of the navigable channel: transverse soundings reveal channel movements and enable marker buoys or perches to be relocated and shoals re-

moved by dredging; longitudinal echo-sounding readings normally suffice to locate shallow lengths on artificial canals.

The dredging plant

The dredging plant is an expensive item of waterway maintenance. Bucket dredgers for major operations are supplemented by suction, or grab, dredgers for localized work; hopper barges are required for transporting dredged materials to disposal sites, which should be numerous enough to minimize the transporting period, so that the dredger remains fully operational with a minimum of hopper barges and towage units.

Bank revetment requires regular attention: special vessels are needed for carrying piling frames and light lifting tackle; other service craft are needed for concrete mixing and general duty.

Lock-gate renewal is a major maintenance item, normally planned to ensure that a predetermined number of gates are replaced annually; special vessels equipped with heavy lifting tackle are needed for transport and site handling.

Divers carry out underwater inspections and repairs; although skin diving has been developed for some operations, helmet diving is still needed for prolonged work. Both types of diving require special craft with specialized crew and equipment for servicing the divers. Salvage craft with pumps and heavy lifting tackle are used for removing obstructions from the channel or for raising sunken vessels. Tugs handle the service vessels because many are used only intermittently and thus power units are not economical. Dry docks or slipways, workshops, fitting shops, welding bays, and other special facilities, usually grouped in the vicinity of the administration offices, are part of every modern canal-maintenance system. (C.M.)

Waterway systems

ADMINISTRATION

Modern inland waterway development has been largely carried out by governments, in contrast to early canal construction, which was mainly undertaken by private enterprise. Most of the older canals were subsequently acquired by the state and are administered by them or their agencies and are subject to comprehensive regulation, frequently by independent commissions. International commissions comprising the states concerned regulate navigation on the international waterways. In the U.S., the waterways are basically a federal responsibility, with their development undertaken by the U.S. Army Corps of Engineers, but state governments and local authorities also participate in the administration of many local waterways. The Interstate Commerce Commission has responsibility for the regulation of the common carriers and requires them to publish their rates. For some major multipurpose projects, public corporations were established to undertake and administer them.

In Europe and the Soviet Union, the national networks, mainly based on navigable and canalized rivers linked by canal, were developed by the governments, who retain responsibility for finance and administration. In Britain, most canals were brought under government ownership beginning January 1, 1948, and are administered by the British Waterways Board.

European waterway regulation

Europe's main waterways have long been accepted as international waterways with navigation free to all vessels and equality of treatment of all flags guaranteed. The chief regulatory commissions are the Central Commission for the Navigation of the Rhine, the Danube Commission, and the commission for the canalized Moselle. There are also a number of bilateral agreements between states. Wars and political considerations following them have from time to time interrupted the freedom of navigation. A provisional Rhine Commission was operating in the early 1970s; a new Danube Commission was established in 1953 after the signing of the Austrian state treaty, when freedom of navigation throughout the river's length was fully restored. With the creation of a number of international organizations in Europe, a high degree of cooperation between states for the development of the inland waterways and the regulation of navigation was achieved, particularly through the United Nations Economic Commission for Europe, the European Economic Community, the Organization for Economic Cooperation and Development, and the Council of Europe.

In North America, a U.S.–Canadian International Joint Commission has functioned since 1909 with general authority over the boundary waters. The St. Lawrence Seaway is a joint Canadian and United States project, administered by the St. Lawrence Seaway Authority in Canada and the St. Lawrence Seaway Development Corporation in the United States.

The Panama Canal was originally administered under the Panama Canal Convention of 1903 by the U.S., under the supervision of the army. Panama–U.S. relations were frequently strained, and in 1964, the U.S. agreed to negotiate new treaties concerning the existing canal and construction of a new canal at sea level. Later, both countries agreed that the 1903 treaty should be replaced by a new treaty recognizing Panama's sovereignty over the Canal Zone.

The international status of the Suez Canal, constructed and administered by the Suez Canal Company, has frequently been a matter for dispute, peaceful and otherwise. Only in 1904, under an Anglo-French agreement, was the Constantinople Convention of 1888, establishing the Suez Canal as an international waterway open to all in war and peace, finally implemented. In 1956 British presence in the area ended and troops were withdrawn from the canal zone; the Egyptian government nationalized the assets of the canal company and the administration was assumed by Egypt, but the 1967 war closed the canal for an indefinite period.

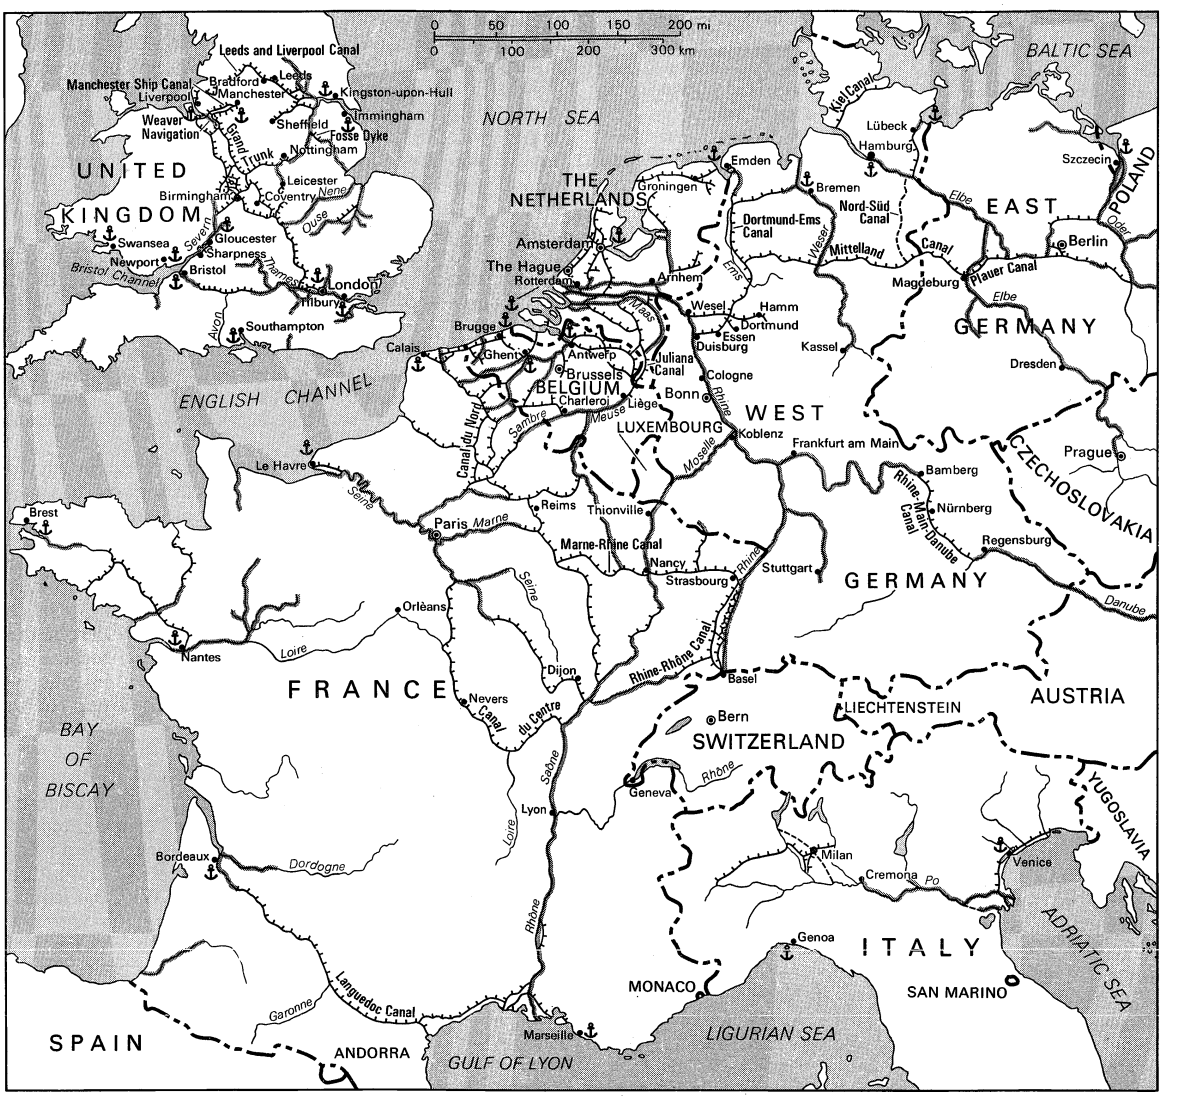
MAJOR INLAND WATERWAYS AND NETWORKS

Europe. After the end of World War II, the growth of transport by inland waterway in Europe, coordinated by the various international authorities, resulted in an enlarged and integrated network brought up to a minimum common standard for craft of 1,350 tons. With the Rhine, Moselle, and their tributaries dominating the German system and providing outlets for the Dutch and Belgian systems and connecting with the French network, main improvements were concentrated on the international Rhine-Main-Danube Canal and on improving the north–south route of the Nord-Sud Canal. The latter canal leaves the Elbe about 20 miles above Hamburg and, running south, is planned to join the Mittelland Canal near Wolfsburg, Germany, in the mid-1970s, reaching a total of 71½ miles (120 kilometres) and shortening the route between Hamburg and the Ruhr by 134 miles (220 kilometres).

The Rhine–Main–Danube waterway

The Rhine–Main–Danube waterway connecting the Rhine with the Black Sea is planned to provide a route for traffic between east and west Europe through Germany by 1981, accommodating craft of 1,350 tons throughout its length. Following the River Main to Bamberg in Germany, the route proceeds by artificial waterway, including a section of the Regnitz Canal to Dietfurt, thence by the River Altmühl to below Kelheim, where it joins with the Danube, crossing the Austrian border at Jochenstein. The 43-mile (70-kilometre) Bamburg-to-Nürnberg canal section, completed in 1970, includes seven locks with a combined lift of 268 feet (80 metres). All locks are 650 feet (189 metres) long and able to accommodate vessels of 1,500 tons. Improvements of the channel of the German Danube, begun in 1965, include a pair of locks at Kachlet, just above Passau. In Austria, four pairs of locks to take 1,350-ton craft have been built and others are planned.

In 1970 the damming of the Danube at Djerdap, the Iron Gate rapids, on the border between Yugoslavia and Romania, was begun in conjunction with the improvement of navigation through these dangerous waters; it will incorporate vast hydroelectric power plants. Two locks, 1,017 feet (310 metres) long and 112 feet (34 metres) wide, with two chambers each, are being built to facilitate passage through the Iron Gates. Journey time for ships travelling from Black Sea ports upstream to Belgrade, Vienna, and central Europe will be reduced from around 100 to 15 hours by this project, and traffic is ex-



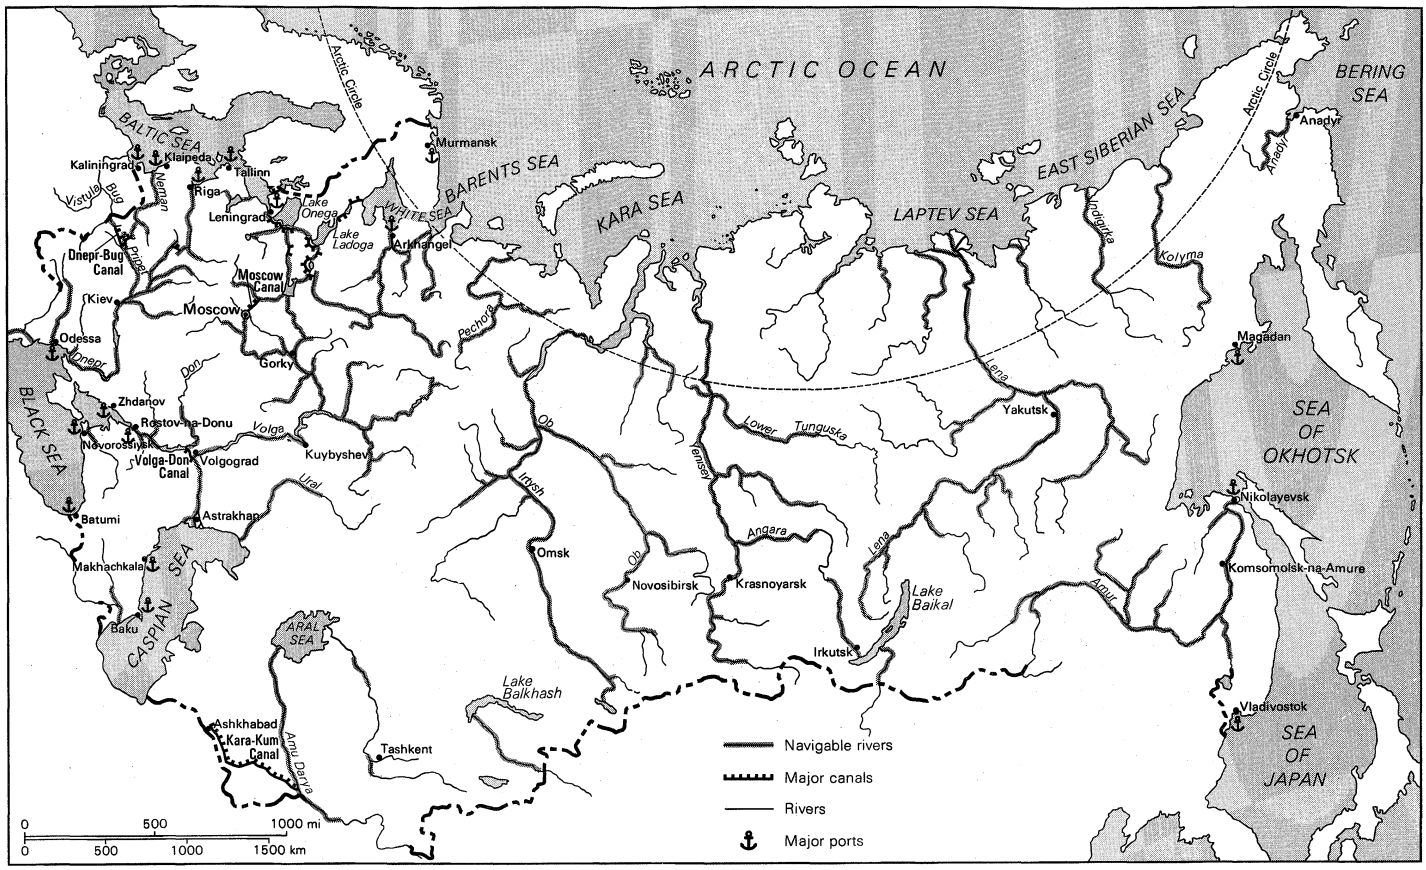
Inland waterway systems of western Europe.

pected to rise from the present 12,000,000 tons annually to 50,000,000 tons.

France's waterway network of nearly 5,000 miles is based primarily on its rivers, but many of the low-capacity canals are being raised to the 1,350-ton standard. The major development under way, in cooperation with West Germany, with completion planned for the mid-1970s, is the construction to this standard of the North Sea–Mediterranean waterway via the canalized Rhône and Rhine rivers. With four existing locks built for the Grand Canal d'Alsace, a projected lateral canal between Huningue and Strasbourg, the project was modified in 1956, and the four remaining dams were to be built on the Rhine itself and bypassed with short canals including four locks, three with two chambers each. Canalization of the Rhône started with the building of the Port of Edouard-Herriot downstream from Lyon, and work has proceeded on 12 locks and dams. Two new ports, serving Valence and Montélimar, are being constructed. Completion of the canalization is planned for 1976, when the North Sea–Mediterranean route, of which the Rhône is an essential part, will also be open. Improvements were also made on the Marne–Rhine waterway, which provides an important internal trade route connecting the Paris Basin with the industrial regions of Alsace-Lorraine. The improvements included major works on either side of the Vosges summit level, replacing 23 old locks. At Réchicourt a new lock with a lift of 32½ feet (ten metres) bypasses six locks and a winding section of the old canal; on the other side of the summit a new canal section bypasses 17 locks, which formerly required eight to 12 hours to navigate. On this section the inclined plane of Saint-Louis Arzviller deals with a difference in level of 146 feet (44 metres) with a horizontal length of 422 feet (125 metres). Two tanks each carry a 350-ton barge. Their 32 wheels run on four rails, and two sets of 14 cables connect the tanks to the two concrete counterweights. On the routes connecting the Seine with the north and east, improvements have also been made. The Canal du Nord was completed in 1965, and a bottleneck was removed on the Oise Lateral Canal with the building of two locks to accommodate through convoys to Paris.

In The Netherlands, the extensive canal system based on large natural rivers and serving the ports of Rotterdam and Amsterdam has required comparatively little modernization; but to avoid the River Maas (Meuse), between Roermond and Maastricht, the Juliana Canal was built in 1935 and improved after World War II. The Twente Canal, opened in 1936, improved communication with the industrial east. Most important of the postwar projects was the building of the Amsterdam–Rhine Canal to enhance the capital's value as a trans-shipment port for the Rhine traffic. The Noord–Hollandsch Canal from Amsterdam to Den Helder was constructed, and the Ijsselmeer was linked with the Ems estuary across the north of Holland. To shorten the distance between Rotterdam and Antwerp by 25 miles (40 kilometres), the Schelde–Rhine Canal has been built.

Italy's waterway system, based on the Po Valley, is cut off from the European network by the Alps, but it is also



Canals and inland waterways in the Soviet Union.

being brought up to higher standards. In Scandinavia, there are two major commercial artificial waterways; the first, the Trollhätte Canal, connects the Götaälv (river) upward from Göteborg with Lake Vänern and with the Finnish lakes and connecting canals; the second, the Saimaa Canal, in southeast Finland, which carries the vast Saimaa Lake system to the sea, was being reconstructed at the time of World War II. After the Soviet-Finnish War, part was ceded to the Soviet Union; but in 1963 it was leased back to Finland, modernization continued, and the canal, with eight large locks replacing the previous 28, was reopened in 1968.

Principal Soviet links

In the Soviet Union, water navigation plays a major role in the country's economy; and after World War I its great rivers—the Dnepr, Dvina, Don, Vistula, and Volga—were linked to form an extensive network, making through navigation possible from the Baltic to both the Black Sea and the Caspian. The Black Sea and the Baltic are connected by three different systems, of which the most important is the link between the Dnepr and the Bug, a tributary of the Vistula, by way of the Pripyat and Pina rivers, a 203-kilometre canal connecting with the River Mukhavets, a tributary of the western Bug. This system is the sole wholly inland waterway connection between western Europe and the Soviet systems, giving through access to the Caspian and Black seas. When the Rhine–Danube and Oder–Danube canals are completed, a second route will be provided, via the River Berezina, a tributary of the Dnepr, the Viliya, a tributary of the Niemen, and a 21-kilometre canal through Latvia to Riga. The remaining link reaches the Baltic through Lithuania and Poland from the Dnepr by way of the Szara, a tributary of the Niemen; the Jasiolda, a tributary of the Pripyat; and a canal 54 kilometres long. Other important links in the Soviet system are the Volga–Don Canal, 101 kilometres long and completed in 1952, and the Moscow–Volga Canal, built between 1932 and 1937, which flows 128 kilometres from the Volga south to the River Moskva at Moscow. The White Sea Canal, built in 1931–33, runs from Belomorskiy on the White Sea through the canalized Vyg River across Lake Vyg and through a short canal to Pavenets at the northern end of Lake Onega, through which the waterway passes to the canalized Svir River, Lake Ladoga, and the Neva River to the southern terminal at Leningrad. The total length of the system is 140 miles (225 kilometres), reducing sea passage between Leningrad and Archangel by 2,400 miles (4,000 kilometres); through its 19 locks it rises to a maximum of 335 feet (100 metres) above sea level. Further developments in the Soviet Union are mainly in the distant Asian territories, where the Ob and Yenisei in Siberia are connected by canal, and the Karkumsky Canal has been built from Kerki on the River Amu Darya and is being continued westward to the Caspian.

North America. The United States and Canadian networks of inland waterways are based on the great navigable rivers of the continent linked by several major canals. Additionally, to reduce the hazards of navigating the Atlantic seaboard and to shorten distances, intracoastal waterways (protected routes paralleling the coast) have been developed. The total inland U.S. system, including protected coastal routes, approximates 25,000 miles (41,000 kilometres), of which well over half has a minimum depth of nine feet (three metres). The largest system is based on the Mississippi, which is navigable for about 1,800 miles from New Orleans to Minneapolis, and its vast system of tributaries. This system connects with the St. Lawrence Seaway via Lake Michigan, the Chicago Sanitary and Ship Canal, and the Illinois River and with the Atlantic coast via the New York State Barge Canal (Erie Canal) and the Hudson River. The two intracoastal waterways are the Atlantic and the Gulf, the former extending from Boston, Massachusetts, to Key West, Florida, with many sections in tidal water or in open sea. The Gulf Intracoastal Waterway comprises large sheltered channels running along the coast and intersected by many rivers giving access to ports a short distance inland. New Orleans is reached by the Tidewater Ship Canal, a more direct and safer waterway than the Mississippi Delta. The Pacific coast canals are not linked with the national network, but two major projects of importance are the Sacramento Deepwater Ship Canal and the Columbia River

development, which will provide over 500 miles of navigable river from the Pacific to Lewiston, Idaho.

The opening of the St. Lawrence Seaway in 1959 saw the fulfillment of a project that had been envisaged from the times of the earliest settlements in Canada. A continuous, navigable, deep waterway from the Atlantic to the Great Lakes was the obvious route for opening up the interior of North America; but natural obstacles, such as the Lachine Rapids north of Montreal, had prevented its realization. The completion of such a waterway required agreement between the U.S. and Canada, which was difficult to achieve. In 1912 the Canadian government decided to improve the Welland Canal to provide a 27-foot (eight-metre) depth with locks 800 feet (236 metres) long and 80 feet (24 metres) wide; but because of World War I, it was not completed until 1932. Although a joint project to include hydroelectric power development on the International Rapids section had been provisionally agreed upon, final agreement between Canada and the U.S. was not reached until the early 1950s. The Canadian government undertook to raise the standard of the waterway to a 27-foot navigation depth between Montreal and Lake Erie, and the U.S. agreed to carry out other works, including the bypassing by canal and locks of the Barnhart Island–Cornwall generating dam at the foot of the Long Sault Rapids. This agreement enabled work on the seaway to begin in 1954. The resultant deep waterway, navigable by oceangoing ships, extends about 2,300 miles (3,830 kilometres) from the Atlantic Ocean to the head of the Great Lakes in the heart of North America.

Locks

After Montreal Harbour the first lock is the St. Lambert, which rises 15 feet (4.5 metres) to the Laprairie Basin and proceeds 8.5 miles (14 kilometres) to the second Côte Ste. Catherine Lock, which rises 30 feet (nine metres) to Lake St. Louis and bypasses the Lachine Rapids. Thereafter, the channel runs to the lower Beauharnois Lock, which rises 41 feet (12 metres) to the level of Lake St. Francis via a 13-mile (21-kilometre) canal. Thirty miles (50 kilometres) farther, the seaway crosses the international boundary to the Bertrand H. Snell Lock, with its lift of 45 feet (14 metres) to the Wiley–Dondero Canal; it then lifts another 38 feet (12 metres) by the Dwight D. Eisenhower Lock into Lake St. Lawrence. Leaving the western end of the lake, the seaway bypasses the Iroquois Control Dam and proceeds through the Thousand Islands to Lake Ontario.

Eight locks raise the water 326 feet (98 metres) over 28 miles (45 kilometres) from Lake Ontario to Lake Erie. The St. Marys Falls Canal, with a lift of about 20 feet (six metres), carries the waterway to Lake Superior, where the seaway terminates.

Indian Subcontinent. In Asia, the full potential of the rivers for navigation had not been developed by the second half of the 20th century; though the rivers constitute one of the main means of transport, there are few navigable canals and no integrated system of inland waterways. The Indus River Basin was being developed in the 1970s, however, and there were plans for international cooperation in developing inland waterway transport on the Mekong and Ganges–Brahmaputra systems.

ECONOMIC SIGNIFICANCE

Despite the large capital investment required to modernize existing inland waterway systems and for new construction, water transport has demonstrated competitive strength as a carrier for commodities in the movement of which the time factor is not of prime importance, such as minerals, timber, and many agricultural products. In the same way as the canals of the 19th century contributed to the development of the Midwest in the United States, the St. Lawrence Seaway has led to an expansion of industrial activity on the regions bordering the Great Lakes. Economic expansion along North America's rivers has followed capital investment in improvement of navigation along them. In the Soviet Union, similar development of vast areas, including the distant Asian territories, was made possible by linking the major rivers to provide through routes.

Growth of water transport tonnage

In continental Europe, the eight member countries of the Conference of European Ministers of Transport (ECMT) experienced a growth in total tons carried by inland waterways from 385,000,000 tons to 472,000,000 tons in the years 1964–68. Whereas in 1938 Germany carried 90,000,000 tons of freight on its inland waterways, by the end of the 1960s the Federal Republic of Germany alone was carrying over 230,000,000 tons a year; East Germany was carrying an additional 12,000,000 tons. Nor was this increase limited to the earlier years of the decade, as is shown by the volume of goods passing along the Rhine, which rose from 187,000,000 tons in 1963 to 265,000,000 tons in 1969. Most European countries had the same experience: the Soviet Union, which carried over its 145,000 kilometres of navigable waterways 239,500,000 tons in 1963, transported 322,700,000 tons in 1969.

It is difficult to judge the economics of water transport compared with other transport forms because of the different operating systems. On most international rivers, for example, there are no navigational charges; but on most national artificial waterways, tolls are charged. Costs of water transport are therefore mainly operating costs, which are considerably lower than the total costs of movement by other transport modes. This situation partly accounts for the fact that in the 1950s and 1960s in the U.S., costs per ton-mile stayed practically the same or fell slightly. Mergers of carrier companies and technological developments also contributed to price stability.

In West Germany it has been calculated that one horsepower could move by road 150 kilograms (330 pounds), by rail 500 kilograms (1,100 pounds), and by inland waterway 4,000 kilograms (8,800 pounds). The water-transport cost is said to be one-sixth the cost of transport by road and two-thirds the cost of transport by rail. Other transport carriers contend that such comparisons are not valid because public investment in permanent structures (*i.e.*, canals and locks) is not always taken into account, whereas for railways, private investment in right-of-way costs is reflected in carrying charges. Nor has the inland-waterway industry been without its difficulties. In Europe, for example, in the 1960s a surplus of carrying craft adversely affected the industry's profitabil-

ity; but by the 1970s this problem had largely been overcome, partly by international action.

In summary, it may be said that the real advantages of water transport are being maintained or enhanced by modern techniques, especially by more powerful towboats capable of hauling up to 50 barges carrying 80,000 tons; around-the-clock operation is made possible with towboats refuelled in midstream and barges attached or detached while the tow proceeds along the river; at ports, automatic loaders cut turnaround time to a minimum. It remains to be seen whether the resurgence of water transport so evident through the 1960s and 1970s will be maintained. A major question mark is the barge-carrying ship, analogous to railway piggybacking of truckloads, which promises to provide through transport by barge from inland ports across oceans to foreign inland destinations. Cancer

Cancer in man is a group of over 100 related diseases that may arise in any of the body's tissues and that are characterized by the uncontrolled and disorderly multiplication of abnormal cells. If their growth is not checked, these cells infiltrate and destroy adjacent tissues. Often cancer cells are transported to distant parts of the body, where they grow as colonies called metastases.

The cancerous or malignant process begins as a progressive, unrestrained division of abnormal cells. Viewed through a microscope, cancer cells may initially maintain some degree of differentiation—that is, their specialized structure and function—so that they resemble those cells from which they arise or some developmental stage of the tissues of origin. Some cancer cells may perform limited normal functions. As the disease progresses, however, the cells usually become increasingly abnormal in appearance, structure, and function until they may not be recognizable as an offshoot of the tissue of origin. They may appear in a great variety of sizes and shapes. Chromosomes in malignant cells undergoing division may appear oversized or may have asymmetrical spindles or other abnormalities. Unlike benign tumours, malignant tumours are not contained within capsules, or, if they are, the capsules are incomplete.

A typical benign tumour is usually encapsulated within a membrane of connective tissue. Microscopically, the benign mass has a homogeneous appearance if it is derived from only one type of tissue. Individual cells all appear alike. Degenerative and regressive changes are much less frequent than in malignant tumours, and the patterns of benign tumours are usually orderly. They do not metastasize. (Both benign and malignant tumours are often referred to as neoplasms.)

Cancer grows in all known groups of animals except the lower forms; many plants even develop cancerlike growths. Cancerlike changes have been found in million-year-old fossil dinosaur bones. In man, the phenomenon has been recognized since earliest time and occurs in all human populations.

Cancer deaths

Human cancer morbidity and mortality vary from country to country, but in most Western countries where infectious diseases are under control, cancer is one of the primary causes of death. In the United States, for instance, cancer is the second leading cause of death and strikes one in four persons. In most countries, cancer mortality for men substantially exceeds that for women. Scotland has the highest overall cancer mortality rate among men, and Portugal the lowest. Among women, Chile has the highest reported cancer mortality, and Portugal the lowest.

CAUSES

Although the precise mechanism of the malignant process is not known, various factors, singly and in combination, are recognized as being able to initiate that process. Chemicals, radiation, genetic factors, repeated trauma, and, most recently, viruses have been proven to cause or to be strongly associated with certain forms of cancer. Geographic variations in cancer incidence can be attributed to varying exposure to such cancer-causing agents, or carcinogens.

In many instances, cancer can be prevented once carcinogenic agents are identified. Knowledge of the causes of cancer makes it possible either to eliminate them from the human environment, to interfere by chemical or other means with their mode of action, or possibly, in the future, to increase the resistance of the human body to withstand their assault.

Chemicals. Hundreds of chemicals are known to induce cancer in animals. Some, including metals, minerals, and other chemicals in the general environment, and in industry and other occupational settings, have been shown to cause human cancer or are suspected of causing it. The evidence in man is complete only with about two dozen materials.

Protective measures designed to prevent cancer initiated by industrial sources include elimination of the carcinogenic agent where possible, increased practice of industrial hygiene, and techniques for controlling such contaminants as dust and fumes.

Occupational chemicals. Industries concerned with coal tar and its derivatives—pitch, tar oils, and creosote —account for the largest known group of occupational cancers. In the past, skin cancer took the lives of many long-time workers in those industries and in others that use benzo(*a*)pyrene (a chemical present in combustion- and distillation-products of coal, oil, shale, lignite, and petroleum). Coal-tar fumes inhaled by workers in coke-oven operations and in fogs, mists, and sprays of various oils, encountered in refineries, have been associated with

high incidences of lung cancer. Benzene, a petrochemical and a product of coal-tar distillation, may affect the blood-forming tissues and produce leukemia, a disease in which there is malignant increase in white blood cells (leukocytes).

Arsenic has been implicated in cancer of the lung and several other body sites among copper ore miners, smelters of nickel and cobalt ores, workers in the insecticide manufacturing industry, and vineyard workers. Smelter workers regularly exposed to arsenic in the atmosphere have a rate of lung cancer death three times that in male populations not so occupationally exposed.

Lung cancer from asbestos

Asbestos, widely used in industrial products, including asbestos cement, fireproofing, textiles, and insulating materials, has been associated with an incidence of lung cancer ten times higher than normal among some men who work in industries that make these products. The risk is even greater for workers who smoke. Recently, an increased incidence of mesothelioma, a rare tumour of the membranes that line the internal body cavities, was found among workers in the asbestos industry. Results of animal studies suggest that some types of asbestos may be less hazardous than others. Consequently, it may be possible to adopt the less hazardous forms for industrial use to protect workers and others frequently exposed to such asbestos-containing products as fireproof theatre curtains, brake linings, ironing board covers, rugs, and mailbags.

Beta-naphthylamine, a chemical formerly widely used in the manufacture of synthetic (aminoazo and aniline) dyes, has been linked to a high incidence of bladder cancer among workers in dye factories. In addition, nickel compounds have been strongly linked with cancer of the nasal sinuses and lungs among persons working with such compounds. Chromates, iron oxide, and dimethylnitrosamine in drugs and rocket fuels may also cause some forms of cancer. Male chemists in the United States have a higher than normal incidence of lymphatic and pancreatic cancers.

Environmental chemicals. Under various conditions certain atmospheric agents act as cocarcinogens (agents that do not themselves cause cancer but enhance the carcinogenic action of other chemicals). Still other chemicals present, called anticarcinogens, inhibit the carcinogenic effect.

Among the most potent of the general atmospheric chemical carcinogens are the polycyclic hydrocarbons that result from incomplete combustion of automobile fuels. Some other chemicals used in the auto industry, especially hydrocarbon-metal complexes of nickel and cobalt, are suspected of contributing to the carcinogenic hazard in the air.

In many countries, certain pesticides were removed from the market after it was shown that they cause cancer in some laboratory animals and persist in considerable quantities in foodstuffs.

Some low-calorie sweeteners (cyclamates, for instance) have been removed from the market because they cause cancer in laboratory animals. Certain ingredients in widely used birth control pills have been shown at very high doses to cause breast cancer in cancer-susceptible laboratory animals, and certain of the pills have been taken off the market.

Aflatoxins, products of the mold *Aspergillus flavus*, which grows on improperly processed peanut meal and other food, have been found to cause epidemics of liver cancer in trout and liver disease in turkeys. In sub-Saharan Africa, where molds contaminate many foods, liver cancer is frequent. And in Japan, where molds are frequently used for fermentation, the rate of stomach cancer is high. Investigations of whether the associations are significant are under way.

Other natural products are suspected of contributing to cancer. For instance, cycasin, from the seeds of palm-like plants used as a food in the South Pacific and other tropical areas, is found to cause cancer of the kidney, liver, and intestine when the unwashed seeds are fed to laboratory animals. In another instance, the arsenic content of well water has been related to skin cancer among residents of Taiwan. In Egypt, peasants who extensively use the waters of the Nile infested with a type of flatworm called schistosomes have a higher than normal incidence of bladder cancer.

Cigarette smoking and lung cancer

In Europe and the United States, lung cancer has increased more than any other type of cancer during the past 40 years. In the United States, 70 percent of the increase has been attributed to cigarette smoking. Retrospective studies have shown that a high proportion of lung cancer patients once were long-term cigarette smokers. Follow-up studies in both Britain and the United States have shown that deaths from cancer are higher among cigarette smokers than among nonsmokers—for example, six times higher among men who smoke than among those who do not.

In laboratory studies, tars from tobacco smoke containing at least a dozen carcinogenic hydrocarbons, and enhanced by phenols and other cocarcinogens, cause cancers in various animals. It has been reported that some dogs have developed tumours after being taught to smoke cigarettes in a laboratory. In addition, changes similar to those of early cancer have been observed in the lungs of heavy smokers. These changes paralyze and destroy a protective mechanism in the lung that normally helps eliminate impurities (normally, foreign particles are swept upward by waving motions of the hairlike cilia of cells lining the air passages of the throat and chest).

Elimination of cigarette smoking is regarded as one of the most important health measures available for the prevention of disease and premature death from cancer. To help discourage people from starting the habit, total or partial restrictions on cigarette advertising have been instituted in Great Britain, Scandinavia, Czechoslovakia, France, Italy, Switzerland, and the United States.

Another factor contributing to the higher lung cancer rates is air pollution caused by industrial wastes, automobile exhausts, and household sources. City dwellers (nonsmokers) have up to ten to twenty percent more lung cancer than rural inhabitants who are nonsmokers.

Radiation. Energy from the ultraviolet rays of sunlight, and ionizing radiations from X-ray, radium, and other radioactive materials encountered in industry and in the general environment cause a variety of cancers.

Occupational radiation. The pioneer workers with radium and X-rays developed cancers of the skin. Even now, radiologists and others exposed to high total doses of ionizing radiation are more likely to develop leukemia than persons not so exposed. Uranium miners have been found to have a higher than normal incidence of lung cancer.

Radium salts are deposited in the bones and give rise to cancers there. Many of the women workers in the 1920s who ingested radium by licking brushes to a point while painting luminous watch dials subsequently died from bone cancer.

An increase of lung cancer and other cancers of the respiratory tract was discovered among Japanese who had worked in the World War II manufacture of mustard gas, a poison gas that mimics the carcinogenic action of ionizing radiation.

Sunlight and cancer

Environmental radiation. Skin cancer has been produced in animals by exposing them to intense sunlight. In lightly pigmented animals, such as albino mice, cancers of connective tissue, skin, and other organs are initiated. Surveys of human populations in Australia and the United States indicate that the incidence of skin cancer is related to the amount of sunshine absorbed. The colour of the skin is another factor. Cancer of the skin is most common among fair complexioned people, and much less frequent among blacks than among lighter skinned populations.

Additional radiation in the general environment increases the hazard. Those who survived exposure in Hiroshima and Nagasaki to the two prototype atomic bombs of World War II have a higher than normal incidence of leukemia and thyroid cancer and possibly also of cancers of the lung and breast.

A slight increase in leukemia has been reported among children who were exposed to X-rays before birth. Un-

necessary X-ray exposure from shoe-store machines that fluoroscope the feet (*i.e.*, cast an image of the bones of the feet on a fluorescent screen), and radiation leaks from machines used for diagnostic X-rays, from colour television receivers, and from microwave ovens can under some conditions contribute unnecessarily to total exposure.

Viruses. Over 100 viruses have been discovered that cause cancers in every major group of animals except the lower forms. Despite the fact that a virus has not been established as causative for any human cancer, sufficient circumstantial evidence has been acquired to indicate that one or more viruses probably cause cancer in man. Several are particularly suspect.

Herpes-type viruses. Herpes-like particles (related to the viruses that cause fever blisters) have been observed with the electron microscope in various human cancer tissues or in preparations from blood serum samples from patients with chronic leukemia. (Blood serum is the fluid left after cells and clotting factors have been removed from the blood.) A variant of herpes virus has been successfully grown in cultured white blood cells taken from patients with Burkitt's lymphoma, a cancer of the lymph system whose selective distribution in African children is itself an indication of its possible infectious origin. This variant is known as the Epstein-Barr or EB virus.

Burkitt's lymphoma

Large amounts of antibody to Epstein-Barr virus have been detected in specimens from persons with Burkitt's lymphoma, and also from persons in the Far East and Africa who have cancers in the back of the nasal cavity.

Colonies of tumour cells have been maintained in tissue culture from the cells of 180 patients with leukemia and lymphoma; in 80 of these lines, herpes viruses have been observed.

Evidence of herpes simplex type II viruses has frequently been noted in cells from precancerous tissues of the uterine cervix as well as in advanced cancers of the cervix (the neck of the uterus, which projects into the vagina). There are immunological indications of other virus-tumour associations involving other herpes-like viruses and other forms of solid tumours and leukemia.

Mammary tumour viruses. Cells from human breast cancers have been successfully grown in tissue culture. In several of these cell lines, viruses that resemble mammary tumour viruses of the mouse, rat, and monkey have been observed.

Viruslike particles have been found more frequently in the milk of women from families with high rates of breast cancer than from others in the general population. This correlation is particularly marked among Parsi women in India who are members of a highly inbred group with a high incidence of breast cancer.

C-type viruses. Virus particles with double encapsulating membranes (called C-type viruses) have been detected with the electron microscope in specimens from human leukemias and lymphomas and from leukemias of cats, dogs, and cattle. These C-type particles are similar in appearance to viruses that cause leukemias in cats, chickens, and mice. The role of C-type viruses in human cancer is not yet established, however.

Genetic factors. The common cancers of man are not generally inherited, although some families show an incidence of a particular cancer beyond expectations. Multiple cases of childhood cancer may occur in a family.

Leukemia in twins

When leukemia develops in one of a pair of identical twins, the other twin will also develop leukemia in about 15 percent of cases. Among fraternal twins, this happens less than one percent of the time. Some familial tendencies have been observed for cancer of the breast, uterus, prostate, stomach, colon-rectum, and lung, although the hereditary effect is not strong. It is possible that familial tendencies reflect common environmental relationships as well as a genetic factor, or instead of it.

In studies of familial tendencies for breast cancer in England, Denmark, and the United States, an incidence two to three times that expected in the general population was noted for close relatives of persons with the disease.

A rare cancer of the eye called retinoblastoma occurs in childhood as a result of the transmission of a single dominant gene (if a gene for a trait is dominant it need be inherited from only one parent for the trait to become manifest).

Pheochromocytoma, a rare cancer of the adrenal gland, and carcinoma of the thyroid medulla (inner portion of the thyroid) sometimes occur in various members of the same family. Either both tumours or only one may occur. Persons with pheochromocytoma also have an increased risk of parathyroid tumours and other rare tumours.

Xeroderma pigmentosum, an inherited, abnormal sensitivity of the skin to ultraviolet radiation, almost always leads to skin cancers.

Children with Down's syndrome or mongolism, a condition of retardation associated with an extra chromosome in each cell, have a much greater likelihood of developing leukemia than do other children. Persons with Fanconi's aplastic anemia (in which all types of blood cells are abnormally few and the bone marrow is not fully developed) and some other rare syndromes characterized by greatly increased chomosome breakages also have an increased risk of leukemia.

In chronic myelocytic leukemia (myelocytes are precursors of certain white blood cells), an abnormally short chromosome called the Philadelphia chromosome is a genetic marker in bone marrow cells and white blood cells of some patients. It is unknown whether the cancer and chromosomal abnormality are independent events, or whether one is the result of the other.

Trauma. Repeated trauma (injury) or irritation has been associated with some cancers. In some instances, ill-fitting dentures can lead to cancer of the mouth.

In India, the custom of wearing a loincloth, or dhoti, which irritates the skin, is associated with an abnormally high incidence of cancers on the groin and abdomen.

METHODS OF SPREAD

The greatest problem in the management of malignant diseases is the ability of cancers to spread. If it were not for this characteristic, most cancers could be successfully treated.

Spreading occurs by one of two processes: either it may progress from one area to adjoining ones by infiltration of surrounding tissue, or a cancer cell or group of cells may separate from the main mass and travel in the blood, in the lymph system, or through body tracts to another part of the body. If not destroyed in transit, the cells may become implanted at the new location and start to grow. This process is called metastasizing, and the new sites of tumorous growths are called metastases.

A very small tumour may invade a large blood vessel and result in widespread metastases. Another tumour may reach a huge size and yet remain confined.

Direct extension. The ability of a tumour to extend into adjacent tissues is influenced by the nature of the adjacent tissue. Some structures, such as soft connective tissue and the walls of lymphatics and veins, offer relatively little resistance to the migration of tumour cells. Bone is as readily invaded as soft tissues.

Other tissues—artery walls, cartilage, and dense fibrous tissues such as tendons and ligaments—are natural barriers against tumour spread. To some extent, muscle also resists invasion. Tumours may extend around an organ rather than force their way through a dense surrounding capsule such as surrounds the kidney, or tumours may remain confined within an organ rather than penetrate a surrounding capsule. For instance, once cancer has established itself in bone, it may remain confined there by the periosteum, the membrane of connective tissue that closely covers the bone. Other tumours, within the larynx, for example, may be enclosed by cartilage and remain confined.

Metastasis. Metastasizing is the process by which cancers spread to distant areas of the body. Its ability to influence survival makes metastasis the most important clinical feature of cancer. In localized cancer of the colon and rectum treated by the best of modern methods,

Effect of metastasis on survival

the five-year survival is 80 percent, whereas in the same kind of tumour metastatic to nearby lymph nodes, five-year survival is only 32 percent. Only 1.2 percent of such persons with distant metastases survive five years. In general, disseminated metastases usually indicate grave outlook.

Metastases often occur after the primary cancer has attained considerable size. Therefore, the purpose of early detection and treatment is to find and eliminate the primary tumour before metastases develop. Most often, metastases appear within five years of recognition of the primary tumour. The interval tends to be short with certain tumours (testicular tumours, for instance) or may range from many years to decades, as in certain cancers of the thyroid. In advanced cancers, metastases may form by the hundreds throughout the body.

The ability of various organs to play host to disseminated tumour cells varies greatly. Certain tissues rarely harbour metastatic cancers: the prostate, breast, thyroid, kidney, spleen, heart, and skeletal muscle are seldom sites of metastatic cancer from other organs.

Other tissues are frequently hosts to metastases. Regional lymph nodes are frequently the first area of spread. The liver is a favourable site for the further growth of many types of cancer. The brain, bone, adrenals, and liver are often sites of metastatic carcinoma of the lung. The lungs, pleura, liver, and bones are common sites of advanced, metastatic cancer of the breast.

Some cancers metastasize to unusual body sites. In 50 percent of cases, melanocarcinoma (a cancer with melanin-pigmented cells) metastasizes to the heart and other rare locations. Some cancers, like the bone tumours called osteosarcomas, rarely spread to the lymph nodes. Other cancers can grow on almost any site.

The principal routes of metastatic spread are the lymphatic system, the blood vessels (particularly veins), and body tracts such as the peritoneal cavity (the area between the membrane—peritoneum—lining the abdominal cavity and that covering the abdominal organs) or, rarely, the alimentary canal. It is sometimes possible to predict where metastases may occur by studying the drainage pattern of blood and lymph vessels, and anatomic pathways of body tracts.

Lymphatics. Metastases most frequently take place through the lymph system. Cancer cells may break away from the main mass and enter a lymph duct, or the tumour itself may invade a lymph channel. Cancer cells may then break off and travel to a lymph node, where they may grow and replace or enlarge the node. There is frequently considerable involvement of one node before the next one in a lymph chain is implicated; nodes often act as temporary barriers to the further spread of cancer.

Each organ varies in the number and distribution of its lymph vessels. This variation influences the extent of metastasis by way of the lymph channels.

Blood vessels. Most tumours have a network of blood vessels that extend through the mass, supply it with oxygen and nutrients, and remove metabolic wastes. Tumour cells may enter the veins when tumours grow into and destroy the walls of the veins. Malignant cells may also break off from a tumour individually or in clusters, migrate to capillary walls, and penetrate them, thus entering the venous bloodstream.

Some cancers invade veins only occasionally. Others metastasize exclusively in this manner. Once tumour cells have penetrated into the vascular system, they are carried in the bloodstream until they are arrested at some point; there they become attached to the wall of the vein and establish a metastasis.

Invasion of veins and arteries

Experimentally, it has been determined that an extremely high number of cells can be released into the circulation without establishment of metastases. In laboratory animals, fewer than one percent of circulating cancer cells from solid tumours survive. The use of cancer drugs and antibiotics may help reduce this percentage.

Elastic tissue and smooth muscle usually prevent the invasion of arteries by cancer cells. Only occasionally can the cells invade an artery and, thus, enter the arterial circulation.

Passage through body tracts. Metastases may occur when cancer cells break from a tumour and travel through one of the body's cavities to another location, where they lodge and grow. Such an event may happen in persons with ovarian cancer when cancer cells drift through the peritoneal cavity and lodge in the peritoneum. It may also occur in cancer of the oral cavity when cells break away and travel through the air passages to the lungs.

TYPES OF CANCER

Pathologists classify cancers on the basis of two factors: the type of tissue and the type of cell in which they arise. By this classification system, there are over 150 recognized types of cancer in man. For convenience, the cancers are also grouped into categories according to the parts of the body in which they originate.

Types of tissues. Each organ or system of the body consists of a variety of tissues, each of which may be the source of tumours of a different class. Tumours of a particular kind of tissue are unlike those of other tissues in the organ, but may closely resemble in structure and behaviour tumours occurring in that kind of tissue in other organs or regions of the body.

In the classification of cancers according to the types of tissues from which they evolve, the two most prevalent types are carcinomas and sarcomas. Carcinoma, the larger category, refers to cancers of the epithelial tissues that cover the external surfaces of the body, including cancers of the skin and breast, and the internal surfaces, including the alimentary tract and those organs derived from the embryo's gut. The latter include cancers of the mucous membranes, liver, pancreas, intestines, prostate, and thyroid. Sarcoma is a term applied to cancer that arises in the connective tissues, such as muscle, cartilage, bone, or fibrous binding tissues. Carcinosarcoma, as the term suggests, is a mixed tumour that combines the elements of carcinoma and sarcoma. Leukemias, lymphomas, and other cancers of the blood-forming tissues, although they arise from nonepithelial tissue, are usually classified separately because they are systematic diseases. Gliomas and other tumours of nerve tissue, and melanoma, a cancer usually of darkly pigmented cells in the skin and sometimes other body sites, are also classed in separate categories.

A carcinoma of the intestine has more in common with carcinomas of the stomach and lung or breast than with lymphosarcoma of the intestine (see the section on lymphoid tissue below). It is the tissue of origin, not the organ of origin, on which the peculiar properties of a tumour more usually depend.

Types of cells. Tumours are also classified according to the type of cell from which they are derived. Thus, a skin cancer made up of malignant basal cells (basal cells are found on the innermost layer of epidermis or outer skin) is called a basal-cell carcinoma of the skin.

Any type of cell, under certain conditions, can undergo malignant transformation. The type of cells that make up a cancer can influence its appearance, rate of growth, and degree of malignancy, and may be critical in determining the success of treatment.

Degree of malignancy

Different types of tumours vary in their degree of malignancy. Various factors contribute to this variation. The ability of a cancer to grow and metastasize quickly is often a critical factor; some kinds of cancer cells divide faster than others. Neoplasms in different organs and individual carcinomas of the same microscopic type of the same organ may have entirely different doubling times—*i.e.*, the time for the tissue mass to double in weight or number of cells. Doubling times observed for lung cancer, for instance, have ranged from 8 to 763 days. In certain cancers, however, the size of the tumour bears no relationship to the outlook for the patient. Even very small nonmetastasizing tumours in the brain may damage vital structures and cause death.

Different types of tumours display various degenerative processes. Some may form mucin (the principal substance in mucus), which causes them to be soft and gelatinous, as often happens in advanced cancers of the

breast and gastrointestinal tract. Tumours that consist of epithelial cells with a delicate framework of connective tissue may also feel soft. Conversely, tumours consisting of dense networks of translucent connective tissue may be hard.

A malignant tumour is not usually the direct cause of death. Death is rather more commonly the result of the effects of the tumour on contiguous tissues. Cancers of the cervix, ovary, rectum, and prostate may penetrate the ureters and cause death from obstruction. Kidney failure is a common cause of death. Gastrointestinal cancers can cause obstruction, perforation, or bleeding of fatal outcome. Infections that would be minor events in a healthy person's life often prove fatal to the person with cancer. Advanced cancer may also produce a wasting away of the body's tissues, or cachexia.

Sites of origin. Common examples of the grouping of cancers by the organs of origin are cancers of the breast or uterus in women, cancer of the prostate gland in men, or cancers of the lung, colon, or stomach in both sexes. These are known as "solid" tumours, differentiated from the systemic leukemias and lymphomas, which primarily involve circulating cells from the blood-forming and lymphatic systems, respectively. The vast majority of cancers originate in the skin, the lungs, the various organs in the gastrointestinal tract, the breast, the uterus, the ovaries, and the prostate gland. Among children, leukemia occurs more frequently than other cancers. Some of the more common forms of cancer are discussed below.

The skin. The two most frequent types of cancers that arise in the skin are basal-cell epitheliomas, which are made up of cells from the inner layers of the skin, and squamous-cell epitheliomas, made up of flat, scalelike cells. Basal-cell epithelioma usually occurs on exposed sites wherever oil gland distribution is greatest. The initial lesion is usually a small papule, or pimple-like elevation, which enlarges slowly and after a few months forms a shiny, somewhat translucent border and a central dell or ulcer. Although epitheliomas do not metastasize, some invade underlying tissues or structures and become troublesome or even fatal. Nearly all basal-cell skin cancers are curable, however.

Mortality for the Ten Most Frequent Sites of Cancer*

(crude death rates per 100,000 population)

rank	men		women	
	site	rate	site	rate
1	lung	41.7	breast	23.9
2	stomach	31.9	stomach	21.6
3	prostate	14.4	uterus (including cervix)	15.4
4	colon	12.7	colon	15.3
5	liver	8.7	liver	9.5
6	pancreas	7.7	lung	7.6
7	rectum	7.5	ovary	7.4
8	leukemia	6.8	rectum	5.9
9	esophagus	6.1	pancreas	5.9
10	bladder	5.8	leukemia	5.2
	all sites	181.8	all sites	150.8
