Austin distinguished three different kinds of speech acts —the various actions that a speaker may perform when he utters a sentence. The locutionary act is that of uttering a sentence that has a certain sense and reference. When a person says, for example, "The gun is on the table," this sentence has a certain sense, derived from the definitions of its constituent words and a certain reference, viz., to the state of affairs of the gun's being on the table. The illocutionary act is what the speaker intends to do in uttering the sentence: he may utter it to inform someone about the gun's location or also to urge someone to pick up the gun or to warn him to be careful about the gun and so forth. Informing, urging, warning are different illocutionary acts; *i.e.*, they are different intentions that a person may have in uttering the same sentence, in performing the same locutionary act. The perlocutionary act comprises the effects that the speaker produces or achieves by uttering the sentence—effects on the feelings, thoughts, or actions of other persons (or perhaps of himself). By saying, "The gun is on the table," for example, he may frighten his hearer or alert him to danger or make him leave the room. Thus, the purview of perlocutionary acts is causal, while that of illocutionary acts is intentional.

A basic question raised for ethics by Austin's distinctions is whether moral judgments can be viewed as locutionary acts the content of which has sense and reference or whether they must be viewed only as performing one or both of the other two kinds of acts. Before attacking this question directly, however, it must be noted that Austin's distinctions serve to differentiate some of the earlier noncognitivists, the emotivists, such as Ayer and Stevenson, from the prescriptivist Hare and the multifunctionalist Patrick H. Nowell-Smith, both of whom are Oxford Analysts. The difference is that the emotivists regard moral judgments primarily as causing or tending to cause certain reactions in other persons (as perlocutionary acts), whereas Hare and Nowell-Smith regard them rather as expressing the speaker's intentions of commending, urging, and so forth (as illocutionary acts). The meaning of a sign is thus, as Stevenson defines it,

> a dispositional property of the sign, where the response, varying with the varying attendant circumstances, consists of psychological processes in a hearer, and where the stimulus is his hearing the sign.

Psychological–causal definition of emotive meaning

When the response or the stimulus is a range of emotions, the meaning in question is emotive meaning. It is this emotive meaning, defined in this psychological–causal way, that Stevenson holds to pertain to moral judgments. Of such judgments, he writes:

> Their major use is not to indicate facts but to create an influence. Instead of merely describing people's interests, they *change* or *intensify* them. . . . The word "good" has a pleasing emotive meaning which fits it especially for the dynamic use of suggesting favourable influence.

Opponents of this perlocutionary, or psychological–causal, conception of the meaning of moral judgments have claimed that there are obvious objections to it. It equates moral judgments with propaganda, they argue, ignoring the many contexts in which they do not have the use or effect of moving, inciting, or propagandizing. The analysis also deprives moral judgments of rationality. When a man makes a moral judgment, he implies that he has reasons for it, and this having or giving of reasons is different from the exertion of causal pressures. (Stevenson wrote that, when one gives reasons, "these reasons which support your ethical judgment are simply a means of facilitating your influence.") Hence, this conception is charged with being false to many facts about moral language.

Hare's illocutionary view. Hare differentiates his own view of both imperatives and moral judgments from the perlocutionary interpretation. He points to the distinction "between telling someone something and getting him to believe or do what one has told him," and he says that commands are similar to statements as well as to moral judgments in that all of them "consist in telling someone something, not in seeking to influence him." But the "telling" in the case of moral and other "value" judgments, according to Hare, consists in a certain kind of illocutionary act. "Value-terms have a special function in language, that of commending. . . ." And it is this commending function that he holds to constitute the primary meaning of "good" and other value terms. But others have argued that, if the perlocutionary force of moral judgments can be separated out as not essentially characteristic of them, then why may not the commending function also be separated out? May not moral judgments function simply to make statements concerning salient facts about the situation, statements that are held to be rationally justified by considerations of happiness or welfare? One may, for example, say that Martin Luther King, Jr., was a good man, not with any thought of commending or praising him but simply with that of indicating his possession of certain qualities importantly related to human welfare. If motivating force is not necessary to a judgment's being moral, then it may be contended that a commending force or intention is also not necessary.

Difficulties posed against Hare's view

It has also been argued that Hare's identification of the meaning of "good," with its illocutionary force (commending), cannot be correct, because "good," as used in affirmative–indicative sentences, has the same meaning as it has when used in negative, interrogative, optative, hypothetical, and other sorts of sentences; yet, in none of these latter is it used to commend. The more general point here, which goes back to Austin, is that meaning taken as locutionary must be distinguished from speech acts that use words having meaning. To this argument Hare has replied that all meaning consists in the illocutionary force of speech acts and that the instances of sentences other than affirmative–indicatives involve combinations of two different speech acts (*e.g.*, that of commending and questioning) such that the original speech act (commending) is transformed by applying to it the other speech act (questioning). The issue is too complex to be dealt with further here. But the important question still remains of why moral words cannot be defined in terms of a certain content, having a certain sense and reference (locutionary), as against being defined only or primarily in terms of certain kinds of speech acts (illocutionary).

Commendatory invariance argument. In addition to the antinaturalistic argument examined above, Hare and other noncognitivists offer another argument for the exclusively illocutionary meaning of "good" in terms of commending. Their argument also purports to show why the meaning of good cannot be exclusively or primarily descriptive or naturalistic. They point out that "good" is applied to many kinds of objects that are descriptively

different—men, cars, apples, breezes, hammers—and yet it has the same meaning in all of these diverse applications. But, if good had primarily a descriptive meaning, consisting of the descriptive features that render these various objects good, then, these noncognitivists argue, its meaning would vary greatly. The descriptive features that make a car good, for example, are its smooth riding, fuel economy, and so forth; those that make an apple good are its being juicy, sweet, firm; those that make a breeze good are its being fresh and invigorating. It seems absurd, however, that good should have a different meaning in all of these contexts. Yet, this is what one would have to say if the meaning of good were exclusively or primarily descriptive.

The only way to avoid this absurd consequence, they hold, is to recognize that the primary meaning of good is not descriptive at all but rather evaluative or prescriptive: it is used to commend. For it is this commending function or illocutionary force that remains invariant amid all of the varying descriptive features that are referred to as good. Hence, according to the argument, a distinction must be drawn between the invariant meaning of good—which is illocutionarily commendatory or evaluative—and the varying descriptive criteria of its application to different objects.

Replies to the argument

To this argument, several replies have been made. One is that, if the argument's premise is that the meaning of a word must be invariant with every standard use of the word, then the commendatory aspect of the use of good varies as well as does the descriptive aspect. For the commending function itself varies with different dispositions of various commenders. The commending engaged in by a bully, for example, differs from that engaged in by a self-effacing person not only as to the objects they respectively commend but also as to the psychological features that directly enter into the commending itself. On the other hand, just as these commendings are generically alike simply insofar as they are commendings, so too the descriptive features to which good is applied are also generically alike simply insofar as they are features of objects. Hence, the argument does not show that the commending function of good is any more invariant than is its describing function.

The commendatory invariance argument has also been answered by pointing to more specific descriptive features that all objects called good have in common. All such objects are regarded by the persons who call them good as satisfying certain wants or answering to certain interests, and their being regarded in this way is just as pervasive a feature on the descriptive side as is the commending function on the evaluative side. It may, of course, be contended that such reference to wants or interests is but another way of indicating the commendatory aspect of good. But wants or interests are, after all, the conative and emotional factors that have figured in the nonepistemic forms of naturalism considered in the preceding section.

A related answer to the commendatory invariance argument has been set forth by another Oxford philosopher, Philippa Foot, who has contended that evaluative adjectives, such as "rude" and "courageous," as well as "good," carry a certain constant descriptive meaning with them. Reference to certain descriptive qualities or objects is essential rather than incidental to the meaning of such words. One cannot apply "rude" to any qualities indifferently but only to certain qualities connoted by it. So too with "good"; at least in its moral use, it always bears some reference to human needs and, in other uses, to specific purposes. This argument, if successful, hence serves to refute the idea that the descriptive meaning of good can vary randomly and that its evaluative meaning is independent of its descriptive meaning. It has been objected, however, that the concept of human needs is itself evaluative as well as descriptive and that the concept's descriptive component has considerable variation.

Cognitive undecidability of moral issues. A noncognitivist argument that has been even more influential than that of commendatory invariance has been the contention, mentioned earlier, that moral disagreements are not decidable by cognitive considerations alone. Noncognitivists recognize that, if two disputants agree on their moral principles, then cognitive considerations alone—especially appeal to empirical facts—will enable them to resolve their dispute. But the crucial question concerns precisely situations in which men disagree on moral principles. Here, cognitive considerations do not avail, so that moral judgments, in this view, are not (or at least not in principle) cognitive. Opponents have contended, however, that this argument overlooks the parallel fact that, when men disagree on matters of basic scientific principle—of fundamental ways of approaching problems—cognitive considerations also do not avail to resolve their dispute, because what they accept as cognitive is then also different. The trouble with this argument—from the cognitive undecidability of disputes over moral principle—has often been that, whereas philosophers refer to moral principles at a quite basic level, they do not refer to scientific principles at a comparably basic level. But a dispute between adherents of Christian Science and of physiological science is no more resolvable by cognitive means alone than is a dispute between adherents of Nazi ethics and of democratic ethics. The difficulty about cognitive decidability applies to all disputes in which there is disagreement on basic principles, not only to moral disputes.

Disagreement in ethics and in science

Logical structure. A further phase of the contention that moral disagreements are not cognitively decidable bears on the logical structure of moral argument. Noncognitivists appeal to the principle that no "ought" conclusion can be derived from exclusively "is" premises; *i.e.*, that purely factual–descriptive premises cannot logically justify any moral conclusion. The reason for this contention is that "nothing can appear in the conclusion of a valid deductive inference which is not, from their very meaning, implicit in the conjunction of the premises." And, because naturalistic and other cognitivist arguments purport to infer "ought" conclusions from premises in which "ought" or some word definitionally related to it does not appear, their inferences are invalid.

One aspect of this argument has already been considered above: that for a judgment to be a moral one, it must serve to guide choices, and that such guidance cannot be given by descriptive statements. Another aspect of the argument, however, bears more narrowly on the contention that an ought statement cannot be derived from non-ought premises. One objection to this contention is based on the logic of material implication, in which "If f then q" is true, except when f is true and q false. Among the theorems of this logic is the proposition that a false statement materially implies any statement. Hence, according to this theorem, an ought statement is logically derivable from any false is statement; *e.g.*, "The moon is made of green cheese" materially implies "One ought to tell the truth." Another theorem of material implication is the law of addition, according to which any statement materially implies (symbolized $\supset$) the disjunction (symbolized $\vee$) of itself and any other statement; *i.e.*, $p \supset (p \vee q)$. According to this rule, the statement "Chicago is in Illinois" materially implies "Chicago is in Illinois or one ought to keep one's promises." These inferences of ought statements from is statements, however, are admittedly vacuous, because any statement could be substituted for the ought statement without changing the validity of the inference.

"Ought" from "is" in material implication

Sets of terms. A further kind of objection to this principle has appealed to the specific meanings of certain crucially relevant terms. One set of such terms is ought and can. It is often held that ought implies can; *i.e.*, that, if one ought to do something, then it must be the case that one is able to do it. But this, in turn, entails that cannot implies "It is not the case that one ought"; *e.g.*, that "A cannot tend B's garden" implies "It is not the case that A ought to tend B's garden." Thus, from a certain recognized principle, it follows that an is statement about someone's inability to do something implies a negative ought statement.

Another set of terms that has been held to refute the no-ought-from-is principle derives from institutional facts; *i.e.*, facts based on institutions such as promising

"Ought" from "is" in such institutions as promising and trading

and buying and selling. It is held that such facts entail corresponding obligations; for example, if *A* says to *B*, "I promise to pay you five dollars"—which is an is statement—then from this there follows the ought statement "*A* ought to pay *B* five dollars." This argument, which has been advanced by John R. Searle, a California philosopher, has aroused great controversy. It may be suggested, however, that, if the entailment validly succeeds in generating an ought conclusion, then its premise is not a purely factual, nonmoral is statement. For only if someone already believes in the moral obligatoriness of keeping one's promises will he agree that *A*'s saying to *B* "I promise to pay you five dollars" entails that *A* ought to pay *B* five dollars. Hence, in this view, the argument does not genuinely go from a nonmoral is to a moral ought.

There may well be, however, other ways in which normative conclusions can be derived logically and nonvacuously from factual premises. There may also be ways in which basic moral principles can be cognitively or rationally established from premises partly conceptual and partly factual. Some of the considerations relevant to these suggestions will be presented below (see *Formal deontological ethics: The principle of universalizability*). The above summaries of recent controversies over noncognitivist meta-ethics, however, indicate that there are strong current tendencies toward a return to naturalism and cognitivism in meta-ethics.

III. Normative ethical theories

Normative ethics is that part of moral philosophy that is concerned with justifying and applying criteria of what is morally right and wrong, good and bad. These activities of normative ethics issue in normative moral rules and judgments, and these, in turn, have direct implications for what human actions, characters, institutions, and ways of life should be like.

PRINCIPAL ISSUES OF NORMATIVE ETHICS

The central question of normative ethics is: What are the criteria for determining which actions are morally right and morally wrong? This question is related in various ways, however, to three other important questions.

Virtues and vices and social ethics

Three traditional questions. The first of these questions is that of moral virtues and vices: What characters of men are morally good and bad? Because men's characters, however, are both developed by and exhibited in the corresponding actions, the question of actions is logically prior. A morally good man is one who does what is morally right, from a firm disposition to do such actions because they are morally right. Thus, as far back as in Aristotle's *Nicomachean Ethics*, the various moral virtues and vices were defined in large part through definitions of the corresponding kinds of action.

Another traditional question of normative ethics concerns social institutions: How should society be organized and what specific policies should its various agencies pursue? This question, which is basic to social ethics, has a twofold relation to the two previous questions of normative ethics. On the one hand, the kinds of actions that men perform and the kinds of character that they acquire are strongly affected by their social environment. On the other hand, what kind of social environment there ought to be is to be determined by considering what kinds of action and character ought to be fostered among men. Consequently, the question of social ethics, like that of moral virtue, logically presupposes the central question of the criteria of morally right actions.

Intrinsic values

A third traditional question of normative ethics concerns intrinsic values: What things or experiences are worthwhile or desirable on their own account? This question constitutes the whole subject matter of axiological (or value) ethics and is basic to teleological ethics. Philosophers have given many different answers to it. The most famous answers are that pleasure and happiness are the intrinsic values; but power, beauty, knowledge, prestige, companionship, love, and many other values have been upheld either as basic to all the rest or as essential components in the whole spectrum of values.

Two points must be made about this question of values. One bears on the relation between values of the kinds just listed and the moral virtues or goods of character previously mentioned. These two kinds of goods or values seem clearly to be independent of one another, for one may have the worthwhile things just listed without having a morally good character, and conversely. Some philosophers, however, have refused to accept this distinction between moral and nonmoral goods. In a tradition going back at least to Socrates, they hold that pleasure, power, and the like are not goods at all unless they are had by morally good men. On this refusal to accept the distinction depends Socrates' famous paradox that it is better to suffer injustice than to do injustice, because any action, no matter how much pleasure it gives the doer, is no good at all if the psyche in which the pleasure occurs is not morally good. In the same tradition belongs Kant's insistence that the only thing that is good without qualification is a morally good will; all other goods become bad in the absence of this good.

These contentions serve to emphasize a second point about the moral import of the whole question of nonmoral values. Persons differ over these values, partly in terms of their native temperaments and other endowments. It seems morally appropriate, therefore, not to try to legislate about what the "true" values are but rather to allow persons to pursue whatever values they want, so long as what they do is not morally wrong. This consideration can be made to fit into both a deontological and a teleological framework—into the deontological on the grounds of justice and equal freedom, into the teleological on the ground of the fullest possible maximization of values. Hence, the question of what actions are morally right or wrong retains its centrality and logical priority in normative ethics, because, so long as the grounds or criteria of moral rightness are fulfilled, the question of intrinsic values may not pose any separate moral issue.

Deontological versus teleological theories

The central question. The answers to the central question of the determining criteria of normative ethics fall into two broad groups, deontological and teleological. The main difference between them is that deontological theories do not and teleological theories do appeal to value considerations in answering the question. The only normative moral concepts used by deontological theories in their answers are themselves deontic ones, whereas teleological theories insist that value concepts must be used centrally in answering the question.

Five further differences between deontological and teleological theories may be indicated. (1) Deontological theories advocate doing certain things on principle or because they are inherently right, whereas teleological theories advocate doing things because of their consequences. (2) Deontological theories set forth absolute obligations, whereas teleological theories set forth only conditional obligations. (3) Deontological theories set forth formal or relational criteria, such as equality or impartiality, whereas teleological theories set forth material or substantive criteria, such as pleasure or happiness. (4) Deontological theories set forth distributive criteria, concerning how goods or evils should be allocated or divided among men, whereas teleological theories set forth aggregative criteria, concerning the maximization of goods and minimization of evils. (5) Deontological theories set forth plural as well as unitary criteria, whereas teleological theories set forth only a unitary criterion, such as doing the greatest amount of good.

Although there are important bases for most of these differentiations, they do not correspond at all points to the full complexities of deontological and teleological theories. Some of the main varieties of these theories will now be examined.

DEONTOLOGICAL THEORIES OF NORMATIVE ETHICS

Deontological theories fall into two main groups, material and formal. Material theories hold that the criterion of the rightness or obligatoriness of actions consists in some feature either of the actions themselves or of the background of the actions, whereas formal theories

hold that it consists rather in some logically necessary relation between the judgments or rules in accordance with which the actions are performed.

Material deontological ethics. Material theories, in turn, vary in several respects. One important respect involves the alternatives of pluralism and monism: whether the features of actions or of their backgrounds that make them duties are of many different kinds or whether they are ultimately of one kind.

Pluralistic theories. A prime example of pluralism is the doctrine of Prichard discussed above in connection with intuitionism. According to that doctrine, actions such as keeping one's promises, repaying benefits, speaking the truth, and showing consideration for the feelings of others are inherently and self-evidently obligatory—*i.e.*, each of these kinds of action is obligatory simply in virtue of being the kind of action that it is, so that no further reason can be given for its being obligatory. Various doctrines of Existentialism and of situation ethics are also of this pluralistic sort.

Classification of prima facie duties in Ross's intuitionism

A closely related example of a pluralistic material deontological theory is that of W.D. Ross, also discussed above, especially his doctrine of prima facie duties. Ross's theory, however, was more complex than Prichard's. He not only expanded Prichard's list of inherently right actions, but he also grouped such actions in ways that came close to accepting, in part, a more unified teleological position. He distinguished six kinds of circumstance having moral significance, each of which was the basis of one or more kinds of prima facie duty. These circumstances include, for example, previous acts of one's own, including one's implicit promise "not to tell lies which seems to be implied in the act of entering into conversation (at any rate by civilized men)"; this is the ground of duties of fidelity. In addition, one's previous wrongful acts are the ground of duties of reparation. Other duty-grounding circumstances include previous acts of other men that are helpful to oneself, on which rests the duty of gratitude; distributions of happiness not in accordance with merit, on which rests the duty of doing justice; and the facts that one can both benefit and harm other men, on which rest the duties, respectively, of beneficence and of nonmaleficence.

Ross went on, however, to "arrange in a more systematic way the main types of duty," and his first step in this direction was to propound as "self-evident that if there are things that are intrinsically good, it is *prima facie* a duty to bring them into existence rather than not to do so, and to bring as much of them into existence as possible." This consideration, however, because it bases the duty to perform certain actions on the intrinsic goodness that they bring about, is close to, if not identical with, a teleological, Utilitarian position. Ross held, in contrast to Prichard, that the duties of beneficence, nonmaleficence, self-improvement, and justice can all be shown to follow from this consideration. He also insisted, however, that this good-maximizing consideration is not the ground of such other duties as that of keeping one's promises, so that his position is not completely teleological, and it remains pluralistic. In this connection, he maintained explicitly, in contrast to the Utilitarians and to monistic deontologists, that "in principle there is no reason to anticipate that every act that is our duty is so for one and the same reason."

Difficulties stemming from pluralism: conflicting duties

In addition to the difficulties that material deontological theories such as those of Prichard and Ross incur through their intuitionist meta-ethics, there are further difficulties that stem from their pluralism. Critics have argued that, if no general reason can be given why certain kinds of acts are obligatory, then the rational justification of moral judgments becomes difficult or impossible; and there is then no rational way, for example, to deal with moral disagreements. Moreover, in the absence of a general reason or principle, there is no way of resolving conflicts between duties—for example, between a man's duty to tell the truth and his duty to refrain from harming other persons.

An attempt to resolve this problem of conflicting duties within a pluralistic deontological framework has been made by A.C. Ewing, a contemporary Cambridge philosopher. He contends that the resolution of such conflicts does not require that all duties be deducible from a single principle, as the Utilitarians insisted; it is sufficient to be able to show that all duties harmonize with one another, in that they form a consistent system and fulfill a kind of coherence test similar to that envisaged in the coherence theory of truth, which defines truth by the cohering relations among propositions. Specifically, this means that "to further one [prima facie duty] on the whole furthers others and to violate one tends to involve sooner or later violating others." Ewing admits that not all conflicts between duties could be resolved in this way; but he holds that, at least in their general tendency, the prima facie duties fit together. This still leaves open, however, the possibility of clashes between duties in particular cases.

Monistic theories. In contrast to the pluralistic varieties of material deontological theory, monistic theories set forth a single, nonformal principle as the criterion of the rightness of actions. Because this principle has to account for the moral quality of a large variety of actions, its content is obviously much less closely related to the description of the specific actions, the rightness of which it is held to ground, than is the content of the pluralistic deontological theories. Examples of monistic material principles to which deontological philosophers have appealed include the will of God, conformity to nature or to human nature, human dignity, the march of history, and consent or contract. Such theories may be more or less naturalistic. Often, however, the principles to which they appeal are not amenable to direct empirical scrutiny, either because they refer to the supernatural, or because of their generality, or because the normative character of the principle is interpreted in such a way as to withstand empirical testing, as when it is denied that any possible empirical test could refute the principle that all men are equal in dignity.

Mixed and pure deontological theories

Monistic deontological theories sometimes include teleological elements. Theories that hold, for example, that what God has commanded is the basis of all right action sometimes also say that obedience to God's commands yields more good than does nonobedience. In such cases, however, the theories may not be properly deontological, if what they mean is that the ultimate reason for obeying God's commands is the good consequences of such obedience. Many monistic material theories, however, remain within a strictly deontological emphasis. They insist, for example, that God's commands must be obeyed not because of any good to be derived therefrom but simply because they are God's commands; or that the imperatives of history must be obeyed regardless of the suffering that this obedience may cause; or that the duty to respect the rights of persons has nothing to do with whether anyone stands to benefit thereby; or that obligations must be grounded on consent even if acting on certain persons without their consent will yield more overall good; or that the dignity of criminals as human persons requires that they receive the legally allotted punishment even if giving them psychotherapy instead will do them or the society more good in the long run.

The principle of consent is an example of a material deontological principle that has had a powerful influence both in general ethics and in political philosophy during the modern era of individualism and liberal democracy. According to this principle, an action is obligatory if and only if the person who has the obligation has consented to undertake it, in the sense that he has voluntarily accepted it either directly or through some indirect, implicit, or tacit agreement. Varieties of this principle range from making the act of promising the paradigm of all grounds of obligation to theories that hold that obligation may derive from a variety of human transactions—but still, the transactions at some point must contain a consensual element. Through the theory of the social contract, political obligation has been held to rest on this basis of consent. Although in its political form the theory has regularly been attacked as fictional, in its more specific interpersonal form, it has often been accepted as

giving a sufficient, even if not a necessary, condition of obligation.

Advantages and problem of monistic theories

The monistic material versions of deontological theory seem to avoid some of the problems of the pluralistic versions. They provide a general reason for men's obligations and hence also a possible way of ordering obligations and resolving conflicts among them. On the other hand, they are faced with the difficult problem of explaining why, apart from any reference to good consequences, the principle they uphold should be regarded as grounding men's obligations. This problem persists even when the principles are fitted into broader philosophical frameworks, such as that provided by proofs of God's existence and creation of the world or by doctrines of the historical development of societies. In one respect, the problem is that of deriving an ought from an is; for, even if the principle is itself held to contain an ought, there still remains the question why the specific descriptive features that define the principle are held to include the ought; *e.g.*, the question of what are the grounds for the connection between God as supreme being or creator of the world and as one who ought to be obeyed.

Formal deontological ethics. Because material deontological theories seem not to be self-validating, for the reasons just suggested, many deontologists have developed formal theories of obligation. Such theories appeal to a logically necessary relation conceived as holding between moral judgments, so that to perform actions that contravene certain judgments is to incur inconsistency or self-contradiction. The appeal to consistency in such theories is hence much more logically rigorous than that contained in Ewing's coherence test, discussed above. The general point of formal deontological theories is that, if to perform certain kinds of action logically commits the agent to self-contradiction, then his performance of these actions is not rationally justifiable; thus, it is both rationally not his duty to perform them and it is rationally his duty to refrain from performing them. Sometimes, this latter point entails also the statement that it is rationally his duty to perform some other, opposed action; for example, if a man is asked a question to which he has to reply and if it is rationally his duty to refrain from giving a false reply, then it is rationally his duty to give a true reply.

The principle of universalizability. Formal deontological theories attain a logically necessary relation between moral judgments by using the principle of universalizability. In its most general logical form, this principle says: if some predicate P belongs to some subject S because S has some quality Q (where the "because" is that of sufficient reason), then P logically must belong to all other subjects S_1, S_2, . . ., S_n that have Q. If someone denies that P belongs to S_1 . . . while admitting that P belongs to S because S has Q, then he contradicts himself, because, in saying that P belongs to S because S has Q, he implies that all that has Q is P; but this is inconsistent with his denial that S_1 . . ., which has Q, is P.

Logical and applied forms of the principle

The principal of universalizability is given a moral application in such a form as: What is right (or wrong) for one person must be right (or wrong) for any similar person in similar circumstances. This is a direct application of the logical form of the principle, in which the P means right (or wrong) and the S signifies some person who performs some action. Thus, if some person S says that it is right for him to do x—for example, to make a lying promise—because he has Q (in which Q means, for example, wanting to avoid mild inconvenience and the "because," as before, is that of sufficient reason or sufficient justifying condition), then he must admit that to make a lying promise is right for any other person who wants to avoid mild inconvenience. If S denies that such action is right for some other person S_1, then S contradicts himself. For, in saying that it is right for him to make a lying promise because he wants to avoid mild inconvenience, he implies that to make a lying promise is right for all persons who want to avoid mild inconvenience; whereas, in denying this judgment in the case of S_1, he is saying that to make a lying promise is not right for some person who wants to avoid mild inconvenience.

Controversial questions on universalizability. Although the logical aspects of the principle of universalizability are clear, its moral application raises at least three controversial questions.

(1) There is the question of commitment to a general rule. This controversial question deals with whether every agent in performing some action logically commits himself to a general rule; *i.e.*, whether every particular moral judgment logically commits one to such a general judgment as: "All persons who want to avoid mild inconvenience have a right to make lying promises." The objection sometimes made is that every situation is unique, so that a person who makes a moral judgment in his own case is not logically required to "legislate for everyone." The chief answer to this objection is that, insofar as a person gives reasons for actions and these reasons are regarded as sufficient justifying conditions of the actions, he is logically required to accept the corresponding general rules that apply the predicate of the original singular judgment to all other persons who fit the description contained in the reason he has given.

Three evasions of universalization

Philosophers have suggested at least three ways of avoiding such generalization beyond one's own particular case. One way is by not giving or having any reasons at all for one's actions. But there are several difficulties with this ploy. It would then become impossible to teach or discuss how to act with other persons, including one's children; for all teaching and discussion involves at least an implicit giving of reasons. A man would also condemn himself to arbitrariness and purposelessness, for it not only is a matter of giving of reasons to others but also of having reasons for one's own actions. The issue, in other words, is not only or mainly the rhetorical one of what to say to other persons but rather the logical one of the agent's own rationale or basis for acting. If he has no reasons, then he cannot guide or control his actions at all; if he has reasons, then he is logically committed to general rules.

A second way of avoiding such generalization beyond one's particular case is by having or giving insufficient reasons for one's actions. The reasons that a man gives would thus be, at most, only necessary conditions, so that, in saying that he had a right to make a lying promise in some particular case because he wanted to avoid mild inconvenience, he may have left out other reasons that are required for the full justification of his action. Hence, if someone is accused of inconsistency because he denies that someone else who wants to avoid mild inconvenience has the right to make a lying promise, he can always answer that the circumstances are different in the two cases. His full reason for making a lying promise may include other factors besides wanting to avoid mild inconvenience, factors that are not present in the second case. In this way he can manage to float along without logically committing himself to accept for others the moral judgments that he accepts for himself. An answer to this criticism, however, is that it is always rationally possible to remove the vagueness of one's reasons for acting by insisting on a fuller account of them, so that he must fill out his previous necessary justifying conditions to make them sufficient conditions. Here again, the rhetorical point must not be confused with the logical one.

A third way of avoiding the generalization of reasons beyond one's particular case is to make the reasons so detailed that they apply only to oneself or to one's particular group and not to any other person or group. Such individualizing or specializing of reasons is prominent in moral and political controversy. "The reason why I have the right to take this money and you do not has to do with the features of my peculiar situation, involving as they do the various debts I have incurred, the causes of my incurring them, and so forth—all of which are quite different from your situation or that of anyone else." "Our group has the right to engage in this violent action, while your group does not have this right, because our group uniquely possesses certain insights about the evils of our society and about their remedies, while no other group, including yours, has these insights." In extreme cases, this individualizing of reasons even adduces the

proper name of the person in question as all or part of his reason for performing his actions.

Arbitrariness of such evasions

Such objections to the universalizability principle based on the possibility of individualizing or specializing one's reasons, however, have been charged with suffering from one or both of two kinds of arbitrariness. One kind consists in the falsity of many of the claims of uniqueness, the other in the fact that the individualized or specialized reason may be irrelevant to the claim being made. This is most obvious when a person's proper name or some other unique property is given as the reason for his having a certain right.

(2) There is also the question of criteria of relevant similarities. The issue of relevance raises a second controversial question for the moral application of the principle of universalizability. The principle refers to similar persons and similar circumstances but does not reveal which similarities are to count as the relevant ones or which reasons that might be adduced for an agent's action are to be regarded as appropriate. Moral philosophers have suggested at least seven different ways of answering the question of the criterion of relevant similarities. They have held that this criterion is to be determined (1) by the specific purposes of acts or institutions, (2) by the consequences for the general welfare, (3) by what will serve to achieve equal rights for all persons, (4) by a person's willingness to allow some quality to be relevant regardless of whether he is on the giving or the receiving side of policies that make that quality decisive, (5) arbitrarily, (6) by history or precedent, (7) or by what is necessarily and hence nonarbitrarily connected with the category of action. Some of these criteria are obviously based on the philosophers' own normative moral principles, whereas others are determined by meta-ethical considerations, including doctrines about the kind of rationality available in moral situations. Further examination of this problem entails more complexities than can be gone into here.

(3) There is the question of its standing as a moral principle. The problem of relevance leads to a controversial question about the moral application of the principle of universalizability: In what sense is it a moral principle?

Necessary or sufficient condition of rightness

It directly requires consistency; but does this requirement give a necessary condition of moral rightness or a sufficient condition or neither? Some philosophers have upheld the last alternative, insisting that the requirement of consistency is in no sense a moral requirement and that, in particular, it must not be confused with the requirement of impartiality; *i.e.*, that one not make exceptions in one's own favour. The contention here is that a person can conform to the principle of universalizability and still be partial toward himself or his group. This, however, involves the difficulties already raised in determining relevant similarities; to the extent to which they can be overcome, the requirement of consistency would entail at least a modicum of impartiality. This point is basic to distributive justice: if a man claims certain goods for himself on the basis of some rule, then he must acknowledge the right of other persons to such goods insofar as they fall under that same rule. Such distributive considerations based on formal criteria are a characteristic feature of the kinds of formal deontological theories encountered in ethics.

The principle of universalizability states only a necessary but not a sufficient condition of moral rightness. The moral rightness in question, moreover, is confined to matters of distributive justice and hence excludes supererogatory actions that, by difinition, go beyond the dictates of duty. Such a limitation entails the conclusion that morally wrong as well as morally right actions and judgments can be universalized, so that conformity to the principle of universalizability is not of itself a guarantee of moral rightness. It also entails the consequence that theories that use this principle cannot rationally be monistic ones, because they must appeal to at least one other, substantive principle in order to supply a sufficient condition for grounding what is morally right.

Universalizability and justice. The contemporary Belgian philosopher Chaïm Perelman has discussed in some detail the bearing of the principle of universalizability on the criterion of justice. He holds that it provides, as such, only for formal justice. To give content to this form requires filling in the criterion of relevant similarities; *i.e.*, what determines the essential category into which persons should be classified for purposes of determining when they are entitled to similar or dissimilar treatment. Examples of such essential categories are the various criteria that have historically competed with one another for acceptance as the basis of just distribution: strict equality, merit, work, need, rank, or legal entitlement. In his earlier work Perelman held that this filling in was a matter of arbitrary preference. In his later work, however, he has emphasized the importance of historical context and precedent in determining the content for the form of justice. In any case, it is importantly true that what is here called the principle of universalizability in its moral application has been basic to the theory of justice from the Greeks until today—but only as a necessary not a sufficient condition of justice.

Need to define content for the form of justice

Kant's use of universalizability. Immanuel Kant was by far the most famous philosopher who has tried to use the principle of universalizability as a sufficient condition of moral rightness and hence as the sole basis of monistic formal deontological theory. The interpretation of Kant's moral philosophy, however, has raised controversies, principally over the question of whether his main doctrine is purely deontological or whether it is also and even mainly teleological. There is also controversy over whether, insofar as it is deontological, it is purely formal or whether it also upholds a material principle.

The chief ground for regarding Kant as a formal deontologist is that he set forth as the criterion of actions that are to be morally right or obligatory the stipulation that their maxims—the rules that the agent intentionally follows in performing the actions—must be universalizable without self-contradiction. This criterion is purely formal in that it stipulates nothing about what makes actions duties except that their maxims must be free from self-contradiction when universalized. This is the first and most famous formulation of the categorical imperative: "Act only on that maxim through which you can at the same time will that it should become a universal law."

Maxims free from self-contradiction: the categorical imperative

It will be helpful to compare the sense in which Kant's criterion is formal with that in which Aristotle's principle of the Golden Mean might be considered to be formal. Aristotle said that, for an action to be morally right, it must fall between the extremes of excess and defect; and this is, in one sense, a formal principle because it is put in terms of certain ratios or proportions. But Aristotle's principle requires careful consideration of the particular contents and circumstances of actions in order to determine just where the Golden Mean lies. Kant's categorical imperative, on the other hand, might seem to abstract from such contents and circumstances. If this were so, however, it would be difficult to see how the categorical imperative could be applied at all; for, in order to determine whether the rule on which one intends to act can be a universal law, he must be as clear as possible about just what the rule is, and this clarification requires consideration of the contents and circumstances of his projected action.

Despite such substantive considerations, Kant's categorical imperative can still be regarded as a formal deontological principle because it makes the universalizability of the rules or maxims of actions the test of the actions' moral rightness. It is important, however, to see just how universalizability operates in such a test. One of Kant's examples was that of the wrongness of making a lying promise in order to advance one's self-interest. His argument was that, if the rule that a person may make a lying promise to advance his self-interest were made a universal law, this would mean that no promises could exist because of the breakdown of the mutual confidence on which promises depend. But this nonexistence of promises would contradict the assumption on which the man acts, viz., that some promise does exist—his own. The contradiction or logical impossibility, then, lies in the relation between the existence of a certain kind of action

Example of a lying promise

when performed by the agent and the nonexistence of that same kind of action given the rule that everyone performs that kind of action. It is the contradiction between "Some promise exists," when made by the agent, and "No promises exist," when there is universal disbelief in anyone's saying that he promises something. Kant's point, then, is that an action is morally wrong if, when its maxim is universalized, it would be both self-annihilating (because such action would become impossible) and self-defeating (because the achievement of the action's purpose would become impossible).

There is an important difference between the ways in which universalizability was used by Kant and by many contemporary moral philosophers. The latter use it not to establish the logical impossibility of the universal performance of certain kinds of actions but rather to establish that a contradiction arises when an agent holds that a rule that he applies in his own case does not apply in other relevantly similar cases. The contradiction or logical impossibility here attaches not to the universal application of certain rules or maxims but to the rightful application of different rules to similar cases. In Kant's use of the principle, the logical impossibility is one of the actual occurrence of the universal application of the rules in question—*e.g.*, it is logically impossible that all promises be lying ones. In the moderns' use of the principle, on the other hand, the logical impossibility is one of the joint rightness of rules or judgments that are mutually inconsistent. When modern moral philosophers prove that to make a lying promise in order to advance one's self-interest is wrong, their argument is not that, if everyone made such promises, there would be no promises but rather that the agent contradicts himself if he holds both that it is right for him to make a lying promise for the reason indicated and that it is not right for some other person to make a lying promise for this same reason. The contradiction is not, as with Kant, between the two statements that a certain kind of action both exists and does not exist but rather between the two judgments that a certain kind of action performed by similar persons in similar circumstances is both right and not right.

Its effectiveness in demarcating wrong from right

The crucial question that Kant's use of universalizability raises for normative ethics concerns the extent to which it can serve to demarcate the morally wrong from the morally right. If actions that are admittedly morally wrong can be universalized in Kant's sense, then his criterion is unsuccessful. The attempt to answer this question is complicated, however, by the fact that Kant introduced various teleological or at least axiological elements into his further discussion of his principle. The most obvious such element is his reformulation of the categorical imperative in terms of ends: "Act in such a way that you always treat humanity, whether in your own person or in the person of any other, never simply as a means, but always at the same time as an end." Another reformulation appeals to autonomy, a point that became central to Kant's political philosophy. In addition, even in his illustrations of the first, formal version of the categorical imperative, Kant distinguished between perfect and imperfect duties on the ground that violations of perfect duties cannot even be conceived as universal laws without self-contradiction, whereas violations of imperfect duties can indeed be conceived in this way but cannot be willed to be universal laws without self-contradiction. This inability seems to introduce a definite teleological consideration. One of Kant's examples of a violation of an imperfect duty is refraining from helping someone who is in need. As Henry Sidgwick, author of a fundamental work, *The Methods of Ethics* (1874), pointed out, however, a man of proud self-reliance might reject being helped by others and could hence will, without self-contradiction, that persons in need not be helped. Kant's formal principle also fails to account even for such a perfect duty as the requirement that deformed infants not be exposed to die.

TELEOLOGICAL THEORIES OF NORMATIVE ETHICS

General considerations. Teleological theories of moral rightness emphasize the vital component that is lacking in deontological theories: goodness or value. An initial way of defining such theories is to say that, in contradistinction from deontological theories, they ground the moral rightness of actions not on nonvaluational features of the actions themselves or of their backgrounds or on formal relational principles but rather on the consequences of the actions evaluated in terms of their nonmoral goodness or badness.

In addition to their concern with good or bad consequences, another important feature common to all teleological criteria is their aggregative emphasis; *i.e.*, their view that the moral rightness of an action depends on its attaining as much good as is possible under the circumstances. This maximizing emphasis stands in contrast to the distributive concern of formal deontological theories.

Unclassified criteria of rightness. Whereas this definition is in many respects appropriate, it has the unfortunate result that two important criteria of the moral rightness of actions are left unclassified, because they fit under neither the deontological nor teleological criteria so far defined.

Intrinsic goodness

One omitted criterion is that which regards actions as morally right not because of their good consequences but rather because of their inherent or intrinsic goodness. Many hedonists (proponents of a pleasure-based ethic), for example, have held that an action is morally right if doing it is in itself pleasant, regardless of the further consequences of doing it. To be sure, there is often a further prudential emphasis on measuring the action's immediate pleasure against its further consequences (which may be painful). Nonetheless, not all nondeontological criteria of moral rightness are consequentialist: the inherent value of experiencing pleasure, exerting power, or "doing what comes naturally" is sometimes held to be the determining factor of the moral rightness of actions. Such criteria may be called axiological: in contrast to deontological criteria, they make goodness or value the determinant of rightness; but, in contrast to teleological criteria, they constitute intrinsic goodness or value. Indeed, it may well be argued that, if there were no intrinsic goods, there could be no consequential goods; for an action is consequentially good only if it produces what is intrinsically good. But such intrinsic goodness may belong to certain actions themselves.

Goodness of act or its consequences

A second criterion omitted from the above classification is that which regards actions as morally right on the basis either of their own moral goodness or of the moral goodness of their consequences. It may be objected that to make moral rightness depend on moral goodness would be circular. There need not be any circularity, however. One reason is that moral rightness pertains to actions, whereas moral goodness pertains to character. A second reason is that, whereas the moral goodness of character may be defined in terms of the moral rightness of actions performed by persons having that character, it may also be defined in other ways; *e.g.*, as the disposition to maintain a certain balance between the well-being of oneself and of others or among various aspects of one's own psyche. These dispositions, like all dispositions, will be exercised in actions. Some philosophers have held, however, that the correct sequence is that the moral rightness of actions is to be determined by their emerging from or by their fostering such dispositions, rather than that the dispositions' moral value is to be determined by their emerging in certain actions. An important, though controversial, example of the use of such a criterion is found in Plato's *Republic*, in which he argues that what makes actions just or morally right is that they either foster or emerge from a harmonious soul in which the rational part rules the other parts for the good of the whole. Moral theories that emphasize the agent's rational autonomy as the criterion of the moral rightness of his actions are also of this sort.

Distinction by the nature of the goods. Teleological theories are differentiated from one another according to what they say is (1) the nature of the goods or values to be maximized and (2) the locus of the goods; *i.e.*, the persons or groups whose good is to be considered or for whose interests the goods are to be maximized. To a

certain extent, the answer to (1) helps to determine the answer to (2), for it is sometimes held that only certain kinds of persons are capable of attaining certain kinds of goods. This is especially true with aristocratic theories such as those of Plato, Aristotle, and Nietzsche, who assert that only the philosopher-kings or the theoretic philosophers or the supermen are capable of having, respectively, the goods of a fully harmonious soul, of theoretic contemplation, and of power. The same point also holds for various nonaristocratic but still exclusivist theories such as that of Augustine and other Christian philosophers who held that only Christians can attain the highest good, which is the vision of God. On the other hand, when the good is identified with such a universally attainable experience as that of pleasure, such limitations of its locus are less inevitable.

In addition to the goods so far mentioned, other goods that have figured prominently in teleological theories include happiness (in some more or less specific sense), knowledge, love or personal affection, aesthetic activity, and various traits of character. Correspondingly, teleological theories, especially utilitarian ones, have been called "hedonistic," "eudaemonistic" (from the Greek word for happiness), "ideal" (in which the good is held to be of various sorts), and so forth.

Distinction by the locus of the goods. The two extremes of teleological theories, so far as concerns the locus of goods, are egoism and utilitarianism, which hold, respectively, that it is the good only of the agent himself or the good of all mankind (or even of all sentient beings) that determines whether actions are morally right. Intermediate between these extremes are theories holding that the goods that ought to be maximized pertain to more persons than the agent himself and yet not to everyone. They include doctrines that say that the goods in question should pertain only or primarily to persons belonging to a certain religion, race, nation, tribe, economic or social class, intellectual or political elite, or some other restricted group. In many obvious respects, such doctrines have been far more practically influential than universalist utilitarian theories, even if not more than egoistic theories.

Locus in the agent or in all mankind

Egoism. Ethical-egoist theories are of two main kinds. The individual egoist holds that the duty of all persons is to maximize the good of only one person, himself. The general egoist holds that the duty of each person is to maximize his own respective good. While individual egoism may be upheld by some persons, it is difficult to think of plausible arguments in its favour. If it appeals to certain characteristics of the one individual whose good is to be maximized, then it must admit that the good of any other persons who have those characteristics should also be maximized. If it appeals only to characteristics that are really unique to the one individual in question, then it is difficult to see how these characteristics could be relevant to the allocation of goods; the difficulty here is the same as that considered above concerning the criterion of relevant similarities in connection with the principle of universalizability. If the individual egoist appeals to no characteristics of any person, then his doctrine is left with no justification at all.

These considerations also apply, with appropriate adaptations, to at least some of the various particularistic theories mentioned above, which single out some favoured religion, race, or nation as the group whose good alone ought to be furthered.

Ethical and psychological egoism

General egoism draws much of its support from psychological egoism, the doctrine that each person in fact pursues or seeks to maximize his own respective good. The support may be merely contingent, or it may be logical. In the latter case, the implicit premise is that each person ought to pursue what he in fact does pursue. This premise, however, may be interpreted as meaning either (1) that men's goals, whatever they are, are always right (which seems hardly plausible) or (2) that it is impossible for persons to pursue anything other than what they in fact pursue, and each person thus pursues his own self-interest because he cannot pursue anything else.

Such a deterministic premise incurs at least three difficulties. First, if men cannot help doing something, there is no point in saying that they ought to do it, for ought implies both can and may not. Hence, psychological egoism, interpreted in this deterministic way, would make pointless both ethical egoism and any other ethical theory of obligation. Second, the deterministic thesis, in general, requires more argument than it has yet received. Third, psychological egoism, interpreted in this deterministic way, attains its counterintuitive result by illicitly moving from the premise that the purpose of any action is the agent's own, to the conclusion that the purpose is always the agent's own good; *i.e.*, the argument confuses the following two assertions: (1) each person in acting always tries to get something he himself wants; and (2) each person in acting always tries to get something he wants for himself or wants for his own interest. But, whereas (1) is true, (2) is false. The doctrine (1) that an agent always has an interest in whatever he does is quite distinct from the doctrine (2) that whatever an agent does is always for his self-interest.

Charge of self-contradiction and rejoinders

It has often been held that the ethical egoist incurs self-contradiction. The argument is that, when there is conflict of interest between two persons A and B, the ethical egoist, holding as he does that each person ought to maximize his self-interest, must hold both that A ought to win at the expense of B and that B ought to win at the expense of A—obviously mutually exclusive outcomes.

Several ways of avoiding this self-contradiction have been suggested. One is that the ethical egoist, in conflicts of interest, will hold not that each person ought to win but only that each person ought to try to win. This solution, however, still leaves a latent inconsistency, and it shifts the emphasis from each agent's achievement of good for himself to each agent's mere attempt at achievement, which weakens the original contention of ethical egoism. Another possible solution is to relativize the ethical egoist's "ought" judgments. What he then says is that A ought-from-the-standpoint-of-A to win, and B ought-from-the-standpoint-of-B to win. Since the hyphenated "oughts" in the two judgments do not have entirely the same meaning, the two judgments are not contradictory to one another. The relativistic interpretation, however, avoids incurring inconsistency only at the price of ceasing to be a theory of what is morally right.

Utilitarianism. Utilitarian theories, in contrast to those of egoism, are universalist; they hold that what a man ought to do is to promote the maximum good for everyone, in other words, the general good.

Good-aggregative versus locus-aggregative views. As it is sometimes formulated, however, utilitarianism raises an ambiguity with the phrase "the general good," in that the emphasis may be either (1) on the greatest good, no matter to whom it accrues, or (2) on distributing the good over as many sentient beings as possible. On the first interpretation the utilitarian might not be concerned at all with whose good is to be promoted: he would be indifferent to its locus, insisting only that good ought to be maximized in the universe, regardless of who gets it. On the second interpretation he would be concerned with its locus, insisting that the good of everyone (or of every sentient being) should be taken into account and maximized so far as possible. Thus, the first type of utilitarian would be concerned only with the total amount of good, whereas the second type would be concerned also or even mainly with how many persons get it. These two types may be called, respectively, "good-aggregative" and "locus-aggregative" utilitarianism. Classical British utilitarians, such as Jeremy Bentham and John Stuart Mill, though not always fully consistent, seem to have been more locus-aggregative than good-aggregative; for the formula that they upheld was "the greatest good of the greatest number."

Possible conflicts and deficiencies

There are two possible conflicts, however, between these two varieties of utilitarianism and, hence, between the two parts of the formula just presented. If one maximizes the locus of goods, spreading them over as many persons as possible ("the greatest number"), then one may decrease the total amount of good. This may be so

for several reasons: by maximizing the locus, one reduces the proportionate share and, hence, possibly the incentives of the more industrious persons, who would work harder if their proportionate share were greater. Some persons also may have a more intense appreciation of certain goods (and hence derive more good) than other persons to whom the goods are distributed. Obviously, many contingent factors, from the economic to the psychological, must enter into such calculations. By the same token, maximizing the total amount of good may require decreasing the amounts of the shares of some persons or even not giving any shares to some persons.

Another point to be noted is that on neither interpretation of utilitarianism, good-aggregative or locus-aggregative, is any specific pattern of distribution required. Even the locus-aggregative type says only that the number of persons or beings receiving the goods must be as great as possible; but this condition is consistent with a markedly unequal distribution of the goods. If, among a total population of five persons, *A*, *B*, *C*, *D*, and *E*, there is a total amount of 15 units of good to be distributed, the good-aggregative utilitarian would be satisfied to give all 15 units to *A*, leaving no units for the others, whereas the locus-aggregative utilitarian would insist that all five persons must have some units of good, but he would be satisfied with such a distribution as 7, 4, 2, 1, 1 or even 11, 1, 1, 1, 1. It is true that Bentham and Mill upheld the dictum, "Everybody to count for one, nobody for more than one." But this formula, as these philosophers interpreted it, provides not for equal distribution of goods among persons but only for impartial or indifferent consideration of persons as possible loci for the distribution of goods. As Mill explicated the formula, it means that "Equal amounts of happiness are equally desirable, whether felt by the same or by different persons." But this is compatible with all three of the unequal distributions indicated above, because, for example, the distribution of 15 units for *A* and none for the others distributes an "equal amount of happiness" and is hence "equally desirable"; with the distribution of 7 units for *A* and 4, 2, 1, 1, respectively, for the other persons. For, as between these two distributions, there are distributed "equal amounts of happiness"; *i.e.* the total amounts of good or happiness in the two cases are equal. In other words, the emphasis falls on aggregative not distributive equality.

Problems of distributive justice. The good-aggregative versus locus-aggregative conflict indicates what is probably the most serious problem confronting utilitarianism: the fact that neither version makes specific provision for distributive justice or for deciding the proportion in which goods are to be distributed among persons, as against the aggregative questions of how either the total amount of goods or the total number of persons receiving the goods are to be maximized. It is true that utilitarians from Hume through Bentham to Henry Sidgwick held, on the ground of the diminishing marginal utility of wealth, that, the more nearly equal is the distribution of wealth in any society, the greater is the total amount of happiness in the society. Even here, however, the determining criterion was the maximizing of good or happiness; equal distribution was valid only as a means to this end and was given no consideration as an independent criterion in its own right. In addition, the utilitarians introduced so many qualifications, based on the possible unfortunate consequences for the total amount of happiness that would follow upon the equalizing of wealth, that they eventually assumed a markedly inegalitarian position.

Ways of formulating distributive justice

Philosophers have suggested various ways of accommodating the claims of distributive justice within utilitarianism. Some hold that an equal distribution of goods is itself a good, so that, of two otherwise equal amounts of good, the amount that has equal distribution is better overall than the amount that is unevenly distributed. This suggestion illustrates the difficulties both of distinguishing between moral and nonmoral goods and of providing noncontroversial criteria of goods. Will persons who regard pleasure, wealth, or power as goods, over the distribution of which they contend, also regard equal distribution as itself a good; and, if so, why should they?

Another suggestion has been made by Nicholas Rescher, a contemporary U.S. philosopher, to the effect that, of two distributions, the one to be preferred is the one that has the higher effective average. The concept of the effective average is defined as the average number of shares had by the population minus one-half the standard deviation from the average. (The standard deviation in any group of numbers is determined by adding the squares of the numbers' deviation from the average, dividing the sum by the number of items, and then taking the square root of the quotient.) Taking the example of 15 units of good to be distributed among five persons, the first distribution (15, 0, 0, 0, 0) would have an effective average of 0, the second (7, 4, 2, 1, 1) would have an effective average of 1.86, and an equal distribution would have an effective average of 3. While Rescher presents some necessary qualifications of his principle, it has the difficulty that the same effective average could characterize distributions that are different in important respects, such as the degree to which they approach equality.

Other distributive problems

"Act" versus "rule" utilitarianism. Utilitarianism is also confronted by other distributive problems closely related to the problem of justice. It justifies the violation of important moral rules, such as those prohibiting the killing of innocent persons or the breaking of promises, whenever the consequences of violating these rules will be better overall than the consequences of obeying them. It ignores the fact that the recipient of one's obligatory actions may be highly particularized: if the same amount of good will be achieved by giving money to *A* or to *B*, then utilitarianism is indifferent as to who receives the money, even though, in fact, because of a previous transaction, the money is owed to *B*. More generally, utilitarianism ignores the fact that actions such as torturing innocent children are wrong on principle, regardless of their consequences. By making all moral obligations matters of calculation of consequences, utilitarianism distorts the nature of at least some basic moral judgments.

To deal with these difficulties, some philosophers have distinguished between "act" utilitarianism and "rule" utilitarianism. According to act utilitarianism, to determine whether an action is right or wrong, one directly considers its overall consequences. According to rule utilitarianism, to determine whether an action is right or wrong, one considers it in the light of some relevant justified moral rule; and, to determine which moral rules are justified, one considers the overall consequences of men's generally acting in accordance with that rule as against its alternatives. Thus, in order to determine whether to keep or break a promise to suit his convenience, an act utilitarian would consider whether keeping or breaking that promise would have better overall consequences; but the rule utilitarian would consider whether the general observance of the rule that men may break their promises to suit their convenience would have better overall consequences than the general observance of the rule that men should keep their promises regardless of whether it suits their convenience.

Philosophers are still in disagreement over whether rule utilitarianism has different implications for action than has act utilitarianism when the rules in question are specified in sufficient detail. Even if the implications are different (so that the act utilitarian may break his promise but not the rule utilitarian), the question still remains: "Why should the rule utilitarian obey a moral rule when in the particular case his obeying it will do more harm than good?" The charge of "rule-worship" has been levelled against the rule utilitarian, for whom, it seems, there implicity enters a supplementary, non-utilitarian consideration of fairness—of not taking advantage of other persons' observance of moral rules, while flouting them oneself, or of not advocating for others rules one does not accept for oneself. Apart from the consideration of the consequences of moral rules, however, rule utilitarianism copes no better than does act utilitarianism with the specific problem of distributive justice.

IV. Good reasons theories

Mixed meta-ethical and normative theories

In addition to the deontological and teleological normative ethical theories that have been considered above, some contemporary philosophers have presented theories of a mixed character. While their theories have obvious similarities to one or another of the normative ethical doctrines, they are presented as being logical or conceptual, as primarily explicating the meanings of such words as moral or ethical or ought, as well as the nature of moral reasons or moral reasoning. Thus, while the theories are presented as mainly or exclusively meta-ethical, their authors derive substantive normative ethical conclusions from them.

Material reasons. These theories focus on the question of logically good reasons in ethics, reasons of two kinds: material and formal. The material kinds of reason have a definite moral content and take one normative ethical position as against another; yet, the philosophers who propound them set them forth as deriving from definitions of what constitutes ethical or moral reasons in general. Thus, Stephen Toulmin, a British-American philosopher of science and of ethics, presents as his main problem to inquire into "the kinds of change in behaviour at which reasoning must be aimed, if we are to call it 'moral' or 'ethical' "; and his solution is that "the 'function' of ethics" is "to correlate our feelings and behaviour in such a way as to make the fulfillment of everyone's aims and desires as far as possible compatible," so that "what makes us call a judgment 'ethical' is the fact that it is used to harmonise people's actions. . . ." It is difficult to avoid the suspicion that a substantive view of moral goodness or rightness as consisting in social harmony is here being set forth as part of the very meaning or definition of ethics or morality. On this view, it becomes logically impossible to refer to ethical egoism as an ethical theory or to the various nationalistic, racialist, elitist, and other particularistic moralities. The view seems to settle by definition what preceding moral philosophers regarded as the central problem for normative ethical argument: how it can be established that one system of normative ethics is rationally superior to its rival systems. Similar considerations apply to the statement of Kurt Baier, a U.S. moral philosopher, that "moral rules must be for the good of everyone alike," especially as this is presented as part of the definition of "the moral point of view" and, hence, also of "moral reasons."

Mixed formal and material reasons. The other kind of reason presented by the recent writers who make "moral reasons" central to their theories is formal, consisting in the principle of universalizability discussed above. Since this principle taken by itself gives no moral results, the "good reasons" writers combine it with various material considerations. Marcus G. Singer, another U.S. moralist, combines it with the negative utilitarian consideration of the bad consequences that would ensue if one were to perform certain kinds of actions. R.M. Hare combines it with the consideration of men's inclinations, consisting mainly in their self-interested desires. The result of this combination in Singer's doctrine yields a line of argument that says that, if the consequences of everyone's doing a certain kind of action would be disastrous, then no one ought to do that kind of action. The corresponding result in Hare's doctrine is a line of argument that may be divided into three steps: First, a person holds that he ought to perform a certain kind of harmful action toward someone else because the latter has some quality. Second, he recognizes that, if he, the prospective agent, were to have that same quality, then it would be right for him to have to undergo that same kind of harmful action himself. Third, since, however, his inclinations are against such undergoing, he comes to judge that he ought not to perform that action on his intended victim.

Bad consequences and human inclinations

Each of these positions makes suggestive points about the logic of moral argument. One of their difficulties, however, is that, in each case, the material considerations that they combine with the formal one are contingent on men's variable beliefs or inclinations. Men may differ in their beliefs about what consequences are disastrous, and they may also differ in the extent to which they are willing to undergo counterinclinational actions. The doctrines of Singer and Hare hence provide no way of arguing against the person who denies that certain consequences, such as colonial war, are disastrous or who persists in certain judgments and actions even when their application to himself would go against his own self-interested inclinations. This means, for example, that the fervent nationalist or racist cannot be proven to be morally wrong by the above kinds of argument.

The normative ethical theories that have been discussed in the last two sections have obvious ramifications for the social problems of our time. The issues of race, poverty, war, crime, ecology, and so forth impinge on some of man's most important goods and bear vitally on the duties of distributive justice and on corresponding rights. The moral philosopher's essential contributions to these problems comprise both clarification and justificatory argument. The contributions have important implications for individual action and social policy.

BIBLIOGRAPHY

Anthologies: R.B. BRANDT (ed.), *Value and Obligation* (1961), readings from both classical and contemporary sources; PHILIPPA FOOT (ed.), *Theories of Ethics* (1967), an excellent collection of recent writings; A.I. MELDEN (ed.), *Ethical Theories: A Book of Readings*, 2nd ed. (1967), mainly classical writings, ending with Prichard; W. SELLARS and J. HOSPERS (eds.), *Readings in Ethical Theory*, (1952), the best collection of writings in meta-ethics from the first half of the 20th century; J.J. THOMSON and G. DWORKIN (eds.), *Ethics* (1968), a copious, excellent collection of recent articles.

Histories: H. SIDGWICK, *Outlines of the History of Ethics for English Readers*, 6th ed. (1931), excellent; A.C. MACINTYRE, *A Short History of Ethics* (1966), provocative, philosophically rewarding, selective in coverage and viewpoint.

Texts: R.B. BRANDT, *Ethical Theory: The Problems of Normative and Critical Ethics* (1959); W.K. FRANKENA, *Ethics* (1963); J. HOSPERS, *Human Conduct: An Introduction to the Problems of Ethics* (1961).

Classical Works (arranged chronologically): PLATO—All of Plato's writings are relevant to ethics, especially *The Republic* (the most basic), *Euthyphro*, *Protagoras*, *Gorgias*, and *Philebus;* ARISTOTLE, *Nicomachean Ethics* and *Politics;* CICERO, *De finibus bonorum et malorum* (*On the Ends of Goods and Evils*), and *De officiis* (*On Duties*); W.J. OATES (ed.), *The Stoic and Epicurean Philosophers* (1957); ST. AUGUSTINE, *De moribus ecclesiae catholicae* (*On the Morals of the Catholic Church*), *De civitate Dei* (*The City of God*), and the *Enchiridion;* PETER ABELARD, *Scito teipsum* (*Ethics, or Know Thyself*); ST. BERNARD OF CLAIRVAUX, *The Steps of Humility;* THOMAS AQUINAS, *Summa theologica* (Eng. trans., 22 vol., 1912–36); DESCARTES, *Les Passions de l'âme* (1649; *The Passions of the Soul*); PASCAL, *Pensées* and *Lettres provinciales* (1656–57; Eng. trans., 1941); THOMAS HOBBES, *Leviathan* (1651); SPINOZA, *Ethics* (1677; Eng. trans., 1927); L.A. SELBY-BIGGE (ed.), *British Moralists*, 2 vol. (1897); and D.D. RAPHAEL (ed.), *British Moralists, 1650–1800*, 2 vol. (1969), two excellent collections; JOSEPH BUTLER, *Fifteen Sermons* (1726); JEAN-JACQUES ROUSSEAU, *Discours sur les sciences et les arts* (1750; Eng. trans., *Discourse on the Sciences and Arts*, 1946); THOMAS REID, *Essays on the Active Powers of Man* (1788); DAVID HUME, *Enquiry Concerning the Principles of Morals* (1751), and *A Treatise of Human Nature*, books 2 and 3 (1739–40); IMMANUEL KANT, *Eine Vorlesung über Ethik* (1924; Eng. trans., *Lectures on Ethics*, 1930), *Grundlegung zur Metaphysik der Sitten* (1785; trans. by L.W. BECK as *Foundations of the Metaphysics of Morals*, 1949), and *Kritik der praktischen Vernunft* (1788; Eng. trans., *Critique of Practical Reason*, 1956); JEREMY BENTHAM, *Introduction to the Principles of Morals and Legislation* (1789); ARTHUR SCHOPENHAUER, *Über der Grundlage der Moral* (1840; Eng. trans., *The Basis of Morality*, 1903); SOREN KIERKEGAARD, *Enter eller* (1843; Eng. trans., *Either/Or*, 2 vol., 1944), and *Frygt og Baeven* (1843; Eng. trans., *Fear and Trembling*, 1939); WILLIAM WHEWELL, *Elements of Morality, Including Polity*, 2 vol. RESCHER, *Distributive Justice: A Constructive Critique of the Utilitarian Theory of Distribution* (1966).

(Al.Ge.)

Ethiopia

Ethiopia is an independent country in eastern Africa. It includes the former Italian colony of Eritrea, along the Red Sea coast, which was federated with Ethiopia in 1952 and became a province in 1962. The country shares frontiers with The Sudan, to the north and west, with Afars and Issas, to the northeast, with Somalia, to the east, and with Kenya, to the south. It has 628 miles (1,010 kilometres) of coastline on the Red Sea, to the northeast. Its total area is 471,800 square miles (1,221,900 square kilometres). By an estimate of 1975 the population was 27,030,400. The national capital is Addis Ababa ("New Flower").

Ethiopia has had a continuous existence as a nation—though with highly variable frontiers—for no less than 2,000 years. For most of this period its contacts with the rest of the world were limited and intermittent. Ethiopia is one of the developing nations of the world; its backward economy is based almost exclusively on agriculture. Until the military coup d'etat of 1974, its political structure had the trappings of a constitutional monarchy superimposed on a traditional autocracy. Despite this, Ethiopia had taken a leading role in the politics of modern Africa, largely because of its last emperor, Haile Selassie I (1892–1975).

The emergence of the country from its long isolation has brought into sharp focus the themes of paradox and diversity that are inherent in so many aspects of Ethiopian life. Ethiopia, a country that embraced Christianity as early as the second half of the 4th century, was known to Christendom throughout the centuries as a lonely outpost of Christianity in a sea of paganism and Islām. Yet a large minority of its present population is Muslim. Several types of animistic religions and even an ancient form of Judaism are also to be found. While Ethiopia's existence as a nation-state is one of the longest in the world, its population is linguistically, culturally, and to some extent racially so diverse that it has aptly been described as "a museum of peoples" (in *Etiopia e genti d'Etiopia* [1937] by Carlo Conti-Rossini). (See the city article ADDIS ABABA; for associated physical features, see EAST AFRICAN MOUNTAINS and NILE RIVER; for historical aspects, see ETHIOPIA, HISTORY OF; for religion, see EASTERN CHRISTIANITY, INDEPENDENT CHURCHES OF; for language, see HAMITO-SEMITIC LANGUAGES; for cultural aspects see ETHIOPIAN AND SOMALIAN CULTURES.)

A country of paradox

THE LANDSCAPE

The natural environment. *Relief features.* The rock foundation of the Ethiopian region forms part of the Precambrian (from 570,000,000 to 4,600,000,000 years old) crystalline block underlying most of Africa. On top of it, younger limestones and sandstones are capped by successive flows of lava, which have accumulated to a thickness of several thousand feet in some areas. Evidence of volcanic activity is still to be found in the form of a few live volcanoes and numerous hot springs.

An important feature of the relief of the region is the East African Rift System—a mammoth cleavage that runs from north to south and cuts through the central Ethiopian Plateau, dividing it into western and eastern sections. The three major relief regions of the country, which tend to influence climatic conditions, vegetation, human settlement, and drainage, are thus, first, the Western Highlands; second, the Eastern Highlands; and, third, the Rift Valley and Western Lowlands.

The Western Highlands lie at altitudes between 8,000 and 12,000 feet (2,400 to 3,700 metres). The northern end of this region is in northern Eritrea, where erosion has cut down to the basement rock. In the Eritrean Highlands, just to the south, some remnants of basaltic rock can be found. The Tigre Plateau of western Tigre Province for the most part has been eroded down to the layer of sandstones and limestones. In the Semien Mountains and neighbouring massifs to the south, basalt caps the plateaus and *ambas* (small, flat-topped tablelands). In the Semien Mountains, the highest peak in Ethiopia—Ras Dashen, or Dejen—rises to 15,157 feet (4,620 metres). The tablelands are surrounded by deep gorges and canyons. The Abbay (Blue Nile) River gorge runs south and west from Lake Tana and cuts nearly 7,000 feet below the general level of the plateau. The gorge isolates the Gojam Massif, to the north, from the Shewan Plateau, to the south. The Shewan Plateau is the widest area, with a general elevation of more than 7,000 feet in the Western Highlands. Like the areas to the north, it is cut by several deep gorges; the plateau surface itself is formed of basalt rock. Southwest of the Shewan Plateau is a region of lower elevation, which has been subjected to much greater erosion.

The rugged plateau region

The Eastern Highlands, like those in the west, have a largely basaltic cover except in the lower elevations and the river gorges. The highest area is a mountain chain that runs along the Rift Valley escarpment, sloping steeply on its eastern side. A number of high peaks include Mt. Encuolo, which rises to 14,144 feet (4,311 metres). Between the upper courses of the Genale and Shebele rivers, which flow southeastward, is an extensive basaltic plateau—the Bale Massif—which is mostly above 9,000 feet. To the northeast is the Harer Plain, which is less extensive and lies at about 1,000 feet above sea level. The plain continues into the Ogaden region, in the extreme southeast, where it is even more eroded and considerably lower. The southernmost part of the Eastern Highlands is the Sidamo-Borana Plain, which is similar to the Harer Plain in elevation but is more eroded in parts.

The Rift Valley region is dotted by a series of lakes, including Ziway, Abayata, Langano, Shala, Awasa, Abaya, and Chamo. The valley, at an elevation of about 5,000 feet, is bounded by an eastern and a western escarpment that are for the most part from 25 miles to 40 miles apart. To the north the valley widens into the Awash River Basin, where the Awash is joined by a number of tributaries. Volcanic activity is indicated in the Rift Valley by a number of hot springs and by the active volcanoes of the Danakil Plain, to the north. The desertic depression runs parallel to the Red Sea and contains salt lakes and the Kobar Sink, a depression that dips below sea level.

On the western fringe of the Western Highlands, in a thin crescent extending from western Eritrea to the northern shores of Lake Rudolf (on the Kenya border, to the south), lie the Western Lowlands, which are the eroded remains of the rim of the plateau.

Drainage. The Western Highlands slope generally toward The Sudan, and drainage is therefore westward. The eastern edge of these highlands constitutes a major watershed draining into the Rift Valley. Similarly, the western edge of the Eastern Highlands constitutes another watershed, with its eastern slopes draining in a southeasterly direction and its steep western face drained by small rivers into the Rift Valley. Since the Western Highlands are an area of high rainfall, the westward drainage is by far the most important, accounting for nearly half the total volume of water drained annually from the country.

Major rivers

The major rivers in this area are the Blue Nile (Abbay), the Tekeze, and the Baro. In the inland drainage area are the Awash River, which flows northward into Lake Abe, in the Danakil Plain, and the Omo River, which flows southward into Lake Rudolf. The Sagan River flows into Chew Bahir (Lake Stefanie). In the area of southeasterly drainage are the Webi, Genale, and Dawa rivers, which in Somalia join to form the Juba and reach the Indian Ocean, and the Shebele, which flows into Somalia but fails to meet the sea.

Soils. The basalt deposits in much of the highland area are rich in phosphorus and potash. The soils are highly fertile, because they are weathered but not leached. They are, however, deficient in calcium. The texture of these soils, mostly of a loam or silt–loam nature, is judged to be excellent. Phosphorus and potash are also to be found in the Rift Valley soils, but these are highly deficient in nitrogen and are alkaline in some areas. Phosphorus deficiency and acidity are problems in the soils of the northern Eritrean Highlands and the Tigre Plateau. By far the most fertile soils in Ethiopia are the rich alluvial deposits in the river valleys. The extensive valleys of the Blue Nile, Awash, and Omo offer the greatest promise for agriculture, but those of smaller rivers are equally rich.

Climate. Although Ethiopia is completely within tropical latitudes, it enjoys a generally temperate climate in the highland areas. The annual range of temperature is small because of its proximity to the Equator, but the average daily range is large because of its altitude. The average daily range for 15 stations is 24° F (13° C), from a minimum of 60° F (16° C) to a maximum of 84° F (29° C). The annual average temperatures of the highland and lowland regions differ sharply. Addis Ababa, at an altitude of 8,000 feet, has an annual average temperature of 60° F (16° C), while Mitsiwa (Massawa), at sea level, has an annual average temperature of 87° F (31° C).

The coldest month is usually January and the hottest usually May. On some parts of the highlands, however, the rainy season (*kremt*), with its peak in June and July, has a lowering effect on the temperature. In Addis Ababa, the maximum monthly average is 72° F (22° C) and the minimum 50° F (10° C). At Aseb, on the Red Sea coast, however, the maximum monthly average is 95° F (35° C) and the minimum 77° F (25° C).

The rainy season

Rainfall for most of Ethiopia is brought by southwesterly winds. In July the high-pressure system that builds up over the South Atlantic and the Gulf of Guinea causes an air movement toward the low-pressure centres of the Sahara and the Middle East. When the prevailing warm and moist winds reach the Western Highlands they are forced to rise, thereby cooling and losing their capacity to hold moisture, depositing it as rainfall from July to September on the highlands.

In January, northeasterly winds come from a high-pressure area in the dry Middle East, blowing toward a Central African low-pressure area. The northeast trades account for the intensity of the dry season (*bega*), in the generally drier northern parts of the country. Whatever moisture they pick up from the Red Sea is deposited on the slopes of the Eritrean escarpment. There is a short and mild rainy season (*belg*) in March and April. May is a short dry interlude, and June leads into the big rains. The major dry season for most of the country is, therefore, from October to February. In the southeastern lowlands there are two rainy seasons, one in spring and the other in autumn.

Local variations in rainfall are determined by the extremely rugged terrain, which interferes with the movements of major currents and causes more rain to be deposited on the windward slopes than on the leeward slopes. Generally, the amount of annual precipitation varies from almost 100 inches (2,500 millimetres) at Gore, in the southwest, to about 2 inches (50 millimetres) at Aseb, in the northeast. Even at the same location, however, both the amount and the time of rainfall may vary annually to such an extent as to involve serious risks in farming. In addition, the violent nature of the thundershowers is a contributing factor to the serious problem of erosion.

Vegetation and animal life. The two major vegetation regions are the wet and cool highlands and the generally drier and hotter lowlands. The Western Highlands are now mostly grasslands and farmland with occasional clumps of trees. Forests occupy about 7 percent of the total area of the country. The southwestern rain forests, found mainly in Kefa and Ilubabor provinces, are composed of large broad-leaved trees such as *Syzygium guineense* and *Cordia abyssinica* and a thick undergrowth of ferns, creepers, and bushes, including the coffee bush. At higher altitudes the subtropical forests are dominated by the yellowwood, an evergreen tree with a pulpy fruit. Still higher are the coniferous forests, dominated by juniper. The upper limit of trees is about 10,000 feet (3,000 metres); above this altitude are found only coarse grasses, giant lobelias, and other high-altitude vegetation.

In the lowlands the most widespread tree is the acacia, which occurs in all its numerous varieties. The exotic eucalyptus is common in inhabited regions. Where there is a relatively greater amount of rainfall—for example, in the southern part of the Rift Valley—there is rich savanna grassland with numerous trees in addition to the omnipresent acacia. The semi-desert and desert areas have scattered dwarf-acacia thornbushes, some tough grass, and succulent plants.

Indigenous animal species

Among the animal species unique to Ethiopia are the *walia* ibex (a type of mountain goat), found on the higher reaches of the Semien Mountains and numbering not more than 200; the mountain nyala (a kind of antelope) of the Arusi, Bale, and Chercher highlands, which number about 2,000; the *simien* fox; and the gelada monkey. The most widespread animals are the spotted and the striped hyena, various species of jackal, the wild dog, and the bat-eared fox. Antelope include the greater kudu, the oryx, the bushbuck, the bush duiker, the klipspringer, and the common waterbuck. Various species of wild pig (bushpig, warthog, giant forest hog) occur in large numbers. The vervet (a black-faced guenon monkey known for its various cries) and the anubis baboon (a gray or brown baboon, the male of which has a heavy mane) are plentiful and are a serious pest in farming areas. Many smaller animals, from the aardvark (a burrowing mammal that feeds on ants) to the white-tailed mongoose, are widespread.

The richest wildlife areas are the lower Omo Valley, the Gambela region of Ilubabor, and the southwest. Animals include lions, elephants, leopards (now quite rare), buffalo, zebras, giraffes, and black rhinoceroses (also

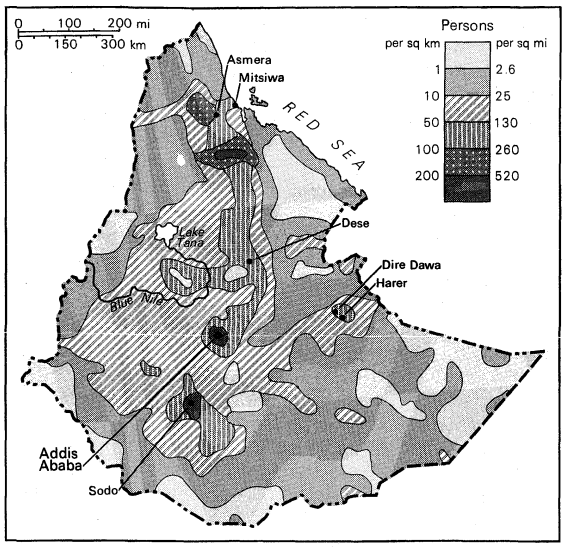
rare). Smaller animals hunted for their skins include the beautiful black-and-white colobus monkey, the serval, and the rare cheetah. Crocodiles inhabit most of the lakes and rivers at lower altitudes.

Rural and urban settlement. Most of the agricultural population lives in walled or fenced family compounds, which are scattered throughout the countryside. Buildings are round with conical thatched roofs in the south and west and rectangular with flat thatched roofs or peaked corrugated-iron roofs in the north. Fields are unfenced, and individual rights to their use are traditional; arguments over land use are a common feature of traditional judicial court procedure. Rural towns are market centres for their surrounding agricultural areas. The cattle breeders of the lowlands are nomadic tent dwellers.

Addis Ababa

The two major cities of Ethiopia are Addis Ababa (*q.v.*), the national capital, and Asmera. Founded in the 19th century, Addis (as it is called locally) occupies the centre of the Shewan Plateau. With a population of about 1,174,000, it is the larger of the two cities and has grown in haphazard fashion. Its modern buildings are surrounded by the traditional housing of the majority of its inhabitants.

Asmera, once a small rural village, developed into the capital of Eritrea, which was under Italian administration from 1890 to 1941. It has a population of about 307,000. In contrast to Addis, the city boasts well-planned streets and avenues and is heavily marked by European influences.



Population density of Ethiopia.

PEOPLE AND POPULATION

Ethnic origins. As there has been so much racial intermixing, racial identifications are of limited use in Ethiopia. Periodic migrations of Caucasoid peoples from across the Red Sea and of Negroid peoples from the West have produced a population that preponderantly manifests a blend of the two physical types. The primary sources of identification for the peoples of Ethiopia are language, religion, and other aspects of culture. The terms Amhara, Galla, and Tigre refer to linguistic and cultural groups rather than to races or tribes.

Languages. There are nearly 100 distinct languages, some of which have several dialects or less well-defined regional variations. The languages fall into the Semitic, Cushitic, and Nilotic language groups; a language group usually classified as Cushitic may be distinct enough to form an independent and coordinate family called Omotic.

Semitic languages

In terms of the historical, political, and cultural role of its speakers, the most important of the language groups is the Semitic. Semitic languages in Ethiopia fall into a northern group—Ge'ez, Tigre, Tigrinya (Tigriña)—and a southern group—Amharic (Amarinya), Gurage, Hareri, Gafat, and Argobba. Ge'ez, the language of the ancient Aksumite Empire, survives as a liturgical and literary language. Tigre is spoken by about 210,000 people in the western and northern lowlands of Eritrea. Tigrinya, with about 3,000,000 speakers, is the language of Tigre province and the highlands of Eritrea.

Amharic, the national language, first emerged into recorded history as the court language in the 13th century and has been the language of the centre of political power ever since. It is spoken as a native language by about 6,000,000 persons in the provinces of Begemdir and Simen, Gojam, Welo, and Shewa but is spreading rapidly and is spoken as a second language by an estimated 3,000,000 persons.

Hareri (or Adere or Adare) is spoken by about 35,000 people within the walled city of Harer. Gurage, the southernmost extension of the Semitic languages, is in fact a cluster of about 12 distinct dialects rather than one homogeneous language. It is spoken to the south of Addis Ababa by nearly 1,000,000 persons.

Cushitic languages

Among the Cushitic languages, by far the most important is Gallinya. The number of native speakers, known as Gallas, is estimated at about 8,000,000, but the language is spoken as a second language by many smaller linguistic groups in the east, south, and west. Not surprisingly, this widely distributed language has considerable dialect variations.

The other important Cushitic language is Somali, which has about 1,500,000 speakers. Of the remaining 20 Cushitic languages, only three—Afar-Saho, Sidamo, and possibly Hadiyya—have more than 500,000 speakers.

The Omotic branch of the Cushitic languages (called the Western branch by some), chief among which is Walamo (600,000 speakers), is spoken in the southwest, by about 2,000,000 speakers altogether. The Nilotic languages are spoken in the western fringes of the country and have fewer than 40,000 speakers each, with the exception of Kunama, which is spoken by about 65,000 persons. English is taught as a second language in the school system, and Italian and Arabic are widely understood in the north.

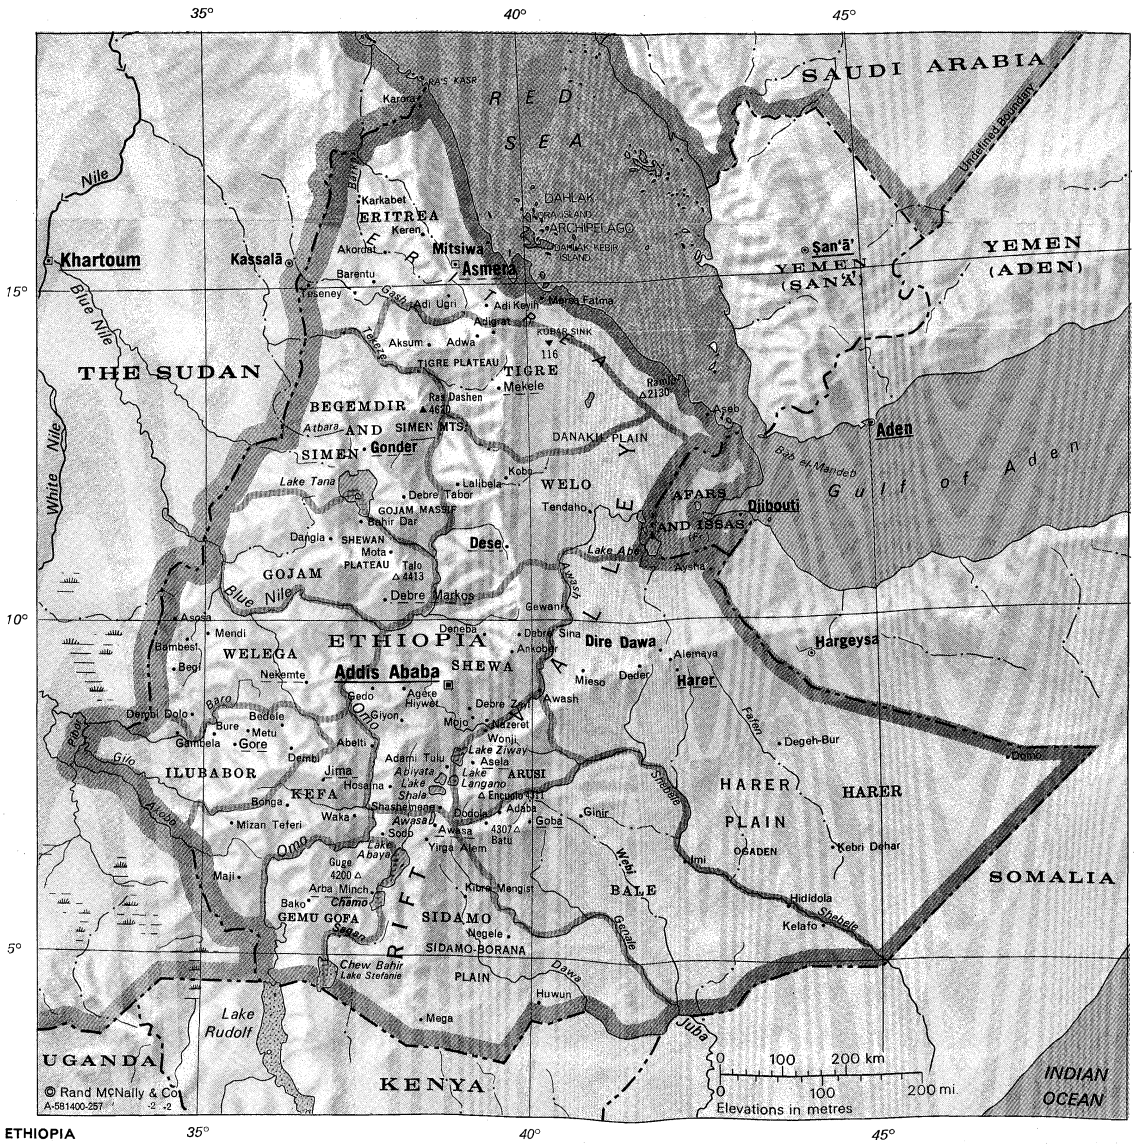
Religions. Christians are generally believed to constitute about half the population. An estimated 35 percent are Muslims, and the remainder are mostly animists; there is also a small number of Jews. The stronghold of Christianity is the northwestern highland region from central Eritrea to Shewa, while that of Islām is the lowland area and much of Kefa province. Animism prevails in the far south and in the southwestern foothills but is losing ground to both Christianity and Islām. The Falashas, pre-Talmudic Jews who were probably converted by Yemenite Jews, are found in small groups in the province of Begemdir and Simen.

The Ethiopian Orthodox Church

Christianity was introduced into Ethiopia in the 4th century, Islām was introduced in the 7th. Historically and culturally, Christianity has been and still is the dominant religion. Ethiopian Christianity had strong formal ties with the Coptic Church of Alexandria, which until 1959 provided the archbishop, or *abuna*, for the Ethiopian Orthodox Church. The Ethiopian Orthodox Church is the established church, and, until the coup of 1974, the emperor and his court were by law of this faith, as were most high government officials, although members of other faiths were not legally proscribed. The church has been viewed in Ethiopian history as the prime source and custodian of the cultural and literary heritage of the nation.

Islām, which includes widely distributed ethnic and linguistic groups, is less homogeneous than Christianity. It has two cultural focuses in Harer and Kefa provinces.

Demography. Demographic data on Ethiopia are limited and unreliable. The average population density is 57



ETHIOPIA

Ethiopia, Area and Population

	area		population*
	sq mi	sq km	1972 estimate
Provinces (*teklai gezatoch*)			
Arusi	9,100	23,500	853,000
Bale	48,100	124,600	708,000
Begemdir and Simen	28,600	74,200	1,356,000
Eritrea	45,400	117,600	1,948,000

Source: Official government figures.

persons per square mile. Densities are about twice the average in the populous provinces of Arusi, Shewa, and Welo. The lowest density, 14 persons per square mile, occurs in Bale. The lowland areas are generally more sparsely populated than the highlands. About 90 percent of the population is rural, the most urbanized provinces being Shewa and Eritrea, which have urban populations of 22.3 percent and 21.5 percent, respectively. Birth and mortality figures are highly unreliable, and immigration and emigration are insignificant. The best estimate for the annual rate of population growth is approximately 2.5 percent.

THE NATIONAL ECONOMY

Ethiopia is among the less developed countries of the world. Many of the characteristics of underdevelopment, such as the predominance of the subsistence sector, the limited role of industry, the underdeveloped economic infrastructure (roads, water supplies, schools, and other facilities), the shortage of domestic capital, and the undiversified export structure, while shared with much of the rest of Africa, are nevertheless more pronounced in Ethiopia. The growth rate of the economy has remained well below the average annual increase in the gross domestic product (GDP) for Africa in general.

Natural resources. Mineral resources had not been accurately surveyed by the 1970s. Preliminary information, however, indicates that mineral deposits are probably considerable. The basement rocks contain valuable metals, the more important of which are gold, platinum, lead, tungsten, and copper. The sedimentary rocks may contain petroleum, but none has yet been discovered in quantities sufficient to make exploitation worthwhile. Limestone deposits are important, and the volcanic deposits of the Danakil Plain contain sulfur, sodium and potassium salts, gypsum, rock salt, and potash.

Mineral deposits

Biological resources include about 22,000,000 acres (9,000,000 hectares) of forest land, covering about 7 percent of the total area of the country. Trees are of varying quality for use as timber; eucalyptus is widely used for construction. Wildlife provides bases for the expanding tourist industry.

Many Ethiopian rivers have great potential for hydroelectric power, while the volcanic areas of the Rift Valley offer possibilities for the development of geothermal power. Accurate surveying of the water resources to enable the selection of suitable dam sites remains to be done. The only river basins surveyed by the 1970s were those of the Abbay (Blue Nile) and the Awash.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture is the mainstay of the Ethiopian economy. It provides a livelihood for 87 percent of the population, constitutes more than half of the GDP, and accounts for nearly all of the country's exports. Except on the few large-scale commercial farms, land is tilled by the ox-drawn plow or the hoe, and seed is sown by hand. Use of fertilizers is limited; natural manure is mostly used as fuel or as an ingredient in building material rather than as fertilizer. The yield is primarily used by the farmer himself, and only a small proportion of the produce reaches the markets.

More than half of the country's total acreage is devoted to pastures, although most of it is suitable for cultivation. The total of cultivable land and pastureland is about 207,814,000 acres (84,102,000 hectares), of which 25,699,000 acres (10,400,000 hectares) are cultivated. This provides an excellent man-to-land ratio. The fertility of the soil is generally considered to be high, and the climate is suitable for varied agricultural production.

Crops vary greatly, depending upon altitude and climatic conditions. The staple crop in the northern half of the Western Highlands is teff (*Eragrostis abyssinica*), a grain unique to Ethiopia. It grows best on the lower parts of the plateau, where maize (corn) and millet are also raised. Wheat and barley are widely grown on the highlands proper, and oats are raised on the highest parts of the plateau. Pulses (lentils and varieties of peas and beans) are also widely grown. In the southern half of the Western Highlands the staple food is a versatile plant known as ensete (or "false banana"; *Musa Ensete*); an increasing amount of maize and sorghum is also grown. In the west the gathering of wild coffee is increasingly supplemented by coffee plantations, and mixed farming with a wide variety of crops is practiced. In the lowlands and foothill areas, pastoralism is supplemented by seasonal cultivation of crops such as maize and sorghum. In the Danakil Plain, nomadic pastoralism prevails.

Coffee is the most important agricultural export. The coffee plant is native to Ethiopia and grows wild in the provinces of Kefa, Welega, Ilubabor, and Gemu Gofa. There is increasing cultivation of coffee in these provinces and in similar highland areas of Sidamo and Harer. Other important agricultural products are sugarcane, various oil seeds, vegetables, and fruits. There are possibilities of large-scale production of cotton on the lowlands. as exemplified by the plantation at Tendaho.

The native coffee plant

Next to coffee, perhaps the most important agricultural resource is livestock. Ethiopia has a livestock population of about 100,000,000 animals, more than one-fourth of which are cattle; they account for about 20 percent of the total cattle population in Africa. The rest are sheep, goats, poultry, and other domestic animals. Prospects for the expansion of the livestock industry are good because of the abundant grassland and adequate rainfall. The meat yield of Ethiopian livestock, however, is rather poor because of poor breeds and feeding methods.

Despite the considerable forestry potential, the contribution of this resource to the economy is small. This is largely a result of the lack of road or rail access to much of the forested area. Most of the forests are owned by the government. The state forests have remained untouched, domestic timber is expensive, and forest products are increasingly imported.

The role of fishing in the traditional economy is negligible. Commercial fishing is entirely restricted to the Red Sea coastal waters and involves little deep-sea fishing. Production fluctuates from year to year because of poor techniques and equipment and the near total dependence on foreign markets.

Fishing

Mining and quarrying. The contribution of mining and quarrying to the economy is also small. Mining activity includes the exploitation of the alluvial gold deposits at Kibre Mengist and the mining of manganese ore near Mitsiwa, salt in the Danakil region and southern Borana, and platinum in Welega. The exploitation of potash was given the highest priority in the 1970s.

Manufacturing. Manufacturing is little developed. It employs less than 1 percent of the population and contributes about 10 percent to the GDP. It is based almost entirely on the processing of agricultural raw materials and the production of light consumer goods. Most industry is located in the few major urban centres; about half is in Addis Ababa and most of the rest in and around Asmera, Nazeret, and Dire Dawa. The main products

are textiles, processed food, beverages, and shoes. The sugar factory at Wonji, in Shewa province, supplies domestic needs.

Handicrafts and small-scale industries produce about 5 percent of the gross domestic product. Activities include hand spinning and weaving, tailoring, carpentry, and the small-scale production of carpets, rugs, rope, twine, handmade shoes, other leather products, and jewelry. These activities are usually located in households and depend on family labour, but also included are such undertakings as cleaning coffee and grain and milling flour.

Energy. The total installed generating capacity in the mid-1970s was 185,000 kilowatts, of which two-thirds was hydroelectric and the rest thermal. At Fincha, on a tributary of the Abbay (Blue Nile) River, a major dam of nearly 100,000-kilowatt capacity was inaugurated in November 1973, increasing the installed capacity of the country by nearly 50 percent. But this and other exploitation, largely concentrated at three large dams on the Awash River, constitutes only a minute fraction of the hydroelectric potential, which is estimated to be 4,300,000 kilowatts.

Tourism. The animal life in the southwest, the majestic highland scenery, recreational fishing in the Rift Valley lakes, year-round bathing on the Red Sea coast, and places of historical interest such as Aksum, Lalibela, and Gonder could draw tourists in significant numbers. In order to encourage tourism, several national parks, game reserves, and bird sanctuaries have been established, historic cities restored, and hotels built.

Commerce and financial services. Wholesale and retail trade is, at least in urban areas, dominated by the local Italian, Arab, Greek, and Armenian communities. Christian highlanders have shown a traditional disinclination to trade, but other Ethiopians are now gradually displacing aliens in commerce. Ownership of dwellings, on the other hand, is almost completely in Ethiopian hands, because aliens are legally barred from owning land except by special dispensation.

Banking

The main banks are the Commercial Bank of Ethiopia (a government-controlled corporation), the Agricultural and Industrial Development Bank (which provides long-term and medium-term credit for agricultural and industrial development), and the National Bank of Ethiopia (which performs the services of a regulatory central bank). Until the coup of 1974, the private Addis Ababa Bank was also active in commercial banking, and branches of two Italian banks had been granted licenses to conduct business in Addis Ababa and other cities. These three private banks and all insurance companies were nationalized in January 1975.

Foreign trade. Ethiopia's exports consist almost entirely of agricultural products, while its imports are dominated by manufactured goods. Efforts to diversify exports had by the mid-1970s reduced the share of coffee from 60 to less than 30 percent. Next in importance are pulses (peas, beans, and lentils), oilseeds, and hides and skins. The United States buys about 70 percent of all Ethiopian coffee exported. Other major customers for Ethiopia's exports are West Germany, Afars and Issas, Saudi Arabia, Italy, and Japan.

Ethiopia's imports include manufactured consumer goods and capital goods necessary for industrialization and the mechanization of agriculture. The largest categories are machinery and transport equipment; about one-third of the value of imports is accounted for by road motor vehicles and manufactured goods. Imports of crude and processed petroleum, though they declined during 1968–74, will continue to be an important import unless substantial deposits are found in the country. Major import sources are the United States, Italy, West Germany, Japan, and the United Kingdom.

Between 1958 and 1972, imports consistently exceeded exports, creating an increasing negative balance of trade. The deficit was met chiefly by foreign capital in the form of loans and grants. During the mid-1970s, however, this imbalance was ameliorated. The operation of the national airline to foreign countries has had a positive effect on the balance of payments.

Management of the economy. *The public and private sectors.* Large-scale economic activity is confined to the public and expatriate private sectors. The private sector is limited to wholesale and retail trade, in which aliens play an important role, and to small manufacturing establishments and agro-industrial concerns, especially in Eritrea, where Italians are prominent in trade. Private investment also has a significant role in newly developed commercial agricultural enterprises, such as those in the Setit–Humera region and in the Awash Valley.

Public utilities, rail, air, and water transport, telecommunications, banking, and much of industry (oil refinery, tobacco, sugar, textiles, beverages, mining) are generally in the hands of government-owned or government-controlled corporations.

Public finance. The chief sources of government revenue are indirect taxes and taxes on foreign trade. The large subsistence sector and the administrative problems of tax collection make the contribution from direct taxes much smaller than it could be. External aid and loans are an important source, usually amounting to not less than one-quarter of total revenue. These are generally used for government investment expenditure, particularly for infrastructural development, such as the building of roads and dams.

The largest items of government expenditure are national defense and internal order and justice (25 percent or more). Expenditures on education (15 to 20 percent) and health (6 percent) are significant but less than might be expected in a developing nation.

Trade unions and employer associations. The Confederation of Ethiopian Labour Unions (CELU) includes about 150 trade unions with a combined membership of about 85,000 in the mid-1970s. Employers are organized under the Federation of Employers of Ethiopia (FEE).

Economic policies. The government's third five-year plan, for 1968 through 1973, gave high priority to agriculture and to the expansion of commercial farming. Other objectives were promotion of efficient foreign and domestic marketing practices, the provision of agricultural credit, diversification in coffee-growing areas, and improvement of the quality of coffee.

Land reform

The need for land reform has been generally recognized. In March 1975 the provisional military government announced a new land policy in which private land ownership was abolished. The policy provided for 25 acres (10 hectares) of cultivable land to be allotted to each farming family and for the formation of agricultural associations. Implementation of the reforms was expected to be slow, hampered by traditional values and a lack of administrative personnel, seed, machinery, tools, and fertilizer.

Economic policy aims at doubling the output of manufacturing, systematically surveying mineral resources, and giving priority to a dense network of feeder roads in key areas rather than building primary highways in economically unproductive areas.

Transportation. At the beginning of the 20th century, modern transportation of any kind was virtually absent. In the 1970s there were about 4,500 miles (7,200 kilometres) of all-weather roads, 744 miles (1,197 kilometres) of railway line, and an airline with well-developed domestic and international services.

The major roads radiate from Addis Ababa, which is near the geographic centre of the country, connecting it with the provincial capitals. Most of these roads do not extend to the borders, and an interconnecting secondary road system is still being developed. Nearly half the population lives more than nine miles from an all-weather road. Rapid improvements are not to be expected because of the difficult terrain.

Rail transport is also handicapped by terrain, and there are only two railway lines in the country. One line runs from Mitsiwa via Asmera to Akordat, in western Eritrea. The other connects Addis Ababa to the port of Djibouti, in Afars and Issas, on the Gulf of Aden.

Where land transport faces so many handicaps, air transport acquires special importance. Ethiopian Airlines began operating in 1946 and has provided quick access

to areas that would have taken decades to open up by road or rail. There are about 40 airports, most of which can accommodate only small aircraft. Ethiopian Airlines operates an international service from the jet ports of Asmera and Addis Ababa, which are also used by a number of foreign airlines.

Water transport is undeveloped. Most of Ethiopia's rivers are not navigable, and, of the lakes, only Tana has transport of any economic significance. Ethiopia has only two ports, Mitsiwa and Aseb on the Red Sea. Djibouti remains the main outlet to the sea because of its rail link to the capital.

Problems and prospects. The development of an effective transport network is only one of the several problems that loom large in the Ethiopian economy. Another is the necessity of bringing the huge subsistence sector into the money economy, mainly through the commercialization of agriculture. The spread of an educational system oriented in its content and methods toward development is a prerequisite for effective utilization of the country's human resources. To continue to lessen the dependence of foreign trade on coffee, impetus is needed for the raising of other agricultural products and livestock, for which there appears to be a market in the Middle East.

Diversification would be aided if prospecting for mineral resources, especially oil, were accelerated. The possibility of developing a regional common market such as the East African Union for manufactured goods offers some promise. External capital could participate to a greater extent if the necessary steps were taken. All this requires effective administrative machinery and an equitable distribution of income.

ADMINISTRATION AND SOCIAL CONDITIONS

Until the military coup of 1974, the Ethiopian state was formally a constitutional monarchy with a bicameral Parliament. In practice, however, the Emperor exercised effective political power.

The structure of government. *Constitutional framework.* The first formal constitution was granted by Emperor Haile Selassie I in 1931; it was superseded by the revised constitution of 1955, which affirmed the descent of the Emperor from King Solomon of Israel and the Queen of Sheba of the Aksumite kingdom. It established succession to the throne by male primogeniture and vested sovereignty in the Emperor. The wide powers the constitution granted to the Emperor included control of the armed forces, foreign relations, and all government departments. Parliament, however, had the power to assent to a declaration of war and to certain types of treaties. The Emperor also had the power to dissolve Parliament. When Parliament was in recess, the Emperor was allowed to legislate by decree to meet emergencies, and such legislation continued to have legal force unless expressly repealed by Parliament when it reassembled.

The government structure was profoundly altered by the "creeping" military coup of February–September 1974. On September 12 the Emperor was deposed and Parliament and the constitution of 1955 were suspended. The throne was at first offered to the Crown Prince, but on March 21, 1975, the crown was abolished in preparation for the establishment of a socialist republic.

Revolutionary government

The revolutionary government is composed of a 120-member Provisional Military Administrative Council, known locally as the Dirgue, and a civilian Technical Advisory Council of 50 members.

Regional government. Ethiopia is divided into 14 provinces, or governorates (*teklai gezatoch*), each of which is further divided into districts and subdistricts. Lower regional units are not uniform and do not occur in all provinces. Historically, the basis for the provincial units has been the linguistic and cultural affinity of the inhabitants, and this remains so to a large degree.

Under the imperial government, the provinces were much more under the control of the central authority in Addis Ababa than was the case in the traditional feudal structure. Whatever measure of local autonomy existed resulted more from difficulties of communication than from any conscious policy of decentralization. The revolutionary government promised a lessening of centralized power and a return to a more traditional system of local power centres.

The political process. The traditional checks on the power of the Emperor—exercised by the semi-autonomous feudal lords, other nobility, and the institution of the church—were either removed or greatly weakened by modernization and centralization. The Emperor appointed government officials down to the level of director, which was about five ranks below minister. Many of these ranks were held by several persons in each ministry, and the number of appointed officials was therefore quite large. The periodic announcements of government reshuffles were eagerly awaited; they were minutely studied as an accurate barometer of shifts in the Emperor's esteem and therefore in political power.

No decisions of any importance were made without the knowledge and approval of the Emperor. The prime minister was in reality a "first among equals" among the ministers and had little political power of his own. He had the derivative power of being close to the Emperor and being able to influence the latter's decisions on some issues; a measure of such power also was enjoyed by some of the Emperor's personal attendants. The prime minister was the chairman of the Council of Ministers; occasionally, this function was taken over by the Emperor himself.

In its policy of "Ethiopia First," the military government affirmed the right of self-administration at village, district, and regional levels. It reserved to the central government jurisdiction in national and other fundamental matters of state and the obligation to assist and support other levels of government.

The military government also announced its intention to form a national socialist political party. Limited political participation had existed in the traditional structure in the form of informal councils of elders. In a few sections of the country, notably among the Galla of Borana, a democratic indigenous sociopolitical structure known as the *gada* system had a marginal existence alongside the imperial structure.

Eritrean separatism

Separatist movements have been strong in the province of Eritrea, formerly an Italian colony and chiefly Tigrinya speaking. After the coup of 1974 the drive for separatism gained strength, presenting the new government with one of its most serious political problems. Major uprisings have also occurred in the provinces of Tigre, Bale, Harer, and Gojam.

Administration of justice. A variegated system of customary laws has operated among the various ethnic and religious groups. In the Christian highlands, a written code—the *Fetha Negast* ("Justice of the Kings")—was adapted from an Arabic original, which itself took inspiration from the Justinian code. Since 1960, civil and commercial codes, drafted by international legal experts, have been in force and presumably supersede all other laws. In practice, customary law still prevails, especially in lower courts and outside the main urban centres.

The judicial system includes the High Court (which has branches in the provinces), the Awraja ("district") courts, the Wereda ("subdistrict") courts, and the Atbia ("sub-subdistrict") courts. Cases requiring the application of Muslim law of the family, succession, and the like are heard by special Sharīʿah courts (based on the body of established Islāmic religious law). Under the revolutionary government, military tribunals were formed to try former government officials.

The armed forces. The armed forces have always been held in the highest esteem in Ethiopian tradition. Every able-bodied man was a potential soldier ready to bear arms for his feudal lord or emperor. The formation of a regular standing army began in the 19th century, and the armed forces are now among the most effective and best trained forces in black Africa.

The army, with about 45,000 men, has detachments strategically posted throughout the country; they are supported where necessary by airborne command units. The Territorial Army is a sizable force of reservists who

are trained for about two months every year. The Ethiopian Air Force is a small, well-trained, fully Ethiopian force whose airplanes include supersonic tactical fighters. The Ethiopian Navy is in the process of consolidation. Training facilities for the armed forces include the old military school at Genet, the Military Academy at Harer, the Air Force Academy at Debre Zeyt, and the Naval College at Mitsiwa.

Military training

The social milieu. *Education.* Traditional education is almost solely the concern of religious institutions and is exclusively religious in aim and content. Church and Qur'ānic schools are widespread, particularly in areas in which secular education is not available. The modern school system—introduced by Emperor Menelik II (reigned 1889–1913)—was greatly developed and expanded under Haile Selassie I. It is still inadequate, however, and an estimated 90 percent of the population was illiterate in the 1970s. Ethiopia has had an indigenous writing system for nearly 2,000 years, but its use has been largely restricted to religious purposes.

Ethiopia has a four-tiered educational system with elementary schools (grades one to six), junior secondary schools (seven and eight), senior secondary schools (nine to 12), and institutions of higher education. In addition, there are several vocational schools and in-service training programs. About 60 percent of all schools are under the direct control of the Ministry of Education and are fully government supported. The rest are mission, private, or Ethiopian Orthodox Church schools. The approximately 950,000 students constitute only about 10 percent of all school-age children.

The main institution of higher education is the National (formerly Haile Selassie I) University, in Addis Ababa. It has faculties of arts, science, education, technology, business administration, social work, law, and medicine. Public-health courses are offered in Gonder and agriculture courses in Alemaya, near Harer.

Medical services. The bulk of the population must rely on traditional methods of medical treatment, such as herbal medicines and holy waters. Modern medical care reaches only about 15 percent of the population, at most. Medical facilities are poorly distributed, being concentrated in Addis Ababa, Asmera, and a few other major towns. While the doctor-to-population ratio for the country as a whole is about 1 to 70,000, the ratios for Asmera and Addis Ababa are 1 to 2,500 and 1 to 3,000, respectively. In the provinces, the ratio ranges between 1 to 100,000 and 1 to 250,000. The distribution of other facilities is similarly lopsided; the establishment of rural health centres and the training of health officers and community nurses may partially correct the imbalance. Many of the hospitals, clinics, and health centres are understaffed, inadequately supervised, and lacking in essential supplies and equipment. Medical-training facilities include the Faculty of Medicine and the Public Health College (at Gonder) of the National University, and several smaller institutions for the training of other medical personnel.

Living conditions. The average annual income, Eth$190 (U.S. $90), is one of the lowest in the world. Most of the population is outside the money economy and lives on a subsistence level.

Because the population is concentrated in the highlands, most people are free from tropical diseases, but communicable diseases such as malaria, tuberculosis, and smallpox are prevalent. Leprosy is being fought with international help. Schistosomiasis (a parasitic infestation that is spread through snails that live in shallow water) is endemic; all bodies of water except Lake Langano are said to be infested, and irrigation schemes are spreading the disease. Preventive medicine is hampered by popular ignorance of hygiene and sanitation, lack of safe drinking water, and low nutritional standards.

Diseases

Social and economic divisions. On the whole, the cattle herders of the lowlands, and particularly the Somali and the Galla of Borana, have a highly egalitarian social structure. Before the land reforms of 1975, the farmers in the south were generally tenants for northern, and especially Amhara, absentee landlords. Among the Amhara and the Tigre, farmers usually owned the land they tilled, and the privileged group before the military coup consisted of the members of the government bureaucracy and the declining nobility. Special status was once enjoyed by members of the clergy, whose importance has waned. Most groups in Ethiopia include a depressed class, which usually consists of landless artisans or musicians.

Cultural life. Religion and language have probably been the two most important focal points of the cultural life of Ethiopia, both historically and in the 20th century. Of the two major religions in the country, Christianity has been traditionally predominant culturally. National holidays, ceremonies, shrines, symbols, myths, and sources of identification are nearly all Christian. The national literature, both past and present, is Christian in either content or orientation. What are regarded as the national dress and national traits and customs are generally those belonging to the Christian peoples. Only in certain localities such as Harer and Jima does Islām dominate. Painting historically centres on the church, and modern artists often choose religious subjects.

The culturally dominant languages have been the Semitic languages in general and Ge'ez and Amharic in particular. Ge'ez has always been held in special veneration, and Amharic, as the traditional court language for many centuries and as the constitutionally established national language, earned cultural prestige for its speakers and their way of life. The military government, however, pledged itself to encourage the development of all Ethiopian languages and cultures in order to promote national unity.

Libraries include the National Library and the University Library in Addis Ababa and the Asmera Public Library in Asmera. Also in Addis Ababa are the National Museum, which contains archaeological exhibits of note, and the Museum of the Institute of Ethiopian Studies, which contains ethnological exhibits and collections of paintings, coins, and stamps.

The press and broadcasting

The few newspapers of national circulation are all published in Addis Ababa. The Amharic daily *Addis Zemen* ("New Era") and the English daily *The Ethiopian Herald* have circulations of 35,000 and 30,000, respectively, while the circulation of the French daily *Addis Soir* is limited. Of the weeklies, the most important are *Ye-zareitu Ityopia* ("Ethiopia of Today") and *Ye-sport fana* ("The Light of Sports"). There is an Amharic monthly, *Menen,* and an illustrated English quarterly, *The Ethiopian Mirror.* The most popular newspaper, the Amharic fortnightly *Polisenna Ermejjaw* ("Police and Progress"), is published by the Ethiopian Police Force; it relies heavily on crime reporting and has a circulation of about 80,000. Other papers published in Asmera in Amharic, Tigrinya, Arabic, and Italian are of primarily local circulation.

The communications medium that reaches the masses in Ethiopia is radio. Radio Ethiopia, the government-owned station, broadcasts from Addis Ababa, Harer, and Asmera. News and information are broadcast primarily in English and Amharic, but other local and foreign languages are also used. A radio station owned by the Lutheran World Federation broadcasts religious and secular programs in several languages from Addis Ababa to African and Asian countries.

The Ethiopian Television Service, which began operations in 1964, has daily programming for several hours in Amharic and English. Though there is increasing local programming, there is still heavy reliance on imported television programs from the United Kingdom and the United States. There have been experiments with educational broadcasts for classroom use. Outside the capital, broadcasts are received only in a few towns stretching southward from Addis Ababa to Asella.

Prospects for the future. History weighs heavily upon Ethiopia, and most of the country remains as it has been for centuries. Yet time caught up with the long-established order, and the forces of change made themselves felt in the coup of 1974.

Economically, many of the problems of Ethiopia are no

different from those of other developing nations, although they may be more acute. The integration of the self-sufficient traditional sector into the modern money economy is a difficult but essential part of economic development if Ethiopia is to become an integral part of the modern world. The military government announced a policy of public guidance, control, or ownership of economic resources, as a means toward abolishing poverty and exploitation. Land reform is a vital aspect of the new economic program, and the development of the country's rich mineral resources is given a high priority. If economic development is to benefit the people, it must be rapid enough to do more than simply feed the extra mouths resulting from normal population growth and must be accompanied by a system that will make possible an equitable distribution of income.

After millennia of existence as a nation-state, Ethiopia is not free from the problems of national integration that bedevil so many nations in an age of popular political awareness. The great ethnic and religious diversity, which caused little discomfort in the highly autonomous quasi-feudal structure of the past, is today a potentially disrupting force. Such threats to unity and stability are made even more ominous by external encouragement. The nation has so far managed to weather periodic threats to its stability, and the military government has made it clear that the final solution to this problem must include the due participation of all groups in the cultural and political life of the country.

BIBLIOGRAPHY. Of earlier works in English JAMES BRUCE, *Travels to Discover the Source of the Nile*, 6 vol. (1790), is a classic—a keenly observed eyewitness account of medieval Ethiopia. Of modern works, EDWARD ULLENDORFF, *The Ethiopians*, 2nd ed. (1960), is especially strong on northern Semitized Ethiopia. G.A. LIPSKY, *Ethiopia: Its People, Its Society, Its Culture* (1962), is more comprehensive, but less dependable in matters of detail. D.N. LEVINE, *Wax and Gold: Tradition and Innovation in Ethiopian Culture* (1965), is a much discussed study of the culture and social psychology of northern Christian Ethiopia. The history and doctrine of Ethiopian Christianity is treated in A. WONDMAGEGNEHU and J. MOTOVU (eds.), *The Ethiopian Orthodox Church* (1970). J.S. TRIMINGHAM, *Islam in Ethiopia* (1952), the most extensive study of Ethiopian Islām, contains the best general account of Ethiopian history. The best source for all manner of statistical information is the latest issue of the annual *Statistical Abstract*, issued by the Central Statistical Office. DAME MARGERY PERHAM, *The Government of Ethiopia*, 2nd ed. (1968); and CHRISTOPHER CLAPHAM, *Haile Selassie's Government* (1969), are similar in approach and together constitute the best account on the Ethiopian polity before 1974. RICHARD GREENFIELD, *Ethiopia: A New Political History* (1965), has information on the coup d'etat of 1960 that is unavailable elsewhere.

There is a scarcity of general accounts of the geography of Ethiopia. G.C. LAST, "Introductory Notes on the Geography of Ethiopia," *Ethiopia Observer*, vol. 6, no. 2 (1962), is a good introduction. MESFIN WOLDE MARIAM, *An Atlas of Ethiopia* (1970), is comprehensive and based on the latest available statistical data. F.J. SIMOONS, *Northwest Ethiopia: Peoples and Economy* (1960); and Y.A. HAGGAG, *A Contribution to the Physiography of Northern Ethiopia* (1961), are among later firsthand geographical studies. J. BLOWER and J.F. VON WOLFF, *Shell Guide to the Wildlife of Ethiopia* (1969), is practical and well illustrated. The basic work on geology is still GIOTTO DAINELLI, *Geologia dell' Africa Orientale*, 4 vol. (1943). D.A. JELEC, *Mineral Occurrences of Ethiopia* (1966), is a good compilation.

A useful general introduction to the Ethiopian economy is ASEFFA BEQUELES and ESHETU CHOLE, *A Profile of the Ethiopian Economy* (1969). The ETHIOPIAN COMMERCIAL BANK, *The Ethiopian Economy* (1970), treats selected topics, notably commercial banking and the share market. Economic history is treated in RICHARD PANKHURST, *Introduction to the Economic History of Ethiopia*, 2 vol. (1961–68).

Competent studies of specific peoples of Ethiopia are WILLIAM SHACK, *The Gurage: A People of the Ensete Culture* (1966); ERNESTA CERULLI, *Peoples of Southwest Ethiopia and Its Borderland* (1956); G.W.B. HUNTINGFORD, *The Galla of Ethiopia: The Kingdom of Kafa and Janjero* (1955); A.E. JENSEN (ed.), *Altvölker Süd-Äthiopiens* (1959); E. HABERLAND, *Galla Süd-Äthiopiens* (1963); and H.S. LEWIS, *A Galla Monarchy: Jimma Abba Jifar, Ethiopia, 1830–1932* (1965).

WOLF LESLAU, *The Scientific Investigation of the Ethiopic Languages* (1956), gives a general overview of the Semitic languages. Further literature on the subject is fully covered in Leslau's indispensable *Annotated Bibliography of the Semitic Languages of Ethiopia* (1965). For other languages of Ethiopia, the best guide is still A.N. TUCKER and M.A. BRYAN, *The Non-Bantu Languages of North-Eastern Africa* (1956).

(A.Dem./Ed.)

Ethiopia, History of

Ethiopia is a unique phenomenon in Africa. Ethiopia and Egypt are the only African nations that can trace their history into antiquity, but Egypt became more and more alienated from its ancient culture by successive conquests, while Ethiopia, except for a few years of Italian occupation in the 1930s and 1940s, retained its original character through the centuries. Ethiopia's historic continuity is largely the result of a favourable geographic location; its high plateaus, which, both fertile and temperate, border on heavily travelled seas on the east and elsewhere, can be defended like fortresses from the hostile deserts that surround it. Thus, Ethiopia has been able to preserve and perfect a unique culture born of the ancient encounter and the slow fusion of two equally gifted peoples: the Cushites, a white race with dark skin, who were probably indigenous, and Semitic tribes that may have emigrated from Arabia.

Historic continuity

EARLY ETHIOPIA (TO THE 11TH CENTURY)

Remotest antiquity: the land of Punt. The Egypt of the pharaohs believed that it had received certain of its divinities from Ethiopia, which it called Punt, or the Land of God. Later, the Greeks thought of it as the original home of wheat and of the olive tree. The legends are partly true. The most recent discoveries confirm the ancientness of man's presence in Ethiopia; even the remains of an archaic hominid (*Paraustralopithecus aethiopicus*) dating back some 1,500,000 years have been found in the Omo Valley. According to Egyptian hieroglyphic texts, an authentic civilization began as early as the 2nd millennium BC. The pharaohs sent fleets there to buy such precious goods as spices, incense, and myrrh. Bas-reliefs in Dayr al-Baḥrī at Thebes, dating from around 1500 BC, depict certain Ethiopians cultivating myrrh and incense. The text commenting on these drawings calls the Ethiopians Habashat, from which later came the name Abyssinia.

The Sabaean period. An Egyptian dynasty—the 25th (*c.* 750–656 BC)—classified as "Ethiopian," in the larger sense of the word, by classical Greek authors, has been erroneously included in Ethiopian history itself. Its princes were, in fact, Sudanese, or Nubian. Direct illustrations of Ethiopia's past, such as monuments and inscriptions, are found on Ethiopian soil beginning only with the 6th century BC. These testimonies indicate the growth on the Ethiopian plateau of a civilization closely related to the Minaeans and to the Sabaeans from South Arabia. This "Sabaean" stage of its past led the Ethiopian nation to include in its ancient traditions the biblical episode of the Queen of Sheba's visit to Solomon, as told in the First Book of the Kings (10:1–10).

Between the 6th century BC and the 1st century AD, approximately, Sabaean influences reached the Ethiopian coasts and plateaus. Among these were astral religion, sacred royalty and social institutions, intensive agriculture, architecture, and art. Sabaean writing was adopted in Ethiopia in order to transcribe a language almost identical to that of the Arabian Sabaeans; that language and its writing have been preserved by the Ethiopian church in the liturgical language Ge'ez.

During the last centuries BC Ethiopia also felt the influence of Hellenistic Egypt. The Ptolemies' fleets founded trading posts on the Ethiopian coasts, through which entered "modern" merchandise, the beginnings of commerce, and a few traces of Hellenistic art and the Greek language. One of these trading posts became the great ancient port of Adulis, the modern hamlet of Zula.

The Aksumite Empire. From the 2nd to the 9th centuries AD the fusion of new immigrants (primarily the Aguezat, who left their name to the Ge'ez language) with people who had been on African soil for some time created an independent nation centred at Aksum on the

Tigre Plateau, which still remains Ethiopia's religious centre. Its busy ports helped the nation develop its military and maritime power and thus to dominate the neighbouring regions in the 3rd–6th centuries; even the South Arabian kingdom of the Ḥimyarites, a fusion of the Sabaean and Minaean kingdoms, came under the suzerainty of Aksum. This expansion of the Ethiopian peoples, all of whom were related, along the two banks of the Red Sea, the African banks of the Gulf of Aden, and even toward the coast of Benadir (then known as Azania) brought economic and financial prosperity and religious, artistic, and social vigour to that part of the ancient world. This was facilitated by intense maritime traffic in the southern Red Sea, through which the fleets had to cross in order to pass from the east to the west and which brought ships of all origins to Ethiopian ports, Adulis principally. Thus, Ethiopians imported commodities from everywhere in exchange for African products, particularly costly gums (incense, myrrh, etc.), which other peoples were then buying in considerable quantities for the needs of their pagan cults and funeral embalmings. Commerce rested on sound financial methods, attested to by the minting of splendid coins bearing the effigies of Ethiopian emperors and by the fact that the Christian Ḥimyarite city of Najrān, a vassal of Aksum on the Yemen plateau, was an early centre of authentic banking activity.

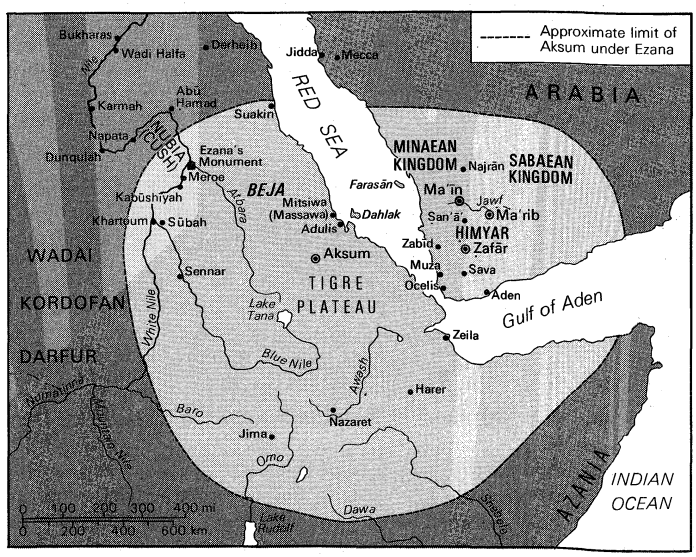
Franco-Ethiopian archaeological investigations, starting in 1954, revealed Aksumite monuments and inscriptions, which, along with data from a few classical texts, have led historians to recognize Ethiopia's role in the development of the southern Red Sea, the Upper Nile, and the eastern Horn of Africa. Some Aksumite emperors were already quite well known, however. Around the 1st century AD an anonymous Greek travel book, the *Periplus Maris Erythraei* ("Circumnavigation of the Erythrean [*i.e.*, Red] Sea"), called King Zoscales a miser but "an expert in Greek language," whose control extended from Aksum to the eastern extremity of Africa. In the 3rd century the Iranian religious leader Mani mentioned the Aksumite Empire in one of his epistles, calling it one of the four greatest existing kingdoms of the world. Sabaean inscriptions in Arabia relate the feats of the Ethiopian emperor Gadarat, who owned the cities of Ẓafār and Sava (now Ta'izz) and the ports of Ocelis and Muza on the Red Sea. Later Arabian inscriptions mention the Ethiopian emperor Wazeb I, to whom certain overseas Habashats made an appeal. Above all, an unnamed Aksumite sovereign toward the end of the 3rd century had engraved in Greek on a monument in Adulis (now lost but copied by the Byzantine traveller Cosmas in the 6th century AD) a recital of campaigns that show that his power extended from southernmost Egypt to the gold-producing regions in the present Ethiopian southwest, including the spice coasts on the Gulf of Aden and even the Sabaean and Minaean kingdoms across the sea. These Ethiopians were powerful enough to defeat Roman ships on the Red Sea.

The Aksumite emperors

Ezana. Ezana came to the throne between 320 and 325. To his title of king of Aksum, he added those of sovereign of Ḥimyar and of Sheba (*i.e.*, Saba), of Cush, or Meroe, and of the Beja, a desert people living between Ethiopia and Egypt. Ezana destroyed the remains of the kingdom of Meroe in the Sudan, erecting a votive monument at the confluence of the Nile and the Atbara. Ezana also caused his nation to adopt Christianity, although it was probably already well implanted by numerous foreign merchants and, more particularly, by the preaching of two young Syrians—Aedesius and Frumentius. Frumentius, still known to Ethiopians as Abba Salama, was the first bishop of Ethiopia, having been consecrated sometime in the 340s by St. Athanasius in Alexandria. This consecration initiated the subordination of the church of Ethiopia to the Egyptian church, which later became the Coptic Church. Ezana also brought about the definitive adoption for Ethiopian writing of an improvement of the Sabaean alphabet.

Ella-Asbeha. Another great emperor was Ella-Asbeha (Caleb), famous for a great expedition to avenge the Christians of Najrān, who had been persecuted around 523 by a local prince who had converted to Judaism. Undoubtedly, also in Ella-Asbeha's time, Christian monasticism was introduced into Ethiopia by a small number of monks who fled Egypt and possibly also Syria because of dogmatic controversies that were then disturbing those countries. Ella-Asbeha had established an Ethiopian viceroy, Abraha, over Ḥimyar. Abraha, who wanted to give his area a special prestige, tried to make the city of Ṣan'ā' and the cathedral he built there a magnet for Christian pilgrims and merchants from all over Arabia, Mesopotamia, and even Iran. Abraha's religious and commercial policies were continued successfully by a nascent Islām. In the Qur'ān there is a powerful, though inexact, reference to an unsuccessful military expedition with which, around 540, he tried to destroy Mecca, already becoming a competitor of Ṣan'ā'. But that period was, above all, marked by the repercussions of the great conflict between Byzantium and the Persians. The Byzantine emperor tried to persuade the Ethiopians to buy as much as possible of the silk produced in China through India and thus diminish the revenues of his Iranian enemies. Meanwhile, the anger of the Persians, stirred up by Abraha's ambition and intrigues, was turned against the regions occupied by the Ethiopians. In 572 the Persians disembarked at Aden, invaded the Ḥimyarite kingdom, and pushed some Ethiopian colonies as far back as the African coastline. Their conquest was followed 30 years later by Arab invasions. Ethiopian power was crumbling in Arabia, while Aksum's decline was

Persian invasion in 572



The kingdom of Aksum under Ezana in the 4th century AD.

beginning on the African coasts and plateaus. Thus disappeared all that still remained in Arabia of the ancient Sabaean and Minaean kingdoms, and the Ethiopians were the only remaining true heirs.

The decline of Aksum. Aksumite power began to decrease in the 7th century, and soon, as a sign of its impoverishment, the empire ceased to mint coins. Already Christianity's expansion in the civilized world had gravely affected the commercial revenues of these regions by devaluing incense and myrrh, resins important in pagan religious rites. The appearance of the Persians and the Arabs and the loss of Ethiopian possessions in Arabia cut Aksum off even further from the West. But not until later did a religious break separate the Aksumites from their Muslim neighbours. During the early years of Islām, relations between the Ethiopians and their Islāmic neighbours across the Red Sea were conducted with a great deal of mutual sympathy. This is easily explained: the Ethiopian Church retained an archaic Christianity that was very Semitic, still imprinted with the Judaism that had nurtured it, and very close to the religious syncretism from which Islām itself developed. Also, when companions of the Prophet Muḥammad fled from Arabia to Aksum in 615, they were well received and returned to their homes full of admiration for the Ethiopian emperor and his faith. Muḥammad expressed great emotion when the Aksumite emperor Armah died and advised his followers never to come into conflict with the Ethiopians.

Ethiopian fleets were active on the Red Sea as late as the 12th century, and in 702 Aksumite ships even harried the Arabian port of Jidda. Even later, the Ethiopians still kept a few possessions on the Arabian coast, such as Zabīd, which was governed by Ethiopian princes. They were no less respected on land: in the Middle Ages the Ethiopian emperors were again considered the masters of the waters of the Nile, which, according to popular belief, they could divert to the point of starving Egypt. But the city of Aksum itself declined to a point at which the seat of power was transferred farther southward, to Nazaret (now Adama), in the mountains of Tigre, while monastic establishments moved even farther to the south—for example, a great monastery was founded near Lake Haik in the 9th century. Most importantly, the land frontiers of the empire came in conflict with new peoples. To the north, along the coast extending from Egypt to Ethiopia, there appeared the short-lived kingdoms of the Naqis (on the southern borders of Egypt), then Baqlin, Bazin, Jarin, and Qata; these last two, vassals of the Ethiopian Empire, occupied the shores and part of the plateaus of the present province of Eritrea. Farther inland, Nubia was entirely Christian, adhering (according to region) either to the Byzantine or to the Coptic Church. From north to south, the kingdoms of Nobatia, Maqurrah, and ʿAlwah (Alodia) resisted the Muslim conquest energetically; not until the 16th century did ʿAlwah finally succumb, the last to do so.

Conflict with new peoples

Toward the south, the coasts of the Indian Ocean were held far back by the Bantu kingdom of the Zanj, the heir to ancient Azania, while in the ports Ḥimyarite merchants were progressively supplanted by Persian or Arabian immigrants. The Zanj kingdom did not decline until it was attacked by the Galla, perhaps from the 11th century, from the interior, and then, after the 14th century came under the attack of an entirely new people —the Somalis, from the mountains near Cape Guardafui. In the south, between the fault of the lakes and the loop of the Blue Nile, was the great Damot (Kingdom), possibly identical to the Demdem people, themselves known as being near Lake Abaya, the homeland of the Galla. A part of these turbulent populations, who were more or less converted to Judaism, launched frequent attacks against the Christian provinces of Ethiopia until the beginning of the 13th century. The most serious of these, led by a queen named Esato (Judith) around 976, laid waste the Christian empire as far as Tigre.

THE LATE MIDDLE AGES (11TH–15TH CENTURIES)

The Zague (Zagwe) dynasty. The Ethiopians saw Esato's invasion as a heavenly punishment for their having failed in obedience to the Coptic patriarchate; once delivered of it, they tightened their bonds with the Egyptian church. Then, under very obscure circumstances—perhaps at the end of the 10th century or perhaps 100 years later—the usurping dynasty of the Zague appeared in Ethiopia. Later ecclesiastical texts accused this dynasty of having not been of pure "Solomonid" stock (*i.e.*, not descended from the union of Solomon and the Queen of Sheba). The Zague, princes from the Lasta region of central Ethiopia, took advantage of the eclipse of the Aksumite sovereigns to transfer the seat of the empire to their own region. Some of them became powerful enough to war effectively against the rebels of southern Ethiopia, to counter Cairo's anti-Christian manoeuvring by threatening the destruction of Mecca, and later to send to Egypt a few elaborate embassies, which are recorded with awe in the Coptic chronicles. But the Zague distinguished themselves above all on the religious plane.

Appearance of the Zague

The Ethiopia of this period was garnering the declining traditions of the last great monasteries of Middle Egypt, the art, rock-hewn architecture, and distinctive literature from which it copied. It was also influenced by the artistic creations of foreign artists, principally Copts escaping persecutions in Egypt in the 11th and 12th centuries. These influences explain the creation by the emperor Lalibela of an admirable holy city that took its name from him. There, a dozen monolithic churches chiselled out of solid rock represent the last and most beautiful artistic expression of the Aksumite stoneworkers.

The Solomonid restoration. Late in the 13th century, partisans of the ancient Aksumite tradition suddenly swept away the Zague, who were replaced by Amhara princes from the Lake Haik region, from Geshen, and from Ambasel. The new dynasty, starting with Yekuno Amlak (ruled 1270–85), transferred the seat of the empire even farther south to Shewa (Shoa), where it remained until the 16th century. The dynasty's rise had been supported by a powerful sector of the monastic church, which proclaimed the new sovereigns to be the legitimate heirs of the Aksumite line as defined by the traditions of the *Kebra Negast* ("Glory of the Kings"). This monastic faction, most closely linked to the Egyptian monasteries of the Wādī an-Naṭrūn and to the Coptic patriarchate, was based in Ethiopia on such great monasteries as St. Stephen on Lake Haik and Debre Libanos in Shewa. In return for its support, the sovereigns gave that faction perpetual title to considerable landed benefices.

In religion and culture the authority of the Coptic Church, represented in Ethiopia by a metropolitan and his following of monks, progressively obliterated the previous Syrian and Byzantine influences. The religious inspiration of the sovereign's policies was unceasingly affirmed in the essays or commentaries of national prophecies. As heads of the church, sovereigns participated actively in the development of religious culture and discipline, as much through their bitter but ineffective battle against dissident sects, such as the Stephanites and Mikaelites (who preserved archaic Christian usages that themselves came from certain Coptic monasteries), as by their repression of surviving pagan superstitions. In addition, such sovereigns as Zara Yakob and Naod made themselves illustrious by beautifying churches and their ceremonies and by composing religious hymns.

This spiritual labour was facilitated by a renewed economic prosperity. Politically, the period was marked by rare and difficult relations with the Christian West—a situation that continued until the Portuguese appeared in neighbouring seas early in the 16th century. The most active diplomatic relations were with the sultans of Egypt. Starting in the 14th century, the empire had to face continual revolts in its southeastern provinces, where Christianity was being pushed back by the force of Islām. These revolts, first caused by economic problems (*i.e.*, the impoverishment of these regions), later took on religious tones. On the Ethiopian frontiers these movements dismembered first the pagan black kingdom of the Zanj and, more slowly, the great Christian kingdoms of Nubia to the north.

Foreign relations

Most sovereigns of this period have justly remained famous. Amda Tseyon (Amda Seyon; ruled 1314–44), who favoured the expansion of Christianity into new areas, defeated four coalitions of rebel Muslim vassals and energetically took up the defense, from a distance, of Egyptian Copts against the Sultan; his fame not only extended to the Muslims but also reached the West. The reign of Saifa Ared (Newaya Krestos; ruled 1344–72) saw the arrival of a Coptic prelate, Abba Salama, who was the author or instigator of numerous translations of Arabic Coptic works into Ge'ez. Dawit (David) I (ruled 1382–1411) obtained in Ethiopia certain highly venerated relics, including an alleged piece of the true cross and an icon representing Christ crowned with thorns, legendarily attributed to St. Luke. Also in Dawit's reign the collection of *Miracles de la Sainte Vierge*, written in France in the 12th century, was translated and introduced into Ethiopia. Yeshaq I (ruled 1414–29) recaptured the port of Zeila from rebel Muslims in 1415 and had the churches there rebuilt. He tried to pacify the northeastern regions, where the judaicized Ethiopians (the Falashas) were in revolt. Cairo suspected him of plotting with the Latins, and, in fact, he had relations with the King of Aragon and with Jean, duc de Berry, in France. These relations were continued, in spite of extreme difficulties, in the time of Zara Yakob (ruled 1434–68), who sent Ethiopian ecclesiastics as delegates to the Council of Florence in 1439. Baeda-Maryam (ruled 1468–78) and Eskender (ruled 1478–94) were distinguished by their struggle against rebellious Muslims. Under Naod (ruled 1494–1508), attempts to initiate some contact with the West became more effective. These efforts even led to the arrival, in 1520, of a Portuguese ambassador, who was received favourably by Lebna Dengal (ruled 1508–40). This meeting was finally possible because the Portuguese had just reached the Red Sea and had eliminated the monopoly held by the Indian and Egyptian fleets.

Arrival of the Portuguese

ETHIOPIA IN THE MODERN PERIOD (SINCE 1500)

Contacts with the Turks and Portuguese (1520–1632). Catholic Europe had been attracted to Ethiopia by the legend, fabricated in the West at the time of the Crusades, that far in the East there was a powerful Christian sovereign, Prester John, whose alliance would have been helpful against Islām. He had at first been vainly sought in Central Asia, where there were Nestorian Christian princes; then he was thought to have been an Ethiopian emperor, about whom there were analogous legends. Also, the discovery of Ethiopia by the Portuguese, starting in 1520, had received as much attention in European literature as had the discovery of America. But this encounter was not to Ethiopia's advantage; the Egypto-Indian fleets that the Portuguese chased from neighbouring seas were quickly replaced by those of the Turks, who had conquered Egypt in 1517 and who had installed themselves in Arabia. The Turks came into conflict with the Portuguese and proceeded to take issue with the latter's allies, the Ethiopian Christians. Lebna Dengal's reign became clouded in the aftermath of these events. His empire was immediately devastated by the worst Muslim invasion the country had yet seen. An uprising started in the southeastern regions, impoverished by the breakdown of a commerce that had been allied to the recently departed Egypto-Indian fleets. This revolt was immediately supported from Arabia by the Turks; it lasted from 1523 to 1543. In 1541 a Portuguese troop, small but well-armed and led by Dom Cristóvão da Gama, brought unexpected help through Mitsiwa (Massawa). The *imām* Aḥmad Grāñ, "the Left-Handed," leader of the Muslim invasion, was killed in the Battle of Waina Dega on February 21, 1543. Though his armies were at first immense, many in them had perished, and, as a result, the southeast provinces were left even poorer than the Christian provinces they had devastated. In spite of that victory, Galawdewos (Claudius; ruled 1540–59) suffered a few last assaults from Harer and himself fell in battle. By then, other peoples—the Galla and Somali—were dividing the spoils of the ancient Muslim provinces that had once extended from Harer to Zeila.

Minas (ruled 1559–63), Sartsa Dengal (ruled 1563–97), and Susenyos (ruled 1607–32) had to face three new problems: Turkish attempts on the coasts of the Tigre, from whence they were dislodged definitively by Ethiopian victories in 1578 and 1589; a great migration of the Galla, who expanded over almost the entire empire; and Roman Catholic propaganda by missionaries who, sent by St. Ignatius of Loyola, arrived with the Portuguese soldiers. The missionaries wished to convert the country to the Catholic (Chalcedonian) faith, and they were so successful that the emperor Susenyos thought he could proclaim the country's conversion in 1626. This transformation was all the more natural, because the Egyptian Coptic Church had itself recently attempted a short-lived union with Rome (1595–1610). Unreasonable demands of the missionaries in Ethiopia quickly raised against themselves and the Emperor great numbers of Christians who adhered obstinately to their ancient faith; and, in 1632, in the face of raging civil war, Susenyos was forced to revoke the union with Rome and to abdicate.

Arrival of Jesuit missionaries

Gonder Ethiopia (1632–1855). This period of Ethiopian history is comparable to the Western Renaissance, of which it was, in certain aspects, the inheritor. Architects, inspired by Indo-Portuguese models introduced by missionaries, produced splendid castles and abbeys. Miniatures were influenced by Western engravings, which had arrived by way of India—those of the Mughals as well as those of the Portuguese. The art of war evolved under Portuguese influence, and armies were formed that would later defeat the Egyptians in 1879 and the Italians in 1896. But this 16th-century Ethiopia, provoked by the Catholic missionaries, closed itself to the Latin West and threw itself into the arms of the Egyptian Coptic Church. It limited its relations to the Muslim powers—Egypt, the Ottoman Sublime Porte, and Mughal India—and to such non-Catholic Westerners as the Lutheran Peter Heylig, the Scottish James Bruce, and the governors of the Dutch Indies.

Fasilides (Basilide; ruled 1632–67) expelled the missionaries in 1633. He founded a new capital, Gonder, and began to build its first palace. Yohannes I the Just (ruled 1667–82) continued his work. Iyasu I (ruled 1682–1706), made a saint by the church, further developed and beautified the city, which, with 100,000 inhabitants, became the second largest city (after Cairo) in Africa. Iyasu brought about humane reforms in the administration, quelled controversies among rival theological factions, and, by his wars, provisorily re-established his authority over the provinces of the south, from which Christianity had been swept away by the pagan Galla. Baqaffa (ruled 1721–30) died too soon to effectively pursue that great work, but his widow, the empress Mentewab, watched over it with wisdom for some 40 more years during the reigns of her children and grandchildren, upon whose advent she, almost each time, exercised a regency. Of these the most brilliant was Iyasu II (ruled 1730–55), who, with Mentewab, had the splendid Abbey of Kusquam built. Iyasu II's armies, however, suffered a costly defeat at Sennar, from which the Fung Muslims had recently swept the Nubian Christians.

Founding of Gonder

To free himself from Mentewab's tutelage, Iyasu II tried to ally himself with the Gallas; he married the daughter of one of their chiefs and introduced Galla warriors into the capital, provoking troubles that became more accentuated after his reign, under Iyoas (ruled 1755–69). The notables appealed to one of the most able Tigre warriors of the empire, Mikael Sehul, to expel the newcomers. Mikael took advantage of the situation to impose himself on the sovereigns; he had the resisting emperor Iyoas assassinated, removed Mentewab, and then himself named the emperors he wished. Tekle-Haimanot II (ruled 1769–77), who was at first submitted to this tutelage, was freed from it in May 1771 thanks to the battles of Sarbakussa, in which the Scotsman Bruce participated. But the empire, still caught between the rival ambitions of the Galla and the Tigre, saw the development, in its government and mores, of a feudal spirit that had been previously unknown and the vestiges of which would continue into the 20th century. Affected

by this decadence, the end of the Gonderian age is known as the "time of the princes," a period in which, at the whim of the new Galla lords or of the Tigre, princes who succeeded one another were from the Solomonid line but had no army, riches, or power.

Reunification (1855–1935). Ethiopia's revival, aided by the church, began simultaneously in the Gonder region and in the province of Shewa, which was kept isolated from the previous troubles by its kings, who descended, as did the Gonderian emperors on another branch, from the line of Lebna Dengal. Ethiopian anger toward the feudals was awakened by the propagation of Islām, undertaken by certain Galla lords, and at the same time by the inability of these leaders to defend against unprovoked attacks that Egypt, already master of the Sudan, was launching against Ethiopia. This anger found a leader in Kassa, a chief of partisans organized against the Egyptians. It was Kassa who gathered enough troops to overthrow the phantom of empire that the feudals had maintained around Gonder.

Anger toward the feudals

Tewodros II. In 1855 Kassa had himself proclaimed emperor under the name of Tewodros II (Theodore; ruled 1855–68). He blamed the ancient Gonderian splendour for the national decadence; he thus despoiled the city of its treasures and established his residence in the austere central mountains. During this period the Western powers were competing to establish themselves in this eastern part of Africa. A misunderstanding with the British government resulted in a punitive expedition led by Lord Napier in 1868; Tewodros chose to kill himself in besieged Magdela rather than fall into the hands of British soldiers.

Yohannes IV. Yohannes (John) IV (ruled 1872–89), an ardent religious reformer, hastily converted the Muslim and pagan populations to Christianity. He defeated Egyptian colonization attempts at Gundet and at Gura (1877). Although he managed to have his rights to the northern part of his empire respected, he failed, through both diplomacy and arms, to prevent the establishment of the Italians at Mitsiwa, where they were introduced by the English to provide aid for the defeat of Mahdism in the Sudan. Furthermore, the Ethiopians were themselves in conflict with Mahdists, who laid waste to Gonder in 1888. Yohannes fell under their blows while winning the Battle of Metemma in 1889.

Menelik II. King of Shewa from 1864, then emperor of all Ethiopia upon the death of Yohannes IV, Menelik II (ruled 1889–1913), in the south, carried out defense policies similar to those of Yohannes in the north, stopping or restraining foreign colonization by arms or by diplomacy. As early as 1871 he attempted to reconquer all the southern provinces that had escaped imperial authority after the 16th century. The Egyptians, established since 1870 on the African coasts of the Gulf of Aden, had taken Harer in 1875 but had less success at Aussa. In 1887, the same year that he founded the new capital, Addis Ababa, Menelik retook Harer. But he came up against the British in the territories that later became the Somaliland Protectorate and against British manoeuvres (despite an Anglo-French treaty of 1888 protecting Ethiopia) attempting to install Italians at Zeila and to open access to Harer for them. In 1889 Menelik II concluded the Treaty of Uccialli with the Italians, which allowed a certain Italian penetration into Eritrea; but he insisted, nevertheless, that on paper, because of a difference between the Ethiopian and Italian wording of this agreement, he had been cheated. He protested, denounced the treaty, and addressed a circular letter to the great powers, defining the ancient frontiers of his empire and proclaiming them sacrosanct. The Italians invaded Tigre, and Menelik II repelled them, finally defeating them in 1896 at Adowa. France, Great Britain, and Italy immediately signed treaties with him (1896–97), limiting their ambitions. After 1892 Menelik entered into a cooperative agreement with France that included plans for a Franco-Ethiopian railroad linking Obock to the Upper Nile along one of the great medieval commercial routes—a project that would have contradicted British plans for linking Cairo to the Cape. With the Mahdists paralyzing the British, Menelik, in 1898, undertook with France to conquer the Upper Nile. But the Franco-Ethiopian expedition was unsuccessful. In addition, in the following weeks English successes against the dervishes permitted the British to dislodge the French captain Jean-Baptiste Marchand, who had been trying to meet the Franco-Ethiopian expedition, from Fashoda (Kodok). As a result, the Franco-Ethiopian railway would not go past Addis Ababa (which it reached in 1917), and, in 1902, an Anglo-Ethiopian treaty forbade the Ethiopians to make free use of the abundant annual floods of the Blue Nile (Ābbay River), the waters of which are indispensable to the prosperity of the Sudan and of Egypt. Menelik was ill in 1906 when, in a tripartite treaty, the Italians, British, and French gave themselves new rights to his empire, and he had to accept a vague treaty between his government and Italy in 1908 for the delimitation of Somalia. This last treaty later gave Italy a pretext for claiming part of the Ogaden region and launching aggression in 1935 (see below).

Agreements with foreign powers

Menelik died in 1913, seven years after the death of Ras Makonnen, who was to have been his successor. Gravely ill, the Emperor had allowed a regency to be instituted in 1907, until his grandson, Lij Iyasu, could reign. But after May 1911 Lij Iyasu, although only 15, rejected all tutelage. He showed himself to be incapable of governing; and, by his tendencies toward Islām and by his alliance with Muḥammad ibn ʿAbd Allāh Ḥasan (the "Mad Mullah"), who had revolted against the British and Italians in Somalia, he seeded defiance among his subjects during a period—World War I—when the Germans and the Turks were trying to gain control of Ethiopia. In 1916 the church and the nobles decided to remove Iyasu, who had not yet been made emperor, and to make Menelik's daughter Zauditu (Zawditu) empress with the assistance of a regent—Ras Tafari, the son of Ras Makonnen, who was proclaimed heir apparent to the throne.

The regency and early reign of Ras Tafari (Haile Selassie I). Zauditu (ruled 1917–30) was crowned on February 11, 1917. Lij Iyasu's reversal saved Ethiopia; tied by Iyasu to the Germans and the Turks, it would have been dismembered by the victorious allies as an enemy power—already the Treaty of London (1915) had promised Ethiopia to Italy—but the proclamation of 1916 had placed it under Ras Tafari's regency in time. Thanks to Tafari's diplomacy, Ethiopia was admitted to the League of Nations (September 28, 1923), which authorized it, in 1926, to protest energetically against a new plan for division of influence drawn up by the British. In order to modernize the country, the Regent had to remove certain feudals and, above all, to regain for his country the outlets to the sea that had been lost to the Italians, French, and British on the former Ethiopian coasts of the Red Sea and the Gulf of Aden. Great Britain offered Ethiopia an outlet through Zeila or Berbera. Italy offered the use, duty free, of the port of Aseb (Assab), a solution which was accepted by a treaty of August 1928 but without follow-up. On April 2, 1930, Zauditu died; Tafari, already crowned king (*negus*) in October 1928, became emperor the next day. On November 2 he was crowned under the name Haile Selassie I.

The crowning of Haile Selassie I

Upon his accession to the throne, Haile Selassie gave his country a constitution (July 16, 1931) and began a vast program of modernization, immediately sanctioned by the opening of an Ethiopian parliament. But international factors accumulated dangers for the country. These included the consequences of the Great Depression, the results of postwar bargaining among the Allies, and Mussolini's desire to avenge the disaster of Adowa and to appropriate Ethiopian territory. Although Ethiopia was Christian, civilized for centuries, and a member of the League of Nations, it could not escape these appetites.

The Italian invasion and occupation (1935–41). Mussolini's plans for conquest emerged in 1928–30, when the Italians began to remove from their maps the roughly outlined frontier between Ethiopia and Somalia, which had been agreed to in 1897 and 1908 but which now seemed too narrow for Italian ambitions. In the international press they paid for an intense campaign against Ethiopia, which did not have the means to defend itself.

The dispute was brought before the League of Nations; the Assembly initiated discussions between the two parties on what seemed to be the basis of the problem: the drawing of the frontier in the Ogaden. But the documents of the treaty of 1897, the basis of the frontier definitions of 1908, had been lost by the Ethiopians, and the Italians asserted that their copies of these same documents were, inexplicably, not to be found. Discussions between December 1934 and March 1935 led to an impasse, and, in spite of the principles of the League of Nations, even the British foreign secretary, Sir Samuel Hoare, and the French premier, Pierre Laval, were resigned to the establishment of an Italian protectorate over Ethiopia (the Hoare–Laval division plans). Italy had massed considerable troops on the Ethiopian frontiers, while the Emperor, through a desire for peace, had retired his troops to about 20 miles (30 kilometres) behind these same boundaries. On October 3, 1935, without a declaration of war, the Italians invaded Ethiopia from Eritrea and Somalia. Sanctions placed on Italy by the League were ineffective. Ethiopia resisted for seven months, but Addis Ababa was taken on May 5, 1936. On June 30 the Emperor personally defended his nation's cause before the League. But Rome had already proclaimed Ethiopia's absorption into its empire, and the League, in taking action, excluded Ethiopia from its debates. (There was an unexpected consequence, however. Egypt, caught between two Italian colonies, one of which controlled the waters of the Blue Nile, became disturbed to the point that the British accorded it independence in August 1936.)

The Italians executed Archbishop Petros (the Coptic *abuna*, sent from Egypt as head of the Ethiopian Church), massacred the monks of the great monastery of Debre Libanos, and, after an attempted coup, decimated the population of Addis Ababa during a three-day period in February 1937. Certain regions of Ethiopia, however, were never conquered. Alliance with Germany in World War II led Italy to invade the British territories of Somaliland, but the British and the free French immediately replied by aiding the Ethiopian partisans and thus delivering Ethiopia. Emperor Haile Selassie returned to his liberated capital on May 5, 1941.

Liberation of Ethiopia

Ethiopia after the liberation. Ethiopia was at first regarded by Great Britain as a conquered Italian colony. It was returned to the Emperor's authority only after agreements in January 1942 and December 1944, except for the Ogaden, which the British kept under military administration until 1948, and Eritrea, which was not reattached to the empire until 1952 and then in a federative form, after a referendum organized by the United Nations; it was finally reunited in 1962. Because it had been removed from official maps as a free nation since 1936, Ethiopia was given incomplete rights in the postwar peace negotiations.

Postwar revival. It took strong efforts by the imperial government to revive Ethiopia after the war. To return the nation to its place in international life, the Emperor appealed to the United States for aid; early in 1945 he met Pres. Franklin D. Roosevelt in Cairo. Several months later he ratified the United Nations charter at San Francisco. A mutual defense treaty with the United States was signed in 1953. The founding of Ethiopian Airlines, sponsored by the U.S.-based Trans World Airlines (TWA) in December 1945, provided the country with vital internal communications and facilitated contact with the rest of the world.

Constitution of 1955

Celebrating the anniversary of his coronation in a resurrected Ethiopia, Haile Selassie I in November 1955 proclaimed an extension of the constitution of 1931; the first general elections to the Chamber of Deputies were held in 1957. An attempted coup d'etat in December 1960 was easily put down. Technical developments, primarily in the highway network, air communications, and electrification, made use of Ethiopia's inexhaustible hydroelectric resources. Education was improved, based on the use of English, together with Amharic, the national language, as a language of instruction; after 1966 French, the principal foreign language before the Italian conquest, officially took the third rank. A university was founded in Asmera (1958), and the university college in Addis Ababa was raised to university status (1961). Considerable work in sanitation was accomplished, primarily in the towns.

Religious reforms. The constitutions of 1931 and 1955 affirmed the traditional religious freedom accorded Ethiopian citizens. By an agreement of 1959, the traditional subordination of the Ethiopian Church to the Coptic patriarchate was reduced to a simple honorary attachment. The Ethiopian Church won international religious prestige that allowed it to push other Eastern "non-Chalcedonian" churches into regrouping; a conference was held in Addis Ababa in 1965, presided over by the Emperor. Renewal of relations with the papacy, broken off since 1632, was sanctioned in June 1969 by a meeting between the Emperor and the Pope in Geneva and, later, by a visit of the Emperor to the Vatican (November 1970).

International relations. In international politics Ethiopia especially dedicated itself to promoting African unity and progress. The charter of the Organization of African Unity, prepared by several conferences, was proclaimed at Addis Ababa in May 1963; the Ethiopian capital had become the principal centre of inter-African conferences.

Regional problems. The regional problems were the legacy of earlier foreign colonization. Thus, the independence of Somalia (1960), formerly two colonies, resulted in complications for Ethiopia. The expansion of the Somali people into the Horn of Africa was a result of the depopulation of the Ethiopian Muslim provinces during the wars of the 16th century. The newcomers had moved southward at the expense of more ancient inhabitants, Gallas and Zanj Bantus. International attempts to obtain, by agreement between Ethiopia and Italy, the delimitation of a precise frontier between Somalia and Ethiopia before Somalia became independent were in vain; Italian representatives again took recourse to arguments founded on the mysterious disappearance of the 1897 treaty documents. From this point there developed among younger Somalis the myth of the greater Somalia, which could be created only by taking certain territories from neighbouring countries, including the Ogaden region from Ethiopia. An intense campaign of anti-Ethiopian propaganda among the Somalis was the prelude to armed confrontation (February–March 1963). After several years, patient diplomacy on the part of enlightened persons on both sides seemed to have restored peace, but the problem was not settled.

Somalia–Ethiopia difficulties

A problem in Eritrea stemmed from analogous causes. In 1962 the Eritrean parliament spontaneously demanded that the province's territory, placed in federative status in 1952, should regain provincial status within the empire. This land, before the Italian colonization, had been one of Ethiopia's oldest provinces, dotted throughout with ancient Christian sanctuaries as well as with historic battle sites. Foreign colonization, propagation of Roman Catholicism, and immigration of Muslims had scarcely affected the Ethiopian character of the region. After 1966 local discontent emerged in Eritrea, which is particularly deprived of natural resources and the needs of which neither Ethiopia nor the occupying Italians had been able to fulfill. A revolt broke out, led by a group known as the Eritrean Liberation Front.

(J.P.Do.)

The fall of the monarchy and after. In 1974 dissatisfaction with the long-established order in the empire of Ethiopia finally amassed sufficient force and popular backing to initiate a process of fundamental change. The movement began in mid-February, when strikes and demonstrations by students, taxi drivers, and trade-union organizations paralyzed life in Addis Ababa. The civilian demonstrators were joined by units of the armed forces, motivated by a number of considerations including a demand for increases in pay. After a series of events that included changes in the Cabinet and widespread action against corrupt officials, the movement culminated on September 12 in a proclamation ending imperial rule and in the deposition and imprisonment of Emperor Haile Selassie. The throne was offered by the Provisional Military Administrative Council—composed of 120 members

of the military forces and the police—to Haile Selassie's named heir, Crown Prince Asfa Wossen. According to the council, the king would act as chief of state but would have no constitutional powers.

These changes were accompanied by measures against the old ruling group of aristocratic families and palace appointees. On November 23, 59 of these, including the last two prime ministers and 18 generals, were summarily executed, and on December 4 a military tribunal began trying former officials on charges of corruption and maladministration. In a policy statement on December 20, the council announced that it would turn Ethiopia into a socialist country with a one-party system, collective farms, and direct government control over all property useful for economic progress.

The monarchy was abolished entirely in March 1975. The proclamation issued by the military council annulled the appointment of Crown Prince Asfa Wossen as king-designate, cancelled the titles of prince and princess, and stated that the Ethiopian people should decide what type of government they wished.

Drought and famine. Thousands of persons—at least 50,000 and perhaps as many as 100,000—died in 1973, particularly in Shewa, Welo, and Tigre provinces, of the effects of a severe drought. By mid-1975 a still worse drought was being predicted, this one centring on the Ogaden region, bordering Somalia. About 500,000 persons were affected, according to official sources.

Eritrean revolt. In December 1974 the Eritrean Liberation Front and a second, more Marxist-oriented guerrilla group that had broken away from it, the Popular Liberation Front, intensified their struggle against the central government. Early in 1975, open warfare between government troops and guerrillas broke out. It continued sporadically thereafter, with considerable loss of life. Popular opinion in Eritrea appeared to be turning more and more toward the guerrillas, and Eritrean independence was attracting more and more supporters. Loss of Eritrea was abhorrent to the government in Addis Ababa: it would mean to Ethiopia the loss of its only seaports and its only petroleum refinery. (Ed.)

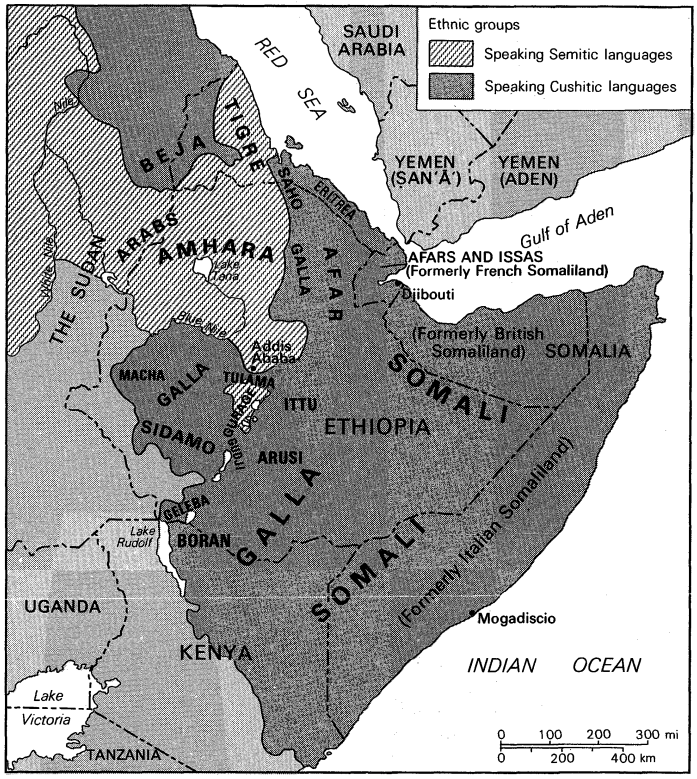
Ethiopian and Somalian Cultures

Ethiopia is a large and ancient state in Africa, with 26,000,000 inhabitants and a history of independent sovereignty extending back at least 2,000 years. Discounting the brief Italian intrusion (1935–40), it was the only traditional empire to survive the colonial partition intact. From those early centuries to the present, Ethiopia has been ruled by leaders drawn almost exclusively from the two dominant ethnic groups: the Semitic-speaking Tigre and Amhara. Ethiopia is thus essentially the political expression of the cultural nationalism of these two closely related peoples, who derive from a fusion of local Cushitic-speaking stock with South Arabian immigrants who settled along the Red Sea coast in the 1st millennium BC.

Ethnic and political origins

The Tigre occupy the northern part of the central Ethiopian Plateau, which consists today of the provinces

From J. Trimingham, *Islam in Ethiopia*



Distribution of Ethiopian and Somalian cultures.

of Tigre and Eritrea and contains the ancient capitals of the empire: Aksum, Gonder, and Lalibela. For over half a millennium, however, power has lain mainly with the Amhara, who live in the southern part of the plateau in the provinces of Begemdir and Simen, Gojam, and Shewa —the seat of government since 1889.

The central Ethiopian Plateau is a generally well-watered and pleasant land producing the indigenous cereal teff (*Eragrostis abyssinica*), as well as wheat, barley, and, in the drier regions especially, maize and millet. Cattle and other stock are reared, the land being tilled by ox-drawn plow. In the lower and hotter southern regions, the false banana, known locally as ensete (*Musa Ensete*), is the main crop, and coffee—which is indigenous to Ethiopia and may be named after a local tribe, the Kafa—is produced as a cash crop. There, for the most part, the hand hoe replaces the ox-drawn plow in cultivation. This ensete-growing region is the home of the Gurage (a Semitic-speaking but partly Cushitic people), of the Cushitic Sidamo-speaking peoples, and, to the southwest, of a few other, more distantly connected peoples, whose linguistic affiliation remains a matter of controversy.

By far the most important Cushitic group, however, is that of the Galla, who number some 10,000,000 and form the largest ethnic unit in northeast Africa. They occupy most of the southern provinces of Ethiopia, with the related Somali on their eastern and southern flanks, and seem destined to play an increasingly significant role in the political development of Ethiopia.

The Galla

The pastoral nomadism that forms their traditional way of life is best preserved today among the Boran (Borana) Galla, who live in the hot dry lowlands of southern Ethiopia and northern Kenya. It is from this region that the many different subdivisions of the expanding Galla nation began their invasion of Ethiopia in the 16th century, sweeping relentlessly in wave after wave into the Christian highlands, where the embattled Amhara and Tigre were unable to check their advance. Those Galla who moved into the rich central highlands, such as the Macha and Tulama, abandoned their nomadic economy and became sedentary cultivators; others, such as the Arusi and Gudji, in the less favoured areas sought to combine both modes of livelihood. Many became Christians, adopting Amhara culture; others embraced Islām, although this was not necessarily incompatible with adopting other aspects of Amhara culture.

The inability of the Christians to withstand the Galla invaders (over whom, however, they later re-established their ascendancy and finally incorporated as subjects in the empire) shows the extent to which Ethiopian fortunes had been reduced by the ceaseless wars of the period with the surrounding Muslim Sidamo and other largely Cushitic sultanates.

The Cushitic Somali became fervent Muslims and put increasing pressure on the southeastern flank of the Galla, thus helping to sustain the latter's continued thrust into Ethiopia. After a long period of turmoil, adjustment, and the re-emergence of Amhara ascendancy, under the forceful rule (1889–1913) of Menelik II, Ethiopia assumed its modern shape. The coast was conceded to the British, French, and Italian colonizers.

Thus, despite their crushing defeat at Adowa by the Ethiopians in 1896, the Italians were allowed to retain the largely Muslim and partly Cushitic territory of Eritrea, which was not returned to Ethiopia until after World War II.

The Somali

Notwithstanding their strong sense of cultural nationalism, the Somali had not previously formed a single political unit, and they were partitioned among the Ethiopians, Italians, British, and French. The French also acquired the closely related Cushitic-speaking Afar (or Danakil) to form their tiny colony around the port of Djibouti. In 1960 the British and Italian parts of the Somali nation became independent and joined to form Somalia (formally known since the coup of 1969 as the Somali Democratic Republic), leaving about a quarter of the total Somali population of 4,000,000 still under alien rule in the neighbouring areas of eastern Ethiopia, northern Kenya, and the minuscule French Territory of the Afars and Issas. Formerly known as French Somaliland (the Issas are a Somali clan), this arid land contains about 100,000 inhabitants, mainly nomads or urban workers.

Traditional ethnic and religious rivalries are thus perpetuated today by the coexistence of a state based on Somali identity (but not yet including the whole nation) and the ancient state of Ethiopia, which, like most of its more recently formed neighbours, includes within its borders a variety of different peoples and tribes. In the three countries the greater number of inhabitants happen to be Muslim in religion and (like the Somali) Cushitic in ethnic affiliation.

TRADITIONAL CULTURE PATTERNS

General characteristics: ethos. The world views of the Christian and Muslim peoples of the region are uncannily alike, and, even in particular aspects of belief and ritual, they reveal many striking resonances. Both believe strongly in a morally significant afterlife and are thus capable of accepting present misfortune and illness with fatalistic resignation. Both are also equally adept at seeking alternative mystical explanations of distress and of resorting to supernatural agencies to seek redress. Otherworldly fatalism is thus tempered by a healthy pragmatic concern for present well-being. Those Galla and Sidamo who retain their traditional cosmologies (and few have remained entirely unaffected by Islām or Christianity) are more firmly anchored in the present and entertain few if any hopes of eternal bliss or fears of eternal damnation.

Differences of outlook and attitudes

The most obvious contrasts in cultural outlook and ethos follow the division between cultivator and nomad. The Amhara–Tigre farmers of the highlands are sturdy, canny peasants whose ready deference to their social superiors conceals hostility and suspicion. Their strongly individualistic and shrewdly calculating attitudes suit their hierarchical but far from closed status system and kinship organization.

Specialist crafts, such as weaving, leatherworking, and ironworking, are traditionally despised, and their practitioners are associated with the evil eye. Other artisan work, unskilled manual labour, and even trade are also considered degrading. Specialist minority groups—such as the Dorse weavers or the Cushitic Falashas (the "Black Jews"), who do a considerable amount of ironwork and pottery—are thus able to establish ethnic monopolies. Similarly, the traditionally disparaged Gurage have acquired a leading role as manual workers in Addis Ababa, and, until quite recently, trade has tended to be monopolized by Muslims.

The ethos of the nomads reflects their egalitarian social structure. Their aggressive self-assertiveness contrasts strongly with the deferential respect of the Amhara peasantry. Pragmatic individualism is tempered by the wider demands of the kinship group. Intense and violent competition rages over access to the sparse resources of the environment—grass and water—on which life depends. Enmities and alliances tend to be ephemeral and shifting, the definition of friend and foe constantly changing. In this, the much divided Somalis, whose constituent fractions are regularly embroiled in savage feuds, contrast with the Galla, whose component groups place a high value on internal peace and count the killing of one of their own fellows as a sin. Yet all these warrior nomads—whether Somali, Galla, or Afar—hold a similar heroic view of life, in which prowess in battle and raiding is the essential manly virtue. The weak and vulnerable receive a certain condescending compassion that is associated with the idea that they may possess special (compensating) mystical powers. In a world in which essentially might is right, however, true prestige is accorded only to those who are manifestly strong and successful.

Descent systems

Social structures. *Territorial, family, and kinship organization.* Groups based upon descent from a common ancestor play some role in the social organization of all the peoples mentioned. Generally, it is patrilineal descent (traced through male ancestors on the father's side of the family) that is of most significance in the inheritance of property and status and in group formation. It is weakest among the Christian Amharas, who regard kinship links traced either through women or men as equally binding. This bilateral kinship system is employed to build up loosely defined clusters of kin each associated with a particular parish or part of a parish. The church-centred local community forms the primary unit in the Amhara administrative system and consists of a series of scattered hamlets rather than a clearly defined village. Through their bilateral kinship ties, its members hold (in principle at least) inalienable use rights (*rist*) in the parish's arable land. These landholding kinship groups are exogamous: descent from a common ancestor over a span of seven generations constitutes a barrier to marriage. Amhara kinship connections, with their important property and status implications, thus ramify widely and enable the poorer peasants to indulge at least vicariously in the fortunes of their distantly related higher placed kinsmen. Clans as such do not exist.

Among the other mainly Cushitic-speaking peoples (including the Semitic-speaking Gurage), descent is more strictly patrilineal, and conventional kinship groups such as patrilineages and clans occur at various orders of social grouping. Where sedentary cultivation is practiced, as among the central and northern Galla, the Gurage, and the Sidamo, there is a tendency for particular clans, or their constituent lineages, to be associated with particular localities. Communities may contain the members

of several separate descent groups, but one of these is identified with a given locality.

The extent of clan and lineage development and ramification is largely a function of the size of the tribal units involved. The Galla, for instance, comprise at least eight major tribes, ranging from the most traditional and largely pastoral Gudji and Boran in the south to the strongly Amhara-influenced, cultivating Tulama and Macha around Addis Ababa. In the large units, kinship is only an ancillary principle of association, supplementing more important ties based on shared membership of an age or generation class, or "set." According to the so-called *gada* system, all the Galla male children of the same generation formed an indissoluble fraternity; and, as members of this fraternity, they moved through the various stages of life and positions open to them. The generation sets held in turn the statuses of bachelor-warriors and later of married elders, each set occupying a given grade for a period of approximately eight years. Each generation eventually supplied the lawgivers and rulers of a given Galla tribe and then retired to make way for its successors.

Galla generation sets

This form of government was essentially democratic and republican since there was a constant rotation of officeholders and each generation set elected its own leaders who, when the time came, would rule the tribe as a whole. The traditional political system was altered radically, however, as the Galla expanded northward and many groups changed their location and economy. Political changes also were influenced by the larger Amhara centralized system and by the adoption of either Islām or Christianity, which were often invoked to legitimize new structures of authority.

The *gada* organization provided the strong sense of cohesion that even large nomadic groups such as the Boran were able to achieve. Age-set organization and descent are also significant principles in the local organization of the Sidamo people. But it is among the Afar and certainly the Somali that descent becomes the most significant principle of social and political allegiance. Ties based on common residence in a given area count for less among the northern pastoral Somali than is true of any other group in northeast Africa, and patrilineal kinship is nowhere more important or more heavily utilized in group formation. The Somali nation possesses a single, all-embracing genealogy in which every member can trace his descent often over more than 30 named generations from the legendary eponym Samaale.

Patrilineal descent, given specific range and content by contractual treaties, provides the key to the traditional Somali political and legal system. Such treaties result in the formation of distinct politico-legal units, containing a few thousand male kin (and their dependents) who have agreed to meet all liabilities in concert. On this basis, if the parties involved in certain deaths and injuries wish to avoid feuding, they can collectively adjudicate their differences through a system of mutual compensations that aim at a kind of balance of payments. So while lineages of the nomads are not identified with any locality, whenever the need arises scattered kinsmen rally together to attack their foes or defend their interests.

Political organization and stratification. In terms of stratification and degree of hierarchically organized government, the republican Somali and Galla stand at one extreme, with the Amhara–Tigreans at the other; the Afar and Sidamo lie between these two poles. Among the Somali pastoral nomads, decision-making is in the hands of ad hoc assemblies of elders, in effect all the adult men involved in a given context. Some Somali clans have traditional clan heads, usually styled "sultans," who are normally little more than *primus inter pares*, symbolizing the general (but not always actualized) unity of this level of grouping. Parallel, though slightly more formalized, arrangements exist in the *gada* system of the Galla.

Among the southern Somali, who, in contrast to their northern kinsmen, are largely sedentary cultivators in the zone between the Shebelle and Juba rivers, a slightly more stratified political system has developed. Political units there are essentially fixed territorial units, and each has a clearly defined representative hierarchy from the village elders to the tribal chief (known by the hybrid Italian–Arabic title of *capo qabila*) at the top. Before their liberation by the Italian colonizers, imported Swahili slaves and local subject Bantu groups were employed by the stronger southern Somali tribes as agricultural labourers, the superior Somali leading the life of pastoral aristocrats. Although the Somali "nobles" or freeborn were more hierarchically organized than the camel-herding nomads, decision-making was still loose and flexible and very different from the proceedings in the more strongly centralized Bantu kingdoms.

The political system of the Afar represents a further step in the direction of stratification. Throughout Afar society runs a cleavage between noble, or "red," groups and subject, or "white," groups, a type of division that also occurs among the Beja pastoralists of Eritrea. The greatest political centralization is achieved by the Afar sultanate of Aussa, a lonely oasis in the Dankali Desert.

Whatever new light archaeology or new historical discoveries may shed on these matters, there can be no doubt that the major centralized political system of the region is that of the Amhara–Tigreans—one of the longest lived states in the known history of mankind. Like so many others, its origins lie in conquest and cultural and ethnic diversity, and it has been dominated throughout its history by the familiar struggle for supremacy between the contradictory pulls of the centre and of the periphery. The emperor's title "king of kings" exultantly expresses the triumph of the central power over the many parochial seats of authority within an empire that is essentially a confederation of kingdoms and principalities. So traditionally the emperor, the "Conquering Lion of Juda"—presently the ruler of the state of Ethiopia—is essentially a war leader, and his court a peripatetic military headquarters with most of his courtiers and ministerial advisers bearing military titles. As God's vice regent on earth and styled the "Elect of God," the emperor rules by divine right, enjoying a special relationship with God that is commemorated in alleged descent from King Solomon and finds expression in imperial ritual and ceremonial. There is traditionally no fixed rule of succession, however. The claim to Solomonic descent is in principle shared among all the Amhara–Tigreans through their wide-reaching bilateral kinship system. This, of course, is the source of the system's flexibility, which enables successful local leaders to aspire to and sometimes achieve the emperorship.

The significance of the empire

Thus supreme power lies with him who can grasp and hold onto it, and to this extent, despite its strongly hierarchical appearance and the inevitable tendency toward aristocratic entrenchment, the system is a partly open one. The successful claimant, however, also requires the support of the Ethiopian church and its head, the *abuna*, who solemnly enthrones and anoints the monarch and administers the oath of fealty that binds his subject princes and leaders to him. Feudal titles are dispensed anew by each imperial incumbent. These titles usually carried with them rights known as *gult*, which entitled those who held them to exact tribute and labour service from the local peasantry, and each lord maintained his own court and subdignitaries in the style of his ultimate master, the emperor. Especially before the establishment of modern communications and military equipment, immense personal energy and skill in statecraft were required of those who held the throne. Their authority was constantly menaced by ambitious rivals and by the many religious, ethnic, and other lines of division within the empire. What is surprising is not that Ethiopia frequently dissolved into a series of warring kingdoms and principalities but that it survived as a unitary empire into the modern era.

The spectrum of political types and degrees of centralized statehood with which this discussion began provides a convenient outline of the main traditional political systems of the region. It omits, however, to mention one of its most widespread features: the existence of despised occupational groups, or "castes," associated with hunting,

fishing, and such crafts as leatherworking and ironworking. Such traditionally despised, and mystically dangerous, endogamous groups occur among all the peoples of northeast Africa and are treated similarly whether they live among the hierarchical Amhara or the democratic Somali. Although, as is usually argued by their more powerful hosts, such pariah communities may derive in part from an early (or autocthonous) population, they have almost certainly also been frequently enriched by dropouts from the very ethnic groups that hold them in such contempt.

Economic systems. Village settlements are not found among the Amhara nor among those who have been strongly influenced by their culture and way of life. The basic settlement unit in the rural areas is the nuclear or extended family (that is, the husband-and-wife family or its extension to kinsfolk, respectively) living in a few circular mud and wattle houses. The typical parish contains a core of some 20 to 30 household heads descended from a common ancestor associated with the parish and holding *rist* landrights in it. These farmers owe fealty to the feudal lord who has been allocated *gult* rights to the same estate. A local steward is responsible to the feudal lord as tax collector and organizer of corvée labour (labour extracted in lieu of taxes). Rights to land use are inherited from either parent and can be acquired by marriage. In the standard form of marriage, equal amounts of wealth (usually cattle) are contributed by each set of parents, and divorce, which is frequent, entails the redistribution of these resources. Children, nevertheless, always retain property rights through both parents, even in the case of the many less formal unions that are contracted.

Settlement patterns

The Amhara pattern of dispersed settlement is replicated fairly closely among the *ensete*-growing Sidamo as well as among most of the settled, cultivating Galla. The Cushitic-speaking Konso with their clearly defined and traditionally fortified villages and the southern Somali with similarly distinct settlements are both unusual. Southern Somali villages are based upon communal water ponds to which access is strictly controlled by membership in the local community and by participation in its blood-compensation arrangements. Among all these groups, land is not traditionally transferable except to other members of the group or to those who join it as clients. Its use entails social and politico-legal obligations, and, when it is abandoned, it reverts traditionally to the local community.

Among the Cushitic pastoralists, settlement patterns are naturally more fluid and flexible. The Boran Galla, who are less mobile and far ranging than the Somali in their movements, have generally separate grazing encampments for each type of livestock. The Boran rank their animals in the following order: lactating cows, dry cows, lactating camels, dry camels, and sheep and goats. The most senior brother in an extended family herds the first category of stock in the grazing regions best suited to it, and other brothers look after the other animals in descending order of seniority and prestige.

The pastoral Somali nomads, on the other hand, have basically only two types of herding unit. The first consists of the camels, which in the dry seasons can go without water for up to 20 days or more. These are in the charge of young unmarried men and, in the dry seasons particularly, seek good grazing, sometimes hundreds of miles from the wells to which other stock—sheep and goats, cattle and milch camels—are compelled to cling closely. These latter are herded by the family unit, consisting of a man and his wife or wives and their unmarried daughters and young sons (boys over the age of seven are out with the grazing camels learning the techniques of camel management). The family moves from pasture to pasture carrying its readily transportable tents and other equipment on burden camels, which are not, however, ridden. Pasture is not owned, and rights to wells are asserted with an intensity that increases in direct proportion to the scarcity of water and the energy expended in utilizing it. In the wet seasons, when lush pasture regions become centres of intensive grazing and settlement, the two herding units move closer together, and social life becomes more expansive and relaxed. With milk and meat in abundance, this is the time for feasts and collective rituals, the season of marriage negotiation and weddings.

Except among the Christians, all these peoples practice polygyny in one form or another, each wife and her children usually forming a separate domestic and economic unit. Marriage payments, largely in livestock among the pastoralists, are probably highest in the case of the pastoral Somali. Among these Somali, however, a bride also brings a considerable dowry in the form of a flock of sheep and goats to provide milk for the children whom she is expected to bear her husband.

Finally, a striking feature of Ethiopian economics is the complex and overlapping system of regional markets held in a given centre on a particular day of the week following a pattern that still obtains in parts of Europe. Saturday is the most popular day. Although such large centres as Gonder or Addis Ababa have daily markets, the weekly market is usually much bigger and has its own distinctive festive atmosphere.

Markets

Religion and aesthetics. The Cushitic tradition, traces of which occur even among such long and deeply Islāmized peoples as the Somali, seems best preserved today (in at least one of its original or early forms) among the Galla Boran. Here Waqa, the God of sky and earth and the creator and sustainer of life, is worshipped in prayer and sacrifice as the guardian of social morality and as the source of all things, good and bad. God's special agents on earth are the sacred dynasties, or lineages, of priests (*kallus*) who still live among the Boran and to whom all the Galla in ancient times used to send emissaries on pilgrimage. The pilgrims came to receive the blessing of the *kallu* priests, or "anointing fathers," who thus made sacred the whole traditional Galla social system. Today, among the Macha and other Galla who now live in the Ethiopian Highlands, these traditional national priests have been replaced by new spirit-possessed charismatic leaders (also called *kallus*) who express the ethnic identity of their tribesmen in the context of the Christian Amhara-dominated Ethiopian state.

The Ethiopian Orthodox Church maintains that Christ had a single, divine nature. It follows the Alexandrian rite, its liturgy being celebrated and recorded in the ancient Ethiopian language Ge'ez (from which Amharic is derived). It is led by the *abuna*, an Ethiopian priest who before 1948 was appointed by the Coptic patriarch in Alexandria but since has been appointed by the local church and emperor. The *abuna* presides over a church that, with its numerous places of worship, its richly endowed monasteries, and its ample priesthood, holds perhaps a third of the land of Ethiopia. Its all-pervasive character is such that one of every five male Christians is estimated to be in orders, and priests are expected to be married, only monks and nuns being celibate. Unordained, but not necessarily unlearned, ritual experts called *debtaras* play a crucial role in dispensing mystically efficacious cures. There is a vast hierarchy of saints and angels, chief among them being the Virgin Mary, St. Gabriel, St. Michael, St. George (patron saint of Ethiopia), and the local saints Takla Haimanot and Gabra Manfas Keddus. On the darker side, a complementary host of demons and evil spirits, many connected with a form of witchcraft (*buda*) and able to possess people and cause illness and even death, are widely feared. The protective cult of the saints, which is officially approved and encouraged, is vast and all-embracing. Every Christian has a special relationship with several saints, and the observance of saints' fasts and feasts bulks large in the Christian calendar. Spirits of every origin and provenance are accepted within the Christian cosmology, where they are naturalized in the continuous process of cultural exchange between the dominant and subject peoples. Thus, for instance, the Galla fertility spirit Atete is readily assimilated to the Virgin Mary, and vice versa (see also EASTERN CHRISTIANITY, INDEPENDENT CHURCHES OF: *Ethiopian Orthodox Church*).

Saints and spirits

Exactly the same pattern is repeated on the Muslim

side, where the cult of saints is equally well developed and the Islāmic cosmology coincides to a remarkable degree with that of the Amhara Christians. Thus among the Somali, who posthumously canonize their own lineage ancestors, saints are petitioned to remedy every distress and anxiety and are venerated as essential mediators between man and the Prophet Muḥammad and God. Again, the process of Islāmization closely parallels that of Christianization: in the case of the Arusi Galla, for instance, the Prophet himself and numerous other Muslim saints are assimilated to traditional spirits and ultimately to God (Waqa).

If the great traditions of Christianity and Islām generously open their arms to assimilate the many local cultures of the region, many elements from the local cultures in turn find their way, by the back door as it were, into the world view of the two major religions. This is very clearly seen in the mystery spirit-possession cults, which attract women and certain underprivileged categories of men particularly and which have a strongly "underground" character. Christians are especially susceptible to harassment by Muslim and pagan spirits, just as Muslims are equally open to attack by Christian demons or pagan sprites. Indeed, one of the salient features of religion in this part of Africa is the emphasis placed on spirit possession and the evil eye as explanations of misfortune that elsewhere would be ascribed to witchcraft or sorcery. The other striking feature deserving notice is the stress placed on food taboos and other commensal restrictions that are applied with particular stringency to maintain social distance from hunting and low-status craft groups. The despised and rejected community, on the other hand, may entertain similar attitudes toward those who consider themselves their superiors. Thus, just as other Ethiopians look down on the religion of the Jewish Falasha and on the ironwork and pottery trades that they follow, the Jewish Falasha themselves seek to remain apart in order to preserve their own ritual purity. Those who have close contact with, or live among, non-Jews are treated with disdain.

The presence for centuries of three world religions in the region, each with its own literate tradition, has preserved a more obvious and tangible literary heritage than in most other parts of Africa south of the Sahara, but the bulk of this literature remains largely untranslated and unknown to the outside world. More accessible are the splendid monuments of the Christian past: the celebrated rock-hewn churches of Lalibela, which were largely constructed during the reign of the 12th-century emperor after whom the city is named; the glorious castles and churches of Gonder with their famous, magnificently decorated ceilings; and, beyond this tradition, the older Aksumite antiquities. Islām too has left comparable memorials in some of the earliest mosques and tombs in such ancient cities as Harer, Zeila, and Mogadiscio (Mogadishu) but, for religious reasons, has left no illustrations comparable to those adorning Ethiopian manuscripts and church walls. Outside these literate traditions, there exists a less well explored heritage of oral literature, both in prose and poetry.

MODERN DEVELOPMENTS

The extension of educational facilities and other modernizing influences, increasingly widely disseminated by better road systems and the diffusion of the transistor radio, are beginning to make some impact on even the remotest parts of the region. On the whole, the Somali area outside Ethiopia has been more intensely and widely subject to such influences than the non-Amhara provinces of the empire. Until recently, modernization in general and education in particular have tended to be monopolies of the Amhara–Tigrean elite, which has thus sought to ensure its self-perpetuation. There have certainly been improvements in the general standard of living, as in health and other social service facilities, in recent years, but the most significant area of change has undoubtedly been the political.

Political parties have not yet been allowed to develop in Ethiopia, but the old style of imperial palace government has been profoundly modified by the innovations of Haile Selassie's reign, particularly by the establishment of an elected Parliament and a ministerial government, both of which show every sign of increasing political ambitions. In the provinces, parallel reforms have been introduced with varying effectiveness. The non-Amhara peoples of the empire are increasingly part of an essentially bureaucratic administrative system in which the impact of the central authorities and the facilities that they have to offer are much more strongly and continuously felt than in the past. Thus the remote Galla pastoralist or Sidamo cultivator tends to look to Addis Ababa as the distant but nonetheless ultimate centre of his universe.

Government reforms

The effect of increasing tribal interaction within Ethiopia has been to intensify ethnic sensibilities. Partly on this account and partly in response to the requirements of the urban situation, one effect of modern urbanization is to stimulate the growth of a vast array of urban associations, many being tribally or regionally based. Although they exist primarily to provide social security for their members in towns, they are also often equally concerned to secure progress and developments for their provincial homes. Here the urban associations of the Gurage in Addis Ababa, which have successfully accomplished major road-building operations, have exerted a pioneering influence. In the absence of political parties, the Amhara authorities seem prepared to extend a limited tolerance to ethnic associations of this kind as a safety valve for the expression of some degree of ethnic nationalism. Here the activities of the Galla association, allegedly involved in attempted coups, have clearly strained the bounds of tolerance. Despite these indications of the potential for divisive ethnic and regional separatism (which the existence of the Somali state inevitably encourages), other countervailing and crosscutting allegiances bind both Muslim and Christian together in what often seems an uneasy acceptance of the status quo. The absence in Ethiopia of clearly defined alternative interest groups, which could realistically claim legitimate leadership on some basis radically different from the present, seems to exert a powerful constraining influence.

There is no doubt that the Somali dispute—which arises from the fact that some Somalis live in Ethiopia and other states while their brothers have achieved self-determination in the Somali Democratic Republic—has on the whole helped to encourage Ethiopian integration. This is all the more remarkable given the fact that the Somalis are Muslims and that the majority of Ethiopian subject peoples (and most notably the Galla) share the same Cushitic identity. For its part, Somalia has no traditional elite, although the southern cultivating Somali (who speak a very distinctive dialect) are not customarily held in high esteem by the northern nomads. Indeed, only the relative size of lineages and their fortuitous proximity to centres of European settlement or, as in the case of the most impoverished nomadic areas, their need for alternative sources of livelihood have given some groups advantages over others in their access to modernity and its benefits. The traditional pastoral nomadic life has continued little changed and has adopted such technological innovations as it can adapt to its uses rather than being changed radically itself. Thus modern firearms, transport, and communications are employed in the nomadic life wherever appropriate; and the traditional ebullient republicanism has readily lent itself to the acceptance of the modern political party system when this form of politics was presented to the Somalis in the early 1950s.

From its inception as a social club in 1943, the Somali Youth League rapidly became the principal vehicle for the expression of Somali nationalism and was the government party from independence in 1960 until the military coup of October 1969 closed Parliament and outlawed party politics indefinitely. Its long success depended upon the delicate balance that it was able to strike (though not always entirely successfully) between the competing interests of the main lineage and clan

Somali nationalism

divisions within the nation. Every group's ambition was quite simply to obtain a seat in Parliament and to do this preferably within the framework of the organization that, being in power, had the most patronage to dispense. The principle of clan balance was so widely (if tacitly) accepted that not only were all senior government appointments distributed between the different constituent units, but this rule was also often followed even in appointing embassy staffs.

The present military regime, led by the Supreme Revolutionary Council, is probably more sincerely and unanimously devoted to the destruction of "tribal nepotism" and inefficiency than some previous civilian administrations, but its constituents judge its actions in terms of the logic of lineage advantage, and no amount of antitribal legislation, however severe, is likely to affect this very much. The present regime encourages the modernist secularizing tendency that appeals to many of the young foreign-educated elite and that deplores the wasteful excesses of the local Muslim saint cults and the general obscurantist conservatism of traditional Islām. This new radicalism (which some find compatible with a fundamentalist interpretation of Islām) favours women's education, their at least partial emancipation, and monogamy. Similar views are held by many of the younger Christian elite in Ethiopia. Finally, the strong martial tradition of both the Ethiopian and Somali cultures is today well represented in the dominant role played by the military in each country.

BIBLIOGRAPHY. EDWARD ULLENDORFF, *The Ethiopians* (1965); and MARGERY PERHAM, *The Government of Ethiopia*, 2nd ed. (1969), give good introductory accounts of the Ethiopian peoples and cultures in their historical setting. J.S. TRIMINGHAM, *Islam in Ethiopia* (1952), is a work of penetrating scholarship analyzing the relations between Muslims and Christians over the centuries. RICHARD PANKHURST, *An Introduction to the Economic History of Ethiopia from Early Times to 1800* (1961), deals with the economic relations of the various communities; while CHRISTOPHER S. CLAPHAM, *Haile-Selassie's Government* (1969), provides a uniquely informed account of the contemporary political scene from the viewpoint of the capital. There are as yet no fully satisfactory books on the social institutions of the Amharas and Tigreans. DONALD N. LEVINE, *Wax and Gold: Tradition and Innovation in Ethiopian Culture* (1965), however, gives a useful account of many aspects of rural Amhara culture; and RICHARD PANKHURST, *State and Land in Ethiopian History* (1966), provides valuable information on the crucial question of land ownership and tenure. Of the other Semitic-speaking groups, W.A. SHACK, *The Gurage: A People of the Ensete Culture* (1966), provides the only detailed account of an *ensete*-growing community. On the Cushitic-speaking peoples of Ethiopia, F.C. GAMST, *The Qemant: A Pagan-Hebraic Peasantry of Ethiopia* (1969), is a short study of an Agau group related to the Falashas; HERBERT S. LEWIS, *A Galla Monarchy: Jimma Abba Jifar, Ethiopia, 1830–1932* (1965), recounts the political history of a settled Galla group on the Gibe River; K.E. KNUTSSON, *Authority and Change* (1967), describes the religion of the Macha Galla in the context of the historical development of Galla social institutions; and G.W.B. HUNTINGFORD, *The Galla of Ethiopia* (1955), with its excellent bibliography, surveys all the existing literature on Galla ethnography and offers brief accounts of the Kafa and Janjero states. ENRICO CERULLI in *Folk-Literature of the Galla of Southern Abyssinia* (1922), indicates the range of traditional Galla oral literature. A. PAUL, *A History of the Beja Tribes of the Sudan* (1954), gives a readable account of the Beja way of life.

I.M. LEWIS, *The Modern History of Somaliland from Nation to State* (1965), relates the political history of the Somali people; the same author's *A Pastoral Democracy* (1961), analyzes in detail their nomadic economy and social institutions, amplified by *Marriage and the Family in Northern Somaliland* (1962); B.W. ANDRZEJEWSKI and I.M. LEWIS (comps.), *Somali Poetry* (1964), displays the riches of Somali oral literature; and I.M. LEWIS, *Peoples of the Horn of Africa* (1969), surveys the literature (in French, Italian, German, and English) on the customs and social institutions of the Somali, Afar, and Saho (contains an enormous annotated bibliography).

(I.M.L.)

Etna (Mount)

Mount Etna is an active volcano on the east coast of Sicily (Greek Aitne, from *aithō*, "I burn"; Latin Aetna; Sicilian Mongibello). It is the highest active volcano in Europe, its topmost point in 1971 being 10,703 feet (3,263 metres). Like other active volcanoes, its height varies: in 1865, for example, the volcanic summit was 170 feet higher than it was in the early 1970s. Etna covers an area of 600 square miles (1,600 square kilometres); its base has a circumference of about 93 miles. It is built upon marine marl and plastic clay of the Pliocene Epoch (up to 7,000,000 years ago), below which are older Eocene sandstones and limestones (of up to 54,000,000 years ago).

Its geological characteristics indicate that Etna has been active since the end of the Tertiary Period, somewhat more than 2,500,000 years ago. The Greeks created legends about the volcano, saying that it was the workshop of Hephaestus and the Cyclops or that underneath it the giant Typhon lay, making the Earth tremble when he turned. The ancient Poet Hesiod spoke of Etna's eruptions, and the Greeks Pindar and Aeschylus referred to a famous eruption of 475 BC. From 1500 BC to AD 1669 there are records of 71 eruptions, of which 14 occurred before the Christian Era. The most violent historical eruption was in 1669 (March 11–July 15), when about 990,000,000 cubic yards of lava were thrown out. The eruption took place along a fissure that opened above the town of Nicolosi, widening into a chasm from which lava flowed and from which solid fragments, sand, and ashes were hurled. The latter formed a double cone more than 150 feet high, named Monti Rossi. The lava flow destroyed a dozen villages on the lower slope and submerged the western part of the town of Catania. Efforts to divert the lava stream away from Catania were made by workers who dug a trench above the village. Historically, this seems to have been the first attempt to divert a lava stream. The effort was initially successful, but 500 heavily armed men, sent by the inhabitants of a neighbouring village who feared that the diverted lava stream might descend on them, prevented further work. Later, increased volcanic activity destroyed both villages, and the lava stream, which partly destroyed Catania, reached as far as the sea. Between 1669 and 1900, 26 more eruptions were reported. During the 20th century there have been eruptions in 1908, 1910, 1911, 1918, 1923, 1928, 1942, 1947, 1949, 1950, 1955, and 1971.

Central and lateral eruptions

Etna has had more than one active centre. A number of subsidiary cones have been formed on lateral fissures extending out from the centre and down the sides. The present structure of the mountain is the result of the activity of at least two main eruptive centres. One, no longer active, can be seen in the Valle del Bove on the east side of the mountain, a great abyss three miles wide and 2,000 to 4,000 feet deep. During the 1669 eruption, the volcanic summit collapsed, and a large circular crater, 8,000 feet in diameter, was formed. Eruptions may take place at one or more central mouths accompanied by lateral activity outward from the mouths, or the eruptions may be entirely lateral. Most of the eruptions in the 20th century have been lateral, except for that of June 29, 1955, when a moderate central eruption occurred. The one beginning on April 5, 1971, was at first near the centre but thereafter was confined to lateral activity.

Among Etna's better known ancient eruptions was that of 396 BC, which kept the Carthaginian army from reaching Catania. An eruption of 1381 sent a lava flow as far as the sea. The eruption of 1852 took many lives. That of 1928 cut the railway that runs around the base of the mountain and buried the village of Mascali. That of 1971 threatened several villages with its lava flow and destroyed some orchards and vineyards.

Life on the slopes

The mountain has three zones, one above the other, each exhibiting its own characteristic vegetation. The lowest zone, sloping gradually upward to perhaps 3,000 feet, is fertile and rich in vineyards, olive groves, citrus plantations, and orchards of cherries, apples, pistachios, and hazelnut trees. Its volcanic soil often yields five harvests a year. Several densely populated settlements, notably the city of Catania, are found on the lower slopes, but they become less frequent as the height in-

creases. Above, the mountain grows steeper and is covered with forests of chestnut, beech, oak, pine, and birch. At heights over 6,500 feet the mountain is covered with ashes, sand, and fragments of lava and slag; there are a few scattered plants such as *Astragalus aetnensis* (local name spino sento), which forms typical bushes almost a yard high, while some alpine plants manage to survive even near the top. Algae have been found near the steam outlets at 9,800 feet.

Etna has been studied systematically since the middle of the 19th century, and three observatories have been set up on its slopes; they are located at Catania, Casa Etnea, and Cantoniera.

The ascent of Etna is best undertaken in summer or autumn, seven to eight hours being required from Nicolosi. The easiest route is by the road from Catania through Nicolosi up to the height of 6,171 feet, a distance of about 21 miles. From the end of the road a cableway runs to the building called Torre del Filosofo at 9,564 feet, a Roman ruin believed to commemorate the ascent of the mountain by the emperor Hadrian.

BIBLIOGRAPHY. D. ANDRONICO, *L'Etna* (1967), includes information on flora and fauna; G. IMBO in the *Catalogue of the Active Volcanoes of the World Including Solfatara Fields*, pt. 18, *Italy* (1965), provides a topographic and morphological description of the mountain. E. RECLUS, *Les Volcans de levre* (1904) and W.S. WALTERHOUSEN, *Der Aetna* (1880) include information on the physical environment.

(G.I.)

Etruscan Language

The Etruscan language was spoken by close neighbours of the ancient Romans. The Romans called them Etrusci or Tusci; in Greek they were called Tyrsenoi or Tyrrhenoi; in Umbrian, an Italic language, their name can be found in the adjective *turskum*. The Etruscans' name for themselves was *rasna* or *raśna*.

The Etruscans lived in Italy in the region of modern Tuscany, in an area bounded by the Arno River on the north, the Tiber River on the southeast, and the Tyrrhenian Sea on the west. At one time they controlled most of an area extending south from Milan through Marzabotto and Sarsina to the Adriatic Sea north of Ancona, and to the southwest their rule extended as far as Capua, Naples, and Pompeii. For the history of the Etruscans and Etruria, see ITALIC PEOPLES, ANCIENT.

Records and scholarship. The Etruscan language is known mainly from epigraphic records originating in the Tuscan area and dating from the 7th century BC to the first years of the Christian Era. There are some 10,000 of these inscriptions, mainly brief and repetitious epitaphs or dedicatory formulas, as well as votive or owner's inscriptions on paintings in tombs and accompanying engraved figures on small artifacts such as metal mirrors. There are, however, some remarkable exceptions to the general brevity of the inscriptions, and there are important differences in their origins. The longest single text, of 281 lines (about 1,300 words), now in the National Museum at Zagreb, is written on a roll of linen that had been cut into strips and used in Egypt as a wrapping for a mummy; a clay tablet found at Capua contains some 250 words; a stone slab from Perugia has two adjacent sides elegantly engraved with an inscription of 46 lines (some 125 words); a bronze model of a liver found at Piacenza, which probably represents the Etruscan microcosm in a form used for instruction in divination, has some 45 words; and a heavy rectangular block found on the island of Lemnos in the northern Aegean has an engraving of what is probably a warrior with one inscription of perhaps 18 words surrounding the head and another of 16 words in three lines on an adjacent side. In 1964 two inscriptions on gold tablets, one in Phoenician and the other in Etruscan, were unearthed at Pyrgi.

Inscriptions

Despite many attempts at decipherment and some claims of success, the Etruscan records still defy translation. While the possibility always remains that an imaginative conjecture or a brilliant inference will suddenly provide the key to the mystery, this now seems remote. The etymological method of investigation, which ultimately depends upon the recognition of presumed cognates from related languages, seems to have failed because no clear and certain relationship between Etruscan and any other language has ever been established. The procedure sometimes called the combinatory method now appears to be the most efficacious if not indeed the only useful one. It requires, first, that note be made of anything unusual in the provenance of the object on which Etruscan writing is found (such as that the mummy wrapping came from Egypt and the Lemnos inscription from the Aegean) and likewise of anything unusual in the object itself (*e.g.*, that it is a bronze replica of a liver or the representation of a god or mythological figure). Finally, each word and phrase and formula is compared with every recurrence of the same element or elements elsewhere, and all variations in the physical and the linguistic contexts are recorded. By this means it has been possible to assign some words to grammatical categories such as noun and verb, to identify some inflectional endings, and to assign meanings to a few words of very frequent occurrence.

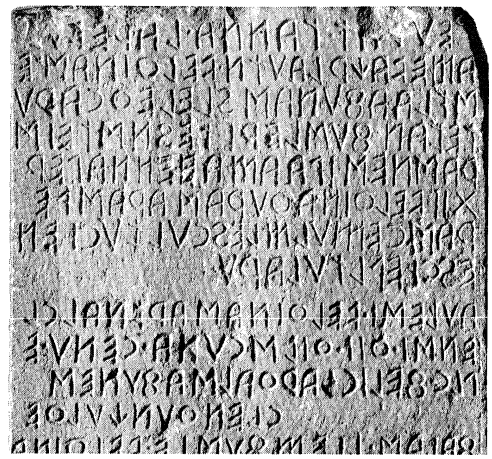


Figure 1: Etruscan inscription from a section of the "Cippus of Perugia." In the Museo Archeologico Nazionale dell'Umbria, Perugia, Italy.
Alinari

The problem of Etruscan origins is insoluble until the language can be translated. While nothing at all is certain other than the existence of Etruscans in Italy, some Etruscan writing in Egypt, and an Etruscan inscription on Lemnos, the weight of all the evidence seems to favour a non-Italic but certainly Mediterranean place of origin of the Etruscan people. It is unlikely, therefore, that the Etruscan language is genetically related to any language or language family existing in an area remote from the Mediterranean. On the other hand, it does not follow that Etruscan must be related to a language or language fragment that can be found in the Mediterranean area.

Linguistic relationships

The Etruscan alphabet. Etruscan is written in an alphabet probably derived from one of the Greek alphabets. It is of very great importance that Etruscan is written in a recognizable alphabet related to the Greek and Semitic because sound values can be assigned with some degree of precision to each symbol. Etruscan writing proceeded from right to left and in earliest times had no word division or punctuation. In about the 6th century BC a system of points, or dots, consisting of four, three, or two dots inscribed vertically, was introduced to mark word boundaries and, in some instances, apparently, to indicate syllables and possibly abbreviations.

There were four vowels in Etruscan, *i*, *e*, *a*, and *u* or *o*, and symbols in the alphabet for *p*, *t*, *c*, *m*, *n*, *l*, *r*, *z* and for the equivalents of the Greek *phi*, *theta*, and *chi*, which in Etruscan as in classical Greek were the aspirated stops *ph*, *th*, *ch* (pronounced as *p*, *t*, *k* with an added brief puff of air). There were two sibilants, written *s* and *ś*, for which the precise pronunciation is uncertain; two front fricatives, *f* and *v*, articulated either with the two lips (bilabial) or with the lower lip approaching the upper

Figure 2: Etruscan alphabet on the edge of a writing tablet from Marsiliana d'Albegna, 7th century. In the Museo Archeologico, Florence.

front teeth (labiodental); and an *h*, which nearly always occurs at the beginning of words and is used to represent, inconsistently, the rough breathing of Greek (*e.g.*, Greek *Hēraklēs*, Etruscan *hercle* or *ercle*). There were also a *k* and a *q*, of which the precise pronunciation is unknown. A marked tendency to make all vowels in a word similar or identical (qualitative vowel harmony) is characteristic: Greek *Klutaimēstra*, which if transliterated directly into Etruscan would be *cluthemestha*, actually occurs as *cluthumustha* and *clutmsta*.

Both historical changes and dialectal differences can be observed. Diphthongs became single letters. Thus Greek *Aiwas* became Etruscan *aivas*, *eivas*, and *evas*, successively; *au* alternated with *a; eu* (like *ai*) became *e* (Greek *Kleopatra* is Etruscan *clepatra;* Greek *Poludeukēs* is, with Etruscan vowel harmony, *Pultuce*). Among consonants the most noticeable changes are *c* to *ch* to *h* (*e.g.*, *casri* becomes *chasri*, *caspr* becomes *haspr*); similarly, *p* changes to *ph* to *f* to *h* and *t* to *th* to *h*. Throughout the history of Etruscan, a first syllable usually remains unchanged, whereas later syllables tend to weaken or lose vowels, at least in writing. Older Etruscan *lavtun* "family" becomes in later Etruscan *lavtn;* other examples are *mutana* changing to *mutna*, Greek *Adonis* written *atunis* and then *atuns*, Greek *Alexandros* appearing as *elchsntre*. The consonant cluster of *elchsntre*, while extreme, is not untypical of Etruscan spelling; words thus written have led some to suggest that a very economical spelling system may have been used that was far removed from the reality of pronunciation, requiring the introduction of lightly stressed vowels in actual utterance. (For a short history and a chart of the Etruscan alphabet, see ALPHABETS: *Etruscan alphabet.*)

Grammatical characteristics. The minimal unit of meaning seems to have been a verbal root, such as *zic* or *zich*, meaning "write." The suffixing of any vowel or certain consonants (*c* or its variant *ch*, *t* or its variant *th*, *l*, *r*, or *n*) produced a noun. The vowel *u* was used to form a gerund that, without further change, could be used as an agent noun; thus *zicu* meant "writing," then, further, "scribe," and then the equivalent of the Roman name Scribonius. From these verbal nouns, denominative verbs could be made; thus from *zicu* plus *-ce*, a past tense of perfective affix, was made *zichuche* "he wrote, he has written."

Because of the large number of names occurring in the inscriptions, the noun declension system can be understood reasonably well. Similar to the process of word building is the construction called *genitivus genitivi*, or "genitive of the genitive," in which several possessive suffixes may be added to a word in succession. Thus, the simple genitive of *larth*, a proper name, is *larthal* "Larth's"; a second genitive suffix added gives *larthalisa* "of that which is Larth's."

The *genitivus genitivi*

There is apparently no grammatical gender in Etruscan. In late Etruscan an *-i* suffix marks some women's names; still later, apparently (or possibly in a different dialect area), *-ia* is similarly used. Although these suffixes appear to be the same as the final elements in some words designating exclusively female functions, such as *puia* "wife" (in one occurrence spelled *pui*, if it is the same word) and *ati* "mother" (in one occurrence *atiu*, if it is the same word), there is no evidence for any syntactic use of gender, and there is no formal marker that can be shown to have marked gender consistently.

Case endings do not differ from singular to plural; in the singular they are suffixed directly to the word stem, and in the plural they are added to the stem, along with one of the plural markers *ar, er, ur*. There is no distinctive nominative (subject) case marker, the word stem or, in some cases, the root alone serving as the nominative. A final marker *-s*, however, does appear to have been added in some instances of a probable nominative case.

The repetitive nature of most Etruscan inscriptions is such that very few distinctively different verb forms are available for analysis. Indeed, probably the only really certain verbal suffix is *-ce*. It must not be assumed, however, that the paucity of the verbal data from inscriptions reflects an impoverished verb system in the language; indeed, judging from the variety of verbal stems to which the recurring *-ce* is added, it is more likely that the Etruscan verb had a more complicated structure than the noun.

Vocabulary. Since the language is undeciphered, meaning can be assigned with certainty to only a few Etruscan words that occur very frequently in the texts. Some kinship terms are sure—among these are *ati*, "mother," *clan* "son," *śec* "daughter," *puia* "wife." Less certain but probably correct are words designating members of the larger societal organization: *lavtn* "family," *zilc* "official," *maru* "official," *spur* "city," *rasna* or *raśna* "Etruscan, Etruria." A pair of dice certainly have on them the names of the numbers from one through six. Although the order of these numbers has been and still is disputed, the arrangement most generally accepted is this: *thu* "one," *zal* "two," *ci* "three," *śa* "four," *mach* "five," *huth* "six."

Among the continuing mysteries of Etruscan are the reasons why the Etruscans left no written records of their great civilization other than inscriptions and occasional texts and why the Romans, who knew the Etruscans intimately, transmitted little or nothing to posterity about either Etruscan literature or their language, which must certainly have been spoken, or at least preserved, by some families in Rome long after the period of Etruscan greatness had passed.

BIBLIOGRAPHY. The following sources provide accurate and reliable information on Etruscan. M. PALLOTTINO, *Etruscologia*, 6th ed. (1968; Eng. trans., *The Etruscans*, 1955), the standard work; A.J. PFIFFIG, *Die etruskische Sprache* (1969), an excellent and complete statement of what is known about the Etruscan language; MURRAY FOWLER and R.G. WOLFE, *Materials for the Study of the Etruscan Language*, 2 vol. (1965), which contains the inscriptions with indexes of several kinds for easy reference—there is no grammatical information included.

Euclid

The most prominent mathematician of antiquity, Euclid is best known for his *Elements*. Almost from the time of its writing and lasting almost to the present, this treatise on geometry has exerted a continuous and major influence on human affairs, even though almost nothing is known of its author's life. It was the primary source of geometric reasoning, theorems, and methods at least until the advent of non-Euclidean geometry in the 19th century. Euclid wrote many other works in mathematics, although some of them are lost. It is sometimes said that next to the Bible, the *Elements* may be the most translated, published, and studied of all the books produced in the Western world.

Euclid flourished *c.* 300 BC but no record of his birthplace has yet come to light. Of his life it is known only that he taught at and founded a school at Alexandria in

the time of Ptolemy I Soter, who reigned from 323 to 285/283 BC. Medieval translators and editors often confused him with the philosopher Eucleides of Megara, a contemporary of Plato about a century before, and therefore called him Megarensis. Writing in the 5th century AD, the Greek philosopher Proclus told the story of Euclid's reply to Ptolemy, who asked whether there was any shorter way in geometry than that of the *Elements*—"There is no royal road to geometry." Another anecdote relates that a student, probably in Alexandria, after learning the very first proposition in geometry, wanted to know what he would get by learning these things, whereupon Euclid called his slave and said, "Give him threepence since he must needs make gain by what he learns."

Sources of the *Elements*

Euclid compiled his *Elements* from a number of works of earlier men. Among these are Hippocrates of Chios (5th century BC), not to be confused with the physician Hippocrates of Cos (flourished 400 BC). The latest compiler before Euclid was Theudius, whose textbook was used in the Academy and was probably that used by Aristotle. The older elements were at once superseded by Euclid's and then forgotten. For his subject matter Euclid doubtless drew upon all his predecessors; but it is clear that the whole design of his work was his own. He evidently altered the arrangement of the books, redistributed propositions among them and invented new proofs if the new order made the earlier proofs inapplicable. Thus, while Book X was mainly the work of the Pythagorean Theaetetus (flourished 369 BC), the proofs of several theorems in this book had to be changed in order to adapt them to the new definition of proportion developed by Eudoxus (*q.v.*). According to Proclus, Euclid incorporated into his work many discoveries of Eudoxus and Theaetetus. Most probably Books V and XII are the work of Eudoxus, X and XIII of Theaetetus. Book V expounds the very influential theory of proportion that is applicable to commensurable and incommensurable magnitudes alike (those whose ratios can be expressed as the quotient of two integers and those that cannot). The main theorems of Book XII state that circles are to one another as the squares of their diameters and that spheres are to each other as the cubes of their diameters. These theorems are certainly the work of Eudoxus, who proved them with his "method of exhaustion," by which he continuously subdivided a known magnitude until it approached the properties of an unknown. Book X deals with irrationals of different classes. Apart from some new proofs and additions, the contents of Book X are the work of Theaetetus; so is most of book XIII, in which are described the five regular solids, earlier identified by the Pythagoreans. Euclid seems to have incorporated a finished treatise of Theaetetus on the regular solids into his *Elements*. Book VII, dealing with the foundations of arithmetic, is a self-consistent treatise, written most probably before 400 BC.

Other books of the *Elements* are not on this high mathematical level. In Book VIII, the second of the three arithmetical books, are found cumbersome enunciations, needless repetitions, and even logical fallacies. Apparently Euclid's exposition excelled only in those parts in which he had excellent sources at his disposal.

Translations and editions of the *Elements*

In ancient times, Hero and Pappus of Alexandria and Proclus and Simplicius all wrote commentaries. Theon of Alexandria (4th century AD) brought out a new revision of the work with textual changes and some additions; his version was the basis of all published Greek texts and translations until, early in the 19th century, an important Greek manuscript containing an ante-Theonine text was discovered in the Vatican. Three Arabic translations were made in the middle ages: by al-Ḥajjāj ibn Yūsuf ibn Maṭar, first for the Abbāssid caliph Hārūn ar-Rashīd (ruled 786–809) and again for the caliph al-Ma'Mūn (ruled 813–833); by Ḥunayn ibn Isḥāq (ruled 808–873), in Baghdad, whose translation was revised by Thābit ibn Qurrah (died 901); and by Naṣīr ad-Dīn aṭ-Ṭūsī in the 13th century. Euclid was first made known in the West through Latin translations of these Arabic versions.

The first extant Latin translation of the *Elements* was made about 1120 by Adelard of Bath, who obtained a copy of an Arabic version in Spain, where he travelled while disguised as a Muslim student. Adelard also composed an abridged version and an edition with commentary. Hermann of Carinthia translated Books I–XII from the same Arabic version. Gerard of Cremona (*c.* 1114–87) translated the 15 books of Euclid from the Isḥāq-Thābit version. The first Latin translation to be printed was by Johannes Campanus in the 13th century.

The first direct translation from the Greek without the Arabic intermediary was made by Bartolomeo Zamberti and published in Vienna in Latin in 1505; and the *editio princeps* of the Greek text was brought out at Basel in 1533 by Simon Grynaeus. But the most important Latin translation of this period was by Federico Commandino in 1572. The first edition of the complete works of Euclid was the Oxford edition of 1703, in Greek and Latin, by David Gregory. All texts are now superseded by *Euclidis Opera Omnia* (8 vol. and a supplement, 1883–1916), edited by J.L. Heiberg and H. Menge. The first English translation of the *Elements* was by Sir Henry Billingsley. The many later editions include Robert Simson's in Latin and English, containing Books I–VI, XI, XII, and the *Data*, in 1756; and the definitive *The Thirteen Books of Euclid's Elements* by T.L. Heath, with introduction and commentary (3 vol., 1908; 2nd ed., 1926).

Other extant works of Euclid include two belonging to elementary geometry: the *Data*, containing 94 propositions, which demonstrates that if certain elements in a figure are given, then other things are given—*i.e.*, can be determined; and a book *On Divisions* (of figures), discovered in both Arabic and Latin versions and restored and edited in 1915, which deals with problems of dividing a given figure by one or more straight lines into parts that are equal or that have given ratios to one another or to other given areas. The *Optics* of Euclid is extant in Greek in two forms, one being Euclid's own treatise, and the other a critical revision by the Greek writer Theon. The *Catoptrica* ("Reflections") is not by Euclid but is, rather, a later compilation from ancient works on the subject. The *Phaenomena*, extant in Greek, is a treatise on the geometry of the sphere for use in astronomy and is similar in content to the work, by Autolycus of Pitane, *Moving Sphere*. *The Elements of Music* is attributed to Euclid by Proclus and Marinus, the latter being another Greek commentator. Included in this work are two treatises that probably are not by Euclid: the *Sectio canonis* ("Division of the Scale"), which gives the Pythagorean theory of music with some later additions; and the *Introductio harmonica* ("Introduction to Harmony"), written by Cleonides, a student of Aristoxenus, in which an identifiable tone separates notes on the scale.

Lost works attributed to Euclid

Four lost works in geometry are described in Greek sources and attributed to Euclid. The purpose of the *Pseudaria* ("Fallacies"), it is said, was to distinguish and to warn beginning students against different types of fallacies to which they might be susceptible in geometrical reasoning. The *Porisms*, in three books, was an advanced work of which Pappus gave a summary account. Although the word means "corollaries," Euclid apparently meant a statement that was intermediate in significance between a problem and a theorem. The *Conics*, made up of four books on conic sections, corresponded in content to the first four books of Apollonius' *Conics*, although Apollonius added new theorems to his own treatment. Euclid called the conics by their previous designations, sections of a right-angled cone, an obtuse-angled cone, and an acute-angled cone, respectively; it was Apollonius who first gave them the names parabola, hyperbola, and ellipse, the descriptions of which he derived. Pappus also mentioned the *Surface-loci*, which is made up of two books that probably dealt with loci on surfaces, perhaps also loci which are surfaces, and with conic sections.

A fragment in Latin, *De levi et ponderoso*, which is included in Gregory's edition of Euclid, contains a statement of the principles of Aristotle's dynamics but is not by Euclid. See also RELATED ENTRIES under EUCLID in the *Ready Reference and Index*.

Euclid may not have been a first-class mathematician.

He certainly was, however, a first-class teacher of mathematics, inasmuch as his textbook has remained in use practically unchanged for more than 2,000 years. It was not until the middle of the 19th century that a so-called "away from Euclid" movement began and led to the appearance of a multitude of rival textbooks of geometry giving the substance of Euclid's early books in many different forms and producing thereby a variety of geometrical teaching.

MAJOR WORKS

Euclid's extant works are collected in *Euclidis Opera Omnia*, ed. by J.L. Heiberg and H. Menge, 8 vol. and a supplement (1916), containing the *Elements*, Books I-XIII (*The Thirteen Books of Euclid's Elements*, trans. by Sir Thomas Heath, 1952), *Data* (*Euclid's Data, restored to their true and genuine order*, trans. by R. Jack, 1756), *Euclid's Book on Divisions of Figures*, ed. by R.C. Archibald (1915), *The Optics*, and *The Phaenomena*.

BIBLIOGRAPHY. GEORGE SARTON, *Introduction to the History of Science*, vol. 1, pp. 153–156 (1927, reprinted, 1968), an extensive bibliography; B.L. VAN DER WAERDEN, *Outwakende wetenschap* (1950; Eng. trans., *Science Awakening*, 1954), a readable orientation to Euclid and his place in history; THOMAS L. HEATH, *A History of Greek Mathematics*, vol. 1, pp. 354–446 (1921, reprinted 1965), an authoritative survey of Euclid's works; ALBERT LEJEUNE, *Euclide et Ptolémée, deux stades de l'optique géométrique grecque* (1948); MARSHALL CLAGETT, "The Medieval Latin Translations from the Arabic of the Elements of Euclid, with Special Emphasis on the Versions of Abelard of Bath," *Isis*, 44:16–42 (1953); and GLENN R. MORROW (ed. and trans.), *Proclus' Commentary on the First Book of Euclid's Elements* (1970), three scholarly studies.

(B.L.v.d.W.)

Eudoxus of Cnidus

The greatest mathematician and astronomer in the age of Plato, Eudoxus of Cnidus substantially advanced number theory beyond the Pythagorean tradition by demonstrating the reality of irrational quantities and by his techniques for measuring curved surfaces. Moreover, with his system of concentric spheres, which was the first systematic explanation of the motions of the Sun, Moon, and planets, he re-emphasized the Greek insistence on spherical perfection. He thereby introduced geometry into the science of astronomy and began the necessary interaction between observation and theory that has characterized its development ever since. His contributions are known through ample Greek sources, including commentaries in Byzantine codices, even though none of his writings has survived.

Born about 400 BC, in Cnidus in southwest Asia Minor, Eudoxus, son of Aeschines, learned mathematics and medicine at a school that rivalled for a time that of Hippocrates of Cos. Impressed by his ability, a well-to-do physician paid his way to Athens so that he could study at Plato's Academy, which had been established in 387. He also spent 16 months in Egypt some time during the reign of Nectanebo I (380–363). At Heliopolis, now a Cairo suburb, Eudoxus learned the priestly wisdom, which included astronomy; there he wrote the *Oktaëtēris*, his first major work, concerning a calendar based on an eight-year cycle, perhaps from a study of Venus. Earning his living as a teacher, he then travelled in the region of the Sea of Marmora before returning to Athens, where he became respected throughout Greece as a legislator. The few facts concerning his life are derived largely from the writings of Diogenes Laërtius in the 3rd century AD.

It is generally agreed that Euclid drew heavily on Eudoxus in writing the *Elements*, particularly Books V and XII and sections of Books VI, X, and XIII. Eudoxus' two major contributions to mathematics are the theory of proportion, found in Book V, and the method of exhaustion, in Book XII. The philosopher Proclus attributed the first to him, and Archimedes credited him with the second. It is also possible that Euclid's axiomatic method was first developed by Eudoxus.

Theory of proportion

Around the 5th and 4th centuries BC, the Pythagoreans had observed relationships between certain geometrically measurable quantities, such as that between the hypotenuse and legs of a right triangle (*i.e.*, the square of the hypotenuse is equal to the sum of the squares of the other two sides). But following this development, they also discovered that the lengths of certain geometric figures (*e.g.*, the diagonal of a square with sides equal to one) could be expressed only as an irrational number (*i.e.*, a nonterminating decimal, such as 1.414213 . . . or $\sqrt{2}$). The discovery of irrational numbers about 400 BC meant that Pythagorean geometry, which dealt initially with commensurable quantities only, was inadequate; it had no means for dealing with irrational numbers.

Eudoxus' theory of proportion is treated extensively in Euclid's *Elements*, Book V, in which the definition of equal ratios (No. 5) is the principal source of the modern view of irrational numbers. With this theory, which was a major contribution to number theory, mathematics for the first time could take into account incommensurable quantities (*e.g.*, those whose ratio is not the quotient of two integers, such as the diameter and circumference of a circle), as well as such well-known commensurables as two sides of certain triangles. Thus, following the early Greek solution to the problem of finding areas and volumes bounded by straight lines that were represented by rational numbers, the theory of proportion allowed Eudoxus to deal, by means of rational approximations, with measurements that involved irrational numbers. He demonstrated that irrational numbers could be defined by means of approximations of rational numbers.

More difficult, however, was the problem of calculating areas and volumes bounded by curves. Eudoxus' solution was the method of exhaustion—a modern term, not used by the ancient Greeks. By successfully including in this method not only the irrational but also the concept of the infinitesimally small quantity, he showed how to subdivide continuously a known magnitude (*e.g.*, the length of a straight line) until it closely approached that of an unknown, such as the properties of a curve. According to Archimedes, Eudoxus used this method to prove that the volumes of pyramids and cones are one-third the volumes of prisms and cylinders, respectively, with the same bases and heights—although Democritus probably had already discovered that this was so. Eudoxus also demonstrated that the areas of circles are proportional to the squares of their diameters. His technique was something like, but far more rigorous than, inscribing polygons with increasing numbers of sides within a circle in order to find its area. Because it could be used to compute areas and volumes bounded by curves, the method of exhaustion, which is fully elaborated in Book XII of Euclid's *Elements*, was a forerunner of integral calculus.

Method of exhaustion

Although the geometric method of calculating the distance of the Sun and Moon from the Earth is usually attributed to Aristarchus of Samos (3rd century BC), there is a possibility that it may have been invented by Eudoxus. He also proposed a solution for another problem in astronomy—how to explain mathematically the observed motions of the Sun, Moon, and five planets. In order from the stationary Earth, these seven heavenly bodies were the Moon, Mercury, Venus, the Sun, Mars, Jupiter, and Saturn. Although Eudoxus' own account of his solution by means of concentric spheres (an idea that may have originated with Parmenides of Elea around 500 BC) has not survived, the 19th-century Italian astronomer Giovanni Schiaparelli described its details from an analysis of brief references in Aristotle's *Metaphysics* and from a substantial discussion in the commentary on Aristotle's *De caelo* (Book II), written in the 6th century AD by the Greek philosopher Simplicius.

Because the stars did not appear to have independent motion, the ancients perceived them to revolve around the Earth as a unit, forming a fixed backdrop against which the complicated and irregular motions of the planets were observed and plotted. To explain the motions Eudoxus constructed a model of 27 spheres. On the outer sphere he placed all the fixed stars, to account for their diurnal (daily) east-to-west motion. He devised a set of interconnected spheres for each of the other heavenly bodies—three each for the Sun and Moon and four each for the five planets. Each planet rode on the equator of its inner sphere except for the Moon, which rode on the

System of concentric spheres

middle; each sphere had its own appropriate axial inclination and rotational velocity. The outermost sphere accounted for the diurnal east-to-west motion.

The Moon's inner sphere was set at an angle to the ecliptic (the apparent path of the Sun through the constellations) and rotated east to west once each lunar (nodical) month (now known to be 27.2122 days). The middle sphere that carried the Moon moved west to east along the ecliptic to account for the Moon's phases. The Sun's inner sphere, moving west to east, was inclined (erroneously) to the ecliptic to account for the inequality of the seasons; and its middle sphere moved west to east along the ecliptic once each sidereal year (a round trip to the same place in the constellations).

To represent the retrograde motions of the five planets, Eudoxus depended on the combined rotatory motions of the two inner spheres of each. The resulting motion described an elongated figure-eight, which he called a hippopede. One of the few noncircular curves in antiquity, it represented the planet's "wandering" motion in latitude and longitude. As the planet, attached to the innermost sphere, oscillated along Eudoxus' hippopede during retrogressions, the hippopede itself revolved daily on the outermost sphere, while proceeding bodily once each sidereal year around the ecliptic by means of the next inner sphere (from the outside).

By devising combinations of spheres, Eudoxus accounted for the apparently irregular motions of the celestial bodies in the solar system, thus maintaining the Greek vision of circular perfection, the ancient symbol of wholeness. His system was an admirable attempt to "save the phenomena," the vivid Greek expression, in that it closely represented the observed motions of Mercury, Jupiter, Saturn, the Sun, and the Moon. But it was unsatisfactory for Venus and failed completely for Mars; nor could it account for variations in brightness, orbital period, apparent size of the Moon, or synodic period.

After his death in about 350 BC, Eudoxus' fundamental contributions to geometry and number theory led to further, lasting developments in Greek mathematics, as exemplified by the work of Archimedes. Eudoxus introduced into astronomy the view that uniform circular motion would account for the irregular motions of all the celestial bodies—the view that, with the epicyclic refinements of Ptolemy, prevailed until the time of the 17th-century astronomer Johannes Kepler. And his perception of circular regularity persists in modern mathematics in the periodic character of the infinite series.

BIBLIOGRAPHY. The classic analysis of Eudoxus' system of concentric spheres is by GIOVANNI SCHIAPARELLI, "Le sfere omocentriche di Eudosso, di Callippo e di Aristotele," in *Pubblicazioni del R. Osservatorio di Brera in Milano*, no. 9 (1873), in which he also corrected certain errors made by Simplicius. This is the basis of the study of Eudoxus by THOMAS L. HEATH in his *Aristarchus of Samos* (1913); and by J.L.E. DREYER, *A History of Astronomy from Thales to Kepler*, 2nd ed. rev. (1953), which has the clearest exposition. OTTO NEUGEBAUER, *The Exact Sciences in Antiquity*, 2nd ed. (1957), examines the question of Babylonian and Greek influences on Eudoxus. Two studies by GEORGE DE SANTILLANA, "Eudoxus and Plato: a Study in Chronology," *Isis*, 32:248–262 (1940), and "On Forgotten Sources in the History of Science," in A.C. CROMBIE (ed.), *Scientific Change*, pp. 813–828 (1963), are discussions of the intellectual interaction of Eudoxus with his contemporaries and possible sources of his ideas.

The most detailed studies of Eudoxus' mathematics are in two works of THOMAS L. HEATH: *The Thirteen Books of Euclid's Elements*, 2nd ed. rev., 3 vol. (1956), and *A History of Greek Mathematics*, 2 vol. (1921). MORRIS R. COHEN and I.E. DRABKIN, *A Source Book in Greek Science* (1948), contains relevant excerpts from the writings of Simplicius, Plato, Archimedes, Euclid, Aristotle, and Diogenes Laërtius on pertinent topics concerning Eudoxus.

Eugene of Savoy

Prince Eugene of Savoy, an Austrian imperial general in the Austro-Turkish War of 1683–99 and the War of the Spanish Succession (1701–14), considered to have been the greatest general of his time, was the teacher of Frederick the Great and the only one among the seven great strategists of all time whose campaigns Napoleon considered worthy of study by posterity.

Eugene was born October 18, 1663, in Paris, the youngest son of the comte de Soissons, of the house of Savoy-Carignan, and of Olympia Mancini, a niece of Cardinal Mazarin. His paternal ancestors were the dukes of Savoy, who later became kings of Sardinia, Sicily, and eventually of all Italy, while on his mother's side the family included not only Roman patricians but also hatters, valets, and humble artisans. A rumour once had it that Eugene was actually the son of Louis XIV, the Sun King, who, although he always denied it, was said to have had an affair as a young man with Olympia Mancini. Louis, in any event, was ashamed of this unprepossessing supposed offspring of his. So severely did he restrain Eugene's ambitions that the latter, after spending some 20 inglorious years in Paris and Versailles left France altogether and offered his sword to the emperor Leopold I, who was busy fighting the Turks.

Military career

In his first battle, at the relief of Vienna from siege by the Turks in 1683, Eugene so distinguished himself that the Emperor gave him a regiment of dragoons to command the following year. Nothing could now retard this young genius on his way to world fame. It was more than just an outstanding strategic ability that made him victorious; it was also a contagious élan, which enabled him time and again to lead his men to triumph on the field of battle. With equal impetuosity he climbed the senior military ranks, becoming an imperial field marshal at the age of 29. He fought seven battles of major historical significance. Through the victories of Zenta, Peterwardein, and Belgrade, he once and for all secured Hungary from the Turks; together with the Duke of Marlborough, his great friend, he won Bavaria and, indeed, all of Germany at Blenheim; at Turin he gained northern Italy; at Oudenaarde and Malplaquet, the Netherlands. He lost only Spain, and that because of the political ineptitude of the emperor Charles VI.

Eugene's battles were among the bloodiest encounters of that sanguinary period, his marches among the most exhausting, and his decisions in difficult situations among the most daring and successful known to the history of war. And yet there was something still greater and rarer than his generalship in 24 battles: his wisdom in regarding military victory as a mere instrument for achieving political ends. Eugene not only made conquests but also secured them, and in his creative hands the works of peace quickly blossomed forth.

During a span of 39 years he continued to lead the Emperor's armies from the River Save all the way to Lombardy, through the Tirol back again to Bavaria and the Rhine, down once more to Hungary against the Turks, and back up again to Flanders. He was wounded 13 times. Even as he faced a world of foes before him, he had a world of enemies at his back, nourished by the hereditary curse of Austria: slothful souls and thoughtless minds, low intrigue, envy, jealousy, foolishness, and dishonesty. He served three emperors: Leopold I, Joseph I, and Charles VI. Toward the end of his life, Eugene observed that whereas the first had been a father to him and the second a brother, the third (who was perhaps least worthy of so great a servant) had been a master.

Victory at Belgrade

Belgrade (1718) was Eugene's most famous victory. In order to take the city, he had deployed his forces in a position that was both daring and dangerous. It was to no avail that others implored him again and again to withdraw the troops in order not to give the Turkish army—which was intent on raising the siege and which surrounded Eugene's forces with a superiority of four to one—the chance to undo them all. Furthermore, Eugene's soldiers were being decimated by disease. But he remained in position and, in a terrible battle that began in a thick fog in the dead of night, annihilated the relief army once the fog lifted at daylight. Capturing innumerable prisoners and the entire Turkish encampment, Eugene took the city shortly afterward.

Worn out by the exertions of an active career, Eugene died in Vienna on April 21, 1736. Posterity has endeavoured to add to his military glory the reputation of sci-

entific, artistic, and literary interests. But although he is known to have corresponded with the philosopher Gottfried Wilhelm Leibniz, his literary interests cannot have been overwhelming because not one of the tens of thousands of volumes in his library (most of them preserved in the Nationalbibliothek in Vienna) bears any trace of having been much used; and they give the appearance of having been opened hardly at all in the more than 200 years since Eugene neglected to read them. Regarding his interest in architecture and painting, it may be said that, although he commissioned great artists to build and beautify his palaces, he involved himself in these matters no more than was expected of any great lord of his time. Aside from the enormous, in fact uncanny, talent with which he led the Emperor's armies to victory, Eugene had a weakness for comic ruses. At the siege of Philippsburg, for example, he intended to change the course of the Rhine so that it would flow through the French camp, an idea that caused him to laugh uproariously; at Belgrade, he had the Austrian flotilla, which had lain at anchor above the city, move through various canals so that it suddenly appeared below the city. He also indulged in primitive soldiers' pranks—a failing that made him many enemies among his victims. The only subject that held his attention as much as politics was finances, not only public monies (he was also imperial minister of finance) but also and especially his own—he had arrived in Austria with 25 guilders, and he left an estate of 25,000,000.

Eugenics

Eugenics is the study of human improvement in all aspects by genetic means. Its goal is to increase the proportion of persons with better than average genetic endowment. It draws from the science of genetics for an understanding of the processes of heredity; from psychology for analysis of the part played by differences in heredity and environment in the development of personality, intelligence, and character; from medicine and medical genetics for information on hereditary defects and susceptibility to disease; and from sociology, and more particularly demography, for the rates of births and deaths, the mating habits, and the social and physical factors that determine the relative increase or decline of persons with different characteristics. In its scientific aspect it is essentially the study of trends and causal factors in human evolution.

A companion science, euthenics, is also concerned with the improvement of mankind, but by adjustment of the environment. Obviously both concerns are essential to the well-being of man, and since neither science can stand alone, the term "humanics" has been suggested to embrace both aspects of human improvement.

HISTORICAL BACKGROUND

Early history. The idea of applying knowledge of heredity to the improvement of the human race goes back to earliest times. References to eugenic ideals appear in the Old Testament, and Plato's *Republic* idealizes a society in which there is constant selection for the improvement of the human stock. A British economist, Thomas Robert Malthus, noted the struggle for existence; an English naturalist, Charles Darwin, saw in it the means of evolution. It remained for Francis Galton, a scientist of many talents, and a cousin of Darwin, to see that the theory of evolution implied that man might in part direct his own evolutionary future. Galton's first important work, *Hereditary Genius* (1869), contained the results of his studies of the families of eminent men as evidence for his belief that "it would be quite practical to produce a highly gifted race of men by judicious marriages during several consecutive generations." In 1883 he published *Inquiries into Human Faculty*, in which he coined the term eugenics. In *Natural Inheritance* (1889), Galton pioneered the development and application of advanced statistical methods to the study of man.

While Galton's thinking was much ahead of his time, he retained some of the prejudices of an English gentleman in regard to social class and race. In his studies of the families of eminent men Galton underestimated the effects of a favourable environment. But his faults in this respect were far less than those of many of his followers. He developed and used many of the statistical methods for the study of populations and was the first to recognize the value of the study of twins for research in heredity. He repudiated the Lamarckian view, then widely held, that acquired characteristics were inherited. Although Galton attached religious significance to the eugenic movement, he did not think of it in revolutionary terms, but rather as ". . . the new duty which is supposed to be exercised concurrently with and not in opposition to, the old ones upon which the social fabric depends."

The slow acceptance of eugenical ideas

For all his wisdom and high ability, Galton was not able to gain any wide acceptance for eugenics, largely because much of the scientific and technical foundation was lacking. Psychology was not sufficiently advanced to help him in his studies of individual differences or in assessing the importance of the environment; there was no cultural anthropology to provide an outline of the growth of civilizations; and birth control was so little recognized or accepted that he did not take it into account as a possible factor in the control and distribution of births.

From Galton to World War II. Galton had endowed a research fellowship in eugenics in 1904 and, in his will, provided funds for a chair of eugenics at University College, London University. The fellowship and later the chair at University College were both occupied by Karl Pearson, a brilliant mathematician who helped to create the science of biometry, the statistical aspects of biology. Pearson was a controversial figure who believed that environment had little to do with the development of mental or emotional qualities. He felt that the high birthrate of the poor was a threat to civilization and that the "higher" races must supplant the "lower." His views gave countenance to those who believed in racial and class superiorities. Thus, Pearson shares the blame for the discredit later brought on eugenics in the United States and for making possible the dreadful misuse of the word eugenics in Hitler's propaganda. The English Eugenics Society, founded by Galton in 1907 as the Eugenics Education Society, opposed Pearson's views, but was itself slow in throwing off the prevalent biases of that time.

Eugenics discredited by early racist views

In the United States the American Eugenics Society was founded in 1926 by men whose views were coloured by the times in which they lived. They believed that the white race was superior to other races, and, further, that the "Nordic" white was superior to other whites. They thought of races as "pure" groups, quite separate from each other. They did not know that all races are mixtures of many types, the distribution of genes among the races varying in proportions rather than in kind, as evidenced by the distribution of the various blood groups among all of the races. They did not realize that environments are so uncontrollable that scientists cannot reasonably put forward views on the genetic differences in the performance of different races. Furthermore, they believed that the upper classes had superior hereditary qualities that justified their being the ruling class.

The science of that day supported extreme views on feeble-mindedness and "criminal types." Intelligence tests, introduced in the early 1900s by a French psychologist, Alfred Binet, were thought, contrary to Binet's views, to be measures of innate, genetic intelligence. People whose test performance (*e.g.*, intelligence quotient or IQ) gave them a mental age of 12 or less could be classified as feebleminded or morons, even though the term would then include most of those brought up in deprived environments, such as the southern Appalachian highlands or the blighted rural and urban slums occupied by the descendants of slaves. Criminality was generally considered a concomitant of feeblemindedness. Studies on

degenerate family stocks were taken to prove that hundreds of persons in each of these families were feebleminded or criminal types because of the inheritance they received from a single ancestor five or six generations back. Claims were made that immigrants from southern and eastern Europe, besides being socially inferior, included a remarkable number of criminal and defective stocks. There was much in the intellectual atmosphere of the U.S. that fostered an extreme hereditarian racist view.

Even before 1905 eugenists had been active in the effort to restrict immigration. Their arguments, along with those of others who advocated restrictions for different reasons, culminated with the passage of the National Origins Quota Law in 1924, which limited quota immigrants to about 150,000 annually, with no more than 2 percent of each nationality according to the number of persons of their national origin in the U.S. as of 1890, and providing that beginning July 1, 1929, the quota of any country shall have the same ratio to 150,000 as the number of persons of that national origin living in the U.S. had to the total population of the U.S., as determined from the 1920 census. In later years it became clear that the material the eugenists had presented to congressional hearings had little scientific foundation.

Movement to sterilize defectives

Eugenists at this time laid great stress on the importance of sterilizing defective persons. By 1931 sterilization laws had been enacted by 27 states in the U.S., and by 1935 sterilization laws had been passed in Denmark, Switzerland, Germany, Norway, and Sweden. Most of these laws provided for the voluntary or compulsory sterilization of certain classes of people thought to be insane, idiotic, imbecilic, feebleminded, and epileptic; some applied equally to habitual criminals, moral perverts, or the feebleminded. In most cases the purpose was clearly eugenic, though some laws tacitly permitted sterilization for social rather than genetic reasons. In the U.S. most states did not generally enforce these rather extreme measures, and the number of sterilizations was seldom over 100 per year. Exceptions were California, where sterilizations averaged over 350 cases per year, with a total of 9,931 by 1935, and some of the southern states, with fairly high sterilization rates relative to their populations.

With the advance of science the background for these laws began to be questioned. In 1935 a committee of the American Neurological Association reported on an extensive investigation and evaluation of the "facts and theories which constitute the subject matter of the inheritance of the mental diseases, feeblemindedness, epilepsy and crime." The committee concluded that there was a serious question whether "many of the eugenic proposals now current take into account the newer genetic data" and that "though the avowed purpose of such sterilization invariably starts out by being a eugenic one, it often ends by becoming a social one." They exposed many fallacies in the reasoning behind the sterilization laws and concluded that there was no sound basis for sterilization on the basis of immorality or character defect. They recommended sterilization only with the consent of the patient, or those responsible for him, and only in the case of certain specified diseases or defects, namely: (1) Huntington's chorea, hereditary optic atrophy, familial cases of Friedreich's ataxia, and a few other rare hereditary defects; (2) feeblemindedness common in a family; (3) schizophrenia; (4) extreme cases of manic depressive psychosis; and (5) epilepsy, mainly on the ground of its social aspects. Their recommendation for concerted, coordinated, and planned long-term research was not followed seriously until after 1945, when medical schools began active research into medical genetics.

In Europe the studies of criminal types were discredited, and serious work in eugenics continued in the form of family studies by government institutes. Only in Nazi Germany did eugenics serve racial and political purposes. There, Hitler, exploiting the concepts of the master race and the superman as expounded by some German scholars, developed racism into a powerful political weapon.

Eugenics after 1945. With the development of atomic weapons, the general public and medical men alike became educated to the dangers of genetic mutations produced by radioactive fallout from nuclear explosions. Medical X-rays came under new scrutiny, and the findings of studies on hereditary factors in diabetes and other diseases received new attention. Medicine and public health, professions previously little interested in heredity, recognized a new responsibility. By the 1960s the major medical schools in the U.S. had included geneticists on their research staffs, and a number had set up departments of medical genetics. Couples planning marriage became more aware of their responsibility to potential offspring, and heredity clinics associated with medical schools began to provide counselling to advise couples on the chances of having defective children.

Still other factors arose to increase public interest in heredity. The great increase in births that took place in the U.S. and most European countries after World War II aroused interest in the type of children being born and the kind of homes they were being brought up in. Birth control, given worldwide publicity as a solution to the problem of too rapid growth of populations, raised questions as to the type of people who would use it, and the kind of children they would have. Publicity was given to the practice of insemination of women whose husbands were not able to give them children, and questions were raised about the heredity as well as the legal status of children so conceived, and about the effect of the psychological environment on the marriage relationship and on the child. New scientific findings were widely disseminated, and the public began to take a more balanced view of the contributions made by both heredity and environment to good health, intelligence, and character.

Genetics made unparalleled advances after 1950, opening up a whole new field of the biochemistry of gene structure and gene behaviour. At the same time, the scientific basis for the new eugenics was being further broadened by advances in psychology and in the field of demography. The Institut National d'Études Démographiques in France sponsored important investigations of human populations. In England the Royal Commission on Population made its report in 1949, and the Population Investigating Committee at the London School of Economics gave attention to quantitative and qualitative aspects of population trends in its publication *Population Studies*. In the U.S. a number of the larger universities established facilities for training and research in demography, and several nation-wide surveys on factors affecting fertility were taken. The atmosphere was appropriate to a balanced reconsideration of eugenic problems.

Scientific basis of eugenics broadened

BASE LINES OF MODERN EUGENICS

Genetic defects. It is generally accepted that genes causing defects originate in mutations that occasionally take place in one or another of the many thousands of genes present in pairs in every human cell. Usually the mutated gene is recessive; that is, it does not have a harmful effect unless the other gene in the pair has the same characteristics. The chances of two such genes meeting as a pair depend on the number of such genes distributed throughout the intermarrying population. Thus under random mating, if a particular deleterious gene is carried by one person in a hundred, the chances of the mating of persons with such genes are 1 in 10,000. While the chances of such an unfortunate mating seem slim, in a large population such a ratio results in a considerable number of defective persons.

With an increase in the proportion of carriers of a particular defective gene, there is an even greater increase in the likelihood of a mating in which two such genes will be paired in the same fertilized cell. When this happens, there will be a defect. If the defect is lethal (*i.e.*, results in stillbirth or infant death), the two deleterious genes will be removed from the population. If the defect is minor, but of a sort to make marriage or reproduction less likely, the genes are to that extent less likely to survive. Thus at some point nature establishes a balance in which, for every new deleterious gene brought into circulation, a similar gene is lost from circulation.

Geneticists believe that most people carry at least a few deleterious genes; some estimate the average to be as high

as 8 percent, and at least 2 percent of the babies born carry some genetic defect, major or minor.

Most scientists believe that the proportion of carriers of deleterious genes may now be increasing, though the results in the form of an increase in defect would not be apparent for a number of generations. Greater exposure to X-rays and to fallout from atomic explosions is currently accelerating the rate of mutations, while medicine is making it possible for an increasing number of persons with some kind of genetic defect to live long enough to rear children unfortunate in having that parental defect. Diabetics, for instance, formerly died at an early age, and the genes for diabetes were lost with them. After an insulin treatment was found, these people led longer useful lives, but were not generally able to have children. Now safe delivery of the children of diabetic mothers is commonplace. The deleterious genes remain in circulation, while new ones are constantly added by mutations. Thus, with good medical care, diabetics live normally and often bear diabetic children of their own. The accumulation of certain severe types of deleterious genes could conceivably reach a point that might seriously threaten man's future. To support and maintain defective members in the population is not at odds with the goal of genetic improvement of mankind so long as such persons do not reproduce defective offspring.

The genetic burden

While present social and medical conditions favour the increase of many genes that cause physical defects and susceptibility to certain diseases, other genes that affect mental disease and mental defect are probably diminishing as a result of the low marriage rate and the institutionalization of the carriers. It is probable that efforts at control will be strengthened by increased use of sterilization in some areas, by increased use of more effective means of birth control, and by a more eugenic use of heredity counselling clinics. Each year increasing numbers of defects are being defined, the type of transmission understood, and, in many cases, means found for spotting carriers. The immediate solution to the dilemma seems to lie in educating those persons known to be carrying a seriously defective gene to their societal responsibility, and thereby, hopefully, to convince them to surrender their right to bear children who might be defective and burden them as well as society. The possibility of "correcting" nature's mistakes at their source, the deoxyribonucleic acid molecule (DNA) of the gene, is a hope for the future. Such genetic engineering has been proposed by several prominent scientists and termed "algeny."

Psychological traits. With responsibility for work on mental and physical defects transferred to the professions of medicine and public health, eugenists are now giving major attention to the genetic factors that provide the base for the development of such complexly inherited traits as intelligence, character, and personality. The genetic base for these psychological traits is provided by multiple genes in various combinations. They may be broken up and recombined with other genes from one generation to another, making them difficult to trace in family lines. It will take time to locate these genes and trace the processes involved in their transmission. Fortunately, the efficacy of selection does not depend on a full knowledge of the genetic mechanism. For the present, at least, eugenists will be guided by familial incidence of intelligence and personality and by the survival of family stocks of different types.

Massive evidence from studies on identical and fraternal twins, nontwin siblings, and adopted children reared away from their natural parents indicates that differences in genetic factors play an important part in psychological differences between individuals. These were Galton's findings, and they have been confirmed by larger and more carefully controlled studies. Identical twins are extremely similar; even when reared apart from infancy, they resemble each other in physical as well as mental characteristics to a degree greater than that shown by fraternal twins reared together.

Children tend to be like their parents in intelligence not only because of their common heredity, but also because they usually share a common environment. The evidence on differences in personality is not so clear, largely because these traits are more difficult to measure. All studies indicate, however, that personality, like intelligence, is the product of interaction between environment and the genetic base. This is shown in the extremes of personality, like schizophrenia, which can often be measured.

Environmental and socioeconomic factors. As work in the field of individual differences has progressed, scientists have come to feel that the old distinction between heredity and environment is no longer useful; both are a part of the processes that begin when the cell is fertilized and starts its separate life; both operate throughout the individual's life; and both contribute to making each individual different from every other individual. Genetic factors can be given value only in relation to specific environments; some qualities that are socially valuable in one environment may be harmful in another.

Apparent racial differences in intelligence

Racial groups differ in their average response to intelligence tests, but these tests invariably involve environmental factors that favour those culturally more fortunate. Even when differences in such factors as place of residence, income, or length of schooling can be controlled, the results may still be influenced by factors affecting motivation and behaviour.

In studies of socioeconomic, or other, groups, there is no evidence of genetic differences, except perhaps in the case of comparisons between certain of the professional classes and the rest of the population, in which there is some indication that the genetic factors for response to intelligence tests may be slightly superior. Differences between socioeconomic classes in intelligence-test response are obviously strongly influenced by differences in environment in much the same way as occurs among racial groups. It is as yet impossible to measure the relative genetic potentialities of any large population groups. But differences between individuals within each group can be measured, and it is these differences that are the proper concern of eugenists today.

Until very recently, from 30 to 50 percent of all children died before maturity, and death was an important factor in the survival of particular stocks. The evidence from some areas where people are still living under primitive conditions seems to favour the belief that under conditions of life as it was everywhere before the mid-18th century, the general tendency was toward the survival of more competent stocks. If so, this situation changed in the industrialized countries, when the death rate began an accelerated decline, dropping to 12 or less per thousand by 1940. In the mid-20th century, about 95 percent of all children lived to age 30, and differential deaths had little effect on differential survival.

Social-class differences in family size

While this change was taking place, social-class differences in births were widening with the introduction of birth-control measures, which reached first into the more educated and wealthy classes. With differential births greatly favouring the less educated, who made little effective use of birth control, the inverse relation between births and education or socioeconomic status widened rapidly. In the United States this inverse relationship reached its peak with the postponement of births and marriages in the last years of the Great Depression. For the period 1935–40 women with one to three years of college education had a net reproduction rate 33 percent below that required for replacement of their numbers, and women with four years of high school had a rate 26 percent below replacement, while women at the elementary school level had a rate twice that of the college women and well above that required for replacement.

The upsurge of births after World War II and the spread of birth control among the less educated changed this trend. By 1960, among women 35 to 40 years old, who had practically completed their childbearing, high school women and women with one to three years of college had borne more children than the number needed for replacement. Women with less than eight years of elementary school education had had about the same number of children as those who had completed their childbearing during the depression. This trend seems likely to continue.

Extensive studies made about 1960 on national samples of the U.S. population indicate that the number of children actually desired by couples in the "blue collar" (factory or industrial) group is less than the number desired by couples in the "white collar" (office or business) group. When both the husband and the wife were college graduates, only 7 percent of the last pregnancies were unwanted, while among the couples at grade school level 33 percent had not wanted their last pregnancy. Of the college couples, 92 percent effectively used contraception, while only 69 percent of the grade school couples used contraception, and they used it less effectively.

It is expected that birth control may soon be used as widely and as effectively at the lowest educational levels as at the highest. Should that occur, present trends suggest that educational and social class differentials in births may soon bear a direct relation to size of family. The public generally, and many scientists, have assumed that an inverse relation between size of family and education or socioeconomic class must represent an unfavourable, or dysgenic, trend, even though there is little evidence for genetic differences between classes. If the relation between size of family and educational level becomes direct, with the more educated groups having the greater proportion of children, the trend would be generally taken as favourable, or eugenic. But its greatest significance would be an increase in the proportion of children brought up in above-average home surroundings. The major opportunity for genetic improvement will be found in selection of individuals within each group.

There is some limited evidence that at the present time in the United States the abler and the more intelligent members of any group tend to have the most children. In studies made as early as 1927 on graduates of Yale and Harvard universities, and again on Princeton University graduates in 1939, the men were rated by a committee of classmates for degree of success some years after graduation. In each group the highest-rated married men averaged over two children apiece, while the lowest-rated married men averaged less than one and one-half children. Many studies have indicated that the probability of being childless increases as IQ decreases. There is thus some evidence that in attempting to increase the comparative fertility of the more intelligent and successful individuals, eugenists are working with and not against present trends, as has been claimed by some.

Individual voluntary selection on the increase

A number of changes taking place in industrial societies today are favourable to individual selection. There are more opportunities for finding work appropriate to one's genetic capacities. There is a wider choice of mates in a highly mobile society, which favours the production of novel types and offers greater possibilities if there is selection. The trend toward more education for all classes would help make birth control selective within each class. Also, the continuing improvement of birth control methods should improve voluntary forms of selection at all levels of education. To further these trends, eugenists urge better training for choice of mate and for marriage, a more general individual and community sense of responsibility for the parents who have more than one or two children, and continuing study of all the psychological, social, and economic pressures and rewards that would tend toward a voluntary and favourable selection of births within every occupational group.

EUGENICS PROPOSAL

Recent trends in the distribution of births suggest the possibility of the development in modern industrial societies of eugenic selection of a wholly voluntary and unselfconscious sort, in which the only controls might be certain moderate changes in social institutions, most of which changes are already desired for other than genetic reasons. Recent eugenic thinking seems to be developing along these lines, but the public and many scientists are still disturbed by the older conception of a controlled or authoritarian eugenics that would threaten other social and ethical values.

The possibilities. The most immediate and most publicized procedure that can be eugenically applied is the use of insemination techniques. The insemination of women whose husbands are unable to give them children is quite frequently practiced in the United States and Europe. A proposal was made by Herman Muller, a U.S. geneticist, that the sperm for insemination be collected from men of high attainment, of family stocks as free as possible from defective strains, and that it be kept, frozen and stored, for as long as possible, perhaps beyond the lifetime of the donor. It would then be available for women who desired to assure themselves of superior children. It was Muller's belief that the advantages of this procedure would result in its rapid and widespread adoption, and an organization was formed to carry on his work.

The "sperm bank"

Other scientific possibilities, not yet in the stage of application, are already being discussed by scientists for their possible effect on the genetic qualities of human beings. Changing hereditary factors in the human cell by chemical means is not an impossibility, but it lies in the future. Another possibility is the implanting of a specified segment of genes into a chromosome. Preliminary experiments have been performed on mice, but it will be a long time indeed before such methods can be used for the improvement of human germ cells. A nearer possibility is vegetative, or clonal, reproduction, similar to the reproduction of cuttings from plants. If this not improbable technique becomes practicable with humans, the way would be open for the reproduction, in any number desired, of individuals as similar genetically as are identical twins. Human beings could then be propagated for diverse valuable characteristics of every sort. Few persons would regard this proposal as desirable or even thinkable. The technical difficulties and social and moral objections to the "mass production" of such twin types make its application unrealistic even in the remote future.

For all practical purposes the measures discussed above are premature. They are just beyond the realm of theory, but far short of general acceptance even as theories. They would violate many established social attitudes. They raise many moral and legal questions. The population at large generally regards such proposals with suspicion. Their fears cannot be dismissed lightly. Who can assure them that eugenical procedures will not be used ulteriorly? Who can promise that there is no danger?

The public's fear of eugenics

Authoritarian controls would have to be employed and extremely difficult value judgments would have to be made. Who, for example, would determine a superior quality in man? Who would make the decisions whether certain qualities should be preserved or extinguished? Modern eugenics is little interested in authoritarian controls. Rather, it believes that the social and economic environment can be shaped so as to influence a eugenic distribution of births throughout entire populations in a voluntary and largely unconscious process of selection.

Euler, Leonhard

The most prolific mathematician of the 18th century, Leonhard Euler made decisive and formative contributions to the subjects of geometry, calculus, mechanics, and number theory. He developed methods for solving outstanding problems in observational astronomy and

demonstrated useful applications of mathematics in technology and public affairs.

Born in Basel, Switzerland, on April 15, 1707, Euler's mathematical ability earned him the esteem of Jean Bernoulli, then one of the first mathematicians in Europe, and of his sons Daniel and Nicolas. In 1727 he moved to St. Petersburg, where he became an associate of the St. Petersburg Academy of Sciences, and in 1733 succeeded Daniel Bernoulli to the chair of mathematics.

By means of his numerous books and memoirs that he submitted to the academy, Euler carried integral calculus to a higher degree of perfection, developed the theory of trigonometric and logarithmic functions, reduced analytical operations to a greater simplicity, and threw new light on nearly all parts of pure mathematics. Overtaxing himself, Euler in 1735 lost the sight of one eye. Then, invited by Frederick the Great in 1741, he became a member of the Berlin Academy, where for 25 years he produced a steady stream of publications, many of which he contributed to the St. Petersburg Academy, which granted him a pension. In 1748, in his *Introductio in analysin infinitorum*, he developed the concept of function in mathematical analysis, through which variables are related to each other and in which he advanced the use of infinitesimals and infinite quantities. He did for modern analytic geometry and trigonometry what the *Elements* of Euclid had done for ancient geometry, and the resulting tendency to render mathematics and physics in arithmetical terms has continued ever since. He is known for familiar results in elementary geometry; for example, the Euler line through the orthocentre (the intersection of the altitudes in a triangle), the circumcentre (the centre of the circumscribed circle of a triangle), and the barycentre (the "centre of gravity," or centroid) of a triangle. He was responsible for treating trigonometric functions—*i.e.*, the relationship of an angle to two sides of a triangle—as numerical ratios rather than as lengths of geometric lines and for relating them, through the so-called Euler identity ($e^{i\theta} = \cos\theta + i\sin\theta$), with complex numbers (*e.g.*, $3 + 2\sqrt{-1}$). He discovered the imaginary logarithms of negative numbers and showed that each complex number has an infinite number of logarithms.

Contributions to pure mathematics

Euler's textbooks in calculus, *Institutiones calculi differentialis* in 1755 and *Institutiones calculi integralis* in 1768–70, have served as prototypes to the present because they contain formulas of differentiation and numerous methods of indefinite integration, many of which he invented himself, for determining the work done by a force and for solving geometric problems; and he made advances in the theory of linear differential equations, which are useful in solving problems in physics. Thus, he enriched mathematics with substantial new concepts and techniques. He introduced many current notations, such as Σ for the sum; $\int n$ for the sum of divisors of n; the symbol e for the base of natural logarithms; a, b, and c for the sides of a triangle and A, B, and C for the opposite angles; the letter "f" and parentheses for a function; the use of the symbol π for the ratio of circumference to diameter in a circle; and i for $\sqrt{-1}$.

After Frederick the Great became less cordial toward him, Euler in 1766 accepted the invitation of Catherine II to return to Russia. Soon after his arrival at St. Petersburg, a cataract formed in his remaining good eye, and he spent the last years of his life in total blindness. Despite this tragedy, his productivity continued undiminished, sustained by an uncommon memory and a remarkable facility in mental computations. His interests were broad, and his *Lettres à une princesse d'Allemagne* in 1768–72 were an admirably clear exposition of the basic principles of mechanics, optics, acoustics, and physical astronomy. Not a classroom teacher, Euler nevertheless had a more pervasive pedagogical influence than any modern mathematician. He had few disciples, but he helped to establish mathematical education in Russia.

Euler devoted considerable attention to developing a more perfect theory of lunar motion, which was particularly troublesome, since it involved the so-called three-body problem—the interactions of Sun, Moon, and Earth. (The problem is still unsolved.) His partial solution, published in 1753, assisted the British Admiralty in calculating lunar tables, of importance then in attempting to determine longitude at sea. One of the feats of his blind years was to perform all the elaborate calculations in his head for his second theory of lunar motion in 1772. Throughout his life Euler was much absorbed by problems dealing with the theory of numbers, which treats of the properties and relationships of integers, or whole numbers (0, ±1, ±2, etc.); in this, his greatest discovery, in 1783, was the law of quadratic reciprocity, which has become an essential part of modern number theory (*q.v.*).

Lunar theory

In his effort to replace synthetic methods by analytic ones, Euler was succeeded by J.-L. Lagrange. But, where Euler had delighted in special concrete cases, Lagrange sought for abstract generality; and, while Euler incautiously manipulated divergent series, Lagrange attempted to establish infinite processes upon a sound basis. Thus it is that Euler and Lagrange together are regarded as the greatest mathematicians of the 18th century; but Euler has never been excelled either in productivity or in the skillful and imaginative use of algorithmic devices (*i.e.*, computational procedures) for solving problems.

Euler died in St. Petersburg on September 18, 1783.

BIBLIOGRAPHY. A bibliography of Euler's works, compiled by GUSTAV ENESTROM in "Verzeichnis der Schriften Leonhard Eulers," *Jahresbericht der Deutschen Mathematiker–Vereinigung, Ergänzungsband IV* (1910–13), lists 856 books and articles. An edition of *Leonhardi Euleri Opera omnia*, begun in 1911 and still continuing, will comprise 72 volumes in three series: mathematics, 29 vol.; mechanics and astronomy, 31 vol.; physics and miscellaneous, 12 vol. The texts appear in the original language of publication, in most cases Latin; but introductions, sometimes substantial, are in the language of the editors. For example, in series 2, vol. 11, there is a long historical account, comprising part 2 of the volume, by CLIFFORD TRUESDELL, of *The Rational Mechanics of Flexible or Elastic Bodies*. There is a large body of secondary literature on Euler, chiefly in German and Russian. See, for example, OTTO SPIESS, *Leonhard Euler* (1929). The most authoritative account in English, together with an extensive bibliography, is that by A.P. YOUSCHKEVITCH in the *Dictionary of Scientific Biography*, vol. 4, pp. 467–484 (1971). Less substantial summaries are found in ERIC T. BELL, "Analysis Incarnate: Euler (1707–1783)," in *Men of Mathematics*, ch. 9 (1937, reprinted 1961); and CARL B. BOYER, "The Age of Euler," in *A History of Mathematics* (1968). For Euler's contributions to specialized aspects of mathematics, see such works as CARL B. BOYER, *History of Analytic Geometry* (1956) and *History of the Calculus and Its Conceptual Development* (1959); LEONARD E. DICKSON, *History of the Theory of Numbers*, 3 vol. (1919–23, reprinted 1952); and ISAAC TODHUNTER, *A History of the Progress of the Calculus of Variations During the Nineteenth Century* (1861, reprinted 1962).

(C.B.B.)

Euphorbiales

The Euphorbiales order is a large assemblage of dicotyledonous flowering plants (*i.e.*, it is a member of the class Dicotyledoneae) consisting of seven families and about 315 genera and 8,000 species. Fifteen genera have more than 100 species each; the largest include *Euphorbia* (over 1,600 species), *Croton* (700), *Phyllanthus* (500), and *Acalypha* (430). One of the three flowering-plant groups that have the interesting cactus-like growth form and that inhabit very dry places is a member of this order. Many plants of the order are useful to man. The complex inflorescence (flower cluster) and the variation found throughout the order in the female flower are botanical features of special interest.

GENERAL FEATURES

Size range and diversity of structure. The Euphorbiales order includes plants having many diverse growth forms, including prostrate and erect herbs, shrubs, and trees. Many members are broad-leaved. The shieldlike leaves of *Macaranga gigantea* are among the largest simple leaves (60–100 centimetres [about one yard] across) in the plant kingdom. Many different tree shapes occur in the order. In the genus *Elateriospermum*, the monopodial (or single, centrally stemmed) state is found with a conical crown, the trunk reaching the vertex and the

leaves spirally set on twigs. In the genus *Emblica*, the twigs appear as doubly pinnate leaves (*i.e.*, they are compound, not from a central point, like a fan, but from either side of an axis, like a feather; in this case the subdivision is repeated twice), and the crown is inclined to be flat-topped. Intermediates between these two conditions are frequent. Some species of the genus *Euphorbia* growing in the desert regions of Africa and the Canary Islands closely resemble cactus plants in having fleshy stems of different shapes armed with spines. A number of Australian species are suffrutescent—that is, woody and living over from year to year in the lower parts of the stem just above ground level—and they have small, ramified stems and narrow leaves similar to those of the Ericaceae family (order Ericales), a growth form known, therefore, as the ericoid habit. Several members possess flattened stems or branches known as phylloclades that function as leaves (*Phyllanthus*). A few are lianas. In the genus *Picrodendron*, the bark is peculiar and peels off in long strips. Several kinds of hairs are present in different members of the order—stinging hairs in the genus *Tragia*, glandular in *Acidodendron* and *Macaranga*, nonglandular in *Mabea* and *Phyllanthus*, and numerous others.

Resemblance of some euphorbias to cactus plants

Distribution and abundance. Euphorbiales species are found chiefly in tropical regions but are spread over the whole earth with the exception of the Arctic and cold Alpine zones. Two major centres of distribution are tropical America and Africa. Few species have a very wide range, and some genera have very restricted distributions, such as *Simmondsia* (California and neighbourhood), *Picrodendron* (West Indies), and *Panda* (west tropical Africa). The most widely ranging genus is *Euphorbia*.

Utility. Several species of the order have abundant milky juice (latex) and attendant complex secretory tissue; in certain cases, the juice is economically important. The genera *Mabea*, *Manihot*, and *Sapium* are the source of caoutchouc (a form of rubber), and the highest grade of rubber is obtained from *Hevea braziliensis*. In some cases, the latex is medicinal, but in many species it is poisonous, as in the manchineel (*Hippomane mancinella*) of South America. *Manihot esculenta*—manioc, or cassava—the source of tapioca, is one of the most important tropical food plants, its large tuberous roots being very rich in starch. Tung oil and wood oil are important commercial oils obtained from the seeds of *Aleurites fordii* and *A. cordata*, respectively. The solid oil of *Sapium sebiferum* is used for making candles in China, and it is also considered to be a good substitute for lard. Castor oil is extracted from the castor bean, *Ricinus communis*. *Croton tiglium* is the source of croton oil, and resin is obtained from species of *Euphorbia* and *Croton*. The dried resin-containing latex of *Euphorbia resinifera* of Morocco is a well-known commercial drug, gum euphorbium. The fruits of a few species, such as *Cicca*, *Beccaurea*, *Antidesma*, and others, are edible, as are the seeds of the candlenut, *Aleurites*. Fruit of *Emblica officinalis* is very rich in vitamin C and is used in several medicines. Excellent jams and wines are prepared in the Philippines from the fruits of *Antidesma bunius*. Timber of some species is valuable, such as boxwood (*Buxus*). Candelilla wax is obtained from *Euphorbia antisyphilitica* and jojoba wax from *Simmondsia chinensis*. Species of *Tragia*, *Mercurialis*, *Euphorbia*, *Phyllanthus*, and *Croton* are medicinal. Many are toxic to cattle and sheep; notably, the leafy spurge (*Euphorbia esula*), sun spurge (*E. helioscopia*), and eyebane (*E. maculata*). The African plant *Dichapetalum toxicarium* contains poisonous levels of fluorine (as fluoro-oleic-acid). This plant accumulates and concentrates fluorine from the soil. Species of *Plukenetia* are used as potherbs in the East Indies, *Euphorbia* in Africa, and *Claoxylon* in Malaysia. Many are ornamental plants: the poinsettia (*Euphorbia pulcherrima*), the crown of thorns (*E. milii*), the scarlet plume (*E. fulgens*), the copper leaf and red hot cattail (*Acalypha*), crotons (*Codiaeum*), and others. Trees such as *Daphniphyllum macropodum* are grown for their large and handsome foliage.

Edible fruits

NATURAL HISTORY

Life cycle. Some species are annuals of the wet season (*Micrococca*, *Sebastiania*, and others). Some, such as *Macaranga*, are rapidly growing, short-lived trees. Most members of the order are deciduous, dropping their leaves during seasons of unfavourable growth. Evergreen plants occur in the genera *Daphniphyllum*, *Buxus*, and others. Some, such as *Euphorbia neriifolia*, have leaves only during the wet season. In many other species of *Euphorbia*, the leaves are dropped early, and the stems not only perform the functions of the leaves but also act as water-storage organs. Some species begin flowering early in life, but others bloom only after five or six years.

Ecology. When certain species of *Euphorbia* that have a cactus-like growth habit are encountered in dry habitats, it is very difficult to determine from the external appearance whether the plant is actually a *Euphorbia* or a cactus unless it is in flower. The presence of latex, however, distinguishes the spurge. It is a matter of great interest to find how similar conditions of life have brought forth, in three different and widely separated families, such a close similarity of habit (*i.e.*, the cactoid growth form) as is met with in the families Euphorbiaceae (genus *Euphorbia*), Asclepiadaceae (genus *Stapelia*), and Cactaceae (numerous genera).

Many species prefer open land, but some members form an integral part of the tropical and subtropical forests of the world. Arborescent (treelike) cactoid species of *Euphorbia* are common in savannas. Plants such as *Bischofia javanica*, when growing on seashores, possess a peculiar oblique, condensed, one-sided habit (wind forms) and always show a decreased leaf size owing to the desiccation of buds. *Excoecaria parviflora* and *E. agallocha* prefer tidal marshes and saline flats. Some species are inhabited by ants, as in *Endospermum moluccanum*, in which the ants bite their way into stem sections, remove and eat or carry away the pith, and live inside the cavity thus formed. Other ant plants of interest are *Drypetes*, *Macaranga*, and *Agrostistachys*. Many species of the order are botanical nomads (widely distributed moving weeds having several methods of dispersal)—*e.g.*, *Croton bonplandianum*.

Stems inhabited by ants

FORM AND FUNCTION

Vegetative characters. Leaves of the Euphorbiales order are mostly alternate but are sometimes opposite; they are extremely variable in shape, ranging from simple, in the genera *Euphorbia*, *Buxus*, *Daphniphyllum*, and others, to deeply cut (palmate), in *Ricinus* and *Manihot*, trifoliate, in *Picrodendron*, and palmately compound, in *Hevea*. Stipules (small, leaflike appendages at the base of leafstalks) are absent in the families Buxaceae and Daphniphyllaceae but are usually present in most of the other families. The stipules may be minute and persistent, as in *Picrodendron*; or deciduous (falling); or they may be represented by branched, hairlike bodies (*Jatropha*), glands, or spines (*Euphorbia*). Extrafloral nectaries are present in several members of the Euphorbiaceae family.

Floral characters. Flowers in the order are mostly unisexual, except in the family Dichapetalaceae, in which they are predominantly bisexual. Bisexual flowers are also found in the family Buxaceae. When unisexual, male and female flowers may be borne on the same plant (bisexual plants, the monoecious condition), as in *Hevea*, or on different plants (unisexual plants, the dioecious condition), as in *Daphniphyllum* and *Panda*. The arrangement of the flowers (the inflorescence) shows great variation, and almost all types occur—heads, spikes, racemes, clusters, catkins, panicles, and others. In mixed types, often the first branching is racemose (*i.e.*, having a main axis with flowers borne on short secondary branches, the lower flowers maturing and blooming first) and all subsequent ones cymose (*i.e.*, similar to racemose, but with the terminal flowers blooming first). In bisexual plants seven types of flower arrangement can be seen: (1) male and female flowers in the same cluster without

any order (*Cicca, Bridelia*); (2) one female flower to each cluster of males (*Euphorbia*); (3) male flower clusters toward the base of the leafy twigs, female toward the ends (*Breynia, Emblica*); (4) male flowers at the base of the inflorescence with female in the upper parts (*Ricinus*); (5) female flowers at the base of the inflorescence, male in the upper parts (*Croton, Sapium*); (6) female flowers singly at the ends of the main branches of the inflorescence, surrounded by the males on the smaller side branches (*Aleurites, Hevea, Jatropha*); and (7) female flowers on one raceme, male on another, the female raceme usually paired with a male (*Codiaeum*). The partial inflorescences of *Dalechampia* and *Euphorbia* are so condensed as to give the appearance of single flowers. In *Dalechampia* the inflorescence is very complex. In the centre is a cushion of nine to 14 male flowers subtended by four small bracts. Anterior to this is a cyme of three female flowers in the axil (angle) of a larger bract. All these are enclosed in two large pink or white outer bracts. In *Euphorbia*, the partial inflorescence is a cyathium, which is a flowering group containing a central terminal female flower consisting of only the gynoecium (*i.e.*, the female parts or pistil, consisting of ovary, style, and stigma; there are no petals or other flower parts) and four or five bracts below that unite to form a cup-shaped involucre (whorl) resembling a calyx. Each bract subtends a small cyme of male flowers, the oldest of which is arranged near the centre. Each such cyme has a distinctive joint halfway up the stalk. Between the segments of the involucre are large oval or crescent-shaped glands, often brightly coloured, forming petallike structures. The cymose umbels (flower clusters radiating from a common point reminiscent of an umbrella and maturing from the centre outward) in some species of the Dichapetalaceae family are fused to the leaves (epiphyllous).

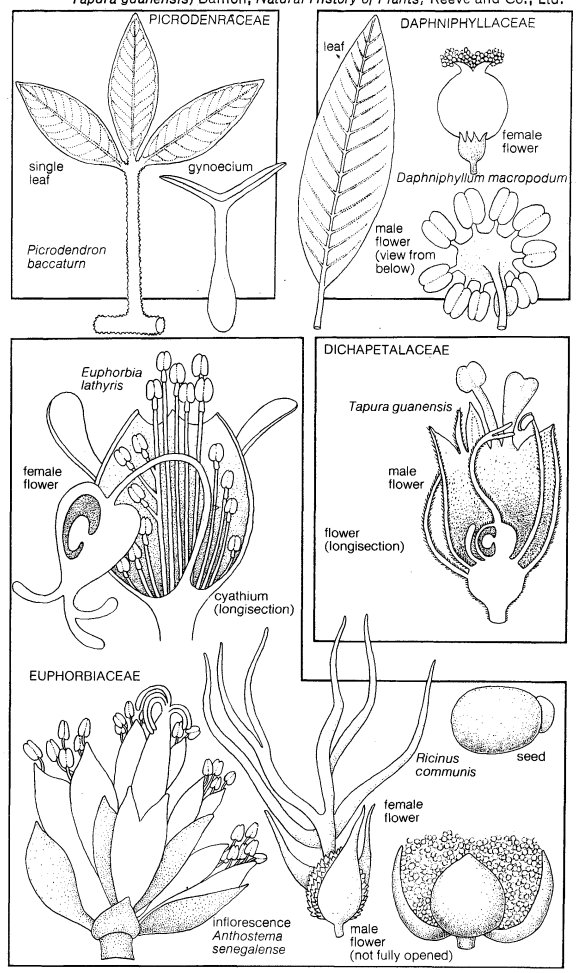
Complex flower clusters

The form of the flowers also shows variation, and the shape and size of flowers of different sex may differ widely, as in *Hevea*. Regular (radially symmetrical) hypogynous (*i.e.*, with a superior ovary—the other flower parts attach at the base of the ovary) flowers occur in almost all the species, except in some of the members of the family Dichapetalaceae, in which the ovary may be inferior. The perianth (the collection of petals and sepals) is mostly in fives or fours, sometimes distinguished into sepals and petals; more often, there is only one whorl of tepals, and, frequently, the flowers are naked, as in several members of the Euphorbiaceae family. When a corolla (the collection of petals) is present, the stamens are usually as many or twice as many as the petals. In naked flowers, the number of stamens is reduced to one (*e.g.*, in the family Euphorbiaceae), or several stamens may be loosely clustered, forming a globose head, as in the genus *Picrodendron*. In *Ricinus* the stamens are branched. In *Phyllanthus cyclanthera* the stamens are united by means of a ringlike common anther (synandrium). Both extrorse and introrse (*i.e.*, opening away from or toward the flower axis, respectively) anthers are present in the group. In the male flowers of several species, a rudimentary ovary is sometimes present. The ovary of female flowers is generally two- to five-chambered, the three-chambered condition being most frequent. Each chamber of the ovary contains one or two pendulous ovules that are usually anatropous (*i.e.*, the body of the ovule is bent back along its supporting stalk) with a ventral raphe (ridge). Placentation (ovule attachment) is mostly axile (along a vertical central axis of the ovary). There are two coats (integuments) for each ovule, and both or either one of them may take part in the formation of the micropyle (a small opening in the ovule). Both of them persist in the seeds of many genera.

Pollination

Cross-pollination is the usual pollination method in the Euphorbiales order. In *Mercurialis* and other genera with inconspicuous flowers, pollination is by wind. Insect pollination takes place in almost all the other members. The flowers being small, insects are attracted to them by the large, brightly coloured bracts, as in *Dalechampia* and *Euphorbia*, or by coloured calyx, as in *Manihot*. Honey glands, present in several members, as on the involucre of the cyathium of *Euphorbia*, are frequently an attraction. Many species are sweet-scented of honey or citronella or have a fetid-wax smell, as in *Elaeteriospermum*, by which means they also attract small flies, beetles, honeybees, wasps, and plant bugs, which pollinate them.

Drawing by M. Moran based on (*Euphorbia lathyris, Anthostema senegalense, Tapura guanensis*) Baillon, *Natural History of Plants;* Reeve and Co., Ltd.



Vegetative and floral structures from four of the families of the order Euphorbiales.

Fruits and seeds. The fruit is a capsule in most members of the families Euphorbiaceae and Buxaceae. They are sometimes prickly, as in *Ricinus*. The fruit may be a drupe (*i.e.*, a fruit with a single-seeded stony pit) or a berry. The capsular fruit often splits into three parts (cocci) from the central column, and at the same time each coccus opens ventrally, letting the seeds escape. Some fruits, such as those of sandbox tree and rubber tree, split with explosive violence, hurling the seeds away. The seeds of some are distributed by animals, either because they have pulpy edible coats or because the fruits themselves are berries. The seeds of several members have a caplike outgrowth called a caruncle. This spongy structure attracts ants, and the seeds carried away by them effect dispersal. The seeds, with the exception of those of the families Picrodendraceae and Dichapetalaceae, contain abundant endosperm (a starchy nutrient tissue for the developing embryo), generally rich in oil. The embryo is usually very large in all but the family Daphniphyllaceae. The cotyledons (seed leaves) are generally flat and emerge above the surface of the ground at the time of germination (epigeal germination) and turn green.

EVOLUTION

The Euphorbiales order appears to be evolutionarily highly specialized, as is evidenced by the very reduced

flowers in many members. It has been presumed that this group evolved from some ancient group intermediate between the family Flacourtiaceae (of order Violales) and the Malvales order. The nonhomogeneity of the order does not support the view that it is monophyletic, however. It is thought that the Euphorbiales order is not a natural assemblage derived from the same ancestors in the distant past but is a synthetic group made up of derivatives from several ancestors brought together merely because of a superficial resemblance and want of knowledge of the true evolution of the groups.

Fossil record

This order does not seem to have fossil representatives below the Upper Cretaceous Period (about 65,000,000 years ago), and such fossils are also few, although such names as *Euphorbiophyllum*, *Crotonophyllum*, and others are occasionally encountered in literature as having been obtained from Upper Cretaceous and Eocene (about 50,000,000 years ago). Tertiary (2,500,000 to 65,000,000 years ago) deposits of *Euphorbia*, *Acalypha*, *Mallotus*, and others are known from various parts of the world.

CLASSIFICATION

Distinguishing taxonomic features. It is impossible to give a set of characters by which the Euphorbiales order can be distinguished absolutely from all other dicots, for there are many exceptions even among the common members. Nevertheless, combinations of certain features are used by taxonomists to set limits to the order and to determine relationships within the groups. Such features include habit, presence or absence of latex, nature of indumentum (hairs on the surface of leaves, stems, and other organs), nature of leaves, presence or absence of stipules, sexuality, nature and arrangement of the flowers, nature and position of the ovary, presence or absence of endosperm, nature of fruit, features of embryo, and others.

Annotated classification. The arrangement of the families presented here is a recent one of wide acceptance.

ORDER EUPHORBIALES

Trees, shrubs, or rarely annual herbs; with simple, stellate, or scaly hairs; leaves simple or rarely compound; stipules mostly present; flowers hypogynous (superior ovary) or very rarely tending to be epigynous (inferior ovary), unisexual or very rarely bisexual, radially symmetric or very rarely tending to be bilaterally symmetric; tepals overlapping or not overlapping in the bud; petals rarely present; stamens numerous to solitary, free or monadelphous (joined by their filaments); ovary with axile placentation; ovules mostly anatropous; seeds with copious endosperm or rarely without it. Seven families, about 315 genera, and 8,000 species.

Family Buxaceae (boxwood family)
Evergreen shrubs or trees with simple leathery leaves; unisexual naked flowers in heads or spikes; stamens 4–6; ovary superior 3-locular; ovules 1–2, pendulous. Five genera and about 60 species distributed in east Asia and North America.

Family Simmondsiaceae (jojoba-wax family)
Evergreen shrubs with opposite simple leaves; flowers without petals, dioecious (*i.e.*, male and female flowers are on different plants), male clustered, female solitary, stamens many; ovary 3-celled with one ovule in each cell. One genus with a single species, *Simmondsia chinensis*, distributed in southwestern North America.

Family Daphniphyllaceae
Leaves simple, crowded, alternate; flowers dioecious in racemes, without petals; sepals of male flowers 3–8; stamens, 6–12; ovary superior, 2-locular with two ovules in each cell. One genus, *Daphniphyllum*, with about 35 species distributed in east Asia and Malaysia.

Family Euphorbiaceae (spurge family)
Herbs, shrubs, or trees; some with milky latex; leaves mostly simple; flowers mostly monoecious (both sexes on one plant); petals rarely present; stamens one to many, free or joined together; ovary superior, 3-locular; seeds often carunculate. About 300 genera and about 7,650 species distributed in tropical and temperate regions.

Family Dichapetalaceae
Small trees or shrubs, sometimes climbing; leaves simple; flowers mostly bisexual; sepals 5, petals 2-parted, free or united with stamens into a tube; ovary superior to inferior, 2- to 3-locular; ovules 2 in each cell. Four genera and 250 species distributed in tropical Africa and America.

Family Pandaceae
Small trees; leaves simple; flowers dioecious; petals present; stamens 10; ovary 3- to 4-locular; ovule solitary in each cell. One genus with a single species, *Panda oleosa*, distributed in west tropical Africa.

Family Picrodendraceae
Trees; leaves trifoliate; female flowers solitary, male in catkins; sepals and petals absent; stamens many, clustered, forming a globose head; ovary superior, 2-locular; ovules two in each cell; fruit 1-seeded. One genus with a single species, *Picrodendron baccaturn*, distributed in the West Indies.

Critical appraisal. There is much disagreement among taxonomists regarding the systematic position of the families included in the Euphorbiales order. Some authorities retain only the family Euphorbiaceae in the order, the remaining families being variously placed—Dichapetalaceae in the order Rosales, Buxaceae (including Simmondsiaceae) and Daphniphyllaceae in Hamamelidales, Pandaceae in Celastrales, and Picrodendraceae in Juglandales. Other authorities treat Euphorbiaceae, Daphniphyllaceae, and Dichapetalaceae as families in the Geraniales order; Buxaceae in Sapindales; and Pandaceae in an independant order, Pandales. Picrodendraceae as a family is not recognized in these systems, and the genus *Picrodendron* is then included in the family Simaroubaceae. Similarly, *Simmondsia* is included in Buxaceae. Three genera of the family Euphorbiaceae —*Micrantheum*, *Pseudanthus*, and *Stachystemon*—have been united by some workers into a special family, Micrantheaceae, but this separation is not widely recognized. Some taxonomists have even elevated many individual genera of the Euphorbiaceae family to the rank of family—*e.g.*, the families Androstachydaceae (from the genus *Androstachys*), Stilaginaceae (*Antidesma*), Bischofiaceae (*Bischofia*), Hymenocardiaceae (*Hymenocardia*), Uapacaceae (*Uapaca*), Peraceae (*Pera*), and others. All these differences of opinion among competent taxonomists probably reflect the polyphyletic (origin from various unrelated ancestors) nature of the order.

BIBLIOGRAPHY. F. PAX, "Euphorbiaceae," in A. ENGLER, *Das Pflanzenreich*, vol. 42, 44, 47, 52, 57, and 63 (1910–14), a long series of papers, some exceeding 300 pages in length, making an authoritative monographic treatment of the genera of the order; F. PAX and K. HOFFMAN, *ibid.*, vol. 68 and 85 (1919–24), continuing the monographic treatment of Euphorbiales genera; A. ENGLER and K. PRANTL, *Die naturlichen Pflanzenfamilien*, 2nd ed., vol. 19a–19c, 20a (1931), a descriptive taxonomic treatment of flowering plants, including those of the Euphorbiales order, written in German; J. HUTCHINSON, *Families of Flowering Plants*, vol. 1, *Dicotyledons*, 2nd ed. (1959), a good source of general information; A. TAKHTAJAN, *Flowering Plants: Origin and Dispersal* (1969; orig. pub. in Russian, 2nd ed., 1961), treatments of flowering plant classification and phylogeny; J.C. WILLIS, *A Dictionary of the Flowering Plants and Ferns*, 7th ed. rev. by H.K. AIRY SHAW (1966), a compilation of all plant genera, families, and higher divisions, including information on taxonomic placement, members of species, and other botanically interesting matters; older editions also include much information on common names and economic products.

(N.C.N.)

Euripides

An 18th-century English man of letters, Horace Walpole, remarked: "The world is a comedy to those that think, a tragedy to those that feel." Euripides, the youngest of ancient Athens' three greatest tragic poets, following Aeschylus and Sophocles, both thought and felt deeply and found little to smile at. His plays were rich in ethical and social comments and have provided a rich ore for later writers and speakers who have found such comments easy to detach from their dramatic context and enshrine in moral essays, anthologies, or even Christian sermons.

It is possible to reconstruct only the sketchiest biography of this thoughtful man who was the associate of philosophers, the owner of an exceptionally big library, and a stranger to hilarity.

Sources for biography. Among the Euripidean manuscripts, the earliest of which is of the 11th century AD, there is a *Life of Euripides*. Put together sometime in late

Euripides, marble herm copied from a Greek original, c. 340–330 BC. In the Museo Archeologico Nazionale, Naples.
By courtesy of the Soprintendenza alle Antichita della Campania, Naples

antiquity, it is an entirely uncritical assemblage of material selected from previous writers. The earliest and most reliable of these, named Philochorus, wrote a *Life of Euripides* in the first half of the 3rd century BC, well over 100 years after the poet's death. He would have had access to certain official records of the dramatic festivals; apart from that, there are only oral traditions to fall back on. For the most part, the extant *Life* consists of literary gossip, some of which looks like more or less intelligent inferences drawn from the plays themselves; much of it is nothing but jokes made against Euripides by contemporary comic poets, jokes now mistaken for sober history. One well-known biographical "fact," for example, is that Euripides' mother was a greengrocer who sold herbs in the market-place. The great comedist Aristophanes said so in play after play and it was always good for a laugh. But it may not be true. Philochorus, in fact, said that Euripides was of a very good family; Theophrastus (a pupil of Aristotle) recorded that as a lad Euripides was given an honorable part in two religious ceremonies, which would indicate that his mother was not a greengrocer; and Aristotle himself records in the *Rhetoric* that in later life Euripides was involved in vexatious litigation of a technical kind that suggests that he was a man of wealth, or at least could be represented as such—and money was not made in ancient Athens by writing plays any more than by selling greengroceries.

Uncertain biographical accounts

Life. Euripides' mother's name was Cleito; his father's, Mnesarchus or Mnesarchides. Tradition said that he was born in 480 BC, on the date of the Battle of Salamis (a decisive Athenian sea victory against Persia). The fiction is obvious. Since the great tragedian Aeschylus fought in the battle and the other great Athenian tragedian Sophocles led a chorus of boys which celebrated the victory, it would be appropriate to select that glorious day as the time of Euripides' birth. A 3rd-century BC inscriptional record of festival dates reckoned that he was born in 484, which may well be correct. The only other biographical dates that are certain (apart from the dates of some of the plays) are that he first received the honour of being chosen to compete in the dramatic festival in 455; won his first victory (with plays now unknown) in 441; left Athens for good in 408, accepting a very honorific invitation from Archelaus, king of Macedonia; and died in Macedonia in 406. According to the *Life*, traditionally, he died in suitably dramatic circumstances: torn to pieces either by dogs or by women. More worthy of belief is the statement that in 406 BC, when Sophocles next led a chorus into the theatre, he and the chorus wore mourning for Euripides, and in 405 Aristophanes produced *The Frogs*, a play based on the idea that Athens no longer had a great tragic poet. History was to show that Aristophanes was not far wrong.

Known biographical dates

Several anecdotes attest to how greatly honoured Euripides was after his death. The *Life* cites an epitaph composed (as it says) either by Thucydides the historian, or by Timotheus, a musician, presumably for a cenotaph built for Euripides in Athens:

> His bones are laid in Macedon, where he
> Ended his life. His tomb? The whole of Hellas.
> Athens his motherland. His muse gave joy
> To many: many give to him their praise.

In what the sources tell of Euripides' personal history, there is one gap that can hardly be accidental. It is known that Aeschylus was proud of having fought at Marathon (a battle in which Athens repulsed Persia in 490 BC) and Salamis. Sophocles, on the other hand, had once or possibly twice been elected one of the 10 generals of Athens and was later appointed to a commission charged with revising the Athenian constitution. Not a word, however, has survived of any of Euripides' public activity, except that an ancient commentator on Aristotles' *Rhetoric* says that he once served on a diplomatic mission to Syracuse in Sicily (some modern scholars have suspected that his name might be a mistake for that of Hyperides, an Athenian orator).

Private life

Of Euripides' private life, very little can be said. Later tradition invented for him a spectacularly disastrous married life. This, no doubt, was based on jokes made by comic poets and was supported perhaps by the naïve thought that the evil women who appear so often in his plays must have been drawn from unhappy personal experiences. It is known that he married a lady called Melito and had three sons. One of these was something of a poet and produced the *Bacchae* after his father's death and may have completed the unfinished play *Iphigeneia at Aulis*.

Dramatic career. The ancients knew of 92 plays composed by Euripides, of which 67 are known in the 20th century, if only by name. Nineteen plays are extant, if one that is disputed—*Rhesus*—is included. The figure 92 may seem a very large number, but it is perfectly credible. A poet allowed to give a performance at each year's dramatic festival had to produce a tetralogy: three tragedies and a lighthearted production called a satyr play. But Greek plays were short, and a normal tetralogy would not exceed 6,000 verses in length (Shakespeare's *Hamlet* runs to about 8,000). Ninety-two plays would correspond with 23 tetralogies. Spread over an active career of nearly 50 years, they would average one tetralogy every two years—implying an assiduous but not a frantic professional life. Shakespeare's average yearly output, by comparison, was greater. At only four festivals was Euripides awarded the first prize—the fourth, posthumously, for the tetralogy that included the *Bacchae* and *Iphigeneia at Aulis*. As Sophocles won either 18 or 24 victories, it is clear that Euripides was comparatively unsuccessful. More to the point, perhaps, is that on more than 20 occasions Euripides was chosen, out of all contestants, to be one of the three laureates of the year. Furthermore, the regularity with which Aristophanes parodied him is proof enough that his work commanded attention. It is often said that disappointment was one of the reasons for his leaving Athens in his old age. That may be true, though it is purely surmise, but there are other reasons, even more plausible, why an old poet might have left Athens in the 23rd year of the Peloponnesian War.

Euripides is said to have made enemies, to have been prosecuted for blasphemy (like Socrates, a few years later), to have given offence by putting immoral women on the stage, and in other ways to have undermined respectable opinion. In particular, he was accused—and still is, occasionally—of misogyny. Certainly, it is easy to extract from his plays, including those now only partially known, a long list of heroines who are fierce, treacherous, or adulterous, or all three at once. It is significant that

one of the plays in his first tetralogy of 455 BC was *Peliades* (*The Daughters of Pelias*, who, legend related, were tricked by the wicked Medea into dismembering and boiling their father in the foolish belief that he would thereby recover his youth); a few years later he produced *Aegeus*; and in 431 *Medea*. Clearly, he was attracted by the devastating character of Medea, who figured in all three of these works. In the plays there are other such treacherous and destructive women, but misogyny is altogether too simple an explanation. For one thing, in the extant plays there are women who nobly sacrifice themselves for others: *Heraclidae* (*Children* of *Heracles*), *Hecuba*, and *Iphigeneia in Aulis*. What is more, even moderate diligence discloses in the extant plays a list of men who are no more admirable than the fearsome women; none of them indeed so passionate, but most of them more contemptible and some of them more destructive. There are also noble male characters—Theseus (*Suppliants*) and Heracles (*The Mad Heracles*), for example—but not many.

The Euripidean heroine

Also to be noticed as distinctively Euripidean are oppressed heroines who begin by attracting sympathy and finish by being as vindictive as were their oppressors: in *Medea*, for example, the female chorus is at first indignant on Medea's behalf and at the end is even more indignant at what she has done; and in *Hippolytus*, Phaedra is first a loyal wife who abominates her uncontrollable passion for her stepson and will die rather than reveal it and then, when her secret is wormed out of her, writes a lying accusation that will involve others in her own doom. A clue to all this, and to Euripidean tragedy in general, is found in the *Medea*. When the enchantress Medea has destroyed not her husband Jason, leader of the Argonauts, but everyone else who is connected with him, she is seen on the roof, inaccessible, with her dead children in her arms. First the horrified chorus, then Jason, appeal to Heaven and Earth to avenge so inhuman an atrocity. But Heaven and Earth do nothing of the kind: in fact the Sun God (in mythology an ancestor of Medea) sends down a chariot to bear Medea triumphantly to refuge in Athens. Aristotle condemned the ending as "illogical." That it was illogical was Euripides' point.

Euripides' tragic outlook. Euripides' view was emotional, given to despair. Instead of a basic order, hard, unforgiving, but in the main intelligible, he saw a universe much harder for man to live with and much more unpredictable. Chance and disorder and human reason continually thwarted by human unreason and passion and confronted by *theoi* (the powers) who seem indifferent to human reason and morality are the elements of his tragedy, and apparently meaningless suffering is the outcome.

It is often said that Euripides, in portraying "gods" in glaring colours, was attacking the traditional Olympian religion as crude and false. That is probably a misconception. Aeschylus and others had already done so, and Euripides, in this respect, was being traditional rather than a reformer.

The war with Sparta broke out in 431 and continued, year after year, with increasing ferocity and folly. In two of his earlier wartime plays, the *Heracleidae* and *Suppliants*, Euripides represents an ideal Athens undertaking a just war to defend the oppressed; but soon came the *Hecuba* with its twofold picture: first the inhuman and stupid brutality of the conquerors toward Hecuba and the other Trojan captives; then the sickening revenge inflicted by "the mobled (muffled, as with a hood) Queen" herself upon the barbarian who had murdered her son for gold. This series of plays is crowned by the *Trojan Women*, in which, again, the conquerors inflict one outrage after another on the vanquished but were themselves to be destroyed at sea on their voyage home. Like Cassandra (a Trojan princess who foretold the Greek capture of Troy in the legendary Trojan War), Euripides prophesied, but in vain. When he was writing this play his own city was engaged in subduing and destroying an unoffending Aegean island, Melos; immediately afterward Athens despatched a powerful force to conquer Sicily, and hardly a man returned alive. It may not be only out of personal disappointment that Euripides left Athens for Macedonia in 408, when the war had dragged on for another seven years.

Euripides' tragedies are not nicely and logically Aristotelian in structure: Euripides did not feel himself to be living in a nicely logical universe. It follows, too, that certain other of the famous Hellenic virtues are not always to be found in his work. He does not make, for instance, a point of avoiding the sensational, nor of practicing reticence. Euripides' character drawing is rarely rich or subtle; his characters rarely grapple. They debate or they deliver little homilies on matters of philosophic or social interest. The choral odes are apt to be lightweight, prettily decorated, rather monotonous in rhythm, sometimes only tangential to what is going on. It could hardly be otherwise when what is going on is often no more than waiting for the next blow to fall. His power lies in the scarifying situations that he creates and in the total and frightening effect of a play. He is an incomparable knife twister.

The tragicomedies

During the last two decades of his career Euripides began to write tragedies that are not "tragedies" in the modern sense of the word but what might be called romantic drama or tragicomedy because they have happy endings. Extant plays in this style include *Ion*, *Iphigeneia in Tauris*, and *Helen*. Unlike the tragedies, they do not deal with anything of intrinsic importance. If gods appear in them they are not to be taken seriously. Such plays might be described as pure "theatre," of the highest order: in them, turning his back for the time being on the real world that he found so unrelievedly tragic, Euripides reveals himself as one of the greatest virtuosos of the stage.

Plays of the tragicomedy type seem to point forward to the drama of the 4th century BC. It is certain that the fame and popularity of Euripides soon began to eclipse that of Aeschylus and Sophocles. The age of Classical Greece was drawing to a close, to be followed by the cosmopolitan Hellenistic period. One can readily understand that in the new age the essentially political and "religious" tragedy of Aeschylus and Sophocles made less appeal than that of Euripides, with its more obvious emotional, even sensational, effect. It may well be that even their Greek became progressively more difficult to follow than his. Also in the extant "fragments"—that is, citations found in later writers—those of Euripides are more numerous than those of Aeschylus and Sophocles put together.

MAJOR WORKS

Alcestis (438), pro-satyric; *Medea* (431); *Hippolytus* (428); *Heracleidae*, *Andromache*, *Suppliants*, and *Hecuba* (all four before 423); *Electra; Trojan Women* (415); *Helen* (412); *Phoenician Women* (411–409); *Heracles*, *Iphigeneia in Tauris*, *Ion*, and *Orestes* (all four 408); *Iphigeneia in Aulis* and *Bacchae* (both posthumous); *Cyclops*, a satyr play; *Rhesus* (disputable). Substantial papyrus fragments have been discovered of the *Hypsipyle* (411–409), ed. by G.W. Bond (1963).

Europe

Among the continents, Europe is an anomaly. Larger only than Australasia, it is a small appendage of the great land mass that it shares with an Asia more than four times its size. Yet the peninsular and insular extremity of Eurasia, thrusting toward the North Atlantic Ocean, provides—thanks to its latitude and its physical geography—a relatively genial human habitat, and the long processes of human history came to mark off the region as the home of a distinctive civilization. In spite of its internal diversity, Europe has thus functioned, from the time it first emerged in the human consciousness, as a world apart, concentrating—to borrow a phrase from Marlowe—"infinite riches in a little room."

All the continents are conceptual constructs, but only Europe was not first perceived and named by outsiders. "Europa," as the more learned of the ancient Greeks first conceived it, stood in sharp contrast to both Asia and Libya, the then known northern part of Africa. Literally, "Europa" is now thought to have meant "mainland," rather than the earlier interpretation, "sunset." It appears to have suggested itself to the Greeks, in their maritime world, as an appropriate designation of the broadening, extensive northerly lands that lay beyond, lands with characteristics but vaguely known, yet clearly different from those inherent in the concepts of Asia and Libya, both of which, relatively prosperous and civilized, were associated closely with the culture of the Greeks and their predecessors. Traders and travellers reported that Europe possessed distinctive physical units, with mountain systems and lowland river basins much larger than those familiar to inhabitants of the Mediterranean region. It was also clear that a succession of climates, markedly different from those of the Mediterranean borderlands, were to be experienced as Europe was penetrated from the south. The spacious eastern steppe and, to the west and north, primeval forests as yet only marginally touched by human occupancy further underlined environmental contrasts. Europe was culturally backward and scantily settled. It was a barbarian—that is, a non-Greek—world, its inhabitants making "bar-bar" noises in unintelligible tongues.

Origins of the "Europa" concept

The Roman Empire, at its greatest extent in the 2nd century AD, revealed, and imprinted its culture on, much of the face of the continent, while trading relations beyond its frontiers also drew the remoter regions into its sphere. Yet it was not until the 19th and 20th centuries that modern science was able to draw with some precision the geological and geographical lineaments of the European continent, the peoples of which had meanwhile achieved domination over—and set in motion vast countervailing movements among—the inhabitants of much of the rest of the globe.

As to the territorial limits of Europe, while these seem clear on its three seaward flanks, they have been uncertain and hence much debated on the east, where the continent merges, without sundering physical limits, with parts of western Asia. Even to the north and west, many island groups—Svalbard (Spitsbergen), the British Isles, the Faeroes, Iceland, and the Madeira and Canary islands—that are European by culture are included in the continent, although Greenland is conventionally allocated to North America. Further, the Mediterranean coastlands of northern Africa and southwest Asia also exhibit some European physical and cultural affinities, and Turkey and Cyprus, while geologically Asian, possess elements of European culture and may, perhaps, be regarded as parts of Europe. Eastward limits, now adopted by European (including Soviet) geographers, assign the Caucasus to Asia and are taken to run southward along the eastern foot of the Urals, and then across the Mugodzhar Hills (Mugodzharskiye Gory), along the Emba River (Vaike Emajogi), and along the northern shore of the Caspian Sea. West of the Caspian, the European limit follows the Kumo-Manych Depression (Kumo-Manychskaya Vpadina) and the Kerch Strait (Kerchensky Proliv) to the Black Sea.

The 4,100,000 square miles (10,600,000 square kilometres) occupied by Europe reveal no simple unity of geological structure, landforms, relief, or climate. Rocks of all geological periods are exposed, and the operation of geological forces during an immense succession of eras has contributed to the molding of the landscapes of mountain, plateau, and lowlands, and bequeathed a variety of mineral reserves. Glaciation, too, has left its mark over wide areas, and the processes of erosion and deposition have created a highly variegated and compartmentalized countryside. Climatically, Europe benefits by having only a small proportion of its surface either too cold or too hot and dry for effective settlement and use. Regional climatic contrasts nevertheless exist: oceanic, Mediterranean, and continental types occur widely, as do gradations from one to the other. Associated vegetation and soil forms also show continual variety, but little is left of the dominant woodland that clothed the continent when *Homo sapiens* first appeared.

All in all, Europe enjoys a considerable and long-exploited resource base of soil, forest, sea, and minerals, notably coal, but manpower, considerable numerically, as well as technically highly qualified, is increasingly its principal resource. The continent, by the 1970s, contained a slightly shrinking fifth portion of mankind, but this represents a population of high skill and initiative. Europe thus supports high densities of population, markedly concentrated in industrialized regions. In manufacture, commerce, and agriculture, it still occupies an eminent, if no longer necessarily predominant, position, and, as agriculture increasingly rationalizes its structure, city life is, everywhere, becoming the norm.

Europe and the world

Europe is pre-eminently the homeland of white peoples. Its early and continuing economic achievements, evidenced by a high standard of living, and its successes in science, technology, and the arts spring from the vigour of its peoples in developing a high civilization, the roots of which lie in ancient Greece and Rome, the Byzantine Empire, and Palestine. Whatever its indebtedness, Europe has always shown its own powers of creativity and leadership: although wracked and exhausted by continued internal conflict, it has nevertheless advanced sufficiently to leave as its heritage the exploration, colonization, and development of other races and regions of the globe, if not always to the benefit of the other races and regions.

This article covers the overall physical and human geography of the European continent. For information on related topics, see the articles EUROPEAN CULTURE SINCE 1800; EUROPEAN DIPLOMACY AND WARS (C. 1500–1914); WORLD WARS; as well as articles on other major topics in the history of the continent and on the history of individual nations. There are separate articles on the major geographical features of Europe, as well as articles surveying contemporary nations and cities; see also CONTINENTS, DEVELOPMENT OF.

This article is divided into the following sections:

I. Geological history
  - Elements and processes in the making of the continent
  - The territorial emergence of Europe
  - The legacy of successive eras

II. Physical geography
  - Relief
  - Climate
  - Drainage
  - Soils

III. Plant and animal life

The outlook for Europe

I. Geological history

The continental framework of Europe is a geologically recent product of earth history, and modern research has outlined the history of the making of the European landmass over a period exceeding 500,000,000 years. This time span starts with the Precambrian, from which the fossils of the first living things are found in the rocks, and includes successive eras known as the Paleozoic (lasting 345,000,000 years), the Mesozoic (lasting 160,000,000 years), and the Cenozoic (which has lasted 65,000,000 years and includes Tertiary and Quaternary periods). Each of these eras is divided into named sequent periods, and the whole of the immense span of the geological record—itself only the latter phase of Earth history—dwarfs that of the human record, which begins towards the end of the Tertiary. In approximations to its present configuration, Europe cannot be traced back before Tertiary times, but some parts of it are made up of rock structures that originated as far back as the Paleozoic, or even the Precambrian, eras.

ELEMENTS AND PROCESSES IN THE MAKING OF THE CONTINENT

Shield, crust, and ocean. The specific molding of the European continental mass resulted from the interplay, over time, of certain basic structural elements and powerful processes, the latter often operating deep within the Earth. Among the elements from which Europe became compounded, special interest attaches to the massive earth blocks, or shields, which form the oldest territorial units of the continent. These consist wholly of the oldest known rocks; the yet older, or primitive, rocks of the earth's crust have disappeared through time. These ancient shield, or platform, rocks of Europe, some of which have stood above the sea throughout much of geological time, were themselves formed up to more than 1,000,000,000 years before the geological record begins. Both major and minor shields can be distinguished: the Fennoscandian (or Baltic) Shield and the Russian Platform are major units, whereas the Tyrrhenian and Aegean shields to the south are only fragmentary. These structures performed two functions: they provided core areas around which younger components of the continent came to be built, and they provided almost immovable obstacles, or forelands, to lateral, horizontal pressures of the Earth's crust.

Crustal layers

These crustal pressures stemmed from the nature of the crust (or lithosphere) itself in and around the region where Europe emerged. The crust is formed of an inner mantle of very great depth, covered by a relatively thin layer of dense rocks, notably basalt, and known as the sima. Above this layer, an even thinner cover of lighter rocks, the sial, underlies the continent but is largely lacking from the surrounding ocean bed; Europe can thus be visualized as a raft of sial rocks, notably granite, buoyed up in the denser sima. A principle of equilibrium, moreover, applied to these crustal processes: the mass of sima, beneath the ocean, and the mass of sial, penetrating deeply from the European land surface until it rests on the sima below, must achieve a state of balance. This operation, isostasy, accounts for continued, small-scale raising or lowering the land surface relative to sea level and has been of vital significance in the molding of Europe.

Another fundamental element is provided by the vast saltwater body, the world ocean, which has always covered much of that part of the crust lacking a sial shell: indeed, at all geological times, sial land areas, in Europe as elsewhere, have been exceptional features. When the volume of water in the ocean surrounding Europe increased, it invaded large land areas. Into these geological seas, later drained, which above all characterized the Mesozoic and Tertiary eras in emergent Europe, masses of sediments and the fossil remains of marine life were deposited, providing an accurate time record.

Endogenetic and exogenetic forces. In addition, both the ocean bed surrounding Europe and the emerged lands comprising the continent have been subjected to strong vertical pressures exerted from within the Earth by way of the very deep mantle enclosing its inner core. These inner forces, summed up by the term endogenetic, are very important to an understanding of the emergence of Europe. They have had various effects; one is that, along tensional fissures, or zones of weakness in the crust, great volumes of magma, or molten rock substance, have been emitted as lava, which has solidified to become the rock (predominantly basalt) known as igneous. Where the magma has not reached the European surface, it has been injected among other rocks to form subterranean sheets, sills, and veins. Such emissions of hot liquid within the crust are believed to account for the great extent of granite there, and indeed the process is known as the granitization of pre-existing rocks. These granitic intrusions, or batholiths (literally: "rocks of the depths") occupy, notably in Finland, areas of considerable size and may become exposed through the removal of rock layers above them. Migmatites, mixed rocks containing some granite, are formed by the same process acting on the margins of granitic bodies and are a common occurrence in Europe. In addition to the sedimentary and igneous rocks of Europe, a final class of rock is known as metamorphic and was formed by such great heat and pressures from within the crust as to change sedimentary and igneous rocks into a new form.

Igneous and metamorphic rocks

In addition to isostasy, noted above, endogenetic forces that have been active in Europe include both epeirogenesis—the continent-making force, exerted vertically through the earth's mantle, which can raise or lower extensive areas—and orogenesis, or the mountain-creating force. This latter process involved not only the ancient shields of Europe but also the equally important structural units known as geosynclines: enormous, elongated, troughlike zones, lying adjacent to the shields, into which sediments—transported waste from the shields—accumulated, over geological time, into great depths, causing the trough itself to sag deeper. The great mountain systems of Europe, with the Alpine System the most recent and pre-eminent example, resulted from powerful and volcanic compressional forces exerted laterally by shield areas against the massive sedimentary content of the geosynclinal basins lying between them, forcing the former troughs upward and folding them into new, elevated mountain systems. This orogenic process took place most markedly in the Paleozoic and Cenozoic eras and involved a dramatic rupturing of parts of the European shields, much volcanicity and metamorphism, and the creation of great masses of basalt and granite. Violent and dramatic as these orogenic processes appear, they took place over many millions of years and were the main force molding the emergent physique of Europe and the important disposition of land and sea. Milder crustal movements, known as warping, also affected the shaping of Europe's surface through their effect on the ancient shields, particularly in the Mesozoic Era, when orogenesis was largely absent.

The operation of exogenetic forces—that is, the endless processes of erosion and sedimentation at the surface, where rocks are exposed to the atmosphere and thus to the effects of climate and weather—provided the finishing touches to the making of the European continent. Over periods of long duration, these forces have worked powerfully on the exposed rocks and landforms of Europe and so have differentiated remarkably the physical geography of the continent. The chemical and mechanical weathering, or wearing away, of rocks was followed by the transportation of rock waste by gravity and the action of glaciers, running water, and winds, eventually depositing the waste offshore (infilling the geosynclines mentioned above), in lakes and inland seas, and on the land surface itself. A final, but most important, exogenetic process active in Europe was associated with the Great Ice Age of the Pleistocene Epoch, which

The role of weathering

lasted for about 2,000,000 years after the close of the Cenozoic Era and formed the initial phase of the Quaternary Period.

Chronological summary. The chronology of the emergence of Europe may be summarized as follows: the first element to be noted is the presence of Precambrian shield areas in the north and east, known, respectively, as Fennoscandia and the Russian Platform. Against these structures, the Caledonian orogeny of the Paleozoic folded and uplifted the Caledonian mountains. The Paleozoic also witnessed the Hercynian orogeny, which created mountain systems in many parts of the present European continent from Iberia and the British Isles in the west, to the Ural Mountains at the eastern margin. Prolonged erosion and deposition from these ancient elevated surfaces continued, while, predominantly during the ensuing Mesozoic and Cenozoic eras, widespread seas, occupying much of the present continent, which had not yet emerged as land, as well as the shield rocks of the Russian Platform, received layer upon layer of sedimentary rocks. The Cenozoic Era brought a new series of orogenic events, known as Alpine, which, in conjunction with later uplifts, bequeathed to Europe the relatively youthful mountain systems that persist in many parts of the continent. Other, less violent, structural changes took place beyond the main regions of mountain-building, and also the whole pattern of land and sea changed drastically. This Cenozoic orogeny is thought to have resulted from an overriding of Europe by the continent of Africa, a process that compressed violently the geosynclinal deposits interposed between the ancient shields of both continents. Other processes important in the making of Europe include continued marine transgressions and sedimentation, minor earth movements and rock warpings, and the effect of glaciation, which, notably in the north, wore down elevated areas and, by the process of isostasy, brought new lands above the sea and molded new regional configurations in the coasts. Finally, earthquakes and volcanic activity continue to mold the European continent in the present day, although the process is relatively quiescent except in local terms.

THE TERRITORIAL EMERGENCE OF EUROPE

The continental shield. The oldest rocks that survive in Europe are the shield areas that formed stable nuclei, or older cratons, around which later rocks accreted. Nothing remains of the earliest continental land, and the Fennoscandian (or Baltic) Shield is merely a relic from Precambrian times. The history of earlier Earth surfaces can only be conjectured. This European shield—part of a vast continental area that included Iceland, Greenland, and the Laurentian or Canadian Shield of North America—owed its emergence to orogenesis in Precambrian times, and it was subsequently folded. In the Cambrian Period the sea, occupying an elongated geosynclinal trough, covered most of Fennoscandia; indeed, all of the western peninsular part of the European continent as we know it was covered by sea, although western Ireland, part of Finland, and the broad mass of eastern Europe, namely the Russian Platform, rose above it.

The Fennoscandian Shield

The Fennoscandian Shield presents basement and even surface rocks in Norway, Sweden, Finland, and adjacent Soviet Karelia. In Norway and Sweden they rise to 6,000 feet (2,000 metres). Granites and gneiss, worn down relentlessly over an immeasurable period, predominate, and only a few portions may have escaped marine submergence. Outlying remnants of comparable rocks of Precambrian age lie in western Ireland and northern Scotland. There, as in Norway, mountain folding of the Caledonian orogeny (early Paleozoic Era) occurred. A succession of marine incursions clearly affected parts of the shield, for Cambrian, Ordovician, and Silurian deposits cover the greatest part of the surface of Sweden. Metamorphism has much changed the character of many of the Precambrian rocks, and volcanicity adds complications to the basic geology of Norway and Sweden, Scotland, and Ireland. In Finland, however, the shield surface, where not exposed, is masked by thin Quaternary coverings. While the concept of the Fennoscandian Shield as an ancient, stable core of continent-making has validity, Europe has been exposed to so rich a geological history, including the recent Pleistocene glaciation and isostatic adjustments, that it presents a physical geography of great variety.

The Russian Platform is low-lying, seldom rising above 800 feet (250 metres). It covers most of the European Soviet Union, with projections westward into Romania and Poland, and ends eastward where the Ural Mountains, created by the Hercynian orogeny, are distended north–south. The Russian Shield was worn down over long geological time and invaded by successive seas of the Mesozoic and Cenozoic eras, but it affords a rigid basement, the rocks of which, notably granites, are exceptionally exposed in Kola and the Ukraine.

The role of geosynclines. The first geosyncline relevant to Europe's geological history began in the Cambrian Period, and continued through the Ordovician into the Silurian. Aligned northeast to southwest, and confined between older blocks represented today by the Baltic Shield and relics of the Precambrian rocks of western Britain (then part of an extensive continental area), it became downwarped and filled with shales and coarse sediments, as well as volcanic rocks, to great depths. This process ended at the close of the Ordovician, when the Taconic orogeny presaged the more violent Caledonian revolution of the Silurian Period, when powerful compressional forces, exerted from the shield flanks, created

Caledonian mountain building

(Left) Coniferous forests and lakes on the ancient Fennoscandian (Baltic) Shield region of Finland. (Right) Scenic fjord, or sea inlet, winding deep into the mountainous coast of western Norway.

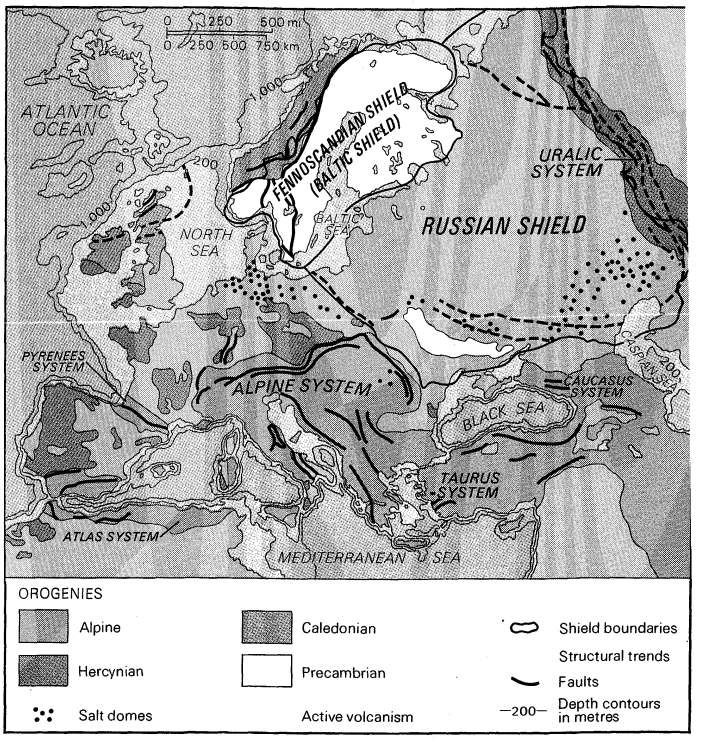
the mountain systems that now cover most of Norway and parts of northwest Britain. Granitization and migmatization dating from this orogeny have also left visible effects on the landscape of these regions. This mountain-building period also produced an uplift of the Baltic Shield, as well as of Arctic and Danish lands. One result of the Caledonian orogeny was that the Hebrides mass, Greenland, and the Baltic–Russian shield grew together to form the Old Red Sandstone continent. A vast new geosyncline, an outstanding feature of the succeeding Devonian Period, formed southward of this dry land: it has been named Hercynian, Variscan, Appalachian, or Altaid, according to region.

In Devonian times the Old Red Sandstone continent consisted of most of the British Isles, its neighbouring seas, parts of northern Europe including the Baltic Shield, and much of the Russian Platform. The Devonian geosyncline, southward of this, edged into Ireland and southwest England and Scotland and stretched deeply into northern Africa and eastward across the present continent beyond the area of the Black Sea.

Alpine mountain building

The Hercynian (or Variscan) orogeny, as violent and probably as lengthy as its Caledonian predecessor, involved Earth movements during Devonian and Carboniferous times, when marine transgression reached its maximum, and culminated in important mountain building late in the Carboniferous Period. Its effects persist widely: mountain ranges were thrown up from Ireland through Britain, Spain, France, Germany, Bohemia, and the Soviet Union. Mineralization and the preservation of coal measures in basin areas were important economic results of this orogeny. Despite all that has happened geologically since Upper Carboniferous times, the lava-penetrated upland and highland massifs of this orogeny survive throughout Europe. Also in the Upper Carboniferous, the sea intruded to divide the Old Red Sandstone land into a Greenland and a Fennoscandian block.

One more major geosyncline is notable. It appeared at the end of the first period of the Mesozoic Era after the deposition of Triassic rocks, including halite (rock salt) and gypsum, on the continental surface of Europe. Known as the Tethys Sea, it originated in areas of subsidence associated with the Hercynian orogeny and covered Alpine areas as well as those of the Mediterranean Sea and lands of today, swinging northeastward across western Siberia and also across the depression west of the Urals in eastern Europe. It lay south of a low-lying desert land carrying deposits of New Red Sandstone, marls, and slates of the Triassic Period, on which further deposits accumulated during the subsequent Jurassic and Cretaceous periods. The compression of the deep sediments of the Tethys between lateral forces exerted by the African Shield against the Paleozoic rocks and structures of this desert land explains the third and final mountain-building period of Europe, known as the Alpine. Starting in the Eocene Epoch of the Cenozoic Era and culminating in the Miocene Epoch, this created the youthful mountain ranges, notably the Alpine system itself, but also those of the Pyrenees, Sierra Nevada, Carpathians, Dinaric Alps, and, just outside the continent, the Caucasus and Atlas ranges.



Tectonic map of Europe.

THE LEGACY OF SUCCESSIVE ERAS

The varying processes described above have bequeathed a geological heritage to contemporary Europe, with each era leaving a legacy of rock layers that differ in both type and distribution.

Precambrian eras. Stretching over an estimated 3,500,000,000 years, the Precambrian eras provided basement rocks for the greater part of the continent: they can be subdivided into an older Archeozoic (or Archean) and a younger Proterozoic (or Algonkian) Era. While most of the Precambrian rocks are deeply covered, they outcrop in Fennoscandia, in Kola and Karelia, in the Ukraine, in Scotland, and, sporadically, in western and central Europe. In age they range between 1,700,000,000 and 3,400,000,000 years, and it is clear that these rocks are remnants of many distinct mountain-building periods and include considerable metamorphic and volcanic components. Five structural units trending northwest to southeast can be distinguished in northern Europe: the oldest is the Saamian, in Kola; abutting this to the southwest is the Marealbian, younger by upwards of 600,000,000 years; the next oldest, the Svecofennian, occupies most of Sweden and Finland and underlies the Baltic Sea and much of European Soviet Union; the Karelian system, stretching across northern Sweden and Karelia, and of about equal size, abuts its eastern flank; finally, on the western flank of the Svecofennian, remnants of the Gothic orogeny are represented by the belt of country southward from Oslo to Skåne Landskap (province), Sweden, as also (probably) by the country westward of it. Outlying relics of Precambrian origin, represented by the Ukraine massif and the oldest rocks of western Scotland, conform with the Baltic Shield in respect to the age and character of their rocks, those of Ukraine being the older. Elsewhere in Europe the Precambrian floor is visible in such elevated areas as the Rhine Plateau, the Bohemian Massif, and the Central German Uplands.

Precambrian rock variety

Precambrian rocks include all types—sedimentary, igneous, and metamorphic—and experienced many cycles of sedimentation, orogeny, granitization, and erosion. Granites, schists, gneisses, and other migmatites are common, as are very thick beds of sedimentary rocks, notably limestones, dolomites, and red sandstone. Glaciations have also left deposits, especially in Finland. These eras have, as yet, yielded few fossils, the commonest being algal forms, and it is inferred that soft-bodied organisms, such as worms, existed but left no record. With a climate broadly cool and humid like that of today but more severe during ice ages, the shield areas must be conceived as having been virtual deserts, although an anthracite-coal deposit in Finland and graphite deposits elsewhere suggest an abundant plant life at one time. It is for its rich contribution of economic minerals—as well as for the many unsolved problems concerning the period—that the Precambrian is of outstanding interest. Ironstone in Arctic Sweden and the Ukraine, graphite, and nonferrous metals are among the varied and abundant sources of wealth the shield areas offered to the enterprise of European peoples.

Proto-Europe of Precambrian times cannot be firmly delineated on a world map. The Caledonian Geosyncline had come into existence, flanked by the edge of the Baltic Shield in Norway to the east and by western Scotland,

including the Hebrides, in the west. There was no Atlantic Ocean, and Greenland, together with the rest of North America, presents a Precambrian history similar and related to that of Europe. The shield areas of Europe, above all in the north and east, at the close of the Precambrian had been worn down to a low plateau, or peneplain, for it is upon this that Cambrian deposits lie.

The Paleozoic and Mesozoic eras. Geological time since the Precambrian amounts to only one-sixth the preceding era. Of a total of 670,000,000 years, the Paleozoic Era occupies the greater part, some 375,000,000 years.

The Cambrian Period. The Cambrian Period, following an ice age, brought an amelioration of climate and considerable marine incursions over the Baltic Shield, the northwest Soviet Union, and parts of central and western Europe. The Caledonian Geosyncline, in fact, extended from the region between the shield areas of the Baltic and northern Britain over much of the Baltic Shield itself and over much of the rest of the continent. Mountain building and volcanic activity was at a minimum, and Cambrian rocks are remarkable for the diversity of fossils of numerous marine invertebrates with hard parts. A thin cover of Cambrian sediments, shales, and limestones overlies the sub-Cambrian floor of the Baltic Shield, arranged, where not subsequently disturbed, in horizontal layers. Lower Cambrian deposits survive in the western parts of the Russian Platform, blue clays (silts and sandstones) are found in the east Baltic lands, while very deep strata were laid down in the geosynclinal areas of Norway and Wales. Cambrian rocks also enter into the structure of Brittany, Bohemia, Germany, Spain, and Arctic areas. Much of Europe as it exists today was left at the end of the Cambrian Period as parts of a wide geosynclinal system swinging from western Scandinavia and the British Isles through western and parts of central and southern Europe, including the Mediterranean area, leaving the eastern part of the Baltic Shield and the Russian Platform uncovered by the sea.

Marine fossils

The Ordovician Period. The succeeding Ordovician Period was marked by a warm climate, more extensive marine transgressions, a diversification of invertebrates (including new forms, notably specimens with calcareous hard parts), intermittent volcanic effusions, and the beginning of the Caledonian orogeny. The Ordovician seas covered the British Isles, the western half of the Baltic Shield, much of the northern Soviet Union, and much of western, central, and southern Europe. Structural and magmatic activity characterized the Caledonian Syncline and its extensions to the south and east, while the Baltic Shield was subject to peripheral undulations. Ordovician rocks occur widely in Europe: in Brittany, the Ardennes, the Black Forest, Saxony, Iberia, Sardinia, the eastern Alps, and Bohemia. Fine-grained limestones of organic origin are the predominant new feature. Iron ores are associated widely with some of these limestones, as in northern Spain, Bohemia, Thuringia, and Brittany.

Limestone and iron ore

The Silurian Period. The Silurian Period is believed to have been one of increasing warmth, although colder at the very end. It witnessed the maximum extent of the Lower Paleozoic seas, which covered the British Isles, the Baltic lands, and much of the European continent, leaving strata of shales, marls, and limestones. The period closed with the Caledonian mountain-building movement, and thus magmatic rocks are also found. Shallow-water invertebrates continue to characterize fossil life, but the Later Silurian period is notable for the emergence of early land plants and the first true (freshwater) fish. The Silurian is devoid of metallic minerals, but it left some thin salt beds that have been put to economic use.

Later periods. The Permian and Triassic periods are noteworthy for the accumulation of chemical salts during phases of semiarid climate. The Carboniferous period witnessed the Hercynian (or Variscan) orogeny, involving the folding of the sediments in a geosyncline newly formed during the preceding Devonian Period. It stands out for its coal-forming forests, which flourished in a moist subtropical climate in swampy ground. The Cretaceous Period was notable for the deep cover of chalk that was deposited widely across Europe and also for the appearance of granite in the Pyrenean area, a hint of the Alpine mountain-building period to follow in the ensuing era.

The Cenozoic Era. It is in the Cenozoic Era, which lasted only some 65,000,000 years, that Europe takes effective and recognizable shape, revealing, successively, ancestral forms of mammals, including apes, and the full development of flowering plants.

The Eocene, Oligocene, and Miocene epochs. Intense compressional forces from the south acted on the deep sediments of the Tethys Sea, pushing them northward against shield obstacles, from the Eocene to the Miocene Epoch. The forces exerted were so powerful they produced complicated folding and even total inversions of rock strata over a wide area from Spain through central Europe to the Balkans and the Caucasus. The first beginnings of Italy are seen with the emergence of islands that would be later contained within the Apennine system and of mountainous structures that joined the Piedmont Alps, via Corsica and Sardinia, with the Atlas Mountains of North Africa. Volcanic outpourings and the formation of adjacent depressions within the Danube Basin and the area that became, as seas withdrew and deposits accumulated, the north Italian Plain also characterized the crustal disturbances of this period.

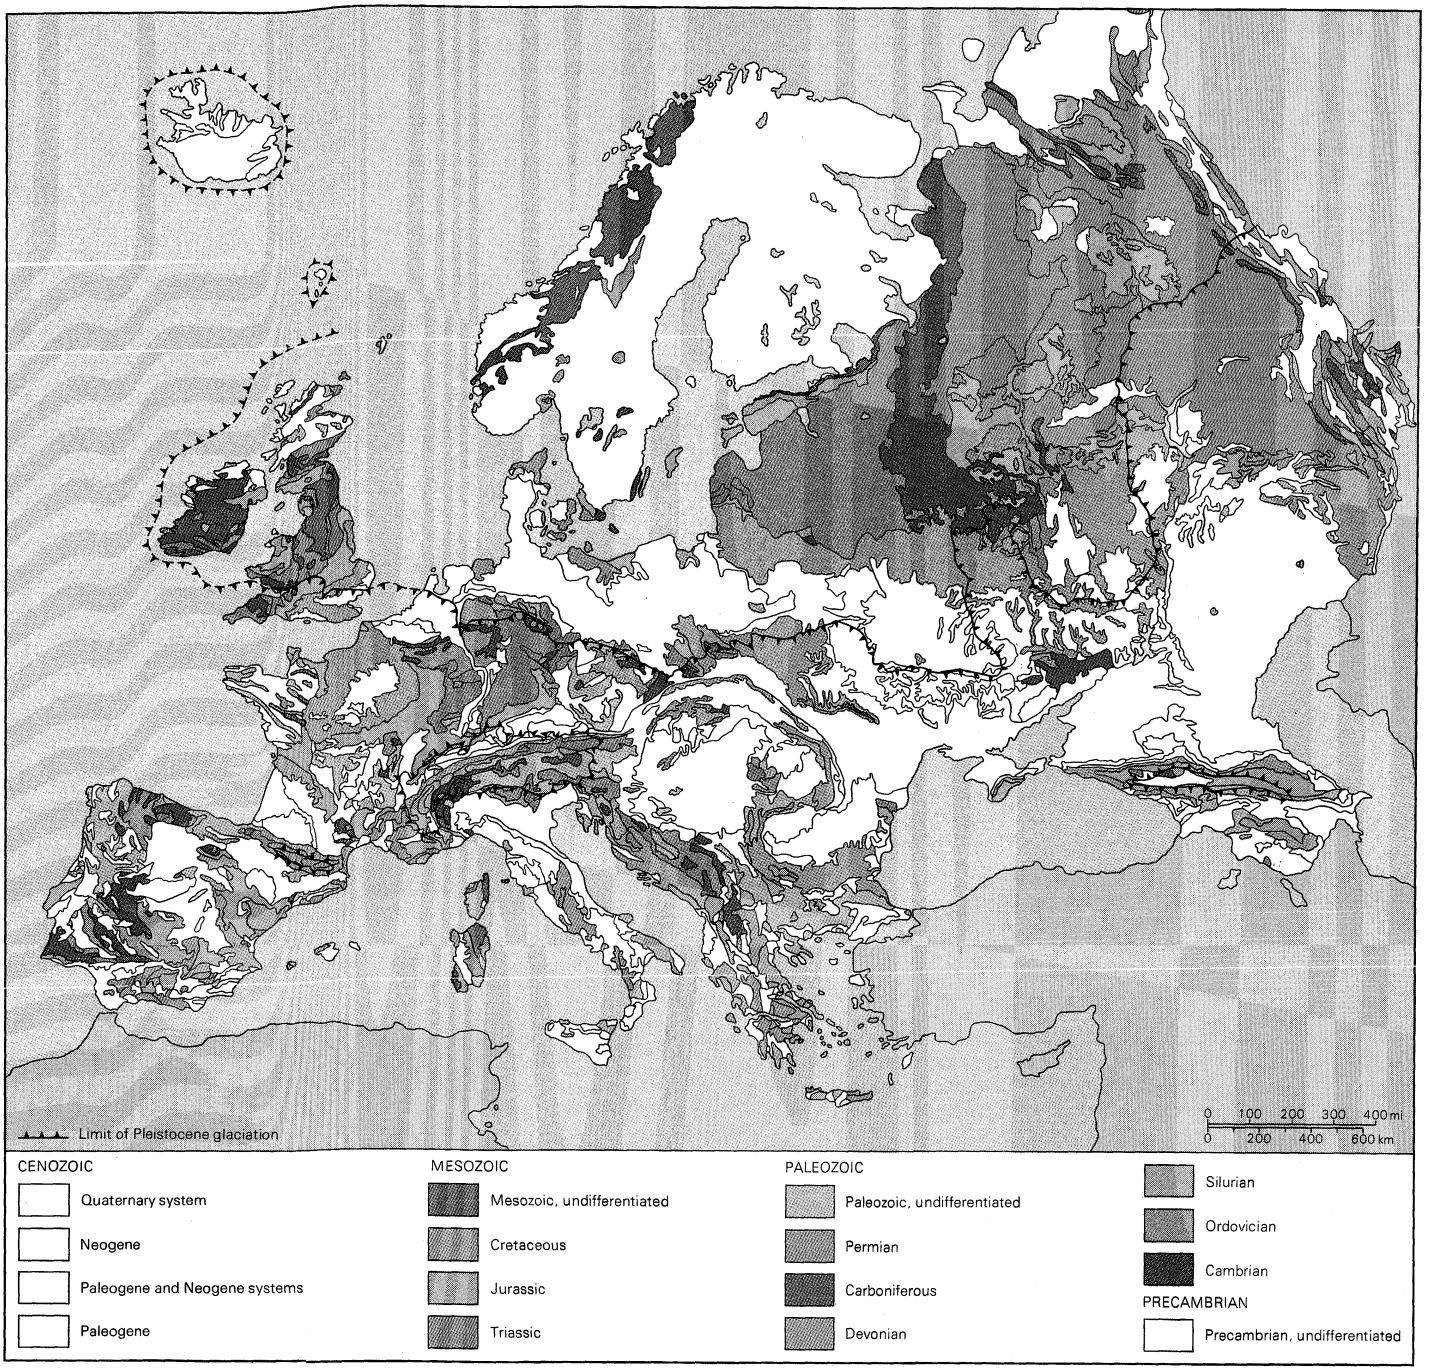
The Pliocene Epoch. Many events in the physical shaping of southern and southeastern Europe occurred during the final Pliocene Epoch. They included the emergence of the Italian peninsula, the creation, by faulting and subsidence, of the islands of Corsica and Sardinia, and the drying of the Hungarian and Romanian plains. A large Aral–Caspian sea survived even into postglacial times, being cut off from the Mediterranean by the Balkan–Caucasus uplift and by dry land where the Black Sea now lies. In postglacial times, after the deep Black Sea had been formed by subsidence, the Dardanelles Strait became cut down, giving access to the Mediterranean. The latter was made up of many distinct basins, notably the Ionian and Aegean, and was studded with insular fragments of either shattered massifs or of Tertiary mountains.

The Quaternary Period. The Great Ice Age, now more usually called the Pleistocene Epoch, occupies the Quaternary Period (2,500,000 years), with the exception of the last 10,000 years, which are called the Holocene or Postglacial Epoch. Although the precise causes of this ice age are controversial, it is known that northern Europe had risen to stand much higher than now and that ice formed to great depths there, as in the rest of the Atlantic landmass and the Alpine areas. The Pleistocene was punctuated by warm interglacial periods separating glacial advances; during its latter part, hominids (early forms of man) occupied niches in the more southerly parts of the continent. They were precursors of *Homo sapiens*, who emerged about 40,000 years ago.

Hominids and *Homo sapiens*

Glaciers are the most powerful engines provided by nature for the transport, by plucking or quarrying, of large masses of rock, and certainly the European glaciers transformed the physique both of their source areas and those to which they moved. Many physical forms of northern and Alpine Europe resulted from glacial erosion, supplemented by weathering, and the areas where the glaciers eventually withered away had their surfaces provided by masses of transported material. Southern Scandinavia, southern Finland, the Swiss Plateau, and the whole North European Lowland were thickly plastered with a variety of forms, including boulder-studded clay, gravels, sands, and the windblown deposits known as loess. And new drainage patterns were formed. The melting of so much ice raised the level of the oceans by an estimated 320 or more feet, while former ice-clad lands, including the North Sea area, began to rise isostatically. It was not until quite late in the Postglacial Epoch that the northern seas of Europe—the Irish, North, and Baltic—took, by stages, their present shape.

The modern geological framework. Although the exposed rocks of Europe are obscured increasingly by the works of man, and while detailed understanding of rock



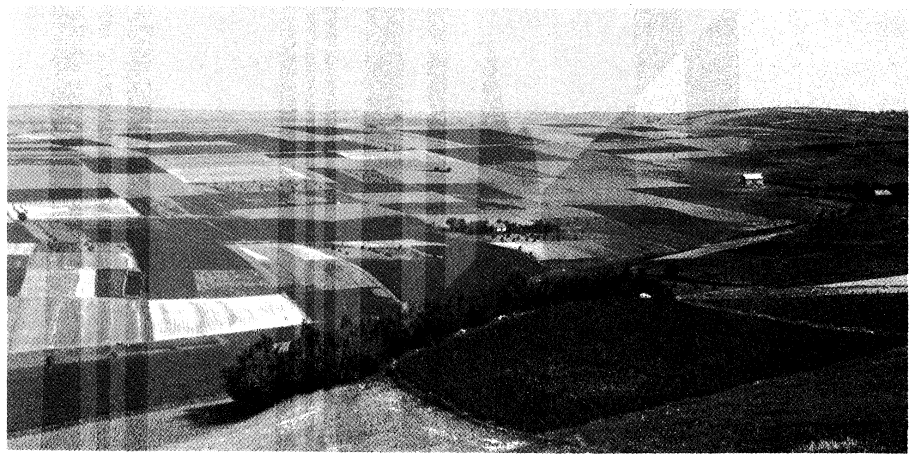
Geologic map of Europe.

Differences between north and south Europe

patterns present challenges even to the expert, the major formations of the continent are clear. In the north lie wide areas of ancient worn-down rocks, stripped of soil by the glaciers but compensated in some measure by the coastal plains created by uplift. In contrast, southern Europe, although incorporating such relics as massifs of Paleozoic rocks, is essentially a youthful world, not yet fully fashioned, as continuing seismic disturbances remind us. Eastern Europe, based on the great Russian Platform, is a stable world still young in surface, since the floor of its shield rocks is deeply concealed beneath Mesozoic and Tertiary deposits, above which glacial material covers the northern half and loess deposits enrich the south. Although in scale this platform is a continental area, river development facilitates access to inland seas both in the north and the south. Ancient rocks, where they lie near the surface, offer mineral wealth, and the former Volga–Ural seas have left a residue of petroleum and mineral salts. For the rest, western and central Europe show great diversity of landforms and landscape as well as varied soil and mineral resources. Alpine ranges in the south and southeast, upraised since their initial orogeny, combine high altitude and relief with scenic attractions and—more importantly—with high precipitation and water dispersion. Highland areas, which are remnants of faulted Hercynian folds surrounded by younger strata, provide another type of wooded landscape, with their contained coalfields. Lastly, lowlands, of outstanding human value, recall their varied origins—former sea and lake basins; lowlands of glacial deposition; parts of eroded synclinal structures; and alluvial and marine plains won from the sea by isostasy or, as exemplified by the Dutch polders, by the triumphant—if precarious—work of man.

II. Physical geography

A contrast exists between the configuration of peninsular (or western) Europe, and east Europe, which is a much



Rolling expanse of the east European plain, consisting of glacial deposits, in southern Poland.
D.C. Williamson

Peninsular and east Europe

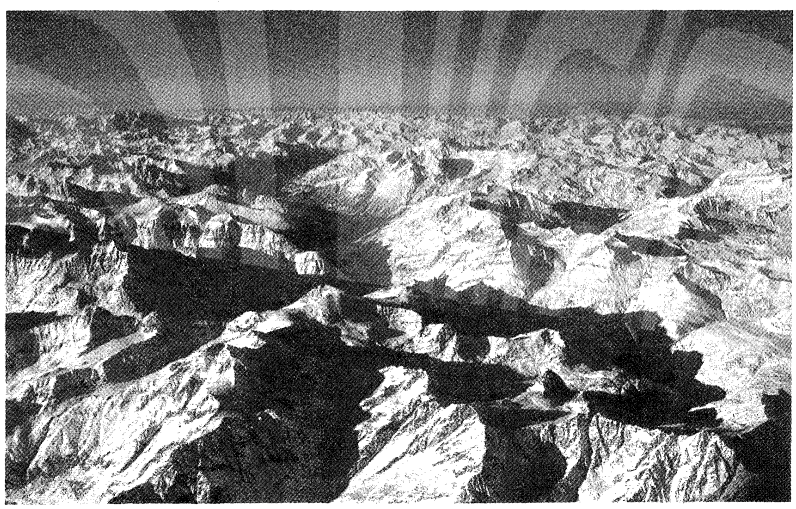
larger and more continental area. A convenient division is made by a line linking the base of the Jutland Peninsula with the head of the Adriatic Sea. The western part of the continent clearly enjoys a high proportion of coastline with good maritime access and often with inland penetration by navigable rivers. Continental shelves —former land surfaces covered by shallow seas—are a feature of peninsular Europe, while the coasts themselves are both submerged or drowned, as in southwest Ireland and northwest Spain, and emergent, as in western Scotland and south Wales where raised former beaches are in evidence. East of the Vistula, Europe's expansive lowlands have something of the scale and character of those of north Asia, but the continent also possesses numerous islands, some—notably the Faroes and Iceland —standing at a distance from the mainland. Fortuitously, Europe has no continuous mountain obstacle aligned north–south, corresponding, say, to the Western Cordillera and the Andes in the Americas, that would limit access into western Europe from the ocean.

RELIEF

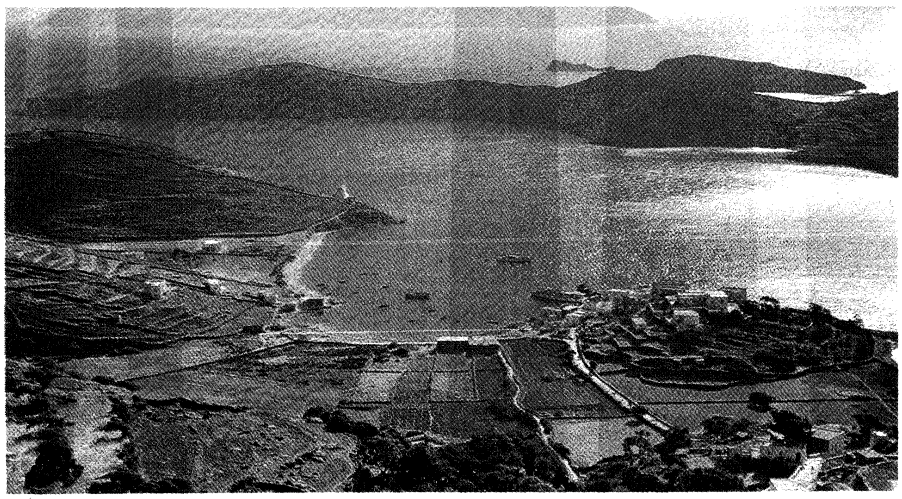
Elevations. Lands lying at high altitude can, of course, be lands of low relief, but in Europe relief tends to become more rugged with altitude. The greater part of Europe combines low altitude with low relief. Only hill masses under 800 feet (250 metres) in height rise gently within the Great Russian Plain which continues northward into Finland, westward into the North European Lowland, and southward in the Romanian, Bulgarian, and Hungarian plains. The North European Lowland, common to much of Poland, north Germany, and Denmark, broadens in western France and continues, across the narrow seas, in southeast Britain and Ireland. The major peninsula of Scandinavia is mostly upland and highland, with relief greatest at the descent to the Norwegian fjords and the sea; eastward and southward the seas are approached more gently. The highest points reached in Norway and Sweden are, respectively, Galdhøppigen (8,097 feet [2,468 metres]), and Kebnekaise (6,965 feet [2,123 metres]). Iceland's highest peak is Hvannadalshnúkur, at 6,952 feet (2,119 metres), while Ben Nevis, the highest summit in Britain, stands at only 4,406 feet (1,343 metres). Greater relief is found in those areas in the heart of western and central Europe where uplifted and faulted massifs survive from the Hercynian orogeny. The worn-down Ural Mountains also belong in this category, and their highest point, Narodnaya, (6,214 feet [1,894 metres]) corresponds approximately to that of the French Massif Central. Altitudes in these areas are mainly between 500 and 2,000 feet, and many steep slopes occur.

The highest altitudes and the most rugged relief of the continent are found further south, where the structures of the Cenozoic orogeny provide mountain scenery. In the Alps, Mt. Blanc rises to 15,771 feet (4,807 metres), and, in the Pyrenees and the Sierra Nevada of Spain, the highest peaks exceed 11,000 feet (3,400 metres). The Apennines, Dinaric Alps, and Balkan Mountains, as well as the arc-shaped Carpathians and Transylvanian Alps, exhibit high altitudes. Above all, in southern Europe—Austria and Switzerland included—level, low-lying land is

(Left) Josef Muench; (right) Harrison Forman



(Left) Mountain ranges of the Swiss Alps in winter, aerial view. (Right) Deep river-cut gorge in the Carpathian Mountains of Romania.



Coastal landscape of submerged mountains and resulting islands and bays characteristic of Greece along the Aegean Sea.
Josef Muench

scarce, and mountain, plateau, and hill landforms dominate. The lowest terrain in Europe, virtually lacking relief, stands at the head of the Caspian Sea many feet below sea level.

Physiographic units. Four topographic units can be simply, yet usefully, distinguished in Europe: coastal and interior lowlands, central uplands and plateaus, the northwest highlands, and the mountainous world of southern Europe.

Lowlands. More than half of Europe consists of lowlands, standing mostly below 600 feet but, infrequently, rising to 1,000 feet. Most extensive between the Baltic–White seas in the north and the Black–Azov–Caspian seas in the south, the lowland narrows westward, lying southward of the northwest highlands; it is divided also by the English Channel and the mountains and plateaus of central Europe. The Danubian and northern Italian lowlands are thus mountain-ringed islands. The northern lowlands are areas of glacial deposition and, accordingly, their surface is diversified by such hills as the Valdai and the North German Heights; by deposits of boulder clay, sands, and gravels; by glacial lakes; and by the Pripet Marshes, a large ill-drained area. Another important physical feature is the southeast–northwest zone of wind-blown loess deposits that have accumulated from eastern Britain to the Ukraine. This *Börde* (German: "edge") belt lies at the northern foot of the Central European Uplands and the Carpathians. Southward of the limits of the northern ice sheets are vales and hills, with the Paris and London basins typical examples. Superficial rock cover, altitude, drainage, and soil have sharply differentiated these lowlands—which are of prime importance to human settlement—into areas of marsh or fen, clay vales, sand and gravel heaths, or river terraces and fertile plains.

The northern lowlands

Central uplands and plateaus. The central uplands and plateaus present distinctive landscapes of rounded summits, steep slopes, valleys, and depressions. Examples are the Southern Uplands of Scotland, the Massif Central of France, the Iberian Meseta, and Bohemia. Routes detour around, or seek gaps through, these uplands, whose German appellation, *Horst* (literally "thicket"), recalls their still wooded character, while their coal basins give them great economic importance. The well-watered plateaus give rise to many rivers and are well adapted to pastoral farming. Volcanic rocks add to the diversity.

Northwest highlands. The ancient, often mineral-laden, rocks of the northwest highlands, their contours softened by prolonged erosion and glaciation, are found in much of Iceland, Ireland, and in north and west Britain and Scandinavia. They include lands of high rainfall, which supplies hydroelectricity and water to industrial cities, and summer pastures for cattle but are of little use for crops. The coasts—notably the fjords of Norway—invite maritime enterprise.

Southern Europe. A world of peninsulas and islands, southern Europe is subject to its own climatic regime, with fragmented but predominantly mountain and plateau landscapes. Iberia and Anatolia (Turkey) are extensive peninsulas whose interior tablelands of Paleozoic rocks are flanked by mountain ranges of Alpine type. The restricted lowlands lie within interior basins or fringe the coasts; those of Portugal, Macedonia, Thrace, and north Italy are relatively large. The Alps furnish much water for electric generating stations, as for major rivers.

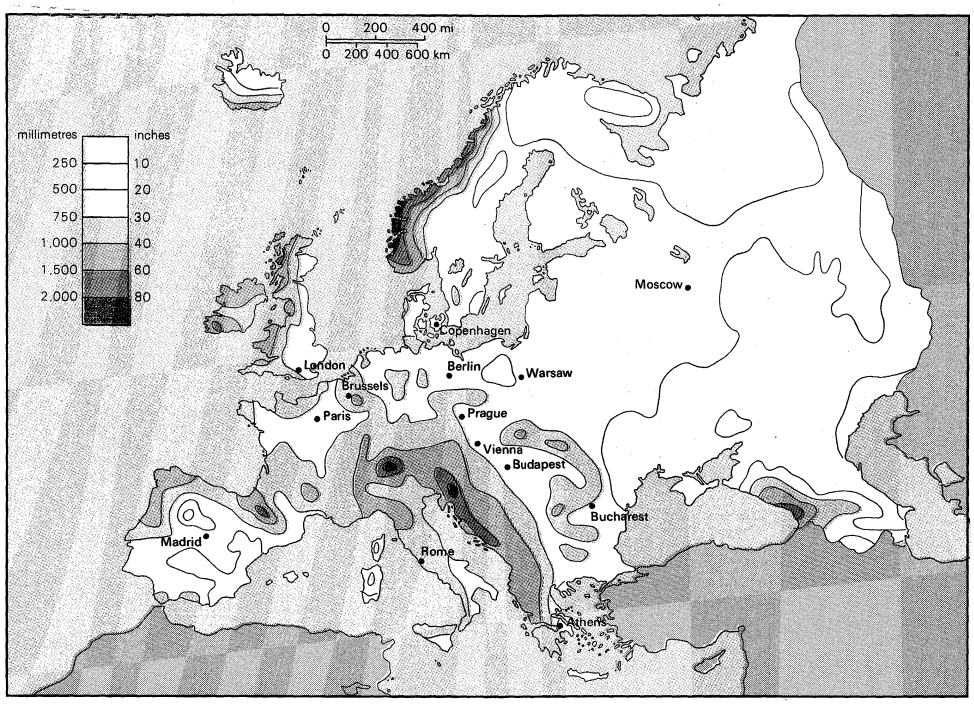
Peninsulas and islands of the south

CLIMATE

As Francis Bacon, the great English Renaissance man of letters, aptly observed, "every wind has its weather." It is air-mass circulation that provides the main key to Europe's climate, the more so since masses of Atlantic Ocean origin can pass freely through the lowlands, except in the case of the Caledonian mountains of Norway. Polar air masses derived from areas close to Iceland and tropical masses from the Azores bring, respectively, very different conditions of temperature and humidity and produce different climatic effects as they move eastward. Continental air masses from eastern Europe have equally easy access westward. The almost continuous mountain belt trending west–east across Europe also impedes the interchange of tropical and polar air masses.

Air-pressure belts. Patterns of some permanence controlling air-mass circulation are created by belts of air pressure over five areas. They are: the Icelandic Low, over the North Atlantic; the Azores High, a high-pressure ridge; the (winter) Mediterranean Low; the Russian High, centred over Central Asia in winter but extending westward; and the Monsoon Low, a low-pressure system over southwest Asia. Given these pressure conditions, westerly winds prevail in northwest Europe during the year, becoming especially strong in winter. The winter westerlies, often southwesters, bring in warm tropical air; in summer, by contrast, they veer to the northwest and bring in cooler Arctic or sub-Arctic air. In Mediterranean Europe the rain-bearing westerlies chiefly affect the western areas, but only in winter. In winter, the eastern Mediterranean Basin experiences bitter easterly and northeasterly winds derived from the Russian High, and their occasional projection westward explains unusually cold winters in western and central Europe, the exceptionally warm winters of which, on the other hand, result from the sustained flow of tropical maritime air masses. In summer the Azores High moves 5–10° of latitude northward and extends further eastward, preventing the entry of cyclonic storms into the resultantly dry Mediterranean region. The eastern basin, however, ex-

Westerlies and the Russian High



Average annual precipitation for Europe.

periences the hot and dry north and northeast summer winds called etesian by the ancient Greeks. In summer, too, the Russian High gives place to a low-pressure system extending westward, so that westerly air masses can penetrate deeply through the continent, making summer a wet season.

It is because of the interplay of so many different air masses that Europe experiences very changeable weather. Winters get sharply colder eastward, but summer temperatures relate fairly closely to latitude. Northwest Europe, including Iceland, enjoys some amelioration due to warm Gulf Stream waters, which keep the Soviet port of Murmansk open all the year.

Climatic regions. Four regional European climatic types can be loosely distinguished, each characterized by much local topographically related variation. Further, the great cities of Europe, because of the scale and grouping of their buildings, their industrial activities, and the layout of their roads, create local climates—including a central "heat island" and pollution problems—quite distinct in themselves (see URBAN CLIMATES).

Maritime climate. Characterizing western areas heavily exposed to Atlantic air masses, the maritime type of climate—given the latitudinal stretch of these lands—exhibits sharp temperature ranges. Thus the January and July annual averages of Reykjavík (Iceland) and Coruña (Spain) are, respectively, 32° F (0° C) and 53° F (12° C), and 50° F (10° C) and 64° F (18° C). Precipitation is always adequate—indeed, abundant on high ground—falling the year round. The greatest amount of precipitation occurs in autumn or early winter. Summers range from warm to hot depending on the latitude and altitude, and the weather is everywhere changeable. The maritime climate extends across Svalbard, Iceland, the Faeroes, the British Isles, Norway, southern Sweden, western France, the Low Countries, northern Germany, and northwest Spain.

Central European (transitional) climate. The central European, or transitional, type of climate results from the interaction of both maritime and continental air masses and is found at the core of Europe, south and east of the maritime type, west of the much larger continental type, and north of the Mediterranean type. This rugged region has colder winters, with substantial mountain snowfalls, and warmer summers, especially in the lowlands. Precipitation is adequate to abundant with a sum-

Increasing continentality

J. Allan Cash

mer maximum. The region embraces central Sweden, southern Finland, the Oslo Basin of Norway, eastern France, southwest Germany, and much of central and southeastern Europe. The range between winter and summer temperatures increases eastward, while the rainfall can reach over 80 inches (2,000 millimetres) in the mountains, with snow often lying permanently around high peaks. The Danubian region has only modest rainfall (24.2 inches [615 millimetres] per year at Budapest), but the Dinarid mountains experience heavy cyclonic winter, as well as summer, rain.

Continental climate. The continental type of climate dominates a giant share of Europe, covering the European Soviet Union (except the Baltic areas), most of Finland, and northern Sweden. Winters—much colder and longer, with greater snow cover than in western Europe—are coldest in the northeast, and summers are hottest in the southeast; the January to July mean temperature range is high, from 50° to 70° F (10° to 21° C). Summer is the period of maximum rain, which is less abundant than in the west: Moscow's annual average is 25 inches (635 millimetres), while, both in the north and southeast of the Russian Plain, precipitation reaches only between ten and 20 inches annually. In parts of the south, the unreliability of rainfall combines with its relative scarcity to raise a serious aridity problem.

Mediterranean climate. The subtropical Mediterranean climate characterizes the coastlands of southern Europe, being modified inland (for example in the Spanish Meseta, the Apennines, and the north Italian plain) in response to altitude and aspect. The main features of this climatic region are mild and wet winters, hot and dry summers, and clear skies, but marked regional variations occur between the lands of the western and the more southerly lying eastern basins of the Mediterranean; the former are affected more strongly by maritime-air-mass intrusions. Rainfall in southern Europe is markedly reduced in areas lying in the lee of rain-bearing westerlies: Rome has an annual mean of 25.7 inches (653 millimetres), but Athens has only 15.8 inches.

The effects of climate. The local and regional effects of climate on the weathering, erosion, and transport of rocks clearly contribute much to the European landscape, and the length and warmth of the growing season, the amount and seasonal range of rainfall, and the incidence of frost affect the distribution of vegetation. Wild vegetation in its turn provides different habitats for animal life. Climate is also an important factor in the making of soils, while modern European industry and urban life depend increasingly on water supplies, with rivers and lakes continuing to provide important commercial waterways in some areas. The winter freeze in northern and eastern Europe is another effect of climate, and the spring thaw, by creating floods, impedes transport and harasses farmers. The snow cover of the more continental regions is useful to man, however, for it stores water for the fields and provides snow ways for sled users. Regional variations of climate also help determine where crops are grown commercially. In southern Europe the climate supports specially adapted wild vegetation and precludes all-year grass in coastal lowlands, while the practice of moving flocks and herds to pastures seasonally available at different altitudes is clearly adapted to other conditions set by climate. In sum, in only a modest proportion of Europe does climate severely restrict human occupance and land use. These areas include regions of high altitude and relief, such as the sub-Arctic highlands of Fennoscandia and Iceland, and the arid areas of the southeast European Soviet Union and interior Spain.

DRAINAGE

Topographic influences. The drainage basins of most European rivers lie in areas originally uplifted by the Caledonian, Hercynian, and Alpine mountain-building periods that receive heavy precipitation, including snow. Some streams, notably in the European Soviet Union, Finland, and Poland, have their sources in hills of Tertiary rocks, while others, including the Thames and Seine rivers, derive from hill country of Mesozoic rocks. Drainage is directly, or via the Baltic and the Mediterranean seas, to the Atlantic and the Arctic oceans and to the enclosed Caspian Sea.

Drainage basins

The present courses and valley forms of the major rivers result from an intricate history involving such processes as erosion by the headstream, downcutting, capture of other rivers, faulting, and isostatic changes of land and sea levels. The Rhine, for example, once drained to the Mediterranean before being diverted to its present northerly course. The courses of many rivers—notably those of Fennoscandia and the North European Lowland—have been shaped since the Pleistocene Epoch. While the Alps, Apennines, and Carpathians provide watersheds, other mountain ranges have been cut through by rivers, as by the Danube at Vienna, Budapest, and the Iron Gate, and the Olt (in Romania). In the Great Russian Plain the rivers are long and flow sluggishly to five seas. In western, central, and eastern Europe, rivers are largely "mature": their valleys are graded, and their streams are navigable. Northern and southern Europe, in contrast, present still "youthful" rivers, as yet ill-graded and thus more useful for hydroelectricity than for waterways. The Atlantic rivers have scoured estuaries widening seaward, while, in the Baltic, Mediterranean, and Black seas, with minimum tidal influences, deltas and spits have been created. The Upper Dnepr, since post-Pleistocene times, has failed to drain effectively the low area of minimal relief known as the Pripet Marshes.

Hydrology. The water volume of, and discharge from, the rivers of Europe are governed by factors that include local conditions of rainfall, snowmelt, and rock porosity. In consequence, the rivers in the western area have more volume and higher discharges in the winter season and

(Top, bottom) FPG, (top) Tom Wright, (bottom) Muller-Brunke

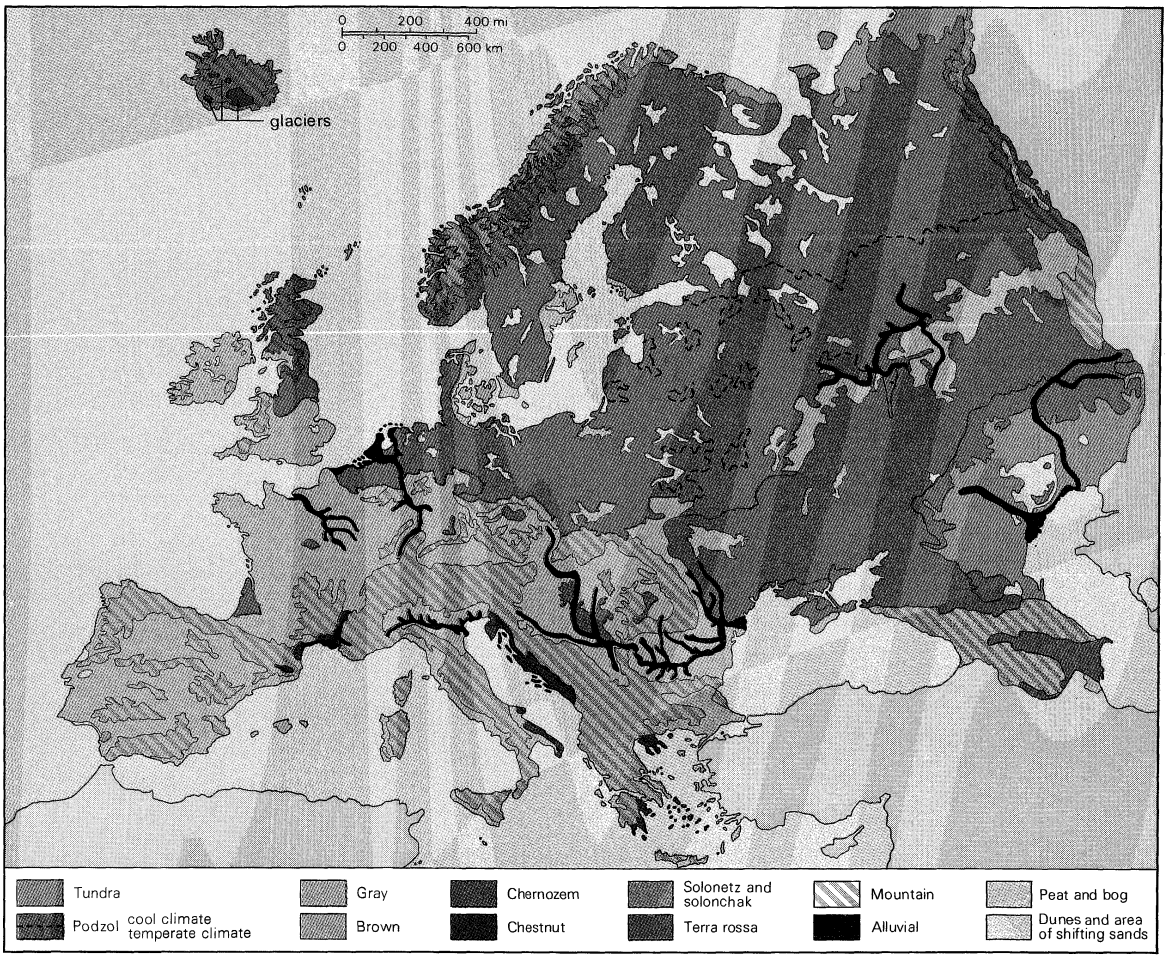
their lowest in summer. In areas of mountainous and continental climate, thanks to the runoff of snowmelt, the rivers are highest in spring and early summer. The longer rivers of the Continent, notably the Rhine and the Danube, have complex regimes, since their basins extend into areas of contrasting climate. Although embanking measures have reduced the problem, flooding is a continued threat. Thus, rivers in the Soviet Union are liable to flood with the spring thaw; oceanic rivers, after heavy or prolonged rain over the whole basin; and Alpine rivers, when the warm foehn wind rapidly melts the snow. In the Mediterranean region some rivers—as in peninsular Greece—tend to dry up in summer through a combination of scant rainfall, evaporation, and porous limestone beds. In the Abruzzi (Italy), however, heavy rainfall, mainly in winter, permeable and porous rocks within the basin, and abundant snow combine to regulate the river regimes.

Flood danger

The Rhône achieves a steady flow throughout the year, deriving a high input from the Cévennes Mountains—which experience heavy winter rain—plus abundant spring and summer snowmelt from the Alps via Lake Geneva. The Rhine and Danube tap supplies from the Alps in spring and summer, and the Rhine, especially, taps areas of winter rainfall maximum. The Volga has its highest water in spring and early summer, thanks to snowmelt, and falls to a summer low. The Saône, lying within the oceanic climatic area, tends to have a good flow all year. The winter freeze of the east only rarely seriously affects the Danube and west European rivers.

Lake systems and marshes. Lakes cover less than 2 percent of Europe's surface and occur mostly in areas subjected to the Pleistocene glaciation. Fennoscandia and the North European Lowland account for four-fifths of the area of lakes; and in Finland lakes cover one-fifth of the surface. The other major zones of lakes lie marginal to the Alpine system, while Scotland, too, has its many "lochs," and Ireland its "loughs." Lakes survive where the inflow of water exceeds loss from evaporation and outflow and should eventually disappear through alluvial accumulation. Their origins lie in the glacial excavation of softer rocks, in the building of dams by morainic material, and in tectonic, or deforming, forces, which may create depressions. This second explanation clearly applies to Alpine lakes; to many of those in the British Isles—including the small but scenic ones of the Lake District of England—and also those of central Sweden. Volcanic crater lakes are found in central Italy, and small lakes of the lagoon type are found along the Baltic and Mediterranean, where spits have lengthened parallel to the coast and hence cut off sea access.

A well-developed zone (*Marschen*) has formed along the low-lying and reclaimed sea marshes of western Ger-



Soils of Europe.

The Marschen zone

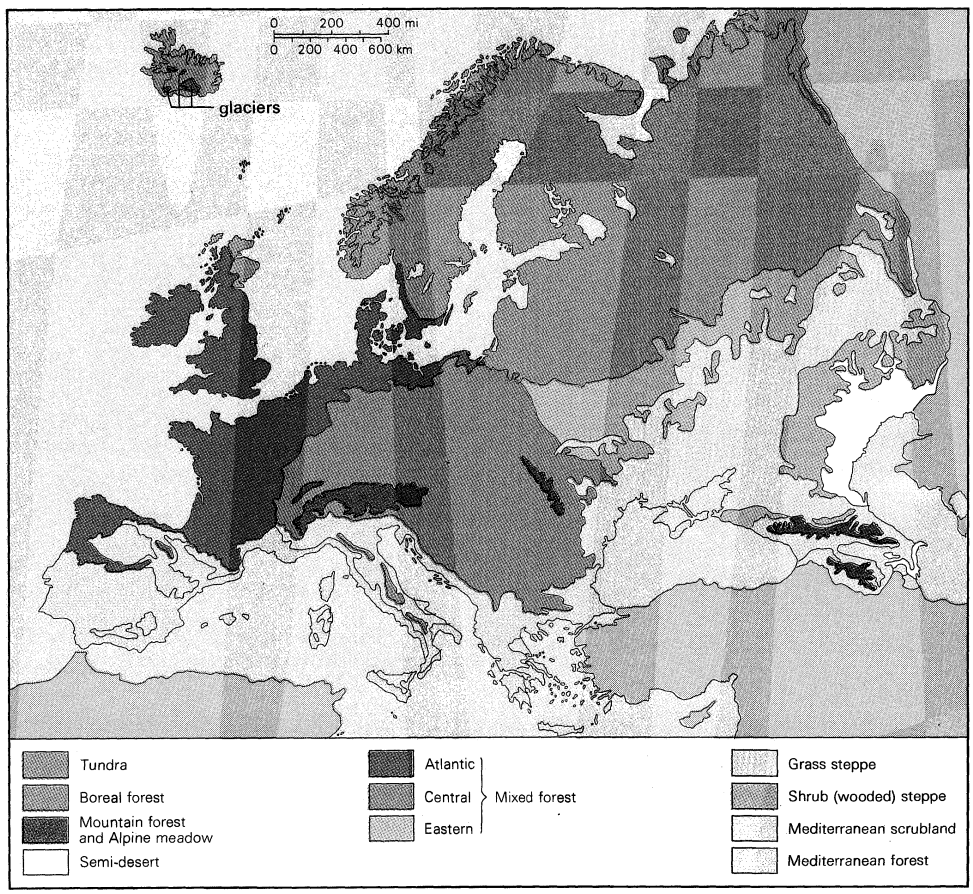
many and The Netherlands, and characteristically the estuaries of Europe's tidal rivers are edged by flat alluvial marshes. Fens, as exemplified by the Dutch polders and the Fenland of England, are made up of either alluvium or peat and stand too low to be drained effectively, except by continuous pumping. The continent's largest marshland is the Pripet Marshes of the Belorussian Soviet Socialist Republic.

SOILS

Regional divisions. The soil patterns of Europe are clearly and zonally arranged in the Great Russian Plain but are much more complicated in the rest of the continent, which exhibits a more varied geology and relief. Tundra soils occur only in the most northerly parts of the Soviet Union and Finland and in high areas of Sweden and Norway; they tend to be acidic, waterlogged, and poor in plant nutrients. South of this zone, and extending around the Gulf of Bothnia and across Finland and the Soviet Union north of the upper Volga, podzols are characteristic. These soils, formed in a coniferous woodland setting, suffer from acidity, the leaching of minerals, hardpan formation and permafrost beneath the topsoil, and excess of moisture; given the climate, they are virtually useless for crops. The larger zone to the south stretches from central U.S.S.R. westward to the British Isles and southward from central Sweden, southern Norway, and Finland, to the Pyrenees, Alps, and Balkan mountains. In this region podzols and brown forest soils have developed in a mixed-forest environment, and these soils, which are very varied, usually have a good humus content. Locally, the farmer recognizes soils of heavy to light texture, their different water-holding capacities, depth, alkalinity or acidity, and their suitability for specific crops. The soils, rich in humus, within this zone that cover loess are excellent loams; lowland clays, when broken down, also exhibit high quality, as do alluvial soils; in contrast, areas covered with dry, sandy, or gravelly soils are more useful for residential and amenity purposes than for farming. In the southeast of the European portion of the Soviet Union, notably in the Ukraine, some soils that have been formed in areas of grass steppe are chernozems (black earths), deep, friable, humus-rich, and renowned for their fertility. In the formerly wooded steppe lying to the north of the grass steppe in both the south central Soviet Union and the lower Danubian lowlands, soils of somewhat less value are known as degraded chernozems and gray forest soils. At best, chestnut soils—some needing only water to be productive—and, at worst, solonetzic (*i.e.*, highly saline) soils cover areas of increasing aridity eastward of the Ukraine to the Ural River. Lastly, in southern Europe, where the countryside is fragmented by mountains, plateaus, and hills, much soil has been lost from sloping ground through forest destruction and erosion, and a bright-red soil (terra rossa), heavy and clay-rich, is found in many valleys and depressions.

Chernozems and terra rossa

Problems of classification. The origin, nature, variety, and classification of Europe's soils raise highly complex problems: so much is involved—bedrock, drainage, plant decomposition, biological action, climate, and the time factor. Man, moreover, has done much to modify soils and, with increasing scientific knowledge, to render soils of greater and continuing value by drainage, crop rotation, and the input of suitable combinations of chemicals. In such ways, naturally poor soils can—as Denmark has shown—be made productive. The practice of an enforced "resting" of soils, by leaving fields fallow to recuperate, began to disappear with the agricultural revolution of the 18th century, and agronomic science continues to show how the best results can be got from specific soils and also how to check soil erosion. Europe's arable land



Vegetation zones of Europe.

lies mainly in the lowlands, which have podzols, forest brown, black earth, and chestnut soils, although the upper level of cultivation, as of animal husbandry, rises southward. New land is won from the sea, and this more than offsets coastal losses through erosion, but the losses to urban expansion and to such competitors for level land as airfields, on the other hand, are becoming increasingly serious.

III. Plant and animal life

VEGETATION

Major vegetation zones. "Natural," "original," and "primitive," as epithets applied to the vegetation of Europe, have no precise meaning unless they are related to a specific time. It is, nevertheless, possible to envisage continental vegetation zones as they formed and acquired some stability during postglacial times, although they are only rarely recalled by present-day remnants.

The tundra. Tundra vegetation, made up of lichens and mosses, occupies a relatively narrow zone in the extreme north of the European Soviet Union and Fennoscandia, although this zone is continued southward in the mountains of Norway. Vegetation of a similar kind occurs at altitudes of 5,000–6,000 feet in the Alps and the northern Urals.

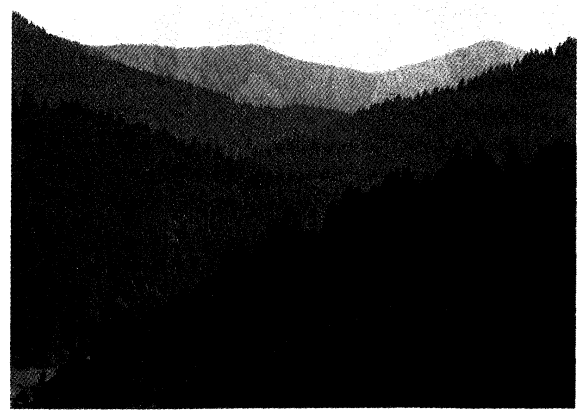
The boreal forest. Southward, the virtually treeless tundra merges into the boreal (northern) forest. The more northerly zone is "open," with stands of conifers and with willows and birch thickets rising above a lichen carpet. It is most extensive in the northern European Soviet Union but continues, narrowing westward, across Sweden. South of this zone, and with no abrupt transition, the "closed" boreal forest occupies a large fraction —mainly north of the upper Volga—of the Soviet Union proper and Fennoscandia. Conifers, thin-leaved and resistant to cold, together with the birch and larch, predominate.

The mixed forest. The northern vegetation may superficially suggest its primeval character, but the zone of mixed forest that once stretched across the continent from the British Isles to central U.S.S.R. has been changed extensively by man. Only surviving patches of woodland—associations of summer-leaf trees and some conifers, summarily described as "Atlantic," "central," and "eastern"—hint at the formerly extensive cover.

The Mediterranean complex. In southern Europe, Mediterranean vegetation has a distinctive character, containing hard-leaf forests and secondary areas of scrub, especially maquis, which is made up of trees, shrubs, and aromatic plants. Such scrub is scattered because of summer drought, particularly in areas where the soil is underlain by limestone or where there is little, if any, soil.

Steppe and semidesert. Three further vegetation zones are confined to the southeastern European Soviet Union, although the first two—the "wooded steppe" and the "grass steppe"—extend into the Danubian lowlands. Finally, semidesert vegetation characterizes the dry lowland around the northern shores of the Caspian Sea.

Marc Riboud—Magnum



Steep hillslopes of the Black Forest region, southern West Germany.

The shaping of vegetation zones. *Climatic change.* The primeval vegetation of Europe began to take shape as the climate ameliorated following the disappearance of the Pleistocene ice sheets. The microscopic study of pollen grains preserved in datable layers of peat and sediments has made it possible to trace the continental spread, in response to climatic improvement, of forest-forming trees. The double barrier of the Alpine mountains and the Mediterranean Sea had checked the retreat of trees at the onset of the Great Ice Age, and there were relatively few indigenous species to return northward from unglaciated refuges. In the first postglacial climatic phase (the boreal), spruce, fir, pine, birch, and hazel nevertheless established themselves as far north as central Sweden and Finland. During the succeeding climatic optimum (the Atlantic phase), which was probably wetter and certainly somewhat warmer, mixed forests of oak, elm, lime (linden), and elder spread northward. Only in the late Atlantic period did the beech and hornbeam spread into western and central Europe from the southeast.

The Alpine barrier

During postglacial times, therefore, when *Homo sapiens*, in small numbers, was finding homes within Europe, the continental surface was thickly clad with trees and undergrowth, except where tree growth was precluded by extreme cold, high altitude, bad drainage, or exposure to persistent gales. Even those relatively attractive areas where windblown loess had been deeply deposited are now known to have had woods of beech, hawthorn, juniper, box, and ash, as did also limestone plateaus. The Mediterranean peninsulas also had evergreen and mixed forests rooted in an ample soil.

The role of man. From prehistoric times onward, with ever increasing force, man, seeking optimum economic use of available resources, has acted as a vigorous agent of vegetation change. The effects of grazing animals may well explain why some heathlands (*e.g.*, the Lüneburger Heide in north Germany) replaced primeval forest. By fire and later by axe, forest clearance met demands for homes and ships, for fuel, for charcoal for iron smelting, and, not least, for more cultivation and pasture. The mixed boreal forests suffered most because their relatively rich soils and long and warm growing season promised good returns from cultivation. The destruction of woodlands was markedly strong when population was growing (as between *c.* AD 800 and 1300). It was later intensified by German colonization east of the Rhine and reached maximum scale in the 19th century. In southern Europe—where naval demands were continuous and sources of suitable timber sharply localized—tree cutting entailed, from classical antiquity onward, serious soil loss through erosion, increased aridity, floods, and marsh formation. Further north throughout the continent, as present distribution of arable land shows, former forests were reduced to remnants; only in the north and below the snow line of Alpine mountains have forests of large and continuing commercial value survived. These coniferous forests of Sweden, Finland, and northern U.S.S.R. are "cropped" annually to preserve their capital value. On the positive side may be noted the reclamation of marshlands and the soil improvement of hill grasslands and heaths, their wild vegetation being replaced by pasture and crops; in timber-deficient countries the afforestation of hillslopes, chiefly with quickly growing conifers, belatedly attempts to restore some of the former forests. Another drastic vegetation change brought about by man has been the virtual elimination of the wooded and grass steppes, which have become much needed granaries.

Afforestation in Scandinavia and the Soviet Union

Exterior influences and European survivals. To a surprising degree, European vegetation stemmed from the importation of plants from other continents, although some imported crops—notably citrus fruits, sugarcane, and rice—can only grow marginally in Europe, and then by irrigation. From an original home of wild grasses in Ethiopia, cultivated varieties of wheat and barley reached Europe early, via Southwest Asia and Egypt, as did also the olive, vine, fig, flax, and some varieties of vegetables. Rice, sugarcane, and cotton, of tropical Indian origin, were introduced by the Arabs and Moors, especially into Spain. The citrus fruits, peach, mulberry, oats, and millet reached Europe from original Chinese habitats, and Europe owes maize, tobacco, squashes, tomatoes, red pepper, prickly pear, agave (sisal) and the potato—first grown for fodder but destined to become the cheap staple food for the large families of low-paid workers of the 19th-century—to the Americas. Europe has drawn greatly on eastern Asia and North America for trees, especially ornamental trees, while some acacias and the eucalyptus derive from Australia. Sugar beet, however, was a European discovery, first grown when much of Napoleonic Europe was subjected to maritime blockade.

The forests of northern Europe and the Alpine ranges, although in no sense primeval, represent unchanging land use during the postglacial period. The "closed boreal forest" occupies 1,000,000 square miles, made up of a spruce-fir association (but with stands of pine, birch, and larch) above an undergrowth of mosses and herbs. This large and valuable reserve of timber is of world importance; forests once covered 80 percent of Europe's surface, and they still occupy about 30 percent.

Human adaptations. Clearly, animal life, wild and domesticated, has been adjusted to fit largely man-made patterns of vegetation, which, in turn, reflect age-long attempts to achieve chiefly economic ends. With such endeavours are associated varieties of *modes de vie*, or "means of livelihood." In the mountains, as in the boreal forests, the environment is exploited by winter lumbering and by the transport of felled trees by river after the spring thaw. So, too, agriculture in its many forms—in part for subsistence but commonly for urban markets—is a basic occupation of the lowlands, long cleared of extensive forests or steppe vegetation. In Mediterranean Europe, rural life, based on horticulture and arboriculture rather than on large-scale cultivation, as well as on the rearing of sheep and goats and wheat cultivation, continues, little changed in many areas. For such deeply rooted fruit-bearing trees as the olive and vine, use is made of sloping, broken, and terraced land. Farming also extends to specialized forms with respect to the subtropical crops that climate, sometimes supplemented by irrigation, permits.

Modes de vie

ANIMAL LIFE

Patterns of distribution. With animals as with plants, the earlier Pleistocene range and variety has been much reduced since man disposed of what nature provided. Wild fauna has been long in retreat since Upper Paleolithic times, when, as cave drawings portray, small human groups held their own against such big game as aurochs and mammoths, now extinct, and also against

such survivors as the elephant, bison, horse, and boar. Hares, swans, and geese were also hunted, and salmon, trout, and pike were fished. Man was, inevitably, a successful competitor for land use. By prolonged effort he won the land for crops and for domesticated animals. And he hunted animals, especially for furs. As population mounted in industrializing Europe, he no less inevitably destroyed, or changed drastically, the wild vegetation cover and the animal associates it housed. With difficulty, and largely on human sufferance, animals have nevertheless survived in association with contemporary vegetation zones.

The tundra. In the tundra some reindeer (caribou), both wild and domesticated, are well equipped to withstand the cold. Their spoon-shaped hooves are useful in finding food in rough ground. Their herds migrate southward in winter and eat lichens and other plants, as well as flesh, notably that of lemmings and voles. Dogs, too, are reared for traction but yield less than reindeer, which also provide meat, milk, pelts, wool, and ivory. The Arctic fox, bear, ermine, partridge, and the snowy owl may appear in the tundra, where, in the short summer, seabirds, river fish, and immigrant birds (swans, ducks, and snipes) vitalize a harsh environment then made almost intolerable by the swarms of midges.

The thinning out of animal species in boreal forests

Boreal associations. In the boreal forests the richness of animal, including bird, life, which persisted during historical times, is now greatly reduced. Among large surviving ungulates are the elk (moose), reindeer, and roebuck, and, among big beasts of prey, the large brown bear. The lynx has been exterminated, but not the wolf, fox, marten, badger, polecat, and white weasel. The sable, much hunted for its fur, only just survives in the northeastern forests of the European Soviet Union. Rodents in the forests include squirrels, the white Arctic hare, and (in the mixed forests) the gray hare and the beaver. Among birds are the black game, snipe, hazel hen, white partridge, woodpecker, and the crossbill, all of which assume protective colouring and are specially adapted to be able to find their food in a woodland environment. Owls, blackbirds, tomtits, and bullfinches may be seen in the forests, and, in meadow areas, geese, ducks, and lapwings may be seen.

The steppes. The fauna of the steppe zones now lacks large animals, and the saiga antelope has disappeared. Numerous rodents, including the marmot, jerboa, hamster, and field mouse, have increased in numbers to become pests, now that nearly all the steppe is under cultivation. Equally plentiful birds include the bustard—who can fly as well as run—quail, gray partridge, and lark. These take on yellowish-grey or brown protective colouring to match the dried-up grass. Eagles, falcons, hawks, and kites comprise the birds of prey; water and marsh birds—especially the crane, bittern and heron—also make their homes in the steppes. Different kinds of grasshopper (cicadas) and beetles are insect pests.

Mediterranean and semidesert associations. In Mediterranean Europe, remnants of mountain woodland harbour wild goats, wild sheep—such as the small mouflon of Corsica and Sardinia—the wildcat, and wild boar. Snakes, including vipers, and lizards and turtles are familiar reptiles, but birds are few. Finally, the faunas of the semidesert areas of the southeast European Soviet Union show affiliations with the grass steppe and the desert between which they lie. Two types of an antelope (saiga and jaran) survive there; as do rodent sand marmots and desert jerboa, and, as a beast of prey, the sand badger. There are also many reptiles—lizards, snakes (cobras and steppe boas)—and tortoises. The saksaul jay and the saksaul sparrow, named after the desert tree, also live there, while scorpions, the karakurt spiders, and the palangid, are insects dangerous to man and camel.

Conservation problems. Pressure on space, hunting, either for sport or to protect crops, the pollution of seawaters and freshwaters, and the contamination of cropland have so reduced many animal species by the closing decades of the 20th century that strong efforts are now being made to preserve those threatened with extinction, in such refuges where they still, precariously, live.

Nature reserves

Nature reserves have been set up in many European countries, with international support from the International Union for the Conservation of Nature and Natural Resources (IUCN) and the World Wildlife Trust (WWT). Seabirds find safe homes, for example, in the Lofoten Islands of Norway, and Farne Islands of northeast England. The snowy owl, which feeds on lemmings, is seen in Lapland, the rare great bustard in the Austrian Burgenland, and the musk-ox in Svalbard. Père David's deer, which had become extinct in China, its native home, was introduced in 1898 at Woburn Abbey, England, where it now flourishes. Nearly half the bird species of Europe, including the egret and the imperial eagle, are represented in the Coto Doñana Nature Reserve, within a setting of wild vegetation in the *marismas* of the Guadalquivir Estuary (Spain); there too the Spanish lynx survives. In Poland the extensive Bialowieza National Park, a wild forest once hunted yearly by the tsars, contains deer, wild boar, elk (moose), bears, lynx, wolves, eagle owls, black storks, the European bison (wisent), and the tarpan, a gray-coloured horse and a survivor from remote days. In Belorussia, in the Belovezhskaya Pushcha, bison are preserved. Italy has its famous Gran Paradiso National Park in the Aosta Valley, which preserved from extinction the Alpine ibex; Austria has a bird refuge in the Neusiedler See, which is the only breeding site of white egrets in western Europe; and the huge and magnificent delta of the Danube is largely left to wildlife. The golden eagle, Alpine marmots, and chamois are to be seen in the German Alps near Berchtesgaden.

Other rare birds are the sandwich tern (at Norderoog Island, western Germany) and the spoonbill and cormorant, found respectively at Texel Island and Norderoog Island, the former in The Netherlands. For ornithologists (as for botanists) Iceland has abounding interest, notably at Stutness, an island in the shallow lava Lake Mývatn. The beautiful wild horses of Réserve Naturelle de Camargue (Rhône Delta), the wild ponies of the New Forest (England), and the Barbary apes, maintaining a politically indifferent foothold on the Rock of Gibraltar, continue undiminished in popular interest.

Thus the European environment, once not so unequally shared by plants, animals, and man, has, with the march of civilization, been subjected to man's attempt at mastery. Favoured by their proximity to the Near East, where crop cultivation and animal domestication first began, the peoples of Europe have fashioned cultural landscapes, at the expense of wild nature, to serve their economic and social ends. Only with difficulty—and sporadically—has wild nature survived, and only just in time has awareness of the cultural losses from the impoverishment of natural vegetation and its animal associates underlined the urgent need for careful protection and preservation of nonhuman nature for communal enjoyment and scientific research.

The war against predators

Against certain predators, notably the rabbit and the anopheles mosquito, war has been waged with good effect, for malaria no longer afflicts the Mediterranean world, and rabbits, competitors for grass, have been greatly reduced and might perhaps be reduced again by the spreading of myxomatosis. On the credit side, too, should be listed the full use made of domesticated animals for pastoral husbandry—on high and rough ground, as well as on farms. The familiar farm animals are selectively bred and reared with some regard to the physical character of their environment as also to market demands and government decisions. In the far north, herds of reindeer are adapted to withstand cold and to find their food in snow-covered ground. In the rough, hilly, scrubland of Mediterranean Europe, the sheep, goat, donkey, mule, and ass have adapted well. The horse, which, in its long history, has drawn chariots, carried mounted knights, hauled the plow, wagons, artillery, stagecoaches, canalboats, and urban trams, is now largely replaced by the tractor, truck, and jeep. He is now reared more for racing, riding, ceremonials, and the hunting of fox and stag, but is still used for farm work, especially in eastern Europe. Distribution maps of animals kept on farms show how widely they enter into

farming: sheep have a special concentration in Great Britain and the Balkan countries, cattle have small place in southern Europe, while pigs are relatively numerous in the north, especially in the highly populated areas of West Germany, Denmark, and the Low Countries.

IV. Natural and human resources

MINERAL RESOURCES

With rocks and structures of virtually all geological periods, Europe possesses a wide variety of useful minerals. Some, exploited since the Bronze Age, are depleted; others have been greatly consumed since the Industrial Revolution. Useful minerals include those that provide energy, ferrous and nonferrous metals and ferroalloys, and those that furnish materials to the chemical and building industries. Europe has a long and commendable prospecting tradition, but, as in the case of North Sea gas, some surprises are still encountered. In relation to the ever-mounting requirements of its economy, however, Europe—the Soviet Union apart—is very dependent on mineral imports.

Recent mineral discoveries

Mineral fuels. *Coal.* Europe commands abundant resources of hard and soft coal, which remains of considerable, if declining, importance as a source of power, in smelting minerals, and for its many by-products. Only exceptionally does northern Europe have coal measures of commercial scale, but Carboniferous coal measures are preserved in Hercynian basins throughout the continent, lying diagonally across Britain, Belgium, The Netherlands, France (especially Lorraine), Rhine-Westphalia and the Saar (German Federal Republic), Upper Silesia (mainly in Poland but also in Czechoslovakia), to the Donets Basin and Urals. There are numerous fields, small but often, as at Pécs and Komló, in Hungary, and in the Arctic fields of Soviet Vorkuta and Norwegian Svalbard, of great locational value. Some, as in southwestern Scotland and southern Belgium, have been either worked out or become uneconomic. Deeper workable seams are sought, in the Ruhr, for example, and, undersea, off Yorkshire, England. Major reserves, encompassing mostly hard deposits of coking, anthracite, and steam coal, lie in the Ruhr, the Pennine fields of England, Upper Silesia, and the Donets Basin. Softer and less calorific brown coal, or lignite, occurs in the two Germanies, the Chomutov fields of Bohemia, and the Moscow-Tula field.

Petroleum and natural gas. Known petroleum and natural-gas reserves are, except in the Soviet Union, Romania, and Albania, wholly disproportionate to Europe's large requirements. The Volga-Ural field dwarfs all others; Romania's reserves from the Carpathian and sub-Carpathian zones, although very much smaller, meet its needs. Many west European countries have located and are exploiting quite modest reserves of petroleum. At Groningen, The Netherlands have a rich source of natural gas, and the United Kingdom has gas and oil beneath the North Sea bed.

Uranium. Sources of uranium for use in nuclear reactors have been discovered in many European countries, including France (centred on the Massif Central); the Soviet Union (in the Ukraine and Estonia); and lesser amounts in parts of central and eastern Europe.

Metallic deposits. *Iron ores.* The largest known iron reserves are the Soviet deposits at Krivoy Rog in the Ukraine Shield, Magnitogorsk, and near Kursk. High-quality ores (of 60 percent iron) from the first two sources are becoming expensive to mine, but Soviet reserves are more than sufficient for the country and its European associates: the Kursk Magnetic Anomaly, located in the south of the Soviet Union proper, has an estimated 15,000,000,000 tons of iron rich quartzites. Deposits in other European countries are small and, except in France and Sweden, inadequate for large-scale heavy industry.

The Kursk Magnetic Anomaly

Ferroalloy metals. The richest ferroalloy deposits occur in the emerged shield rocks of Kola (titanium and molybdenum), the Urals, and the Ukraine. Nickel is also mined at Pechenga, in Kola, and at several Ural sites. The southern Urals have also deposits of manganese, required for basic steel manufacture, but these are dwarfed by that at Nikopol, near the Krivoy Rog iron field, which is the largest and best located in the world. Other countries have virtually no significant nickel or tin reserves and only small manganese resources. There are chromium deposits of some scale in the Soviet Orsk-Khalilevo region and in Macedonian Yugoslavia, which also contains antimony and molybdenum. Wolframite (for tungsten) is mined from Iberian Hercynian rocks. Norway has molybdenum workings, and Finland has deposits that yield titanium, vanadium and cobalt—valuable and scarce alloys for special steels—and ranks as Europe's largest producer outside the Soviet Union.

Nonferrous base metals. With notable exceptions, known European reserves are small, partly as a result of the depletion, for example, of Cornish tin and Swedish copper. Deposits yielding copper, often from copper pyrites, are found in Scandinavia, the southern Urals, and Mediterranean lands. At Bor, Yugoslavia has the largest reserve of copper (low grade) in Europe; its reserves in lead and, especially, zinc are also high. Mercury is obtained near Krivoy Rog, in Yugoslavia, and in southern Spain. Europe has much bauxite, the principal basis for aluminum, with Hungary alone possessing some 16 percent of world reserves. Nepheline, an alternative raw material for aluminum, is worked in Kola.

Bauxite reserves

Precious metals. Europe's once widely available reserves of gold appear largely exhausted. A little silver is still produced, mainly in north European countries, but only in the southern Urals is gold found on any scale.

Nonmetallic deposits. Minerals within this large category are widely available. Clay minerals include fuller's earth—used to cleanse wool and to finish cloth—derived from the decomposition of feldspar; kaolinite, of similar origin, and valuable as china clay, occurs in a pure form in southwestern England: it surpasses coal as a United Kingdom export; rock salt, important in the chemical industry, occurs widely, much of it being precipitated in such geologically ancient salt lakes as the Soviet Lake Baskunchak (lower Volga), which contains 130-feet-thick strata. Europe also has substantial sulfur deposits, and the mining of sulfur in Miocene beds in Sicily gave Italy a virtual monopoly before the opening up of New World deposits in Texas. The carbonate rock, dolomite, like talc, is used as a refractory material, as in lining metal furnaces, and is widespread. Graphite, a crystalline form of carbon used as a lubricant and the basis (with clay) of the "lead" in pencils, is worked in Norway, Finland, and England. Nitrates, for fertilizers and explosives, are made from the air electrolytically in England, Norway, and the Soviet Union, and deposits generating potash and phosphate fertilizers are relatively abundant. The Soviet apatite (calcium phosphate) deposits at Kola are the world's greatest, as are its potash deposits at Solikamsk, in the Urals. Corundum, a very hard abrasive, occurs widely. Building materials for cement and bricks, as well as stone, are abundant, although only regionally available, depending on geological structure. Particular building stones—marble from central Italy, granite from Norway and Scotland—have localized sources. Except in the Urals, precious stones are rare: these mountains also contain the chief European deposit of asbestos.

Building materials

WATER RESOURCES

Surface water. The mountainous and upland areas of Europe collect great amounts of surface water, which supply the rivers and lakes; the lowlands, with lower rainfall, thus receive "exotic" water from the higher portions of their river basins. In the Mediterranean lands, surface water is minimal in summer, exceptions being northern and northwestern Iberia (which gets ample rain), the north Italian plain, which has Alpine rivers, lakes, springs, and summer rain; and the Apennine zone of Italy. In the European Soviet Union, surface water is relatively abundant in the centre and north but decreases south and southeastward, where, fortunately, rivers, collecting water from extensive basins, bring in supplies, and the Volga and Dnepr dams have created enormous lake reservoirs.

The increasing water requirements of thermal power stations and industry and, to a lesser extent, domestic

needs make those little populated and industrialized European highlands, which offer surplus water, indispensable to the lowlands. The pollution of water by effluents containing nonoxidizable detergents from the cities and by those from oil refineries, chemical, and metallurgical plants has reached such proportions in, for example, the Rhine below Basel, the Ruhr region, and Lakes Geneva and Garda as to present serious problems and to incur high reclamation costs. In reaction to water shortages, water is, as in the Thames, recycled many times, a practice that, happily, improves river-water quality.

Groundwater. Europe is relatively well watered, for the water table is normally not far below the surface in the lowlands, and wells and springs are widely available there; underground supplies (groundwater), held particularly in porous rocks, are sporadically utilized by pumping. A growing trend is, artificially, to add to supplies of groundwater and thus integrate surface and underground water; nearly half of Sweden's urban water requirements are thus supplied. High capital costs, rather than lack of water, leave some areas—notably the southeastern European Soviet Union and parts of interior Spain and Turkey—in an arid state. The needs of major European cities and industrial regions involve continuing efforts to collect enough water by impounding surface water, by pumping groundwater, and by encouraging the economy, reuse, and reclamation of water.

Recycling of water

BIOLOGICAL RESOURCES

Some reference to plant, animal, and human resources is needed to complement any discussion of European resources. Reference has already been made (see above *Plant and animal life*) to what remains of Europe's plant and animal heritage, supplemented as this is by such vigorous developments as the breeding of livestock to specific purposes and the acclimatization of trees and plants of economic value, which have taken place throughout its history. The following sections (see below, *Human resources; Resource development; Demographic patterns*) turn attention to the development of the natural heritage and to humans themselves, the creators of wealth and the disposers of animate nature.

HUMAN RESOURCES

Origins of the Europeans. The highly skilled peoples of Europe constitute its principal resource. While they can be distinguished clearly on the basis of nationality, language, religion, standards of living, and political ideology and organization and are of predominantly white skin colour, they can claim no clear-cut racial origin. The continent had a scanty population of human types, now extinct, before *Homo sapiens* appeared some 40,000 years ago, and throughout prehistory it received continual immigrants from Asia. Scientific investigation has thrown little light on the race or races from which European peoples are derived, if "race" is taken strictly in its biological sense. Efforts have been made to characterize their different "ethnic types," but this refers only to selectively defined physical traits of the present population and, at best, has a certain descriptive and statistical value. Fortunately, much more is known about nationality and language, which have had immense social and political import in the continent.

Race and ethnic types

The coming into the continent from the east of peoples, Aryan, or Indo-European, in language, and Bronze Age in culture, and their widespread settlement provide a clear vantage point for the discussion of European origins. Caucasian (white skinned) in ethnic type, they were semisedentary farmers. They moved along such routeways as the loess-covered country, which they could clear of light woodland by fire, and settled in clearings or on the edges of forests.

Linguistic patterns. Most of the European languages of today—notably those that fall into the Germanic, Romance, and Slavic language families—derive from the speech of these Indo-European immigrants. Thus English, German, Netherlandish, (Dutch and Flemish), the Scandinavian languages, Icelandic, and various dialects such as Swiss-German derive from German, originally spoken in, and spread from, the Baltic region. The Romance languages—French, Spanish, Catalan, Portuguese, Italian, and Romanian—are regional derivations from the Latin speech of Roman conquerors, the western portions of whose empire lasted more than 400 years. The great Slavic language family bequeathed numerous national tongues, notably Russian, Ukrainian, Belorussian (White Russian), Polish, Czech, Slovak, Serbo-Croatian, and Bulgarian. Finally, Greek, Albanian, Latvian, Lithuanian, and Celtic are additional Indo-European languages, while the non-Indo-European languages represented in Europe are Finno-Ugrian (to which Finnish, Estonian, Karelian, Lapp, and Magyar belong), and Turkic (Turkish and some groups in the European Soviet Union), Semitic (spoken by Maltese), and the mysterious Basque.

The geographical patterns of Europe's language map were simplified by both voluntary and forced migrations during and after World War II. In general, the national languages follow compact patterns, but such old surviving languages as Basque, Wendish, Welsh, and Breton are of exceptional interest to the linguist.

Linguistic survivals

Political groupings. *The historical legacy.* Europe is unique in that it has given the world so many national languages and literatures; the continent also holds a multiplicity of self-conscious and clearly recognizable national groups and states. National groups have long existed, but only by stages have European nations become self-conscious and highly emotive about their identities and used them vigorously and articulately as the basis of claims to separate statehood. The United States War of Independence (1775–81) and the French Revolution of 1789 created, dramatically, the modern concept of the nation state, although the English, the Scots, the French, and some others had created nation states even in the Middle Ages. Multinational empires—foundering only in the 20th century, with the collapse of the German, Austro-Hungarian, Russian, Ottoman, and, in particular respect to Ireland, the British empires—were also important. Even in the early 1970s, when so many states had acquired independence all over the world, Europe had over 30 independent states (Gibraltar alone remaining formally a self-governing colony), or nearly a quarter of the world total.

Contemporary trends. The political map of contemporary Europe appears fragmented when compared with that of 1815, or even that of 1913. The two great wars waged in Europe, each followed by territorial resettlements, saw the great empires replaced by many small national states, some of which, like Czechoslovakia and Yugoslavia, were nationally composite. The Russian Empire was replaced by the Soviet Union, the territories of which were at first sharply curtailed in the west, a situation remedied during and after World War II. The 1919–39 period saw western Europe separated from the new Soviet state by a zone of weak national states oriented to the West; but the post-World War II developments saw their replacement by a new belt of Socialist nation states. The ensuing cold war era saw great importance attached, by the British leader Winston Churchill and others, to the sharp linear boundary, publicized by Churchill as the iron curtain, dividing countries associated closely with the Soviet Union from those in the West where United States influence became important. Other legacies of World War II were a politically divided Germany, shorn of its former eastern territories, with part of Berlin a Western enclave in the East.

This political fragmentation of Europe, with all the attendant disadvantages from a continental viewpoint, has been qualified by the growth of the concept of peaceful coexistence and by a trend toward the creation of international organizations with a measure of sovereignty. These associations have come about through common political and defensive interest, by the clear advantages of economies of scale in industrial production, and perhaps, too, by a genuine attempt to bury a warlike past beneath more civilized ideals.

The political fragmentation of Europe

The chief of these associations of states are the Western-oriented Organization for Economic Cooperation

and Development (OECD), which also counts the United States, Canada, and Japan as members; the North Atlantic Treaty Organization (NATO) and the Warsaw Pact, both military and defense alliances; the European Free Trade Association (EFTA), a trade grouping; the European Economic Community (EEC), popularly known as the Common Market, and the Council for Mutual Economic Assistance (CMEA, or Comecon), political and economic groupings of western and eastern Europe respectively.

Intracontinental and intercontinental movements. Although Europe's population remains large absolutely, its share of mankind has decreased to approximately one-sixth. This results not only from demographic changes (see below *Demographic patterns*) but also from emigration, since Europe has sent its people in great numbers to the other continents, notably to the Americas, Australasia, and northern Asia. This outflow, originating in the age of maritime discovery, assumed massive proportions when the steamship and railway facilitated passage overseas. British and Irish, French, Spaniards, and Portuguese, in particular, moved in such numbers and with such political effect that their languages are now spoken over extensive areas beyond Europe.

Within the continent there has always been some mobility of population, high during prehistoric times, and well-marked during the centuries that witnessed the decline and fall of the Roman Empire in the West, when many tribal groups—especially of Germans and Slavs—settled in specific regions where they grew into distinctive nations. During and after World War II many Germans from outlying settlements in central and east central Europe returned to western Germany, some as forced migrants. Many East Germans, too, made their way to the West until the building of the Berlin Wall checked this flow. More recently, and where this is permitted, migrants are chiefly workers, seeking temporary work and, often with less success, new homes. The Common Market countries draw workers from southern Europe, as does Switzerland. The United Kingdom has received sizable numbers of Commonwealth citizens, including West Indians, Indians, Pakistanis, Kenyan and Ugandan Indians, as well as Irish and some aliens. Two other conspicuous forms of mobility in Europe are the daily commuting of city workers and the increasing movements of tourists (see below *Demographic patterns: Extracontinental movements*).

Recent migrations

The European contribution. Human enterprise and labour create wealth, and, in this respect, Europe has outstanding assets. Its early start in civilization, with which only Asia compares, the creative abilities of its peoples, who, despite their apparent diversity, share common cultural sources, their traditional fertility, and thus their substantial numbers (some 640,000,000 by the 1970s)—all these have contributed to Europe's success in exploiting the resources provided by a richly variegated environment. These successes relate to agriculture, mining, and forestry, as well as to manufacturing industry, commerce, transport, and finance. They relate also to science and technology, to literature and the other arts. The population of Europe is nevertheless very unevenly distributed, and the same standards of living and degrees of urbanization are not equally achieved in all parts. There are lowland and plateau areas, where, associated with mining, modern industry, and urbanization, the population is very densely settled. In contrast, areas of really scanty settlement lie mainly in northern Europe and, elsewhere, mostly in mountainous and arid zones.

V. Resource development

The resources of Europe, since they result from the efforts applied at an ever-rising technical level, are in some respects inexhaustible. Although the cultivation of soil and mining and quarrying for metallic minerals were initiated in prehistoric times, the winning of some resources began only in relatively recent times, in response to new needs and new technology. The clearing of woodlands for the plow has continued since the early Middle Ages; the cultivation of the steppe lowlands of the Ukraine and the Lower Danube Basin commenced only in the late 18th century. Effective drainage, in which the Dutch excelled, especially during and following the 17th century, made use of former marshlands. The large-scale mining of coal and iron ore date from the Industrial Revolution. Some industries—many concerned with products of the chemical industry and the refining of aluminium—belong to the 20th century, which also brought electricity as a form of energy and, for transport, the petrol-fuelled engine for use on land, sea, and in the air. Recent international groupings facilitate large-scale economic units, and the value to Europe of both a variety of Socialist planning and the post-World War II United States financial aid channelled through the Marshall Plan should also be noted.

The concept of stage, too, helps an understanding of Europe's economic development, for the application to industry and agriculture of modern technology and scientific research has reached different parts of the continent successively. Great Britain, as the home of the Industrial Revolution, stimulated economic change in western, central, and northern Europe. The Soviet Union and its present east European associates were mostly late starters, and the pace and scale of their industrialization quickened markedly after 1945 on Socialist bases. The countries of southern Europe, notably northern Italy, also advanced economically following World War II, although much progress remains to be made. Europe is thus an outstandingly well-developed part of the world, and, although economic development is uneven regionally, no clear limits appear to impede further progress.

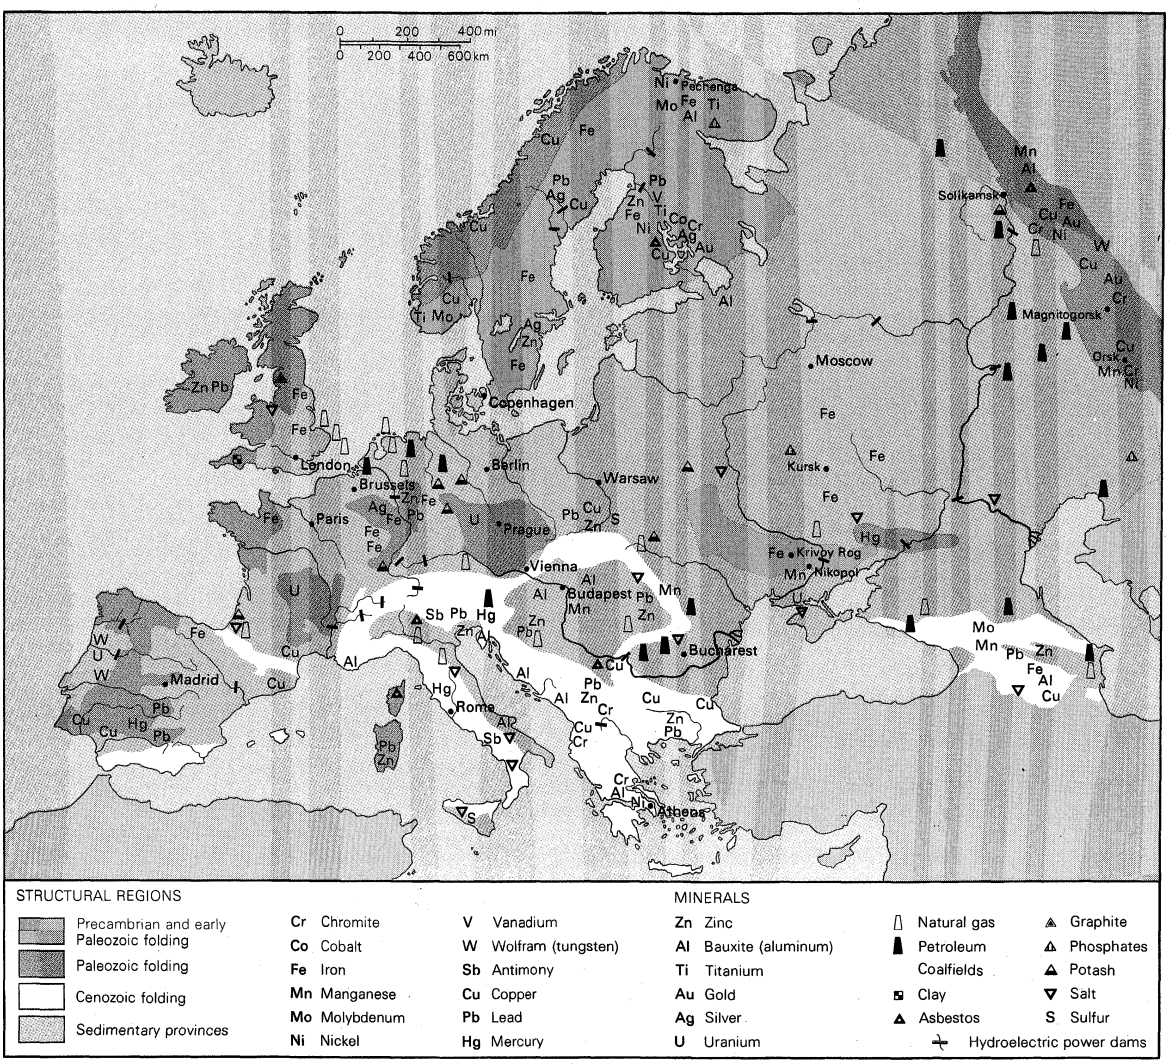
Economic growth stages

EUROPEAN INDUSTRY

Mining. Mining provides employment in all countries, although for smaller numbers as mechanization is applied. High-grade iron ores are mined at Krivoy Rog and near Kursk, Magnitogorsk, and in Arctic Sweden and Norway; these are supplemented by the low-grade minette ores of Lorraine and Luxembourg, low-grade (quarried) Jurassic ores of England, and low-grade Spanish ores. Europe, including the Soviet Union, accounts for nearly a half of the world's coal production and over three-quarters of its lignite, although coal output is shrinking as other forms of energy, especially oil, natural gas, and hydroelectricity become increasingly economic. The chief producers are Great Britain, West Germany (the Ruhr and Saar), Poland (Upper Silesia), and the Soviet Union, where the Donets Basin yields a third of the national output. East Germany is the world's chief source of lignite, mined also in West Germany, Czechoslovakia, and the central European Soviet Union. Many mineral deposits are of only local interest but, as a whole, Europe produces about a quarter of the world's bauxite, a fifth of its copper, and a third of its lead and zinc. Minerals of more than domestic importance are natural gas in The Netherlands; bauxite in France, the Soviet Union and Hungary; petroleum, apatites, and manganese from the Volga-Urals, Kola, and the Ukraine respectively; and china clay from England.

Heavy industry and engineering. The change from charcoal to coke as fuel in blast furnaces led to the localization of Europe's iron and steel industries on its coalfields to economize transport costs, although imported iron ore, cheap American coal, electric furnaces, and technological efficiency have loosened this tie. Thus Northumberland and Durham in England, Rhine-Westphalia, Upper Silesia, and the Donets Basin have their coalfield furnaces and mills, while others are grouped near sources of the ore, as at Krivoy Rog and in Lorraine, or such convenient estuary or port sites as Port Talbot (south Wales), Genoa, and Dunkirk. Europe produces a half of the world's steel, with the Common Market and the Soviet Union each accounting for about two-fifths of the output, but only two-fifths of its iron ore. Steel-using industries making heavy machine tools, and mining, smelting, construction, and electrical equipment favour coalfield locations, while shipbuilding, motor-vehicle, and aircraft construction show a wider distribution, including new sites.

Coalfield-based industry



Basic structural regions and principal mineral and hydroelectric sites of Europe.

Chemical industries. Covering many new and old products, chemical industries have expanded greatly since 1945, partly in relation to hydroelectricity generation and partly as a result of the market-oriented use of refinery by-products. Many heavy chemicals are produced on the coalfields, notably in the Ruhr, where by-products of coke ovens and metallurgical plants are available. Other chemical industries utilize Europe's deposits of salt, potash, phosphates, and sulfur, and the industry has been revolutionized by the increasing production of synthetic rubber, plastics, synthetic fibres, detergents, insecticides, and fertilizers.

Manufacturing, timber, and fisheries. A wide range of light consumer industries is found throughout Europe, but some countries acquire reputations for speciality goods, as in the case of English and Dutch bicycles, Swedish and Finnish glass, Parisian perfumes and fashion goods, and Swiss cheese and chocolate. The United Kingdom's once leading textile industry now concentrates on high-quality goods, including many synthetic fibres, of which, together with the German Federal Republic, France, and Italy, it is a large producer.

Specialty goods

The timber and fisheries extractive industries, now mechanized, are of considerable scale: the Soviet Union, Sweden, and Finland are leading producers of soft and hardwood, and exporters of timber, wood pulp, and newsprint. Fishing and whaling are large industries for Norway, Britain, France, Iceland, and the Soviet Union: catches yield not only human food but materials for many subsidiary industries.

Handicrafts and other industries. Of small importance in a continent where the economies of mass production involve standardized production, handicrafts nevertheless survive to serve a wide market, including that of tourists, who seek speciality goods. Knitwear and Harris tweed are produced by crofters in the Scottish islands; traditional costumes are made and displayed in many eastern European countries; and custom-made ("bespoke") tailoring for men, like dressmaking for women, survives as supplements to ready-made clothing; artistic pottery making is another active craft.

Some other European industries fall but uneasily into the preceding categories. Printing and publishing, especially in English, French, German, and Russian are substantial industries with worldwide effects, notably in the educational field. Europe is a large producer of pharmaceutical drugs and produces such world-famous beverages as the wines of the west and south, the northern beers, and not least, whisky, the status drink from Scotland. Technological and scientific researches have produced nuclear-fuelled plants generating electricity, while the outstanding growth industry of tourism, supplementing business, professional, and student travel, brings employment and foreign exchange to many, especially in the Mediterranean countries, where sunshine, beaches, scenery, and historical monuments provide exploitable capital since workers have become relatively affluent and paid holidays are the rule. Europe, with 86 percent of international tourism, is the tourist "Mecca" of the world.

Growth of tourism

POWER

The message of the Industrial Revolution was that mechanical energy harnessed to machines could so supplement human muscle and animal power as to produce revolutionary changes in the scale and pace of factory production. Contemporary Europe, covering only 8 per-

cent of the inhabited earth, and with 18 percent of its population, uses 43 percent of the world's energy. World energy consumption by the 1970s was equivalent to 0.4 tons of coal per head of population, for Europe, 2.4 tons, ranging from 5.1 tons (Sweden and the United Kingdom), 5.6 tons (Czechoslovakia and the German Democratic Republic), to 1.1 tons (Spain) and lower in Portugal, Yugoslavia, and Greece.

Coal and hydroelectric power. Coal, used to drive steam engines and, as coke, in the smelting of metals, long held the predominant position. Although the United Kingdom depends on coal to the extent of 59 percent of its energy needs, only 37 percent of the energy consumed by the other Common Market countries is derived from coal and lignite. Coal continues to provide energy to coalfield-based industries and is still of prime importance for the production of electricity.

Hydroelectricity has been markedly developed where precipitation and landforms provide good opportunities to dam rivers, as in northern and Alpine Europe and the Soviet Union. Finland, for example, derives 80 percent of its power from this source; Spain, France, Bulgaria, and Yugoslavia derive a large fraction. France has developed power-consuming industries, such as aluminum refining, close to the Alpine and Pyrenean generating sites.

Other power sources. In other countries, hydroelectricity contributes very little, and petroleum and natural gas claim an increasing share of the energy consumed. By 1970 petroleum accounted for more than half of the Common Market energy requirements and natural gas for 5 percent or more. Natural gas has replaced coal gas in the Soviet Union, Romania, and The Netherlands, and supplements it in Great Britain. Fuel oil is widely used by diesel locomotives and electricity-generating stations, and for space heating. Geothermal heat—utilizing underground waters heated by volcanic action—is available in Iceland, while Ireland, which also lacks both coal and oil, makes efficient use of abundant peat resources. Nuclear-reactor electricity generation, promoted by the European Atomic Energy Community (Euratom) in the Common Market countries, provides, as in the Soviet Union, a small but growing source of electrical energy, scheduled to reach 15 percent of electricity production in the Euratom area by the mid-1970s.

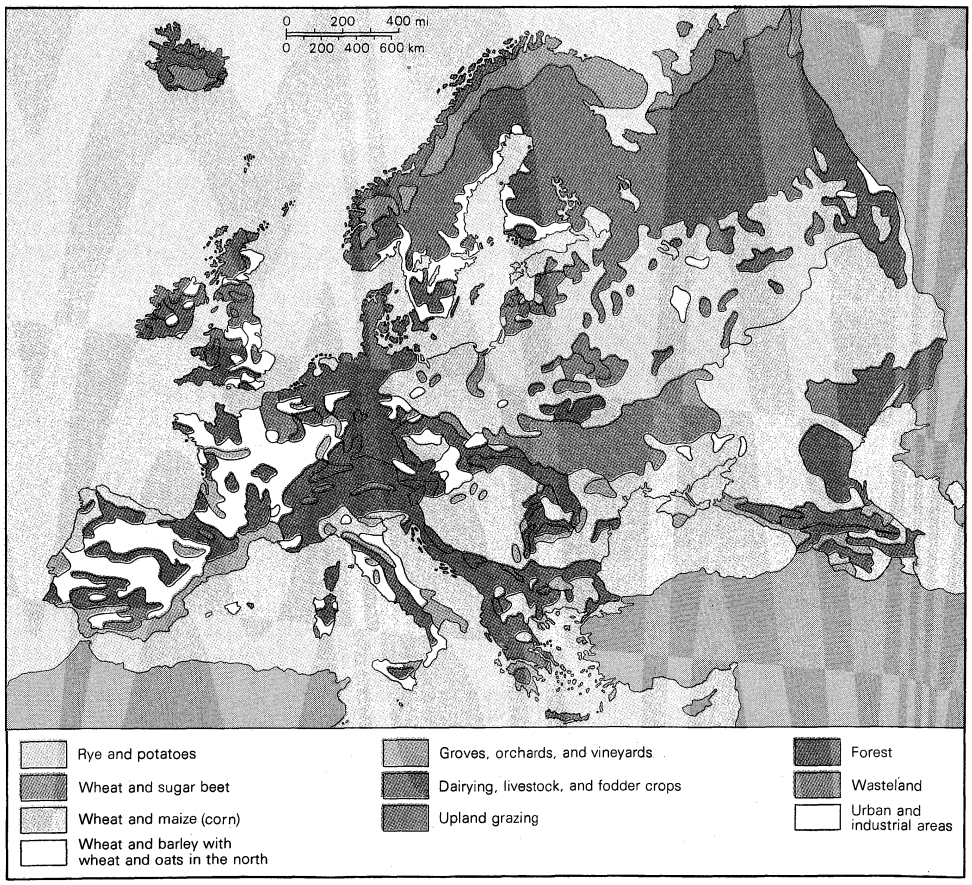
Nuclear-reactor electricity generation

AGRICULTURE AND LAND USE

Distribution. Cultivated land in Europe covers a full quarter of total area, a favourable comparison with both the United States (16 percent) and the Soviet Union (11 percent). Figures for individual countries vary sharply: from over 70 percent in Denmark and 66 percent in The Netherlands; 50 percent in Poland; 40 percent in Romania and Spain; around 30 percent in the United Kingdom, the German Federal Republic, and France; and upward of 25 percent in the European Soviet Union; to about 8 percent in Sweden; below 3 percent in Norway; and virtually nil in Iceland.

Europe's industrialization and urbanization tend to conceal the fact that it is a great producer of cereals, roots, edible oils, fibres, fruit, and livestock and livestock products, accounting for half of the world's rye and potato output, a third of the oats total, and almost a quarter of the wheat output.

Europe's climatic range helped mark out production areas; thus the vine is commercially grown south of about latitude 50° N and the olive is restricted to Mediterranean climatic regions. Maize (corn), grown mainly for silage, is an important crop in the lower Danubian lowlands and southern Soviet Union appearing also in France and Italy. Rice (in north Italy) and citrus fruits (in Spain, Sicily, and Cyprus), depend on irrigation. The northern countries grow few cereals (mainly oats) and concentrate on animal husbandry, especially cattle and dairying. Grain cultivation is found in the lowland belt stretching from eastern Britain to the Urals. Wheat, in rotation, seeks the better soils, oats and rye the poorer soils and moister lands. Mixed farming—*i.e.*, crop and animal farming—and the use of well-tried crop rotations, becomes increasingly the best economic practice.



Agricultural regions of Europe.

Viticulture, although widely distributed, is most important in France, the leading world producer, where it is as remunerative as grain cultivation. As to technical crops, the Soviet Union is the largest producer of flax and hemp, sugar beet (also grown widely elsewhere as a rotation crop in the better soils), sunflower seeds (for edible oil), and tobacco, which figures importantly also in Bulgaria and Macedonian Greece.

Agricultural organization. There are sharp differences in the way that European agriculture is organized and in its regional efficiency. Collective and state farming is the pattern in the Soviet Union and most countries of the Socialist bloc, but cooperative systems, with or without individual land ownership, prevail elsewhere, with the consolidation of over-small holdings progressing steadily in western Europe, paralleled by the breakup of large estates in the east. The capital-intensive agriculture of The Netherlands and Britain, where yields per acre and per man are high, differs from the extensive Soviet system, where, despite the benefits—notably mechanization—brought by collectivization, labour costs are high and yields low. Less than 2 percent of the labour force of the United Kingdom is engaged in agriculture, 13.4 percent in West Germany, 16.5 percent in France in 1967, over 30 percent in Ireland, Spain, and Hungary, over 40 percent in Bulgaria, Greece, and Poland, and 57 percent in Yugoslavia, the higher figures indicating high densities of rural population, a shortage of investment capital, and persistent underemployment.

The relative use of fertilizers—as high as 518 pounds per acre yearly in The Netherlands, and as low as 63 in Poland and 32 in Spain—hints also at the range of crop productivity.

Irrigated areas, lying mainly in southeast Spain, the North Italian Plain, and Mediterranean France, are very small, but disproportionately productive. Long-term prospects for utilizing the irrigation capacity of the Lower Danube and Volga are good.

Livestock farming and dairying associated with pigs and poultry is characteristic of European farms, except in the Mediterranean lands, which are better adapted to sheep and goats. Europe produces well over a third of the world's meat, chiefly beef, pork, and bacon, but this is insufficient to meet rising living standards. Domestic production of wool, hides, and leather is also insufficient, except in Spain and the Soviet Union, which derives much wool (and cotton) from its Asiatic territories. Special features of west European farming include market gardens and glasshouse production of tomatoes, cucumbers, green vegetables, and flowers for urban markets, and production of *primeurs:* table fruit, new potatoes, vegetables, salad crops, and flowers, produced when prices are high, and thanks to the early spring that visits coastal Brittany, Cornwall, and the south of France.

Specialty crops of west Europe

Despite advances in agronomic science, the hazards of harvest shortfalls due to climate have not been eliminated, and intermittent emergency, as well as regular, claims have to be made on grain-surplus areas overseas.

VI. Commerce

Internal and external trade, both by land and by sea, has always been a vigorous part of Europe's economy, and no less so in the 1970s when it faces such strong competitors as the United States and Japan. Trade is made necessary by the regional specialization of production, largely initiated by capitalist enterprise in the past, and now predominantly guided by national or even supranational policy decisions. Economic geology partially explains, for example, the localization of Swedish iron, and Soviet petroleum production, while climate localizes olive-oil and citrus-fruits production. Europe acquired a central position in modern times in the well-settled Northern Hemisphere, which oceanic and air transport systems still exploit. Simultaneously providing large managerial, market, and labour-force attractions, Europe inevitably attracts extra-European traders, with its ever more sophisticated industry producing outstanding exports and its large importation of petroleum, metals, raw materials, and foodstuffs.

Within the continent, the distinction should be drawn between western Europe, which depends greatly on foreign trade, and a Socialist sector that chooses to apply the doctrine of economic self-sufficiency with more inter-regional than international trade. Indeed, because of its territorial extent and the range of its resources, the Socialist sector can do so.

TRANSPORT

All forms of transport are found in Europe. Although they are not equally well-developed everywhere, the traveller can make his way to settled places throughout the continent. The European Soviet Union is, compared with western Europe, where motorways provide fast movement for business and tourism, relatively deficient in engineered motor roads. Motorable roads become ever more widely available; those of Spain and Ireland have particularly improved, and road tunnels now supplement railway tunnels beneath the Alpine passes. Animal transport has minimal importance yet survives locally: the horse-drawn cart may still be seen in east-central Europe; and the ox-drawn plow and the loaded ass, mule, and donkey—sure-footed in rough, hilly country—are still used in parts of southern Europe. And the dog- or reindeer-drawn sled has little competition for short journeys in such winter snow-covered regions as the Soviet North.

The role of animals in transport

Railways. Railways link European ports with their hinterlands and fan out from capitals and major cities to points on the international frontiers where they meet the railway system of their neighbours. In some cases—notably from France to Spain, and the Soviet Union to Poland—this involves a change of gauge. Underground and suburban railways also play an indispensable role for metropolitan commuters. Railways permit passage between the western and eastern European extremities but not quite to the extreme north; they have lost some of their passengers and freight to automobile, coach, and road hauliers, and many uneconomic local lines have been closed. Even so, rail services have notably improved with the use of electrified track or diesel locomotives, faster intercity passenger trains, and container freight trains; and Soviet railways remain all-important.

Waterways and pipelines. Seaports have been modernized and enlarged to deal more efficiently with the increasing size of ships and volume of oceanic trade; even landlocked Switzerland has seagoing ships utilizing Dutch port facilities. The United Kingdom, Norway, and Greece also hold large freighter tonnages for hire.

Inland waterway transport, slow but cheap, is regionally important for the carriage of heavy and bulky commodities. The best waterways—the Rhine below Rheinfelden and the Danube below Belgrade—can carry 1,500-ton barges. The navigable Rhine has the legal status of an international waterway open to all users. Other rivers and canals are usable by smaller vessels. The Soviet Volga, however, is a valuable waterway linking Moscow with Caspian ports and, via the Volga–Don Canal, gives water access to the Donets Basin.

Barge carriers

Giant tankers, up to and beyond 300,000 gross registered tonnage and too deep in draught for most seaports, deliver their cargoes by pipelines that—for petroleum, natural gas, and water—provide the cheapest overland form of transport. They have been built in the United Kingdom for North Sea gas and imported oil; in France, Spain, and Italy for North African oil; and within and beyond the Soviet Union, whose Friendship Pipeline carries crude oil from the Volga-Ural field to east European refineries.

Airways. Air services between principal European cities and to all parts of the world are extensively organized: London, Frankfurt am Main, Paris, and Moscow stand out as airports of first importance. Passengers, mail, and other commodities—such as gold and early spring flowers—of high value in relation to their weight, make use of air transport.

INTERNAL TRADE

Within each European country, a wide variety of goods is moved continually from ports and production centres

to urban markets. Miscellaneous home-produced goods are also traded to consumer centres. Imported goods include fuels, tropical foodstuffs and drink stuffs and raw materials, textile fibres, metals and metallic ores, and a wide range of manufactured goods.

Trading blocs. Active trading within groups of countries that have associated primarily for this purpose, and to rationalize and so increase the profitability of their national economies, is advancing: European Economic Community and Comecon policies have been directed toward economic specialization in increasingly interdependent member countries. West Germany supplies coking coal and chemicals to France, which provides Belgium with iron ore from Lorraine; steel is moved to extranational markets; Dutch natural gas is piped to France, Belgium, and West Germany. Speciality foodstuffs—wines, cheeses, spring vegetables, and fruit—find an enlarged market far beyond their production centres, as do such manufactured items as fashion goods, automobiles, and washing machines. Comecon countries direct their trade largely to each other, with the Soviet Union pre-eminent as producer and market. The U.S.S.R. supplies petroleum, manganese, iron, and chrome ores as well as cotton and other textile fibres; receives machinery, textiles, and Hungarian bauxite.

Comecon and EFTA

The European Free Trade Association (EFTA) has also encouraged trade between its members, who exchange such complementary, rather than similar, products as Swedish and Finnish timber; Danish dairy products and manufactures; Portuguese tungsten, wine, cork, and canned fish; British automobiles, woollen textiles and china; and Swiss watches and food products.

The accession of Norway, Ireland, and the United Kingdom to the Common Market in January 1973 was expected to alter substantially the volume and direction of some trade patterns both within and between EFTA and Common Market blocs. This was expected to be especially true for agricultural commodities and for Commonwealth trade with Britain.

Trade between the West and a Socialist bloc eager for foreign exchange, though much smaller than its pre-World War II equivalent, has increased markedly since the mid-1960s. Soviet petroleum is sold to Italy, Denmark, and the United Kingdom, and Western markets are also used for the sale of gold and diamonds in exchange for ships, machinery, and chemicals. European Socialist countries also supply Soviet automobiles, canned salmon and caviar, and vodka, Polish bacon, Czech glass, and Hungarian and Yugoslav wines.

Intra-Soviet trade. Given its continental scale, the regional trade of the Soviet Union, carried largely by a heavily worked railway system, supplemented by pipelines and an elaborate waterway system, deserves special notice. From the south, grain, meat, vegetable oils, sugar, tobacco, wine, and fruits are moved to central and northern Soviet Union, where consumption exceeds local production; dried fish and salt are carried up the Volga; timber is moved from northern, including Ural, areas to largely unforested southern regions; and Donets Basin coal is shipped by canal to Volgograd.

EXTERNAL TRADE

A major part of the external trade of European countries is with each other since, with regional specialization, dense populations, and relatively high standards of living, they provide strong markets. For the Common Market countries, as well as for those of northern Europe, this trade proportion ranges between 60 and 75 percent, and the British figure, accommodating traditional Commonwealth relations, was still around 45 percent just prior to its admission to the Common Market. About 70 percent of Socialist-bloc foreign trade is intra-Comecon. There is, nevertheless, trading between EEC, EFTA, and Comecon members, and, especially in the United Kingdom and the German Federal Republic, a vigorous two-way trade with the United States. Last, but certainly not least, European trade extends to all parts of the world, including the developing countries, where —in exchange for manufactures—vital supplies of energy, raw materials, metals, ores, and foodstuffs are obtained.

North American trade links

The extracontinental exports of Europe include machine tools, automobiles, aircraft, chemicals (including pharmaceutical drugs), and such consumer items as clothing, textiles, books, expert services, and works of art. Western Europe depends heavily on imported petroleum from the Middle East, Algeria, and Libya, and many raw materials and metals. Europe imports much natural rubber, tea, coffee, cacao, cane sugar, vegetable oilseeds, tobacco, and fruit—fresh, canned, and dried—although its dependence on imported agricultural products, both of food and raw materials, has decreased substantially with greater domestic production and the manufacture of synthetic substitutes for vegetable fibres.

THE COMMERCIAL OUTLOOK

Europe plays the leading role in world commerce, making up about half the total of world exports and imports. The bulk of this trade is carried on by the Western countries, which own nearly half the world's oceangoing tonnage, but there is every indication that the Soviet Union intends to claim a larger share than hitherto. Most of the European countries long held political dependencies overseas where they created captive markets, and this imperialist trading momentum persists. Common Market countries have former colonial territories as associate members, and, similarly, the British Commonwealth nations engage in much trade, now strictly competitive, with Britain, although the latter's new Common Market trading associations will eventually alter many long-standing trade patterns within the Commonwealth.

The international financial crisis

One of the continuing international difficulties that Europe has faced has concerned currency and fluctuating exchange rates, as, in turn, sterling, the French franc, and the United States dollar have come under strain, while the currencies of West Germany, The Netherlands, and Switzerland have grown harder, or relatively more valuable. The survival of sterling as a reserve currency through which a third of the world's population conducts business transactions, is a tribute to its convenience and success, although the process has involved persistent financial crises for the United Kingdom. European financiers play an important world role, as do a variety of such finance-related industries as banking, insurance, and shipping.

VII. Demographic patterns

Europe has always been one of the most populous parts of the world. Although its estimated population numbered only one-third of Asia's in 1650, 1700, and 1800, this nevertheless accounted for one-fifth of mankind. Despite large-scale emigration, this proportion increased to one-quarter by 1900, when Europe's total just exceeded 400,000,000. Such high numbers, achieved by high birthrates and falling death rates, were sustained by expanding economies. As numbers have grown proportionately faster in the Americas, Asia, and Africa, Europe's population, totalling 640,000,000 in 1971, has settled at about one-sixth of the world total.

"Core areas"

In contrast to such recently settled lands as the United States, Canada, and Australia, Europe has many sharp divisions based on language, nationality, political organization, and standards of living. Given the agelong occupation of its soil and minimal mobility for the peasantry—long the bulk of the population—Europe became the home of many linguistic and national "core areas," separated by mountains, forests, and marsh. Its many states, some long established, introduce another divisive element that was augmented by modern nationalistic sentiments. Efforts to associate groups of states for specific defense and trade functions, appear, slowly, to point toward wider unitary associations, with fundamental East–West differences. Europe thus presents two clear-cut, opposing units, open to trade and cultural exchanges, and a number of such relatively neutral states as Ireland, Sweden, Austria, Switzerland, Yugoslavia, Finland, and Spain.

Qualitatively as well as quantitatively, Europe's overall

population is outstanding, with special skills, inventiveness, and initiatives that enable its peoples more than to hold their own in a highly competitive world.

POPULATION DISTRIBUTION

Overall densities. Southern Europe lost its numerical domination as, from medieval times onward, settlement developed vigorously in western and central Europe and as, later still, the steppe lands of the Ukraine and Hungary were settled for crop farming. While northern Europe, from Iceland and the Scottish Highlands to the northern European Soviet Union, is only scantily settled, the population reaches high densities in a more southerly belt, stretching from England across northern France and industrial Germany to the Moscow region, with an outlier in northern Italy. High populations are often associated with coalfields that, in the past more than today, strongly attracted industry, although giant cities like London, Paris, and Leningrad, offering large markets and labour forces, have created regions of high density. Other populous areas are sustained by mining, industry, commerce, and productive agriculture. The Netherlands, with over 1,000 persons per square mile, is the most densely populated country; and Norway and Iceland, the latter with five persons per square mile, the least dense. Population is scantiest in mountain regions, some highlands, and arid parts of Spain and the southeastern Soviet Union.

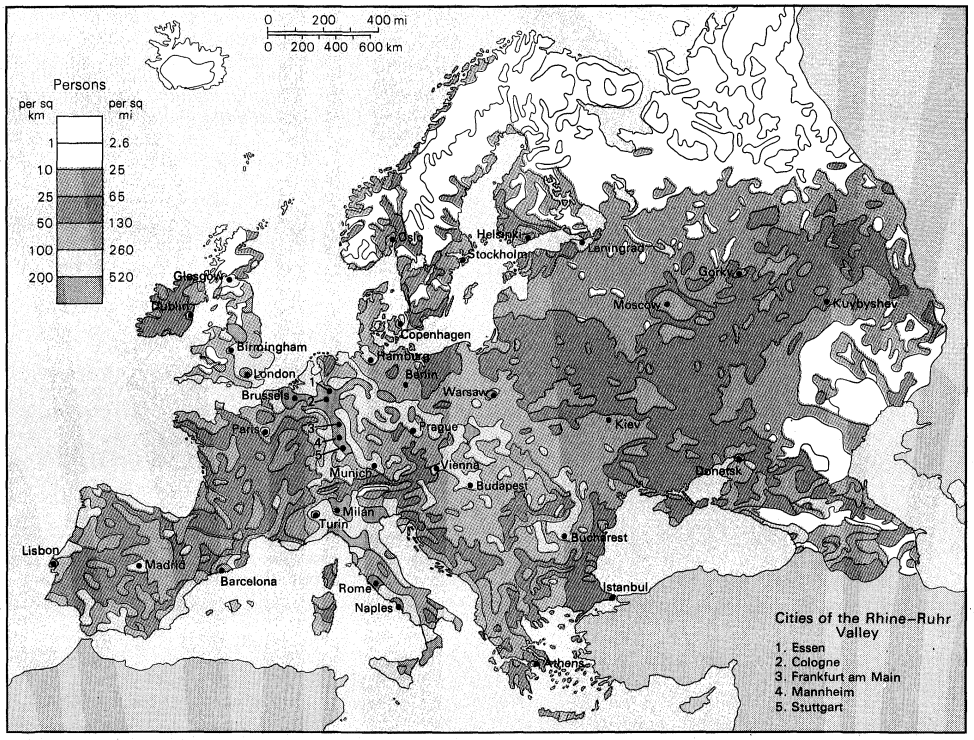
High density areas

Town and country. With easier travel and the lure of developing industrial areas, many culturally-rich, high-altitude areas have suffered severe depopulation. Urbanization, offering varied employment, better social services, and, apparently, a fuller life, has further reduced the rural population, a drift aided by the mechanization of agriculture. City life has, from classical antiquity, nurtured European culture, although tributary rural life was, for centuries, the common lot. The 19th and 20th centuries, however, have seen a revolutionary urbanization that embraces the majority of contemporary Europeans. Some towns are old, containing architectural survivals from their historic past; many more are creatures of the Industrial Revolution. In most of the highly industrialized countries the proportion of urban-dwellers is high: 77 percent in the United Kingdom and The Netherlands and 70 percent in France and Sweden. Others with figures around 50 percent, include Iceland and Norway, Belgium, Poland, and Bulgaria; the Soviet Union's figure is 56 percent and rising steadily. Towns of different scale and varying function continue to grow rapidly, usually in concentric rings outward from the original core. By the early 1970s, Europe contained almost 50 cities of 1,000,000 population, more than a quarter of the world total, and many of the more highly industrialized parts of the continent were marked by giant, sprawling metropolitan areas. One distinct type is represented by the conurbation resulting from outgrowth from London; another, as in the Ruhr, by the fusing together of separate cities. Both stem from an unchecked industrial expansion associated with population growth—including immigration from rural areas. As elsewhere in the world, these giant agglomerations present difficult social and aesthetic problems; however, by concentrating population, they help to preserve the countryside from being too built-up.

Conurbations

Population trends. Western and northern Europe took the lead in the medical and social "death controls" that, since the mid-19th century, have sharply reduced infantile mortality and lengthened life expectancy. Although infantile mortality rates remain relatively high—up to 60 per 1,000—in developing Romania, Portugal, and Yugoslavia—a low of only 13 per 1,000 has been reached in The Netherlands and Sweden. Low crude mortality rates have been achieved virtually everywhere in Europe, with the Soviet rate at only eight per 1,000.

Birthrates fell to low levels in western and northern Europe during the 1930s but recovered substantially after World War II to figures of 15 to 20 per 1,000. In southern Europe, the Iberian countries excepted, and in the Socialist countries other than Poland and Yugoslavia, birthrates now fall within this range; Sweden has the lowest rate—about 13.5—and Romania the highest —23. For the whole continent (the Soviet Union excepted), the annual increase of population is about eight per 1,000, and the comparable figure for the whole U.S.S.R. is little, if at all, higher, for despite its low mortality rate, the birthrate in the U.S.S.R. has fallen to 17 per 1,000 from 25 per 1,000 in 1959. Emigration—notably the Soviet exodus to its Asian lands—retards the European U.S.S.R.'s population growth. The fact that Europe's numbers now edge only slightly upward is one indication of the lesser role it now plays in the world and, given its already high population densities, this may perhaps be regarded as satisfactory.



Population density of Europe.

Birth rates and death rates, as they vary in time and place, necessarily affect the proportion of manpower available to the different European countries for the economy and the armed forces. In most countries, increased longevity and lowered birthrates have generated a rising proportion of retired citizens. Also, the trend toward education over longer periods draws more young people—postwar babies made up a conspicuously large such age-group in the 1960's—from the economy. The labour force thus shrinks somewhat, although it is everywhere (except in Spain) more than 40 percent of the population, and in the Soviet Union, Romania, and Bulgaria it exceeds 50 percent. The economic advantage accruing to such countries results largely from the greater employment of women, especially in agriculture.

EXTRACONTINENTAL MOVEMENTS

Despite heavy mortality resulting from continual wars, Europe has always been in modern times a generous source of emigrants. Since the geographical discoveries of the late 15th century, both "push" and "pull" factors explain an exodus greatly accelerated by modern transportation. The push factors were often sheer poverty, the desire to escape from persecution, or loss of jobs through economic change. The pull factors included new opportunities for better living, often at the expense of original inhabitants elsewhere. All of Europe shared in this huge transfer of population, which effected the settlement and economic development of the Americas, Australia, South Africa, and New Zealand, countries with untapped resources but insufficient manpower. Through their involvement in the horrors of the African slave trade, Europeans also produced forced migrations of non-white peoples that were also to have immense consequences in the Old and New Worlds. Since early in the 19th century, an estimated 60,000,000 persons left Europe itself for overseas, more than half to settle in the United States. Ireland exported most of its population following the potato famine of the 1840s. Northwest Europe—British Isles, Scandinavia, and the Low Countries—contributed the largest share of emigrants, who settled, above all, where English was spoken. Emigrants from central, eastern, and southern Europe moved later, many in the early decades of the 20th century. Affinities of languages, religion, and culture clearly explain migration patterns; South American countries, for example, had more appeal to Spanish, Portuguese, and Italians. It has been estimated that emigration from 1846 to 1932 reduced the growth rate of Europe's population by 3 per 1,000 per annum. The year 1913 marked a peak, with over 1,500,000—one-third Italian and over a quarter British—migrating overseas. Subsequent United States entry restrictions reduced this flood; contemporary European migrants seek new homes mainly in Australia, Canada, South America, and South Africa.

Despite high population densities, some European countries still attract settlers from other continents, mainly because their expanding economies involve labour shortages. Thus France, to increase a manpower depleted by war losses and low 1930s birthrates, has received numerous French-Algerians (as well as other Europeans, including Turks) to supplement its labour force. The United Kingdom, which steadily supplies immigrants to Australia and Canada and specialist workers to the United States, has also attracted immigrants, notably Commonwealth citizens: from 1931–61 immigrants from Ireland, the West Indies, Pakistan, and elsewhere exceeded emigrants by 1,000,000. These immigrants, who largely provide workers for the construction industries, transport, hospitals, and domestic service, include also doctors, scholars, and businessmen. Some, having established themselves, are able to provide homes for their immigrant relatives. Finally, there is a continued and significant migration of Russians and Ukrainians from the European to the Asiatic Soviet Union.

THE OUTLOOK FOR EUROPE

In its landscapes, many nations and tongues, in its political divisions and ideologies, in its cities and historical monuments, Europe presents regional variety and richness; yet it exhibits its own identity, based on a unity of culture, with roots in the common past of Judaism, Christianity, and Islām, ancient Greece, Rome, and Byzantium. Though the citizen of Europe does not exist, the nationals of Europe can feel at home between the Atlantic and the Urals, Stockholm and Rome. The peoples of Europe always showed remarkable fertility, energy, and originality. During their long history, they developed successfully their not ill-favoured geographical plot, created national cultures of great interest, and discovered how to achieve and sustain high living standards. Certainly the Europe of the 1970s has lost the leadership of the world to three great subcontinental powers—the United States, sprung from European settlers; the Soviet Union, itself occupying the greater part of the continent; and China, the modern successor to Europe's ancient contemporary, Cathay—whose resources and technology provide the material bases for world leadership. Europe nevertheless retains the power and spirit to withstand decline and to preserve a high relative status. Europe also shows signs of overcoming its traditional fragmentation: as the European Economic Community enlarges itself, and as the Socialist bloc becomes consolidated, a trend toward closer association points toward the distant goal of unification. In the popular mind, there remain many "Europes" and the unification of the Europe that, as conventionally delimited and as de Gaulle conceived it, stretches from the Atlantic to the Urals, remains a dream for the future. Yet this is an attainable dream since its essential basis—a high common civilization—already exists.

Rise of the superpowers

BIBLIOGRAPHY. GEORGE W. HOFFMAN, *A Geography of Europe Including Asiatic USSR*, 3rd ed. (1969); and JEAN GOTTMANN, *A Geography of Europe*, 4th ed. (1970), provide the best accounts of the whole continent. M.R. SHACKLETON, *Europe: A Regional Geography*, 7th ed. rev. (1969), underlines the geological background; while DENYS HAY, *Europe: The Emergence of an Idea* (1957), discusses the concept "Europe."

Standard texts that deal with the geography of major parts of Europe include: R.J. HARRISON CHURCH *et al.*, *An Advanced Geography of Northern and Western Europe* (1967); F.J. MONKHOUSE, *A Regional Geography of Western Europe*, 3rd ed. rev. (1968); A.C. O'DELL, *The Scandinavian World* (1957); W.R. MEAD, *An Economic Geography of the Scandinavian States and Finland* (1958); A.F.A. MUTTON, *Central Europe*, 2nd ed. (1968); N.J.G. POUNDS, *Eastern Europe* (1969); D.S. WALKER, *The Mediterranean Lands*, 3rd ed. (1965); and J.M. HOUSTON, *The Western Mediterranean World: An Introduction to Its Regional Landscapes* (1964). G.W. HOFFMAN (ed.), *Eastern Europe: Essays in Geographical Problems* (1970), examines the effects of state plans on geographical aspects of national economies. Many studies of Europe restrict themselves to specific aspects of the land and the people. W. GORDON EAST, *An Historical Geography of Europe*, 5th ed. (1966), examines geographical changes since Roman times; while M.M. POSTAN, *An Economic History of Western Europe, 1945–64* (1967), discusses the major social and economic changes since the end of World War II. R. BRINKMANN, *Abriss der Geologie*, 8th ed. (1956; Eng. trans. condensed from vol. 2, *Geologic Evolution of Europe*, 1960), summarizes the geological history of the continent; and W.G. KENDREW in *Climates of the Continents*, 5th ed. (1961), describes the climates of its different parts. C.S. COON, *The Races of Europe* (1939), attempts to distinguish and classify the ethnic types of which the peoples of Europe are composed. J. BEAUJEU-GARNIER, *Géographie de la population*, 2 vol. (1956–58; Eng. trans., *Geography of Population*, 1966), discusses past, recent, and current trends of the population of Europe in relation to those of the other continents. S.H. FRANKLIN, *The European Peasantry: The Final Phase* (1969), relates to countries on both sides of the Iron Curtain; while P. LAMARTINE YATES, *Food, Land and Manpower in Western Europe* (1960), brings out relevant economic and regional aspects of agriculture. I.M. COSGROVE and R.T. JACKSON, *The Geography of Recreation and Leisure* (1972), shed new light on tourism—one of the rapidly growing industries of Europe.

Of special interest are two publications resulting from conferences of geographers sponsored by the Council of Europe: E.C. MARCHANT, *Countries of Europe As Seen by Their Geographers* (1970) and *Geography Teaching and the Revision of Geography Textbooks and Atlases* (1967). In the former book a geographer of each member country has written a brief geographical account of his own country, and in the latter are

included accounts of the five major parts of the continent and an assessment of Europe's unity.

For statistical information, the annual publications of the UNITED NATIONS are invaluable, notably *Statistical Yearbook*, *Demographic Yearbook*, and the *Economic Survey of Europe*. The *Statesman's Yearbook*, published annually, contains useful information about European (and other) countries.

(W.G.E.)

Europe, Ancient

For the purposes of this article, Europe will be defined as the land area west of the Ural Mountains and north of the Black Sea and the Mediterranean, with its adjacent islands. The article consists of a survey of the cultural development in this area from the beginning of the Neolithic Period until the 1st century AD. Ecologically Europe falls into three zones:

1. The circumpolar zone of birch, pine, and tundra, comprising much of Scandinavia and European U.S.S.R., in which hunting and catching were the basic modes of subsistence in prehistoric times.
2. The temperate zone, marked by the predominance at low altitudes of deciduous forest, which was able to support mixed-farming economies.
3. The Mediterranean coastal zone, in which tree culture and viticulture were early combined with stock raising and cereal cultivation, and which was the first area in Europe to support urban, literate communities. The histories of these communities (Rome, the Greek city-states, etc.), about which far more is known than about their nonliterate neighbours, are mainly covered in articles specifically devoted to them. The emphasis in this article is on "barbarian" Europe.

Sources. Apart from occasional and sometimes valuable references to the barbarian world in the texts of Greek and Latin authors, and some more remote clues in Egyptian or Hittite records, knowledge of the peasant phase of European prehistory depends primarily upon archaeology. The different cultures belonging to this phase are often identified by the distinctive style of their artifacts, especially their pottery. But there are many difficulties in seeking to interpret such archaeological data in historical terms. For example, the language a people spoke cannot be determined unless they left inscriptions or others recorded it in literature. Again, there is a fundamental divergence between those who interpret every change in style as evidence of intrusions of new peoples and those who see in them indications of dynamic indigenous development. Frequently, of course, both factors may be involved. In determining chronology radiocarbon dating is of prime value for the Neolithic Period; for the Bronze Age, projections from Aegean dating systems can be used; and for the Early Iron Age, Greco-Roman historical dates put matters on an even firmer basis.

Spread of Neolithic farming communities. Agriculture and stock raising, the economic basis of peasant and ultimately of urban life, first appeared in the Aegean about the end of the 7th millennium BC but did not reach the more remote parts of temperate Europe for another 2,000 or in places even 3,000 years. Although settled life based on farming had been developed earlier in parts of southwest Asia, Europe played a far from passive role. Horses, for instance, were almost certainly domesticated first in south Russia and dogs in northern Europe; and it may even be that cattle were first tamed in southeast

Asian and indigenous influences

Chronology of Ancient Cultures

	Britain	Western Europe	Scandinavia	Danube, Central Europe	Eastern Europe, Western Russia	Greece, Aegean	Egypt	Mesopotamia	Rome
7th millennium						Neolithic farming communities			
6th millennium					Starčevo-Körös culture			Neolithic civilization	
5th millennium			Ertebølle-Ellerbek and Funnel-Neck Beaker cultures	Danubian culture	Boian, Cucuteni-Tripolye				
4th millennium	Megalithic cult	Megalithic cult					1st dynasty		
3rd millennium		Bronze Age civilization		Bell-Beaker culture, Bronze Age civilization	Fatyanovo culture	Bronze Age civilization (Minoan)	Old Kingdom	Sumerian civilization	
2nd millennium		Bell-Beaker and "battle-ax" culture				Early Helladic culture (first half of millennium)		Amorite conquest	
2000–1800 BC	Bronze Age civilization			Únětice, Straubing, Alderberg			Middle Kingdom	Babylonians	
1800–1100 BC		Urnfield culture	Urnfield culture	Urnfield culture	Kistapostag, Perjámos, Tomaszów	Dorian invasion	New Kingdom	Assyrians	
1100–600 BC				Hallstatt culture			period of colonization	Neo-Babylonian period	Etruscans early republican period
600–400 BC		La Tène civilization		La Tène civilization		classical period			
400–300 BC		Celtic Early and Waldalgesheim styles			Celtic Early and Waldalgesheim styles	Macedonian conquest			
300–200 BC		Celtic Plastic style, Celtic Sword style, Roman control of the Mediterranean	continuation of La Tène culture		Celtic Plastic style, Celtic Sword style	Roman ascendancy			beginnings of Roman expansion
200–100 BC									expansion into western Europe
100 BC–AD 1	continuation of Sword style								dictatorship, formation of empire
AD 1–100	Roman conquest								

Europe. Again, while it is true that many elements of material culture, notably pot making and the equipment used in harvesting, were invented earlier in southwest Asia, there was certainly no question of the spread of a single, uniform culture over the European continent. The development of Neolithic farming communities, which lay at the very basis of European civilization, was as complex as it was prolonged, and the diverse pattern in the archaeological record reflects considerabe variety in the culture of the indigenous Mesolithic population.

First phase. Thanks in large measure to the application of radiocarbon dating, it is now possible to trace the progressive enlargement of the territories supporting a peasant way of life. Evidence for this appears first in mainland Greece and on Crete, where communities of mixed farmers appeared about 8,000 years ago, men whose most visible memorials are the mounds, or tells, formed, as in southwest Asia, by the disintegration of settlements of mudbuilt houses rebuilt generation by generation on permanently occupied village sites. The artifacts from such settlements—the handmade pots, clay figurines of women, stamps or seals, reaping knives, querns, and polished stone axes—resemble in their general form and character those from Syria, Iraq, and Iran. Yet the pots from Greece have their own idiosyncrasies of style. The vessels with simple, geometric, painted designs that accompany plain wares from this period in Thessaly or western Macedonia differ from comparable Asiatic wares and contrast even more strongly with the deeply incised wares from early levels at Cnossus in Crete, whose affinities lie rather in Anatolia.

Second and third phases. By the middle of the 6th millennium permanent tell settlements had begun to grow up in the southern Balkans. Pottery and ancillary objects in the Starčevo-Körös style occur with minor local variations over a territory extending from the Adriatic coast of Yugoslavia, across to Bulgaria and Romania, and as far as the Prut River in present-day U.S.S.R. The main characteristics of this extensive culture are common to those earlier established in Greece, and it is significant that some of its distinctive features, such as the prevalence of surface roughening or rustication and the occasional use of naturalistic plastic ornamentation, appear on pottery from Greek Macedonia. The middle of the 5th millennium witnessed the expansion of farming economy over a territory centred on middle Europe, but extending to the Rhineland, the Low Countries and northern France in the west, to Hannover and Silesia in the north, and in the east outflanking the Carpathians as far as the western Ukraine. This culture, called Danubian, used pottery ornamented by pairs of parallel lines arranged in spiral or meander patterns. The Danubian peasants lived in communities very similar to large modern villages in the same territories. Their rectangular farmhouses, commonly up to 30 or even 40 metres long, were built on massive timber frames and apparently included storage space and possibly stalls. Their settlements were not marked by tells as those of the Starčevo-Körös and Aegean culture areas. This was due in part to the fact that it was no longer practicable in more temperate latitudes to build in sundried brick or *pisé* but in part also to the fact that the first peasants to occupy the loess of middle Europe appear to have practiced a form of shifting agriculture that involved frequent changes of settlement. In addition to practicing the same form of economy, living in the same sorts of houses, and making the same kind of pottery, the Danubians everywhere favoured polished stone adz blades for working timber, buried their dead in crouched positions in inhumation cemeteries and, at least in the later stages of their culture, were careful to provide them with ornaments made from the *Spondylus gaederopus* mussel.

Danubian culture

Fourth phase. The fourth phase in the expansion of farming economy in Europe can be studied in three main areas. In the east a new peasant culture, the Boian, grew up in Romania beyond the limits of the Starčevo-Körös area; it used distinctive forms of pottery decorated by surface rippling, painting, and excised or incised linear designs. To the north of this culture, and owing something to its inspiration as well as to that of the Danubian, another one, called after Cucuteni and Tripolye, developed between the Seret and the Bug rivers with an extension to the Dnieper. The pottery of this culture was fired in well-controlled ovens to a red or orange colour after having been decorated in curvilinear designs painted onto or grooved into the surface. Its makers occupied rectangular houses grouped into substantial villages. In some of these the houses were arranged radially. Kolomiishchina, near Kiev, comprised a circular setting of about 39 houses with others in the middle; another at Vladimirovka, also near Kiev, had at least 162 houses in five concentric rings.

On the North European Plain during the 4th millennium, it appears that the hunter-fisher population was influenced by the Danubian peasants to the immediate south. The immediate outcome was the Ertebølle-Ellerbek culture based on a mixed hunter-farmer economy and marked in the archaeological record by pointed based pottery and specific forms of flint and antler artifacts. The end of the 4th millennium saw the emergence of the Funnel-Neck Beaker culture, a farming economy extending from the Netherlands across Poland and as far north as southern Norway and middle Sweden.

The Funnel-Neck Beaker culture

The Megalithic cult. At approximately the same time, a distinct cultural province developed in western Europe over a territory which included much of Switzerland, France, the British Isles, and Iberia. Excavation of the waterlogged deposits of the Swiss lakeside settlements belonging to the Cortaillod culture have yielded particularly full information about subsistence and crafts, such as weaving and embroidery, generally absent from the archaeological record. More significant is the region's contribution to the spiritual life of the time, both as regards funerary ritual and public ceremonial activities. The most numerous visible monuments dating from the 3rd millennium and the centuries either side of it are chamber tombs, sometimes cut out of the living rock, more usually built from megalithic blocks packed around with smaller stones, and held in place by overlying mounds. The construction of such tombs, designed as burial places for successive generations of families or clans, involved a physical and social effort comparable to that implied by the building of churches in early historic times and implies well disciplined religious emotion. Some insight into the nature of the Megalithic cult is provided by the symbolic designs pecked, carved, or painted on stones incorporated into megalithic structures. The spread of this cult can hardly be accounted for in simple terms of diffusion, still less of wholesale ethnic movements. The variety of tomb forms and the varying form and incidence of symbolic art point to intense local and regional development and the transmission of ideas over a rather long time. It is significant that by and large the grave goods relate to the indigenous cultures.

In addition to funerary structures, these people erected single, standing stones, or menhirs, alignments and other elongated structures, and circular monuments, sometimes on a massive scale. The most impressive alignments are those at Carnac, Brittany, comprising nearly 3,000 menhirs in parallel rows over a distance of between three and four miles. Smaller alignments occur in southwest England. The British Isles have many circular settings of menhirs or heavy timbers dating from this period; the best known example is Stonehenge.

Menhirs

The closing centuries of the 3rd and the opening ones of the 2nd millennium were marked by the widespread adoption over much of north, central, and eastern Europe of perforated stone battle-axes. This was a time when farming economy spread in European Russia far beyond the forest steppe (to which the Tripolye peasants had been confined) over the southern Taiga up to the Oka-Volga basin, the homeland of the Fatyanovo culture. In northern Europe the Funnel-Neck Beaker culture gave place to a variety of local battle-ax-using groups all associated with single-grave burial, but in other respects showing many differences. Here, again, it seems that

mixed farming continued to provide the basis of subsistence, and there is evidence that a light plow was already in active use as well as disk-wheeled wagons which likewise were drawn by yoked oxen. The construction of collective tombs was abandoned about the same time in western Europe. The rapid and widespread occurrence over large parts of central and western Europe of pots of bell-shaped beaker form, decorated in horizontal zones by finely toothed stamps, suggests the movement of small mobile groups; and there is evidence that these actively sought out copper and gold.

The Bell-Beaker culture

The circumpolar culture. North of the farming zone, extensive parts of circumpolar Europe continued to support communities that lived by hunting, fishing, and gathering. Although there was some overlapping and contact, the culture of the circumpolar people was quite distinct from that of the peasant peoples of the rest of Europe. Even the art of potting, which they took over from their neighbours, was used to make distinctive ovoid pots reminiscent of basket forms; and the deep pits, which together with stamped comb imprints served to decorate these vessels, themselves stemmed, like much else in the culture, directly from Mesolithic antecedents. The widespread use of polishing was another archaic element originally developed in relation to bone but now applied to a variety of knives, projectile heads, and hollow-ground adzes of slate and stone. As hunters the people were accustomed to movement. During the extensive period of snow cover they used heavy sledges, presumably drawn by dogs, for shifting camp and skis for hunting and personal movement. Skin-covered boats represented on rock engravings were probably used for hunting seals and porpoises and for fishing. Dependence on hunting helps to account for the keen observation shown in the representation of animals that played a leading role in their graphic art. Engravings, sometimes life-size, of game animals and carvings of animal heads on a variety of artifacts, from perforated stone axes to the handles of wooden ladles, reveal a mentality totally opposed to that of the peasants to the south, whose art was mainly abstract and repetitive. Burial rites were also distinctive, taking the form of interment in cemeteries, the body fully clothed and in an extended position.

The Bronze Age (c. 2500–c. 650 BC). While the peasants who pioneered farming economy in remote territories of the temperate zone were restricted to stone, metallurgy was already being practiced in parts of southeastern Europe and Iberia. The smelting of metallic copper from its ores was in itself a remarkable feat in the history of technology; it marked the first of what was to prove a long series of operations by which men were able to conjure up new materials, and it is worth emphasizing that to obtain ore, smelt it, and convert it into artifacts implied a more advanced degree of specialization of labour than was needed for a technology based on working flint or stone. It is no accident that in the Old World metallurgy should have been one of the features persistently found in the context of the earliest literate civilizations. Indeed, it has commonly been assumed that the appearance of metallurgy in prehistoric barbarian societies can only be explained in terms of their contacts with early centres of civilization. In the case of southern Iberia, eastern Mediterranean and specifically Cycladic (south Aegean) influence has been detected at copper-working settlements dating from the mid-3rd millennium; the defenses of Los Millares, for instance, display bastions identical in pattern with those of Chalandriani on Syros (Greece). Here it looks as though there were "factories" established for the prime purpose of securing supplies of copper for Aegean markets. The initial impetus for opening up the copper resources of Transylvania may also have come from the demands of Aegean and possibly even Asiatic markets. It is no less true that the exploitation of copper ores in southeastern and central Europe underwent its own development. Whereas in Iberia the initial impetus was soon lost, the opening up of ores in Transylvania led to the development of cuprous industries, first in Bohemia, central Germany, and the east Alps, and ultimately as far away as Ireland, where copper deposits were first sought out by the Bell-Beaker prospectors at about the end of the 2nd millennium. These copper resources catered wholly or in large measure to barbarian markets. Thus shafthole axes and ax-adzes of Transylvanian copper are found predominantly in Transylvania and the Danubian basin both above and below the Iron Gate, though a few reached the Elbe basin; spiral armbands and embossed disks reached as far north as Denmark, where they occur at the end of the local Early Neolithic. Again, flat axes of trapezoidal plan of the form made from east Alpine and central German copper found their way as far north as Scania (Scandinavia).

The beginnings of European metallurgy

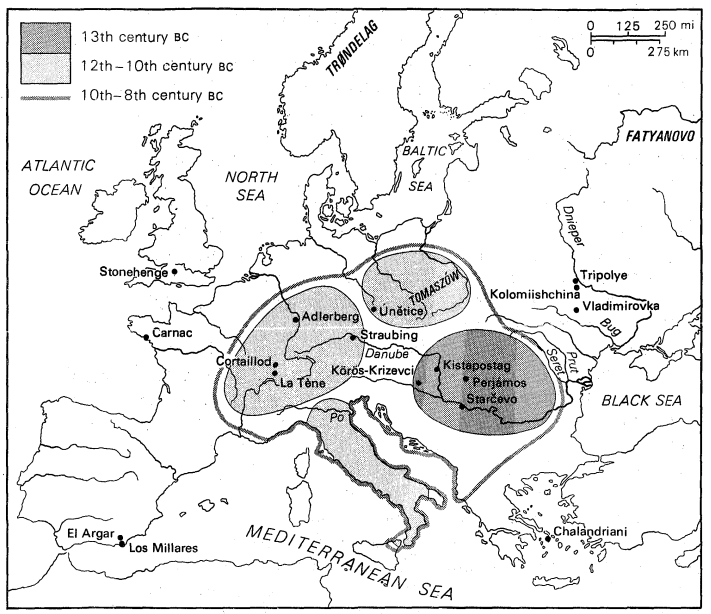
Central Europe was also the original focus of the local use of bronze alloys that not only resulted in tougher tools, but, by making it easier to use valve molds, made it possible to produce more complex forms. The new industries—those of Únětice on the Upper Elbe, of Tomaszów in Poland, of Kistapostag and Perjámos in Hungary, of Straubing on the Upper Danube, and of Adlerberg on the Middle Rhine—produced a variety of bronze items, including daggers, neck ornaments, and pins for securing garments. The occurrence of similar ornaments at Byblos in Lebanon and Ugarit in Syria dating from *c.* 2000–1800 BC suggests continued contact between middle Europe and areas of higher culture to the southeast, but this does not mean that one must attribute the advanced bronze industries of middle Europe around the middle of the 2nd millennium to stimulus from this direction. The Únětice and allied metal industries rested on a middle European tradition already many hundreds of years old. Again, regional bronze-working traditions were developing at this time in many parts of Europe as far apart as Spain, where metallurgy revived in the El Argar culture, and Britain and Ireland, which gave birth to a distinctive Hiberno-British style.

The earliest bronze industries

The use of tin as an alloy laid a great emphasis on organized systems of exchange, since this metal was one with a more restricted distribution than copper. These involved the movement not only of ingots but of finished artifacts, as may be seen in the importation of Hiberno-British and middle European forms of ax to Denmark during the final phase of its Stone Age, a period significantly marked above all by flint daggers based ultimately on metal ones too expensive to import in adequate numbers. It is interesting to note how the Aegean and by this time the specifically Mycenaean world became enmeshed in this wide-ranging system of exchange, due in all probability to their need for central European or Cornish tin. The occurrence of segmented faience beads, of a kind invented in Egypt but probably made also in the Aegean, in the territory of the Únětice and allied cultures, and also notably in Wessex, a territory that probably controlled supplies of Cornish tin, is suggestive of Mediterranean influence in the north. But the importance of the Mycenaeans in the European Bronze Age should not be overemphasized. The indirect effects of the play of the Mycenaean market may have been important —for instance, the Mycenaean demand for amber probably played its part in the rise of the Nordic Bronze Age by making it possible for the Danes to import central European bronzes and ingots—but metalsmiths in several parts of barbarian Europe were producing bronzes that compare favourably with anything produced in the Aegean at the time; and faience beads of local shapes were produced even in northern Britain.

The loss of Mycenaean markets was no longer enough to affect the prosperity of central Europe. Copper was mined on an increasing scale and, being cheaper, was used for tools, armour, and containers, as well as for weapons and ornaments. The later stages of the Bronze Age also were marked by a greater emphasis on cremation and the burial of ashes in urns. Urnfield burial, together with many innovations in industry and armament, was adopted over extensive tracts of Europe from Iberia to eastern Europe and from Italy to south Scandinavia. How much this was due to the normal process

Urnfield cultures



The expansion of Urnfield cultures in Europe.

of diffusion by which innovations spread over extensive territories in the course of time, and how much to ethnic movement, is still obscure. Yet it is hard not to believe that raids by armed marauders did not play a part more especially in relation to the rich territories of the Mycenaean world. Already in the 15th century BC heavy slashing swords, with flanged grips to secure the handle, were being made in east central Europe, and such swords were among the innovations that spread widely with the adoption of urnfield burial. The sudden appearance of these in mainland Greece, Crete, and Cyprus has been identified by some scholars with intrusion of the Dorians mentioned by Thucydides as entering the Peloponnesus at a time when archaeology speaks of the destruction of Mycenaean civilization. Egyptian records tell of raiders from the north as early as the 13th century BC and, in the ensuing centuries, the east Mediterranean region as a whole underwent a time of troubles, a period that witnessed the decline not only of the Mycenaean but also of the Hittite power. Other peoples were on the move at this time and may well have been more important, but it looks as though pressure may have come in part from the north.

The Iron Age in barbarian Europe (c. 650 BC–1st century AD). The main reason why the working of iron was to prove so important is that the ores were widespread and their smelting made it possible for the first time to produce cheap implements in a quantity sufficient to transform technology. Meteoric iron had been utilized from antiquity, but only rarely. Traditionally iron ores were first worked in northern Anatolia, and the Hittites owed some of their military power to their lead in using iron weapons. Conversely, the breakdown of Hittite power early in the 12th century BC allowed ironworking to spread. The first Europeans to practice it were the Greeks; and Greek colonists during the 8th and 7th centuries carried the craft with them both to the Black Sea, on the northern shores of which they established close relations with the Scyths (Scythians), and to much of the European shore of the Mediterranean. Ironworking was brought to east Sicily and Italy as far as Neapolis (Naples) by Greeks, and farther north was adopted by the Etruscans. In the west Mediterranean the Greeks founded Massilia, predecessor of Marseille, around 600 BC and by *c.* 550 BC had established the colony of Emporium on the Catalan coast. Other parts of Mediterranean Europe, notably Sardinia and southern Iberia, were colonized by Phoenicians, who likewise brought ironworking with them.

North of the Alps, ironworking first appeared around the middle of the 7th century BC in the Hallstatt culture centred in Austria, Bohemia, and Bavaria. Thanks largely to a change in burial rites from cremation in urnfields to inhumation in wooden chambers under barrows, a much fuller picture is available at least of the leading members of Hallstatt society. Its warrior chieftains were helmeted and armoured in bronze with breastplates and greaves and were armed with long swords of iron or bronze. In war they were mounted on horses, and in death they were borne to the grave on richly decorated funeral carts mounted on two pairs of spoked wheels. This evidence for armed mobility, with its counterpart of strongly defended hill forts and marsh fortresses, suggests that armed raids, accompanied in some cases by folk movements, may well have played some part in the rapid diffusion of Hallstatt fashions over the territories of the old Urnfield culture, down the Rhine to the Low countries, across France to central Iberia in the west, and in central Europe over the extensive territories from southern Poland to far down the coast of the Adriatic. The Hallstatt culture

The La Tène culture. The later stages of the Iron Age in barbarian Europe were marked above all by the style that takes its name from the Swiss site of La Tène and that first arose between the Upper Danube and the Marne during the 5th century BC. It is hardly possible to explain how the geometric heritage of Hallstatt was transmitted into the brilliant new art of La Tène; nevertheless, certain influences can be recognized. The fantastic treatment of animals and parts of animals could well have been inspired by contacts with the Scyths to the east. Even more important was the impact of Greek art, which influenced both naturalistic representation and the use of designs such as the palmette and tendril. Contact with the Italo-Greek world is indicated by a trail of bronze vessels on the main routes through the Alps; and this can only have been intensified by the Celtic conquest of the Po basin in the 4th century. One outcome was the adoption by the Celts of the two-wheeled horse-drawn chariot.

Celtic art comprised monumental stone figures of men or their heads; coinage; and decorative metalwork related to the warrior class and their women. The last included such things as jewelry, mirrors, armament, and equipment for horses and chariots. Many styles have been recognized. Whereas the Early style still showed strong Greek and Oriental features and was relatively more naturalistic and symmetrical than later Celtic art, the Waldalgesheim style that first appeared around the middle of the 4th century was flowing, nonrepresentational, and asymmetrical. The Plastic style that came in at the beginning of the 3rd century preserved links with both the earlier styles, but laid a significant emphasis on three-dimensional effects. In opposition to this, the Sword style that began at the end of the century relied on flat linear designs. Echoes of continental styles can be detected in Britain, but objects produced there are nevertheless quite distinctive; and since Britain remained outside the Roman Empire until the middle of the 1st century AD, the linear style underwent a prolonged development, particularly well displayed in the engraved bronze mirrors and scabbards. The Celts

The expansion of the Roman Empire over almost the whole of the Celtic-speaking world, apart from northernmost Britain and Ireland, necessarily involved a drastic contraction in the sphere of La Tène culture. The only parts of barbarian Europe to flourish unaffected either by the standardized production of material goods or by the substitution of alien bureaucrats for native heroic chiefs were the extensive tracts to the north and east inhabited by the Teutonic and Slav peoples. These territories, over which ironworking had been practiced for some centuries—in Denmark since *c.* 400 BC—were not of course isolated from what went on in the empire. Mercenaries returning from service must have brought ideas home, and Roman products were imported as far north as Trøndelag (Norway) and Gotland. Yet the importance of the Teutonic and Slav peoples is precisely Romanization and barbarian Europe

that they retained their native vigour and had something positive to contribute to the building of medieval Europe.

European Atlantic Coast, Folk Cultures of the

The European Atlantic coast, defined as a cultural area rather than in strictly geographical terms, stretches from the far north of Norway to the west coast of the Iberian Peninsula and includes the Baltic coast areas of Scandinavia, as well as the British Isles. Characterizing this Atlantic fringe of Europe is both the fact and the sense of regionalism, a peculiar fusion of culture and geography backed by an ancient and stubborn ethnicity. The peoples of the area have persistently remained culturally conservative, although they have frequently been forced to switch political allegiance.

PEOPLES AND LANGUAGES

Although they are superficially linked by a common European tradition, these northern and western peripheral areas are the home of diverse peoples of different ethnic stocks and languages. Although the term race has dubious utility for marking off distinctive biological characteristics, most of these coastal peoples have usually been classified, like other Europeans, under the general and geographic racial group Mediterranean, the oldest of the primary Caucasoid races and the one that dominated Europe, North Africa, and the Near East at least from Neolithic times. In the past, scholars also used additional subdivisional terms, such as Nordic, Germanic (or Teutonic), and Alpine (Celtic). But ethnic mixing through migration and intermarriage proceeded on a grand scale for millennia, and regional types blended with the predominant Mediterranean, especially after the extension of ancient Roman influence throughout Europe. Nevertheless, many of these coastal folk cultures successfully resisted complete domination by Rome and thus preserved much of their ethnic and cultural identity. Population geneticists classify peoples in terms of blood-group frequencies; anthropologists use the term "local race." The O-type blood group, for example, is particularly frequent among the Basques, the Irish, the Scots, and the Icelandic peoples. Sometimes, these local races have segments known as isolates, with extremely high endogamy, or inbreeding. Such groups may be called microraces. The Lapps of southern Scandinavia provide a good example of a microrace: low of stature and sallow-skinned, the Lapps's physical characteristics are in marked contrast to their immediate neighbours, the tall, light-skinned, blond Nordic stereotype (*e.g.*, Scandinavians or Celtic-speaking Scots), with gray or blue eyes.

Persistence of local races based on breeding populations

Languages spoken in the Atlantic coastal fringe area are nearly all subfamilies of the Indo-European group—Celtic, Germanic, Baltic, and Romance.

The only modern Celtic language of the Continent, Breton, was taken to Brittany by 5th-century-AD Cornish colonists and refugees from Britain; its closest existing relative is Welsh. There are many descendants of Celtic peoples in Europe who no longer speak Celtic tongues. Continental Celtic or Gaulish languages were once spoken widely in France, in the Iberian Peninsula, throughout central Europe, and into Galatia (Anatolia), but they succumbed well before the Middle Ages to Germanic, Slavic, and Romanic languages. Celtic is divided into the Brythonic (Cymric) branch (Welsh, Breton, and Cornish, the latter extinct since 1777 despite spasmodic attempts to revive it) and the Goidelic (Gaelic) branch (Irish, Scottish, and Manx, the latter virtually extinct).

The Germanic languages of the coastal areas include the Icelandic, Faeroese (in the Faeroe Isles), Norwegian, Danish, and Swedish tongues, in the north, and Dutch, Flemish (in Belgium and northern France), Frisian (closely related to English and spoken in the Dutch province of Friesland), English, and Low German, in the west. The Baltic subfamily includes Latvian, Lithuanian, and Old Prussian (extinct since the 18th century). The Romance (Italic) subfamily includes French (under which is included Walloon, spoken in south Belgium and neighbouring French regions), Provençal, Castilian Spanish, Portuguese, and Galician (spoken in northwest Spain).

Lappish, Estonian, and Finnish properly belong to a separate language family, Finno-Ugric. Basque, which is spoken on both sides of the Pyrenees—in France and in Spain—also defies classification and is not usually included in the Indo-European language family. Also found are vernaculars, or pidgins, which are not true languages since they are derivations from two or more parent tongues. An example is Russenorsk (from Russian and Norwegian), used by Norwegian fishermen with Russian traders.

TRADITIONAL CULTURAL PATTERNS

The diverse peoples occupying this area may be delimited and described in terms of "culture clusters"—regional complexes of cultural traditions that are geographically localized and of long duration.

A main culture cluster is located primarily around the North Sea and also around the Baltic Sea—regions that have frequently attracted peoples from the north European floodplains. This region includes Scandinavia, the Low Countries, and the British Isles. Iceland, settled by Norsemen since the 9th century, is generally included in any survey of the area, whereas Greenland, with its resident Eskimo population and relatively recent Danish colony, is not. At the northern edge, delimited by the Barents Sea, European and Circumpolar peoples (Ostyaks, Samoyeds, Lapps) interpenetrate.

Western France, a peripheral zone of composite character where various cultures have blended, forms a second culture cluster. A zone transitional to the Mediterranean and Alpine areas, it is aptly termed the isthmus of Europe. Linguists distinguish the north of France from the southwestern region, which is associated with the Catalonian fringe.

The Pyrenees form the northern limit of a third culture cluster located in the north and west of the Iberian Peninsula and including the Basques, Portuguese, Asturians, and the Galicians. The Basques are uniquely different from everybody, and Galicia, in northwest Spain, is much closer culturally to northern Portugal than to Castilian Madrid.

Patterns of settlement and economic organization. *Peasants and farmers.* The rural settlement pattern of the Atlantic fringe area has always been notable for its single-family farms in dispersed neighbourhoods or hamlets (*tun* in Norway, *clachan* in Scotland, *bally* in Ireland, and *minifundio* in Galicia). Hayfields and grazing, grain, and kitchen gardens in meadowlands are the predominant forms of land use. Male crofters, or small farmers, tend the cattle, with no pooling of herds and flocks.

Settlement patterns are influenced by a variety of factors, such as ethnic tradition, economic necessity, security, shifting agriculture, specialized cultivation, and fishing. Concentrated settlement is found more among Germanic peoples, and dispersed settlements are common among the Celts; but contrary examples are found. Be-

fore the construction of dikes, settlement sites may have been elevated and agglomerated, becoming dispersed later when tides and floods were controlled. Dependency on the sea and the need sometimes to protect oneself from it are evident in the agglomeration in Norwegian fishing villages and in the dike villages of Holland. No doubt, too, fear of the Norse sea rover drove plainsmen in the coastal areas to the more mountainous regions. Dispersion seems to increase as the land rises and the surface becomes more rugged and broken. There is certainly not the close relationship between water resources and concentration of settlement that occurs in the Mediterranean.

Main agricultural areas

Mixed farming or commercial livestock farming and cereal crop farming extend in a broad belt across the north of Spain, south and middle France, and well into eastern Europe. Subsistence crop and stock farming with little or no surplus and a dependence on rye, maize, potatoes, and barley is restricted, by and large, to the marginal highland areas in Scotland, Wales, and parts of Norway. Commercial dairy farming, which is profitable only in proximity to a large urban market, is found in most of the English Channel and North Sea coastal area —Brittany, Normandy, the Low Countries, northeastern Germany, Denmark, south Sweden, and England.

Holland—with its mixed-farming villages closely related to the topography and nature of the soil, strip villages with farms along a road, peat colonies, and market towns —is characterized by wide agricultural diversity. In the Spanish Basque provinces there is pastoralism in the higher mountains, peasant small holdings in the hills of the northern regions, large agricultural estates in the flat, arid plains of the southern areas, and a fishing and merchant-marine economy on the seacoast. On the ragged coastlines of Scandinavia, the British Isles, Brittany, northern Spain, and Portugal, there is a local dependence on small-scale agriculture supplemented with fishing and pastoralism and perhaps typified by summer pasturing of livestock in the hills.

These forms of economy and the cultural patterns that go with them establish cultural boundaries that are not mutually exclusive or strictly delimited by area; rather, they shade by degrees into each other. Within them there are sub-areal specializations such as that of the wine-growing area of the eastern Paris basin—one of the most ancient districts of specialized horticulture—and the cider-apple belt of Brittany, Normandy, and Devon (England) farther north.

With few exceptions (Belgium, Holland, the Channel Islands, and the Spanish Basque coast, for example), there is a remarkably low population density. Norway, with only 4 percent of its area under cultivation, has the lowest average density (31 persons per square mile in 1970) of any continental European country. Other Scandinavian countries also have low densities because of the high proportion of tundra, waste, lakes, and forests. Where climates and soils are more benign and productive, as in the south and southeast, the people settle thickly. By contrast, some provinces in south Holland have as many as 2,500 persons per square mile (1,000 persons per square kilometre).

Landholdings are small and generally fragmented. Farms in western or southern Ireland may be up to 50 acres (20 hectares) but are usually less than 30 acres, especially in the more remote regions. In the northeast province of Trás-os-Montes, Portugal, or the coastal province of Beira Litoral or scattered and isolated among the mountainous and heath-covered districts of Galicia, Spain, the majority of small farmers cultivate less than 2.5 acres each. Production is low and necessarily wasteful of human energy when only an elementary plow or hoe is used and when much time must be spent going from one small fragmented parcel of land to another.

Land tenure

Land-tenure systems vary. The family-community system, in which the property belongs to the family and the family head chooses his successor, is common in Ireland and to the whole Pyrenean region, though this is customary rather than national law. So, too, is share-tenancy (métayage in Brittany; *aparcería* in northern Spain), by which rent is paid by a share of crops, livestock, or cash. Particular forms of tenancy shade into near-proprietorship and have been the subject of bitter divisions, as, for example, in Galicia. Conflicts generated by the landholding system in Galicia were accompanied by large-scale emigration, debt servitude, and local political bossism (*caciquismo*) until well into the 20th century.

Cooperative work groups are not uncommon, whether, in the past, for road maintenance in Denmark by corvées, for peat cutting in Ireland, for slash-and-burn preparation of the ground for planting (*roza ambulante*) in Galicia, or, in contemporary Ireland, for building a haystack (*meitheal*). Communal or collectivist ownership of resources among agriculturists, shepherds, and fishermen were once found in a great many small towns or villages in northern Spain and the Pyrenees.

The peasant, conceptualized as an ideal type, is locally bound to his subsistence economy, whereas the farmer is ideally conceptualized as a producer for commercial agriculture and the larger world. While both peasants and farmers produce a variety of crops and livestock, it is peasant culture that gives a local stamp to these goods. Since the processing is done locally, products vary in flavour or design according to the locality. Hence, distinctive cheeses, wines, confections, clothes, and handicrafts distinguish one traditional area from another. Some of these, caught up by national or international markets, have become famous beyond the locality. Examples are Mechlin lacework from Mechelen (Malines), Belgium; the knitted jersey from the Channel Island of Jersey; or champagne from the former province of Champagne in northeast France; however, only in remote communities has the local craftsman, or artisan, resisted the competition of the urban factory. More often than not, he is a landless man with little but a garden patch. Indispensable though his services may be, they do not give him equality with his peasant-proprietor neighbours.

Pastoralists. Nor is the social standing of the shepherd and pastoralist high when this is his full-time occupation. True nomadism, in which whole families or communities accompany their herds in seasonal movements between grazing areas, exists only among a declining number of Lapps, among whom herding is a collective undertaking. Their Swedish, Norwegian, and Finnish neighbours tend to look down on them as inferior and uncivilized. Transhumance, in which only those needed to herd the livestock move, is common in Scandinavia and northern Spain, especially in the rainy mountainous areas, such as Galicia and Oviedo. There—known and regarded as a distinctive social, if not ethnic, group—the *vaqueiros de alzada* move from their winter quarters on the seacoast to their summer pastures in the high Cordillera Cantábrica and the Pyrenees. Also semi-nomadic are small bands of Gypsies, who can still be found in most European countries in occupations related to horses and smithing; the tinkers in Ireland, peripatetic salesmen and minor craftsmen, are notoriously distrusted by the settled populace.

Fishermen. Sea fishing has been an integral part of the coastal folk way of life since Neolithic times. Local patois in Normandy and the Channel Islands both abound with old Norse terms related to ships and the sea. Nearly 20 percent of all Norwegians take to the sea in one form or another of merchant craft, their fleets of small boats plying inshore fishing grounds for sardines, in contrast to the deep-sea, distant-water trawlers of the British fishermen seeking cod. Many coastal Lapps are settled now as fisherfolk. The only Gypsies, who traditionally abhor the sea, known to have become sailors were 40 families living among the French Basques in the area of Saint-Jean-de-Luz. Longboat regattas are the only vestiges of a whaling culture in northern coastal towns of Spain, where fishing as a local industry has been closely regulated for centuries. Until dissolved by royal order in 1865, for example, the Cantabrian coastal brotherhood (*cofradía* or *gremio*) of San Martín de Hijosdalgo, in Laredo, Santander, controlled and apportioned fishing grounds, especially for bream, by lot. Fishing can be a cooperative enterprise requiring large numbers of men (and women, for net

mending), and elaborate rules still exist for regulating disputes. Especially in smaller villages but even in the larger ports, local traditional lore still sets formulas for sharecropping of the catch, which is usually auctioned at the wharfside. Yokes of oxen may even now be seen dragging enormous pocket seines to the beach at Finisterre and other ports in the Galician fjords.

Social organization. Atlantic coastal folk did not usually fall under the sway of feudal lords or great princes as serfs or villeins, for the power of feudal lords did not reach effectively into the mountains, forests, or fenny marshlands where the peasantry more freely practiced their autonomous forms of social control and organization based on a local rather than a "national" stratification of society. Absentee landlord systems in these marginal areas permitted tenants to maintain a cultural isolation; at most, a local political bossism affected them in times of crisis, rather than with calendrical regularity.

Kinship patterns

Local endogamy reinforced a bilateral (patrilineal and matrilineal) family system (possibly patrilineal in old Ireland) and ensured that most members of a small community were related in some way. The small, or stem, family from which branches broke away was the norm. A group of kindred was the repository for land property ownership and the unit of cooperative action, especially in the case of factional dispute with another locality. But control of land and capital was invested in the male family head, not in any lord of a manor. Sons often remained throughout their youth and into middle age as unmarried labourers on the family farm, until the family head chose their successors. Late and uncertain marriage was a condition of this arrangement, which, in both Ireland and Norway, is known as a marriage-succession system.

Isolated coastal folk generally had few links with their more stratified neighbours in larger villages or towns. Nonpeasant itinerants, such as entertainers, salesmen, bards, and the like, were the most important agents for the transmission to isolated coastal villages of beliefs, proverbs, ballads, and news.

Religion. Local traditions of cult practice and belief have persisted despite the national or international impact of organized religion, for local gods proved difficult to supplant. Scandinavian mythology is full of culture heroes immortalized in sagas or heroic poetry (*Eddas*) and exalted to divine rank. This polytheism, or veneration of many deities, gave a local quality to worship, for the gods were regional champions. Associated beliefs and practices relating holy wells or medicinal springs, megaliths, sacred trees or groves, sacrifices, divination by oracle (consulting the waters), burials, and pilgrimages were common, as were fairy and witch cults, the laying of curses, and spiritual punishment for polluting the wells.

Local religious traditions were to some extent linked with Christianity through the cult of early Christian saints. Before the Reformation, pilgrimages to holy wells (and devotional exercises there) were undertaken by the highest in the land, and, despite insistent attack since the Reformation, such local cults have persisted into the 20th century in one form or another. Pilgrims streamed to Santiago de Compostela, in northwestern Spain, throughout the Middle Ages after the 9th-century discovery there of the St. James' tomb. Fátima in Portugal and Lourdes in France are more modern pilgrimage sites. Watering places, or spas, are simply examples of a laicized tradition. The tossing of coins or pins into a "wishing well" may be compared to the prehistoric votive offerings of bronze at medicinal springs (in Denmark) and is an example of a superstitious practice supplanting a religious one. The patron-saint complex is still very much alive among Catholic folk, and pastors and priests in Protestant and Catholic areas alike are still called upon to serve a spiritual need in local agricultural and pastoral activities, as, for example, in the blessing of crops or animals on selected festival dates.

MODERNIZATION

The move from a medieval localism to a centralism personified by a temporal sovereign substituted the lord–follower relationship, by which Atlantic coastal folk were rarely affected, for a king–subject relationship, which affected them increasingly. The sense of nationalism that developed in Europe from the 16th century on was based on a common language, common religion, and patriotic military service, which tended to submerge the cultural distinctiveness of the coastal areas. But, if, at times, the isolation of folk cultures was broken by this new cultural system, the limited contact that ensued did not result in acculturation or complete integration. Political wars between European nations and overseas expansion, in fact, drew attention away from these marginal areas.

Regionalism, in the sense of mere physical isolation, was not completely broken down in many folk communities until the 19th century. Begun by an economic process and increased communications, it is now being completed by tourism. "Park-keeper peasants" is an ironic term applied to those living in areas that governments are developing for tourism rather than for industrial or agricultural growth. In general, the important changes can be described in terms of an opening up of local economies to national markets. This involves a shift from either mixed farming to market gardening or from subsistence farming to commercial agriculture and other forms of enterprise.

The linking of Brittany by a new railway to Paris in 1880 greatly accelerated cash cropping and the growth of canneries. It also led to larger fishing fleets; today, in all major ports along the Atlantic coast, corporations rather than individuals provide vessels, equipment, hire fishermen at fixed wages, and generally govern the industry. One Lapp herdsman on a snowmobile and with a walkie-talkie radio can now do more than ten herdsmen did in bygone years. Those who are thus freed from traditional tasks are not all re-employed in the mining, railway, or hydroelectric projects that are invading previously pastoral retreats.

The mobility—physical and social—of coastal folk has dramatically increased, and there has been much emigration abroad, especially to the United States, and, internally, to the cities, a phenomenon that has not ceased.

Politicized cultural movements of the later 20th century

Political representatives of many European folk minorities see their people as victims both of dominance and neglect by central governments. There have been repeated demands from these minorities for sovereignty over their own political affairs, as in Wales, or militant movements in favour of separate nationhood, as among Basques, Bretons, and Galicians; and, under the banner of the Celtic cross, Bretons and Welshmen have combined in a Pan-Celtic movement to fight to maintain their cultural heritage. Separatist-movement leaders are generally urban based but have recourse to a rural folk symbolism already propagated by intellectuals in cultural movements. A doggedly persistent cultural consciousness has thus been given new political expression in recent years.

ANDERSON, *Traditional Europe: A Study in Anthropology and History* (1971), deals with Europe in general up to 1800; his *Modern Europe* (1972), synthesizes the period from 1800 to the present day, delineating trends of culture change. JOHN GEIPEL, *The Europeans* (1969), covers origins, interrelations, and languages and explodes racial myths. WILLIAM Z. RIPLEY, *The Races of Europe* (1899), persisted as the classic authority for racial classification until superseded by population geneticists, such as W.C. BOYD, *Genetics and the Races of Man* (1950). STUART PIGGOTT, *Ancient Europe from the Beginnings of Agriculture to Classical Antiquity* (1965), covers the interrelations of literate innovating cultures and nonliterate conservative cultures. V. GORDON CHILDE, *Prehistoric Migrations in Europe* (1950), presents the diffusionist view of culture change but makes minimal use of the migrationist hypothesis. R.W. EHRICH, "On the Persistences and Recurrences of Culture Areas and Culture Boundaries During the Course of European Prehistory, Protohistory, and History," in *Bericht über den V. Internationalen Kongress für Vor- und Frühgeschichte, Hamburg 1958*, item 77, pp. 253–257 (1961), provides a dynamic view of the culture area approach that is discussed

as part of a more detailed subareal coverage by MICHAEL KENNY and CONRAD ARENSBERG *et al.*, "Europe and Its Cultures," *Anthrop. Q.*, vol. 36, no. 3 (1963). The evolution and interrelation of different types of economy and settlement may be found in HERBERT J. FLEURE, "Social Organisation and Environment," in PHILIP L. WAGNER and MARVIN W. MIKESELL (eds.), *Readings in Cultural Geography*, pp. 491–505 (1962), and his and others' articles in *Jl. R. Anthrop. Inst.* (1916, 1920, 1936, 1958); and DERWENT S. WHITTLESEY, "Major Agricultural Regions of the Earth," *Ann. Ass. Am. Geogr.*, 26: 199–240 (1936). Useful, more localized, sources are GERALD BRENAN, *The Spanish Labyrinth* (1960); T. LYNN SMITH, "The Social Relationships of Man to the Land in Portugal," *Sociologia*, 25:319–343 (1963); CONRAD M. ARENSBERG, *The Irish Countryman* (1937, reprinted 1968); RONALD FRANKENBERG, *Communities in Britain* (1966); ROBERT T. and BARBARA G. ANDERSON, *The Vanishing Village* (1964), on Denmark; GORDON WRIGHT, *Rural Revolution in France* (1964); and WILLIAM A. DOUGLASS, *Death in Murélaga* (1969), on a Basque village. Detailed discussions of local and regional phenomena are found in FRANCIS JONES, *The Holy Wells of Wales* (1954); and J.A. MACCULLOCH, *The Celtic and Scandinavian Religions* (1948). The blurring of the rural–urban distinction and the growth of a predominantly middle-class society is examined in ROBERT T. ANDERSON (*op. cit.*); see also S.H. FRANKLIN, *The European Peasantry: The Final Phase* (1969); and for contrast JOHN J. HONIGMANN (ed.), "Modernization and Tradition in Central European Rural Cultures," *Anthropologica*, vol. 12, no. 1 (1970). The political cost of integration is lucidly presented by ORIOL PI-SUNYER (ed.), *The Limits of Integration: Ethnicity and Nationalism in Modern Europe* (1971).

(M.Ky.)

European Culture Since 1800

In the cultural history of the 19th and 20th centuries, the first notable fact is the continuous presence of two great sources of energy: one, the French Revolution with its sequel, the Napoleonic saga; the other, the Romantic movement, whose origins lay in the human tendencies that the preceding Enlightenment had tended to ignore. Thanks to the momentum of these two forces, what happens in European culture during the years following 1789 is an unfolding rather than a series of clashes and reactions. The continuity and kinship between the numerous schools of art and thought exist despite evidences of opposition, and they are particularly evident in the realm of artistic techniques. Nor does this connectedness contradict the actual conflicts—often violent—between the moods of the successive generations and between the aims they verbalized while producing the works now classified under the various labels of Romanticism, Realism, Pre-Raphaelitism, Symbolism, Naturalism, Impressionism, Neoclassicism, and Modernism.

This article is divided into the following sections:

Romanticism, reaction, and revolution (early 19th century)
- The legacy of the French Revolution
- General character of the Romantic movement
- Romanticism in literature and the arts
- Social and political thought
- Philosophy
- Religion and its alternatives

The middle and late 19th century
- Realism and *Realpolitik* in midcentury
- Realism in the arts and philosophy
- Late-century decadence and doubt

Alienation and despair (20th century)
- Attempts at improvement
- The prewar period
- The impact of war
- Culture since 1920

ROMANTICISM, REACTION, AND REVOLUTION (EARLY 19TH CENTURY)

The legacy of the French Revolution. To make the story start in the year of the French Revolution is at once convenient and accurate, even though nothing in history "starts" at a precise moment. For although the Revolution itself had its beginnings in ideas and conditions preceding that date, it is clear that the events of 1789 brought together and crystallized a multitude of hopes, fears, and desires into something visible, potent, and irreversible. To say that in 1789 reform becomes revolt is to record a positive change, a genuine starting point. One who lived through the change, Liancourt, was even sharper in his vision when (as the story goes) he answered Louis XVI, who had asked whether the tumult outside was a revolt: "No, sire, it is a revolution." In cultural history as in political, significance is properly said to reside in events; that is, in the acts of certain men or the appearance of certain works that not only embody the feelings of the hour but also prevent other acts or works from having importance or effect. To take an example from English poetry, after Wordsworth and Coleridge's *Lyrical Ballads*, which appeared in 1798 and remained a long while obscure, the writing of heroic couplets in the 18th-century manner could be but a pastime—not poetry, as it had once been. A good many such "punctuation marks" can be noted in the text of cultural activity and in its context of political and social life.

To say, then, that the cultural history of the later modern age—1789 to the present—begins with the French Revolution is to discuss that Revolution's ideas rather than the details of its onward march during its first 10 years. These ideas are: the recognition of individual rights, the sovereignty of the people, and the universal applicability of this pair of propositions. In politics the powerful combination of all three brings about a permanent state of affairs: "the revolution" as defined here has not yet stopped. It continues to move the minds of men, in the West and beyond. The revolution is "dynamic" because it does not simply change rulers or codes of law but it also arouses a demand and a hope in every man and every people. When the daily paper tells of another new nation born by breaking away, violently or not, from some other group, the Revolutionary doctrine of the sovereignty of the people may be observed still at work after two centuries.

The ideas of the French Revolution

Cultural nationalism. The counterpart of this political idea in the 19th century is cultural nationalism. The phrase denotes the belief that each nation in Europe had from its earliest formation developed a culture of its own, with features as unique as its language, even though its language and culture might have near relatives over the frontier. Europe was thus seen as a bouquet of diverse flowers harmoniously bunched, rather than as a uniform civilization stretching from Paris to St. Petersburg, from London to Rome, and from Berlin to Lisbon—wherever "polite society" could be found, a society acknowledging the same artistic ideals and speaking French. In still other words, the Revolutionary idea of the people as the source of power ended the idea of a cosmopolitan Europe.

The "uniform" conception presupposed a class or elite transcending boundaries; the "diverse" implied a nation of citizens attached to their native soil and having an inborn and exclusive understanding of all that had been produced on it. In each nation it is the people as a whole, not just the educated class, that is deemed the creator and repository of culture; and that culture is not a conscious product fashioned by the court artists of the moment: it is the slow growth of centuries. Thus can be seen one of the motives of the post-Revolutionary passion for historical studies—the change to cultural populism as the replacement of a single horizontal, Europe-wide, and "sophisticated" culture by a series of vertical, national cultures, popular not only in their generality but also in their simplicity.

This new outlook, though propagated by the Revolution, began as one of those subdued feelings mentioned earlier, as undercurrents beneath Enlightenment doctrine. In England and Germany especially, a taste developed for folk literature—the border ballads, the legends and love songs of the people, their dialects and superstitions. Educated gentlemen collected and published these materials; poets and storytellers imitated them. Horace Walpole in *The Castle of Otranto*, Macpherson in *Ossian*, Chatterton in his forgeries of early verse, and Goethe in his lyrics exploited this new vein of picturesque sentiment. A scholar such as Herder or a poet-dramatist such as Schiller drew lessons of moral, psychological, and philosophical import from the wisdom found in the subculture of *das Volk*. The folk or people was not as yet very clearly defined, but the Revolution would shortly take care of this omission.

Beginnings of cultural nationalism

In France, where the Revolution occurred, the situation was somewhat different. There were no collectors of border ballads or exploiters of Gothic superstitions. France by 1789 had been for more than a century the cultural dictator of Europe, and it is clear that in England and Germany the search for native sources of art was stimulated by the desire to break the tyranny of the French language and literature. The rediscovery of Shakespeare, for example, was in part a move in the liberation from French classical tragedy.

Simplicity and truth. But it was also the expression of a genuine desire for simplicity and truth and for the release of feelings that the confidence of the Enlightenment in the power of reason had tended to suppress. Two 18th-century figures tapped this fount of emotion, Richardson and Rousseau. The novels of Richardson, in which innocent girls are portrayed as withstanding the artful seductions of titled gentlemen, might be said to foreshadow in symbolic form the struggle between high cosmopolitan culture and the new popular simplicity. These novels were best sellers in France, and Rousseau's *Nouvelle Héloïse* followed in their wake, as did the bourgeois dramas of Diderot, Beaumarchais's satirical comedies about the plebeian Figaro, and the peasant narratives of Restif de la Bretonne, to mention only the most striking exemplars of the new simplicity.

At the very centre of sophistication the simple life became a fad, the French court (including Marie-Antoinette) dressing up and playing at the rustic existence of milkmaids and shepherds. However silly the symptoms, the underlying passion was real. It was the periodic urge of complex civilizations to strip off the social mask and recover the happiness imagined as still dwelling among the humble. What was held up to admiration was honesty and sincerity, the strong and pure feelings of people unspoiled by city and court life. Literature therefore came to express an acute sensitivity to scenes of undeserved misfortune, of heroic self-sacrifice, of virtue unexpectedly rewarded—a sensitivity marked by tearfulness, actual or "literary."

Back-to-nature movement

This surge of self-consciousness about sophisticated culture has often been confused with an idealization of primitive man and attributed to Rousseau. But contrary to common opinion, the so-called back-to-nature movement does not at all echo the noble-savage doctrine of the 17th century. Rousseau's attack on "civilization," which evoked such a powerful response in the latent feelings of his contemporaries, goes with a characterization of the savage as stupid, coarse, and amoral. In Rousseau and his abettors, what is preached is the simple life. What nature and the natural really are remains to be found by trial and error—the fit methods and forms of religion, marriage, child-rearing, hygiene, and daily work.

Populism. It is easy to see in these beliefs and sentiments (which often passed into sentimentality) additional materials for the populism that the Revolution fostered. Revolution, to begin with, is also an urge to simplify. The Revolutionary style was necessarily populist—Marat's newspaper was called "The Friend of the People." The visible signs that a revolution had occurred included the wearing of natural hair instead of wigs and of common trousers instead of silk breeches, as well as the use of the title of *citoyen* instead of *Monsieur* or any other term of rank. Now, equality coupled with sincerity and simplicity logically leads to fraternity, just as honest feeling coupled with devotion to the people leads to puritanism: a good and true citizen behaves like a moral man. He is, under the Revolutionary principles, a responsible unit in the nation, a conscious particle of the will of the sovereign people, and as such his most compelling obligation is love of country—patriotism.

With this last word the circle of ideas making up the cultural ambient of the French Revolution might seem to be complete. But in the effort to trace back and interweave the strands of feeling and opinion that make up populism, one must not overlook the first political axiom of revolutionary thought, which is the recognition of individual rights, often said to be natural rights as well. Their essence is a subject for political theory. Here their cultural role is of interest, and it can be stated in a very obvious way: individual rights generate individualism. The "ism" rightly suggests an attitude or doctrine—sometimes a passionate faith—asserting that every human being is an object of interest in himself, an end in himself. What is more, the truly valuable part of each individual is his uniqueness, which is entitled to thrive and develop free of oppression. That is why the state guarantees the citizen rights as against itself and other citizens. Again, this power accrues to him for himself because he is inherently important—not because he is son or father, peasant or overlord, member of a clan or a guild.

Doctrine of individualism

These ideas shift the emphasis of several thousand years of social beliefs and let loose innumerable implications. Individualism lowers the value of tradition and puts a premium on novelty. True, the individual soul had long been held unique and precious by Christian theology, but Christian society had not extended the doctrine to every man's mundane comings and goings. Nor were his practical rights and powers attached to him as a man but, rather, to his status within the social scheme. Now the human being as such was being officially considered self-contained and self-propelling; it was a new regime and its name was liberty.

Nature of the changes. The contents and implications of these potent words—liberty, equality, and fraternity, individualism and populism, simplicity and naturalness—aid in the understanding of the cultural situation of Europe at the dawn of the era under review. But these continuing ideas necessarily modified each other and in different times and countries were subject to still other influences.

For example, the active phase of the Revolution in France—say, 1789 to 1804—was influenced by the classical education of most of its public men. They had been brought up on Roman history and the tales of Plutarch's republican heroes, so that when catapulted into a republic of their own making, the symbols and myths of Rome were often their most natural means of expression. The eloquence of the successive national assemblies is full of Roman allusions. Later, when General Bonaparte let it be seen that he meant to rule France, he was denounced in the Chamber as a Caesar; when he succeeded, he took care to make himself first consul, flanked by two other consuls, to show that Caesar was in abeyance.

Changes in the fine arts

In the fine arts this Roman symbolism facilitated a thorough change of taste and technique. The former "grand style" of painting had been derived from royal and aristocratic elegance, and its allusions to the ancient classical past were gentle and distant, architectural and mythological. Now, under the leadership of the painter David, the great dramatic scenes of ancient history were portrayed in sharp, uncompromising outlines that struck the beholder as the utmost realism of the day.

In David's "Death of Socrates" and "Oath of the Horatii" civic and military courage are the respective subjects; in his pencil sketches of the victims of the Terror as they were led to execution, reportorial realism dominates; and, in his designs for the setting of huge popular festivals, David, in collaboration with the musicians Méhul and Grétry, provided the first examples of an art in scale with the new populism: the taste of the court and the city was transcended by the needs of the nation.

But it must be added that except for a few canvases and a few tunes (including the "Marseillaise") the quality of French Revolutionary art was not on a par with its aspirations. Literature in particular showed the limitations under which revolutionary artists must work: political doctrine takes precedence over truth, and the broad effects required to move the masses encourage banality. There is no French poetry in this period except the odes of Chénier, whom the Revolution promptly guillotined, as it did France's greatest scientist, Lavoisier. The French stage was flourishing but not with plays that can still be read. The Revolutionary playwrights only increased the dose of sentiment and melodrama that had characterized the stage at the close of the old regime. The aim was to hold up priests and kings to execration and to portray examples of superhuman courage and virtue.

Modern opera goers who know the plot of Beethoven's *Fidelio* can judge from that sample what the French theatre of the Revolutionary years thrived on. Others can imagine for themselves Molière's *Misanthrope* rewritten so as to make Alceste a pure patriot and hero, undermined by the intrigues of the vile courtier Philinte.

It may seem odd that once the Revolution was under way there should be so much indignation and protest against courtiers, priests, and kings and such fulsome homage paid to virtue and patriotism. What accounts for it is the difficulty of transforming culture overnight. People have to be persuaded out of old habits—and must keep on persuading themselves. Even politically, the Revolution proceeded by phases and experienced regressions. Manners and customs themselves did not change uniformly, as one can see from portraits of Robespierre at the height of his power wearing a short wig and knee breeches, republican and Rousseauist though he was.

Bonaparte's coup d'etat

Napoleon's influence. After Bonaparte's coup d'etat tension eased as the high ideals dropped to a more workaday level, just as the puritanism was replaced by moral license. And as a by-product of Bonaparte's expeditions to Egypt in 1798–99, a new stylistic influence was added to the Roman: sphinxes and the lion-claw motif appeared in furniture, and the Near East began to attract attention. The Roman idea itself shifted from republic to empire as the successful general and consul Bonaparte made himself into Napoleon.

The Emperor had an extraordinary capacity for attending to all things, and he was concerned that his regime should be distinguished in the arts. He accordingly gave them a sustained patronage such as a Revolutionary party rent by internal struggles could not provide. But Napoleon had tastes of his own, and he had to control public opinion besides. In literature (he had been a poet and scribbler in his youth), he relished the Celtic legends of *Ossian* and encouraged his official composer Lesueur in the composition of the opera *Ossian ou les Bardes.* In painting, he favoured the surviving David and the younger men Gros and Géricault, both "realists" concerned with perpetuating the colour and drama of imperial life, including the life of the battlefield. But to depict contemporary issues on the stage (except perhaps in the ballet, which was flourishing) did not prove possible, for the stage must present genuine moral conflict if it is to produce great works, and moral issues are not discussable under a political censorship.

The paradox of the Napoleonic period is that its most lasting cultural contributions were side effects and not the result of imperial intentions. Two of these contributions were books. One, Chateaubriand's *Génie du christianisme* (1802; *The Genius of Christianity*), was a long tract designed to make the author's peace with the ruler and revigorate Catholic faith. The other, Madame de Staël's *De l'Allemagne*, was a description of the new culture in Germany. Napoleon prohibited the circulation of the book in France, but its message easily survived. The two other sources of future light were men. One was the group of philosophers known as Idéologues, who were scientific materialists and concerned with abnormal psychology. The other was Napoleon Bonaparte himself, or rather the figure of Napoleon as seen by his age after Waterloo.

General character of the Romantic movement. The mention of Waterloo (1815) suggests the need to make clear a number of chronological discrepancies. It has been possible so far to discuss the general shift in the temper of European life without naming fixed points. It sufficed to say "before or after 1789" or "from 1789 to the Napoleonic Empire." But from now on the generations of culture makers and the dates of some of their works must be duly situated, without on that account losing sight of unities and similarities in the onward march of artistic and intellectual movements. If, for example, one takes the Romantic poets, one finds that Goethe came to maturity in the 1770s, when the English Romantics were just beginning to be born. Their French, Italian, Russian, Polish, and Spanish counterparts were, in turn, born about the year 1800, when the English were already in mid-career. The same irregularity in the onset of Romanticism is found in the other arts, and it is complicated (at least superficially) by the names given to various movements and persons in the different countries of Europe. Thus, in Germany the term *Romantismus* is applied to only a small group of writers, and Goethe and Schiller are called classic. In Poland and in Russia, classic is likewise the label for the great writers whose characteristics in fact align them with the Romantics elsewhere.

Chronological discrepancies in the Romantic movement

All these accidents of birth and nomenclature can be taken in stride by remembering the patterns found in each country or decade and the reasons for their appearance at that time and place. Within the slightly more than half century between 1789 and 1848, the phenomenon of Romanticism occurred and developed its first phase. Those who made it may have come early or late, belonged to this or that nationality, proved to be originators or synthesizers of existing elements—all such considerations appertain to individual biography or the history of a particular art or nation. What matters in the evolution of European culture considered as a whole is the orchestration of all the voices as they come in to swell the ensemble.

The main purport of the Romantic movement is said to be a revolt against 18th-century Rationalism and a resulting variety of new attitudes and activities: a turning in upon the self, a love of nature, the rediscovery of the Middle Ages, the cult of art, a taste for the exotic, a return to religion, a fresh sense of history, a yearning for the infinite, a maudlin sentimentality, an overvaluing of emotion as such, a liberal outlook in politics, a conservative outlook, a reactionary outlook, a Socialist-utopian outlook, and several other "characteristic features."

It is clear that not all of these can be equally true, characteristic, or important, since some contradict the others. At the same time it was inevitable that so sweeping a cultural revolution as Romanticism should contain incompatible elements. For instance, the political opinions enumerated above did in fact win the allegiance of different groups among the Romantic artists and thinkers for a longer or shorter time. But—to take note of other supposed definitions—not all Romanticists returned to religion: Goethe and Berlioz were pantheists; Byron and Heine, atheists; and Victor Hugo, a sort of Swedenborgian. As for sentimentality, its occurrence was rather a hangover from the 18th century than a new fashion of feeling, for the Romantic cult of art and of strong emotion goes dead against the weak sentimental mood. Similarly, the taste for history, for the Middle Ages, and for the exotic shows a strong curiosity about the particulars of what is real though ignored by previous conventions. All critics, however, are agreed upon one Romantic trait: individualism. And it is here that the figure of Napoleon plays its cultural role.

Incompatible elements of Romanticism

Napoleon was regarded as the model of a new man, even during his life, because his career was manifestly the product of his own thought and will working against the greatest imaginable resistance. He typified the individual challenging the world and subduing it by his genius. A movement that numbered as many artists and geniuses as did Romanticism was bound to find in Napoleon the individual par excellence or, as might be said in modern jargon, a supremely autonomous personality. This perception explains why nearly all the great names of the first half of the 19th century are found on the roster of those who praised Napoleon—from Beethoven and Byron to Hazlitt and Stendhal and Manzoni. Some who were politically his enemies—Sir Walter Scott, for example—nonetheless respected and pondered over the miracle of his achievements. No comparable attention has been paid to the dictators of the 20th century, a fact sufficiently explained by the real difference between Napoleon and them. Stendhal, who had taken part in the Russian Campaign of 1812, analyzed that difference ahead of time: Napoleon had intellectual power—and not merely political and military. In whatever he did, he

showed originality of conception, a stupendous grasp of detail in execution, and the utmost speed in acting out his vision. This sequence, translated to other realms, was the very pattern of the creative imagination. It also seemed the vindication of individualism as a philosophy of life: open the world to the individual and the world will witness marvels unimagined before.

The Romantics' attitude toward themselves

These remarks about Napoleon should convey a sense of the Romantics' attitude toward themselves and their situation. It is true that culturally they stood in opposition to their immediate forebears. But all generations do the same, and yet it is only once in a while that the conflict produces great things. Romanticism had the paradoxical advantage of making its way during and after the 25 years of Revolutionary and Napoleonic wars. For the tumult of battle and political overturns did its share to clear the ground for artistic innovation. When habits and expectations are repeatedly upset and frustrated in the broad public realm, the general mind opens up to novelty offered in other realms. That is one avenue of cultural, stylistic, and emotional change. When Stendhal was expounding Romanticism to the French in 1822, he argued that to go on writing in the Neoclassic vein was "to provide literary pleasure for one's grandfather." His remark was readily understood—at least by his young readers. Mighty events had dug a chasm between past and present, making plain the remoteness of the 18th century.

And yet a paradox remains. When the Romantic innovator produced his first characteristic work—say Wordsworth with the *Lyrical Ballads* of 1798—he had to wait a good while for a hearing though his sense of the death of Neoclassicism was clear; it arose from a poet's quick perception of the decay of forms. Already in 1783 Blake had written of contemporary English verse that "The sound is forced, the notes are few." But these two poets' estimate of the state of poetry was not widely shared till the passage of time—*i.e.*, of men, and events—had worn down old routines. It is generally said that Blake and Wordsworth and most other Romantic artists were ahead of their time; it would be more accurate to say "ahead of their audience."

This phenomenon, characteristic of the modern age, further complicates the question of when Romanticism emerged or was established in different countries. Even so, it is possible to assign, with sufficient reason, a particular decade when in a given nation the movement was in being and active in the production of important works, though not necessarily accepted by a large public. In England and Germany that decade was the 1790s: Blake, Wordsworth, and Coleridge; Goethe (with the first fragment of *Faust*), Schiller, Herder, Jean Paul (Richter), Beethoven, Tieck, Wackenroder, Hölderlin, Schelling, Schleiermacher, together with the beginning of a German translation of Shakespeare by Tieck and Schlegel, mark the advent of the new age.

In Italy, France, and Russia, the decisive years opened in 1820. They are signallized in Russia by the abundant poetic output of Pushkin, in Italy by the work of Manzoni and Leopardi and by the surrounding discussions of literary theory, and in France by the poems of Lamartine, Vigny, Victor Hugo, and Mme Desbordes-Valmore. The paintings of Delacroix, the first compositions of Berlioz, and Balzac's *Chouans* show that a new spirit was at work. Finally, in the 1830s, Poland—through its poet and novelist Mickiewicz—and Spain—through the works of Rivas, Espronceda, José de Larra, and Zorrilla—joined the rest of Europe in its richest artistic flowering since the Renaissance: the leading nations can boast one or more Romantic artists of the first magnitude.

The fundamental Romantic purpose

Romanticism in literature and the arts. The fundamental Romantic purpose was to grasp and render the many kinds of experience that classicism had neglected or had stylized. Romanticism was the first upsurge of realism—exploratory and imaginative as to subject matter and inventive as to forms and techniques. The exploration of reality surveyed both the external world of peoples and places and the internal world of man. The Scottish and medieval novels of Sir Walter Scott, beginning with *Waverley* in 1814, illustrate the range of the new curiosity, for Scotland was a "wild" place, outside the centres of civilization, and the Middle Ages were similarly "barbarous" and distant in time. When Byron went to the Near East and used it as the setting of his adventure poems, he was creating the same sort of interest, this time in a region as real and "central" (to itself) as Paris and London. In both these writers, factual detail is essential to the new sort of effect: the scenery is observably true, and so is the history, given through local colour. As Byron said when criticized: "I don't care two lumps of sugar for my poetry, but my costume is correct." Blake, 20 years earlier, had taken a stand against Sir Joshua Reynold's academic doctrine that the highest form of painting depicted the broadest general truth. Said Blake: "To particularize is the only merit."

Particulars, moreover, are all equally proper for the artist; the use he makes of them is what matters. When Wordsworth and Coleridge sought to revivify English poetry, they hit upon two divergent kinds of subject: Coleridge took superstition and the folk tale and wrote "The Rime of the Ancient Mariner" in the form of an old ballad; Wordsworth took the modern street ballad—a kind of rhymed newspaper—and produced his versified incidents of common life in common speech. In France, where the division of the vocabulary into "noble" and "common" (*i.e.*, unfit for poetry) had been made and recorded in dictionaries, the Romantics led by Hugo used the prohibited words whenever they saw fit. Hugo's verse drama *Hernani* (1830) created a scandal in the audience when the heroine was heard to speak of her handkerchief and when a character did not use a roundabout phrase about the march of the hours to say: "It is midnight."

The rediscovery of Shakespeare

The importance of such details can hardly be exaggerated and can perhaps be best understood by recalling what the rediscovery of Shakespeare meant to the Romantics. His rise from grudging esteem, even in England, to European idolatry by 1830 had a significance beyond the one already mentioned of serving to put down French classical tragedy and, with it, French cultural tyranny. The German scholar, critic, and playwright Lessing was among the first to use Shakespeare for that purpose, but the arguments in his theatre reviews, called *Hamburgische Dramaturgie*, sprang from critical genius and not mere national resentment. Shakespeare spelled freedom from narrow conventions—the set verse form in couplets, the lofty language and long declamations, the adherence to verse throughout, the exclusion of low characters, comic effects, and violent action—or, in a word, from the atmosphere of the court and the aristocratic etiquette.

What Shakespeare typified (and not in poetry or plays alone—witness his influence on Berlioz) was the right of the creative artist to invent his own forms, loosen the joints of grammar and metric (or the canons of any art), follow the promptings of his spirit (tragic or gay, vulgar or mysterious, but in any case venturesome), and see where this emancipation from artificial rules led the muse. There was danger in freedom, as always; the conventions ensure safety. But the aim of the Romantic genius was not to play safe or even to succeed; it was to explore and invent, multiply modes of feeling and truth, and thereby revigorate a dead or dying culture. The motto was not common sense but courage. This resolve explains why the men who came to idolize Shakespeare also rediscovered Rabelais and Villon and revalued Spinoza, the lone dissenter who had worshipped a God pervading the cosmos; Benvenuto Cellini, the fearless artist at grips with the principalities and powers; and "Rameau's Nephew," the ambiguous hero of Diderot's posthumous dialogue, a strange figure disturbingly in touch with the dark forces of the creative unconscious.

Drama. With so much feeling astir and so many novel ideas being agitated, it might seem logical to expect a flourishing school of Romantic drama. But only a few isolated works, more interesting than irreplaceable, compose the dramatic output of the Romanticists—Shelley's *Cenci*, Byron's *Manfred*, and Kleist's brilliant pieces in several genres. Ironically, Shakespeare's new role as

emancipator had a curiously paralyzing effect on the theatre down to the middle of the century and beyond. In England, poet after poet tried his hand at poetic drama, only to fail from stage fright at the thought of Shakespeare. On the Continent, various misconceptions about him and old habits of classical tragedy prevented a new drama from coming to life. Victor Hugo's plays contained brilliant verse, and their form influenced grand opera (Wagner's no less than Verdi's), but the fact remained: the dramatic quality could be found everywhere in Romanticist art except on the stage.

Reflection on this point suggests that, quite apart from Shakespeare, the very concern of the Romantics with exploring the inner and outer worlds precluded the writing of great plays. These perhaps require that one world or the other be taken as settled, at least at the start of the dramatic action. Be that as it may, the double reality in flux was the stimulus of all Romanticist endeavour.

Painting. This generality holds for the painters as well; their "reality," too, was by no means "given," so that the notation of fresh detail and the study of new means to transmute the visible into art occupied all those who came after David. Goya led the way in Spain by depicting the vulgarity of court figures and the horrors of the Peninsular War. In England, Constable painted country scenes with a vividness at first unacceptable to connoisseurs. He had to argue with his patron, Sir George Beaumont, about the actual colour of grass. To prove that it was not of the conventional brownish tint used by academicians, he seized a violin, ran out of the room with it, and laid it on the lawn, forcing the unaccustomed eye to perceive the difference between chlorophyll and old varnish. At the same time, Géricault astonished the Parisians by painting, in harrowing detail, "The Raft of the Medusa," not an antique and noble subject but a recent event: the survivors of a shipwreck adrift and starving on a raft.

The new "reality" in painting

The young Delacroix was emboldened by the example and, inspired also by the work of his English friend Bonington, began to paint contemporary scenes of vivid realism—*e.g.*, the Turkish massacre of the Greek peasants at Chios. Later, Delacroix was to visit Morocco (exoticism again) and to discover there the secret of coloured shadows and other pre-Impressionist techniques. His English counterpart, J.M.W. Turner, was pursuing the same goal of realistic truth, though along a different path that nonetheless also led to Impressionism—and beyond. When asked one day why he had pasted a scrap of black paper on a portion of his canvas, he replied that ordinary pigment was not black enough. And he added: "If I could find something even blacker, I would use that."

Sculpture and architecture. No similar transformations of the visual occurred in sculpture or architecture. Canova and Thorvaldsen continued to produce figures and busts on Neoclassical lines; and only Barye, the great sculptor of animals, and Rude, the creator of the Marseillaise panel on the Arc de Triomphe, showed any signs of the new passions. As for architecture, it may have been the love of history that prevented distinctive work. Pugin and Viollet-le-Duc did grasp the principles of what a new style should be, the former's love of Gothic reinstating the merit of framework construction and the latter's breadth of vision as a restorer leading him to predict that iron construction would one day pass from mere utility to high art.

It was actually in railway construction that the seeds of a new architecture were sown. Tunnels and bridges and terminals were needed as early as the mid-1830s, and unassuming engineers such as Brunel and Robert Stephenson set to work to design them. All they had for solving the new and awkward problems of topography, speed, and cost were the ideas they drew from machinery and the vulgar materials they knew how to handle. The results were often remarkable, and they remained to inspire the makers of 20th-century steel and concrete architecture.

Music. It may seem as if the art of music by its nature would not lend itself to the exploration and expression of reality characteristic of Romanticism, but that is not so. True, music does not tell stories or paint pictures, but it stirs feelings and evokes moods, through both of which various kinds of reality can be rendered or expressed. It was in the Rationalist 18th century that musicians rather mechanically attempted to reproduce stories and subjects in sound. These literal renderings naturally failed, and the Romanticists profited from the error. Their discovery of new realms of experience proved communicable in the first place because they were in touch with the spirit of renovation, particularly through poetry. What Goethe meant to Beethoven and Berlioz and what German folk tales and contemporary lyricists meant to Weber, Schumann, and Schubert are familiar to all who are acquainted with the music of these men.

Changes in the relationship between music and literature

There is, of course, no way to demonstrate that Beethoven's *Egmont* music—or, indeed, its overture alone—corresponds to Goethe's drama and thereby enlarges the hearer's consciousness of it; but it cannot be an accident or an aberration that the greatest composers of the period employed the resources of their art for the creation of works expressly related to such lyrical and dramatic subjects. Similarly, the love of nature stirred Beethoven, Weber, and Berlioz, and here too the correspondence is felt and persuades the fit listener that his own experience is being expanded. The words of the creators themselves record this new comprehensiveness. Beethoven referred to his activity of mingled contemplation and composition as *dichten*, making a poem; and Berlioz tells in his *Memoires* of the impetus given to his genius by the revelation not only of Beethoven's and Weber's music but also of Goethe's and Shakespeare's works and—not least—of the spectacle of nature. Nor did the public that ultimately understood their works gainsay their claims.

It must be added that the Romantic musicians—including Chopin, Mendelssohn, Glinka, and Liszt—had at their disposal greatly improved instruments. The beginning of the 19th century produced the modern piano, of greater range and dynamics than heretofore, and made all wind instruments more exact and powerful by the use of keys and valves. The modern full orchestra was the result. Berlioz, whose classic treatise on instrumentation and orchestration helped to give it definitive form, was also the first to exploit its resources to the full, in the *Symphonie fantastique* of 1830. That work, besides its technical significance just mentioned, can also be regarded as uniting the characteristics of Romanticism in music: it is both lyrical and dramatic, and although it makes use of a "story," that use is not to describe the scenes but to connect them; its slow movement is a "nature poem" in the Beethovenian manner; the second, fourth, and fifth movements include "realistic" detail of the most vivid kind; and the opening one is an introspective reverie.

Self-analysis. In this Romantic investigation of the self, some critics have seen little more than excessive ego or, in modern terms, a tiresome Narcissism. No doubt certain Romantic works arouse boredom or disgust with hairsplitting analysis. But the boredom is often due to the fact that after a hundred years the discoveries have staled. When fresh, they came as a revelation; in the works of the great poets and novelists, in Hazlitt's essays and Jean Paul's fictions, and the irony of Byron's letters or Heine's journalism, the truth has not grown dim or platitudinous.

Desirability of self-analysis

It was in any case desirable that this extensive analysis of the self should be attempted then, for only an age in which individualism was both theoretical and passionate could see the logic of the undertaking and act upon it. The logic was this: given the autonomous and unique individual, a search by himself into his moods, motives, fears, and loves must bring forth data otherwise unobtainable. Add these results together, and you have a repertory of clues to the inner life of mankind as a whole. For the uniqueness of each individual is bounded by traits he shares with his fellows, and this common element enables the psychologist to connect and organize the reports of the self-searchers. It is on this hypothesis, incidentally, that the demand for originality in art has

continued unabated since the Romanticists. Forget the model, for there is no such thing; avoid conformity; discover your true self, the buried child; be authentic and sincere—these precepts, which still govern art and criticism, are the legacy of Romantic individualism.

Introspection naturally implies an inner life worth looking into, and most Romantic artists brought forth extraordinary findings. They form the groundwork of modern thought. One cannot easily imagine Freud or Joyce, much less the degree of self-consciousness shared by Western men today, without the deliverances of Blake, Wordsworth, Keats, Leopardi, Stendhal, Benjamin Constant, Sainte-Beuve, Heine, and innumerable other writers of the early 19th century. And towering above them as the creator of the prototype of Romantic introspection is Goethe with his Faust.

Faust was the figure in which a whole age recognized its mind and soul; and the adjective Faustian, as Spengler's use of it makes clear, still describes tendencies at work in culture today. The principal one, already mentioned, self-consciousness—the identity crisis—remains. The belief, moreover, that movement, activity, is better than repose and that striving is better than achieving is clearly the great postulate of contemporary civilization. Faust himself ends by giving his life to practical works in behalf of his fellow man. But he sets himself on that path only after a slow and deep analysis of his divided soul, which has been ruled together or in turn by despair, lust, superstition and the forces of the unconscious, the love of innocence, the conviction of sin and crime, the horrors of hypocrisy and conventional life, the temptations of wealth and power, the disgust with pedantry and established religion, the yearning for infinite knowledge, and through knowledge, peace. Faust, in short, traverses the whole cosmos, made up of the inner and outer worlds, to find in the act of self-dedication to humanity the justification of his existence.

Social and political thought. The Romantics who studied society through the novel or discoursed about it in essays and pamphlets were also devoted to the cause of humanity, but they arrived at politically different conclusions from Goethe's and from one another's. Scott and Disraeli were forerunners of Tory democracy as Burke was of liberal conservatism. Dickens, a passionate humanitarian, stirred the masses with his examples of the law's stupid cruelty, but he proposed no agency of betterment, content to despise Parliament, the law courts, and the complacency of the wealthy. Balzac wrote his "social zoology," *La Comédie humaine*, to show that society becomes a bloody jungle without the church and the monarchy to restrain human passions.

The cause of humanity

Stendhal noted the same reality but was more concerned with the free play of individual genius; he resigned himself to the social struggle, provided not too many stupid men ran the inevitably heavy-handed regimes. Freedom might be found by the happy few through the loopholes of a mixed government such as England's, whereas in the ostensibly free United States there was no protection against social pressure and no likelihood of genius, in art or in politics.

The great authority on American democracy was Tocqueville, whose astonishing survey in two volumes is still packed with useful lessons. Tocqueville confirmed Stendhal's low estimate of freedom of thought in America, but he foresaw in the United States the first example of a type of democracy that would surely overtake the Western world. He found in such a future many good things and many defects; he predicted a day when slavery would threaten disaster to America; he foretold what kind of poetry a democracy would produce and delineated the art of Walt Whitman; he apprehended the complication of laws and the declining quality of justice; but he was reconciled to what must be.

Post-Revolutionary thinking. What lay behind all 19th-century writings on politics and society was the shadow of the French Revolution. In the 1790s the Revolution had aroused Burke to write his famous *Reflections* and Joseph de Maistre his *Considérations sur la France*. They differed on many points, but what both saw, like their successors, was that revolution was self-perpetuating. There is no way to stop it, because liberty and equality can be endlessly claimed by group after group that feels deprived or degraded. And the idea that these principles are universally applicable removes any braking power that national tradition or circumstance might afford.

Proof that the revolution marched on, slow or fast, could be read (as it still can be) in every issue of the daily paper since 1789. In the early 19th century the greatest pressure came from the liberals, whether students, bankers, manufacturers, or workmen enlisted in their cause. They wanted written constitutions, an extension of the suffrage, civil rights, and from time to time wars of national liberation or aggrandizement in the name of cultural and linguistic unity. For example, all the intellect of western Europe sided with Greece in the 1820s when it began its war of emancipation from Turkey. Byron himself died at Missolonghi while helping the Greeks. Poets wrote odes, and painters painted scenes of war. Between liberalism and national liberation the line could not be clearly drawn. In Italy, Germany, Poland, Russia, Spain, Portugal, and South America, revolt in the name of liberty was endemic until the middle of the century. Only England escaped, but it was by a narrow margin, after threats and violent incidents expressing the same animus as elsewhere.

Meanwhile, the first disturbances resulting from machine industry—sabotage, strikes, and conspiracies (for trade unions were generally held illegal)—reinforced the Revolutionary momentum, not only in fact but also in theory. As early as 1810 the business cycle, the doctrine of the exploitation of the worker, and the degradation of life in industrial societies had been noted and discussed. By 1825 the writings of the Comte de Saint-Simon, which proposed a reorganization of society to cure these evils, had won adherents; by 1830 the Saint-Simonians were an acknowledged party with sympathizers abroad, and by 1832 the words Socialism and Socialist were in use.

Industrialization

The Saint-Simonian doctrine relied on a benevolent dictatorship of industrialists and scientists to remove the inequities of the free-for-all liberal system. Other reformers, such as the practical Robert Owen, who organized successful communities in Scotland and the United States, depended on a strong leader using ad hoc methods. Still others, such as Leroux and Cabet, were Communists of divergent kinds seeking to carry out elaborate theories of the perfect state. Proudhon denounced the state, as such, and all private property. As a philosophical anarchist, he wished to substitute free association and contract for all legal compulsions. In England, the school of Bentham and Mill—Utilitarians or Philosophical Radicals—attacked existing institutions in the name of the greatest good for the greatest number, and by their arguments they succeeded in reforming the top-heavy legal system. Without doctrine but moved by a similar sense of wrong, Thomas Carlyle fought the Utilitarians for their materialistic expediency and himself sought light on the common problem by pondering the lessons of the French Revolution and publishing in 1837 what is still the greatest account of its catastrophic course. Later, Carlyle gave in *Past and Present* a suggestive picture of what he deemed a true community: quasi-medieval, based on the Faustian joy of work, and relying for its cohesion on its leader's genius and strength of soul.

Numerous other schemes of reform or revolt could be mentioned. One irony about them is that the name that has clung to most of them is utopian Socialism, which suggests unrealizable visions, whereas the historical fact is that a great many were tried out in practice, and some lasted for a considerable time. As in Carlyle's book, the force of character of one man (Owen was a striking example) usually proved to be the efficient cause of success. Throughout this social theorizing, whatever the means or ends proposed, two assumptions hold: one is that men have a duty to change European society, to purge it of its evils; the other is that men *can* change society—they need only come together and decide what form the

change shall take. These axioms by themselves, without the memory of 1789, were enough to keep alive in European culture the hope and the threat of continuing revolution.

The principle of evolution. Yet it should not be imagined that revolution by force inspired every thinking European. Even if liberals and reactionaries were still ready to take to the barricades to achieve their ends, the conservatives were not, except in self-defense. The conservative philosophy, stemming from Burke and reinforced by modern historical studies, maintained the contrary principle of evolution. Evolution indeed swayed as many 19th-century minds as its rival, and it was sometimes the same minds.

Evolution was the belief that lasting and beneficial change comes about by slow and small degrees. It is often imperceptible and therefore congenial to human habits. It breaks no heads and spills no blood; it is natural, organic. In truth, the idea of evolution is patterned on biology—the slow growth and decay of living things. More than that, evolution in the zoological sense of "descent with modification" had been a recognized speculation among men of science since 1750, when Buffon included it in his *Histoire naturelle*. Lamarck had elaborated the idea at the turn of the 18th century, while Erasmus Darwin, the grandfather of Charles, had by 1796 worked out for himself a compendious theory of similar import. In 1830–33 the geologist Lyell, setting forth the corresponding notion that changes in the Earth take place through the operation of constant and not cataclysmic causes, devoted a chapter to Lamarckian biology—to the evolution of species by imperceptible steps.

Revival of interest in history

As if these teachings were not enough to implant a form of thought, the revival of interest in history made easy and obvious the transition from the world of nature to that of man. It seemed logical to think of both as evolutions and even to liken the state to an organism. Certainly the student of institutions finds them steadily and profoundly altered by minute incidents and variations. Compared to these causes, the violent breaks made by war and revolution seem more superficial and less permanent.

The evolutionary scheme permitted several other beliefs while affording a number of arguments and conveniences. Anyone who had inherited from the previous era a faith in progress could now attach it to this motive power, evolution. Anyone who wished to classify nations or institutions by rank could place them as he thought proper on an evolutionary scale. Anyone who resisted change or wished to speed it up could be admonished with some evolutionary yardstick. Finally, anyone who intended to write a work of history or propaganda found his organizing principle ready-made for him. In the first half of the 19th century, every subject of interest, from costume to the criminal law, was presented in innumerable studies as proceeding majestically at an evolutionary pace.

Another way of stating the influence of this great idea is to say that the mind of Europe had experienced the "biological revolution." Whereas in the 17th century the Newtonian revolution had imposed the model of mechanics and mathematics, what impressed itself on the 19th century was the living organism—change and variety as against fixity and regularity. The logic of preferring "biology" to "mechanics" in an age of individualism, of realism about concrete particulars, and of passionate imagination and introspection need only be stated to be evident.

Science. This is not to say that the science of physics stood still during the Romanticist period. It was the time when the conservation of energy was established and the mechanical equivalent of heat demonstrated. There also prevailed the "physical" pseudo-science of phrenology, which professed to relate individual attributes to bumps and hollows in the skull, and which led to the physical anthropology that defined three, 10, 20, and 100 different races of man by the end of the century. Still, the 19th was more emphatically the century that furnished the theory of the cell (Schleiden and Schwann, 1838–39), which led ultimately to the notion of microscopic creatures responsible for putrefaction and disease and, later still, to cytology and genetics.

It is noteworthy, too, that the 19th century saw the establishment of chemistry on the Daltonian hypothesis of the atom, but it was coloured by the "biological" notion of elective affinities to explain compounds. Goethe, who was an early evolutionist and the scientific expositor of the metamorphosis of plants, called his last novel of human love *Elective Affinities.*

Poetic ideals versus science

On the surface the poetic mind of the age seemed hostile to both science and technology. Wordsworth looks like an enemy of science when he says: "We murder to dissect" and deprecates the man who is willing to "peep and botanize upon his mother's grave." But reflection shows that the animus here is not so much against science as for the science of life. And to make the effort of recapturing the temper of the times is to be at once struck by the precarious status of science itself. Thought in the 18th century had ended in materialism and skepticism. Some writers, such as d'Holbach, had reduced all phenomena to the interaction of hard and unfeeling particles; others, such as David Hume, had "proved" that man can know nothing beyond his impressions and therefore can have no certainty about the truth of cause and effect, on which scientific statements depend. The Romanticist generations could neither agree that life was a concourse of unfeeling atoms nor trust the physicists' assertions based on a law of causation that the most acute thinkers discredited.

Such were the iron constraints within which the famous "crises of the soul" and conversions to religions new or old took place in the '20s and '30s of the last century. Carlyle, Mill, Lamennais, and many others described them in autobiographical works. The choice seemed to be a blind and meaningless universe or a meaning restricted to the motions of matter, equally blind. Even if the latter scheme "explained," it was vulnerable to David Hume's irrefutable doubts.

Philosophy. What enabled 19th-century culture to pursue the scientific quest and regain confidence in spiritual truth was the work of the German Idealistic philosophers, beginning with Immanuel Kant.

Kant. Kant took up Hume's challenge and showed that although we may never know "things as they are," we can know truthfully and reliably the data of experience. The reason for this certitude is that the mind imposes its categories of time and space and causation on the flowing stream and gives it shape. Science, therefore, is not a guess, nor is human knowledge a dream. Both are solid and verifiable. Indeed, certainty, according to Kant, extends as far as morals and aesthetics. The essence of morals is the commandment not to perform any act that one would not want to become a precedent for all human action and always to consider an individual as an end in himself, not as the instrument of another's purpose. The fusion in Kant of ideas stemming from Rousseau and the Enlightenment with ideas fitting the needs of the coming century (Kant died in 1804) made him the fountainhead of European philosophy for 50 years.

Kant's disciples. His disciples—Fichte, Hegel, Schopenhauer—twisted or amplified his teachings. Coleridge in England and Victor Cousin in France adapted to home use what seemed fitting. The school as a whole was known as German Idealism because it relied on the distinction between the thinking subject and the perceived object; "idea" and "thing" were unlike, but idea (or the mind) played a role in shaping the reality of things, from which derived all stability and regularity in the universe.

German Idealism

Stability was desirable as a guarantor of natural science, but to any observer of human history it seemed contradicted by events, especially those since the French Revolution. Hegel, coming after Kant and witnessing Napoleon's victory at Jena in 1806, was therefore impelled to modify the Kantian logic. To account for the great torrent of human history, he imagined a logic of movement, by which opposing forces are in perpetual battle. Neither side wins, but the upshot of their struggle is an

amalgam of their rival intentions. Hegel called the pros and the cons and their survivors thesis, antithesis, and synthesis. Human affairs are ever in dialectic (dialoguing) progression. At times a "world-historical figure" (Luther, Napoleon) embodies the aspirations of the masses and gives them effect through war, revolution, or religious reformation. But throughout the succession of events, what is taking place is the unfolding of Spirit or Idea taking on itself the concrete forms of the real. Hegel's was another version of evolution and progress, for he foretold the extension of liberty to all men as the fulfillment of history. It is interesting to note that until 1848 or '50 Hegel was generally considered a dangerous revolutionary, a believer in an irresistible progress that mankind must earn by blood and battle. Karl Marx, as a younger Hegelian, was to carry out Hegel's unspoken promise on a different base.

Other branches of the all-powerful German philosophy deserve attention but can be spoken of only as they relate to high Romantic themes. Fichte's modification of Kant made the ego the "creator" of the world, an extreme extension or generalization of individualism. At the other extreme, but more in tune with contemporary science and art, Schelling made nature the source of all energy, from which individual consciousness takes off to become the observer of the universe. Nature is a work of art and man is, so to say, its critic, and because human consciousness results from an act of self-limitation, it perceives moral duty and feels the need to worship.

Religion and its alternatives. That need made itself felt ecumenically throughout Europe from the beginning of the 19th century. It had indeed been prepared by the writings of Rousseau as early as 1762 and the pastoral work of John and Charles Wesley much earlier. The atheism and materialism of the late 18th century was in truth far more responsible for the religious revival of the 1800s than the brief secularism of the French Revolution itself, so that when the Catholic writings of Chateaubriand and Lamennais in France, the neo-Catholic Tractarian movement in England, and the writings of Schleiermacher and his followers in Germany began to take effect, their success was due to the same conditions that made Romanticist art, German idealism, and all the "biological" analogies succeed: the great thirst caused by dry abstractions in the Age of Reason needed quenching. Religious fervour, artistic passion, and "gothic" systems of philosophy filled a void created by the previous simple and mechanical formulas.

The political consequences of the religious revivals

The religious revivals, Catholic or Protestant, also aimed at political ends. Their participants feared the continuation in the 19th century of secularism and wholly material plans. In every country the liberals proposed to set up in the name of tolerance ("indifference," said the Christian believers) governments that would serve exclusively practical (indeed commercial) interests. Church and state were to be separated, education was to be secular, which would really mean anti-religious. National traditions would be broken, forgotten, and youth would grow into "economic man," Benthamite Utilitarian man, with no intuition of unseen realities, no sensitivity to art or nature, no humility, and no inbred morals or sanction for their dictates.

Scientific Positivism. The alternatives to the richness of a life lived within traditional religion were two: scientific Positivism and the cult of art. The name Positivism is the creation of Auguste Comte, a French thinker of mathematical cast of mind, who in 1824 began to supply a philosophy of the natural sciences opposed to all metaphysics. Science, according to Comte, delivers unshakable truth by limiting itself to the statement of relations among phenomena. It does not explain but describes—and that is all mankind needs to know. From the physical sciences rise the social and mental sciences in regular gradation (Comte coined the word sociology), and from these man will learn, in time, how to live in society.

Having elaborated this austere system, Comte discovered the softer emotions through a woman's love, and he amended his scheme to provide a "religion of humanity" with the worship of secular saints, under a political arrangement that the sympathetic John Stuart Mill nonetheless described as "the government of a beleaguered town." Comte did not attract many orthodox disciples, but the influence of his Positivism was very great down to recent times. Not alone in Europe but also in South America it formed a certain type of mind that survives to this day among scientists and engineers.

The cult of art. The second "religious" alternative, the cult of art, has had even greater potency, being at the present time the main outlet for spirituality among Western intellectuals. In the Romantic period this fervour was allied with the love of nature and the idolatrous admiration of the man of genius, beginning with Napoleon. A writer as sober as Scott, a thinker as cogent as Hegel, and an artist as skeptical as Berlioz could all say that to them art and its masters were a religion; and they were not alone. At the death of Goethe in 1832, Heine inveighed against the great man's followers who made art the only reality. In the second and third Romantic generations, born around 1820, the religion of art grew still more pronounced and took on an antisocial tone that became more and more emphatic as time passed. "Art for art's sake" ended by signifying, among other things, "art the judge of society and the state." This doctrine was expounded in full detail by the Romantic poet Gautier as early as 1835 in the preface to his entertaining and sexually daring novel, *Mademoiselle de Maupin.* In those pages the familiar argument against bourgeois philistinism, against practical utility, against the prevailing dullness, ugliness, and wrongness of daily life was set forth with much wit and that spirited defiance of all established things which is associated rather with the 1890s and the present day than with Romantic passion. Its occurrence then is but another proof that Romanticism was the comprehensive culture from which later styles, thoughts, and isms have sprung—down to our own time.

"Art for art's sake"

THE MIDDLE AND LATE 19TH CENTURY

During the half century when Romanticism was deploying its talents and ideas, the political minds inside or outside Romanticist culture were engaged in the effort to settle—each party or group or theory in its own way—the legacy of 1789. There were at least half a dozen great issues claiming attention and arousing passion. One was the fulfillment of the Revolutionary promise to give all Europe political liberty—the vote for all, a free press, a parliament, and a written constitution. Between 1815 and 1848 many outbreaks occurred for this cause. Steadily successful in France and England, they were put down in central and eastern Europe under the repressive system of Metternich.

A second issue was the maintenance of the territorial arrangements of the treaties made at the Congress of Vienna in 1815. Metternich's spies and generals also worked to keep this part of the post-Napoleonic world intact; that is, the boundaries that often linked (or separated) national groups in order to buttress dynastic interests. Except in Belgium, the surge of national, as distinct from liberal, aspirations throughout Europe was unsuccessful in the 1830s. But defeats only strengthened resolve, particularly in Germany and Italy, where the repeated invasions by the French during the Revolutionary period had led to reforms and stimulated alike royal and popular ambitions. In these two regions, liberalism and nationalism merged into one unceasing agitation that involved not merely the politically militant but the intellectual elite. Poets and musicians, students and lawyers joined with journalists, artisans, and good bourgeois in open or secret societies working for independence: they were all patriots and all more or less imbued with a Romanticist regard for the people as the originator of the living culture, which the nation was to enshrine and protect.

Merger of liberalism and nationalism

To be sure, this patriotic union of hearts did not mean agreement on the details of future political states, and the same disunion existed to the west, in England and France, where liberals, only half satisfied by the compromises of 1830 and 1832, felt the push of new radical demands: of the Socialists, Communists, and anarchists. Reinforcing these pressures was the unrest caused by in-

dustrialization—the workingman's claims on society, expressed in strikes, trade unions, or (in England) Chartist groups. This cluster of parties agitated for a change that went well beyond what the advanced liberals themselves had not yet won. Add to these movements those that purposed to hold still or to restore former systems of monarchy, religion, or aristocracy, and it is not hard to understand why the great revolutionary furnace of 1848–52 was a catastrophe for European culture. The four years of war, exile, deportation, betrayals, coups d'etat, and summary executions shattered not only lives and regimes but also the heart and will of the survivors. The hoped-for evolution of culture was broken and, with all other hopes and imaginings, rendered ridiculous. The search began for new ways to achieve, on the one side, stability and, on the opposite, the final desperate revolution that would usher in the good society.

For although they seemed decisive, the battles of '48 and after did not, in fact, test the worth of any one idea. Nationalism won and lost in different parts of Europe. Liberalism gained in Italy and Switzerland, but was set back in Germany and France. English Chartism seemed to collapse, yet its demands began to be carried out. The Socialist experiment in France (Louis Blanc's national workshops) also seemed discredited; yet the ensuing regime of Napoleon III made attempts, however clumsy, to deal with poverty by welfare methods. Repression had shifted men and territories—Metternich was gone from Austria—but Germany and France were not on that account flourishing under liberty, equality, and fraternity. There was peace, but war was imminent; and subversive groups continued to plot and publish and frighten the bourgeois, while industry and urbanization contributed their gains at the cost of the now familiar miseries and sordor.

Mood of despondency

In these circumstances the mind of Europe suffered an eclipse, followed by a protracted mood of despondency. Many established or emerging artists and thinkers had been killed or torn from their homes or deprived of their livelihood. Richard Wagner fleeing Dresden, where he conducted the opera; Chopin and Berlioz at loose ends in London, because in Paris music other than opera was moribund; Verdi going back to Milan with high patriotic hopes and returning to Paris in a few months, utterly disillusioned; and Victor Hugo in exile in Belgium and later in Guernsey—all typify the vicissitudes in which men of reputation found themselves in mid-career. For the young and unknown, such as the poet Baudelaire or the English painters who formed the Pre-Raphaelite Brotherhood, it was no time to invite the public to admire boldness and accept innovation. Critics and public alike were all nerves and hostility to subversion. To read Flaubert's masterpiece, *L'Éducation sentimentale*, is to understand the atmosphere in which the first phase of Romanticism ended and its ramified sequels came into being.

Realism and Realpolitik in midcentury. The dominant feeling was that high hopes had perished in gunfire, and this realization bred the thought that hope itself was an error. Any new effort must therefore stay close to the possible, the "real." Realism with a capital *R* and *Realpolitik* together sink their roots in a distrust of man's imagination. This grim caution born of harsh experience coincided with a sense of fatigue that made Romanticist work seem like the foolishness of youth.

The appropriate cultural note must no longer be the infinite or heroic or colourful but rather their opposites. If the commonly accepted term Realism for this reaction of the 1850s is used, it must be with these presuppositions in mind. For the Romantic passion for the particular and exact was a realism, too; it was what Dr. Johnson much earlier had called "vehement real life." The Realism of the disillusioned '50s dropped the vehement, the passionate and, in order to run no risk of further illusion, limited what it called real to what could be readily seen and felt: the commonplace, the normal, the workaday, and often the sordid.

Limitation of "real"

In the same spirit *Realpolitik* rejected principles. The word did not mean "real" in the English sense; in German it connotes "things"—hence a politics of adaptation to existing facts, pursuing plain objects, admitting no obligation to ideals. In this light we can understand the unexpected epithet "scientific" that Marx and his followers bestowed on their brand of Socialism. It was a science not merely because it was presumably based on the laws of history but even more because in its view the advent of the Socialist state was to result from the interaction of things (classes, means of production, and economic necessity) and not, as in earlier socialism, from the will (that is, the imaginative efforts of thinking men). The "objective" appearance given to the new politics of things, Socialist or other, generated that tough, no-nonsense atmosphere, which men then wanted as a source of reassurance in all their dealings.

Scientific Materialism. This search for certainty went with a swinging back of the pendulum in science itself from the vitalism of the previous period to the Materialism of the midcentury. German philosophers derided Idealism and taught the equivalence of consciousness and chemistry: "without phosphorus, no thinking." The machine once more became the great model of thought and analogy—and nowhere more vividly and persuasively than in biology, where Darwin's advocacy of natural selection won the day because it provided a mechanical means for the march of evolution. The struggle for life (Spencer's phrase of 1850, adopted by Darwin in his subtitle) obviously had the requisite "toughness" to convince and, like *Realpolitik*, it followed no principle—whoever survived survived. That Darwin to the very last included other factors in his theory of evolution—Lamarckian "use and disuse" as well as direct environmental forces—carried no weight with a generation bent upon machine certainty. These secondary explanations were ignored, in the usual way of cultural single-mindedness, and for 30 years after the publication of the *Origin of Species* in 1859, an orthodoxy of universal mechanism reigned over all departments of thought.

It prevented the recognition of Mendel's work on genetics; it put religious, philosophical, and ethical thought on the defensive—only what was "positive" (*i.e.*, material) held a presumption of being real and true. The same reasoning produced a school of social Darwinists who saw war between nations and economic struggle among men as beneficent competition leading to the survival of "favoured races"—another phrase from Darwin's subtitle. And by a final twist of logic, Materialism reinforced the moral gloom of the period by casting doubt on both the permanence and the validity of all that was being redefined as "really real." For on the one side, the second law of thermodynamics guaranteed the cooling of the Sun and the pulverization of the cosmos into cold and motionless bits of matter; and, on the other, orthodox "machine-ism" brought its leading prophets, Huxley and Tyndall, to consider men and animals as automatons moved as helplessly as atoms and planets. Consciousness is an epiphenomenon—in plain word, an illusion—precisely as in Karl Marx consciousness and culture are illusions floating above the reality of economic relations.

The "really real"

Victorian morality. To be sure, not everybody in Europe believed or cared about these affirmations. And although ideas long debated do in the end filter down to the least intellectual layers of the population, the time and place of triumph for a philosophy are limited by this cultural lag—a fortunate delay, without which whole societies might collapse soon after the publication of a single book. What kept mid-19th-century civilization whole was a subdued faith in the reality of all the things Realism and materialistic science denied: religious belief, civic and social habits, the dogma of moral responsibility, and the hope that consciousness and will did exist.

The sum of these invisible forces is conveniently known as the Victorian ethos or morality, a formula applicable to the Continent as well as Britain and one whose meaning antedates not only the midcentury revolutions but also the accession of Queen Victoria in 1837. Like Romanticism, this powerful moralism had its roots in the late 18th century—in Wesleyan Methodism, the Evangelical movement, in Rousseau, Schiller, and Kant. Its earnestness was of popular origin; it was anti-aristocratic in man-

ners, and it sought the good and the true in a simple, direct, unhesitating way. Perceiving with warm feeling that all men are brothers under God, the moral man saw that slavery was wrong; and having so concluded, he proceeded to have it abolished by act of Parliament (Britain, 1833).

Such fervent convictions when widely shared exert tremendous power, and it was this concentration of belief and emotion that made Victorian morality for so long impregnable. As Chesterton said of the Victorian painter Watts:

> He has the one great certainty which marks off all the great Victorians from those who have come after them: he may not be certain that he is successful, or certain that he is great, or certain that he is good, or certain that he is capable: but he is certain that he is right.

The sense of rightness generated a sense of power, which the Victorians applied to the monumental task of keeping order in a post-revolutionary society.

Partly by taking thought and partly by instinct, they perceived that the drive to revolution and the sexual urge were somehow linked. Therefore they repressed sexuality; that is, repressed it in themselves and their literature, while containing it within specified limits in society. Further, they knew that the successful working of the vast industrial machine required a strict, inhuman discipline.

Idolatry of respectability

The idolatry of respectability was the answer to natural waywardness. To pay one's bills, wear dark clothes, stifle individual fancy, go to church regularly, and turn aggression upon oneself in the form of worry about salvation became the approved common modes of pursuing the pilgrimage of life.

It could not be expected that everybody would or could conform. From its beginning to the end, the Victorian age numbered a galaxy of dissenters and critics who scorned the conformity, called the religion a sham, and viewed respectability as mere hypocrisy. But the front held, and the massed forces behind it were at their strongest after the multiplied assaults of 1848.

Nothing gives a better idea of the astonishing moral structure called Victorianism than the development of the London Metropolitan Police, begun under Sir Robert Peel in 1829. A lawyer and a former captain who had fought in the Peninsular War were the first joint commissioners and creators of the force. At first they had to weed out the drunks and the bullies who had been the main types of recruit in earlier attempts at policing cities. At first, too, the people both ridiculed and fought with the new police. Gradually, the "peelers" came to be trusted; they remained unarmed regardless of circumstances; they learned to handle rioters without shedding blood; and in the putting down of crime they finally enlisted the public on their side. For something less than a century this unique relationship lasted, in which "law-abiding" and "police" were terms of respect—correlative terms, since the peelers (later "bobbies") could not have become what they were without the self-discipline and moral cohesion of the "respectable."

The upheavals of the midcentury, cultural as well as political, subjected Victorianism to a severe test, for after wars and civil disorders laxity is natural, and ensuing despair induces a reckless fatalism. There was cause indeed for apprehension. When the Great Exhibition of 1851 was being planned on a scale hitherto unattempted, many expressed the fear that to allow tens of thousands from all over Europe to come together under the Crystal Palace in Hyde Park was to invite massive riots. Ministers and heads of state would surely be assassinated. In the event, no protracted assembly of common people and their leaders was ever so quiet and orderly. The moral machinery worked as efficiently as that which was on display under the glass dome.

The advance of democracy. Yet, while a stringent moralism held in check endemic subversion and anarchy, Darwinism and the machine analogy stimulated endless forms of self-consciousness. If man could fashion and continually improve these engines, perhaps he could also engineer an improved society. Because evolution was at last "proved," thanks to Darwin, perhaps it also gave warrant for social and political progress by gradual steps. Spencer's all-inclusive philosophy, likened then to Aristotle's, foresaw an inevitable movement from the simple and undifferentiated to the complex and specialized—as in modern life. Clearly, whether automatons or not, men kept thinking and having purposes; and among evolutionists and scientific socialists alike, thought and purpose included the hastening by voluntary action of what was sure to come by force of natural laws. These and other desires acting in the light of Realism and taking shape in the increasing organization of the toiling masses brought Europe to accept democracy as inevitable.

Evolution as a warrant for social and political progress

The word democracy is used here in a cultural sense. It does not imply a set of political institutions so much as the signs and the agencies that herald the coming populist state of our day: for example, the extension of the franchise, in parliamentary or plebiscite form; the secret ballot; the legalization of trade unions; the rise of a Catholic social movement; the passage of education acts providing free, public, and compulsory schooling; the formulation of Tory democracy as a cure for the evils of free-for-all economic liberalism; the beginnings of welfare legislation (in France under Napoleon III, in Germany under Bismarck); the secularization of life by state action, by the prestige of science, and also by the liberal movements within the churches themselves; and finally, after a decade or so of public education, the great extension and popularization of the press. At the passage of the Reform Act of 1867 in Britain, which gave the vote to urban workingmen, Robert Lowe had said, "Now we must educate our masters." In a parliamentary system the means to that education cannot be the schools alone. The adult "common man" must continually be informed and appealed to for his satisfaction as well as for coherent policy in government. The instrument for this purpose was the new journalism. The quarterlies of the early 19th century gave way to the monthlies in the '60s and they in turn to the weeklies, while the daily papers, costing now but a penny and simplifying all they touched, began to reach the millions.

Realism in the arts and philosophy. In the period of so-called Realism, the arts and philosophy as usual gave both form and substance to the prevailing fears and desires. The mood of soberness and objectivity was alone acceptable, and what art presented to the public confirmed the reasonableness of the mood.

Literature. This interaction accounts for such things as the marked change of tone in Dickens' novels that occurs between *David Copperfield* (1850) and *Bleak House* (1853). The temper expressed in most concentrated form the very next year in *Hard Times* now dominates Dickens' mind and works to the end: life is a dreary sort of underworld; happy endings are artificial conventions not to be believed.

The same mood explains why Flaubert's *Madame Bovary*, which ranks today as the realistic novel par excellence, and is on all counts grim enough in its rendering of boredom and vulgar misery, was judged "too artistic" by some contemporary critics, not close enough to the most common of realities, that of common speech.

Yet the evolution of Flaubert's work remains instructive for an understanding of Realism as a literary creed. Flaubert had begun by writing a highly coloured, imaginative story on *La Tentation de Saint Antoine*, which the author's friends advised him to burn, tone down, or rewrite. Flaubert put it aside and began the novel that became *Madame Bovary*. Its setting was the provincial world around him, not the Egyptian desert; the characters were of the most ordinary type, not an improbable Christian ascetic haunted by visions. But even in the working out of his plain tale Flaubert had to subdue his lyrical Romantic genius to the discipline he had adopted. The description of a rainstorm, for instance, had to be done over and over again so that it would not stand out and be "interesting" by virtue of the observer's mind. It had to be made ordinary and the observer kept outside, just as in science. *Madame Bovary*, begun as a magazine serial, was soon censored by the editor and then prosecuted as immoral by the state. For Flaubert's Realism had gone so far as to

The significance of *Madame Bovary*

portray in no flattering colours the dreary lives and motives of average provincials of both sexes, and the picture violated the rules of the indispensable moralism. What is more, the fate of Flaubert's unhappy heroine symbolized what had happened to the more daring and poetic-glorious time before 1848: as Flaubert said, Emma Bovary was himself.

His novel is thus simultaneously a model and a critique of the new genre—a critique, too, of the state of Europe that produced it. Many other writers between 1850 and 1890 pursued matter-of-factness without this ulterior effect and rendered the details of middling life with such impassiveness and fidelity that to this day many use "realistic" as a synonym for dreary or sordid and regard "the novel" as a reliable historical source. On the precise definition of Realism, George Gissing gave, through a character in one of his own novels, a brilliant commentary: the character is at work on a novel which shall be so true to the dullness of daily life that no one will be able to read it.

Painting and sculpture. The term Realism applies no less to the plastic arts than to literature, but in painting and sculpture it proved difficult to give form overnight to the change of attitude just noticed in literature and political life. The transition between the passionate poetry and drama of Géricault and Delacroix and the Realism of Courbet and Manet was gradual. It came by way of the "open-air" school of Barbizon, whose landscapes seemed arid (at least to the classically trained academic painters of the day) and pointless in the sense that they depicted the commonplace. Still, when the full shock of realism inflicted by the works of Courbet and Manet occurred, it was severe: here were coarseness and violence in manner and subject. Courbet's backgrounds are thick and his people drab; Manet's nude "Olympia" is no goddess nor even a beautiful woman; she is a prostitute, and her name seems like a piece of irony. The portrait of his parents is a painful representation of simple poverty unrelieved by any glow of spirit or intelligence—yet the work itself is beautiful: such was, throughout, the aim and achievement of Realism.

The gradual transition to Realism in painting

In England, by an historical accident, pictorial realism was embodied in subjects that seem far removed from the commonplace. The school that took up the challenge against academic painting and modified the vision of Constable and Turner called itself Pre-Raphaelite. Its members were Holman Hunt, John Millais, and Dante Gabriel Rossetti, and the name they took for their "brotherhood" expressed their resolve to paint like the masters who came before the imitators of Raphael. It is necessary to put it in this clumsy way in order to make clear that Raphael himself was not being condemned, but only his academic followers who introduced "unreality."

To be a Pre-Raphaelite was to see the world with a sharp eye and an undistorting mind and to render it with intense application to solidity of form, bright colour, and natural pose and grouping. All this was to be understood from the motto *Death to Slosh!* In order to make the new virtues vividly clear and also because the Pre-Raphaelites were reared on great literature, their subjects tended to draw upon legend, or Dante, or the New Testament. It was the conception and treatment that constituted the innovation. Everybody could see it, because it went against the habit of "pretty-pretty" illustration. In fact the nominal subject dropped out of sight in the startled response to form and colour. Paradoxically, then, the commonplace subjects of the French realists and the legendary ones of the English Pre-Raphaelites were alike insignificant when compared with the effort to re-create by art the texture and "feel" of actuality—and nothing more. Such was precisely the goal Flaubert pursued and reached in *Madame Bovary*.

Popular art. It hardly needs to be added that this conscious purpose of high art could interest but a relatively small portion of the public and that, for the growing mass of readers of fiction and viewers of art, other kinds of satisfaction were necessary. The ordinary three-volume novel from the lending library and the continued serial in the magazine or newspaper supplied the demand by aping, adapting, and diluting not one but half a dozen literary tendencies, old and new. The number of novels produced in all languages in the 19th century has never been estimated, but it surely must be of the order of astronomical magnitudes. And the whole output was realistic in the sense that it professed to impart the real truth about life. It was contemporary in setting and speech, took the form of a history, and taught its readers how other people lived. The pictorial counterpart was the "chromo," the cheap colour lithograph that illustrated either fiction or news stories in forms which, however false they must seem to a critical eye, again gave the illusion of commonplace reality.

Growth of the novel in the 19th century

Music. At first sight, it would seem as if music were a medium in its nature resistant to Realism. But that is to reckon without the obvious use that music has always made of sounds directly associated with life—church bells, hunting horns, military bands, and the like. In an age when Realism was at a premium, the opera would be the form where these and other associations easily found their place. So it was in midcentury Europe, where Meyerbeer and others provided the effects to suit the fussily "real" staging of all plays, musical or not. Clocks, tables, animals, waterfalls, and especially costume could be relied on to be genuine up to the limit of the possible: live bullets for real deaths were shied away from, and real lightning was out of reach.

But a genius who is often mistakenly grouped with the Romantics, Richard Wagner, supplied this ultimate deficiency—and by musical means. As critics have pointed out, Wagner's system of leitmotives, or musical tags that denoted an object, a person, or an idea, was consciously or unconsciously an accommodation of Realist intent to operatic understanding. This is true not simply because the musical notes "wave" up and down as Isolde waves her scarf at Tristan—a trivial enough device of a sort found in many composers; it is also true in the deeper sense, which constitutes Wagner's unique genius, namely that he was able to compose great music that was steadily and precisely denotative of items in the story by repeating and interweaving their assigned musical tags.

Late-century decadence and doubt. The combination of Realism in art and thought with its cheap derivatives intended for a mass audience gave rise to a characteristic temper, which we find reflected in writers as different as Baudelaire and Matthew Arnold, Henry Adams and Flaubert, Ruskin and Nietzsche. They and many others were exasperated by the banality and smugness of surrounding humanity. It seemed as if with the onset of Positivism and science, *Realpolitik* and Darwinism, realistic art and popular culture, all noble thought and true emotion had been suffocated. The only things that stood out from banality and smugness were their own appalling extremes—vulgarity and arrogance—against which all the weapons of the mind seemed powerless.

Such intellectuals and artists were hopelessly outnumbered not only in the literal sense but also in the means of influencing culture. A newspaper that reached half a million readers with its cliches, its serial story, and its garish illustrations "educated" the people in a fashion that actively prevented any understanding of any part of true culture. The barrier was far more insurmountable than mere ignorance or illiteracy; and it was cutting off not just the populace but also—to use Arnold's terms—the barbarian upper class and the Philistine middle class. Similarly, Nietzsche anatomized the culture Philistine; that is, the person whose mind was being filled by the mediocre thoughts of writers and artists high in repute and generally believed to be leaders of civilization. In other words, the prudent, self-limiting impulse of Realism after 1848 had generated the middlebrow, while the evolution of industrial democracy had generated the mass man. By the late 1880s the gap between this compact army with its honoured officers and common soldiers and the hostile, half-visible avant-garde was a permanent feature of cultural evolution.

The diminished influence of the intellectuals

The individual expressions of disgust with Realism naturally took many forms, but they can be grouped

into half a dozen kinds, not all on the same plane and only some of which have come to bear distinctive names. Some artists retreated from the ugly world into a species of Neoclassicism. Such were the French poets known as Parnassiens. Strict form, antique subjects, and the pose of impassivity constitute their hallmark. In painting, the work of Puvis de Chavannes stands in parallel.

In music, the explicit revolt against Wagner and Liszt, of which Brahms was made the torchbearer, offers similarities, particularly in the desire to learn and employ the "purer" forms of an earlier time. Likewise, the shift in tone and temper of the later poems of Tennyson, Arnold, or Gautier; the resurgence of Thomist orthodoxy in Catholic thought; the haughty detachment in the plays of Becque and those of Ibsen's middle period, all suggest a search for stability, for a fixed point from which to judge and condemn contemporary "progress."

It was also possible, after withdrawing by conscious effort from any struggle with vulgar actuality, to make art itself an independent and inhabitable world and to escape alienation in beauty. This cult of beauty goes by the names of Symbolism and Impressionism. The Impressionists were able to take as subjects some of the sights that most depressed their fellow man and by recomposing them in brilliant, shimmering colour to create a refreshing world of new sensation. Subject once again mercifully disappeared. As Monet said: "The principal subject in a painting is light."

Symbolism and Impressionism

The Symbolists in literature had a more difficult task than the painters, because their medium, words, must be shared with all those who speak the language for ordinary purposes. To disinfect grammar and vocabulary for poetry and "art prose" required severe measures. All set phrases had to be broken up, unusual words revived or common ones used in archaic or etymological senses; syntax had to be bent to permit fresh juxtapositions from which new meanings might emerge; above all, the familiar rhetoric and rhythms had to be avoided, until the literary work, poetry or prose, created the desired "new world." It is a world difficult to access but worth exploring, all its tangible parts being the symbols of a radiant reality beyond—in short, the antithesis of a newspaper editorial.

In music there was no need of any indirect device to establish the mood of Impressionism. It was already to be found here and there in the great Romantics, and when the new generation began to compose on themes drawn from literature, the hints and opportunities needed only a delicate genius to develop them into a style. Debussy was that genius, soon followed by Ravel, Delius, Hugo Wolf, and others. Alike, yet independently of one another, they replaced eloquence, melodic clarity, and harmonic consecutiveness by capricious melodic contour and pointillist chord progressions to produce the shimmer and mystery of musical Impressionism.

To those who dedicated their lives to Symbolist literature and criticism the name of aesthetes is often given, for it was at this time, from 1870 to the end of the century, that questions of aesthetics became the intense concern of artists, critics, and a portion of the public. The old Romanticist phrase "art for art's sake" was revived; many persons not themselves artists confessed to a "cult of art"; much time was devoted—necessarily—to deciphering, commenting, and discriminating, for much of the new art was obscure and arcane and took time to master and enjoy. Other observers called these manifestations decadent—some with contempt, others with pride. For a time, a group of French artists took the name to themselves as a badge of honour.

Aestheticism

But aestheticism was by no means as languid and fatalistic as it tried to appear. At its centre stands the active figure of Oscar Wilde, whom it is easy, because of his notoriety on many counts, to dismiss as colourful but ephemeral. Yet he is far more than a symptomatic figure; he is a representative one, and a good part of his work, namely his entire critical output, some of his fiction, one or two poems, the autobiographical *De Profundis*, and the greatest farce in the language, *The Importance of Being Earnest*, deserves to last. What Wilde accomplished through these works was the liberation of English literature from ancestral (and not merely Victorian) preconceptions. He reconnected England with the Continent artistically by phrasing with finality their different assumptions. He showed that art could be morally responsible only by discarding moralism. In a word, he played again in 1890 the role Gautier had played in France in 1835 with his art for art's sake diatribe in *Mademoiselle de Maupin*. Whoever, starting with Wilde or Gautier, wishes to follow the historical sequence and recapture the atmosphere in which this activity went on, will find no better source than the journal of the Goncourt brothers, the inventors of "art prose" as well as the recorders of contemporary lives, characters, and gossip.

But the reader of their voluminous pages will also find there references to the movement called Naturalism, which does not merely parallel but also intermingles with Symbolism and Impressionism. The Goncourts themselves wrote a number of Naturalistic novels; their friend Zola was the theorist and greatest master of the genre; another novelist, J.-K. Huysmans, passed from Naturalism to Symbolism, as did several other writers. In the poets Rimbaud and Verlaine, as later in the Irish Yeats, the elements of the two tendencies alternated or mixed.

Naturalism

The name Naturalism suggests the philosophy of science, and the connection is genuine. Zola thought that in his great series of novels, *Les Rougon-Macquart*, he was studying the "natural and social history" of a family during the time of Napoleon III. The claim was bolstered by the method Zola used of gathering data like a scientist—every material fact could be proved by reference to actuality or statistics. Naturalism would thus appear to be an intensification of Realism, as indeed it was—more "research." But it differed markedly in spirit. Realism professed to be depiction of the commonplace in a mood of stoicism or indifference—a photographic plate from a camera held almost at random in front of unselected mediocrity; it was, as Flaubert was the first to say, a refusal to share previous Romanticist hopes and interests. Naturalism, on the contrary, readmitted purpose and selectivity. Each novel was a "study" designed to show up and denounce the dismal truths of social existence, for which purpose the worst are the best. Zola's novels throb with a passionate love of life, a life which he showed as tortured and twisted by character and condition. In the end he defined his scientific or "experimental" novel as "nature seen through a temperament."

In the plastic arts, a plausible counterpart of Naturalism is the work of those known as Postimpressionists, notably Cézanne and van Gogh in painting, Rodin and Maillol in sculpture. Their various styles and aims had a common result in restoring solidity and "weight" to the visual object after the fluidity and lightness of Impressionism.

Musical naturalism was, by contrast, an attempt at dramatic literalness. Richard Strauss boasted that he could render a soup spoon in music if he wanted to; but he could not and he did not. The noises of his *Sinfonia Domestica* are standard orchestral sounds fitted with a preliminary explanation, like the libretto or synopsis of a Wagnerian or other opera. When the sheep bleat in Strauss's *Don Quixote*, the clarinets play notes that are decorative on their own account and do not in the least suggest wool. It is rather the thickness of Strauss's orchestration and chromatic harmony that connect him with naturalist doctrine—the headlong embrace with matter. And so it is also in the operas of Bruneau or Charpentier or in the *verismo* of Puccini and the late Italian school generally. Music remains atmospheric; never, except in Wagner's system, denotative.

This definition of Naturalism, coupled with the aesthetic, or "art for art's sake," impetus in Symbolism and with the Impressionists' transmutation of concreteness into light, justifies the name of Neo-romanticism that has been given to the cultural temper with which the 19th century ended. After the glum self-repression of the middle period, it was an outburst of vehement self-assertion, whether directed inward or outward. "Art for art's sake" and Naturalism are indeed but twin branches of one doctrine: art for life's sake.

The final phase of Romanticism

To redefine in this way the cult and the products of art in this period is not to say that the participants in this final phase of Romanticism were necessarily joyful. Love of life and of beauty can coexist with angry despair. The contrast between what man is capable of and what he actually does may prove unendurable; and not everybody can find in art the solace of his woes. Some took to drugs, that "artificial paradise" that Baudelaire had earlier said was indispensable to life in the modern city. Others, with a last confused hope of total transformation, joined those anarchists who thought that a bomb or an assassination would bring down the whole wretched "system."

Still others fled to more primitive parts of the world: Rimbaud to the Near East, Stevenson and Gauguin to the South Seas. Many became Catholic converts—some of them to retreat in monastic orders—the conversion expressing in yet another way a condemnation of "the world." Baudelaire, who died in 1867, just before this period begins, was in fact its true prophet, and his fame coincided with the fulfillment of his word; small as is his output of verse and prose, it affords a complete review of the century. In it is seen the last glow of original Romanticism, the griminess of realistic description, the perversity of Satanism and drug addiction, the impulse to violence and destruction, the intimations of a universal symbolism, the remnants of sincere Christian belief, and the effort to fashion in words a realm for the sole contemplation of beauty.

As these various emotions rioted in the souls of Western men, the revelation of "the Russians" came with Tolstoy and Dostoyevsky. The novel *Fathers and Sons* by Turgenev (1862) had already acquainted Europeans with "moral nihilism," which is the paralysis of the will from an excess of self-conscious mind. But Tolstoy and Dostoyevsky stirred deeper layers by showing that the impossibility of coming to terms with a godless civilization was a general and inevitable state and not a remediable accident. Western facts bore out the conclusion, or seemed to: the hospitals were filled with mental cases, the suicide rate went up with urbanization, everybody was (in the current jargon) "neurasthenic" and distraught. A physician writing in 1892–93 under the pseudonym of Max Nordau entitled his huge best seller *Entartung* (Eng. trans., *Degeneration*, 1895), and after elaborate diagnoses found all the styles and schools of contemporary art one vast confirmation of his social and medical statistics. It was the end of the century, anyway, and the phrase *fin de siècle*, taken over unchanged in every language, exerted a magic spell persuading its users that the numerical close of the 1800s meant also the close and fall of civilization.

ALIENATION AND DESPAIR (20TH CENTURY)

In that same year 1895 George Bernard Shaw said: "France is certainly decadent if she thinks she is." The remark is characteristic of Shaw, but also symptomatic of a new wave of energy. From under the despair and decadence, the scattered retreats and the violent nihilism, the same human strength that produced Symbolist and Naturalist art was trying to reshape the civilization that all found so unsatisfactory.

Attempts at improvement. In England, the Fabians, of whom Shaw was one, were preaching the "inevitableness of gradualism" toward the socialist state. It was they, seconded by the growing strength of the trade unions after a spectacular dock strike of 1889, who paved the way to Labour governments and the British welfare state. Throughout Europe, Socialism was no longer the creed of a lunatic fringe but was the ideal of many among the masses and the intellectuals. The original fight for liberty and democracy in political action had turned into a fight for economic democracy—freedom from want. Laissez faire liberalism had turned inside out, and the liberal imagination at work in the many brands of socialism now demanded state interference to remove the appalling conditions causing all the despair.

The growth of Socialism

Arts and Crafts movement. Among the Socialists belonging to no party, Ruskin and William Morris worked also to effect immediate changes in the quality of their surroundings: they started the so-called Arts and Crafts movement, whose aim was to make objects once again beautiful. Because machine industry produced only the cheap and nasty, they tried by hand to produce the cheap and handsome—good furniture, hangings, and household articles; fast dyes of good colour; well-printed books on good paper; and jewelry and ornaments of all kinds that showed visual talent as well as manual skill. In a word, the movement reinstated the ideal of design and succeeded in forcing it on machine industry itself. Within two decades manufacturers began to hire artists as designers, and by 1910 the 20th-century omnipresence of design, from clothes to print and from gadgetry to packaging, was a *fait accompli*. The visual revolution can be seen easily by looking back with modern eyes to a page of advertising at the turn of the century.

New trends in technology and science. In parallel with the new craftsmanship, the new technology of the 1900s began to give hope of wider improvements. The use and transmission of electric power suggested the possibility of the clean factory, all glass and white tile. Better machines, new materials and alloys, a greatly expanded chemical industry—all supplied more exact, more functional, less hazardous objects of use and consumption, while the application of science to medicine nourished the hope of greatly reducing the physical sores of mankind. Those closest to all these developments were certainly not among the despairers and fugitives from the world. Like all men who struggle successfully with difficulties, they were inspirited by what they knew to be demonstrable progress along their chosen lines.

The same outlook animated workers in the natural and social sciences. It was for both a time of transformation, and genuine novelty exerted its usual invigorating effect. From the '80s onward it had been clear that simple mechanistic explanations based on "dead" matter were inadequate. The Michelson–Morley experiment of 1887 had given the *coup de grace* to the mere push-pull principle by showing that though light consisted of waves, the waves were not in or of anything, such as the ether, which did not exist. Even earlier, James Clerk Maxwell's attempt to work out the facts of electromagnetism on Newtonian principles had failed. And on the philosophic front, the notion of natural "laws" was being radically modified by thinkers such as Poincaré, Boutroux, Ernst Mach, Bergson, and William James. All this prepared the ground for the twin revolutions of relativity and quantum theory on which the 20th-century scientific regime is established.

The breaking away from the machine analogy had its counterpart in the biological sciences. With narrow Darwinian dogmas in abeyance, the genetics of Gregor Mendel were rediscovered, and a new science was born. The fixity of species was again regarded as important (Bateson), while the phenomenon of large mutations (de Vries) caught the public imagination, as the opposite slow, small changes had done 60 years earlier. The mysterious "fitness of the environment" was held deserving of study, and new formulas for evolution—emergent, creative—received serious attention. Vitalism itself once more reasserted its claims, as it seems bound to do in an eternal seesaw with mechanism.

Rediscovery of genetics

The social sciences. Finally, in the social sciences, fresh starts were made on new premises. Anthropology dropped its concern with physique and race and turned to "culture" as the proper unit of scientific study. Similarly in sociology, Durkheim, seconded by Tönnies, Tarde, and Le Bon, concentrated on "the social fact" as an independent and measurable reality equivalent to a physical datum. Psychology, also long under the exclusive sway of physics and physiology, now established at the hands of William James that the irreducible element of its subject matter was the "stream of consciousness"—not a compound of atomized "ideas" or "impressions" or "mind-stuff" but a live force in which image and feeling, subconscious drive and purposive interest, were not separable except abstractly. A last domain of research was mythology, to the existence of which James

George Frazer's *Golden Bough* gave massive witness, thereby exerting proportional influence on literature and criticism.

Re-examination of the universe. The net effect of these innovations in the sciences of man and of nature was liberating. Whatever each specialty or subspecialty meant to its practitioners, the persons who carry in their minds the general culture of an age took the new message to mean that the universe, formerly closed forever, had been reopened, and that on fresh inspection it had proved more alive than dead. These conclusions offered a field for strong individual action. Subjective choice became again respectable as a genuine fact. Truth, God, beauty, and immortality obviously were in need of re-examination.

In philosophy, politics, and criticism this re-examination may be called the pragmatic revolution; in social and moral life, the liquidation of Victorianism. But the Pragmatic Revolution must not be thought of as being only the work of those who, like James, called themselves Pragmatists. Nietzsche, Samuel Butler, Shaw, Bergson, and others constitute the headwaters of the stream of thought that issues in present-day Existentialism. The common features are the turning away from absolutes and unities to pluralisms and the method of testing by consequences. Subjective and objective tests looking to future thought and action—not authority or antecedents—are to decide the true, the good, and the beautiful.

Turning away from absolutes

Such an outlook, of which the refinements are, like the defects, beyond the scope of this article, is the logical and appropriate one for an age of reconstruction. It boils down to trying all things new and holding fast to that which is good. But it presupposes the creation of new things to try, and here it is allied to the liquidation of Victorianism. In morals the work of destruction generally begins by affirming the opposite of the accepted rule. An excellent source book for this attitude is Samuel Butler's *Way of All Flesh*, written in 1885 but not published till 1903. The Victorian Tennyson had said: " 'Tis better to have loved and lost than never to have loved at all." Butler said: " 'Tis better to have loved and lost than never to have lost at all." This inversion of values —don't weep over loss; there are plenty of loves to be had and the more the merrier—is but an indication of method. At first the denial was uttered as humour and paradox: Butler's *Note-books*, Shaw's *Arms and the Man* (the soldier wants chocolate, not ammunition), Wilde's *Importance of Being Earnest*, Jarry's *Ubu roi*, Strindberg's tragicomedies—to cite but a few subverters of the Victorian—all used derision and topsy-turviness to make their point.

But underneath the joke was the new purpose, which soon found open expression in positive utterance and action. In the plays of Hauptmann and Brieux, the novels and anticipations of H.G. Wells, the essays of Tolstoy, Péguy, Georges Sorel, Ellen Key, Havelock Ellis, Unamuno, Ortega y Gasset, or Shaw, the new modes of feeling and the new scale of virtues and vices are set forth with as much earnestness and vigour as the old Victorian kind.

Nor did action wait until all the books were out. From the onset of the overturn, say 1890 onward, the rebellion was a biographical fact. People braved public opinion and got divorced, lived together unmarried, practiced and preached contraception, studied the psychology of sex, and defended homosexuality. Or again, the sons of the rich turned Socialist, became labour leaders, and fomented syndicalist (*i.e.*, direct action) strikes, while the daughters demanded the vote as suffragettes, assaulted policemen, and went to jail for chaining themselves to door handles. Meanwhile, students rioted about international incidents or university affairs; schools were subjected to the devastation of the softer pedagogies; "rational clothing" exhibited itself in spite of derision, like the bicycle and the newfangled automobile; and new cults multiplied like mushrooms—outdoor sports, nudism, Theosophy, esoteric Buddhism, Rosicrucianism, New Thought, the Society for Psychical Research, Christian Science, the Salvation Army, and the "Maximinism" of Stefan George.

Of these, hardly any need explanation here. But a word must be added about Theosophy if only because of its historical importance in developing Yeats's genius and for expressing once again the attraction that the "wisdom of the East" has for Westerners. Not that the doctrine elaborated by Madame Blavatsky rested on any genuine knowledge of Hindu religion and philosophy. That is not its point. The point is rather that Theosophy supplied the need for quietude, mystery, transcendence, and immortality in the wearied souls of Europeans. In Theosophy the doctrine of reincarnation offers satisfaction of immortal longings and inspires to wisdom, the demands of which are periodically revealed by mahatmas, or holy men.

Theosophy

As for the poet Stefan George's worship of his young friend Maximin, who died at 15, it answers a similar impulse to permanent truth but with the additional urge to abolish (rather than escape) "contemporary materialism." George was but one among many European writers who wanted to found a new society in place of the actual one. What has fitly been called the politics of cultural despair fastened on a great many saviours as the new hope—monarchy, "integral nationalism," a new aristocracy (usually tinged with intellect), technocracy (rule by science and the engineers), the proletariat (in syndicalist "cells" or communist collectives), trade and professional guilds federated in a corporate state, or again the mystic unity of "blood" and "race." In all these creeds, at least at their beginnings, the thirst for the ideal is evident; together they formed a new utopianism, of which the later fruits are familiar but quite other than those predicted: Soviet and Chinese Communism, Italian Fascism, German National Socialism. Beyond them, in the present, elements of this second wave of cultist thought and practical utopianism that ushered in our century are easily discerned.

In one country, as the 19th century passed into the 20th, all the energies seeking an ideal found an unexpected outlet. The occasion for battle was the conviction of a French officer for espionage; *i.e.*, the Dreyfus affair. Its cultural suggestiveness is apparent: on one side, the ideal of justice and the regard for the individual as an end in himself; on the other, the social or collective ideal typified by the army and the nation; throughout, the ideal of truth—the facts—pursued, lost, and found again in an embittered struggle that threw up a host of endemic prejudices—about race, about class, for and against intellect—to say nothing of individual egotisms and obsessions that had been charged with the force of pent-up aggression.

The prewar period. The same universal aggressiveness was to have its field day in the coming war of nations, but in the intervening decade (1905–14) occurred the remarkable outburst of a creativeness, which, for the first time since 1789, had its source elsewhere than in Romanticism. The "Cubist decade" (as it has been conveniently called) gave the models and the methods of a new art, just as the natural and social sciences had begun to do for science a little earlier. Cubism in painting defined itself as a new classicism, but it was obviously not Neoclassical. In painting and sculpture, in music and poetry, and in architecture especially, the new qualities were: simplicity, abstraction, and the importance of mass.

The Cubist decade

Since the artists at work were numerous and diverse, in both origins and purpose, it is idle to try to derive their productions from any single set of conditions. Clearly, the Cubist painters found encouragement in the canvases and ideas of their immediate predecessors, the Postimpressionists. But the new architects found it rather in new materials—reinforced concrete and the steel constructions of the engineers. Some of the poets (Futurists, Unanimists, Simultanists) were influenced by sociological theories about the group; others (and novelists too) read the new psychologists and philosophers. The sculptors responded to African and Javanese artifacts. And the musicians perceived at once the exhaustion of a system of

harmony, the impact of the crowd and the primitive, and the opportunities offered by using and making sounds hitherto ignored by composers. In a culture as cosmopolitan and quick-witted as that of Europe before 1914, it is unlikely that any important concept or speculation should not have found its mark somewhere in art, even if the individual artist did not consciously record it.

Consequently, it is not arbitrary to say that the Cubist decade was stimulated and prepared for its characteristic work by everything that was pouring in upon it—motion pictures and the airplane, X-rays and organ transplants, the philosophy of time and space in relativity and Bergsonism, wireless and the Eiffel Tower, the Jamesian "stream of consciousness" and Le Bon's analyses of the crowd, the importations of colonial art and the European discovery of Walt Whitman, the myths in Frazer and the double personalities in the psychopathic clinics, the fever of revolution and of sexuality reacknowledged, the transcendental visions of various orientalisms and the vitalist current that was reanimating the cosmos and authorizing an infinite number of geometries. Multiplicity outside, bottomless depths within, equally validated by science and intuition, furnished unlimited scope to perceptive genius; it was only a question of pondering, choosing, and creating fit forms.

The impact of war. To the many-sided productiveness the war of 1914 put an instantaneous stop. It was a war of a sort Europe had not known since 1815—the nation in arms. And at that earlier time, the absence of large industry had precluded the involvement, physical and mental, of every adult citizen simultaneously throughout Europe. In 1914 Beethoven, Hegel, and Goethe would have been in the trenches.

The death of Renaissance high civilization

The cessation of cultural activities; their replacement everywhere by a propaganda of hate; the rapid decimation of talent and genius in the murderous warfare of bombardment and infantry assault; the gradual demoralization through four years of less and less intelligible war aims; and after the Armistice, the long sequel of horrors—starvation, dispersion, disease, and massacre—together shattered the high civilization born of the Renaissance and based on the idea of the national state. Too many able men and women had been killed at the start or at the peak of their creative powers for the continuity of culture. Too many intimate faiths and civil traditions had been ground down for any recovery of self-confidence and public hope to be possible. Skepticism about this conclusion is easily met by reference to the present-day view of "the human condition" as it is reflected in novels and plays.

The period "between wars"—1920 to 1939—gave sufficient indications that forward direction had been lost. It combined a frivolous neo-decadence (if the term may be allowed) with a restless search for starting points. The artists who survived were unable to pursue their individual development from the point of its interruption, whether physical or spiritual. Many felt a kind of shame to be busy with art after the human disaster they had witnessed. This feeling accounts for the tiresome mocking of oneself and one's work that marks the production of the 1920s and '30s. Nothing being important, everything is silly, and it can be offered at all only if one laughs at it first. Hence the appearance of Dada, the meaning of which is that the thing is a harmless and even childish obsession.

More serious minds—Stravinsky's, for example—looked farther back than prewar times for possible models: the 18th-century or the late Middle Ages. Playwrights took up the ready-made of antiquity, like 17th-century "ancients," but turned the plots inside out or upside down, those acrobatics mirroring their times and their souls simultaneously. T.S. Eliot, after expressing his disgust at all he saw and felt, declared himself a royalist, an Anglo-Catholic, and a Neoclassicist. In all the arts, eclecticism and, even more, allusiveness were the preferred methods. The partakers' enjoyment came from recognizing the borrowed plums. To this device the sole alternative was to deny the validity of art itself, as in Surrealism, which relied for its deliverances on automatic writing uncensored by the conscious mind. The ultimate creator was believed to be the dark side of our common nature.

Culture since 1920. It is always true, of course, that as the observer comes nearer to his own times his blindness increases. When he has said his say, it turns out that something or someone remarkable has been overlooked—Blake or Kierkegaard, the aesthetics of Poe and Whitman, or the scientific truths of Mendel or Semmelweis—all delayed by the myopia of the ignorant and the well informed. Therefore, any generalities made about the period since 1920 are and ought to remain suspect for a good while. Still, they are not without value for the present for two reasons: they are suggestive and they allow for a sifting through of a variety of tenable views. In addition, such conclusions inform later comers of how things seemed before time had cleared away the rubble.

The most important truth about culture since 1920 is the so-called cultural lag. The meaning of the term is simple: culture in any sense at all is being made somewhere and it takes five, 10, or 20 years to become known and diffused. The contributions of Freud and Einstein, for example, did not enter the public domain until 1920, though clearly perceivable by 1905. Subtracting five years for war and peace leaves a net lag of a whole decade. Again, there is the North Atlantic cultural lag. Until the first war sent American youth to Europe and conscious expatriation followed, the lag between the continents was 20 years or more. But since 1920, in both Europe and America, a different kind of cultural lag has been noticeable. It is the joint result of swift social evolution and failure to move creatively beyond the Cubist decade.

The "cultural lag"

The social evolution has consisted in bringing new layers of the population in contact with cultural affairs. The mass media have done the work of popularizing—radio, television, magazines have reached the millions and told them in words and pictures "all about art"; while display advertising has quietly adapted the tone and techniques of modern literature and painting to charm and seduce the customer. The schools, including the universities, have likewise "gone modern" and bred a taste for novelty in place of the classics. But with each enlargement of the public exposed to these influences, the revelation has been less and less up-to-date. It is still necessary in Europe and America to exhibit and explain Baudelaire, who died more than a century ago. His continuing relevance is unquestionable, both because he follows upon what the popular mind has previously absorbed and because in a certain sense European culture has taken no great step beyond him.

The summing up can only be that except for the work of the Cubist decade, the 20th century has not fashioned a culture of its own. It has solaced and entertained itself with historical mixtures and retrospects and what the 1960s and 1970s believe to be the newest of the new is repetition half-disguised: anti-art is all in Futurism; madness and the absurd are in Jarry and Unamuno; jazz, serial, and electronic music (and *musique concrète* as well) antedate 1914; "ecology" and consumerism are full-fledged in Ruskin and Shaw; youth movements, feminism, sexual freedom, and the liberated school are today the second viewing of a former script; existentialism merely amplifies; even science fiction and the spy story as emblematic of the possible and the actual are old stories. What is new in the 20th century is the magnification of all the predicaments and the blinding concentration on details.

The enlargement of scale has obvious causes—more people, more "communication" (which clogs its own channels and bewilders wider constituencies), more apprehension resulting from World War II and its prospects—nuclear fire and biological blight. Fear is a cultural force, too; it inspires wholesale rejections and temporary hopes, and when large numbers of people have at least an inkling of what is and what was, the moods of favour and disgust are violent and short. Schools of

thought and their leaders are taken up and dropped with quick boredom and panic rapidly. Persons and things are "in" or "out" with scarcely an argument for or against. But the cultural lag remains for want of definitive assimilation. Although all profess to desire a world of reason—that is, of peace and plenty, of brotherhood and equal rights—the prevailing dogma is that Western civilization, heartless because of rationality, deserves to perish.

The means proposed to put an end to it is a general emancipation and loosening of all bonds. Language (or "free speech") is to be purposefully obscene; art is to be "disposable" (that is, impermanent and stripped of meaning, even aesthetic); manners and dress must be improvised, like schooling—and indeed society had best be "deschooled" lest something fixed be transmitted, which would clearly be oppression. The cultural war of the '60s against the Establishment was in truth not against any caste or clique in power that might deserve the capitalized name; it was against anything established, including a rule or a fence set up with the very consent of those who tore it down.

The drive to self-destruction

Whether or not such an attitude lasts, it is permissible to see it as part of a larger tendency affecting all European culture—the drive to self-destruction. It could be argued that for 80 years or more, the preponderance of effort has been aimed at making an end of the aristocratic, elitist high culture of Renaissance man and his successors. That that culture has democratized itself and brought to the fore all the ideas of liberty, equality, social responsibility, humaneness, world unity, and cosmic brotherhood has not helped to save it. It is, many believe, being destroyed from within in the name of the very ideas it forged in the teeth of opposition and promulgated for the good of its present destroyers. Nor is this destruction the work of healthy barbarian appetite; it is led by the heirs of the great tradition, including the best artists of the time, who sense, share, and express the hatred requisite to annihilate. As Jarry said as early as 1900: "We will bring down everything to ruin—and then we will go on and destroy the ruins."

In such a state of affairs, only one supposition may be possible: European man has thrived for half a millennium on the principle of individualism and has exhausted all its possibilities. A new type of man, actuated by a different principle, is required to cope with the conditions created by his predecessor. If he arises, a new culture—art, science, philosophy, social and moral relations, political state, and personal metabolism—will follow. Meantime, the conscious and unconscious prophets of his coming are busy at their proper work, which is to undo, to pulverize, and to level the ground for the unimaginable creature of tomorrow.

BIBLIOGRAPHY. EUGEN WEBER, *Paths to the Present* (1960), is a full and well-organized collection of documents and extracts covering the period from Romanticism to Existentialism. For the corresponding historical narrative, the *Columbia History of the World*, ch. 66–101 (1972), together with E.J. HOBSBAWM, *The Age of Revolution, 1789–1848* (1962), is useful. HAROLD T. PARKER, *The Cult of Antiquity and the French Revolutionaries* (1937, reprinted 1965), is an excellent introduction; as is CRANE BRINTON, *The Political Ideas of the English Romanticists*, rev. ed. (1962). JACQUES BARZUN, *Classic, Romantic, and Modern*, rev. ed. (1962), fills out the interpretation given in the present article. ROBERT C. BINKLEY, *Realism and Nationalism: 1852–1871* (1935); and C.J.H. HAYES, *A Generation of Materialism: 1871–1900* (1941), amplify the political and economic narrative and also interpret culture. EGON FRIEDELL, *Kulturgeschichte der Neuzeit: Die Krisis der europäischen Seele von der schwarzen Pest bis zum Weltkrieg*, 3 vol. (1927–31; Eng. trans., *A Cultural History of the Modern Age*, 3 vol., 1930–32, reprinted 1952–54), is uneven in pace but full of brilliant insights. G.M. YOUNG, *Victorian England* (1936), paints the portrait of an age. JACQUES BARZUN, *Darwin, Marx, Wagner*, rev. ed. (1958), takes up more than the three figures named and outlines the thought of mid-century Realism and of its critics. HOLBROOK JACKSON, *The Eighteen Nineties* (1913, reprinted 1971), is lively and comprehensive, but should be read in conjunction with ARTHUR SYMONS, *The Symbolist Movement in Literature* (1899, reprinted 1971). For a 19th-century view of the literature the century itself produced, GEORG BRANDES, *Hovedstrømninger i det 19de Aarhundredes Litteratur*, 6 vol. (1872–90; Eng. trans., *Main Currents in Nineteenth Century Literature*, 6 vol., 1901–05), is unsurpassed and may be supplemented by PAUL MILIUKOV, *Outlines of Russian Culture*, pt. 2–3 (1942; orig. pub. in Russian, 1898–1903). For all scientific subjects the best synthesis will be found in WILLIAM DAMPIER, *A History of Science and Its Relations with Philosophy and Religion*, 3rd ed. rev. (1942), but can be usefully supplemented by the brief essay by J.D. BERNAL, *Science and Industry in the Nineteenth Century* (1953); and two books by BANESH HOFFMANN: *The Strange Story of the Quantum*, 2nd ed. (1959), and *Einstein* (1972). JOHN BOWLE, *Politics and Opinion in the Nineteenth Century* (1954), offers a careful survey, the reading of which should be followed by H. STUART HUGHES, *Consciousness and Society: The Reorientation of European Social Thought, 1890–1930* (1958); FRITZ STERN, *The Politics of Cultural Despair* (1961); and JOSE ORTEGA Y GASSET, *La Rebelión de las Masas* (1930; Eng. trans., *The Revolt of the Masses*, 1932). On the earliest influences on Romanticism, see A.M. OSBORN, *Rousseau and Burke* (1940); A.B. COBBAN, *Edmund Burke and the Revolt Against the Eighteenth Century*, 2nd ed. (1960); E.H. WRIGHT, *The Meaning of Rousseau* (1929, reprinted 1963); and the symposium by PIETER GEYL, *Napoleon, voor en tegen in de franse geschiedschrijving* (1946; Eng. trans., *Napoleon, For and Against*, 1949). For studies of writers and their contribution to the modern temper, see ERICH HELLER, *The Disinherited Mind*, 3rd ed. (1971); WALTER SOKEL, *The Writer in Extremis* (1959); and KARL LOWITH, *Von Hegel zu Nietzsche*, 3rd ed. (1953; Eng. trans., *From Hegel to Nietzsche*, 1964). Three overlapping but diversely oriented surveys of the period since the 1880s are G.P. GOOCH, *A History of Our Time, 1885–1914*, 2nd ed. rev. (1946); FELIX GILBERT, *The End of the European Era: 1890 to the Present* (1970); and J. KIM MUNHOLLAND, *Origins of Contemporary Europe: 1890–1914* (1970). For the plastic arts, see BERNARD S. MYERS, *Modern Art in the Making* (1950); WYLIE SYPHER, *Rococo to Cubism in Art and Literature* (1960); and JOHN GOLDING, *Cubism* (1959). On music, the most compact and stimulating single volume is CECIL GRAY, *The History of Music*, rev. ed. (1947), to be followed by his essays on modern composers in *Predicaments; or, Music and the Future* (1936) and *A Survey of Contemporary Music*, 2nd ed. (1929). CONSTANT LAMBERT, *Music Ho!* (1934), adds valuable interpretations as does ANDRE HODEIR, *La Musique depuis Debussy* (1961; Eng. trans., *Since Debussy*, 1961), for the ensuing period. For the philosophic and social ideas underlying the culture of the last hundred years, see A.C. MCGIFFERT, *The Rise of Modern Religious Ideas* (1915); and the two anthologies: WALTER KAUFMANN (ed.), *Existentialism from Dostoevsky to Sartre* (1956); and D.O. WAGNER (ed.), *Social Reformers*, rev. ed. (1941). Interpretations from various points of view are found in GERALD HEARD, *Morals Since 1900* (1950); A.N. WHITEHEAD, *Science and the Modern World* (1926); LLOYD R. MORRIS, *William James: The Message of a Modern Mind* (1950); NIKOLAUS PEVSNER, *Pioneers of Modern Design, from William Morris to Walter Gropius*, rev. ed. (1964); CAROLINE PLAYNE, *Society at War* (1931); ARTHUR MARWICK, *The Deluge: British Society and the First World War* (1965); and COLIN WILSON, *The Age of Defeat* (1959). In addition, two important collections, *The Popular Arts*, ed. by IRVING and H.A. DEER (1967); and *Modern Culture and the Arts*, ed. by J.B. HALL and BARRY ULANOV (1967), contain the views of some 75 writers, painters, musicians, and critics on their several disciplines and the present state thereof.

European Diplomacy and Wars (c. 1500–1914)

This article is intended to provide a broad narrative of the diplomatic and military history of Europe from the beginnings of the European state system at the end of the 15th century to the outbreak of World War I in 1914. The end of the 15th century roughly marks the transition of Europe from a congeries of petty feudal interests under the theoretical rule of the Holy Roman emperor and the pope into a system of competing sovereign nation-states. Henceforth, relations between the nations of Europe must be seen through a prism of constantly shifting national alliances entered into for fear that one nation might become too strong and upset the "balance of power." For nearly four centuries concern for the preservation of the balance of power engendered an almost endless series of European wars. But that concern also exerted a restraining influence that kept the

states of Europe from complete mutual destruction. Indeed, between 1500 and 1914 Europe achieved a mastery over the globe. In 1914 the tension of the balance-of-power system exploded in fratricidal war. The period of European hegemony came to a close, and the European focus of balance-of-power wars and diplomacy gave way to international relations on a world scale.

This article is divided into the following sections:

I. About 1500–1648
The Italian wars, 1494–1516
The struggle between the Habsburgs and the French
Religious wars and dynastic struggles prior to the Thirty Years' War
II. 1648–1814
Europe after the Thirty Years' War
The Age of Louis XIV
Peace and war, 1713–89
The French Revolution and Napoleon
III. 1815–1914
The Age of Metternich and the challenge of 1848
Revision of the settlement of Vienna
The impact of economics on politics
The Bismarckian period, 1870–90
The new imperialism
The German challenge

I. About 1500–1648

THE ITALIAN WARS, 1494–1516

The advent of the balance of power. Between the onset of invasion of Italy in 1494 by King Charles VIII of France and the advent of general peace in 1516, a great political revolution occurred in Europe: the transfer of the balance-of-power system in Italy to all Europe. Since the mid-15th century, a balance of power had been established among the five large Italian states that sought to dominate the peninsula—the Venetian Republic, the duchy of Milan, the Republic of Florence, the Papal States, and the Kingdom of Naples. With the creation of the Venetian League in March 1495 against France, this system of political equilibrium became a European-wide system—one that was to last for four centuries.

The balance-of-power system was first defined by the Venetian Humanist Francesco Barbaro in 1439 and was further discussed by the Florentine historian and statesman Francesco Guicciardini in the early 16th century. Italian metaphors found entrance into the diplomatic language of Europe: "balance of power," "equilibrium of forces," "equal balance of powers," "counterweight of forces"—all metaphors deriving from the use of scales.

The system was based on recurring patterns of political behaviour. Whenever one state threatened to become too powerful, the other states formed a coalition to topple it. Thus, governments worried not only about neighbouring countries with common borders but also about distant states, the progress of which made them potentially dangerous, even in the remote future. States claimed the right to intervene either in disputes between two or more states or within each state to support a given political or religious party against the government of that state. It therefore became necessary to know at every moment the intentions and available strength of each government. Toward that end, the states of Europe began to send permanent ambassadors abroad—a Venetian custom imitated throughout Europe. These ambassadors, together with their hosts of secretaries and agents, bribed statesmen and civil servants, hired informers, supported opposition groups, organized conspiracies; in short, they were privileged spies. To lessen the chance of war, the states tacitly agreed upon a number of rules that, in time, came to be considered international law. To re-establish the balance of power, reversals of alliances became commonplace.

The growth of formal diplomacy

The medieval concept of a united and stratified Christian Europe ruled from on high by the pope and the Holy Roman emperor gave way to the idea of a system of states based on the principle of equal rights. These rights formed "the freedoms of Europe." They did not, however, create a politically united Europe. They simply meant, in law, the independence of each state and, in fact, the opportunity for the stronger states to dominate the weaker ones.

The great powers and Italy. From 1494 to 1516 Italy became the battleground of Europe. All the great powers of Europe had interests in Italy. In 1486 the Habsburg Maximilian I of Austria ("king of the Romans," *i.e.*, the emperor-elect of the Holy Roman Empire), possessor of Austria, Styria, Carinthia, Carniola, the Tirol, Trieste, Vienna, and the city of Trent, wanted control of the Alpine valleys that opened onto the Adriatic and the Po Valley. He dreamed of receiving the imperial crown in Italy from the hands of the Pope and of joining northern and central Italy (including the Papal States) to the empire.

Ferdinand II the Catholic, king of Aragon, held Sardinia and Sicily, and the western Mediterranean was virtually a Catalonian lake. As a kinsman of King Ferrante of Naples, an Aragonese, Ferdinand had rights to the Kingdom of Naples. The Spaniards—Aragonese as well as Castilians—enjoyed a privileged position in Italy, thanks to their influence with the Pope; and many Spaniards were appointed bishops or government officials in Italy, thus paving the way for Spanish penetration.

The Swiss Confederation, too, sought to control the approaches to the Alpine passes, particularly those leading toward the states of Milan and Venetia, in one direction, and toward Burgundy, in the other. The Swiss peasants were formidable soldiers; their armies of pikemen and harquebusiers (musketeers), their light artillery, which they used in combination with infantry, and their battle formations of compact squares had revolutionized military tactics in the late 15th century. The Swiss victory over Charles the Bold, duke of Burgundy, in 1476–77 marked the beginning of the end of the dominance of heavily armed cavalry.

Swiss military tactics

The French, also, had diverse interests in Italy. The House of Anjou had laid claim to the Kingdom of Naples since 1266, when Charles of Anjou, brother of King Louis IX, had conquered the kingdom. Charles was expelled by the Aragonese in 1282, but the Angevins kept trying to re-establish their authority. In 1398 Louis, duc d'Orléans, brother of King Charles VI of France, married Valentina Visconti, daughter of Gian Galeazzo Visconti, duke of Milan. By this marriage the Orléans family inherited rights to the Duchy of Milan. The Sforza family had usurped power in Milan, but the House of Orléans had not renounced its heritage. King Charles VI had purchased Genoa in 1396. The kings of France continued to be protectors of the Genovese Republic and acted as mediators between the Genovese and their enemies. They had given Genoa to the Sforzas on condition that the latter remain vassals. The kings of France were also protectors of the Duchy of Savoy in order to assure free transit from Italy to France through the Alpine passes. At the same time, however, they also protected the Marquis of Saluzzo and the Marquis of Montferrat against the power of the Duke of Savoy.

The Italians did not resent these foreign intrusions into their affairs. They were accustomed to them and were even glad to call upon the help of their powerful neighbours to the north. Despising these "barbarians," the Italians felt that with their political adroitness they could always make use of the foreigners. But a great change had occurred without their realizing it: by the end of the 15th century, the great powers of Europe had become national states, the territories, resources, and internal unity of which far exceeded those of the regional states of Italy. What is more, those states had terminated their far-flung civil and foreign wars. France had put an end to the Hundred Years' War (1337–1453) against England, the Burgundian Wars against Charles the Bold, and the internal wars against the insurgent barons. Spain, unified by the marriage of King Ferdinand of Aragon and Queen Isabella I of Castile, had finally expelled the Moors from the country by conquering Granada in 1492. Now the great powers were capable of acting effectively in Italy.

Charles VIII's invasion of Italy. Charles VIII, at the head of his army, left Lyons for Italy on July 27, 1494.

Some historians claim that he was forced to invade the Italian peninsula by compelling economic interests in his own kingdom. In point of fact, the young king of 22, an avid reader of romances of chivalry, dreamed of the glory of the knights errant and of a crusade against the infidel, as well as of the riches of the Orient. Charles's invasion of Italy in support of the ancient Angevin interests was, in Charles's eyes, merely the first step in the launching of a great crusading venture. By yielding the conquests of his father, Louis XI, Charles had obtained the neutrality of the great powers. He returned Artois to Maximilian of Austria, heir of Mary of Burgundy, gave back Roussillon and Cerdagne to Ferdinand of Aragon, and gave large sums of money to King Henry VII of England.

Dissension among the Italian states and internal squabbles of their political parties accomplished even more than the French army's obvious superiority in heavy attack cavalry and siege guns to afford Charles VIII an easy passage through Italy. He took Florence, Rome, and, finally, Naples on February 22, 1495. The King entered the city bearing the imperial globe, the symbol of imperial authority, inscribed with the titles "king of Sicily and of Jerusalem" and "emperor." Though the inscription referred to the Byzantine Empire, all Europe took it to mean the Holy Roman Empire. The kings grew uneasy. The Germans were offended, inasmuch as they had had custody of the Holy Roman Empire ever since the time of Otto I (960). Ferdinand of Aragon was fearful of Sicily's fate and worried also about his rights to Naples.

Formation of the Holy League

Hence, on March 31, 1495, the Venetians, Maximilian I, Ferdinand of Aragon, Ludovico Sforza "the Moor" (duke of Milan), and Pope Alexander VI formed the Holy League (Venetian League) in order to restore peace and Italian independence. The League was the first coalition to maintain the balance of power in Europe. The allies massed an army. Since the person of the king of France embodied the nation, Charles VIII had to be brought to safety. Leaving an army in Naples, he began a homeward retreat. At Fornovo di Taro (July 6, 1495), Charles fought off the League's army, which strove to cut off his retreat as he crossed the Apennines. The Marquis of Mantua, general of the League, claimed victory. Charles VIII, however, returned to Lyons on November 7, 1495.

Gilbert, comte de Montpensier, whom Charles had left in command at Naples, had to fight on three fronts: against the Aragonese army led by a general of genius, Gonzalo Fernández de Córdoba (El Gran Capitán); against the Neapolitan barons; and against the common people of Naples. The French won all the pitched battles, but guerrilla warfare tore them to shreds. In June 1496 the remnants of the French army surrendered at Atella. The King of Naples returned to his kingdom, and Charles VIII signed a truce with Ferdinand. Soon thereafter, in 1498, he died accidentally.

Louis XII's invasion of Italy. His successor, Louis XII, was of the House of Orléans. On his accession to the throne, he assumed the titles of king of France, king of Naples, and duke of Milan. Since Ferdinand and Maximilian had been the winners against Charles, Louis XII soon formed allies to restore the balance of power. He came to an understanding with Pope Alexander VI, who did not relish the Spanish inroads into Italy. Louis XII married off the Pope's son Cesare to Charlotte d'Albret, whose father disputed Ferdinand of Aragon's right to the Kingdom of Navarre; Cesare was made duke of Valentinois and a *grand seigneur* ("great lord") of France in 1499.

Louis also made an alliance with the Swiss, who then were at war with Maximilian of Austria. At Lucerne, in 1499, the Swiss gave him permission to recruit from their infantry, the best in Europe. Louis next entered into an alliance with Venice, enemy of the Sforzas who, in turn, were vassals of Maximilian, and even with Philip I the Handsome, son of Maximilian, and the duke of Burgundy (who now ruled over the Low Countries), as well as with Henry VII of England.

Louis retook Milan and captured its Sforza ruler Ludovico (il Moro) at Novara (1500), sending him as a prisoner to France, where he died in 1508. Louis XII initiated the organization of the duchy of Milan as if it were a French province. He thought he would achieve a political master stroke by sharing the Kingdom of Naples with Ferdinand of Aragon. Together, their armies conquered the kingdom; the King of Naples was taken prisoner and sent to France. At the same time, Louis sent a fleet into the Aegean to launch a crusade against the Turks.

With the death of Pope Alexander VI in 1503, Louis XII's chief minister, Bishop Georges d'Amboise, posed his own candidacy for the papacy. The election of d'Amboise however, would have put the French in too strong a position, and the majority of the cardinals voted at first for Pius III, who died 22 days later. The cardinals then elected Giuliano della Rovere, who became Pope Julius II (1503).

At that moment, Ferdinand of Aragon, no longer worried about the Aragonese of Naples, thanks to his collaboration with Louis XII, broke with the latter. D'Amboise kept the French relief army too long in Rome to back his papal candidacy. The Aragonese navy controlled the sea, preventing the French troops in Naples from receiving provisions. Gonzalo Fernández de Córdoba instituted military reforms in Naples that led to the formation of *tercios*, or infantry regiments. The French lost Naples in 1503. By March 1504 the Spaniards had taken the whole Kingdom of Naples.

French loss of Naples

Against the victorious Spaniards, Louis XII now tried to reverse alliances by making an agreement with Maximilian I. By the three treaties of Blois, Louis was to marry off his 18-month-old daughter, Claude de France, to the future emperor Charles V, then only 12 months old, who was the grandson of Maximilian and the son of Philip the Handsome and Joanna the Mad. Claude's dowry was to comprise the French provinces of Brittany, Burgundy, the county of Blois, the duchy of Milan, and the Kingdom of Naples. If Louis XII should produce no sons, all these territories would ultimately remain with Charles.

The King's council, refusing to sanction this act of folly, forced the King to sign a will in May 1505 whereby his daughter would marry François d'Angoulême, the future Francis I. In May 1506 Louis summoned the States General of the Realm. The latter insisted on the proposed marriage with d'Angoulême "because Monsieur François is completely French." As a result, the Blois treaties were broken.

The coalition against France. Pope Julius II sought to humble Venice, which was expanding at the expense of the Papal States, and then to expel all foreign powers from the peninsula. Julius formed the League of Cambrai (March 1508), which was ostensibly directed against the Turks but was in reality aimed against Venice. Joining the League were Ferdinand of Aragon, Emperor Maximilian, Henry VII of England, and, to the surprise of everyone, Louis XII, who turned against his Venetian allies because they had been delinquent in carrying out the agreements of 1499.

It was Louis himself who pulled the chestnuts out of the fire for the coalition. The French army defeated the Venetians at Agnadello in 1509; Venice gave back to the Pope the towns in Romagna it had seized. Then, on October 4, 1511, the Pope formed the Holy League against France, with Venice, Spain, and the Swiss led by Matthäus Schiner, cardinal of Sion. The Swiss, eager to acquire the Duchy of Milan, felt that Louis XII was not paying them enough and was not taking their interests sufficiently into account. Although an outstanding French general, Gaston de Foix, won several victories, notably at Ravenna on April 15, 1512, the Swiss attack against the French lines of communication forced the French army to retreat.

Then, exploiting religion for political ends against the Pope, Louis XII forced the convocation of an "ecumenical" church council at Pisa. Pope Julius II was ordered to appear before the council to be tried as an enemy of

Christianity. On April 21, 1512, the council suspended Julius from his holy office. Julius countered by summoning another council at the Lateran on April 19, 1512. This council declared that the pope alone could call an ecumenical council.

Julius excommunicated those who claimed that such a council had higher authority than the pope. He condemned the Gallican religious articles of the Kingdom of France, which were embodied in the Pragmatic Sanction of Bourges (1438). At this juncture Pope Julius II died, in February 1513. The French were driven out of Italy, but the other "barbarians" remained. The Spaniards dominated the Italian peninsula. Contrary to his own intentions, Julius II had worked for them.

Spanish control of Italy

Louis XII remained isolated against the coalition. The Swiss gained a decisive victory over the French at Novara (June 1513). They then invaded Burgundy and laid siege to Dijon. The English, in turn, landed at Calais in July 1513, but the distance involved made it difficult to supply their armies. The belligerent powers negotiated. Louis XII, a widower, married the young Mary Tudor of England (October 1514) but died on January 1 of the following year.

The various kings were short of money and none felt like fighting for the Swiss or the Spaniards. Louis XII's successor, Francis I, was therefore able to break up the coalition. He bought peace with England and negotiated the betrothal of Louis XII's second daughter Renée to young Charles of Austria, duke of Burgundy, who had just come of age. Francis renewed his alliance with the Venetians and was able to defeat the Swiss at Melegnano (September 13–14, 1515). The League powers were forced to negotiate. Pope Leo X, a Medici, proffered Francis an alliance with Florence (October 1515) and signed the Concordat of Bologna with him (August 18, 1516). Charles, having become King of Spain by the death of Ferdinand of Aragon, concluded the Treaty of Noyon (August 13, 1516): by its terms, Francis I renounced all his rights to Naples in favour of his infant daughter Louise, who was betrothed to Charles. In November 1516 Francis I made a "lasting peace" with the Swiss, which gave him the right to recruit soldiers in the Swiss cantons. By the Treaty of Brussels (December 1516), Maximilian returned all his conquests to the Venetians. By the Treaty of Cambrai (March 1517) between Francis, Maximilian, and Charles, the powers agreed to settle their differences and to undertake a crusade against the Turks.

The Treaty of Cambrai

The effect of the Italian Wars on Europe. With the signing of these treaties the Italian Wars had, in effect, come to an end. They had been decisive for Europe. Policy had expressed and strengthened a change in human attitudes: the natural laws emanating from God were forgotten; the specific laws described in the Old and New Testaments were neglected. Foreign policy henceforth took into account only the desire for domination and, to satisfy it, only the most effective means, whatever those means might be. The shifting relationship of forces was constantly under assessment. The Italian Wars had exposed to broad daylight the ruin of European unity and the division of Europe into jealous, antagonistic states and nations, each striving its utmost to gain pre-eminence in Europe. These wars had transferred the pattern of Italy to that of Europe as a whole: instead of a Christian republic under the jurisdiction of emperor and pope, there now came into being a system of states in balance, with equality and freedom, in principle, but, in fact, the freedom of the strong to dominate the weak. Europe still had a chance for unity in its adherence to a universal church, which might serve as a rallying point for a crusade against the Turks. But, within a generation after the Treaty of Cambrai, the unity of Christian Europe was permanently shattered by the Protestant Reformation, which completed the division of Europe along religious and ideological lines (see REFORMATION).

THE STRUGGLE BETWEEN THE HABSBURGS AND THE FRENCH

During the turbulent period from the imperial election of 1519 to the Peace of Cateau-Cambrésis in 1559, the House of Austria and the House of France contended for mastery of Europe. In the course of this struggle, the King of France—at first the weaker contestant—sought help against the Emperor from the Protestant princes of Germany and even resorted to an alliance with the infidel Turks. As a result, the last chances for the achievement of European unity were shattered, and the subsequent European balance of power was built on the divisions of Europe.

The election of Charles V. Maximilian of Austria, king of the Romans, died on January 12, 1519. According to the Golden Bull of 1356, his successor was to be chosen by seven Imperial electors: three of them ecclesiastics, the archbishops of Mainz, Trier, and Cologne; and four of them secular rulers, the Count Palatine of the Rhine, the Duke of Saxe-Wittenberg, the Margrave of Brandenburg, and the King of Bohemia. Since 1438 the emperors had been chosen from the House of Habsburg, and it seemed only natural that Maximilian I's grandson Charles of Ghent (duke of Burgundy [1506], king of Spain [1516], and archduke of Austria [1519]) should be elected.

From 1516 onward, however, King Francis I of France was also a candidate for accession to the imperial throne. He was acting in accordance with an old French tradition. Since the time of Philip the Fair (reigned 1268–1314), the kings of France had proclaimed themselves emperors in their own kingdom and had laid claim to imperial privileges (1302), and a long succession of French princes had been candidates for the imperial throne. In the late 15th century Louis XI had emphasized the sacred and "imperial" nature of French royalty and had made the cult of Charlemagne compulsory in France, declaring January 28, the date of Charlemagne's death in 814, a national holiday. But Francis I had another reason for his candidacy: if Charles of Ghent, whose possessions already ringed France, were elected emperor, his enormous power would threaten the very existence of the French kingdom.

The election of 1519 gave rise to much hard bargaining, in the course of which both Francis I and Charles bribed the electors. But German national sentiment ran strongly against Francis, who was unable to gain the support of the Fuggers, the leading family of bankers of Germany. Instead, the Fuggers lent large sums of money to Charles. Francis then promoted the candidacy of a German, Frederick of Saxony, head of the opposition to the Habsburgs. But Francis's action was too late. Though Frederick was elected unanimously on June 27, 1519, he abdicated three hours later, after being intimidated by a pro-Habsburg army that had surrounded the electoral hall. On the following day, Charles was elected Emperor Charles V.

Charles V—sober, lonely, introspective, and religious—took seriously his duties as emperor and as heir to the House of Burgundy. He considered himself superior to the kings and princes of Europe, whose policies he continually tried to control. Moreover, he believed that, as their commander in chief, he was to lead the armies of Europe in a crusade against the heathen, especially the Turks. On the other hand, his duty as head of the Holy Roman Empire was to restore its territorial integrity—to regain the territories that had previously belonged to it but that had been torn away during earlier struggles for power. Among these were several French provinces: the Dauphiné, Provence, Burgundy, Flanders, and the Duchy of Milan.

Charles's Burgundian inheritance

As heir to Mary, duchess of Burgundy and wife of Emperor Maximilian, Charles also inherited the vast Burgundian realm once ruled over by John the Fearless, Philip the Good, and Charles the Bold—"the grand dukes of the west." Much of Burgundian inheritance had been lost to Louis XI of France at the end of the 15th century, but Charles V considered it an act of reverence to his lineage to claim the entire Burgundian inheritance, which included Franche-Comté and the Duchy of Burgundy, Flanders, Artois, and the towns on the Somme River (at that time France's strategic boundary). Charles

V found himself in a strong position to wrest territory from France. With installations in several Alsatian territories, in Franche-Comté, and in Spain, he had begun the encirclement of France.

The contest between Charles V and Francis I. As France and the empire prepared for war, both wooed the English, who could prove a powerful ally: the English had extensive commercial ties with Flanders and supplied wool for the Flemish cloth industry; as masters of Calais, the English controlled the entry into France. Francis I, moreover, had aroused the jealousy of King Henry VIII of England by the lavishness of his entertainment at the meeting of the two sovereigns on the Field of Cloth of Gold in 1520. Henry therefore allied himself with Charles and in 1522 invaded Boulogne and Picardy and even threatened Paris. Charles also received the support of the Pope, who sanctioned the restoration of the Kingdom of Naples to the imperial crown because of Charles's active support of the Roman Church against the Reformation. (In 1521, at the Diet of Worms, Charles banished Luther and his followers from the Holy Roman Empire, ordering governing authorities and theological schools under their jurisdiction to approve all writings bearing on the Catholic faith.) Before the close of 1521 Charles had seized Tournai and his generals had reconquered the Duchy of Milan. Charles V claimed the Duchy of Burgundy and, in his will of May 22, 1522, asked that he be buried in the Carthusian church at Dijon beside the dukes of Burgundy who had gone before him. To focus his efforts more effectively, he entrusted his brother Ferdinand with the Austrian territories of the House of Habsburg.

In 1523 Charles V negotiated an alliance with Francis I's chief vassal, the Constable of Bourbon, seigneur of central France. In 1524 the Constable invaded Provence and laid siege to Marseilles in order to ensure connections between Aragon and Italy. His defeat and subsequent retreat allowed the French to reoccupy Milan and besiege Pavia. Called upon for help, the imperial army routed the French at Pavia on February 24, 1525, and took Francis I prisoner.

French defeat at Pavia

Contrary to Charles V's expectations, France did not collapse. Francis' mother, Louise of Savoy, together with the King's council, maintained order, saw to it that the armies were paid, and kept up the resistance. Charles's victories had upset the balance of power, and the states of Europe turned against him. Pope Clement VII, the Venetians, and Henry VIII of England signed with the French a first treaty of alliance, the Treaty of Moore, in August 1525. In Germany Charles V was unable to enforce the edicts of Worms or of Nürnberg (1522). He made preparations for the Diet of Speyer, scheduled for 1526. But the outlook seemed unfavourable inasmuch as he needed the votes of the Lutheran cities and Lutheran princes John of Saxony and Philip of Hesse for his proposed war against the Turks, who, under Süleyman the Magnificent, were readying an invasion of Hungary. Thus, on January 14, 1526, Charles V signed the Treaty of Madrid with Francis I. By that treaty Francis I was to "restore" Burgundy and its dependencies to Charles V, renounce all rights to Naples, Milan, Asti, and Genoa, relinquish his suzerainty over Flanders and Artois, pardon the Constable of Bourbon and his supporters, provide the Emperor with a fleet and an army for his coronation at Rome and his crusade, marry Charles V's sister Eleanor, assume all of the Emperor's financial obligations to Henry VIII of England, swear to keep his pledges on his honour as king and knight and on his faith as a Christian—and also leave as hostages the two sons he had had by Claude of France: the nine-year-old dauphin and the four-year-old Charles, duke of Orléans.

On March 17, 1526, Francis I left Spain. As early as January 13 he had sworn before a notary that he had signed the Treaty of Madrid under duress, and he declared it null and void. He asserted that he did not have the right to dispose of the Duchy of Burgundy without the consent of that province. The deputies of Burgundy, who visited the King at Cognac, protested that he could not part with his domains, and they wished to remain obedient subjects of the French crown. On May 22, 1526, Francis I formed the League of Cognac with the Pope, the Venetians, and the leading Italian princes. He renewed relations with the English. He also inaugurated a policy that envisaged striking at the Habsburgs from the rear. He entered into negotiations with Sigismund I, king of Poland, and John (János) Zápolya, voivode (governor) of Transylvania. Then, shutting his eyes to deep-seated differences in religion and culture, he took the unusual step of negotiating with the Muslim leader of Bosnia, to induce the latter to invade the Habsburg territories of Styria and Carniola in the Balkans. Finally, he made an alliance with the Ottoman sultan Süleyman. The latter, after capturing Belgrade in 1521, advanced into Hungary. He won the Battle of Mohács, where the Hungarian king Louis died in combat, and attacked Vienna, although without success (1529). Charles V's brother Ferdinand was elected king of Hungary by one Hungarian diet; but another Hungarian diet named Francis I's ally John Zápolya.

Charles V's situation was in jeopardy. His army, commanded by the Constable of Bourbon, had taken Rome, where the Constable was killed (May 6, 1527). The Emperor's Lutheran mercenaries had looted and pillaged the world capital of Christendom. Thereupon, Henry VIII and Francis I declared war on the Emperor (January 23, 1528). Charles V, outraged by what he considered treachery on the part of Francis, challenged him to a duel. The French invaded Milan and Naples. But Francis could not pay a high enough price for Andrea Doria's Genovese fleet, which went over to Charles V. Soon lack of money forced the two monarchs to negotiate. Margaret of Austria, the Emperor's aunt, and Queen Mother Louise of Savoy arranged the so-called "Ladies' Peace," the Treaty of Cambrai on August 3, 1529. The Treaty of Madrid was confirmed but its terms were softened. The French retained Burgundy, the cities on the Somme, and the counties of Guines and Ponthieu—that is, a protective screen for Paris. Francis granted the County of Charolais to the Emperor for life. He promised gold *écus* (crowns) to get back his children, who were returned to France in July 1530. He married Eleanor.

The "Ladies' Peace"

Charles V, in turn, renounced his Burgundian dream but remained, nevertheless, the leading monarch of Europe. He was master of Italy, where he maintained a secure hold over the territories of Milan and Naples. In Florence, Alessandro de' Medici was restored by Charles as ruling duke and made to marry the Emperor's illegitimate daughter Margaret. Thenceforth, Alessandro became one of his faithful followers. On February 22, 1530, Charles V had received the iron crown of the Lombard kings and two days later, on February 24, he had been crowned emperor by the Pope. On January 1, 1531, the Augsburg Diet, at his bidding, elected his brother Ferdinand as king of the Romans. Thus, he could pursue his dream of forcing the King of France into submission.

French anti-Habsburg alliances. Faced with this threat, Francis I negotiated feverishly with all those opposed to the Emperor. Appealing to the concept of the balance of power in Europe, Francis gradually outlined a policy of protecting Europe's "liberties" against the Emperor—a policy that was to become a constant in the policy of the French kings until the time of Louis XIV. Francis first came to terms with Henry VIII of England, who was hoping to annul his marriage to Catherine of Aragon and wed Anne Boleyn. Henry, needing Francis' backing in dealing with Pope Clement VII, signed the Treaty of Boulogne (October 20, 1532) with Francis, ostensibly against the Turks. The Anglo-French alliance deteriorated, however, when Henry VIII cut the Gordian knot, marrying Anne Boleyn and proclaiming a national church separate from Rome.

The Treaty of Boulogne

For his part, Francis I came to an agreement with the Lutheran princes of Germany. At the Diet of Speyer in 1529, the Lutherans had protested against the imperial decree of April 29, 1529, which guaranteed the Lutherans the principle of "*cujus regio, ejus religio*" (*i.e.*, the religion of a region or city would be that of its prince or municipality) but with tolerance for the Catholics. The

Lutherans did not want tolerance. On June 25, 1530, they presented to the Augsburg Diet their "Confession of Faith" approved by Luther—the Augsburg Confession. It had been signed by the elector John of Saxony, his son John Frederick, George, margrave of Brandenburg-Culmbach, Francis and Ernst, dukes of Brunswick-Lüneburg, Philip, landgrave of Hesse, Prince Wolfgang of Anhalt, and the delegates from the free cities of Nürnberg and Reutlingen. At the end of December 1530, the Protestant princes, together with 15 free cities, formed the Schmalkaldic League and took up arms against the Emperor. The Protestants looked to support from England and France. Charles V tried concessions to his traditional enemies and persuaded the Pope to summon a general church council. Several treaties that Francis I signed with the Protestants enabled him to recruit Protestant mercenaries, who were first-rate soldiers. But he could not derive maximum advantage from this alliance because of his suspicions vis-à-vis the French Protestants, his understanding with the Pope, and his alliances with the Turks.

Francis I also sought an alliance with the Medicis, who controlled the strategic Florentine seaports on the route of the Spanish galleys. Pope Clement VII, also a Medici, was seeking a royal marriage for his niece Catherine. An interview at Marseilles between the Pope and Francis led, on October 28, 1533, to the marriage of Prince Henry and Catherine de' Médicis.

Francis I and Charles V both sought alliances with the Muslims. In 1529 Charles V sent Jean de Baldi to Persia to try to provoke a Persian invasion of the territories of Süleyman the Magnificent. Charles had also tried to make an alliance with Moulay Ḥasan Agha, king of Tunis. Francis, on the other hand, strove above all to forge an alliance with Süleyman, who possessed the best army and best galley fleet in Europe. His armies could take Vienna—and thus the Holy Roman Empire—from the rear. His fleets could ravage the coasts of Italy and, above all, cut Charles V's lines of communication in the western Mediterranean.

The core of Charles V's armies was made up increasingly of Spanish soldiers. His navy consisted mainly of unseaworthy galleys that had to stick closely to the coasts. The best method of bringing Spanish troops into Italy, Burgundy, and Flanders was by way of Barcelona to Genoa, thence through Milan, the Alpine passes, Savoy, Franche-Comté, and Lorraine or, alternatively, via the St. Gotthard Pass, the Rhine Valley, and the principality of Liège. If the Barcelona–Genoa route were cut—an easy feat for the French with their bases on the shores of Provence—then reinforcements would have to journey along the coast of North Africa and then up the west coast of Italy.

Franco-Turkish Alliance

Francis therefore tried for an Ottoman alliance with Süleyman. The Sultan had appointed as admiral (captain pasha) the Algiers pirate Barbarossa (Khayr ad-Dīn). The latter was plundering the coasts of Spain and had seized Tunis in 1534, from which he threatened Malta, Sicily, and the Kingdom of Naples. In 1535 Charles V recaptured Tunis and installed a Moorish king there as his vassal. But in the process he had freed 20,000 Christian prisoners and had thus retained his lustre as head of Christendom against the infidels. Then, Francis I endeavoured to send Barbarossa against Genoa, and in February 1536 he signed a trade agreement with Süleyman that gave France commercial mastery in the Near East. Thereupon, Charles V invaded Provence and attempted to take Marseilles to keep open the Barcelona–Genoa route. As Charles advanced, the French laid waste to the country. Hunger and disease decimated Charles' army, forcing him to withdraw in late summer 1536. The French armies occupied Savoy and Piedmont and treated them as French provinces. Barbarossa, after occupying Bizerta, ravaged the Adriatic. Süleyman threatened Italy. Charles V was forced to come to terms with Francis.

Pope Paul III intervened to unite all the Christian forces against the Turks. On July 14, 1538, the two monarchs restored friendly relations at Aigues-Mortes, where they feasted together with a great show of amity and reconciliation. Charles then passed through France to repress the rebellious people of Ghent. In early January 1540 he stopped at Paris, where he was entertained lavishly.

A condition of the agreement between Charles V and Francis I was that the latter's second son, the Duke of Orléans, marry the Emperor's daughter Maria and receive the duchy of Milan as a fief from the Emperor. The territory of Milan, however, was indispensable for the passage of Spanish troops, and in October 1540 the Emperor gave it as a present to the Infante Philip (later Philip II of Spain). Chagrined, Francis I again became Charles V's adversary. John Zápolya, who had died on July 22, 1540, had left behind an infant son. Ferdinand, the Emperor's brother, sought to exploit the situation by capturing Buda. Francis I aided Sultan Süleyman in the latter's efforts to make peace with Venice (October 1540). On July 30, 1541, Süleyman won a notable victory at Buda and conquered eastern and southern Hungary, while the Emperor failed in an attack against Algiers. On July 2, 1541, Francis I's envoy to Süleyman, Rincon, was assassinated in the Po Valley on orders of the Marchese del Vasto; a year later, on July 12, 1542, Francis I used this as a pretext to declare war. He had William of Cleves, duke of Cleves and Gelderland, and his allies—Denmark, Sweden, and Scotland—attack the Low Countries. But he made the mistake of diverting the main body of his forces against Perpignan, a town in southeastern France, near the Spanish border, where he suffered defeat. Charles V, triumphant in 1543, restored Gelderland and Zutphen to the Low Countries, where 17 provinces were made into one entity, and the Pragmatic Sanction of 1549 defined uniform rights of succession for the region. The Diet of Speyer (1544) with the Danes allowed the latter to levy tolls on ships passing through adjoining straits.

Barbarossa's Turkish fleet, joining with the French fleet, took Nice from the Duke of Savoy (August 1543). Toulon now became a base for the Turkish fleet, which launched assaults on the coasts of Spain and Italy but missed a chance to capture Genoa (1544). Süleyman welcomed the French fleet at Constantinople with great pomp. In Italy, the Duca di Enghien defeated the imperial troops at Ceresole in Piedmont (April 13–14, 1544). But Charles V invaded Champagne and, by way of the Marne, came as far as Château-Thierry, while Henry VIII besieged Boulogne and Montreuil with a view to marching on Paris by way of Saint-Quentin and the Oise. The French followed a "scorched-earth" policy of systematic devastation. The imperial army, short of food, had to retreat. Charles V left Henry VIII in the lurch and negotiated at Crépy (September 18–19, 1544). He gave up Burgundy. Charles, duke of Orléans, was to marry either the Emperor's daughter Maria, with the Low Countries and Franche-Comté as a dowry, or Ferdinand's daughter, with Milan as dowry. These were the "alternatives." Charles V was given four months to decide. Francis I was to give his son the duchies of Orléans, Bourbon, Châtellerault, and Angoulême as an appanage (*i.e.*, feudal grant for future inheritance), renounce his suzerainty over Flanders and Artois, and restore Savoy and Piedmont to their duke. But Charles V could not make up his mind. The duke of Orléans died in 1545, and the treaty lapsed.

Francis I next sent his Scottish allies against Henry VIII (who had captured Boulogne) and even attempted an invasion of England. Shortage of funds forced Henry VIII to negotiate. By the Peace of Ardres (June 7, 1546) Francis I had to promise to abandon his Scottish allies and pay 800,000 crowns over eight years for the return of Boulogne.

Like the rest of Europe, the German Protestants had been shocked by the alliance between the French king and the Ottoman sultan and were further disturbed by the reconciliation between the King and the Emperor and by the summoning in December 1545 of the Council at Trent, which called for the reform of the Roman Catholic Church and a new offensive against the Reformation.

The Council of Trent

The Protestants therefore offered to mediate between Henry VIII and Francis I. Francis and his second son, Henry, used the occasion to renew relations with the German Protestants. Charles V, however, banished the Landgrave of Hesse and the Elector of Saxony from the empire; and, with Ferdinand I, he sought forcibly to crush the Protestants who had banded together in the Schmalkaldic League. He negotiated with the Turks so that he could bring all his forces to bear against the rebels, who were now backed by the Czechs. Francis I made preparations to come to the aid of the insurgents, but he wanted Henry VIII's prior agreement. But the latter died in January 1547, and Francis himself died a month later. In April Charles V won the Battle of Mühlberg against the Schmalkaldic League, while Ferdinand I, for his part, crushed the Bohemian revolt. The Emperor was now able to assemble a Diet of Augsburg, which, on May 15, 1548, published the 26 articles of an "Interim" proclamation, which ran counter to the religious formulations established by the Council of Trent. Although the proclamation re-established church jurisdiction, worship of the saints, and the seven sacraments, it authorized communion in the two rites and marriage for priests—at least until a council could meet, the formulas of which the Emperor could accept. The Emperor was now at odds with the Pope on matters of discipline, not dogma, and he disavowed the council, which had moved to Bologna and then came to a halt (1549).

Flushed with victory, Charles V dreamed of restoring the hereditary imperial crown to his family. After lengthy family negotiations, it was decided in 1551 that, after Charles' death, Ferdinand I would become Emperor and would have the Infante Philip elected king of the Romans; the latter, in turn, would bring about the election of Ferdinand's son Maximilian, husband of one of Charles V's daughters and regent in Spain during Philip's stay in the Low Countries (1548–50). Thus, the imperial crown would pass alternately to the two branches of the Habsburgs.

But to the Protestants of Germany, the Augsburg Interim seemed to threaten "Germanic freedoms," and, when the Protestant city of Magdeburg was banned from the empire in 1549, they turned to the King of France as the "protector" of those "freedoms." The new French king, Henry II, had betrothed his son Francis to the six-year-old Mary Stuart, queen of Scots. Mary was also the niece of the powerful French Guise family, and the threat of a Franco-Scottish alliance compelled the new English king, Edward VI, to give Boulogne back to Henry II for a small sum. With peace with England assured, Henry II was able to lend his support to the German Protestants. After consulting among themselves, the German princes decided, on January 15, 1552, that Henry II should occupy the imperial cities Charles V might seize: Metz, Toul, Verdun, and others where German was not spoken. In these cities Henry II would act as agent for the empire, defending the latter's rights against the Emperor. Maurice of Saxony forced the Emperor to flee from Innsbruck. Henry II made the "Rhine journey," occupied Toul and Metz (April 10, 1552), reached the Rhine at Haguenau, then withdrew and entered Verdun on June 12. The "Three Bishoprics" were occupied. Charles V tried in vain to recapture Metz (autumn of 1552 to January 2, 1553), which was defended by François de Guise.

The Franco-Scottish alliance

In Italy, the town of Siena revolted against the imperial garrison on July 26, 1552, and received help from a French army. A Franco-Turkish fleet incited Corsica to rebel against the Genovese (1553). Siena was recaptured from the imperial armies in 1555 and annexed to Tuscany. In July 1554 Charles V had arranged the marriage of his son Philip to the new queen of England, Mary I, daughter of Catherine of Aragon and a Roman Catholic. By terms of the marriage agreement, the children of Philip and Mary were to inherit England, the Low Countries, and Franche-Comté, thus re-establishing the old Anglo-Burgundian alliance against France. The rest of the Spanish empire would revert to Don Carlos, Philip's son. If Don Carlos died childless, the son of Philip and Mary would inherit the entire Spanish empire. But, if Mary Tudor died childless, Philip would no longer have any ties with England; and on November 17, 1558, Mary Tudor died childless.

At this point, Charles V, ill and exhausted, sent his brother Ferdinand to represent him at the Diet of Augsburg, where Protestantism was established permanently in Germany. The treaty of October 3, 1555, between Catholics and Protestants officially recognized the existence of Lutheranism in Germany. Princes and cities could freely choose between Catholicism and Protestantism. But individuals had to follow the religion of their prince or local ruler: *cujus regio, ejus religio*. Under the principle of *reservatum ecclesiasticum* (retention of church rights), secular conversions of religious property made before 1552 remained in effect. Thereafter, any church beneficiary who adopted the Reformation had to restore the property he had acquired to the Roman Catholic Church. This was a decisive defeat for Charles V in his efforts to maintain religious unity in the empire and to wage the anti-Muslim crusade that might have become the basis for a united Europe.

The Diet of Augsburg, 1555

Abdication of Charles. The Emperor's policies had failed, and Europe was hopelessly divided. Charles V summoned the States General of the Low Countries at Brussels and abdicated before them as sovereign of the Burgundian territories in favour of his son Philip (October 25, 1555). At Brussels, too, he signed an act of abdication as king of Spain on January 16, 1556, yielding to Philip the crowns of Spain, Italy, and America. On February 5, 1556, he relinquished to Philip Franche-Comté and the Charolais region. On March 28, 1556, Philip was proclaimed king at Valladolid, Spain. Next, Charles renounced the hereditary possessions of the Habsburgs in Germany and the imperial crown (September 1556) in favour of his brother Ferdinand, king of Bohemia and Hungary. On February 3, 1557, he retired to Spain, in a palace he had built in Extremadura, close by the monastery of Yuste.

His imperial abdication was formally accepted on May 3, 1558, and Ferdinand became emperor. Charles died at Yuste on September 21, 1558.

RELIGIOUS WARS AND DYNASTIC STRUGGLES PRIOR TO THE THIRTY YEARS' WAR

Lines of communication between the Habsburgs. Emperor Ferdinand had inherited from Charles V most of the strategic entry points into central Europe (Alpine passes, Belfort Gap, Vienne Gap). From 1522 on, Ferdinand was in possession of the hereditary territories of the House of Austria: the duchies of Styria, Carinthia, Carniola, the Tirol, Freiburg im Breisgau, Sundgau in Alsace, and, in principle, a part of Switzerland: Constance, Lucerne, Thun, and Fribourg, gateways to the main passes. After 1526 he was made king of Bohemia and Hungary, which had not belonged to Charles V, and also margrave of Lusatia and Moravia.

Philip II, king of Spain, had received the Netherlands, Franche-Comté, Castile, Aragon, the Balearic Isles, Sardinia, Sicily, the Kingdom of Naples, the duchy of Milan, the imperial vicariate general (*e.g.*, overall authority) over all Italy, and the enormous wealth of the Spanish possessions in the New World.

Collaboration continued between the two Habsburg branches under the guidance of the King of Spain. The poorer Austrian Habsburgs sent their younger sons and those of the leading families in their domains to the Spanish Habsburgs in order to further their careers. Thus, the Spanish Habsburgs were well supplied with military leaders, government administrators, and diplomats. The Austrian Habsburgs received financial aid, as well as Spanish and Italian troops, from the Spanish branch; the Austrians, in turn, lent imperial prestige and influence to their Spanish kinsmen. Marriages strengthened the ties between the two branches of the family.

Now more than ever, the Habsburgs needed military lines of communication. If they had Genoa and its harbour and could keep the Duchy of Milan as a strategic turntable and if, beyond that, they held the Stelvio, Ma-

The role of the Alpine passes

loja, and Engadine passes, Spanish troops in the Milan region could maintain constant contact with Austrian troops in the Tirol. For ease of communication with the Rhineland states and the Netherlands, they had to control the Splügen and St. Gotthard passes, the Valtellina, Lake Constance, the "forest" towns of the Rhine (Waldshut, Säckingen, Rheinfelden), Freiburg im Breisgau, and the right bank of the Rhine; or, by way of Turin, the Mont Cenis and Little St. Bernard passes, the Tarentaise and Maurienne regions; or, by way of Savoy, Bugey, Valromey, the Gex region and from there to Franche-Comté, Dôle, Besançon, Brisach in Alsace, and the Rhine. From the Rhine, Spanish military highways traversed the Lower Palatinate, the archbishopric of Trier, and Luxembourg; and it was over these roads that Spanish troops reached the Netherlands. All along their route the Habsburg forces could invade France. As the Atlantic and the English Channel became increasingly denied to the Spanish fleets, these land routes became the theatre of most of the battles.

The Treaty of Cateau-Cambrésis. In his "instructions" to his son, Charles V stressed his duty "never to abandon the heritage bequeathed to him." This heritage included the Habsburg dream of mastery of Europe and the concept of protecting Roman Catholicism. It signified, consequently, a constant crusade against the Turks as well as the Lutheran and Calvinist heretics. So Philip II became the champion of the Counter-Reformation.

On February 5, 1556, at Vaucelles, the Spanish government had signed a truce with France. But the new pope, Paul IV, dreamed of freeing Italy from the yoke of Spain. An attack by the Duke of Alba, viceroy of Naples, against the Roman Campagna in September 1556 led Henry II to proclaim himself "protector of the Holy Roman Church" and to send an army into Italy. The imperial forces, allied with the English, attacked France through the Vermandois Gap. Prince Emmanuel-Philibert of Savoy routed the French at Saint-Quentin (August 10, 1557). Henry II, at Compiègne, stood guard over Paris. Then, on January 6, 1558, the Duc de Guise was able to retake Calais, then Guînes, and occupy Dunkirk and Thionville, thus cutting off the English from the imperial armies.

A financial crisis throughout Europe in 1557–59 brought both rival camps to the point of exhaustion. Henry II turned his attention to the spread of Calvinism in France, while Philip II undertook the suppression of Protestants in the Netherlands. On April 3, 1559, the Peace of Cateau-Cambrésis was signed, which stabilized international relations in Europe until the Peace of Westphalia. Philip II and Henry II restored to each other their respective recent conquests. Henry II got back the cities on the Somme but returned Corsica to the Genovese; he also gave up Milan, restored to Emmanuel-Philibert of Savoy the regions of Piedmont, Savoy, Bresse, and Bugey that had been ruled as French provinces after 1536, but retained Metz, Toul, and Verdun, and kept Calais for eight years—and was to retain it for a longer period thereafter if he paid 500,000 gold crowns. On June 22, 1559, Philip II wed by proxy Elizabeth of Valois, Henry II's eldest daughter, who arrived in Spain in January 1560.

The Treaty of Cateau-Cambrésis

Campaigns against the Turks. Philip II, a Habsburg, though Spanish-oriented and Castilian to the core, hastened to Spain as soon as the war was over, never to leave the country again. His possessions constituted a Spanish empire. Spain, born of the crusade against the infidels, understood Charles V and Philip II best. A source of noblemen-soldiers, possessing the best infantry in the world, Spain guided the empire and the course of European politics—accepting the burdens as well as the glory. But the fight against heretics blended with the desire for Spanish domination.

Spanish interests and the idea of a Crusade merged. Henceforth, great events bypassed Germany, where civil wars of religion had become endemic and which now turned into the great marketplace for mercenary foot soldiers and cavalrymen for all Europe. Ferdinand I was succeeded as emperor in 1564 by his son Maximilian II, who, two years later, invaded the Hungarian territories of young Zápolya, voivode of Transylvania and vassal of the Sultan. The new sultan, Selim II, successor to Süleyman, forced the imperial troops to retreat and extracted from them a large annual tribute and an eight years' truce. Now the Emperor was nothing but a dependent of the Ottoman Empire.

Spain required security in the eastern Mediterranean for the transport of Spanish troops, for the protection of the seaborne trade of Barcelona and Valencia, and for the transport of Sicilian grain to Castile. But the only bases the Spaniards retained on the southern coast of the Mediterranean were at La Goulette (Ḥalq al-Wādī; near Tunis), Oran, and Melilla—all of which suffered constant attack from the Barbary Turks, the successors to Barbarossa. The Turks were in the ascendancy in the Mediterranean. Although they failed to capture Malta in 1565, they seized the island of Khíos (Chios) from the Genovese in 1566 and then ousted the Venetians from Cyprus, gateway to Anatolia, Syria, Palestine, and Egypt. Once in control of the eastern Mediterranean, the Sultan could effectively intervene in the western Mediterranean. Pope Pius V was unable to unite Europe against the Turkish menace. He had to settle for a Holy League comprising Philip II, Genoa, and Savoy (May 20, 1571). The three fleets, commanded by Don John of Austria, illegitimate son of Charles V, destroyed the Turkish fleet at Lepanto, at the outlet of the Gulf of Corinth, October 7, 1571. Don John was able to recapture Tunis and Bizerta. Selim II, however, equipped a new fleet, and the Turks recovered Tunis and La Goulette (1575), offsetting the brilliant naval victory at Lepanto. The Turks of North Africa thus threatened Spanish communications throughout the western Mediterranean.

The Battle of Lepanto

The Sultan, suzerain of the voivodes of Moldavia, Walachia, and Transylvania, having humbled the Emperor, intervened as far away as Poland. Mehmed Sokollu, a Bosnian and grand vizier after 1565 under Süleyman, Selim II, and Murad II, made a pact with the Berbers, who supplied the naval forces; then he tried to incite the Moriscos of Spain against the crown, to pit France against the Habsburgs, and to set Venice against Naples. Only after the death of Sokollu in 1579 did the decline of the Ottoman Empire set in.

Events in northern Europe. Emperor Maximilian II tried in vain to reassert the authority of the Holy Roman Empire in the regions of the southern Baltic. Denmark, a Lutheran country after the Diet of Speyer in 1544, imposed a levy on all ships crossing the straits adjacent to it. But the Baltic Sea became the prey of all who sought to control the export of grain, wood, hemp, and copper to the West: of the Muscovite tsar, Ivan IV (the Terrible), who captured Narva in 1558 and proceeded to lay waste to Livonia and Courland (Kurland); of Sweden, which fought strenuously to defend Reval (Tallinn) against Ivan and against Denmark; and of Poland, which, anxious to have Danzig enjoy a trade monopoly with the West, placed the estates of the Knights of the Teutonic Order under its suzerainty. The King of Denmark, in control of southern Sweden, laid claim to the Swedish crown. He allied himself with King Sigismund of Poland, while Sweden made overtures to its former enemy, Ivan the Terrible. A "Seven Years' War" (1561–68) devastated the regions bordering on the Baltic. Emperor Maximilian managed to re-establish peace between Sweden and Denmark (with both countries restoring their respective conquests) and obtained an acknowledgment of German suzerainty over Livonia (1570). Sigismund II Augustus, having united Poland and Lithuania, had the union recognized at Lublin in 1569.

But in Poland the death of Sigismund Augustus in 1572 ended the line of Jagiellon kings and created a European problem. At first the Poles appealed to the French prince Henry of Valois, who became king of Poland (April 1573). But, when Henry's brother Charles IX died on May 30, 1574, Henry quit Poland to become Henry III, king of France. Maximilian II proposed his own candidate for the Polish throne; but it was Sultan Murad who won out: Murad's vassal, Stephen Báthory, voivode of Transylvania, was crowned at Cracow in May 1576.

The French Wars of Religion. The Austrian Habsburgs did not succeed in uniting eastern and northern Europe to check the infidels and heretics; the Spanish Habsburgs fared no better in western Europe. Nevertheless, they profited from the gradual weakening of France, where in quick succession Henry's weak sons Francis II, Charles IX, and Henry III mounted the throne and where the government fell under the influence of the queen mother, Catherine de Médicis. Catherine yearned for an understanding with Spain and wanted French princes to marry Spanish princesses. Philip II had been able to turn the Spanish Embassy in Paris into an espionage centre, and the Spanish ambassador became an advisor of the French government. On the other hand, the death of Francis II and the departure of his wife, Mary Stuart, for Scotland and the spread of Calvinism in Scotland by John Knox, with resultant difficulties for the young queen, ruled out the danger of joint action by the French and the Scots. Moreover, France was weakened by the religious wars. At one moment Charles IX seemed to draw closer to the French Protestants. Their leader, Gaspard de Coligny, had great influence in the King's council. Coligny was getting ready to send a French army into the Netherlands on behalf of the Protestant rebels there and was preparing colonial expeditions in South America against the Spaniards. Coligny's assassination and the St. Bartholomew's Day Massacre (August 24, 1572) rid Philip II of these dangers. The intrigues of Henry III's brother, François, duc d'Alençon, his efforts to marry the English queen, Elizabeth I, his negotiations with the French Protestants, his attempts to introduce Protestant French armies into the Netherlands —attempts that foundered in the face of Spanish military superiority—did not pose a serious threat to Spanish policy. (For the religious wars in France, see further FRANCE, HISTORY OF: *France, 1490–1715: The wars of religion.*)

St. Bartholomew's Day Massacre

The revolt of the Netherlands. The principal problem facing the Habsburgs was the task of repressing heresy in the Netherlands. In 1568 Philip II sent the Duke of Alba to the Netherlands, where he set up the so-called "Council of Blood" and waged a reign of terror, which provoked a general uprising in August 1571. William I the Silent, prince of Orange, had escaped into Germany, where he recruited mercenary troops. The States General of Holland named William stadholder (chief of state) in May 1572. But the St. Bartholomew Massacre deprived William of Coligny's 12,000 troops and the French fleet; Alba recaptured Mons, Malines (Mechelen), and Haarlem, where savage slaughter and looting became the order of the day. The Protestants in the Netherlands held on to Alkmaar in the north and Leiden in Zeeland, threatening to open the dikes and flood the country. Philip II was forced to recall Alba, admit the failure of his policy, and attempt to negotiate. It was no use. In April 1576, at Delft, the States General of Holland and Zeeland established a federation, temporarily entrusted William of Orange with authority, and decided to appeal to the other provinces in the Netherlands to defend their liberties. The loot of Antwerp by mutinous, unpaid Spanish soldiers—"the Antwerp fury" (November 4, 1576)—was the last straw in compromising the Spaniards in the eyes of the inhabitants of the Netherlands. Alessandro Farnese, who now became imperial governor of the Low Countries, succeeded in uniting only the southern, French-speaking provinces: Artois, Hainaut, Lille, Douai, and Orchies, where the Catholic religion continued (Arras, January 6, 1579), while, by the Union of Utrecht, the provinces of Holland, Zeeland, Utrecht, Gelderland, Overijssel, Friesland, and Groningen formed the United Provinces against Philip II. The latter put a price on William the Silent's head. Then, on July 24, 1581, at The Hague, the States General proclaimed an end to the rule of Philip II as sovereign of the Netherlands. Acting in accordance with the right of self-determination, a new nation was born in Europe.

William the Silent offered sovereign power to François de Valois, Henry III's brother, who entered Antwerp as the duke of Brabant and entered Ghent as the count of Flanders (1582). But the "insolences" of the French hordes incited the Dutch burghers and peasants to revolt. François de Valois died. William the Silent was assassinated at Delft by Balthazar Gérard (1584). It was a useless crime: the Dutch–Zeeland fleets controlled the mouths of the strategic Scheldt (Schelde) River. See further LOW COUNTRIES, HISTORY OF: *The Netherlands to c. 1600: The revolt and the formation of the republic (1567–79).*

Philip II was going to have to cope with England. In Morocco the Sa'dī (Sharīfian) dynasty opted for a holy war rather than a crusade against Portugal. Sebastian, king of Portugal, was killed and his army wiped out at Ksar el-Kebir (1578). He left no immediate heir. Philip II had himself declared king of Portugal (1580). Then he nurtured the scheme of assassinating Protestant Queen Elizabeth, whose marauding sea captains were threatening Spanish and Portuguese overseas colonies; of having his daughter Isabella declared queen of England; and of building, thus, a solid Catholic front from Algarve, in southernmost Portugal, to the Shetland Islands. The murder plot was uncovered in 1583. Elizabeth then made an alliance with the United Provinces and sent them troops (1585). After another plot, she ordered her Roman Catholic rival Mary Stuart executed (1587). Then Philip II attempted an invasion of England. But his "invincible Armada" was destroyed by the English fleet, which, with its superior ordnance and greater manoeuvrability, thus acquired control of the strategic waterways (1588).

The Spanish Armada

Shortly thereafter, Henry III was assassinated in France by the monk Jacques Clément, and the fanatical Catholics of the League refused to recognize Henry of Navarre, a Protestant, as King Henry IV (1589). In the ensuing civil war Henry IV was aided by 4,000 English soldiers sent by Elizabeth, while Philip II assumed the title of protector of the French Catholics and, to help the French Leaguers, sent Alessandro Farnese and the Spanish army in the Low Countries. Next, Philip II seized the bridgehead of the Blavet River in Brittany, sent a Spanish army into Languedoc, a Spanish garrison to Paris, and demanded the French crown for his daughter Isabella. But the Parlement of Paris proclaimed France's independence; Henry IV became a Catholic and was crowned on February 27, 1594, entering Paris on March 22 of that same year. He next set out to reconquer his kingdom. As a shield for Burgundy, at Fontaine-Française on June 5, 1595, he forced the Spanish army back across the Saône River. The Pope gave him absolution on September 17, 1595, and thus disavowed Philip II's crusade. In May 1596—at Greenwich—England, France, and the United Provinces re-formed their alliance. The Anglo-Dutch fleet sacked Lisbon (July 1596). On the ground, the Battle of Amiens ended in a Spanish defeat (March–September 1597). Philip II found himself forced to deal with France. The Treaty of Vervins re-established the Treaty of Cateau-Cambrésis (May 2, 1598). Philip had to relinquish the Low Countries to his daughter Isabella and her husband, Archduke Albert. Thus ended the great dream of refashioning Catholic unity in Europe under the hegemony of Castile.

The beginning of the Thirty Years' War. After 1598 the dream of European unity faded little by little. The Habsburgs saw their European hegemony drift ever farther away. Spain was going into decline with rampant inflation while the Holy Roman Empire was being gradually pulled apart by political and religious struggles.

Henry IV of France worked assiduously against the Habsburgs. After he defeated the Duke of Savoy, the Treaty of Lyons (1601) gave him Bresse, Bugey, Valromey, and the territory of Gex. He thus became a neighbour of the Swiss, with whom, in 1602, he renewed the traditional alliance, guaranteeing him access to the Alpine passages and driving the Habsburgs' communication axis farther east. In 1594, Spain made peace with England, set up a fortress barring the roads to the Valtellina Pass, and tried to put an end to its problems with Holland. But Henry IV negotiated a defensive alliance with the United Provinces, forcing King Philip III of Spain to sign the Twelve-Years' Truce (April 9, 1609) with his

rebellious subjects, who thus took their place within the framework of sovereign states. The expulsion of the Moriscos from Spain (1609–11) completed the weakening of Spain.

On the Rhine, the succession of Jülich–Cleves, in dispute among several pretenders, gave the Habsburgs the idea of forming a Habsburg bloc including this principality and the Netherlands. As early as 1606, Spanish garrisons had moved into the territory. In 1609 the Emperor took possession of Jülich. But in 1608 the German Lutherans and Calvinists had formed a Protestant Union. In 1609 Bavaria set up a Catholic League to oppose it. Henry IV made an alliance with the Union on February 12, 1610, in order to support the Protestant heirs to Jülich–Cleves and, on April 25, 1610, another with the Duke of Savoy against Spain, so as to cut the Habsburgs' communication lines. The assassination of Henry IV on May 14, 1610, precluded the departure of the army. But Marie de Médicis's government, in 1614, under the Treaty of Xanten, obtained the Emperor's de facto renunciation of his project.

The tolerant attitude of Emperor Maximilian II, followed by that of his successor, Rudolf II, had encouraged the development of Protestantism within the empire. Rudolf II had even given the Protestants of Bohemia a "Letter of Majesty" (July 9, 1609), echoing Henry IV's Edict of Nantes, which guaranteed their liberties to them. After a period of divergences among the Habsburgs, which had gone as far as degenerating into civil war under Emperor Matthias, the Habsburg Ferdinand V of Styria, a disciple of the Jesuits, succeeded in being "accepted" as king of Bohemia (June 6, 1617). He began the persecution of the Protestants. The latter countered with the "defenestration of Prague," by throwing from the windows of Hradčany Castle two of the imperial lieutenants on May 23, 1618, the traditional date for the start of the Thirty Years' War (*q.v.*). (R.E.M.)

II. 1648–1814

EUROPE AFTER THE THIRTY YEARS' WAR

The Peace of Westphalia. For 30 years, from 1618 to 1648, western Europe was rent by war. Though the original recourse to armed strife had come in large measure from the breakdown of the religious settlement of the Peace of Augsburg (1555; see above), far more than religious controversy was involved in the Thirty Years' War. As the war broadened and deepened, the religious differences that pitted reformed Catholicism against militant Calvinism were relegated to the background, and secular issues became more important in the fighting.

The fighting of Catholics and Protestants, of course, involved the issue of religion; but another conflict was constitutional in character, somewhat akin to a civil war: to determine with whom authority would rest in the Holy Roman Empire—*i.e.*, with the emperor or with the large member states. Lastly, the Thirty Years' War was an international war among the states of Europe, a war in which the stakes were largely territorial power, strategic frontiers, and defensible boundaries.

French entry into the Thirty Years' War

France was involved in the war from the outset, giving subsidies and diplomatic counsel to common anti-Habsburg enemies. It was not until 1635, however, that the great French minister Cardinal de Richelieu made a formal declaration of war on Spain. The religious aspects of the war were not of primary importance to the Cardinal, but the territorial aspects were: with France caught between the troops of the Habsburgs in Italy and in the empire, Richelieu's first concern was to win defensible frontiers so that France could have military security. To gain that security, however, he had to destroy the military might of the enemy, first of all of Spain, whose armies could encircle France along its eastern front from north Italy to the Spanish Netherlands.

Richelieu cast the die in 1635. The moment had come, he reasoned, for France to throw all its reserve strength in the balance. His calculation was sound. After serious reverses, French military strength began to tell. Richelieu died in 1642, before the final victory was won, but the troops of Richelieu's successor, Jules, Cardinal Mazarin, compelled the Austrian Habsburgs to open negotiations.

Prolonged and acrimonious peace parleys opened in 1644 in the towns of Münster and Osnabrück in Westphalia. Not for two centuries had so many negotiators gathered to discuss so much and to reach so many compromise decisions.

The religious provisions were a clear acknowledgment of altered reality. The principle of *cujus regio, ejus religio*, set down at Augsburg in 1555, was not only reaffirmed but was extended to cover Calvinism as well as Lutheranism. Religious passions were far from eradicated in the spiritual life of millions of believers, but religious wars were no longer fought in Europe.

The territorial provisions provided generously for the victors at the expense of the empire. The French title to the strategically important bishoprics of Metz, Toul, and Verdun was confirmed. Though deliberately ambiguous clauses seemingly fell short of giving France full sovereignty in Alsace, in reality they allowed the French to extend their influence within Germany. Sweden, allied with France, emerged as an important European state, obtaining the bishoprics of Bremen and Verden and the western half of Pomerania (Hither Pomerania). Sweden thus acquired a hold over the shores of the Elbe, Oder, and Weser rivers. Of the larger German states, the electorate of Brandenburg, another ally, was confirmed in its possession of eastern Pomerania (Farther Pomerania) and in its succession rights to the archbishopric of Magdeburg. The Upper Palatinate went to the elector of Bavaria, an ally of the French, and the Rhine Palatinate went to the son of the former elector Palatine, another French ally.

The political arrangements were not less important than the territorial. The authority of the empire, already in manifest decline, was further weakened. The 300-odd states into which Germany was divided were recognized as sovereign states free to make alliances outside the empire as well as among themselves within. It was stipulated that the empire could not raise taxes, recruit troops, declare war, or make peace save with the consent of the states. France and Sweden won the right to sit and vote in the Imperial Diet. The effective authority of the Austrian Habsburgs, from whose family the emperors traditionally had been elected, were restricted to their hereditary lands of the Austrian duchies and the recently conquered kingdom of Bohemia.

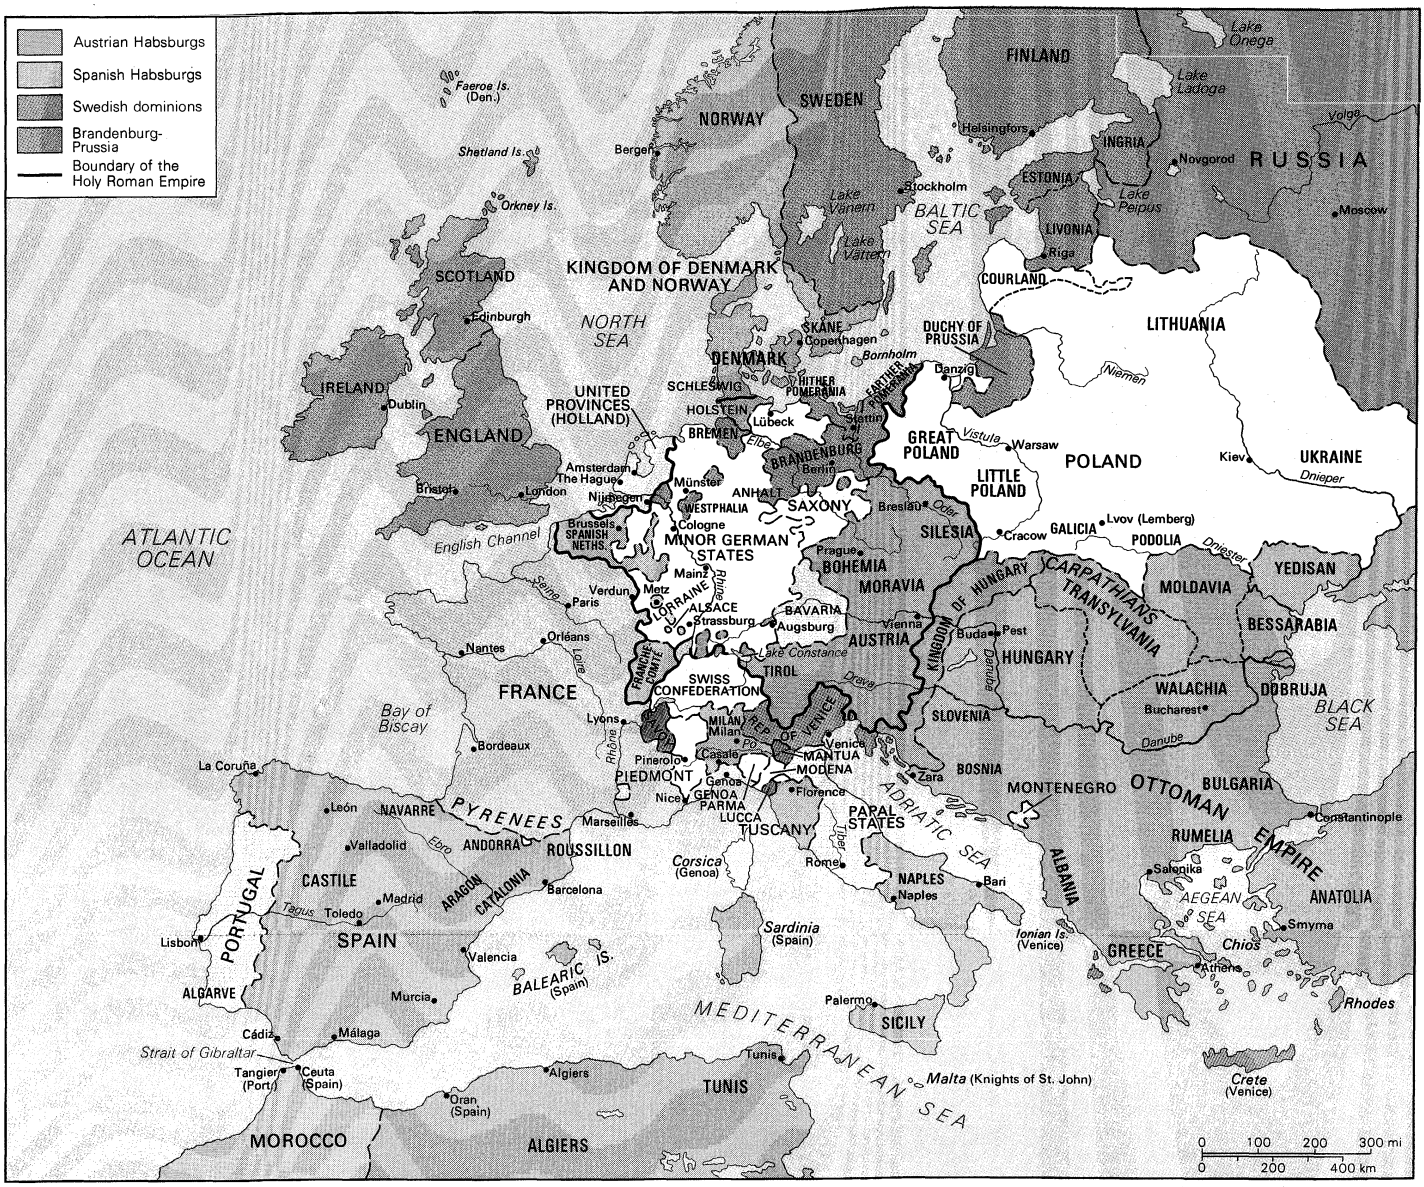
The physical devastation was appalling. Mercenary troops, and their field commanders, roamed freely over the ruined countryside. Hunger and pestilence decimated the population, in the opinion of many historians, by at least a third. The war could not have ended too soon.

The Peace of the Pyrenees. War between France and Spain continued for 11 more years after Westphalia. Almost to the end neither contestant was strong enough to win by itself. Neither Spain, beset by revolts in Catalonia, Naples, and Portugal, nor France, tormented by an aristocratic rebellion known as the Fronde, could mount an overpowering offensive. In the circumstances, Cardinal Mazarin sought to break the deadlock by diplomacy. One string to his bow was to neutralize Germany and prevent the Emperor from putting troops in the field. When Emperor Ferdinand III died in 1657, Mazarin intrigued to win the imperial throne for the young Louis XIV of France. The effort failed, for the Habsburg Leopold I was unanimously elected as Ferdinand's successor.

Neutrality of the empire

But Mazarin's intrigues were not futile. The electors wrung from Leopold an agreement to remain neutral between France and Spain so long as the imperial territory itself was not involved in the fighting. A year later, in 1658, Mazarin took another long step forward toward neutralizing Germany by having Louis XIV named "protector" of the newly formed League of Rhine Princes, which proclaimed unity and peace as its aim.

Meanwhile, Mazarin made a bid for the support of England on the seas. Though a cardinal of the church, he did not scruple to invoke the aid of the Protestant regicide Oliver Cromwell, the Puritan leader who had come



Europe in 1648.

to power in the wake of the English Civil War (1642–51). Cromwell was receptive to overtures. The transaction reached successful issue in 1657 when by a formal alliance Cromwell agreed to support France against a common Spanish enemy. With British fleets on the seas, Cromwell could look forward to acquisitions in the Spanish colonies as compensation for joining France in an attack upon Dunkirk, which was still in Spanish hands. The fall of Dunkirk and the French general Henri de Turenne's great victory over the Spanish at the Battle of the Dunes (1658) wrote a finish to the long struggle that Westphalia had only partially ended. The Peace of the Pyrenees in 1659 destroyed Habsburg Spain's long military ascendancy over Europe. Spain lost much and obtained nothing. The territorial provisions of Westphalia were reaffirmed. France retained the vital bridgeheads across the Spanish lines of communication from Milan to the Netherlands and on the southwest obtained Roussillon and Perpignan, which established the Pyrenees as the boundary between the two countries. In addition, France acquired most of Artois from the Spanish Netherlands, along with several cities in Flanders.

To seal the peace, the infanta Marie-Thérèse was given in marriage to the young French king. Aware of the implications of that marriage for the future, King Philip IV of Spain had insisted that his daughter renounce all claim to the Spanish throne. The astute Hughes de Lionne, chief French negotiator, acceded to this condition, adding, however, the all-important proviso that the renunciation be made contingent upon the payment of a dowry of 500,000 Spanish crowns. The marriage was appropriately celebrated in a splendid ceremony, but the dowry remained unpaid. And when a sickly child, the future Charles II, was born of Philip's second marriage, the shadow of his precarious existence, somehow prolonged for almost 40 years, fell athwart the political scene. Meantime France had entered upon its own ascendancy in western Europe.

The Treaty of Oliva

A year later, in 1660, the Treaty of Oliva ended the ruinous fighting along the Baltic known as the First Northern War, which had been fought since 1655 between Sweden on the one hand and Poland, Austria, and Brandenburg on the other. For the first time since 1618, all of Europe, in the east as well as in the west, was at peace—at least on a formal treaty basis. But no formal apparatus or mechanism existed to keep the peace. In its absence the states of Europe sought to compose the fears, rivalries, and ambitions that set them apart by combining two approaches: one was to invoke procedures that implemented the concept of balance of power; the second, employed concurrently, was to make the state strong enough to deter attack. Hence, to maintain a balance of power abroad while making their state strong at home became the leitmotiv of the makers of policy. Every-

where on the Continent they looked toward France as the model to be emulated.

France's position in Europe. They could do so with good reason. Just as its leadership of western Europe became established in the political affairs of the Continent, so within the span of two generations the cultural ascendancy of France became undisputed. By its language and its literature, its arts and its philosophy, France was the recognized leader, the standard bearer, and the envied model of the civilization that prevailed in the western world from London to Vienna.

Cultural predominance of France

France was not only foremost in the arts of peace, it was also unmatched in the concentration of royal power that had been achieved both for affairs within and state relations outside. There was first the king himself, the "Sun King" Louis XIV. Not exceptionally endowed in intellect, only exceptionally vain and avid of flattery, Louis systematically sought to establish his mastery within the state that he would make master in western Europe. Considering himself the instrument of France's destiny, he rejected, at least in outlook, all inherited feudal conceptions of the nature of the state and the relation of the king to it. He was the embodiment of the dominant political concept of his century, the conviction that to the king belonged plenary control over civil and military policy and regulation. It was this deeper sense of his position and not mere vanity that lay at the core of his repeated statements that he was the state: *L'état c'est moi.*

Policy lines were laid down by the few ministers and secretaries of state in whom he had confidence and with whom he worked in close collaboration. Enforcement came from the civil servants, the *grands commis*, as Louis XIV called them. Not complete enforcement, however, for the old "constituted bodies" of *parlements* and other sovereign courts, provincial estates, and municipal corps remained and often obstructed the implementation of policy at the summit. Within the administrative revolution that was being effected there were margins for resistance. The fact remains, nevertheless, that Louis had power possessed by no other monarch. He was the supreme example of royal absolutism.

Colbert's reforms

Another increment of state power came from the stimulus that Louis's finance minister, Jean-Baptiste Colbert, gave to French economy. Colbert instituted a sustained and comprehensive program to link the reform of the taxation system with a massive government-directed development of industrial and commercial activities. The fiscal program broke down before the opposition of the privileged classes and the debilitating demands of war, but the thrust of his endeavour was neither completely blunted at home nor ignored by France's enemies or rivals abroad.

They appreciated his intent to stimulate economic development and end France's dependence upon the import of vitally needed goods manufactured abroad. Colbert's full program was frustrated; indeed, it was too demanding to be capable of realization, but what was achieved under its aegis was considerable.

Revolutionary changes in military and naval organization and practice were not less radical than those effected in civil administration and economic behaviour. Under the direction of Michel Le Tellier and his son François-Michel Le Tellier, marquis de Louvois, the crown created a new formidable instrument of power. In large measure the disorderly rabble of Louis XIII was transformed into a trained, disciplined, and centrally controlled standing army. Many of the colonels and generals who had purchased their commands were replaced, and new commissions came from the King. A ladder of promotion by merit was introduced. A sustained attempt was made to integrate the branches of service, the infantry, cavalry, and the artillery, the latter under civil control. In increasing measure military intendants, government appointed, attended to multiple details concerning recruitment, and upon them devolved enlistment, feeding, equipping, clothing, and paying of new recruits. From a force of 72,000 in 1667, the soldiery increased to 120,000 five years later and to nearly 300,000 at the beginning of the War of the Spanish Succession (1701–14). Nowhere in Europe did a comparable military power exist.

It was not only in its military apparatus that France could not be matched. Except for the United Provinces of the Netherlands, the states of western and central Europe were strikingly weak in all the respects that made France strong. If France disliked and feared the Dutch Republic, that feeling derived in great measure from irritation over the extraordinary strength of a state that was both republican and Protestant. Dominated by businessmen possessed of a business ethic, the republic had extraordinary wealth and power, well beyond its national resources, population, and territorial extent. It carried a large part of the seaborne commerce of Europe. It was a leading colonial power, and Amsterdam was a world financial mart. Louis XIV disliked the spectacle of Dutch power that presented itself; Colbert had an obsessive fear of it and favoured a preventive war. From England there was no challenge. Allowing for Louis XIV's exaggeration, his verdict was accurate enough: "England could hardly breathe again after her past ills." The Italian peninsula, once so important and powerful in the politics of the states, had been relegated to the margins of history. The great days of the Austrian Habsburgs and their own Danubian kingdom were yet to be. As for the empire itself, though enfeebled by the recent wars, it still had to be reckoned with regarding alliances made and unmade, and reckoned with not least by France.

France's relations in the north and east

The wars in northern and eastern Europe, waged separately from those in the west, were not of first moment to France in the play of balance-of-power policy and diplomacy. Still, by its traditional policy of maintaining a tier of allies along the eastern frontier of the empire, France was marginally involved in those struggles that the Peace of Oliva ended. The states engaged in that power struggle in the years immediately before and immediately after the beginning of the personal rule of Louis XIV in 1661 were Sweden, Denmark, Poland, Brandenburg, Russia, and the Ottoman Empire. Though Sweden was to decline catastrophically during the second half of the century, its position was still strong in 1660 when the Treaty of Oliva ended the war with Poland over the Swedish throne and left Sweden in control of the Baltic. France judged that Sweden could still be counted upon as the northern link of its alliance system in eastern Europe. A role in French calculations was also cast for Poland in order to keep eastern Europe from becoming a second theatre of operations if France should have a war in the west on its hands. Here French confidence was little justified, for Poland's decline was accelerated when its wars against Russia and the Ottoman Empire ended disastrously with the loss of the eastern Ukraine to Russia. Russia's entry into the power relations of Europe was not to begin for some years after 1661. Its steady advance against the Ottoman Empire notwithstanding, Russia did not count in the strategy of wars and diplomacy of the West in 1661, nor did developments in the Ottoman Empire, still regarded as a reliable pro-French state.

In 1661, then, all seemed relatively quiet and secure for France when Louis XIV turned to consult his interests in the West.

THE AGE OF LOUIS XIV

The War of Devolution. During the early years of Louis XIV's rule, French relations with the powers were largely focussed on the problems of the succession in Spain. The normal difficulties attending such matters were accentuated by the presence of the wretched Charles II on the Spanish throne from 1665 until his death in 1700. Afflicted by multiple ills of body and mind (not quite imbecilic but, what was more injurious to the interest of his state, certainly impotent), he was the problem child of international relations.

Since Charles could have no offspring, the Spanish branch of the Habsburgs was doomed to expire with his death. The future of the Spanish monarchy was therefore at stake. Involved also was the disposition of the

personal estates of the royal family in the Spanish Netherlands. This Spanish question was at the heart of the jealousies, rivalries, intrigues, and combinations that worked themselves out in diplomatic manoeuvres and wars.

Bourbon claims to the Spanish throne

By virtue of his marriage to Charles's sister, Louis XIV established claims and fashioned designs on the great heritage, arguing that his wife's renunciation was invalid since the stipulated dowry had not been paid (see above *The Peace of the Pyrenees*). One consideration of his policy was to advance French frontiers eastward to the Rhine by annexing the Spanish Netherlands and Franche-Comté. Another thrust of his policy, which was not defensive, was to pool the resources of France with those of Spain, both in Europe and overseas, by getting the entire Spanish inheritance exclusively for his kingdom. To attain these ends, Louis intrigued with all the states, large and small, giving subsidies with fine impartiality, so long as they served his purposes.

Louis XIV chose not to fight in support of his claim to the Spanish throne in 1665, when the heritage passed from Philip IV to his son Charles II. Louis bided his time, isolating Spain diplomatically and familiarizing his fellow rulers with the term devolution, which he applied to his claim. The term derived from legal principles and procedures in private law prevalent in Flanders, according to which property rights of the deceased devolved to children of the first marriage to the exclusion of the children of the second. This criterion was certainly not relevant to royal heritages, and to use it as Louis did in 1667, when he declared war, was to set up a facade to validate his claim. Behind that legal front were his troops, poised for action.

His generals Turenne and Sébastien Le Prestre de Vauban struck in 1667 and drove deep into the Netherlands. This offensive galvanized the state system into action. England and the United Provinces came together in an alliance to wage war on France if France rejected their mediation. Sweden joined and made it a triple alliance; Emperor Leopold, lacking the military strength to do otherwise, covered himself by a secret treaty of partition to go into effect on the death of Charles II—an event regarded, however mistakenly, as impending.

The Emperor's hedging and the vigorous mediation of the alliance gave Louis pause. Reasoning that time was on his side anyhow and reassured of his strength by the Great Condé's spectacular conquest of defenseless Franche-Comté, Louis found an opportunity to get out with honours. By the Treaty of Aix-la-Chapelle (1668), Louis withdrew his troops, retaining only some 11 border cities in Spanish Flanders.

The Dutch War. French relations with the Dutch Republic steadily deteriorated after the war on Spain, and a second major conflict broke out in 1672. On the Dutch side there were deep, well-grounded fears of French aggression and expansion, while the French, for their part, had their grievances, particularly resentment over the republic's initiative in having contracted an alliance with England. These differences might have been composed had the will existed. Even Colbert's almost pathological fear of Dutch commercial and financial strength need not have led to war. The ultimate responsibility lay with Louis XIV himself. Without even the pretext that the Dutch army threatened French security, he deemed war necessary for his personal glory.

The fighting began in 1672 when Turenne dramatically crossed the Rhine and then penetrated deeply into Holland itself. The victorious French troops, however, delayed their advance against Amsterdam, providing a delay that gave the retreating Dutch time to elect the unyielding young William of Orange stadtholder. The delay also gave the defenders time to make a desperate decision. They breached the dikes and Holland lay flooded. The water did not freeze, and the invaders were forced to abandon their advanced position and evacuate the territory they occupied.

The flooding of Holland

The war changed character when, after the retreat of the French, the Emperor came into the fighting by the side of William of Orange. The latter, in his new capacity as elected executive officer of the state, bestirred himself to form the broad Coalition of The Hague, to which adhered such disparate members as Spain, the Holy Roman emperor, England, most of the Rhenish states, Denmark, and Brandenburg.

As the network of alliances that France had formed began to rip apart, it became the turn of the French to defend their now threatened lines of communication as best they could. Their armies fought brilliantly on several theatres of operations, but, despite great victories in the Netherlands, spectacular successes along the Rhine, and the occupation of Franche-Comté, they could not mount an overpowering offensive. Nor could the coalition troops break the French defense. The Treaties of Nijmegen (1678–79) terminated the long-drawn, inconclusive fighting.

Though the French seemed victorious, the Dutch were far from conquered. In fact, in the larger context of French designs, the war could be held a blunder. France surrendered its conquest of the Spanish Netherlands, obtaining in exchange a number of cities on the northeast frontier. From Spain it also obtained recognition of its conquest of Franche-Comté, so necessary for France's defense. From the Dutch themselves France obtained no territory. The restrictive tariffs were quietly abrogated. In a larger perspective the war had significantly altered state relations. The Dutch republic had withstood the best war machine in Europe. The great maritime powers of England and Holland had come together, and in William of Orange France had an implacable and unyielding foe.

War of the League of Augsburg. The Peace of Nijmegen did not close the chapter of French aggression. Once again a coalition of states was required to check Louis XIV in his course. Blocked along the Lower Rhine by Holland, France nibbled at the territory of the Holy Roman Empire along the Middle and Upper Rhine. For a long time French jurists had been gathering data concerning territorial dependencies that had been or might not have been ceded to France by the deliberately ambiguous provisions at Westphalia. In 1680 courts of claims called *chambres de réunion* were set up to make rulings on doubtful or disputed territory. Since the judges were French, most of their verdicts were favourable to their country. After scattered small bits of territory, largely in Lorraine, had thus been incorporated into France, another ruling in 1681 held that the important imperial city of Strassburg was also a dependency of France. It was at once occupied by French troops.

The intent animating this *réunion* policy was clear: to sever such bonds as still linked the occupied territory to the empire and, by integrating them completely under French sovereignty, to establish a territorial boundary that France regarded as essential for its defense. The annexationist tactic went further. It fitted into the larger pattern of taking what could be acquired one way or another from the enfeebled empire. Direct territorial despoilment in the west also fused with the French conception of embarrassing the empire in the east by giving generous subsidies to Magyar rebels in Hungary and encouraging Turkish attacks.

Renaissance of Habsburg military strength

This classical ploy of *Realpolitik* misfired because of a remarkable and decisive renaissance of Habsburg military strength. After containing the Magyar and Turkish threats, Leopold became free to turn to affairs in western Europe and make himself the leader of a Catholic union of states against Louis. In those same years and immediately following, William of Orange was playing upon the fears and indignation of Protestant states who were menaced not only by Louis's military aggression but also by his decision in 1685 to revoke the Edict of Nantes, which since 1598 had extended toleration to Protestants within France. These anti-French combinations were strong enough to force Louis to accede to the Treaty of Regensburg (1684). By its provisions Spain recognized the annexations in Luxembourg and the Netherlands, while Louis, retaining Strassburg, renounced further annexations.

Louis kept Strassburg, but he did not keep his word.

After his troops again occupied the Palatinate, the two separate anti-French groups centred around Leopold and William of Orange pooled their strength into the defensive League of Augsburg (1686), adhered to by all those states threatened by France and England—the Holy Roman Empire, Spain, Sweden, the electorates of Bavaria, Saxony, and the Palatinate, and the Dutch Republic. In 1688 William of Orange also became king of England as William III. After that great power also joined the League, it was transformed into an offensive alliance, the Grand Alliance. An open war then began, and France faced a reconciled Europe alone. If France had had even a semblance of a case for its aggressive measures in a war-oriented polity of states where the line between defense and expansion was not always clear, Louis spoiled it by his domineering tone and unilateral decisions.

The Grand Alliance

He had hoped, by early decisive victories over each adversary in turn, to obviate the necessity of waging a general war with all at once. That hope disappeared as the allies quickly organized their forces, coercing France to fight on a broken front on the Continent and at the same time almost everywhere on the high seas. The coalition was at least equal in strength to France in effectives, leaders, and financial resources. The armies in the field were immense, as were their losses. By 1693, the fourth year of the war, it was clear that no decisive military solution was possible. France itself was safe from invasion, but the French could not penetrate into the heart of the empire or shatter the joint naval might of the English and the Dutch. There were no decisive engagements on the seas, and a French attempt to invade England broke on the defeat at La Hougue in 1692, where the fleet of Anne-Hilarion de Cotentin, comte de Tourville, was annihilated.

To maintain 200,000 men in the field and two squadrons on the seas strained French finances to the breaking point. Moreover, the crop failed in many regions of France in 1693, and famine and disease swept the country. Famine prices, collapsing wages, and unemployment came together in a chain reaction of suffering unparalleled since the terrible years of the Fronde. Among the allies, also, there was keen misery and war weariness. The Grand Alliance crumbled, and in 1697 the war ended with the two treaties of Rijswijk, the first between France, England, Spain, and the United Provinces, and the second between France and the empire.

By the treaty provisions France gave up its conquests in Italy and returned the occupied strategic fortresses of Pinerolo and Casale. In Germany, France abandoned its claims to the succession in the electorates of Cologne and the Palatinate. Alsace was retained but not the *réunions* effected prior to 1679. The French also retained Strassburg, but Lorraine was restored to its duke. On the right bank, too, all the land seized by the French reverted either to the empire or to individual princes. The United Provinces also gained by the terms, winning commercial concessions together with the right to garrison the Barrier fortresses between France and Holland. Both France and England restituted colonial territory, and France formally accepted William of Orange as king of England. Louis's *réunion* policy was completely blunted.

The War of the Spanish Succession. No mutually acceptable arrangements had meantime been worked out among the rival claimants for the disposition of the Spanish heritage. Between 1698 and 1700 Louis XIV, understandably wishing at all costs to avert war, took the diplomatic initiative to draft partition treaties acceptable to France, England, and the United Provinces while defeating Leopold's design to be sole heir. Neither of the two treaties that France proposed proved acceptable to the Emperor. The moribund Spanish king then tossed a bombshell into the already tense situation by proposing his own arrangements for the Spanish succession. He had been persuaded by pro-French counsellors that only the House of Bourbon possessed the military strength required to hold the Spanish inheritance intact both on the Continent and overseas.

In the autumn of 1700, shortly before his death, Charles drafted a will embodying that conviction. It bequeathed the whole inheritance to Louis's grandson, Philippe, duc d'Anjou, stipulating, however, that if Louis refused for his grandson, the entire heritage would go to the archduke Charles, son of the Emperor. In either contingency there would be no partition of the heritage. The future lay with Louis, and, after long discussions with advisers, he decided that he could not reject what seemed like a gift from heaven. He accepted Charles's will, enjoining upon Anjou to be a good Spaniard.

The terms of Charles's will

The maritime powers bowed to reality, not without a protest from the Emperor and deep misgivings on the part of William III, who argued that England had everything to lose and nothing to gain by acceptance. All seemed propitious for France when Louis committed a series of blunders that confirmed William III in his fear that Madrid was to be governed from Versailles. At the very moment that France should have been tactful and conciliatory, Louis acted as though he wished gratuitously to alienate and defy the powers. The Parlement of Paris was forced to register a royal letter patent that reserved Anjou's rights to the French throne. French troops occupied the Barrier fortresses, temporarily driving out the Dutch. The French government also advanced the claims of French companies to share in the English trade with the Spanish colonial empire—another display of arrogance that outraged public opinion in England. And in a final belligerent move, Louis formally recognized the son of the ousted James II of England as James III.

Perhaps Louis intended by this peremptory behaviour to impose an image of his overwhelming strength upon the powers; but he succeeded only in heightening apprehensions and bringing the powers closer together in the Grand Alliance for which William III had so tenaciously laboured. William died in 1702, and the union was his final bequest to block French aggression. Facing the greatest threat to the political balance of Europe since the days of Emperor Charles V, William had fashioned a coalition that was to be France's undoing. The War of the Spanish Succession began in 1701.

The allies gradually established their domination, largely because of their two great field commanders, the Duke of Marlborough and Prince Eugene of Savoy. By 1708 France was open to invasion, and the year 1709 was a catastrophe at home. It was the year of the "great winter," which brought suffering that surpassed even that of 1693–94. War weariness, exhaustion, and the threat of bankruptcy generated a peace movement. But the terms offered by the victorious allies were so onerous that Louis XIV would not accept them, and military operations were renewed. Marlborough won his last great victory at the bloodbath of Malplaquet in the Netherlands, and peace negotiations were soon reopened under the insistence of the pro-peace Tories, who won the general election of 1710. After Marlborough was relieved of his command, England virtually withdrew from further military operations, leaving its allies to fend for themselves as best they could. Encouraged by England's example, they, too, made their own arrangements. A series of peace treaties in 1713–14, of which Utrecht and Rastatt were the most important, brought peace to Europe.

Allied victories

The Peace of Utrecht. The French paid heavily for their military reverses: they abandoned their designs to annex the Netherlands and also gave up all conquered territory east of the Rhine. Of Louis's conquests only Franche-Comté and some towns and cities in Flanders remained in French hands. After a half century of aggression this territorial reward was not striking. With respect to the troubled successions, the English recognized the Bourbon Philip V, the former duc d'Anjou, as king of Spain, while France accepted Anne on the English throne. Several bastions were set up against possible future French aggression. The treaties recognized Prussia as a kingdom with possessions on the Rhine. The Dutch again occupied the Barrier fortresses. In the southeast of the line set up against France, the new kingdom of Savoy stood on guard, retaining occupation of Nice and acquiring Sicily. French expansion was contained, but France lost no territory of its own on the Continent and remained the richest, the best-governed, and the strongest

country in Europe. Though France was forced to cede valuable possessions to England in North America (Newfoundland, Nova Scotia, and sovereignty in the Hudson's Bay territory), the country's extraordinary vitality and rich resources nevertheless remained. Within a few years after the peace France embarked upon a remarkable, century-long economic expansion that was to make the country a formidable rival of England for maritime and colonial supremacy.

The territorial provisions of the peace settlements fell heavily upon Spain, which lost the Netherlands, Milan, and the kingdom of Naples to the Austrian Habsburgs. The greatest victors of all were the English, who occupied Gibraltar and Minorca, which had been conquered early in the war and which opened the way toward British control of the western Mediterranean. By the Methuen Treaty (1703), Portugal became a virtual commercial satellite of Britain, giving England valuable trading rights with Brazil. The cessions of French colonial territory noted above, together with those acquisitions from Spain and Portugal, contributed significantly toward the building of the first great British empire. Of all these changes, the most immediately valuable, at least for the merchants, was the *asiento* agreement. By its provisions England won a 30-year monopoly to import Negro slaves into the Spanish-American colonies and, also, the exclusive right to send one ship a year via Portobelo, on the Isthmus of Panama, to provision the colonies.

The *asiento* agreement

Peace in the North. While the War of the Spanish Succession was being waged in the west, the final great struggle was fought in the east to end Sweden's control of Baltic shores. So long as France's allies, Sweden and Poland, were strong and stood on guard as buffers against involvement, there had been no occasion for either France or England to be seriously concerned. The military collapse of Sweden in the Great Northern War (1700–21) against a broad coalition of states that included Poland, Denmark, Saxony, Prussia, Hanover, and, most important of all, Russia, significantly altered the military and diplomatic pattern. Sweden, France's outpost in the east, lay prostrate, and Russian troops had reached the Baltic.

Peacemaking between Sweden and the lesser states to settle rival territorial claims was speedily effected. The settlement of the Russo-Swedish boundary limits and the reorganizing of their relations proved more difficult. France and England, for instance, had to be reckoned with. France was concerned to keep Russia from acquiring full Baltic control in the place of Sweden. England was anxious to gain assurances of unmolested shipment of needed naval stores from Scandinavia.

With these considerations in mind, France and England, linked in alliance since 1716, planned to put pressure on Russia in the settlement of what was becoming a general European problem. Peter I the Great was not inclined to be so influenced, and he had in a benevolently neutral Austria a decisive supporter of his views and intentions for Russia. Hence he was free to impose, almost to dictate, territorial terms to Sweden in the Treaty of Nystad (1721). That peace stripped Sweden of its provinces of Karelia, Ingria, Estonia, and Livonia as well as some small islands.

The Treaty of Nystad

All Europe was now at peace from west to east; and Russia, in uncontested control of the Baltic, had entered into the diplomatic relations of the Continent.

PEACE AND WAR, 1713–89

Postwar problems, 1713–40. After Utrecht and Nystad many problems and issues still remained to threaten the peace and challenge the firmness and ingenuity of the directors of state policy. The solutions were made at several congresses of diplomats, at ministerial conferences, and all under the aegis of ad hoc alliances. Among these alliances the first was that of France and England in 1716, which two years later out of necessity developed into the Quadruple Alliance, including the United Provinces and Austria.

One postwar problem concerned the succession to the thrones of France and England. In France, where Louis XV was still in his minority, two rivals advanced their claims to the throne: Philip V of Spain, whose rights Utrecht had denied, and Philippe, duc d'Orléans, Louis XIV's nephew and regent for the young king. The Quadruple Alliance validated the rights of Orléans, but since Philip persisted in maintaining his claims, tension over this matter remained. In England the danger arose from the Jacobite supporters of the Old Pretender, the self-styled James III, who refused to recognize George I as king. The government crushed the Jacobite rebellion in 1715, but plotting to seat his son, Charles Edward, the Young Pretender, continued with sporadic foreign aid until 1745.

There were also diplomatic clouds over the troubled situation in the Barrier fortresses, where the Emperor refused to allow the Dutch to garrison those posts. Here, too, a congress meeting was required. Problems in Italy made for trouble because Philip V remained unreconciled to the Utrecht provisions that ratified Spain's heavy territorial losses to Austria. Two local wars were waged in Italy between Spain and Austria until, in 1720, the Quadruple Alliance successfully mediated the disputes, compelling Spain to abandon its Italian claims and, at the same time, inducing the contesting states to endorse the solution of the succession difficulties in both England and France. There was difficulty, too, in the unfriendly relations between Spain and the maritime states concerning the settlement in Italy, as well as over the tireless manoeuvres of the Emperor to obtain signatories to the Pragmatic Sanction, which provided for the powers to accept inheritance by his daughter Maria Theresa of all the hereditary Habsburg possessions. In the east, there was the War of the Polish Succession (1733–38) over the election of the king of the Polish republic and, also, the liquidation of the wars waged by Russia and Austria against the Ottoman Empire. Austria lost heavily to the Turks by the Treaty of Passarowitz, and Russia, too, was temporarily checked in its advance.

The Pragmatic Sanction

Nevertheless, Europe as a whole gained because a general European conflagration was averted. These settlements in both the west and east preserved the peace, but barely. The built-in predisposition toward war had not been eradicated. Warfare and competitive militarism were neither condemned nor rejected. The procedures animating the balance settled crises; they made no contribution to lasting peace. As the range of state competition widened and as its substance deepened, to increase security became the primary concern of all policy makers. In 1740 a generation-long respite from general war ended with a series of conflicts that gripped Europe until 1763. In these wars, the balance again revealed itself, in the words of a contemporary, as a mechanism for

> recognizing the strength, resources, interests, rights, fears, and hopes of the different powers, so that as the occasion warrants it, we may appease these powers, divide them, defeat them, or ally ourselves with them, depending on how they serve our advantage and increase our security.

War of the Austrian Succession. All appeared quiet after the last settlements of 1739. The pent-up resentments erupted in the following year, and the balance was shattered by two wars fought more or less simultaneously, one colonial and commercial overseas, the other dynastic and territorial on the Continent.

The former, an Anglo-Spanish conflict, had its origins in the repeated violations of the *asiento* agreement. English privateers, going beyond the provisions stipulated in the Peace of Utrecht, engaged in a lucrative smuggling trade, which Spanish naval officers repeatedly broke up by a rigorous policy of search. After many mutually injurious incidents and outrages, the clamour of the merchants forced England's chief minister Robert Walpole to abandon his longtime policy of peace and declare war on Spain—the War of Jenkins' Ear (1739–43), so-called after an English seaman whose ear was amputated by the Spanish patrols. France, because of its heavy financial interests in colonial trade, prepared to support Bourbon Spain by dispatching two powerful squadrons to fight the English in the West Indies. These instructions were quick-

Anglo-Spanish hostilities

ly rescinded when Frederick II the Great of Prussia invaded Habsburg Silesia without warning. Frederick's aggression brusquely and brutally undid the Emperor's prolonged diplomatic efforts to have all the powers sign the Pragmatic Sanction. Frederick found in the accession of the young, inexperienced Empress a tempting opportunity to round out the strategic Prussian boundaries and take for his kingdom another step toward military hegemony in Germany. The invasion of Silesia and Frederick's early triumphs stimulated other states to press their claims against Maria Theresa. His invasion also gave impetus to the anti-Habsburg coterie at Versailles in its plan to repudiate the policy of peace that the wise nonagenarian André-Hercule de Fleury, Louis XV's great minister, had been pursuing for almost two decades. This hostile faction succeeded in bringing France into the Austro-Prussian War at the head of a coalition against the traditional continental enemy Austria. Bound to France by the Pacte de Famille, Spain entered into the war.

The fighting might well have ended in 1742 when, by a separate agreement with Maria Theresa, Frederick withdrew, with Silesia in his possession. Instead, it took on European dimensions. The Empress declared war against France. In England, Walpole fell from power, and then England chose, like France, to engage in a limited war in Italy, with the end in mind of weakening Spanish total resources by a military diversion on the Continent. This English strategy of a holding operation provoked, in turn, a needless French declaration of war against England prompted by panic in high governmental circles. Thus the two wars were joined into the single War of the Austrian Succession, though again in 1745 Frederick's straitened resources forced him to make peace with Austria and withdraw from the fray; but, with Silesia still in his hands, the now pointless fighting continued. On land the French troops were in the main victorious. Outside Europe the British fleet and privateers destroyed the French escorts and drove both French and Spanish merchantmen off the seas.

Treaty of Aix-la-Chapelle

The financial exhaustion of all the powers finally brought sanity into play, and France and England undertook secret peace negotiations that resulted in the Treaty of Aix-la-Chapelle (1748). The signatories confirmed the Pragmatic Sanction, and Austria formally accepted the cession of Silesia to Prussia. As for Frederick, his *démarche* paid off. Silesia was his. Overseas nothing essential was changed. France and England made mutual restitutions of their conquests. The *asiento* was not altered. This War of the Austrian Succession, the first round of the mid-century wars, had settled nothing. "As stupid as the peace," cried the wits. The war only bequeathed a legacy that was the seed of future conflict, the legacy of the Austrian determination to compel Frederick to disgorge Silesia and restore the older balance in place of the new one.

The "Diplomatic Revolution." In the years immediately following Aix-la-Chapelle, the only force that seriously threatened the peace was the studied resolution of the Austrian chancellor Wenzel Anton, Graf von Kaunitz, to win back Silesia. To be sure, an undeclared war between England and France was being fought in America (the so-called French and Indian War), but, far from desiring to have it spread to Europe, England shrank from that prospect. The English were fearful that in the event of war on the Continent either France or France's ally Prussia might overrun the Duchy of Hanover to which the English king held title and, also, perhaps occupy the Netherlands. As England's own ally, Austria, could not give adequate assurances of military aid, England turned to Russia. By the Subsidy Treaty of September 1755 England purchased the services of 50,000 Russian soldiers, who aligned themselves on the border of East Prussia, poised to advance into Prussian territory. The English did not regard the subsidy arrangements with Russia as incompatible with England's existing friendly relations with the Habsburgs. The arrangement was designed to give England double assurance.

Developments belied intentions. Prussia saw in the arrangements not a defensive move but a threat. Frederick already knew of a secret Russian–Austrian understanding against Prussia. His sense of security gave way to a deep fear that his state might well be sucked into an unwanted war against Russia. The way out, he reacted in his fear, was to undercut Russia by offering England the assurances concerning Hanover. Since Prussian troops would be appreciably closer to Hanover than the distant Russians, England readily accepted Frederick's proffered assistance. The two states accordingly signed the Convention of Westminster (January 1756), in which Prussia agreed to deny entry into and passage through Germany of any foreign troops (*i.e.*, Russians). England obtained the desired guarantees, and its relief was great. Frederick's was equally great. He saw in the Convention an instrument to keep the peace.

The Convention of Westminster

Westminster, however, did not produce the desired effect. It was a bombshell. Vienna was outraged, or professed to be, by the "treachery" of its English ally. Louis XV and Versailles bristled with indignation over the seeming defection of Prussia, and, overwhelmed by fears over what seemed an English–Prussian combination, France turned toward Austria as a shield.

Reversal of Bourbon-Habsburg enmity

France first allowed its alliance with Prussia to lapse and then contracted a defensive alliance with Austria, the First Treaty of Versailles (May 1756), by which France agreed to come to the assistance of Austria if the Habsburgs were attacked. To defend Austria, so French calculations ran, was also to protect themselves. Thus, out of this reflex of fear, France took the first long step toward a reversal of alliances and the abandonment of its centuries-old anti-Habsburg policy.

St. Petersburg's reaction was, if anything, more violent still. To Russian eyes, Westminster was clearly an unscrupulous repudiation of earlier English policy. Thus, a third set of fears obtruded on the diplomatic scene—Russia's fears that it might have to fight alone against Prussia covered by England. Russia thus turned to Austria for self-protection; in May 1756 Russia agreed to give Austria limited military aid in the event of a Prussian attack.

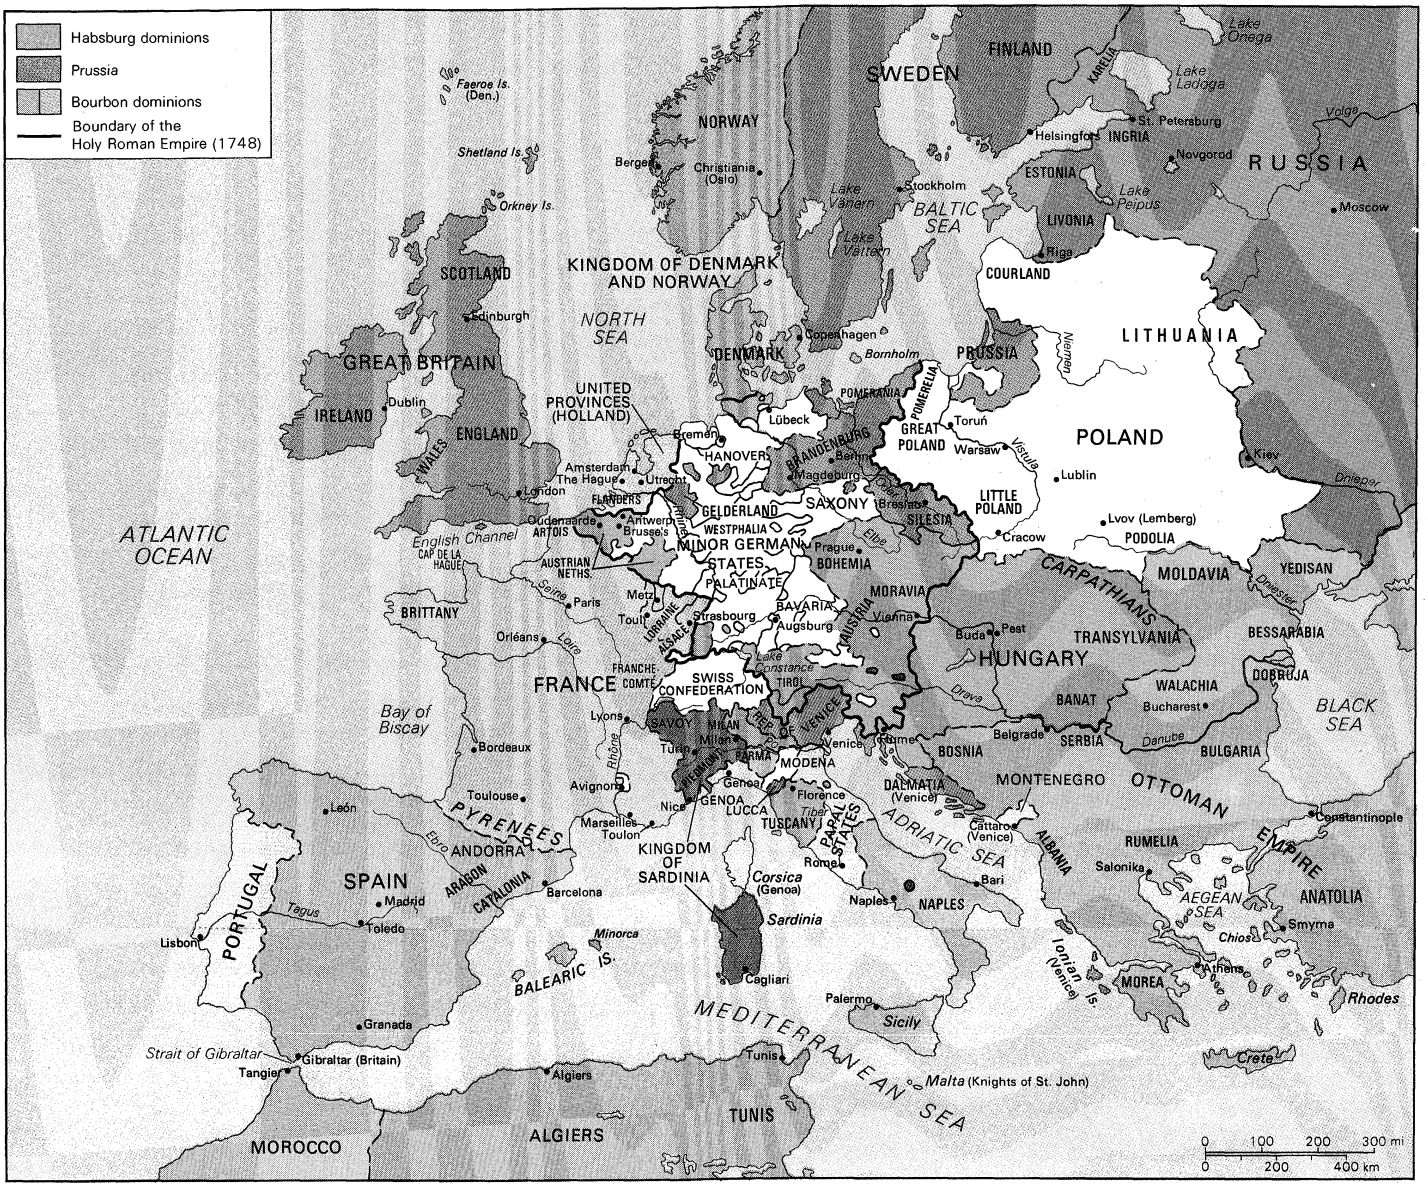
Frederick did not wait to be attacked first. In August 1756 he invaded Saxony, which he considered the centre of plotting against him. It was now too late for diplomacy: the generals had taken over. France contracted a full military alliance with Russia in the fall of that year. In the following spring, before the campaign began, France signed the Second Treaty of Versailles with Austria, a full offensive–defensive military accord. By this agreement, the last of the three bilateral pacts, the reversal of alliances had become a *fait accompli*.

This diplomatic revolution was a lesson in futility, revealing the fatal inadequacy of the balance of power. Seeking peace, the great states were led to create a situation beyond their control. Obsessed by reciprocal mistrust, they made the appeal to arms inescapable.

The Seven Years' War and the Peace of Paris. Frederick's invasion of Saxony opened the war on the Continent, which merged with the commercial–imperial conflict into the Seven Years' War (*q.v.*; 1756–63). In the European theatre, the Austrians at once invoked the provisions of the military agreements that bound them to France and Russia. Frederick, for his part, demanded and obtained English aid in the form of large subsidies and a small task force dispatched to the Continent. French tactics envisaged a rapid campaign for the conquest of Hanover. Military calculations in England were initially divided, veering after Frederick's great victories at Rossbach and Leuthen in 1757 toward a full military understanding with Prussia and the use of Hanover as the base of operations for a large-scale military diversion to contain the enemy.

Frederick's stubborn defense

Frederick's conduct of the war was heroic for its daring, flexibility, and dauntless courage against overwhelming odds. It was victorious, too, for a brief span of years. Operating on inner lines until 1759, he prevented the Austrian and Russian armies from joining forces. In 1759 the Russians inflicted a shattering defeat upon him at the Battle of Kunersdorf, and his future seemed hopeless. Yet somehow he held on, suffering defeat after de-



Europe in 1748.

feat but refusing to sue for peace. For three years the war in Europe was a protracted and ruinous combat in which the Prussian and Austro-Russian armies confronted each other in the east, while French and Anglo-Hanoverian troops effectively neutralized each other in the west. In Prussia's exhaustion Frederick could not have resisted indefinitely, particularly since England withdrew its financial support, but on January 5, 1762, "the miracle of the House of Brandenburg," as patriotic Prussian historians call it, or "her sacred majesty, chance," as Frederick put it, saved him. Tsarina Elizabeth died and was succeeded by her deranged nephew Peter III, an unmeasured admirer of Frederick. With Peter's accession the anti-Prussian coalition fell apart. After signing immediate peace with Prussia the Tsar restored all Russian conquests and placed the Russian army at Frederick's disposal. Though Peter was assassinated within a half year, Peter's wife and successor Catherine II the Great wanted no renewal of a war in which her country would be fighting against Austria for the benefit of Prussia. Prussia's eastern front was at last secure. "Thanks to providence," Frederick jubilantly cried out, "our back is free."

The major war in the Germanies now virtually ceased, but the fighting for empire continued on the seas in America, the West Indies, Africa, and India. The British conquests outside Europe propelled William Pitt the Elder, Britain's war leader, into the pages of history as the great empire builder. On the other hand, in France the dictatorship of Étienne-François, duc de Choiseul, not less embracing and intransigent than Pitt's, failed to win security for France. With rising opposition at home, defeats on the high seas, and the failure of a direct invasion of England and Scotland, Choiseul made overtures for peace early in 1760, not without first playing the Spanish card in his negotiations. Fortunately for England, Pitt's fears of Spanish might were exaggerated. Spain suffered crushing defeats on all fronts in its brief military venture.

After these reverses nothing remained but for Choiseul to sue for immediate peace, which was signed on February 10, 1763. The end of the war between England and France did not come, however, until John Stuart, 3rd earl of Bute, the chief English negotiator, had already taken his country out of all fighting on the Continent. He broke completely with Prussia, cutting off all subsidies and leaving his erstwhile ally to its own resources. Austria, too, was then ready for negotiations, for after Catherine's withdrawal the Habsburgs stood alone in Europe.

The Treaty of Paris was less severe than might have been expected in view of Britain's overwhelming victories. The peace was the handiwork of Lord Bute and of still lesser men who had forced Pitt from office and were prepared, to secure their advancement, to sacrifice

if necessary some of the imperial interests that Pitt had so tenaciously and energetically pursued. The guiding consideration of Bute was to turn the diplomatic negotiations to the account of his young royal master, George III. The tactics of the imaginative Choiseul, the chief French negotiator, were to drive a wedge between the British peacemakers and exploit to the full their fear that Pitt might be returned to office and reopen the war. For Choiseul the peace was to be only a respite from actual fighting, an armistice so to speak, which France would terminate when it was again prepared to reopen the duel for overseas empire. Though he made bitter concessions to the victor, he saved France from the status of a second-rate power, which Pitt had planned. Though Britain did not obtain the Carthaginian peace that Pitt would have imposed, it had emerged as the leading commercial and colonial power in the Western World.

The emergence of Britain's colonial supremacy

In North America, Britain became master of the vast territory east of the Mississippi as well as "the frozen acres" of Canada. Patriots angrily clamoured that their country also retain the captured West Indies sugar islands; however, despite the great strategic naval importance of Guadeloupe and Martinique, the sugar bloc in Parliament sacrificed imperial interests to financial profits and voted their return to France. Moreover, France was permitted to keep the island of Gorée, commanding the slave trade of Senegal, along with a number of trading posts on the eastern coast of India.

Spain, too, fared better by the peace terms than might have been expected by virtue of its overwhelming defeat. The Spanish lost Florida to England and gave up their old claims to the Newfoundland fisheries, but they kept their South American colonies and islands in the West Indies. The victor restored Cuba and the Philippines to Spanish rule. Choiseul, in order to place a lien upon his Bourbon ally's goodwill, ceded to Spain that part of the French territory of Louisiana, including the port of New Orleans, which lay west of the Mississippi.

Prussia also ended the war a victor, for the separate Treaty of Hubertusburg (February 15, 1763) formally recognized Frederick's conquest of Silesia. In Prussia there was great devastation and suffering, but that did not last. What lasted was "the miracle of the House of Brandenburg," the survival of Prussia, its new status as a great power, and the continuing confrontation of Prussia and Austria for mastery of Germany.

Renewal of Anglo-French competition. Choiseul was the directing intelligence behind his country's foreign and colonial policy during the 1760s. He counted heavily on the Habsburg alliance of 1756 and on the network of Habsburg–Bourbon dynastic marriages to cover French security on the Continent and leave France free for action outside Europe. Working via the Pacte de Famille with Spain, Choiseul looked ahead toward a joint Bourbon thrust against England and bent every energy toward restoring the shattered might of French armed services and strengthening the bases for naval operations. This aggressive policy could not be implemented, however, and under Charles Gravier, comte de Vergennes, who took over in 1774, it was toned down. On the Continent Vergennes relied less on the Habsburg alliance (which he feared would entangle France in Austrian intrigues) and more on developing friendly relations with Prussia, with the German states along the Rhine, and, most of all, with Russia. There was appeasement in this approach, but he was prepared to pay the price of lessened French prestige and influence to obtain economic benefits. "In the present state of affairs," he declared, "commercial questions are political questions and as such are within the province of foreign affairs."

The U.S. War of Independence

Vergennes's great opportunity to strike directly against England came in 1776 with the armed resistance of the American colonies to British rule. Initially, he adopted a policy of open non-belligerency against England and more or less secret assistance for the Americans. The decisive change from secret aid to open alliance came after the U.S. Declaration of Independence in July 1776 and Gen. John Burgoyne's defeat at Saratoga in 1777. In February 1778 Louis XVI signed treaties of alliance and commerce with the Americans, and within a few months France was openly at war with England. Vergennes had not miscalculated on the Bourbon ally. In 1779 Spain contracted an open alliance, contributing with the United States, 40 ships of the line that gave the associates naval superiority. In return, Spain obtained from Vergennes a reluctant agreement not to withdraw from the war until Gibraltar had been retaken from the British.

In 1780 England declared war against the United Provinces, who had built up a lucrative trade conveying supplies to the colonists and allowing American privateers to refit in Dutch ports both in Europe and the West Indies. But Vergennes appealed to the neutrals to encompass England's defeat by turning them against "the tyrant of the seas." Here his warm relations with Russia stood France in good stead, and Russia was persuaded to sign the declaration that established the League of Armed Neutrality. By the terms of the declaration, contraband was narrowly restricted to munitions and arms, and the armed neutrals regarded themselves as free to navigate along the coasts and to the very ports of all belligerents. Vergennes had gone far toward arraying the Continent against England.

The peace treaties of 1783, signed by England, France, Spain, and the Netherlands, ended the fighting. The treaties recognized the independence of the colonists. Spain retained Minorca and Florida. To France England ceded Tobago and Senegal. England retained bitter memories of a long and humiliating series of naval reverses. Though Adm. George Brydges Rodney's victories in 1782 restored English superiority, the antiwar mood of shame and humiliation was deep. The English wit Horace Walpole caught it in a striking phrase: "You must be happy now," he wrote, "not to have a son who would live to grovel in the dregs of England." England's enemies were jubilant, more jubilant than reality warranted. "Thus is the great power . . . fallen completely and forever," wrote Leopold of Tuscany, ". . . sunk to the ranks of a second class power. . . . France, delivered for all time of that formidable adversary, thereby doubles her intrinsic strength, her commerce, her authority, and her prestige. . . ."

The growth of French commerce

France did not double its "intrinsic strength," least of all in the military affairs of eastern Europe. With respect, however, to the French commercial position between 1783 and 1789, Vergennes's policy did add greatly to the strength of the country. He negotiated a trade treaty with Russia that gave French merchants terms as good as those given to the English. By opening trading facilities to foreigners in its West Indies colonies (1784) and concluding a practically free-trade treaty with England in 1786, France accelerated the remarkable increase in the volume and value of its commerce. And England was far from "fallen completely and forever." By skillful diplomacy England formed a triple alliance with Prussia and the United Provinces. As an ally of the United Provinces, England was assured of navigation on the Scheldt and a point of entry for trade with the Continent. As an associate of Prussia and in possession of Hanover, England could build a trading clientele in the Germanies. A dominant member of the alliance and Russia's greatest customer, England pursued active trade relations in the North Sea and the Baltic. With Gibraltar in their hands and with the support of Portugal, the English also held Spain in check. By supporting the territorial integrity of the Porte (Ottoman government) they had access to the eastern Mediterranean, and their share in the trade with free America surpassed the total reached before 1776. On the eve of 1789 the two maritime states still confronted each other in the competition for empire.

Aggression in the East. For the better part of a decade after the Peace of Paris, a civil war within Poland and renewed warfare between Russia and Turkey again threatened the peace of Europe. The immediate crisis began in 1764. After the death of the Polish king Augustus III in the preceding year, Prussia and Russia reached an understanding to secure the election of a native nobleman, Stanisław August Poniatowski (Stanisław II), who presumably could be counted on to fit the

role of convenient tool for their ambitions. They also agreed to "defend the peace of the Republic" and protect the religious rights of Greek Orthodox Catholics. By virtue of this understanding, Russian troops occupied Poland and imposed upon the Poles a pact that named the empress Catherine II as "Protector" of Polish laws and liberties. Rejecting this intervention, a group of ardent Polish patriots and Catholics organized a political and religious uprising against the Russian "Protector." While civil war raged within Poland, the Russians inadvertently became involved in war with the Ottoman Empire (1768), whom France had encouraged to support Polish liberties.

Veteran Russian troops quickly crushed the Turkish forces and occupied the two Danubian provinces of Moldavia and Walachia. Here was an immediate threat: should Russia's neighbours, particularly Austria, permit Russia to cross the Danube and overrun the Balkans without getting any territorial compensation? If Austria ordered its troops to attack the flank of the invading Russians to enforce its claim to a share of the Turkish territory, most likely Russia would have to fight Austria alone without the military support of her Prussian ally, for Prussia needed peace to recuperate from the Seven Years' War. With that consideration in mind the European forces veered away from the idea of despoiling the Ottoman Empire toward the project of partitioning enfeebled Poland instead. Russian troops, therefore, did not cross the Danube; Turkey was neither totally crushed nor partitioned; and the general peace was preserved. There would thus be no need to fight over the spoils. An amicable arrangement, mutually advantageous, could solve the Polish problem without involving the powers in war.

The first partition of Poland

A solution along those lines was casually suggested by Prussia, and within a year and a half, in the summer of 1772, the details were worked out; three separate treaties were signed, which specified the respective shares of the contracting powers. By this first partition, Poland lost nearly one-third of its territory and almost one-half of its population. Frederick's share was the smallest in land and population, but it was valuable for its strategic location and political worth. It closed the gap that separated the Prussian provinces, so that Prussia became one continuous stretch of territory between the Elbe and Lithuania, with control of the basin of the Lower Vistula and its enormously important grain trade. To Catherine went the eastern part of the old state of Lithuania. The chief importance of that territory was military, but it also gave Russia political as well as economic control over those eastern Polish provinces that had been penetrated by Russian traders for a full century. To the Habsburgs went 2,750,000 new subjects and a huge stretch of land that included Galicia, the northern slope of the Carpathians, and a corridor through Silesia to the new possessions.

Nevertheless, the partition of Poland set precedents for similar action against the Ottoman Empire. Continuing Russian military successes in the war begun in 1768 compelled the Porte to sue for peace. By the treaty of Kücük Kaynarca in 1774, the sultan recognized the independence of the Crimea, which the Russians had conquered, and ceded three of its great fortresses. The sultan paid a heavy war indemnity, opened the Black Sea to Russian navigation, and gave Catherine II a commercial treaty with the most-favoured clause. Russia restored the Danubian principalities that its armies occupied, but Catherine reserved the ominous right to intervene in their behalf. The Russians also won the right to build an Orthodox church in the foreign quarters of Constantinople, along with a vague and therefore doubly dangerous right to make representations in behalf of its worshippers.

In 1775–76 the Holy Roman emperor Joseph II acquired Bukovina and Fiume, which gave Austria outlets for trade to the north and west. In 1777 he troubled the peace again by seeking to acquire succession rights to the duchy of Bavaria. The attempt failed because Vergennes ruled that the alliance clause was not involved and because Prussia did its utmost to block a move that would have given Austria military roads from Bavaria to the Tirol and north Italy. Russia obtained additional prestige and influence from this dispute, serving as mediator (1779) between Prussia and Austria—that is, mediator within the internal affairs of Germany.

Stopped in that venture, Joseph allied himself by treaty with Russia (1781). Temporarily blocked in the west, he was associating himself with Catherine II in her "Grand Plan" for the partition of European territory of the Ottoman Empire. During a lull in the pressures in the east, Joseph again felt his way in the west. He sought to win consent to his effort to have the Scheldt opened to Belgian commercial navigation. He was thwarted in that venture as well as in the concurrent move to exchange the Belgian provinces for Bavaria. Neither Vergennes nor Catherine supported him, while Frederick of Prussia organized a League of Princes (1785) to block an arrangement that could have rounded out the Habsburg kingdom.

Russian occupation of the Crimea

Meanwhile, the Russian attrition of Turkey continued. In 1783 Russia occupied and unilaterally annexed the Crimea, which the Ottoman Empire was forced to recognize by treaty. A year later the Russian colossus occupied Georgia, there, too, declaring that it was "Protector." By 1787 the Ottoman Empire had had enough and declared war on Russia when the latter rejected a Turkish ultimatum for the restitution of the Crimea. Russia appealed to its new Austrian ally, and Joseph responded by deploying his troops on the Turkish line of the Danube. Joseph himself was soon to hasten home when word came that a revolt against his rule had broken out in Hungary, but the two predators were on the loose. This is where matters stood when the outbreak of the Revolution in France in 1789 threw old diplomacy and issues into the discard. All the great powers had fared well in the late 18th century; the only victims were the lesser and weaker states and the home populations that footed the bill for militarism, navalism, and balance of power diplomacy.

THE FRENCH REVOLUTION AND NAPOLEON

War with Europe. The Revolution in France revolutionized the nature and scope of international relations. The deputies of the National Assembly (1789–91), the Revolutionary government of France, had no intention of making war on the great powers. On the contrary, they voted a decree (May 22, 1790) formally renouncing all wars of conquest and promising that new France would never use its troops against the liberty of others. Out of the great reconstruction, however, arose frictions that within three years led to a war that was to be waged intermittently for almost a quarter of a century.

Conflict with the papacy

There was antagonism between the papacy and the assembly over the Civil Constitution of the Clergy (July 12, 1790), which sought to harmonize the relations of the secular clergy with the new civil administration. After protracted negotiations, the papacy condemned the constitutions and later declared the entire Revolution anathema. Pius VI also condemned the incorporation of the papal enclave of Avignon into France as an unjustifiable application of the principle of popular sovereignty in the conduct of international relations.

Other issues drew objections from the Holy Roman Empire. Various powerful German princes, who held feudal rights over certain territorial possessions in Alsace, appealed to the Emperor in protest against the application of the antifeudal decrees passed by the National Assembly. From the French point of view, since Alsace was politically part of France, the princes were pleading for special rights of extraterritoriality. So the National Assembly ruled against them.

Disputes notwithstanding, the powers did not use them as pretexts to intervene in the internal developments of France. Nor did they so use repeated secret appeals for help from the French rulers and the émigrés. Though the Emperor signed the preliminaries of a defensive military alliance with Prussia, he otherwise limited himself to a war of nerves, repeating that the restoration of the authority of the French monarchy was a matter of common concern to the powers.

Direct responsibility for going beyond this war of nerves lay with the bloc of Girondin deputies (then known as Brissotins) in the new Legislative Assembly (which replaced the National Assembly) who deliberately initiated a policy to provoke Austria into intervention and war. They were not alone in wishing that course to be followed. They themselves counted on a victorious war that would unmask what they called "the treason" of Louis XVI and Marie Antoinette and give them control over French policy. Military leaders like the Marquis de Lafayette, Louis, comte de Narbonne, and Charles-François du Périer Dumouriez, who also desired war, did so out of their conviction that France would be defeated and a grateful nation would then turn to them.

Leopold, while still holding to his tactic of verbal denunciation of "the pernicious sect of Jacobins," nevertheless tightened his military alliance with Prussia, while the Prussian king Frederick William II went further and drew up a plan of campaign. The Brissotins then presented an ultimatum to the Emperor, summoning him not only to renounce the Austrian–Prussian alliance but also all other treaties that threatened "the sovereignty, independence, and security of the nation." They counted on Leopold's rejection, and when the response of Leopold's son and successor, Francis II, was held "unsatisfactory" on April 20, 1792, France declared war on "the king of Bohemia and Hungary." The deputies defined the war as "the just defense of a free people against the unjust aggression of a king."

The early fighting against the Austrians was disastrous on the northeast front, and Prussia's entry in the war greatly intensified the military danger. As the steady Prussian advance brought their troops onto French soil and as the great fortress of Verdun fell into their hands, it seemed as though only a miracle could save Paris and the entire Revolution. The "miracle" occurred on September 20 at Valmy in the passes of the Argonne. The raw French recruits held firm against the Prussian line while their artillery fire stopped the enemy advance. Though only a minor skirmish, Valmy was in effect the decisive watershed of the war. The Prussians yielded their position and began a long retreat back to the frontier. As they retreated, the French advanced in a three-pronged offensive. Savoy fell to them, the Middle Rhine, too, and most important, the Austrian Netherlands, which Dumouriez overran.

The fall of Verdun

The problem then arose in all the conquered territory of future relations between the Gallic liberators and the pro-French native sympathizers. The solution came in a momentous declaration of policy. By the decree of November 19, 1792, the new assembly of the French Republic declared "in the name of the French nation that it will bring fraternity and aid to all peoples that wish to recover their liberty. . . ." This memorable decree threw down the gauntlet to the powers. It proclaimed an ideological crusade against the old European regime of kings and privileged order of society. A complementary decree (December 15) put teeth into the declaration of policy. It stated that in all occupied territory the system of taxation, the tithe, the titles of nobility, and all special privileges and feudal dues would be abolished, and all property belonging to local rulers was to be taken over by the agents of the French Republic. These self-styled "Friends of Liberty" would institute the new administrative system, and all who resisted them would be treated as enemies.

This mystique of a crusade, coupled with the older *politique* of conquest and annexation, laid down the bases for the war of Revolutionary France against all European states, immediately against England. Threatened by the French occupation of the Austrian Netherlands and by the opening of the Scheldt to French commerce, England prepared to fight. The Convention declared war on February 1, 1793, including the United Provinces in the declaration. A month later Spain, too, was at war, then (in rapid succession) Sardinia and Naples, the lesser Italian States, Denmark, Sweden, and the Ottoman Empire. England contracted treaties of alliance and subsidy with the member states of this First Coalition.

War with England

From a limited war between France and Austria, the conflict had broadened into a confrontation over two conceptions of human relations.

The defeat of the First Coalition. The fighting was a succession of defeats on all fronts. With Paris again exposed to direct attack and England declaring all France under a state of blockade, the Convention rescinded the decrees of November and December. The allies refused to negotiate: they were now discussing plans for a partition.

At this desperate juncture the Convention voted the decree of the *leveé en masse* (August 23), which was designed to transform France into an armed camp. "All Frenchmen," it read, "both sexes, all ages are called by the *patrie* to defend liberty." Implemented systematically, this declaration of total war released untapped vital energy, and the tide of battle turned to victory. By the last days of 1793 the invaders were beaten back on all fronts. Toulon was recaptured from the English, a young captain of artillery, Napoleon Bonaparte, distinguishing himself in the final attack. The Spanish withdrew to the Pyrenees and Savoy was cleared.

The élan of 1793 carried the Republican troops to victories in 1794. As the armies repulsed the invaders, they took the offensive. The line of the Rhine was regained. The Republican armies overwhelmed all of Italy. The Dutch fleet surrendered. Prussia was the first of the allies to sue for peace in the autumn of 1794. The supporters of a separate peace in Prussia reasoned that to give up territory along the left bank of the Rhine and later to receive compensation within Germany by the terms of a general European peace was a satisfactory end of the fighting.

For France the Peace of Basel (April 1795) was fully acceptable: it kept open the line of armed advance along the Rhine. To Prussia it brought the end of war and the highly advantageous status of being a neutral. By the Treaty of The Hague (May 1795), the United Provinces was compelled to cede strategic bits of territory and pay a heavy war indemnity. The reorganized Dutch government, called the Batavian Republic, was then bound to France by an alliance that drew the Dutch and their great resources into the war against England. A month later, in June, it was the turn of Spain, which had to recognize the French Republic and cede to it the Spanish part of Santo Domingo (Hispaniola). The final step taken by the French annexationists (in October) was to vote the incorporation of the Austrian Netherlands as an integral part of the territory of the Republic. The language of the French crusade to liberate enslaved peoples was kept in all these transactions; but the deeds of the liberators resembled nothing so much as the play of old-fashioned power politics.

Annexation of the Netherlands

The government of the Directory, the conservative government that came to power in France in 1795, set its sights on a general European peace. The two allies still in the field were also eager for a comprehensive settlement, but they were not ready to accept the preestablished terms set by France. So the Directory prepared to continue the fighting. Since victory on the seas was unlikely, the French plan of campaign called for limited naval operations. The main thrust was to be on the Continent. The major attack was directed against Austria, where in a broad pincer movement two great French armies were to converge upon Vienna. A minor supporting campaign was envisaged in Italy, where the assignment given to Bonaparte, who was in command of the Army of Italy, was to conquer Lombardy. The ultimate political aim of these military operations was to compel defeated Austria to retain Lombardy in return for its acceptance of France's retention of the annexed Austrian Netherlands.

It was not only the military genius of Bonaparte but also his views concerning the territorial settlement that completely upset the plans of the Directory. As he was winning his resounding victories in northern Italy in 1796 and 1797, his thinking ranged far beyond the objectives of his government. He agreed that the conquered Rhineland would be retained. He would not,

however, acquiesce in installing Austria in conquered Lombardy. He intended to retain French military control over the territory that he was reorganizing as the Cisalpine Republic and to use it, along with French-occupied territory on the Adriatic and in the Ionian Islands, as a stepping-stone toward Egypt. For he planned to turn next to the east and strike at England by severing its imperial communications.

Treaty of Campo Formio

With such projects in mind he carried on negotiations with Austria in the summer of 1797 that eventuated in October with the Treaty of Campo Formio. Austria recognized the French annexation of the Austrian Netherlands and agreed (in secret articles) to cede approximately two-thirds of the imperial territory on the left bank of the Rhine, provided that this cession were ratified at an imperial congress to be held at Rastatt. The ousted German princes were to receive compensation elsewhere within the empire. Prussia, however (and this, too, in a secret article), was not to share in the dismemberment as the Treaty of Basel had stipulated. In Italy, Austria received Istria, Dalmatia, and the Venetian mainland in return for the loss of Lombardy. The Cisalpine Republic was formally recognized by Austria. The Ionian Islands that Bonaparte was so anxious to gain went to France.

Such were the main provisions of Campo Formio that the Directory reluctantly ratified. It was an imperialistic peace, a sorry end to the crusade for liberty. The French statesman Emmanuel-Joseph Sieyès spoke wisely when he said: "This treaty is not peace; it is a call to a new war."

The Second Coalition, 1798–1802. The Peace of Campo Formio was an interlude. While Bonaparte went off on his romantic odyssey to wrest Egypt from the Porte (Turkish government), in his absence the agents of the Directory mercilessly victimized the satellite republics set up by the military commanders. Threatened again by all these acts, Austria, England, and Russia formed the Second Coalition (1798), to which the Porte, Naples, and Sardinia adhered. Though in the early months of 1799 the allies pushed back the French on several fronts and by mid-year republican defenses were crumbling, the allied victories were transitory. By early fall, when Bonaparte returned from his Egyptian fiasco, French victories had dispelled the military danger. France was secure against invasion and could negotiate for peace from strength.

The great majority of Frenchmen yearned for peace, but not Bonaparte. He needed a major military victory to consolidate the power he had seized by the coup d'etat of Brumaire in November 1799. He drew up plans for the campaign of 1800. Once again, as in 1796 and 1797, his spectacular victories in Italy were decisive. And again, as four years earlier, Austria asked for peace. Negotia-

Europe in 1798 and the expansion of the French Republic.

The Treaty of Lunéville

tions ended with the Treaty of Lunéville (February 1801). The salient terms of Campo Formio were reaffirmed. The piecemeal ousting of Austria from the Italian peninsula continued, but more important than its expulsion from the Duchy of Tuscany was the Habsburg recognition of the new Italian republics as sovereign powers.

Only England remained at war, and the English government had to yield to the insistent clamour for an end to the struggle. Peace talks were begun a month after Lunéville. The preliminaries of October 1801 were converted into the definitive Treaty of Amiens on March 27, 1802. The provisions were harsh. Egypt was restored to the Ottoman Empire. Both Malta, which went to the Knights of St. John, and the Cape of Good Hope were restored under conditions that made their future security precarious. Save for Ceylon and Trinidad, England restored its maritime conquests. Moreover, England tacitly accepted the main territorial changes on the Continent as they had been agreed upon at Lunéville. Amiens contained no provisions for a favourable commercial treaty that would reopen the continental markets for English goods.

In the circumstances, a chorus of recrimination fell upon the government. England obtained, so it seemed, only what Bonaparte gave it: peace on his terms. After ten years of war England's great rival and competitor emerged as the most powerful state in Europe. "One may state without the slightest exaggeration," Talleyrand was to write later, "that at the time of the Peace of Amiens, France enjoyed abroad, thanks to its military supremacy, such power, glory, and influence that the most ambitious person could desire nothing more for his country."

Bonaparte desired more. The conqueror who had needed peace in 1801 no longer needed or desired it two years later. His head was filled with vast projects, and to realize them he opted for war. War, he often stated, was essential to his plans.

Napoleon's grand design. The provocations by which Bonaparte deliberately forced England in self-defense to rupture the Peace of Amiens in 1803 reopened the coalition warfare that did not cease until the Treaty of Tilsit in 1807. Within the span of those four years Napoleon (as he was known after he established the French Empire) won his greatest victories at Ulm, Austerlitz, Jena, and Auerstädt, crushing Austrian and Prussian resistance. He also defeated the Russian armies at the battles of Eylau and Friedland, but he could not vanquish Russia itself.

Napoleon's Continental System

In those years he pursued against England that ruthless commercial warfare that he called the Continental System. To strike at England's prosperity and power by denying it entry of colonial products and manufactured goods was not new. What was new was his project, by a self-blockade, of destroying England completely by closing the markets of the entire Continent that had fallen under his domination. He would reduce England by "glutting her with excess." Such was the sense of the decrees of 1806 and 1807 by which he coordinated commercial war with conquest in Europe. The British tried by one means or another—smuggling, licenses, coercion of neutrals—to keep the channels of trade open.

In these circumstances, the role of Russia was crucial, and it was to enlist Russian support that Napoleon made peace and arranged an alliance with the colossus whom he could not decisively defeat in battle. This reversal of alliances was made at Tilsit in 1807. For Alexander I the gains of Tilsit were immense, or seemed so at the time. His position of a half-defeated enemy was transformed into that of an ally of the French emperor. The immediate gains of Napoleon were greater still: in return for recognizing Russia's special interests in eastern Europe he obtained an associate for his intention; the preamble to his treaty with Alexander put it "to assure the happiness and tranquillity of the globe."

For a "grand design" was maturing in Napoleon's mind. He had become the embodiment—and the victim—of a seductive vision. He brought to that design the force of his powerful personality, his traits of character, and his early intellectual conditioning. Into it entered a Plutarchian conception of the hero of classical antiquity. The example of Alexander the Great, who had striven to attain world domination, was a component of his grandiose dream; and perhaps most of all the idealized memory of the career of Charlemagne, who had restored the Roman Empire in the West, fashioned his thinking. He conceived himself as a new Charlemagne, the head of a European empire permeated by the sober ideals of the French Revolution, as he saw it, and resting upon an enlightened institutional rearrangement of state and society that would do away forever with the injustices and inequities of the lingering old order in Europe.

Napoleon's vision

He referred publicly to the Grand Empire that was to replace the moribund Holy Roman Empire. While kingships, duchies, and fiefs were established (none of them to survive his defeat) for members of his immediate family and his high civilian and military subordinates, the most momentous changes took place in the Holy Roman Empire itself. They had been initiated in 1803, when he secularized the ecclesiastical state. They continued with the extinction of the medieval city-states and the possessions of the imperial knights. The climax came in 1806. The surviving large secondary states became members of the Confederation of the Rhine of which he was protector, and it was these states that renounced their loyalty to the empire. There was now an empire without subjects, and on August 6 the Austrian emperor Francis II foreswore his titles and prerogatives. Now there was no old empire. The Grand Empire of Napoleon replaced the 1,000-year-old Holy Roman Empire.

For several years more Napoleon extended the boundaries of imperial France and the Grand Empire. In 1810 imperial France stretched from the Elbe to the Pyrenees and from the English Channel to Rome. In the south it included Genoa, Tuscany, Parma, Piacenza, the states of the church, and the Illyrian Provinces on the Adriatic. In the north it had incorporated parts of Hanover and Prussia, the Hanseatic cities, and all of the Netherlands. Outside imperial France, northern and central Italy fell under the authority of the Grand Empire, as did Spain, Naples, Westphalia, Frankfurt, and the new Duchy of Berg on the Rhine. Napoleon himself was king of Italy, protector of the Confederation of the Rhine, and mediator of the Swiss Confederation (now called Helvetia). Through the king of Saxony he held effective control over the Grand Duchy of Warsaw. Prussia and Austria, both nominally independent, were bound by treaties of alliance. Only England, Russia, Portugal, and the Porte lay outside Napoleon's control.

This vast Grand Empire rested on no firm structural foundation. With each apparent increase of its power Napoleon underscored its personal character. He never fully elaborated any single principle of political organization except that of hierarchical paternalism. The son whom the Habsburg princess Marie-Louise bore him in 1811 was to be the guarantee of the permanent rule of his new dynasty. But by then the tide was running sharply against him.

Resistance and opposition. The working of the Continental System inflicted heavy losses, but the grim years of English endurance were also years of increasing hardship for the French, too, years of swelling opposition. Resistance and opposition rose even more outside France.

Revolt of Spain

The first great revolt came in Spain, where religious and patriotic revolt broke out against French rule. Napoleon had counted on a small task force to wrest and hold military control. The nationalist uprising, the "cancer," as he called it, ravaged Spain for six terrible years. To contain it he had to invest many thousands of his veteran soldiers.

The reverses in Spain opened the Iberian Peninsula to an English expeditionary force under Sir Arthur Wellesley (later duke of Wellington), who, from his fortified lines in Portugal, methodically penetrated Spain.

Defeats in Spain and the sapping of French military strength ignited combustible hatreds in central Europe. They fired the fighting of 1809, when the Austrians pro-

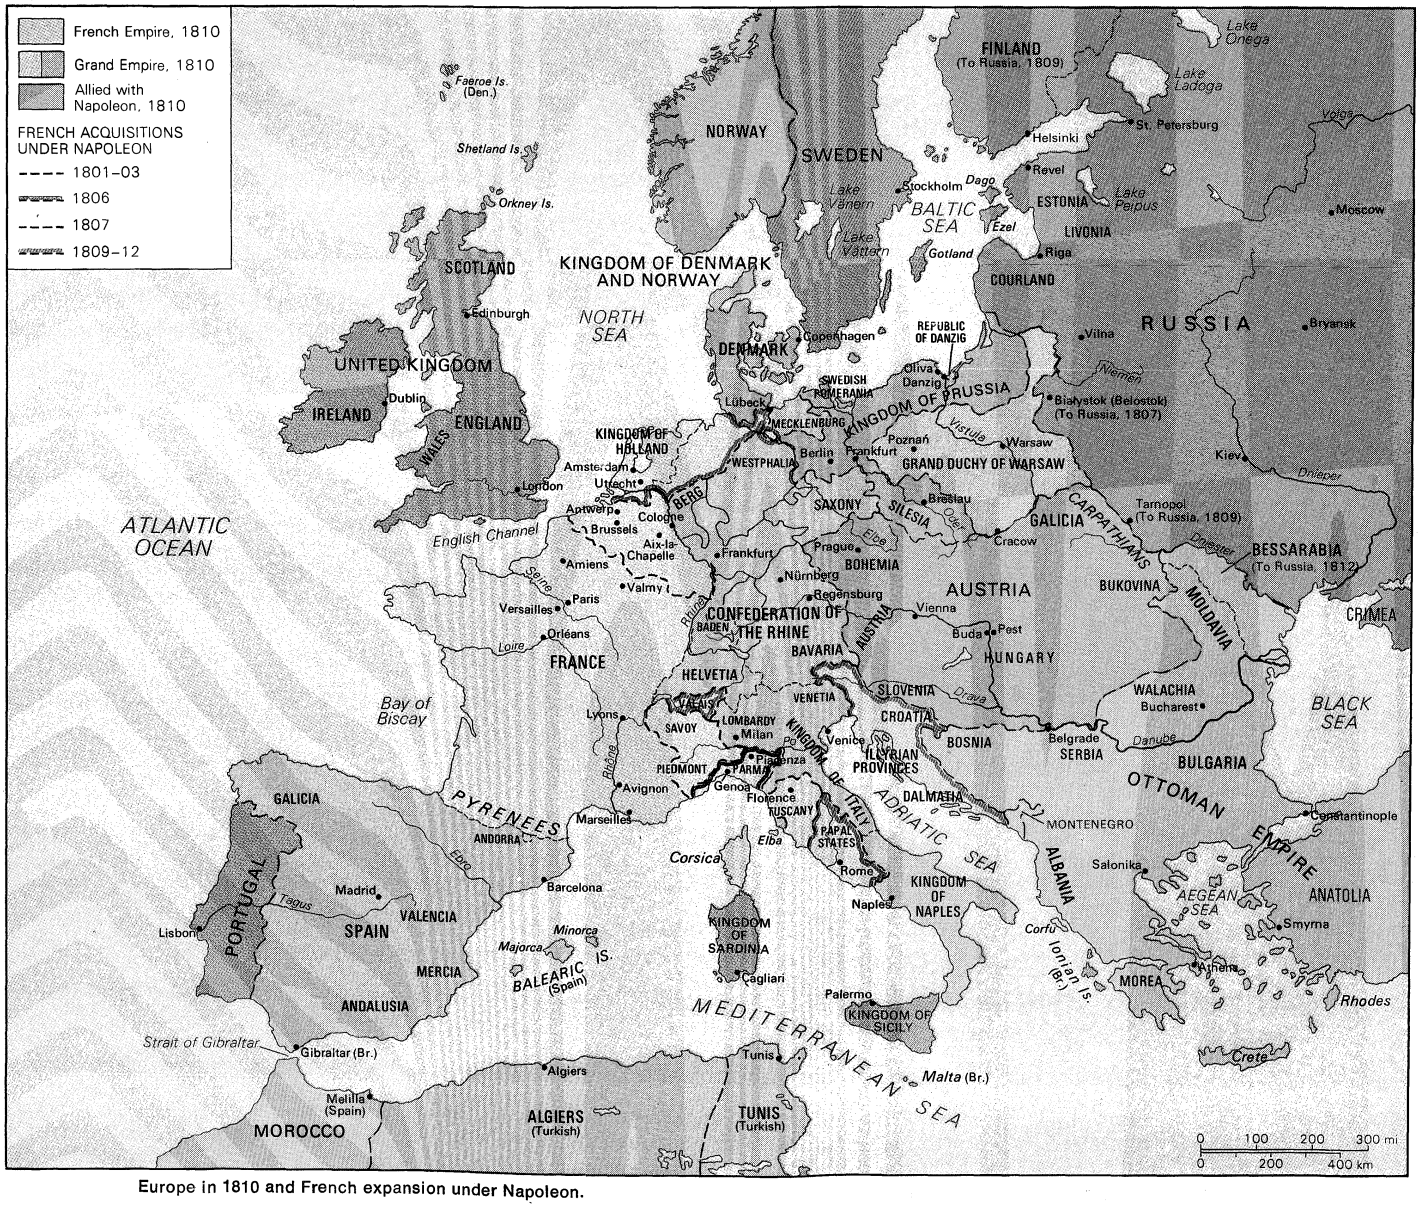
claimed a "war of national liberation." To his troops, as he took the field, the young Archduke Charles addressed a ringing appeal: "The liberty of Europe has taken refuge under your banners . . . your German brothers, now arrayed in the ranks of the enemy, await liberation at your hands."

The Austrian uprising was premature. Napoleon overwhelmed the enemy at Wagram and dictated onerous peace terms. He could not, however, arrest the preparations that Prussia was making for its emancipation. While the German philosopher Johann Gottlieb Fichte was penning his resounding *Reden an die deutsche Nation* (*Addresses to the German Nation*), resolute civilian reformers, among whom Karl, Freiherr vom Stein, and Karl von Hardenberg were the foremost, put down the foundations for a remarkable reconstruction of Prussian administration and pursued a policy of social regeneration. Under the guidance of Gerhard Johann David von Scharnhorst and August Wilhelm Anton, Graf Niedhardt von Gneisenau, military reformers rebuilt the armies that Napoleon had earlier shattered.

Break with Russia

The break with Russia was the catalyst of the final collapse of Napoleonic domination. The seeds of conflict had been sown in the very arrangements of Tilsit, by which France agreed to further Russian interest vis-à-vis the Porte and Sweden, and Alexander, conversely, promised his support of Napoleon's great design. Though it became apparent soon enough that neither partner was acting in good faith, strained relations were patched up after a fashion at a meeting at the summit at Erfurt in 1808. The Tilsit provisions were reaffirmed; so, too, were misgivings and secret hostile reservations. Relations were maintained on that level of mutual mistrust until the final break in 1812. The specific grievances concerned the future settlement of Poland and the European territory of the Porte, but the break came because in the last analysis there was not room enough in Europe for two competing imperialisms. Napoleon never doubted that he would win out. "In five years," he declared, "I shall be master of the world. Russia alone remains and I shall break her in pieces." In that expectation (of 1811) he invaded Russia on June 24, 1812.

Napoleon's collapse. The invasion of Russia ended with the holocaust of the Grande Armeé. Of almost 400,000 men who had crossed the Niemen into Russia, fewer than 100,000 struggled back to safety. The rest were dead or wounded, deserters or prisoners. With incredible rapidity Napoleon raised a new army with which he planned to renew the fighting. The enemy gave him no pause. Alexander made the fateful decision not to conclude a separate peace but to continue the war and liberate Europe. Prussia renounced its alliance and, in the early spring of 1813, before the campaign opened, declared war on France. The Austrians moved more



Europe in 1810 and French expansion under Napoleon.

slowly, Chancellor Metternich combining military preparations with diplomatic manoeuvres to gain Napoleon's acceptance of the peace terms that he offered. When those negotiations broke down during the armistice between the spring and autumn campaign, Austria, too, declared war. The spring campaign of 1813 was indecisive. The fall campaign was a disaster as calamitous as the Russian debacle. The troops that succeeded in escaping from Leipzig barely cut their way back to the Rhine.

The victors at that "Battle of the Nations" (Battle of Leipzig), their contacts established with the pro-peace leaders within France, invaded France in December—not, however, without first addressing an appeal to the nation over Napoleon's head. Meanwhile, victorious at Vitoria in Spain, Wellesley stood ready to invade France from the southwest. The net was tightening. In the spring campaign of 1814, fought on French soil, Napoleon won brilliant victories, but he lost the war to the allied invaders, whom the English foreign secretary, Viscount Castlereagh, barely kept united. By the Treaty of Chaumont (March 1814) Castlereagh also laid the foundations of the Quadruple Alliance, which, it was hoped, would enforce the peace once it was made. When Alexander and King Frederick William entered Paris on April 1, the true fighting ended. Napoleon's final effort at Waterloo a year later, after his escape from Elba, was in the nature of a quixotic game too late to have either lasting political or military significance.

For the military events of the period from 1789 to 1814 see FRENCH REVOLUTIONARY AND NAPOLEONIC WARS.

III. 1815–1914

THE AGE OF METTERNICH AND THE CHALLENGE OF 1848

The Congress of Vienna. For a quarter of a century France had kept Europe in turmoil. The French Revolution and its Napoleonic sequel had introduced a new liberal ideology into Europe and had boosted the national consciousness of its peoples. In 1814 France was finally defeated, and peace was restored by the Treaty of Paris. The Bourbons returned as the legitimate heirs to the French throne.

The restoration of the "legitimate" order—that is, the order existing in Europe before 1789—was the avowed intention of the victors who met in Vienna in 1814. The principal delegates to the Congress were four: Metternich for the Habsburgs, Viscount Castlereagh for Britain, Tsar Alexander I for Russia, and Talleyrand for France. Napoleon's brief return to power during the Hundred Days did not materially affect the decisions of the Congress. A second Treaty of Paris, somewhat more severe than the first, once more made peace with France.

In broad terms the Congress restored the former order, yet not without some qualifications. The Holy Roman Empire, ended by Napoleon in 1806, was replaced by a simplified German Confederation. The ancient republics of Genoa and Venice were absorbed: the former into the Kingdom of Sardinia, the latter, together with Milan, into the Habsburg domains.

The Habsburgs were thus compensated for their loss of the Austrian Netherlands, which was by this time joined to the United Provinces as compensation, in turn, for that country's loss of certain overseas possessions to Britain. Tsar Alexander's ambitions in Poland almost wrecked the Congress until a compromise was reached, and Poland, save for Cracow, remained divided between Austria, Prussia, and Russia. Prussia acquired part of Saxony and territory in the Rhineland. The King of Saxony correspondingly suffered a territorial loss, as did the Danish king; Norway was severed from its Danish connection and joined to Sweden in compensation for the latter's loss of Finland to Russia. Britain retained Ceylon and the colony of the Cape of Good Hope and gained Malta and a protectorate over the Ionian Islands—these last two an expression of Britain's heightened interest in the Mediterranean. Ottoman affairs were not dealt with at Vienna, and Russia retained Bessarabia, which it had acquired from the Turks in 1812.

One of the main concerns of the peacemakers was the preservation of the balance of power, a concern that caused Castlereagh and Metternich to enlist Talleyrand's support in opposing Russian encroachment. Indeed, Castlereagh staunchly defended France, which was deprived of its conquests but not otherwise diminished, for France was an essential component of the European equilibrium.

Preservation of the balance of power

This relative absence of a vengeful spirit, perhaps surprising to a later age, may be credited to the fact that rulers rather than the representatives of the peoples contrived the settlement of Vienna. All agreed that the task of ruling was the proper appanage of a small class; yet there were differences. The three eastern powers—Austria, Prussia, and Russia—were absolute autocracies, whereas Britain was a constitutional monarchy. The charter that Louis XVIII granted to his subjects foreshadowed a cleavage between liberal (Britain and France) and conservative (Austria, Prussia, and Russia) Europe. After 1815 "constitution" became the shibboleth of liberals everywhere. Metternich was concerned with the preservation of the social order, and Tsar Alexander invented the Holy Alliance, a somewhat mystical rulers' international, which Britain declined to join. Castlereagh set greater store by the Quadruple Alliance, a more concrete and limited instrument, designed to contain France. Whatever ideological affinity there may have been between the two countries, at the level of power the Anglo-French rivalry was solidly established.

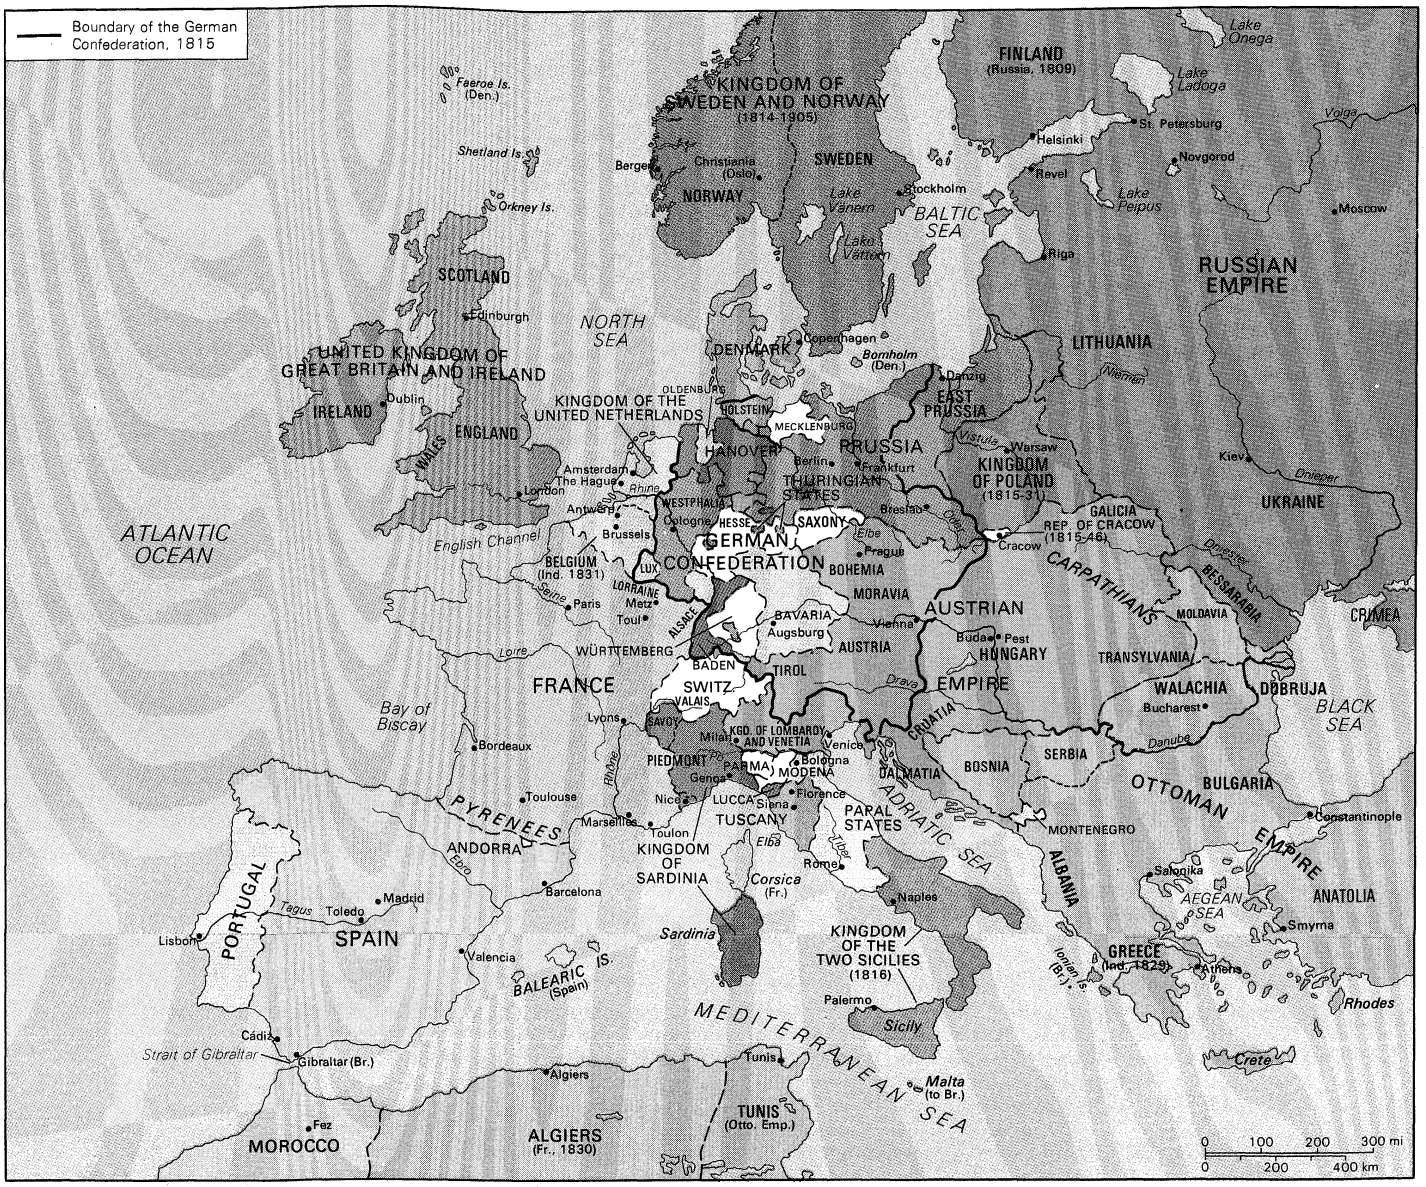
The Restoration period. On the basis of a somewhat ambiguous understanding the European order was maintained for a time. The shock of the Napoleonic Wars was strong inducement for the powers to cooperate to maintain the peace. France gave no evidence of aggressive ambitions and was soon admitted as a member in full standing to the Concert of Europe, an informal organization, yet one not devoid of reality, which for a century had perhaps greater effectiveness than the more formalized 20th-century attempts to organize international order. In one respect the European concert was far simpler: it assumed it to be both the right and the duty of the Great Powers to impose their collective will on those states not admitted to the charmed inner circle.

The peacemakers took the position that a disturbance anywhere in Europe was the legitimate concern of the powers. But on this score a cleavage soon appeared. When there were liberal risings in Italy in 1820, Metternich summoned the powers, which met at Troppau and later at Laibach. From them he received the mandate to restore order in Naples with an Austrian army. But a constitution in Naples little concerned Britain, whose consent to the Austrian intervention was rather due to its view that Italy was an Austrian sphere of influence.

An extremely important issue was involved here—that of the right of outside intervention in the internal affairs of another state. The revolutionary contagion of 18th-century France or 20th-century Russia gives profound reality to the question, which has remained a vital one to this day.

A similar problem arose in connection with Spain, where an army mutiny in 1820 grew into a rebellion, but the cleavage was sharper among the powers when they dealt with that problem at the Congress of Verona in 1822. None of the powers was keen on Russian intervention, which the Tsar would have willingly provided; France was the logical candidate for a European mandate to restore order in Spain. France itself was hesitant, and George Canning, who had replaced Castlereagh as the British foreign minister, opposed such an intervention mainly because it would be French. In the event, a French army marched into Spain, restored King Ferdinand VII's autocracy, and returned home. Europe had enforced its collective will.

Canning did not carry his opposition to French intervention so far as to threaten the use of force, but he did make it clear that Britain might use force to prevent the extension of European assistance to Spain in putting down rebellion in its American possessions. Canning



Europe after the Congress of Vienna.

The Monroe Doctrine

proposed to the United States a joint Anglo-U.S. policy statement against European intervention in the Americas. But the United States decided to act independently. The result was the Monroe Doctrine, proclaimed in 1823. Although it was a U.S. declaration, it was dependent for some time for its enforcement on British naval power.

Reaction was on the ascendant everywhere in Europe around 1820: the British Parliament passed the notorious Six Acts (1819) against radical activities; Metternich procured the Carlsbad Decrees (September 1819) suppressing student societies and freedom of speech; and in France the reactionary aristocracy inaugurated the White Terror against republicans. The last Bourbon ruler of France, Charles X, a thoroughgoing reactionary, came to the throne in 1824. But, by the end of the decade, at least in France and Britain, the temper was changing. Britain was showing signs of returning to a more liberal practice—civil restrictions against Roman Catholics were removed in 1829—and there was much agitation for parliamentary reform and the broadening of the franchise. Across the Channel the liberals' pent up frustration with Charles X was reaching explosive proportions.

In July 1830 a revolution in Paris drove Charles X from the throne and replaced him with Louis-Philippe, who styled himself "king of the French" rather than king of France. France was approximating ever more Britain's constitutional monarchy, and with the enactment in 1832 of the great Reform Act in Britain, the political ordering of the two countries achieved considerable similarity: the rising class of commercial and financial bourgeoisie had gained substantial power. But in both countries, especially in France, workers felt denied and frustrated.

France still possessed its revolutionary tradition. Liberals everywhere turned to Paris for inspiration, and a rising in France contained contagious possibilities. There were again risings in Italy and some agitation in the Germanic world, but these movements received no assistance from France. Metternich's control remained secure in his domain; the Prussian king was content to follow Metternich's lead in Germany in exchange for Austrian consent to the Prussian-promoted policy of economic integration, the developing Zollverein, or customs union, from which Austria was excluded.

One particular problem arose in connection with the July Revolution that subjected the Concert of Europe to a severe test. Belgium (roughly the former Austrian Netherlands) had since 1815 been a possession of the Dutch king. Belgium, however, possessed a distinct identity that caused it to resent a somewhat less than tactful—and for that reason all the more apparently alien—rule. Here was the meeting ground of the French

and Germanic worlds, a fact reflected in the linguistic division between Flemings and French-speaking Walloons, the former staunchly Catholic, the latter more influenced by French liberal thought. But the two groups finally joined in a demand for greater control over their own affairs.

The rising in Brussels in August 1830 and the intransigent attitude of King William I resulted in a Belgian proclamation of independence in October. A double question arose: would the powers respond to the Dutch king's appeal for assistance in putting down unquestionably rebellious subjects, and would Louis-Philippe aid the rebellion, which enjoyed not a little sympathy in France?

Louis-Philippe was no revolutionary and determined not to intervene in affairs outside the borders of France. He had to overcome British doubts, for the freedom to trade on the Scheldt River in Belgium rated high among British interests. But once Talleyrand persuaded the British of Louis's good intention, the policies of the two countries coincided, for Britain felt little concern for Metternichian legitimacy. Metternich himself and the Prussian king had no stomach for a confrontation with France, and the Tsar was busy with his own Polish rebellion. This meant Belgian independence unless King William could deal with the situation with his own means.

The powers, which met in London to deal with the problem, accepted a de facto situation: they collectively sanctioned Belgian independence, settled the matter of its frontiers, and underwrote the perpetual neutrality of the new country. They also found a ruler for it in the person of Leopold I of Saxe-Coburg, an uncle of the future Queen Victoria. King William bowed to the inevitable and Belgium endowed itself with a liberal constitution.

Belgian independence

Clearly, here was also an instance of nationalistic success—a breach in the existing European order. But it had been effected nevertheless in peace through the agency of the Concert of Europe.

The Eastern Question. The powers meeting in London to deal with affairs in The Netherlands were also involved in the discussion of Ottoman affairs, which had not fallen within the purview of the Congress of Vienna. The Tsar's characterization of Turkey as "the sick man of Europe" was an apt one. The still vast Ottoman domain was beset by general decline and maladministration that resulted in a centrifugal tendency, most marked in its peripheral marches; in its European section, the Balkans, the forces of nationalism were gaining increasing strength. In addition, the Balkan peoples were overwhelmingly Eastern Christians, but the Sultan was caliph of Islām; the theocratic nature of the Ottoman state was an impediment to its modernization. The impotence that went with decadence created a temptation for the Great Powers, who could either maintain the status quo in the Ottoman lands or agree to their partition. Inability to agree on the latter resulted in an attempt to adhere to the former, an attempt attended by a number of crises. The Eastern Question, as it came to be known, remained a perennial of the 19th-century diplomacy of Europe. Among the powers, Russia, Britain, and France all had important interests in the Near East; Austria's were more narrowly confined to the adjoining Balkans; Prussia had none.

The Greek revolt

The combination of Turkish maladministration and of a reviving Greek national consciousness resulted in a revolt and, in 1822, a Greek proclamation of independence. The revolt dragged on inconclusively, a temptation to the Tsar in particular, torn between his devotion to legitimate rule, in this case Turkish, and the possible enhancement of the purely Russian interest.

The 1827 Treaty of London between Russia, Britain, and France was the outcome; it expressed their agreement in exerting pressure in Constantinople to grant concessions and reforms. But things went wrong at this juncture, for the accidental destruction of a Turco-Egyptian fleet by a mainly Anglo-French one in Navarino Bay in 1827 and open war between Russia and Turkey the next year created a new situation. The Russians eventually defeated the Turks, and imposed peace on them, but they were willing to join in the subsequent collective arbitrament of Europe.

In this instance also the powers managed to agree, with the consequence that, as in the case of The Netherlands, an independent Greece was born whose frontiers the powers established and on the personality of whose ruler—Otto I, the second son of the King of Bavaria—they likewise agreed. Again, the European concert had proved its effectiveness, and nationalism registered a success. But, from the standpoint of the latter, the story of Balkan emancipation was only beginning.

It was a measure of Turkish decline that during the Greek revolt the Sultan had enlisted the assistance of his vassal Muḥammad ʿAlī Pasha, an able soldier of fortune who had established himself in control in Egypt. The aftermath of the Greek episode was a falling-out between the Sultan and his vassal. In war Muḥammad ʿAlī was successful, but Russian pressure rescued the Sultan in 1833. When, six years later, the Sultan sought revenge, he was once more defeated by the Egyptians. But matters this time took a different turn. Britain was now the chief supporter of the Sultan, while France was playing the Egyptian card. It came close to a dangerous confrontation, but once Louis-Philippe had replaced the belligerent Adolphe Thiers with the more accommodating François Guizot as foreign minister, agreement among the powers was restored. Muḥammad ʿAlī had to remain content with the rule of Egypt alone.

The Anglo-French confrontation inserts itself as an episode in the long record of imperial rivalry between the two countries. But in general that activity was at a relatively low ebb during this period. The French did, hesitantly at first, lay the bases of their North African establishment, and the British, with the French and others in tow, began to open up China, in whose trade the United States was also interested. The British and the French were also active elsewhere in Asia (Malaya and Aden) and in the Pacific (New Zealand and Tahiti), and both kept an interested eye on Mexican and Texan affairs.

The events of 1848–49. Despite their rivalry, there was a measure of agreement between the two powers, and in mid-Europe Metternich had things under control. But liberals everywhere were also active; once more, in 1848, an explosion occurred, and again its Parisian phase was the signal for others. In France the Second Republic was established, but for Europe as a whole the main question was whether the new French regime would extend assistance to revolution elsewhere.

Revolution in Paris

The news of the Parisian uprising was the spark that set off liberal demands in mid-Europe. In Vienna and Berlin and in the small German states the cry was for constitution, but in Prague, Budapest, and Milan the nationalistic force equally asserted itself. Metternich's system everywhere was in collapse; he himself fled into exile, while the frightened rulers, taken by suprise, granted their subjects constitutions.

On two occasions, in 1848 and again in 1849, there was war between the Kingdom of Sardinia and Austria, the former being defeated both times. Prague was subdued and so likewise was Budapest, though it took a little more time—and Russian assistance—to effect the latter result. The army had remained loyal, and under the stern but able leadership of Felix, Furst zu Schwarzenberg, Habsburg rule was everywhere re-established; the momentarily frightened Prussian king took back his concessions, while the representatives of the Germanic world, assembled in Frankfurt am Main, gave proof of the ineffectiveness of mere high-handed talk in the absence of concrete power. But, mainly as a consequence of France's abstention, the disturbances did not spread into a major international conflict.

In France the February revolution was followed by another in June, in which the forces of order reasserted their control. The majority of the French people refused to follow the lead of the more radical Parisian workers. By the end of the year, the election to the presidency brought to that office Louis-Napoleon, a nephew of the first Napoleon, who exploited with skill the widespread

desire for order and the by-now legendary associations that were connected with the name. But Louis-Napoleon continued the French policy of nonintervention, and reaction was unimpeded in reasserting its control in mid-Europe in 1849. By the end of that year the revolutionary urge was spent and had apparently accomplished little.

What international complications there had been were limited and did not threaten the peace among the powers: a brief Prussian incursion in Denmark, a Russian one in Hungary in assistance to the Habsburg ruler, and a French force in Rome protecting the Pope were the sum total of these interventions. Yet there was also warning for the future. The impotent Frankfurt National Assembly in 1849 offered the German crown to the Prussian king; in fear of a sufficiently restored Austrian power, he declined, and, when a year later he attempted a scheme of his own to somewhat similar effect, he withdrew in the face of an Austrian ultimatum. Nevertheless, the issue of German unity and of the bases of it, whether Grossdeutschland or Kleindeutschland (*i.e.*, including or excluding Austria) had been seriously agitated. The events of 1848–49 may be summed up as a challenge to the existing order, an unsuccessful one at the time but a challenge that cast a shadow on the future.

The Frankfurt National Assembly

REVISION OF THE SETTLEMENT OF VIENNA

More than three decades after the Vienna settlement, Europe was still organized essentially as it had been in 1815; and the Great Powers had proven themselves capable of acting in accord. France, to be sure, remained a question mark, especially after 1852, when Louis-Napoleon ended the Second Republic by a coup d'etat and became Emperor Napoleon III. The Emperor's declaration that "the empire means peace" was only partially convincing to the Great Powers; in fact, Napoleon's 18-year reign was to witness an extensive revision of the settlement of 1815, a process in which France played an important part, though not always a directing hand.

The Eastern Question again: the Crimean War. The first major shock to the Concert of Europe after 1848 was the Crimean War. The war grew out of a minor squabble over the respective rights of Eastern Christians and Roman Catholics in Jerusalem, which was under Ottoman control. Napoleon III, for reasons of prestige, undertook the vigorous defense of Roman Catholic interests in the Near East. The effect, however, was to provoke a Russian reaction, ostensibly in defense of the Eastern Christians but also an attempt to gain further concessions from the Turks. Thus, the quarrel of the monks escalated into a larger competition. The Turks adopted their familiar tactic of encouraging differences among the powers, which they did with total success.

The Franco-Russian difference soon turned into an Anglo-Russian one, for the British feared Russian expansion into the Mediterranean. The crisis was slow in unfolding, to the accompaniment of poor diplomacy, but eventually a Turkish declaration of war against Russia at the end of 1853 was followed by British and French declarations early in 1854.

Both sides sought support from Austria, which, however, remained neutral. Austria earned thereby the discontent of all, but Vienna remained the centre of diplomatic activity throughout the conflict. The Austrians occupied the Danubian Principalities in the Balkans, thus preventing land contact between the belligerents, save in the Caucasus. Making use of their naval power, the western states carried the war to the Russians in the Crimea.

The war itself has been described not unfairly as a contest in incompetence; but in the end, the more technically advanced western powers were able to defeat the Russians on their home ground. The advent of a new tsar, Alexander II, in 1855 finally made accommodation possible, and the belligerents met in Paris in 1856.

The Congress of Paris

The Congress of Paris is an important landmark in the history of the Eastern Question. The Russians did not pay an exorbitant price for their defeat, as the war had been one of limited aims. The congress took place in a friendly atmosphere of festivities; the Concert of Europe had momentarily broken down, but the fundamental consensus of the powers persisted.

Europe, collectively, replaced Russia in the assertion of supervisory rights in the principalities, and a small loss of Bessarabian territory deprived Russia of access to the Danube, but otherwise the status quo ante-bellum was restored. The Black Sea was demilitarized, a clause that rankled in Russia. Also, the Ottoman Empire was admitted to membership in the Concert of Europe, though, curiously in a sense, simultaneously placed under what was tantamount to a collective European protectorate.

The powers gathered in Paris used the occasion to deal with some other matters, such as diplomatic procedure and international law, especially its maritime aspects, including the perennial concern over the rights of belligerents and neutrals at sea in wartime. One question, however, that received little more than passing attention was that of conditions in Italy, where the quality of administration in the Kingdom of the Two Sicilies and in the papal domain was not much better than in the domain of the Turkish sultan.

The making of Italy. There were two reasons for raising the Italian question at the Congress of Paris: the interest of the French emperor in Italian affairs and the presence of Count Cavour, who represented the Kingdom of Sardinia. Sardinia was not a great power but had sent a contingent of troops in support of the allies in the Crimean War.

Cavour is properly credited with the making of a united Italy; he was responsible for Piedmontese participation in the Crimean War, precisely in order to bring the Italian problem to the attention of Europe. His reward in Paris was small, but the interest of Napoleon III was not; and the consequences of it were soon to be apparent.

Since the days of ancient Rome, Italy had been little more than a geographical expression—more recently a battleground of rival influences, Spanish, French, and Germanic. But the consciousness of a common culture, especially among the literate and the educated, persisted. The French Revolution and its Napoleonic sequel had introduced nationalism as an active political force in the Italian world. The settlement of Vienna, making Austria the paramount power in the peninsula, inevitably gave Italian nationalism an anti-Austrian point.

Nationalism was to a considerable degree associated with the liberal agitation for constitutional reform, one of the chief spokesmen for which was the Italian patriot Giuseppe Mazzini. Mazzini hoped to make Italy a unitary republican state by doing away with all the existing ruling houses. But his was an extreme solution; a more moderate approach was that of federation, which had the advantage of leaving unimpaired the temporal power of the Pope, who might be called upon to head a federal Italy.

Other nationalists looked for leadership to Piedmont rather than to the papacy, for the popes were often reactionary. Piedmont in northern Italy was united with Sardinia under the House of Savoy as the Kingdom of Sardinia; the country was the most advanced independent Italian state.

Austria had successfully suppressed Italian risings in 1820 and 1830, and attempted Piedmontese leadership in 1848 fared little better; but the events of 1848–49 did have a clarifying effect; the republican and the federalist tendencies—Mazzini and the Pope—both lost their credibility. Piedmont, though defeated in war, had stood up to Austria and even managed to retain its new constitution, the Statuto of 1848.

Cavour's policy

Also, the 1848 disturbance brought Cavour to power in Piedmont. Essentially a practical man, Cavour had little use for romantic revolution or Mazzinian plotting. Once in charge of Piedmontese affairs, he proceeded on the realistic assumption that the only way to evict the Austrians was with the help of a foreign force—which France alone could supply.

In July 1858, Napoleon III and Cavour met at Plombières and worked out a secret agreement whereby France would gain territorial concessions in Italy in return for French military help in throwing off Austrian

rule. Cavour was forced to a compromise, for the well-meaning but irresolute French emperor was, after all, primarily in charge of the interest of France, from whose standpoint a divided Italy was preferable to a united one. Also, Catholics were powerful in France.

In April 1859 Cavour provoked a war with Austria, which found itself confronted with France as well. The brief war was successful for the allies; but Napoleon, concerned over Prussia's mobilization, put a sudden end to it at a meeting between himself and the emperor Francis Joseph I at Villafranca on July 11. Cavour, feeling betrayed, resigned in anger.

But it was too late for the limited stabilization that Napoleon and the Emperor tried to devise at Villafranca. The war precipitated nationalist revolts throughout Italy. Venice remained in Austrian hands, but the rest of the Italian structure toppled. Risings and plebiscites in the central states, and Giuseppe Garibaldi's colourful and successful expedition against the Kingdom of Naples, essentially brought Italy together. In March 1861 the Kingdom of Italy was proclaimed, which became a centralized, unitary state patterned on the French model. Sardinian constitutional arrangements were extended to the whole under the Savoy dynasty. The pope, however, continued to rule in a much reduced domain under French protection. Within another decade Venice and Rome were incorporated into the main body of Italy as footnotes to larger events.

The appearance of united Italy on the map of Europe was unquestionably a success of the nationalistic force, the undoing of which was hardly possible, even though most Italians had been merely passively acquiescent. France had acquired Nice and Savoy on the plea of ethnic affinity, but the manner in which the war with Austria had been settled and the Roman issue dealt with added little to Napoleon's credit in either Italy or France. As a new major power, even if the weakest, a united Italy was welcomed by Britain as an additional potential counterweight to France.

The making of Germany. The success of Italian nationalism had been followed with special interest in Germany. There were both similarities and differences between the two situations. The most fundamental fact was the existence of a German people. A claim to universality comparable to the Roman and expressed in the institution of the Holy Roman Empire had long been voided of content, and, as in Italy, there was a long record of particularistic divisions and loyalties. Two rivals contended for possible leadership in the Germanic world—the Habsburgs and the Hohenzollerns. The very nature of the Habsburg state, with its agglomeration of diverse nationalities, could not but make it antagonistic to national aspirations, which, conversely, Prussia could more easily espouse. A new component—nationalism—was thus introduced in the 19th century into what had been hitherto a dynastic contest. In Germany, as in Italy, the impact of French influence, revolutionary and Napoleonic, had given a fillip to national aspirations.

For nearly 30 years Metternich had successfully presided over the Germanic world, and his departure from power in 1848 was soon followed by a seeming return to the prerevolutionary order. The events of 1848–49, not least those in Frankfurt am Main, were a liberal failure, even though a Prussian constitution was promulgated in 1850.

The whole Germanic world remained uninvolved in the Crimean War. Order prevailed in it during the 1850s, but neither the Habsburg–Hohenzollern rivalry nor liberal hopes had been lastingly eliminated. It was a domestic Prussian problem, the issue of army credits, which developed into a dispute between the crown and the Landtag, that finally in 1862 brought Otto von Bismarck to the minister-presidency of Prussia. One is reminded of Cavour after 1848, and there are points of similarity between the two men, their diplomatic skill above all. But there is also contrast. Whereas Cavour believed in liberalism, Bismarck was a typical representative of the Prussian Junkers, the landowning aristocracy that formed the conservative backbone of the Prussian state.

The rise of Bismarck

Contemptuous of the idle speeches and resolutions of the ineffectual revolutionaries of 1848, Bismarck, believing in "blood and iron" methods, solved the constitutional issue through the simple device of ignoring the constitution. His first great accomplishment was to settle clearly the Austro-Prussian competition in Germany through the radical solution of ousting Austria from the Germanic world outside the Habsburg domain proper; Bismarck was a Kleindeutscher.

The operation was conducted with masterful skill. The method was to isolate the issue from larger international complications, then to deal with Austria through the test of military force. Bismarck secured Russian neutrality by cooperating with Tsar Alexander II in putting down a Polish rising in 1863. The grateful tsar, already incensed by Austria's neutrality in the Crimean War, shifted his support from Austria to Prussia.

Danish affairs offered Bismarck his next opportunity. Posing as the defender of oppressed German nationality in the Danish duchies of Schleswig and Holstein, Bismarck persuaded Austria to join him in war against Denmark in 1864. The duchies were put under joint Austro-Prussian control, an arrangement highly suitable for later bickering. The British and the French could not agree on joint action and left Denmark to its fate.

Having beguiled Napoleon III into neutrality through hints of possible compensation, Bismarck then proceeded to pick a quarrel with Austria over Schleswig–Holstein, and the Austrians unwisely went to war. The Austro-Prussian War of 1866 lasted only seven weeks, the Prussians defeating the Austrians at Sadowa (Königgrätz) in July. Austria was evicted from Kleindeutschland, which was reorganized in 1867 under the Prussian-dominated North German Confederation, while the South German states were left undisturbed. Austria was not otherwise punished, but its loss in the war pointed up the need for internal reform. In 1867 the Habsburg domain was reorganized as the Dual Monarchy of Austria-Hungary, under which the Habsburg lands in Hungary achieved constitutional parity with Austria—another success of the nationalistic force. Italy, which had joined in the war, though she fared poorly in it, acquired Venetia as a result of the Austrian defeat.

The Seven Weeks' War

Events had moved too fast for Napoleon III to intervene, but the ambition of Bismarck was clear. Bismarck did not think that France would stand idly by while German unification under Prussia was completed. Realizing that another war would be necessary, Bismarck prepared for it in the same fashion that he had for the showdown with Austria: the conflict must be isolated. The Tsar was still sympathetic; England was on the whole indifferent; and the reorganized Austria-Hungary was increasingly Balkan oriented.

This time it was Spain that provided Bismarck with his opportunity. A revolution in that country resulted in the search for a new ruler, in the course of which the candidacy of a member of the Hohenzollern house was advanced. France, understandably, objected to the possibility, and Bismarck brilliantly manipulated the controversy to provoke a military showdown. Napoleon III, himself not desirous of war but by now a sick and an ever vacillating man, fell victim to the trend of circumstances. France declared war in July 1870 and was ostensibly the aggressor, but Bismarck had led the game all the way.

The war remained confined to France and Prussia (or rather Germany, since the south German states joined Prussia). The outcome was shortly apparent. A large French army, with the Emperor himself, surrendered at Sedan in September. The succeeding French provisional government could only prolong the futile contest for a time. Paris was besieged and surrendered in January, and the French had no alternative but to accept the harsh terms of the victor: a large indemnity and the surrender to Germany of Alsace and a part of Lorraine.

The Franco-Prussian war

Peace was restored by the Treaty of Frankfurt in May 1871, while the new French government established in February was harshly putting down the episode of the Paris Commune. Thus, in hesitant fashion, the Third French Republic was born.

Meanwhile, in January at Versailles, the German Empire had been proclaimed, which, having successfully passed the test of force, took France's place as the first power on the Continent.

There were two footnotes to the Franco-Prussian War. In September 1870 the Italians entered Rome, henceforth their capital. (The Pope declared himself a prisoner in the Vatican, refusing to acknowledge the *fait accompli.*) The Russians also took advantage of the war to denounce the demilitarization of the Black Sea imposed upon them in 1856.

The Franco-Prussian War was the major international event of the period 1815–1914, which it divides into two nearly equal parts. But some other events had occurred since the Crimean War.

The Eastern Question was relatively quiescent during this period. What complications arose in connection with it were settled by the powers in agreement. Between 1858 and 1864 the Principalities (Moldavia and Walachia) achieved their union and their virtual independence as the country of Romania (then Rumania).

The French interest in Egypt persisted and was enhanced by the successful construction of the Suez Canal by a French company, despite some English obstructionist attempts. The canal, inaugurated in 1869, soon proved to be a great commercial and financial success.

In 1863 the Poles revolted against Russia. They were subdued, though not without difficulty, and Poland became, in effect, a Russian province. The Polish hopes of external assistance were frustrated, and, as a consequence of the episode, a Russo-Prussian understanding replaced the previously existing Franco-Russian (see above).

Events outside Europe. Outside of Europe some developments of considerable significance, especially for the longer term, also took place. The long self-imposed isolation of Japan came to an end when, in 1854, the American commodore Perry succeeded in negotiating the Treaty of Kanagawa. After a period of hesitation, in 1868 Japan deliberately embarked upon the path of Western imitation as the only manner in which it could retain its independence.

The opening of Japan

In China, a process of decline and disintegration continued reminiscent of that of the Ottoman Empire. The Taiping Rebellion eventually led to foreign intervention, mainly Anglo-French, the forcible opening of China, and the imposition upon that country of discriminatory treaties. The Russians were expanding in Siberia, securing the boundary of the Amur River. Vladivostok, on the Pacific, was founded in 1860.

In Southeast Asia the British influence was reaching out from India, reorganized after the great Indian Mutiny of 1857, toward Burma and Siam, while the French established themselves in Cochin China and Cambodia, thinking of the Mekong River as a possible southern route of access to China.

The American continent was supposedly out of bounds for European intervention, but the British and French maintained interests in Mexico and in Texas; Britain's maritime and commercial empire made the possibility of an isthmian canal of equal interest to Britain and to the United States. Manifest destiny meant territorial expansion for the latter, mainly at the expense of Mexico, but domestic issues exploded into civil war between the North and the South in 1861. Aware of the potential rivalry of the United States, the British and the French, at the governmental level at least, tended to be sympathetic to the fragmentation of U.S. power and toyed with recognition of the South. The war gave rise to some incidents—the "Trent" affair and the "Alabama" claims—but the ultimate success of the North preserved the unity of the country while laying the bases for its subsequent astounding growth. The emergence of the United States, Germany, and Japan within less than a decade is worth noting.

The French in Mexico

The U.S. Civil War facilitated French intervention in Mexico, and Napoleon III succeeded in placing his candidate, Archduke Maximilian of Austria, on the Mexican throne in 1863—an action highly unwelcome in the United States. The termination of the Civil War and the menace of a united Germany induced Napoleon III to recall the French force from Mexico, and, lacking local support, luckless Maximilian was captured and executed. The Mexican episode contributed to the impression of the French emperor as a meddler, a factor that, in turn, contributed to British and American indifference during the Franco-Prussian War.

THE IMPACT OF ECONOMICS ON POLITICS

During the 19th century economic change had an overwhelming impact on international affairs. At the opening of the century, Britain was the foremost commercial state in the world, and British wealth was the mainstay of the coalitions against Napoleon. Britain was the first nation to undergo the Industrial Revolution, and its early lead in this field, combined with its far-flung empire, ensured its primacy of power in Europe and the world for the rest of the century. Britain was also dedicated to the policy of free trade, adopted in the 1840s.

But the Industrial Revolution did not remain confined to Britain. It appeared in Belgium and in northern France, then gradually spread eastward. By 1870 Germany had equalled France in both population and industrial development, but between 1870 and 1914 Germany rapidly outstripped France in both respects.

The early 19th century was the age of coal and steam, perhaps best symbolized by the railway. The main lines of the network of railways in Britain, France, and Germany were laid during the three decades preceding 1870. It is said that the Franco-Prussian War was decided by the Germans' superior use of the railroad. Railroads required large amounts of capital; the business of dealing with money as a commodity—banking—assumed correspondingly large proportions; the financing of the construction of the Suez Canal is another illustration of its role.

These economic changes profoundly altered the structure of society. The machine, increasingly located in the factory, needed tenders. An essentially new class arose, a largely propertyless proletariat, which tended to congregate in cities. Under the system of free enterprise, labour was looked upon as a commodity. The labourer himself was dependent upon the fluctuating cycles of the economy, and his lot was usually miserable.

The workers had been important contributors to the Parisian revolutions of 1830 and 1848. At that time, however, they were neither sufficiently numerous nor adequately organized, and bourgeois capitalists were the beneficiaries of whatever changes occurred. The growth of proletarian numbers, hence of their possibilities of action, was powerfully aided by the subsequent course of economic development.

The "second Industrial Revolution"

After 1870 one may speak of a "second Industrial Revolution"—that is, a great expansion in such traditional industries as coal and steel and the appearance of new ones, such as the chemical and electrical industries. All the while, industry was spreading geographically, until one could speak of an "inner" Europe, the area enclosed by a line running from Glasgow through Stockholm, Stettin, Trieste, and Barcelona—the Europe of industry. "Outer" Europe was predominantly agricultural, but the "inner" was steadily encroaching on the "outer."

The loss of the American colonies had a profound impact on British economic thinking. Why seek to impose political control on others when trade was what mattered? Free trade was more important than colonial conquest. Imperial activity was at a relatively low ebb during the first half of the 19th century. But, as others turned to a policy of protection and as the European market showed signs of saturation, imperial activity revived. Economic motivation is not the exclusive, but certainly is the most important, driving force of the "new imperialism," which registered notable achievements during the closing decades of the period (see below). In the 30 years after 1880, virtually the whole of Africa was divided among the European powers, and the sharpening competition for colonies became a major concern of the chancelleries of Europe and a decisive factor in shaping international alignments.

The uneven growth of industry affected decisively the power standing of states. After 1870 France declined from second place to the bottom of the list of advanced industrial nations. Britain retained its primacy, but the margin of its advantage was diminishing, challenged in the main from three quarters—the United States, Japan, and Germany. But the impact of the first two is essentially a 20th-century story; the German, on the other hand, was quite clear, sharpened before 1914 by the German policy of naval construction; thus Germany, after unification, lay at the centre of international politics.

The European record over a 100 years seemed to belie the gloomy predictions of overpopulation made by Thomas Malthus at the beginning of the century. Although some 50,000,000 Europeans swarmed to other continents, the population of Europe roughly trebled. But the condition of the masses generally improved. The fundamental reason for the change, allowing for political agitation and some humanitarian pressure, lay in the increase in the production of wealth, industrialization most of all. The 19th-century experience of Europe on this score constitutes a perhaps exceptionally fortunate accident, for industrial Europe could draw on the resources of the outer world for food and raw materials.

This growing wealth had other repercussions besides that of raising the standard of living. The combined impact of the rights of man and of scientific and technological development was favourable to the rise of the masses, one aspect of which was the spread of literacy, education in general, and a cheap press. The business of government became less and less the appanage of a restricted privileged class, though the conduct of foreign affairs continued to be a largely esoteric preserve. Yet, at election time and as the franchise spread, the temptation could not be resisted to appeal to the masses. The obverse facet of the democratic coin is demagoguery. How to conduct foreign policy in a democratic milieu has been an increasingly delicate and complicated problem. In the age of nationalism, the simplest way to arouse the masses was to appeal to their national prejudices and emotions. The enthusiasm with which the peoples of Europe responded to the outbreak of World War I in August 1914 bears out the point.

Outside of the United States and Japan, Europe was the mistress and the powerhouse of the planet. The state of European culture, both in the scientific domain and in the letters and the arts, was added grist to the mill of those who confidently believed that Europe *was* civilization, even if this civilization was an increasingly materialistic, godless one. As to the proliferation of arms, it was used as an argument for confidence in the lastingness of peace, ensured by what is now called the balance of terror, although the phrase itself is of later coinage.

There were Cassandras to be sure, and in the end they were, at least in a sense, to be proved right; but, at the time, they were mainly voices crying in the wilderness. When they went to war in 1914, the peoples and the governments of Europe had little inkling that they were initiating the closing chapter of the European Age.

THE BISMARCKIAN PERIOD, 1870–90

Bismarck's system of alliances. Bismarck was a practical man rather than one dedicated to abstract principle. His social bent was undoubtedly conservative, but he understood the active forces of the modern world. Having achieved his purpose of Prussian enhancement in the form of uniting Germany under the Hohenzollern crown, he was now satisfied and entertained no further aggressive designs. He believed that the maintenance of peace and the status quo would provide the best climate in which the new Germany could thrive.

Bismarck's peace policy

During the 20 years that he remained in charge, his skillful diplomacy dominated the international scene.

Germany had no enemies save France, which had been humiliated in 1870 and stripped of Alsace-Lorraine. Bismarck had no fear of France if France could be kept in isolation. In France he preferred the republican government and even favoured colonial ambitions, which he hoped would divert French attention away from the Rhine and revanche while possibly embroiling France with others. As for the British, Bismarck was content to leave to them their monopoly of empire.

His relations with Russia were good, and in the new hyphenated Austria-Hungary the Hungarian half was satisfied with the *Ausgleich* (Compromise of 1867) and would emphasize a compensating interest toward the southeast—the Balkans. This would, however, give added point to possible Austro-Russian rivalry. Bismarck's own solution for this problem was simple: divide the Balkan apple of discord between the two contenders—he would be Austrian in Serbia and Russian in Bulgaria. Moreover, the three great conservative states of Europe shared an outlook reminiscent of the Metternichian.

These thoughts bore fruit in 1873 in the Dreikaiserbund (League of the Three Emperors). But agreement was not long lasting, for by 1876 local Balkan events resulted in a falling out between Austria and Russia. Bismarck's control had limits. If he must choose between the two, though he would rather not, he would opt for the wholly European and partly Germanic Dual Monarchy. The Austro-German Alliance was concluded in 1879, henceforth the cornerstone of German foreign policy. In Bismarck's eyes it was undoubtedly a defensive alliance, designed as much to reassure as to restrain Austria.

Within two years Bismarck was able to revive the tripartite connection, but the second Dreikaiserbund foundered, like the first, over local Balkan differences—this time over a war between Bulgaria and Serbia in which Serbia was rescued by Austrian diplomatic intervention.

This drove Bismarck into an extremely complicated scheme. His alliance with Austria was a fixed point, and he even informed the Russians of its terms. But in order to insure against the nightmare of the war on two fronts —a Franco-Russian coalition—he contrived an understanding between himself and Russia, the Reinsurance Treaty of 1887. This treaty has been described by some as Bismarck's greatest diplomatic achievement, by others as an attempt at political bigamy. It was a tightrope-walking act and lasted only as long as Bismarck himself was in power. The Austro-Serbian Alliance and the connection with Romania rounded out the Bismarckian network of eastern alliances.

The Reinsurance Treaty

Italy had a low power rating in Bismarck's eyes, but, in order to secure Austria's rear and to prevent a possible Franco-Italian connection, he enlisted Italy as well in his camp. The Triple Alliance of 1882, made possible in part by Italian fears of French designs, implied a stabilization of the still-existing Austro-Italian antagonism (a legacy of the Risorgimento) and a muting of the Italian irredentist claim against Austria. Italy also fitted into Bismarck's desire for general stability in the south.

Balkan problems. Ottoman affairs, particularly in the Balkans, which were still in the process of achieving national emancipation, continued to be a sensitive and unstable area. In the mid-1870s, revolts flared up in Bosnia and in Bulgaria, out of which ensued a Russo-Turkish war in 1877–78. The victorious Russians imposed the Treaty of San Stefano on the Turks. The treaty called for a drastic rearrangement of the Balkans, whereby a large Bulgaria would be created under the protection of Russia. But the Russian gains in the treaty alarmed the powers. In the face of determined British opposition, the Russians therefore agreed to a collective European revision of the treaty. The powers met at the Congress of Berlin in 1878 and produced a new Balkan arrangement: a much smaller Bulgaria was created and a series of compensations arranged for some of the powers, both large and small. The Balkan provinces of Bosnia and Hercegovina were put under Austrian occupation and administration, and Cyprus was "temporarily" occupied by the British. The Treaty of Berlin was a source of dissatisfaction to the Russians, who, after all, had won the war, and the Dreikaiserbund was a victim.

Seven years later, the Balkans flared up again, though the fighting, Serbo-Bulgarian, remained confined to their locale, and Bulgaria, joined by Eastern Rumelia, achieved full independence from the Sultan. As mentioned above, these episodes dissolved the second Dreikaiserbund.

THE NEW IMPERIALISM

Events in the more peripheral regions of the Ottoman Empire are perhaps better placed within the purview of colonial activity. At Berlin in 1878 it had been suggested to the French, by both the Germans and the British, that Tunisia might be suitable compensation for them. Italy was also interested in Tunis, where the reality of an Ottoman connection was cloudy.

In France there were those who insisted that revanche and the German danger should be the first cares of French policy, while a colonial party thought this a sterile attitude that merely prevented France from taking part in Europe's growing interest in the wider world. In 1881 the latter group scored a success with the establishment of a protectorate over Tunisia. Italy was annoyed and joined the Triple Alliance, but there were no repercussions in Constantinople.

Anglo-French involvement in Egypt

In the 1870s both the French and British became deeply involved in Egypt. The French interest was of long standing, and the Suez Canal was mainly used by British shipping. The Khedive's finances were mismanaged and the British and the French intervened to impose a joint Anglo-French supervision of Egyptian finances. Local Egyptian conditions led to further Anglo-French interference, and in 1882 the British took military action, the French having declined at the last moment to join them. This was the beginning of the effective British control of Egypt, for the supposedly temporary occupation of the country proved to be but the initiation of a continuing and deepening involvement.

The cases of Tunis and Egypt may be conveniently regarded as the launching of the new imperialism, a vigorous recrudescence of Europe's imperial activity. The longer established British and French priority in the imperial domain was being emulated by others. Even initially anticolonial Bismarck yielded to the pressure generated by the rapidity of German economic growth; by the mid-1880s Germany claimed various areas in Africa, and even Italy was developing an interest around and in Abyssinia.

In modern garb the age of discovery and conquest had returned, and the partition of Africa was under way. With a view to avoiding conflict, acknowledging the equal right of all, the powers met in Berlin in an attempt to put some order in the process. Actually, the Berlin West Africa Conference (1884–85), the result of a Franco-German initiative, affirmed the freedom of navigation and trade in the basins of the Congo and Niger rivers. The Free State of the Congo, the outcome of a private initiative headed by King Leopold II of the Belgians, achieved international recognition, and general rules for the establishment of colonial claims were agreed upon.

Penetration of Asia

There were manifestations of imperial activity (primarily British, Russian, and French) in Asia as well. The penetration of China was continuing, as was Russian expansion in Central Asia. This last, pushing toward the western and northern back doors of India, was a source of concern to the British, who found themselves involved in protective, "defensive" expansion. The two influences met in Afghanistan. Likewise, on the opposite side of India, a British protectorate over Burma was proclaimed in 1885, while the French became involved in war with China as a result of their activity in Tonkin.

This colonial activity was largely conducted by a handful of men with small bodies of troops. The peoples of Europe to a large extent were unaware of this aspect of the activity of foreign and colonial offices and had in general no consciousness of being involved in war. While there were also critics of imperialism among Europeans, theirs was but a small voice.

The conscious leaders of Europe's imperial urge nurtured ambitious schemes. Granting the priority of the economic interest and the rationalization of the white man's burden, or *mission civilisatrice*, the factor of national interest, of prestige and pride, should not be minimized. Control of Egypt meant control of the vital artery of the Nile. It was not long before the British were involved in The Sudan, where they suffered a temporary setback. They were also active at the southern tip of the African continent, where Cecil Rhodes, businessman and statesman of ruthless vision, was at work. From these two points as bases, Cairo and the Cape, plus British East Africa, the vision of a vast empire, roughly the eastern half of Africa, symbolized by the Cape-to-Cairo railway project, was born.

The French could entertain a comparable dream, an extension of France across the Mediterranean all the way to the Congo—the northern half of the continent. Around the sources of the Nile, British, French, German, and Belgian influences met, to which the Italian may be added. Here was incipient rivalry and a potential source of conflicts, but these did not flare up until the 1890s, when exploring activity had laid sufficient bases for overlapping political claims.

Meanwhile, the focus of international relations, over which Bismarck presided, was still predominantly in Europe. But already the seeds of disintegration of the Bismarckian system were planted. The combination of the Triple Alliance, his own treaty with Russia, and the Mediterranean agreements constituted a fragile edifice, undermined by inner inconsistencies. Russia and France were the two revisionist states that Britain was willing, to a degree at least, to help contain. But difficulties, of an economic nature at first and not necessarily irretrievable, began to appear in the Russo-German relationship. Bismarck's dismissal in March 1890 opened a new chapter in the relations among the European powers.

THE GERMAN CHALLENGE

The period of transition, 1890–1904. It is a proper measure of the authoritarian nature of the German state that Bismarck could be dismissed from office by the emperor; no constitutional issue was at stake. Bismarck's own place in the roster of statesmen is secure; if personally not a very attractive character, his rank nevertheless belongs among the first: like a good craftsman, he used the proper tool for the right job at the right time; war having served his purpose, he endeavoured to maintain the peace, all the while directing the energies released by the very fact of his unifying success.

Assessment of Bismarck

One reason for his dismissal was the advent, in 1888, of a new emperor, William II. Friction developed between the crusty old man and his young, arrogant, touchy, and romantic new master. The last Hohenzollern proved to be, in a sense, the most adequate and, for that very reason, the most unfortunate embodiment of the insecure, arrogant success that was Wilhelmine Germany, all too effectively conveying to others an impression of aggressive intent out of proportion to the reality of that intent.

A major foreign-policy decision faced the new German administration—whether or not to renew the Reinsurance Treaty with Russia. There were solid arguments pro and con, and the Tsar was desirous of renewal; but the German answer was finally refusal. This decision compounded the uneasiness that had already begun to cloud Russo-German relations before 1890, one consequence of which was the fact that Paris took the place of Berlin in the financing of Russia.

France had been anxious to escape from the isolation in which Bismarck had successfully kept it confined. But France and Russia had few common interests. Russia felt as little concern for French revanche as France did for Russia's Central Asian expansion, with its consequence of Anglo-Russian friction. The focus of France's rivalry was also Britain, to be sure, but it lay mainly in Africa, where Russia had no interest. The only possible binder of a Franco-Russian connection was common fear of Germany, which in the Russian case could arise from the Austro-German alliance.

The Franco-Russian connection began with a series of loans, launched on the Paris market, from 1888 on. A Russian purchase of French arms in 1889 was the next step, followed by military conversations, the elaboration of a contingency plan. The Tsar felt little attraction for what he considered a godless republic, but, eventually, in 1893, he underwrote the results of the military discussions, while the French, on their side, evaded their own constitutional issue through the contention that no formal

Europe, 1871–1914.

Franco-Russian alliance

political alliance was involved, thereby bypassing parliament. Yet from 1893 it is proper to speak of a Franco-Russian alliance as existing. This was the first major breach in the Bismarckian system, made possible in part by the confident but incorrect German assumption that such a possibility was excluded. Like all such instruments at this time it was defensive, and the terms of it were secret.

But the situation was still very fluid, and the focus of European rivalries was becoming increasingly extra-European. The Russians were pleased when, in 1893, friction developed between France and Britain in Southeast Asia. The difference was composed, however, and Siam, as a buffer, retained its independence.

By this time the Japanese had made sufficient progress in their imitation of European ways to have developed imperial ambitions of their own. They turned to China, with which they dealt successfully in war, imposing upon it their demands in the Treaty of Shimonoseki in 1895. This Japanese success was of concern to Russia, and an unexpected combination ensued, for Germany—this was its way to weaken or undo the newly formed Franco-Russian connection—gave Russia support in opposing Japan, while France, rather embarrassedly, followed suit. The tripartite combination, Britain excluded, was successful in frustrating Japan of some of its gains; it had special appeal to the German Kaiser, who again and again returned to his project of a continental league.

Africa was at this time also the locale of a similar imperial competition. When in 1894 the British arranged for the purchase of a strip of the Belgian Congo that would connect their African holdings in the north and the south—the Cape-to-Cairo scheme—joint Franco-German pressure caused them to abandon the plan.

The Fashoda incident

But, on the entire course of the Nile, Britain would not allow any control other than its own. When in 1895 the French launched from Gabon an expedition led by Capt. Jean-Baptiste Marchand that was to march across Africa, effecting a connection with their East African base of Djibouti, a cautionary warning was issued in London. But in September 1898 Captain Marchand reached the Nile at Fashoda, near where British forces under Lord Kitchener had been conducting operations. The confrontation of two handfuls of men on the Nile grew into a major clash between Paris and London.

It was a delicate passage. In Paris the French foreign minister, Théophile Delcassé, a convinced colonialist, came to the conclusion that war with Britain was not desirable. In the face of British intransigence, there was nothing to do but yield. French feeling ran high, but French prestige was seriously injured. Yet out of this situation was to develop one of the most important changes in European power relationships.

Britain's interest in South Africa had been enhanced by the discovery of gold and diamonds in the Transvaal, and Britain was thus brought into collision with that little Boer republic and its twin, the Orange Free State. The South African War began in 1899, after the Fashoda incident had been settled. The British underestimated the guerrilla capacity of the Boers. As a consequence, the protracted conflict entailed a far greater effort on Britain's part than had been thought necessary. In the end the Boers could not stand up unassisted against the resources of Britain. In 1902 the Boer republics were annexed into the colony of the Cape.

The episode had important repercussions. In Britain it led to soul-searching, arousing both strong criticism and nationalistic emotions. Of greater significance was its im-

pact on Britain's international position. The worldwide sympathy for the Boers drove home to Britain the fact of its diplomatic isolation. Britain's traditional stance, that of preferring to remain uncommitted and to eschew alliances in peacetime, might stand in need of reconsideration in the light of the range of Britain's worldwide commitments and of challenges from a variety of quarters. Britain's margin of advantage was diminishing in the face of other rising powers.

Three powers—the United States, Germany, and Japan —were growing at a faster rate than others but at the moment it was Germany that mattered. Since the traditional rivalries with France and Russia still existed, the possibility of a German one being added was a proper source for concern in Britain, especially if it should develop into the Kaiser's plan of a continental league. Preservation of the divisions of Europe, the balance of power, had long been the first directing rule in the defense of Britain's interest.

The German challenge had two aspects. The first was commercial, an expression of the faster German economic growth. It could hardly be expected that Germany should deliberately restrain its expansion in that domain. The other, not unrelated to the first, was in essence political, reflecting the German desire for recognition by others of its right to a place in the sun. Such expressions as *Weltpolitik* and "our future lies on the water," fondly espoused by the Kaiser, expressed it to perfection. In concrete terms, it took the form, in 1898, of embarking on the building of a large navy; it was a considered decision, taken in full awareness of its political implications, the credit—or blame—for which was shared by the Emperor himself and Adm. Alfred von Tirpitz, the father of the German navy. It could hardly be expected that Britain would remain indifferent to such a decision.

Thus, the British reaction to the shifting relationships of power was to re-examine the merits of isolation; put in different form, to reduce the range of commitments by coming to terms with one of the rivals. Bearing in mind Fashoda and the rivalry with Russia across the breadth of Asia, not to mention the currently popular view of the racial affinity and superiority of the Nordic peoples and the tradition of friendly relations with Prussia, Germany was the logical candidate for an approach.

Joseph Chamberlain, a convinced imperialist, opened negotiations with the Germans. Discussions took place on three occasions between 1899 and 1901 but resulted in failure to reach an understanding, a failure that was in large measure due to German psychological misjudgment. The advice of the German chancellor, Bernhard, Fürst von Bülow, to the Kaiser to hold the bid high, regarding Britain as a demandant from whom a political commitment of abstention from continental involvement could be extracted, had a counterproducing effect. Proud Britain may have had difficulties but, after all, had had its way with both the French and the Boers. Even Chamberlain, a Britisher above all in the last analysis, had cautioned his German interlocutors that there were possibilities other than Germany open to Britain.

The first possibility materialized in an unexpected quarter. In 1902 an Anglo-Japanese Alliance was concluded that was not even secret. Though the alliance represented a break in the traditional British avoidance of peacetime alliances, it did lighten the burden of British responsibilities in the Far East and thus enhanced Britain's freedom of action in Europe.

Franco-Italian relations

The opening years of the century witnessed a marked shift in the power relationships of Europe. Following nearly a decade of unfriendly relations with France, Italy put an end to the tariff war with the conclusion of a commercial treaty; it also reached an understanding with France over Tunis. Francesco Crispi's dream of an East African empire was frustrated by the defeat of Adowa in 1896. In 1900 Italy further acknowledged France's interest in Morocco in exchange for a reciprocal French acceptance of Italian hopes in Tripoli. The ambiguous Interpretation of the Triple Alliance that Italy gave France in 1902 to a considerable degree voided that pact of content, though it was simultaneously renewed. Bülow urbanely turned a good face on Italy's potential infidelity, but Germany entertained few illusions on the score of Italian dependability; Italy's position has aptly been described as being "on the fence."

In Serbia a domestic upset resulted in the murder of the pro-Austrian king, an Obrenović, and his replacement by the representative of the rival Karageorgević house; henceforth, Serbia abandoned its subservient Austrian allegiance and turned to Russia for protection.

The most important diplomatic shift at the opening of the century, however, was in Anglo-French relations. Fashoda convinced Delcassé that France should eliminate its traditional rivalry with England. He was ably assisted in this policy by Paul Cambon, his ambassador in London, who found receptive ears in Britain, especially after Chamberlain's failure in Germany.

Unlike the Germans, the French did not insist on a political commitment from England. Protracted Anglo-French discussions resulted in the Entente Cordiale of 1904, whereby France agreed to abandon its withering Egyptian hopes, Britain, in turn, sanctioned French ambitions in Morocco, and a number of other important differences were settled. In the context of the imperial activity of the day, this was a fair and reasonable quid pro quo. The understanding contained no hint of an alliance; it was a public document, but secret clauses were attached to it.

The meaning of this in 1904 was problematic, and it might have proved to be no more than a passing flirtation. Time and succeeding events proved it otherwise, however, and it became the opening of a significant new chapter in the affairs of Europe. The British and the French continued to differ on many things, but what gave solidity to the Entente was the fundamental fact that, allowing for differences of power in 1904, the two countries were increasingly finding themselves placed in a similar defensive position vis-à-vis the rising powers. With a time lag of roughly 50 years, the relative decline of the French power position was followed by a comparable British decline. Here was not a passing condition but rather a long-term change in the position of both countries.

The last decade of peace, 1904–14. Two fundamental assumptions of German policy—the impossibility of either a Franco-Russian or an Anglo-French connection—had proved mistaken. The precise nature of the second was uncertain, but Bülow soon had the opportunity to clarify its meaning. The proximity of two dates is significant: in February 1904 the Japanese, without warning, attacked and destroyed a Russian squadron in Port Arthur; in April the Entente agreement was concluded. France's ally, Russia, was at war with Britain's ally, Japan. The Anglo-Japanese alliance had a restraining effect on the possibility of French assistance to Russia; Britain and France shared a common interest in Russo-Japanese accommodation, and the Far Eastern conflict remained localized.

The Russo-Japanese War

To the surprise of much of the world, the "little yellow men" inflicted a series of defeats on a major European power. To be sure, Russia was handicapped by logistics —the difficulty of supplying a theatre of war over a still incomplete Trans-Siberian Railroad—while the Japanese enjoyed the converse advantage of proximity, hence, of shorter lines of communication. They controlled the sea as well; the pathetic odyssey of Russia's Baltic fleet, sailing halfway around the world, ended in its destruction in the Battle of Tsushima Strait (May 27, 1905). There was nothing for it but to acknowledge defeat, all the more so as internal Russian conditions were taking on a revolutionary hue in 1905. The interposition of American good offices brought the belligerents together at Portsmouth (New Hampshire), where Japan collected the fruits of its competent preparations, having passed the test that insured great-power status. Manchuria and Morocco are far apart, but the simultaneity of the two situations created a connection between them. Britain could indeed renounce its own claims in Morocco; it could certainly not dispose of the rights of third parties. In the form of an ostentatious visit that the German kaiser paid to the Sul-

tan of Morocco, Germany asserted its claim to an equal position in Morocco. The French tactics had been to isolate Germany, and this had been one of their purposes in reaching understandings with Britain, Italy, and Spain in regard to Morocco. On both sides of the Rhine there was complete understanding of the facts and the realities of the Moroccan situation; while Germany felt that Morocco logically "belonged" to France, it would claim a price, as others had, for its consent to that outcome. The issue was, precisely what price? The highest possible was the German view; the smallest was the French.

But Morocco was also a pretext. By asserting equal rights in Morocco, Germany could discover the depth of Britain's commitment in support of France. Bülow himself described his stance as that of "the Sphinx": keep others in uncertainty, and frighten the French; either or both of two results might thereby be achieved: a wrecking of the budding Anglo-French Entente, or the securing of a high price for Morocco.

The Moroccan crises

This is the substance of the First Moroccan Crisis, which meant on the German side raising the spectre of possible war. The French were indeed frightened, to the extent that Delcassé found himself alone among his Cabinet colleagues in opposing a policy of accommodation, insisting that Bülow's tactics were bluff. Properly, he resigned. In what had come to be a duel between two men, the German chancellor had scored the major victory of forcing the resignation of the French foreign minister. But, unwisely, Bülow sought to push his advantage too far, for, if the French yielded to the German demand for an international conference, they were resentful of what they considered undue foreign interference in their domestic affairs.

The Conference of Algeciras in 1906 was a surprise to Germany, which found itself virtually isolated, and the resulting Act of Algeciras, in effect, enhanced the French position in Morocco. Bülow had been all too successful in conveying abroad the impression of German aggressive intent, implemented by tactics of intimidation, the mailed fist, and sabre rattling. One result of the episode was the strengthening of the Entente, the opposite of his intentions; Anglo-French military discussions, again a contingency plan, began in 1906.

After a few years of quiescence, the Moroccan issue flared up again when the French moved in to restore order in the country. The Agadir Crisis of 1911 bears close resemblance in its unfolding to the one just outlined. Sending a German gunboat (the "Panther") to Agadir was a way of asserting a German claim equal to that of the French. From the very outset of the crisis, Britain took a much stronger position in support of France than it had in 1905, and after a tense passage the issue was finally resolved as it might have been in the first place, through a bilateral Franco-German understanding: Morocco to France in exchange for a substantial section of the French Congo to Germany. But the manner in which that result had been procured left a legacy of bitterness and suspicion, especially in Franco-German relations; in France there soon followed the *réveil national*, a resurgence of nationalistic feeling. Between the two Moroccan crises a good deal else had happened.

The impact of the impression created by German tactics in the First Moroccan Crisis and the continued growth of the German navy are to be largely credited for another development. Britain would maintain its naval superiority but proceeded further to reduce the range of its commitments. The Anglo-Russian agreement of August 1907 brought into existence the Triple Entente. The Anglo-Russian understanding is comparable to the Anglo-French one of 1904, dealing with Asiatic rivalries in this case. The heart of it was a division of Persia into three zones—British, Russian, and neutralized. The cry went up in Germany of *Einkreisung*, and indeed encirclement it was, though not with aggressive intent but rather as a response to German impatience expressed in tactics that to others seemed aggressive. Appearance can count for more than reality, and a vicious circle of misunderstanding was closing.

German encirclement

The forces of nationalism, meantime, continued to threaten both the Ottoman and the Habsburg empires. The policy of the latter oscillated between the grant of belated and insufficient concessions and repression. The South Slavs in particular were a troublesome problem, which the shifting of Serbia into the Russian camp in 1903 served to accentuate.

In 1897 Austria and Russia had together "put the Balkans on ice," but the Russian defeat in the Russo-Japanese War shifted the focus of Russian policy back toward Europe. In 1906 the Russian and the Austrian foreign ministers, Aleksandr Izvolsky and Alois Aehrenthal, met and agreed on a scheme for certain changes in the arrangements of 1878. Where Austria was concerned, it would put an end to the ambiguity of its position in Bosnia–Hercegovina by outright annexation of these provinces. The looseness of the understanding and the uncertainties arising from a successful Young Turk takeover in Constantinople—formal title to Bosnia–Hercegovina was still Turkish—induced Austria to create the *fait accompli* of annexation in October. This was the opening gun of the Bosnian annexation crisis of that year and the following. Russia this time, as Germany had done in the case of Morocco, demanded a European conference, which Austria, like France in 1905, was seeking to avoid. The tension lasted until the following spring, when Russia, militarily unprepared and but lukewarmly supported by France, felt that it could not face the prospect of hostilities when Germany took a determined stand in support of its own ally.

The outcome was an undoubted success for the Austro-German combination—a preview in many respects of July 1914—emphasized by a Serbian surrender to an Austrian ultimatum that demanded formal acknowledgment of satisfaction with the annexation. Germany had been the key factor in the resolution of the crisis, but it had acted in support of an initiative that was Austrian; the Bismarckian direction of the alliance had been reversed, in part because Germany considered that in the existing constellation of powers it could not afford to allow its one dependable ally to suffer a setback. But, as a consequence, the distrust and resentment of which Germany was the focus had been deepened.

There followed a two-year lull in the accelerating tempo of crises, during which, however, the arms race was intensified. In 1912 Viscount Haldane, the British war minister, visited Germany in yet another attempt to moderate the naval competition. The effort foundered on the usual reef of the German demand for a political commitment on England's part. Meanwhile, the Agadir Crisis had again raised the spectre of war. Though also resolved, as has been indicated, that confrontation may be regarded as the opening of the last chapter in the story of nearly a half-century of peace.

The Franco-German agreement had not even been concluded when Italy declared war on Turkey for the purpose of acquiring the vilayets of Tripoli and Cyrenaica. The Italians' diplomatic preparations had been adequate, all the powers having at various times acknowledged the validity of the Italian claim. With some difficulty Italy had its way, and the war was concluded with the surrender of Libya by Turkey in October 1912.

The Italo-Turkish War and the Balkan Wars

The Italo-Turkish War was unpopular with the powers, who feared that an attack on the Ottoman Empire might lead to larger complications. These fears were wholly justified. In March 1912, the Russians scored a notable diplomatic success in contriving a Serbo-Bulgarian alliance, which was joined by Greece within two months. It was clearly an offensive alliance, and in October the Balkan allies went to war against Turkey. A final attempt by Austria and Russia to restrain them came too late.

The allies were surprisingly successful. By December, save for a few isolated centres of resistance, the Turks were defeated and surrendered the entirety of their Balkan holdings with the exception of their capital and the straits connecting the Mediterranean with the Black Sea.

The prearranged division of the spoils, underwritten by Russia, proved unacceptable to some of the other powers. Austria, supported by Italy in this case, interposed a veto on Serbian access to the Adriatic. The Balkan allies

fell out. Bulgaria, unwisely, attacked the Serbs and the Greeks and found itself confronted with the Turks and the Romanians as well and shortly went down in defeat. The Treaty of Bucharest (August 1913) settled matters for Bulgaria, but in the western Balkans the powers imposed their own will by creating the state of Albania.

This settlement may be considered as the last instance of the successful operation of the Concert of Europe. The outcome of the Balkan wars was, nevertheless, regarded on the whole as a setback for the Austro-German combination, and the specific form of the settlement had the effect of exacerbating Serbian feeling toward Austria, now the exclusive focus of South Slav irredentism.

Outbreak of World War I

The explosion of the powder keg of Europe, the Balkans, in 1912–13 had failed to ignite the whole continent. But it was only six months before Austria decided to give its own South Slavs a demonstration of its power and determination. On June 28, 1914, the heir to the Habsburg crown, Archduke Francis Ferdinand, visited Sarajevo, the capital of Bosnia, to review army manoeuvres. Some young and irresponsible nationalists, idealistic martyrs to a cause in another view, succeeded in carrying out their plot. Francis Ferdinand and his wife fell victims to their pistol shots—shots that, more than an earlier one, truly were destined to ring around the world. The opening week of August saw all the major powers of Europe, save one, and two minor ones at war. The last chapter of the European Age had begun. (R.A.-C.)

BIBLIOGRAPHY

1500–1648: The following general works include their own bibliographies: *The New Cambridge Modern History*: vol. 1, *The Renaissance, 1493–1520;* vol. 2, *The Reformation, 1520–1559;* vol. 3, *The Counter-Reformation and Price Revolution, 1559–1610;* and vol. 4, *The Decline of Spain and the Thirty Years War, 1609–1648/59* (1957–70), the best recent textbook of general history written in English; *Handbuch der mittelalterlichen und neueren Geschichte*, vol. 2, *Geschichte des europäischen Staatensystems von 1492–1559* (1919; Italian trans., 1932); WALTER PLATZHOFF, *Geschichte des europäischen Staaten-Systems, 1559–1660* (1928, reprinted 1968), a concise, useful account of international relations; GASTON ZELLER, *Les Temps modernes*, vol. 1, *De Christophe Colomb à Cromwell* (1953), a critical and stimulating study; and HENRI HAUSER, *La Prépondérance espagnole, 1559–1660* (1933, reprinted 1972), most illuminating.

1648–1815: Two multivolume series cover this period in its entirety: *The Rise of Modern Europe*, ed. by W.L. LANGER, 20 vol. (1936–71); and *The New Cambridge Modern History*, planned by SIR GEORGE N. CLARK, 14 vol. (1957–). Each set deals at length with diplomatic and military developments. The annotated bibliographies in the Langer series are useful and valuable. For special studies of war and diplomacy, see GASTON ZELLER, *Les Temps modernes*, vol. 2, *De Louis XIV à 1789* (1955); and ANDRE FUGIER, *La Révolution francaise et l'Empire Napoléonien* (1954), both diplomatic and military histories at their broadest, linking them to economic organization and social forces. JOHN U. NEF, *War and Human Progress* (1950); and SIR GEORGE N. CLARK, *War and Society in the Seventeenth Century* (1958), convincingly refute the traditional thesis that war and militarism were the matrix of cultural progress. The later-17th century is treated in two admirable studies by JOHN B. WOLF: *The Emergence of the Great Powers, 1685–1715* (1951) and *Louis XIV* (1968). Both are broadly conceived, rich in details, and persuasively written. Also balanced and judicious is PIERRE GOUBERT, *Louis XIV et vingt millions de français* (1966; Eng. trans., *Louis XIV and Twenty Million Frenchmen*, 1970), which makes a strong case for the greatness of Louis XIV. For Marlborough there is WINSTON CHURCHILL's six-volume authoritative tribute to his ancestor, *Marlborough: His Life and Times* (1933–38). The old study by ALFRED ARNETH, *Prinz Eugen von Savoyen*, new ed., 3 vol. (1864), is still basic. Three consecutive volumes in the Langer series deal with the period from the 18th century to the French Revolution: PENFIELD ROBERTS, *The Quest for Security, 1715–1740* (1947); WALTER L. DORN, *Competition for Empire, 1740–1763* (1940); and LEO GERSHOY, *From Despotism to Revolution, 1763–1789* (1944)—all have chapters on the central themes of balance of power diplomacy, competitive militarism, and the global war for markets and colonial goods. Prussia's place in the wars is discussed acutely in PIERRE GAXOTTE, *Frédéric II* (1938; Eng. trans., 1942). V.O. KLIUCHEVSKY, *A History of Russia*, vol. 5 (Eng. trans., 1931), deals with the diplomacy and wars of Catherine II. For orderly introductions to the troubled years from 1789 to 1815, there are LEO GERSHOY, *The French Revolution and Napoleon*, rev. ed. (1964); and GEOFFREY BRUUN, *Europe and the French Imperium, 1799–1814* (1938). Commercial war is discussed with fresh acumen by ELI F. HECKSCHER, in *The Continental System: An Economic Interpretation* (1922, reprinted 1964). There are many reprints of the once authoritative *The Influence of Sea Power upon the French Revolution and Empire, 1793–1812*, by ALFRED T. MAHAN, 2 vol. (1892). ROBERT B. MOWAT, *The Diplomacy of Napoleon* (1924, reprinted 1971), is a useful brief introduction; while EDOUARD DRIAULT, *Napoléon et l'Europe*, 5 vol. (1910–27), is a storehouse of details. Still quite useful and authoritative is THEODORE A. DODGE, *Napoleon: A History of the Art of War*, 4 vol. (1904–07). The settlement at the Congress of Vienna is studied in CHARLES K. WEBSTER, *The Congress of Vienna, 1814–1815* (1919, reprinted 1963); and, in a pragmatic temper, in HENRY A. KISSINGER, *A World Restored: Metternich, Castlereagh and the Problems of Peace, 1812–1822* (1957).

1815–1914: The best comprehensive treatment of the subject is contained in the two volumes by PIERRE RENOUVIN: *Le XIX^e Siècle:* vol. 1, *De 1185 à 1871* (1954) and vol. 2, *De 1871 à 1914* (1955). A.J.P. TAYLOR, *The Struggle for Mastery in Europe, 1848–1918* (1954), covers most of the period in the author's provocative, if unorthodox, fashion. RENE ALBRECHT-CARRIE, *A Diplomatic History of Europe Since the Congress of Vienna*, 2nd ed. (1973), which covers the 20th century as well, is a dependable, balanced treatment; it can be supplemented by the same author's *Concert of Europe* (1968), a critical documentary collection that deals with the major episodes and settlements of 19th-century international affairs of Europe. ROBERT B. MOWAT, *A History of European Diplomacy, 1815–1914* (1922), is still useful though dated. Two works dealing with British policy, both of them of high quality, deserve special mention: ADOLPHUS WARD and GEORGE P. GOOCH (eds.), *The Cambridge History of British Foreign Policy, 1783–1919*, 3 vol. (1922–23, reprinted 1970); and ROBERT W. SETON-WATSON, *Britain in Europe, 1789–1914* (1937, reprinted 1968). The second half of the first, and the second and third volumes of a collective Russian work, published under the editorship of VLADIMIR P. POTEMKIN and available in French translation, *Histoire de la diplomatie* (1946–47), covers the 19th century; it has the advantages and the limitations that can be expected of a Soviet treatise in this domain. Two books with a revisionist approach are the pioneering work of SIDNEY B. FAY, *The Origins of the World War*, 2nd ed. rev., 2 vol. (1966); and of ERICH BRANDENBURG, *Von Bismarck zum Weltkriege* (1924; Eng. trans., *From Bismarck to the World War*, 1927). The two masterful volumes by WILLIAM L. LANGER, *European Alliances and Alignments, 1871–1890*, 2nd ed. (1950), and *The Diplomacy of Imperialism, 1890–1902*, 2nd ed. (1951), which are also somewhat informed by the revisionist tendency, are very detailed and dependable. Representing a different orientation, but of similarly high quality, is BERNADOTTE E. SCHMITT, *Triple Alliance and Triple Entente* (1934, reprinted 1971). PIERRE RENOUVIN, *Les Origines immédiates de la guerre, 28 juin–4 août, 1914*, 2nd ed. rev. (1927; Eng. trans., *The Immediate Origins of the War, 28 June–4 August 1914*, 1928) deals exclusively with the July 1914 crisis. The single best and most balanced work is LUIGI ALBERTINI, *Le origini della guerra del 1914*, 3 vol. (1942–43; Eng. trans., *The Origins of the War of 1914*, 3 vol., 1952–57), which has the merit of having had at its disposal a fuller documentation. The last two volumes of it, like the second of Fay's work, deal with the July crisis.

(R.E.M./L.Ge./R.A.-C.)

European Law, Medieval

In medieval Europe, law was the expression of a common civilization. This essential unity was not inconsistent with an extraordinary variety of local law at the level of the kingdom, the town, and the village, for embodied in the diversity of individual laws was the reality of a social and religious life common to medieval Europe.

In the Middle Ages a new science of law was born, together with a class of professional jurists to cultivate and practice it. The foundations of monarchical states were laid, and the traditions of the early Middle Ages were adapted to the exigencies of a society in transformation. A complex of public and private rules of law were thereby generated that, for variety within a framework of unity, represent a high achievement of civilization. In no small measure they survive to the present day.

THE SOURCES OF LAW

From personal to territorial law. One may begin by inquiring how law was made in medieval Europe, by

whom, and for whom. In this respect the Middle Ages span a period of profound change. In the 9th century in the Carolingian era, one finds a system of personal laws still operative throughout Europe. Within each kingdom, just as within the Carolingian Empire as a whole, there was not one legal system but a multiplicity of legal systems, written and unwritten, originating in custom or laid down by authority. Every free man, wherever he found himself, could appeal to the laws of his own kin, who might be Romans, Franks, Visigoths, Lombards, Bavarians, Saxons, Angles, or Alamanni.

The Carolingian era

Under the emperor Charlemagne this system began to show signs of strain. Frequent conflicts of law arose as a consequence of increased trade between men of different groups living in the same territory. More and more often it happened that one of a number of laws applicable to the same issue was found preferable because it was clearer or more equitable or better adapted to the region and the times, and it would be singled out by all those in the territory who knew of it, regardless of their origin. Racial mixing, although gradual and uneven, favoured these tendencies. Over a period of about three centuries, a transition took place from a personal system of law to a territorial system, in which the laws a man had to observe were determined no longer by his ethnic origin but by the territory he lived in.

This evolutionary process did not at the outset produce a greater uniformity of law. It is true that the territoriality of written law—of the Carolingian *Capitularia generalia*, for example—brought uniformity within a given kingdom or even throughout the empire; but, in the many important fields of community life not previously disciplined by written law, the establishment of the territorial principle signified rather the triumph of local law. In each separate territory the plurality of coexisting laws resolved progressively into a single common custom. Each land thus had its own *consuetudo loci*, perhaps with an imprint of Roman law, perhaps Germanic, but more often the result of a synthesis of various elements that gave the local system features of its own.

By the 11th century this process had ended in most of Europe. At this moment, when the fragmentation of the law was at its highest, a new development began that was destined to re-establish a common juridical system in continental Europe.

The glossators and the revival of Roman law. The flowering of intellectual life was accompanied by profound changes in economic and social life: the development of trade and craftsmanship, the rebirth of cities, and the appearance of the first universities. All of these played a decisive part in the revival of juridical science. In the city of Bologna, at the end of the 11th century and the beginning of the 12th, scholars began rereading and interpreting the emperor Justinian's 6th-century compilations of Roman law: the *Digest*, the Codex, the *Institutes*, and the *Novels*. A judge and master of the liberal arts named Irnerius, soon to become legendary, laid the foundations of the new school. Its members were known as glossators from the marginal or interlinear annotations (*glossae*) they made in the texts of Roman law. These original texts were incomparably more complex and enlightening than the extracts and summaries that had circulated in the early Middle Ages.

The Bolognese school

The method of painstaking and subtle analysis adopted by the glossators enabled them to demonstrate the inner consistency of the classical texts and their applicability to the most various cases. Though there had been an important revival of juridical science at Pavia in the 11th century, this new advance was on a different plane. The rich juridical literature produced by the glossators took a variety of forms; the individual glosses were assembled in *apparatus*, along with collections of *dissensiones, distinctiones, quaestiones, brocarda, casus, lecturae*, and finally *summae*—a synthesis of the whole system of law. Their activities lasted from the beginning of the 12th century to the middle of the 13th, through five generations of scholars. The terse, concentrated thought of Irnerius was followed by an equitable tendency in Martinus, contrasting with the interpretative rigour of the latter's contemporary Bulgarus. The development proceeded through the realism of Johannes Bassanius and the profundity of Azo to the giant tapestry of law compiled by Accursius in the middle of the 13th century from a selection of his predecessors' glosses. Accursius' *Glossa magna* remained for about 500 years the indispensable complement to the texts of Roman law.

The spread of civil and canon law. The mainspring of all this work was the glossators' conviction that the great Justinian collection—rounded off with the feudal customs gathered in the *Libri feudorum* and with other minor additions—constituted the only true source of *civilis sapientia* for the whole of Christendom, standing above all other laws and customs. Corresponding to civil law was canon law, the province of which was religious. The monk Gratian, a contemporary of the glossators, completed his great compilation of the sources of canon law, the *Concordia discordantium canonum*, about 1140. This was also known as the *Decretum Gratiani*. In ensuing decades there was much papal legislation in the form of rules and principles, often innovatory in their effect, which were issued in deciding the cases that streamed to Rome from all over Christendom. These judgments and decisions were brought together in numerous collections from the 12th century onward, the most famous being that authorized by Pope Gregory IX in 1234 (*Liber Extra*), which proved of fundamental importance in the history of medieval and modern canon law. The works devoted to Gratian's *Decretum* by Rufinus and Huguccio in the 12th century and those devoted to the papal decretals by Henricus of Susa and Pope Innocent IV in the 13th century and by Johannes d'Andrea in the 14th century indicate the intensity of the research that grew up around these sources. The influence exercised by canon law was very profound throughout medieval Europe not only in the ecclesiastical sphere but also in the development of secular law, public and private, penal and procedural. Some important examples are cited below.

The new juridical science spread with amazing speed. Around the masters of Bologna there gathered an ever-increasing number of pupils, *cupida legum juventus*, who were the founding members of what was, with Paris, the oldest of the medieval universities. They came from all over Europe, and, on returning to their native lands, they spread the knowledge of Roman law. At the university they had acquired a capacity to interpret juridical sources and a sureness and logical rigour in argument that were entirely foreign to the jurists of the preceding centuries. The chief reason for the success of the school of Bologna lay in the fact that the political, social, economic, and intellectual awakening of the 12th century had created a need for trained judges, advocates, notaries, and administrators that only the sound and supple teaching of the glossators could ensure. A new figure appeared on the scene, unknown to the society of the early Middle Ages: the professional jurist.

The centres of research soon multiplied. The glossator Vacarius took the new methods to Oxford in England, and Placentinus took them to Montpellier in southern France. Independent centres of scholarship arose in the Rhineland, in Normandy, in Paris, and in England, for canon law, and in Provence and the Dauphiné, for Roman law. By the middle of the 13th century, in Accursius' time, the school of glossators was already in decline. For a few decades, however, some jurists addressed themselves to certain aspects of the law that had been overlooked, such as penal and statute law, which were studied in a practical way quite free from theorizing. Contemporaneously, in the University of Orléans, a second great school of law grew up—that of the commentators.

The commentators. The commentator's new approach was characterized by a greater concern with the law as practiced and by a marked analytic rigour in the interpretation of sources. Their knowledge of the daily business of the law is attested by the vast collections of legal opinions (*consilia*) drawn up by them with reference to particular suits. The commentators made use of this practical experience in their theoretical studies, which they illus-

The new juristic school

trated with hypothetical or actual cases (*quaestiones*). The novelty of this lay not in the literary form of the *quaestio*, already familiar to the glossators, but in its widespread use in the interpretation of Roman texts. The laws commented on were illustrated by means of the questions (*quaestiones*) they might give rise to in practice. But a solution was often impossible within the letter of the Roman law, and, therefore, the commentators were induced to inquire into the principles inspiring the law (*ratio legis*); in this way they succeeded in extending by analogy the validity of the ancient texts to new kinds of cases coming up in the courts.

Primacy in juridical science passed from France back to Italy in the 14th century. Cynus of Pistoia, a poet and contemporary of Dante, was the first to introduce the new method into Italy. One of his pupils was Bartolus of Saxoferrato, whose commentaries excel in their clarity and profundity of thought. No other jurist of the Middle Ages achieved such authority as Bartolus enjoyed for about three centuries throughout continental Europe. The work of Bartolus' greatest pupil, Baldus de Ubaldis, was also very influential.

The commentators dominated juridical science in Europe for two centuries. The training of jurists in the universities of Italy, France, Spain, Germany, and central and eastern Europe followed the method of commentary. The only exception was England, where the education of professional jurists was done in law offices and neither Roman studies nor the universities had any real influence on them.

Influence of custom

Local law. The ascendancy enjoyed by Roman law in European universities did not mean that it was the only form of law. The basis of private law, even in the era of the rebirth of juridical science, was still to be found in the local customs dating from the establishment of territorial law. In the 12th century, throughout Europe, these customs were established in writing. This both strengthened its validity when disputed by sovereigns, lords, or neighbouring cities and satisfied the need for clarity in the law. Many new rules of law were, of course, introduced.

Spain. From the 11th and 12th centuries on, many towns in Castile, León, Navarre, Aragon, and Catalonia obtained from their respective sovereigns grants of privileges and the recognition of local customs (*fueros*). In addition to these municipal *fueros*, regional *fueros* developed, chiefly in the 13th century; they were private collections of laws applying over a larger area. In Castile a central role was played by the legislative work of Alfonso X the Wise, who sought to give statutory form to the juridical principles of Roman and canon law as elaborated by the glossators.

France. At the beginning of the 13th century two distinct juridical areas emerged in France. The customs prevailing in the north (*pays de droit coutumier*) were inspired by Germanic tradition, chiefly Frankish. Some treatises by private individuals at the end of the 13th century (as the *Établissements de St. Louis* and the *Coutume de Beauvaisis*, by Philippe de Beaumanoir) give a vivid picture of them. Only two centuries later, sovereigns promoted an approved collection of customary laws. But in the south (*pays de droit écrit*), Roman law prevailed almost everywhere. The kings resisted it, fearing that open recognition of Roman law would diminish their independence of the empire, since the emperors were considered the personification of Roman law as legitimate heirs of their classical predecessors.

Italy. In Lombardy between the 11th and 12th centuries, a collection of feudal customs was put together that was to form the basis of the *Libri feudorum*, the first organic text of feudal law. This was destined to spread widely and achieve great authority in every part of Europe. The cities of northern and central Italy, on obtaining political independence, wanted an explicit recognition of their customs from the emperor. Subsequently, in the 12th to the 14th centuries, every commune adopted its own municipal law, partly new and partly traditional. Later, the formation of principates led to a revision of municipal statutes, with the aim of bringing them into line with the principles of absolute government. In southern Italy, however, the Norman and Swabian kings were energetic in their policy of centralization; they issued general laws among which Frederick II's *Liber constitutionum* of 1231 stands out for its originality and perfection.

Germany. Territorial law had already become established in Germany when, in the course of the 13th century, certain works of synthesis appeared that had a lasting success. The most famous was written by the judge and knight Eike von Repkow and was renamed the Sachsenspiegel ("Mirror of the Saxons") for its brilliant and lucid exposition of the traditional nucleus of Saxon customs. Although a private work, it was soon invested with the authority of law in northern Germany. A similar work, the *Schwabenspiegel* (*Swabian Mirror*), appeared in southern Germany half a century later. Equally noteworthy was the contemporary flowering of German municipal law; sovereign privileges, autonomous statutes, and private collections of law (*Stadtrechtsbücher*) multiplied in many 12th-century German cities. Later, from the end of the 15th century onward, the widespread acceptance of Roman law stimulated the revision of many city statutes in an attempt to adapt them to Roman principles.

England. The Norman conquest did not destroy the vigour of Anglo-Saxon laws and customs. But the powers of the king's courts of justice and the authority of their decisions so increased as to become the creative source of a new system of law, common to the whole kingdom and prevailing over all other laws and local courts. It became known as common law. A clear picture of the system and its rapid evolution emerges from two famous works, both of which came out of the circle of the royal judges: the *Tractatus de legibus* (*c.* 1190), attributed to Ranulf de Glanville, and the treatise *De legibus et consuetudinibus Angliae* (*c.* 1250), by Henry de Bracton. Coming half a century later, Bracton's tract paints a much fuller and more complex picture; the author cites numerous actual cases in his exposition and exploits the logical and systematic framework elaborated by the jurists of Bologna. Aside from this influence, Roman law did not penetrate England, the effect of Vacarius' teaching having been ephemeral. An essential role was played, on the other hand, by royal legislation. The granting of Magna Carta (1215–25) by John and Henry III was followed in the first period of Edward I's reign (1272–1307) by the publication of legal texts such as the second Statute of Westminster (1285), the influence of which has been felt to the present day in many fields of English public and private law. This was historically all the more remarkable since legislative interference by kings in the field of private law was rare in the Middle Ages.

Common tendencies. Underlying the immense local variety, certain common tendencies can be detected in European law. About one century after Bologna saw the revival of the scientific study of law, the need to provide a clear and organic framework for the various juridical systems was felt almost everywhere. The need was the same, whether the system in question was Roman law (as in the works of Azo and Accursius), canon law (as in the clear syntheses of Henricus of Susa and Pope Innocent IV), Saxon law (as in the *Sachsenspiegel*), English law (as in Bracton's treatise), or French customs (as in the *coutumiers*). All these works were to have centuries of success and in many cases were still very much alive after the end of the medieval era. It seems no mere coincidence that they appeared in the course of a few decades of the 13th century. Without the spread of Bolognese teachings throughout Europe, none of them, not even those furthest from the principles of Roman law, would have been written in quite the same form.

CONSTITUTIONAL LAW

Changes in political structure

The king. The 13th century was also a crucial period for legislation by sovereigns. Royal lawmaking included Frederick II's constitution for the Kingdom of Sicily, Alfonso the Wise's compilation for Castile, and Edward I's legislation in England, not to mention the great collection of decretals authorized by Pope Gregory IX in canon

law. As the age of feudalism waned and the national monarchies began to consolidate themselves, the judge-king of the high Middle Ages gave way to the legislator-king.

At the summit of the medieval order stood the two universal authorities of pope and emperor. The thorny problem of their ideological, political, and juridical coexistence was brought into the open in the 11th century by radical differences over the investiture of bishops. The papacy won its struggle with the Holy Roman Empire, freeing the church of feudal obligations both centrally and in the provinces. The empire remained politically powerful, however, until the middle of the 13th century. In its relationships with the cities and kingdoms, it retained for a long time the prestige of being at the summit of human affairs in the temporal sphere. The grandiose concept of the politico-juridical unity of humankind survived the political failure of the empire.

Even when a monarchy succeeded, as in France or England, in asserting its complete independence from any higher authority, the medieval sovereign always considered himself bound by observance of divine law in dealing out justice or dictating his own laws. This was symbolized in the ceremony of investiture of the king by the church at the moment of coronation.

The question of succession to the throne was resolved in a variety of ways. Wherever the monarchy was weak, as in the post-Carolingian era or in late medieval Germany, the king was nominated by a small group of powerful men of the kingdom. The powerful Capet and Norman dynasties of France and England succeeded, however, in imposing the hereditary principle on their feudal lords, the throne passing undivided to the eldest son upon the death of the king.

At the same time, there was a transformation in the relationship of the king to his people. In barbarian kingdoms the king had been essentially the chief among men of his own kin: *rex Francorum* or *rex Langobardorum*. Later, when victor and vanquished had merged into one people, they became equally bound to their king by an oath of allegiance.

Feudal institutions. Around the 9th century, as feudalism spread throughout Europe, powerful lords interposed themselves between the king and his subjects. Feudalism was based upon the institutions of vassalage and the benefice, or fief. Those who served the king in peace and war received grants of land, in return for which they became his vassals, doing him homage and swearing loyalty to him. The rights and the duties of each party were gradually defined. For a long time, the feudal bond retained a distinctly military character, in that the essential obligation of the fief holder was to support the sovereign in war with cavalry and foot soldiers. From the juridical point of view, the vassal's devotion and loyalty to his lord were of fundamental importance; the gravest crimes in the feudal world were those involving the breaking of faith with the lord (the English word felony originally meant such a breach of faith).

Growing power of the lords

In time, the network of feudal relationships became more complex as the principal fief holders passed on a part of their possessions in fief to others, creating a hierarchy of feudal lordships at the summit of which stood the king. Fiefs were originally revocable at any moment by the king; but between the end of the 9th century and the beginning of the 11th century, they became hereditary everywhere. The precise rules varied. In Germany the sovereign was obliged to make a new grant whenever the benefice reverted to him for lack of heirs or for any other reason.

As the powers of the sovereign declined, those of the feudal lords grew. In the 10th century it even became normal for the sovereign to grant immunity (*immunitas*) to the great lords, giving them the right to exclude the king's judges and tax collectors from their fiefs. The basic functions of government thus passed gradually into the hands of the lords. Along with the power to collect a variety of direct and indirect taxes, they also acquired the right to sit in judgment over their vassals. In its most complete form, this right covered the whole range of jurisdiction, including civil and criminal cases; but in many countries, including England, Germany, and Italy, the feudal lords only exceptionally achieved such wide powers and then only by citing that characteristic institution of medieval law, prescription *ab immemorabili*—the long exercise of such jurisdiction. In cases concerning fief holders, a limitation of the powers of the lord in relation to his vassal grew out of the principle, which spread throughout feudal Europe, that a fief holder had the right to be judged in his lord's court by his peers only.

Communal institutions. The feudal order was eventually upset by new forces, those of the towns and the rising national monarchies. The growth of towns, closely linked to the revival of trade, brought pressures for local independence as townsmen everywhere claimed, with varying success, the rights to self-government, exemption from the lord's justice, nomination of their own judges, and preservation of local customs. An outgrowth of this movement was the city commune.

The characteristics of the commune varied greatly. Some towns remained under the jurisdiction of their lords or of the sovereign himself, although with a limited degree of self-government. In others, after a hard struggle, the citizens were able to form a commune that had the power to make its own laws, mint money, declare war, and enter into alliances. Between these extremes, of course, there was a wide range of local situations.

Between the 11th and the 14th centuries, communal institutions underwent profound changes, especially in Italy and Germany where they flourished the most. The Italian commune abandoned the democratic council form of government (*consoli*) and entrusted the running of affairs to an outsider (*podestà*) appointed every year by a more limited group. Later, in both Italy and Gemany the merchants and artisans formed associations (*arti, Zünfte*), the political weight of which grew until it often achieved the leadership of the commune. In Italy a further stage was reached in the 14th century with the passage of all power into the hands of a single ruler (*signoria*). In the period of the 14th to 16th centuries, the rulers became hereditary princes.

The kings' courts

Monarchical institutions. The 12th and 13th centuries brought, among the monarchies, a progressive strengthening of the king's position. In England, France, and Spain the sovereigns strove tenaciously and long to win direct control of their territory by appointing their own officials throughout the country, free of feudal ties to local lords. The authority of the king's officials gradually increased, notwithstanding the opposition of the lords, especially in the administration of justice.

At the centre was the sovereign, surrounded by a small group of advisers. For financial, legislative, and judicial problems, special bodies of counsellors and magistrates were formed, which acted in the name of the king and were constantly consulted by him. The king's courts of justice acquired increasing influence. In England as early as the 13th century, the more important civil and criminal cases were already being heard in the central courts. Later, in 15th-century England, the expanding jurisdiction of the chancellor's court led on to the development of the system of equity. France developed, from the middle of the 13th century onward, the Roman–canonical appeal system that permitted the highest court of justice in the realm, the Parlement of Paris, to reconsider decisions by the king's local judges; later on, it was able to reconsider sentences passed by the feudal lords as well. A class of professional judges developed in the central courts whose work was to be decisive in the elaboration of a uniform law throughout the kingdom.

The sovereign's power over his subjects was, although ample, not unlimited. His subordination to the higher principles of divine law was recognized in rights such as *Widerstandsrecht* (right of resistance), which could be invoked to resist the sovereign's unjust actions. Above all, the monarchs were restrained by certain representative bodies, the history of which varied in different countries. In 13th-century Spain the king's legislation could not override the deliberations of the Cortes, which already included, in addition to the nobles and ecclesiastics, repre-

sentatives of towns and boroughs. In France the representative assemblies of the three estates (*États généraux*) partially established themselves only later, in the 14th and 15th centuries; the king succeeded in preserving for himself a maximum of autonomy, in some degree tempered by the courts (*parlements*), which were not representative national bodies. Only in England had a constitutional balance between the monarchy and other forces in society already been reached. The king was bound by Magna Carta to seek the lords' assent in the crucial matters of taxation and war. In 1295 representatives of the middle classes and landed commoners entered Parliament, and in 1433 the assent of both houses of Parliament became necessary for the passage of bills.

THE RULES OF LAW

Personal and family law

Persons. Social stratification in the medieval world took not only economic forms but juridical ones as well. The law recognized differences in personal status, generally as a function of birth. On the lowest rung of society were the serfs, tied to the land, subject to the lord, and without property rights. Not until the 13th century did large numbers of serfs begin to win enfranchisement in various parts of Europe. A class of *coloni* enjoyed better status, cultivating land that was not their own and paying a rent to the lord. But in some countries, such as England, the distinction between these two classes had lapsed by the 13th century, and they acquired rights against all but their lords. Under feudalism the nobles occupied the highest rungs of the ladder of power and privilege, at the top of which was the sovereign. With the rebirth of towns, a new class arose, chiefly in Italy, Flanders, and Germany, concerned with trade and crafts. To pass from one class into another, difficult enough in the towns, was almost impossible in the rural areas.

In a society so full of juridical distinctions, minorities often found themselves disadvantaged. Foreigners were in a difficult position. Jews were insecure. Persons holding heretical opinions were threatened by the severest penalties, especially from the 13th century onward.

Women were juridically inferior, as they had been for centuries. Slowly their position changed, and they became able to inherit property. In places where commercial life developed, women acquired, as early as the end of the 12th century, the power to draw up and sign legal documents, such as wills, bills of sale, and company agreements, even without the presence or agreement of a legal guardian.

The family. Almost everywhere the old Germanic traditions of matrimony faded away, and the church's conception was gradually superimposed; as a sacrament, marriage belonged to the spiritual sphere and was therefore regulated by canon law. While tradition gave primacy to the wishes of the betrothed's families, the medieval church vigorously upheld the free consent of the betrothed themselves as essential to the validity of a marriage. Solemn rites were not required until the 16th century.

Within the family the father was pre-eminent, although the classical Roman concept of paternal power had been moderated by medieval tradition and Christian views. In regions where the influence of Roman law was still felt, children remained permanently under paternal control unless they had obtained emancipation. Elsewhere, the Germanic principle prevailed, by which children passed out of paternal control on coming of age. Until they became independent, the father was responsible for his children's acts and administered their property. In the countryside it was still normal in this period for family holdings to be kept undivided and farmed in common. A harsh strengthening of paternal power, particularly in the upper classes, was to come about after the end of the medieval period, in the era of absolute states.

Laws relating to family property were diverse and complex. In certain regions, such as northern France, the possessions of husband and wife formed a single estate. Elsewhere, their property remained juridically separate; the husband contributed various possessions subject to limitations (*donatio propter nuptias, morgengabe, tertia, quarta*), and the wife contributed her dowry, retaining her rights in it, although its administration was her husband's task.

Inheritance. In the Middle Ages the laws of inheritance followed the Germanic tradition for a long period. Heirs were drawn from the family circle according to rigorous rules of succession. No one had the free disposal of his property after death; it was destined for his legitimate offspring or other relatives, and their consent was needed for any alienation of property during his lifetime. Only if there were no descendants could the estate pass to an outsider, but such a person had to be previously adopted and thus juridically a member of the family.

A breach was opened in these principles by the practice of making bequests to churches and religious bodies. The right to do so had been admitted in the early Middle Ages. Free disposal of property after death was fully admitted around the 12th century with the return in many regions of Europe to the Roman *testamentum*, which differed from a donation in that it could be freely revoked by its author.

The laws governing the inheritance of feudal property remained more rigid. By the 11th century it had been established that a fief could be inherited. A little later, the principle gained ground in England, Normandy, and elsewhere that a fief must pass undivided to the eldest son. In England this rule of primogeniture was soon extended to commoners' property, while in other countries it was not. In Italy the fief itself could be divided among the sons at the death of the lord.

Property and business law

Property and possession. The variety of differences in personal status in the Middle Ages was reflected in a diversity of legal rules relating to property, both movable and unmovable. Land, the most precious possession in a predominantly rural society, carried with it a great variety of rights and duties. Traces of the ancient practice of common property in land, pasture, and woods lingered for a long time. Common family rights in property frequently survived, even though individual ownership had become more usual. There was also "servile" land, generally cultivated by men who were not free, in which rights of possession were weak; it was rarely inheritable. The *coloni* held land belonging to a lay lord or an ecclesiastical body, to whom contributions were due in money or in kind fixed by various forms of contract (*census, libellus, precaria,* and others). On a very large scale, land was held of the king by feudal grant or of great lords by feudal lords of lesser rank. Finally, properties might be held outright, free of any dependent tie (*allodio, alleu*); this was not the case everywhere, for England had no absolute ownership.

Whereas in the Roman world the principle had prevailed that property was an absolute and unlimited *dominium*, medieval society developed the different principle of divided ownership. There was, on the one hand, the *dominium directum* of the man who held the land but leased it to another and, on the other, the *dominium utile* of the man who, by virtue of his lease, made use of the land. As the practice of leasing spread widely, the juridical position of the lessee grew stronger to the point of recognizing in many cases a power not originally accorded him—that of ceding his own right in the land to others, either during his lifetime or at his death. But the restrictions on free exchange of property remained considerable, partly because of the principle of inalienability governing the vast ecclesiastical holdings.

In the course of the Middle Ages, the primitive Germanic concept of property was superseded by the Roman concept, in which mere possession, a person's use of things, was distinguished from property, the rightful ownership of things. The principle that possession deserved primary protection also made headway; anyone forcefully dispossessed had the right to repossess through the courts independently of any inquiry into title. The first complete statement of this principle was in canon law, which thus provided an effective means of discouraging the age-old practice of despoilment. Protection of possession was given clear recognition in England from the 12th century by the action of "assize of novel disseisin."

Contract and commercial law. The development in this period in the vast field of contract law was no less profound. In the early Middle Ages agreements had been considered binding if certain rigorous and solemn forms were observed. But the basis of obligation gradually changed. The fundamental element of consent regained full weight, so that the forms observed by the contracting parties were of importance only in proving that a contract existed. The most consistent development of this principle was in canon law, where the effort was made to bring the precepts of the law into line with morality; in canon law, even a simple informal agreement (*pacta nuda*) was considered fully binding. Civil lawyers, however, following Roman law more closely, distinguished between simple agreements and contracts; full protection was given only to agreements entered into under the terms of the law (*pacta vestita*). Both the Roman and the canonical concepts had great influence throughout Europe from the 13th century on and were not absent even in English law, where the history of contract followed a course of its own. In fact, during the age of the English legal writers Glanville and Bracton in the 12th and 13th centuries, the royal court protected formal contracts only, by means of specific actions of the creditor (*writ of debt, writ of covenant*), while a wider protection was assured by ecclesiastical and merchant courts. English common law reached maturity in this field later, at the end of the 15th century.

The law of agency developed at the end of the Middle Ages when it was admitted that a person could assume obligations and rights in the name of another, who was then accountable in law for his agent's actions without any subsequent transfer of rights being required. This fundamental principle, novel to Roman law, made juridical relationships easier in an increasingly dynamic economy. It was partially recognized by 13th-century canon law and subsequently by secular law.

The growth of commerce brought a need for new legal forms. Canon law had rigorously forbidden the charging of interest upon loans, considered to be usury. This was gotten around, sometimes by subtle juridical expedients, and, in the business practice of northern and central Italy, a complex of institutions developed that were to spread throughout Europe. These included the first limited liability companies, from which the joint-stock company, or corporation, later developed. Bills of exchange began to be used, soon becoming an indispensable instrument of credit. The first insurance contracts were drawn up to protect shipowners against losses at sea. Among the compilations of customs relating to commercial maritime contracts, the Barcelona collection was well-known; a 15-century revision of this, the *Consulado del Mar*, or "Consulate of the Sea," became the standard text of maritime common law until the 18th century.

Criminal law. In criminal law the last centuries of the Middle Ages in a large part of Europe may be considered a period of transition. Certain principles rooted in the early Middle Ages were still very much alive. Collective responsibility for the actions of an individual was frequently attributed to a family group, to the inhabitants of a village, or to the culprit's fellow citizens. The outstanding phenomenon of the 9th to 11th centuries was the revival of the practice of self-protection. The absence of authority led men to administer their own justice, falling back upon family solidarity in the form of the vendetta (*faida, Fehde*). Private wars spread in the feudal world.

In the 12th century, renewed attempts were made by the state to eliminate the vendetta by requiring an offender to pay money to the injured party (*compositio, Sühne*). The institutions of the *pax Dei* and the *treuga Dei* were established by the church and the emperors in an effort to ensure brief periods of truce. The principle that crime should be punished by the state rather than by the victims or their families gained ground. States with strong monarchies—England or 13th-century Sicily, for example—made the greatest progress in this direction, although in Germany and Italy an abundant legislation multiplied the punishments inflicted by the state.

Penalities were generally very severe, ranging from imprisonment or retaliatory corporal punishment to banishment or death. Discriminatory treatment accorded to different social classes accentuated this severity, and the moderation of many judges served to temper it only partially. A judge could, however, exercise considerable discretion, as the principle subordinating every crime to a relevant law had not yet matured. The harshness of the penalties could frequently be mitigated by the payment of a fine or by agreement between the accused and the accuser—a survival from the system of private justice. A more general affirmation of the state's exclusive power to punish criminals was established only in the 16th century.

Procedure. During the 12th century a fundamental change occurred in trial procedure. Feudal Europe had reverted to the primitive method of the ordeal or judgment of God, in which a dispute was won by the person who remained unharmed after ordeal by fire and water or who defeated his adversary in a duel. In the 11th century, distrust in this method of proof grew, along with increasingly frequent denunciations of its injustice. In 1215 the church expressly condemned ordeals. Canon law and the revived Roman law required trial to be founded on the rational evidence of written or oral testimony or, alternatively, admitted testimony under oath, widely employed in medieval law. The judge's function was to weigh the evidence according to certain rules.

From ordeal to jury

A different system was adopted in certain northern countries: in Normandy, Flanders, and England the decision was entrusted to a group of men who, by their origin and status, were qualified to determine the truth and to formulate a just verdict (*inquisitio, veritas scabinorum*). In this way, the cardinal institution of the jury developed in the English royal courts.

The parties to an action were represented in court by attorneys and advocates. The Romano-canonical trial was a series of long and complicated procedural stages, and summary procedures were introduced in the 14th century. The right of appeal won wide recognition throughout Europe; it was favoured by sovereigns and utilized very fully by litigants.

Procedure in criminal cases came to differ from that in civil cases. In both canon and secular law the public authorities might intervene and make an investigation (*inquisitio*) into certain crimes and punish culprits even in the absence of an accusation. On the Continent the two procedures, accusatory and inquisitory, survived together for a long time, and only slowly did the latter prevail. In English law, on the other hand, the accusatory procedure remained the only one.

BIBLIOGRAPHY. The classic work on the history of Roman law in the Middle Ages is F.C. VON SAVIGNY, *Geschichte des römischen Rechts im Mittelalter*, 7 vol. (1834–51). A work by various authors designed to provide an updated account is *Ius Romanum Medii Aevi* (1961–); part 5 deals with the spread of Roman law in individual countries. PAUL VINOGRADOFF's lucid outline, *Roman Law in Medieval Europe*, 2nd ed. (1929), still deserves to be read as does PAUL KOSCHAKER'S very fine *Europa und das römische Recht*, 3rd ed. (1958).

Research into the comparative history of medieval European law is still in an initial stage. By 1971 about 30 volumes had been published of the *Recueils de la Société Jean Bodin pour l'histoire comparative des institutions*. Each volume is the work of various authors and deals by country and period with such historical aspects of public and private law as *Le Servage*, *La Tenure*, *La Ville*, *La Femme*, *La Paix*, *La Prevue*, or *La Monocratie*, with large sections on the Middle Ages. Another series *Vorträge und Forschungen*, of which 12 volumes had been published by 1971, is exclusively concerned with the Middle Ages and follows a similar formula, with volumes devoted to kingship, feudalism, and the towns. The Centro Italiano di Studi sull'alto Medioevo in Spoleto, has been publishing annually since 1954 *Atti delle Settimane di Studio*, each volume devoted to a topic of medieval European history.

Outstanding among monographs using the comparative method are those of MARC BLOCH, *La Société féodale*, 2 vol. (1939–40); and HEINRICH MITTEIS, *Der Staat des hohen Mittelalters*, 8th ed. (1968). EDITH ENNEN, *Frühgeschichte der europäischen Stadt* (1953), should be consulted for the

history of towns, and a lucid survey of feudal institutions may be found in ROBERT BOUTRUCHE, *Seigneurie et féodalité*, 2 vol. (1968–70). Notable essays on the comparative history of the medieval theory of the state include ERNST H. KANTOROWICZ, *The King's Two Bodies: A Study in Mediaeval Political Theology* (1957); and GAINES POST, *Studies in Medieval Legal Thought* (1964). Few attempts have been made at a comparative history of private law in the late Middle Ages; one is EDUARD M. MEIJERS' bold and stimulating *Le Droit ligurien de succession en Europe Occidentale*, 4 vol. (1928–36).

Fundamental for the history of political and juridical ideas in the Middle Ages are OTTO GIERKE, *Das deutsche Genossenschaftsrecht*, vol. 3 (1881), trans. in part by FREDERIC W. MAITLAND as *Political Theories of the Middle Age* (1900); and ROBERT W. and ALEXANDER J. CARLYLE, *A History of Medieval Political Theory in the West*, 6 vol. (1903–36).

For medieval canonical sources three classics suffice: JOHANNES F. VON SCHULTE, *Die Geschichte der Quellen und Literatur des canonischen Rechts*, 2 vol. (1875–77); PAUL FOURNIER and GABRIEL LE BRAS, *Histoire des collections canoniques en Occident depuis les fausses Decretales jusqu'au Décret de Gratien*, 2 vol. (1931–32); and STEPHAN KUTTNER, *Repertorium der Kanonistik (1140–1234)* (1937).

The vast *Continental Legal History Series*, 10 vol. (1912–18), consists of translations of histories of national law with additions and notes. A useful guide to further literature is the *Bibliographical Introduction to Legal History and Ethnology*, ed. by JOHN GILISSEN (1963 *et seq.*).

It is necessary to limit suggestions in the field of national histories of medieval law. The classic work for England is FREDERICK POLLOCK and FREDERIC W. MAITLAND, *The History of English Law Before the Time of Edward I*, 2nd ed., 2 vol. (1898), reissued in 1968 with a new introduction and updated bibliography by S.F.C. MILSOM. T.F.T. PLUCKNETT, *A Concise History of the Common Law*, 5th ed. (1956) is a rich general account. For France, an excellent treatment is FRANCOIS OLIVIER-MARTIN, *Histoire du droit français des origines à la Révolution*, 2nd ed. (1951); for private law, PAUL OURLIAC and JEHAN DE MALAFOSSE, *Histoire du droit privé*, 3 vol. (1961–68). For Germany, HEINRICH BRUNNER, *Deutsche Rechtsgeschichte*, 2nd ed., 2 vol. (1906–28) is fundamental, though it stops short at the Carolingian era. RICHARD SCHROEDER and EBERHARD VON KUNSSBERG, *Lehrbuch der deutschen Rechtsgeschichte*, 7th ed. (1932), is particularly informative, while an up-to-date picture is offered by HERMANN CONRAD, *Deutsche Rechtsgeschichte*, 2nd ed., vol. 1 (1962). For Italy, the foremost work is FRANCESCO CALASSO, *Medioevo del diritto*, vol. 1, *Le fonti* (1954), to which may be added the analytical exposition of ENRICO BESTA, *Fonti:legislazione e scienza giuridica*, 2 vol. (1923–25). ARRIGO SOLMI, *Storia del diritto italiano*, 3rd ed. (1930) is a useful synthesis. For Spain, ALFONSO GARCIA GALLO, *Manual de Historia del Derecho español*, 3rd ed., 2 vol. (1967); and LUIS G. DE VALDEAVELLANO, *Curso de historia de las instituciones españolas* (1968), provide lucid general accounts.

(A.P.S.)

European Peoples and Cultures

Among the continents, Europe is unique in several respects: its coast is the most indented of all, its climate the most temperate, and it is the only continent the autonomy of which is culturally rather than geographically determined. Europe is, in fact, only a peninsula of Asia, and, but for its historical and cultural peculiarities, there would be no reason to view it as a separate continent.

In Europe, as in other areas of the world, geography is merely a conditioning and not a determining factor in cultural evolution; this is reflected by the fact that its major cultural areas do not correspond with its main topographical divisions. Not one of the large, more or less isolated geographical divisions—the British Isles or the Scandinavian, Iberian, or Balkan peninsulas, for example—is culturally homogeneous, for any tendency toward such cultural polarization has been negated by numerous other influences, including linguistic, religious, and political expansions and repeated technical and social revolutions.

Elements of European ethnocultural uniformity

The ethnocultural structure of Europe nevertheless shows more uniformity than is found in other parts of the world. None of the other four continents succeeded as Europe did in realizing a racial homogeneity such as the Europoid (Caucasoid), a linguistic predominance such as Indo-European, a religious and moral order such as Christendom, an almost unanimous defense of common values such as the Crusades and the campaigns against the Turks, Tatars, and Moors, a common intellectual ethos such as Latinity, a uniform economico-political structure such as feudalism, or such a great similarity of social structure, based on economic classes.

GEOGRAPHIC INFLUENCES ON CULTURAL EVOLUTION

Explanations of this European cultural unity and of Europe's technical and economic leadership tended in the 19th century to focus on the idea of the superior racial characteristics of Europeans. Geographical and ecological explanations, however, seem at present to have a better scientific basis. Among Europe's geographical advantages have been listed its variety of landscapes, its climatic mildness, its wealth of natural resources, and a location that has left it open to influences from Asia and Africa, thus minimizing the possibility of insular stagnation.

Natural geographical thoroughfares have played a leading part in the shaping of European cultures, prescribing, on the one hand, the intensity and direction of the main demographic streams and, on the other, permitting contact with extra-European groups. Fishermen, hunters, and, later, cattle breeders and agriculturalists followed the large river valleys, so that, since Paleolithic times, the Volga, Dnepr, Danube, Rhône, and Rhine rivers have been the main highways of European peoples and the most important factors influencing culture contacts and diffusion.

Its geographical location gives Europe three communication junctions with the neighbouring continents: the Iberian Peninsula provides a link with Africa, the Balkan Peninsula connects Europe with Asia Minor, and the large, marshy plain that forms an aperture between the south end of the Ural Mountains and the Caspian Sea acts as a gateway to Central Asia. Ethnic migrations have repeatedly taken place via these passages since the appearance of man in Europe and especially since the Neolithic. During prehistory the migratory direction was almost always centripetal, the refugees or invaders who came from Asia and Africa entering Europe through one of the above routes. But the more evident the economic, political, and military superiority of Europe becomes, from protohistorical times on, the more centrifugal the direction of cultural influence becomes. This process began with Hellenistic colonization in Asia Minor but attained a considerable volume only during the Renaissance. Then European man rapidly discovered and conquered remote territories, with a resulting demographic diffusion that shook the old historical boundaries of Europe and transplanted substantial masses of its inhabitants to other continents. Within four and one-half centuries the temperate zones and large river valleys of North Asia, the eastern Mediterranean, southern Africa, the Americas, Australia, and Oceania were populated by European white men.

PEOPLES AND LANGUAGES

Europe may be ethnologically divided into four major culture areas, then into 22 culture provinces that contain numerous cultural subdivisions from peoples to enclaves (see legend to map).

Difficulties of cultural delimitation in Europe

It should be noted that every cultural division of Europe, above the level of the basic ethnic group termed by anthropologists ethnos (a historically formed autarkic, often endogamous group), is to some extent arbitrary. In primitive societies an ethnos is generally represented by a tribe or a quite distinct tribal unit; in Europe the delimitation of ethnoses is more difficult because of numerous interethnic influences that blur clear boundaries and distinctions. Even so, it is possible to trace the origin of almost every European ethnos to a prehistorical tribe, from which it has usually evolved into a group of villages or hamlets often corresponding to a distinct area of local jurisdiction such as a canton, *Landschaft*, or barony. Ethnoses generally possess their own particular dialects and can be grouped together linguistically into larger units that ethnologists call culture regions. European nations are in most cases divided into several such culture re-

Distribution of European ethnic culture areas.

gions, which may, in turn, be grouped into larger units termed culture provinces or culture sub-areas according to historical, linguistic, and other criteria. This hierarchical classification is illustrated by the following example of a Hungarian village (one asterisk [*] denotes a basic ethnic group; two asterisks [**] denotes other principal ethnic units): village Mezőkövesd, ethnos* Matyók (Mezőkövesd and other villages), culture region the Felföld (Matyók and other ethnoses), culture subprovince Hungarians in a narrow sense (the Felföld and other culture regions), culture province** West Ugrics (Hungarians and other culture subprovinces), culture sub-area the Carpathian Mountains and the Carpathian Basin (West Ugrics and other culture provinces), culture area** the Carpatho-Alpine-West Plain Climax (the Carpathian Mountains and the Carpathian Basin and other culture sub-areas), continental framework Europe (the Carpatho-Alpine-West Plain Climax and other culture areas), intercontinental culture complex** European culture complex (Europe and Europeans in other continents). Linguistically, Europe is dominated by Indo-European languages (*q.v.*) believed to have evolved first on the steppe lands of the Black Sea area or, perhaps, farther east in Central Asia. Archaeology illustrates the general movement westward of people from this area, and some of these movements in the 3rd and 2nd millennia BC resulted in Indo-European forms being modified by local contacts and intermarriage. Proto-Celtic was spoken on the southern German loess lands soon after 1800 BC and spread westward to survive as Gaelic and neo-Celtic (perhaps much modified by contact with some earlier forms) in Ireland, Scotland, the Isle of Man, Wales, and Brittany.

Of non-Indo-European languages, Basque and some Caucasian idioms represent the few survivals of paleo-European cultures. The 14 living Finno-Ugric languages are also autochthonous European, and, among them, Hungarian, Finnish, Mordvinian, Estonian, Votyak, Mari (Cheremis), and Zyrian are each spoken by more than 500,000 people. Turkish languages, in the Middle-Volga-Kama, the Ponto-Caspian, and here and there in the Balkan regions, are results of ancient invasions from Asia.

CULTURE PATTERNS

Religion. Christianity has conquered almost the whole of Europe, with the exception of the Islāmic area in the Balkans and the Turco-Tatar southeast.

The three great branches of Christendom—Catholicism, Protestantism, and Orthodoxy—are linked with Latin, German, and Slavic culture, respectively. Further, almost everywhere in Europe, religion is closely related to ethnic consciousness. In Ireland, Catholicism acts as a shield against English assimilation, and in Finland, Estonia, and Latvia, Protestantism is a fortress against Russification. The spread of Orthodoxy proved to be the first step in the Russian assimilation of the Karelians and other Finno-Permian, Baltic, and Turkish peoples. But it may also be observed that ethnic minorites often survive more because of their religious particularity than because of their language. The Catholic Germans of the Volga, at least until their extermination after World War II, thus preserved their ethnic traditions among Orthodox Russians; the Protestant Saxons of Transylvania likewise survived among Catholic Siculi, as did the Catholic Csangos of Moldavia among Orthodox Romanians. Greek minorities living under Islāmic domination defend their culture first of all through their Orthodoxy.

Religion and ethnic consciousness

The faithfulness to Rome of the Hungarians and Poles is a consequence of their particular devotion to Latinity. In Hungary, including Transylvania, the Latin language was for 1,000 years an intellectual shelter against the permanent threat of Germanization. In the same way, in Poland, it was a defense against Russification. These two countries, actual confines of Western civilization facing Eastern ideology, kept Latin alive longer than any other people. In the 17th century, in Poland, Latin literature reached its highest level of development, and Latin remained the official language at Hungarian diets until 1825 and still later in the universities.

European sociocultural dualism also affects religion. The liturgy, interpretation of dogmas and symbols, and religious practices of the city man come nearer to the official ideas of the high clergy than do those of the common country people. Peasant religious activity is based upon agropastoral life, and pre-Christian ideas penetrate every custom and feast. Fertility rites and invocations for favourable weather and plentiful harvests are prominent in the half-pagan, half-Christian rites and magic still surviving in many areas of Europe, and the calendar of popular religious rites contains feasts grouped around solstices—a practice surviving from prehistoric times. Practices such as noise to drive away harmful jinns, masks to transform the bearers into supernatural beings, ceremonial fire, and various individual abstentions to ensure the success of magic acts are also common in many areas.

Shamanism, which prevailed in many Siberian cultures, may be found still deeply rooted among groups living from the sub-Arctic to the line of the Volga and Kama rivers, where it is strongest among the Nenets (Yurak) Samoyeds. Old pre-Christian ideas and rites are particularly alive among the Cheremis, three-quarters of whom are more or less converted to Christianity, while the remainder continue to practice their ancestral faith, which is linked to the Siberian cults, and refuse any kind of Russification.

The survival of pre-Christian religions in the large eastern plain of Europe is made possible by the fact that in these isolated areas Orthodoxy has always been represented by almost illiterate priests without any theological training. In the Catholic regions of Europe, the clergy demands a stricter break with pre-Christian ideas and practices but often permits customary ceremonies and symbols to survive with a Christianized interpretation. Because of its ascetic principles, Protestantism simplifies to the utmost not only the official liturgy but also the folk ritual. The cult of saints, a foundation of the Catholic tradition calendar, is, for example, almost entirely lacking in most of the Protestant regions. Among Christmas traditions, the Nativity crib is typically Catholic and scarcely appears in Protestant homes. In Switzerland the two confessional groups have different ways of greeting. Diversities also appear in clothing. In Hessen, for example, the traditional costume of Protestant women is dark, whereas the Catholic women's is colourful.

Industrial and traditional ethnic cultures. Superficial observation of the European urban milieu may give rise to a misleading impression of uniformity. In proceeding from the major cities to the villages, burghs, small provincial towns, and even the outskirts of the large, modern cities, the variegated cultural inheritance of the pre-industrial past becomes increasingly evident.

This contrast between urban industrial civilization and traditional ethnic culture is a manifestation of a very old sociocultural dualism that has been dividing Europe more and more deeply since Neolithic times and that is based mainly on differences in life-styles, in means of communication, and, more fundamentally, in the dynamism of the entire culture system. In illustration of the latter dualism, one might point to the role of deliberate and consciously applied individual initiatives in the intricate mechanism of the city, and, on the other hand, to the role of collectively determined and controlled behaviours moved by unconscious, traditional forces in the village. Collective memory may also be a basis of this dualism: in a traditional village, anywhere in Europe, everybody knows everything. Collective knowledge penetrates every social relation and every technical field. Everybody knows the lineage, social connections, daily and seasonal occupations, religious and political beliefs, and working methods of everybody else. Nothing escapes this interknowledge. A peasant, for example, is perfectly acquainted with every technical step of horseshoeing or cart making, even though it is performed by the blacksmith or the cartwright. In the same way, agricultural tasks are familiar to the village craftsmen, even though the latter take no part in farming. This complex mechanism of collective memory is quite similar to that found in the tribal societies that preceded European feudalism (see below

Collective memory and rural traditionalism

Prehistoric cultures) and still exists in some eastern ethnic enclaves of the continent. In urban societies the phenomenon of collective memory disappears or at least is very weak. In large city buildings, even neighbours ignore one another, and extreme professional specialization tends to restrict the individual's knowledge and social relations.

Cultural change. Certain generalizations may be made concerning the processes of cultural change and acculturation in Europe. First, there has been a clear tendency for traditional culture patterns to disappear more rapidly in west central Europe than in the eastern, northern, and southern regions. West central Europe (focussing, say, on the area included in the quadrangle of Paris, London, Amsterdam, and Frankfurt) is also the most economically developed, so that one may point to a certain coincidence between economic and cultural geography; in moving away from this central area, the population's material standard of living gradually declines, but traditional cultural elements are much more in evidence. In other words, the geography of material poverty coincides with the geography of ethnic traditionalism.

In the acculturation process the economically stronger groups are invariably the givers and the weaker the receivers. It is also true, however, that the farther an area is from west central Europe, the more fiercely it protects its cultural inheritance. The real strongholds of traditional cultural elements are, in fact, the islands, such as Iceland, the Faeroes, the Hebrides, the Orkney Islands and the Shetland Islands, the thousands of islets off the Norwegian and Finnish coasts, the Channel Islands, the Balearics, Corsica, Sicily, Malta, and the Greek archipelago, and mountain and moorland areas, such as the Scottish Highlands, the Pyrenees, and the deltas of the Danube and the Po. In these peripheral areas survive linguistic, social, religious, and technical relics of European prehistory. In the Caucasus and the western Pyrenees, for example, were preserved elements of pre-Indo-European languages, while Celtic traditions, once dominant in the Middle Danube Valley, have receded to the farthest coasts and islands of Ireland, north Scotland, Wales, Cornwall, Brittany, and Iberian Galicia. Finno-Ugric peoples, who until the Middle Ages occupied the greater part of the eastern half of Europe, were first driven back and partly assimilated by the Bulgaro-Turks and Turko-Tatars, then squeezed toward the Barents Sea and the Urals by Russian invaders. Some of them, such as the East Ugric Voguls and the Ostyaks, fled toward the Asian slopes of the Urals and are now settled in the basins of the Irtysh, the Ob, and their tributaries.

Strongholds of ethnic traditionalism

Whereas traditional cultural elements move back toward the borders, a dynamical demographic countercurrent flows toward the centre: great wars and political and economical commotions result in migrations mainly directed toward the economically strong countries. The Bolshevik Revolution drove about 2,500,000 Russian citizens westward, and, between World Wars I and II, streams of Polish (450,000), Czech (60,000), Jewish (170,000), and other immigrants rushed into western-European countries. After World War II, 16 million Germans arrived in West Germany from the regions occupied by the Red Army; 200,000 Poles fled to France and England, 415,000 Karelians to Finland, and some 500,000 Balkan and central European people to western Europe. The Hungarian Revolution of 1956 and the Prague revolt of 1968 similarly resulted in a westward flow of population. Workmen's migrations also show a tendency toward west central Europe: in the 1950s and 1960s 1,500,000 Italians, 1,000,000 Yugoslavs, and as many Iberians settled in western Europe. Internal migrations from rural areas, known in every European country, are also directed toward economically prosperous areas. One of the most remarkable examples of the influence of the westward trend of population groups on social morphology is the orientation of the various class districts in the large European capitals. Residential and fashionable districts in Moscow, Berlin, Budapest, Vienna, Rome, Paris, London, and other cities are invariably situated in the "west end," whereas almost everywhere the "east end" is the slummy district.

Such demographical tides have important consequences. On one hand, they increase the density of population in the west central regions, where the natural rate of increase is generally low, and, on the other hand, they deprive the surrounding areas chiefly of their youth and of their most dynamic, transformer elements, thus contributing to their cultural traditionalism.

ETHNOGENIC AND PROTOHISTORICAL BACKGROUND

Bio-racial diversities. There have been numerous attempts by anthropologists to classify European racial types and to determine their geographical distribution. Among the best known classifications of modern times, that of the Russian Joseph Deniker (1900) identifies six main European races and four secondary ones: (1) Nordic, with the Sub-Nordic subrace (tall, long skull, blond); (2) Littoral or Atlanto-Mediterranean, with the northwest subrace (tall, flat head, dark); (3) Adriatic or Dinaric, with the Sub-Adriatic variety (tall, round head, dark); (4) Ibero-Insular (small, long head, dark); (5) Occidental or Cevenol, also called Slavic, Rhaetic (Raetic), or Ligurian (small, round head, dark); (6) Oriental, with the Vistula subrace (small, round head, blond).

Despite his being a sociologist, the American W.Z. Ripley influenced a whole generation of physical anthropologists with his original tripartite racial division (1899): (1) Teutoni, limited to the northwest (tall, long head and face, short nose, blond); (2) Celtic or Alpine, occupying central Europe (small and thick-set, round head, wide face, gray or hazel eyes, short nose, brown hair); (3) Mediterranean, south of the Pyrenees, Provençal coast, and southern Italy (long head and face, wide nose, brown eyes and hair).

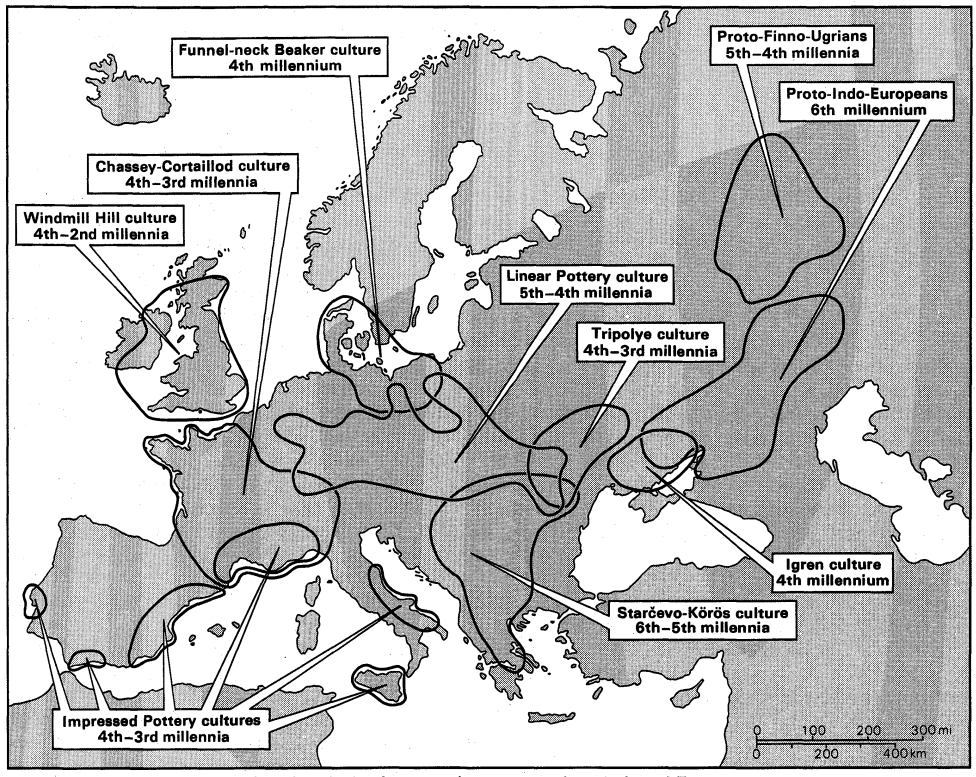
Another American, Carleton S. Coon, is perhaps the most often quoted and his racial classification (1939) probably the most appreciated by his contemporaries. He counts ten European races divided into four major groups: (1) large-headed Paleolithic survivors (fossils); (2) pure and mixed Paleolithic survivors of moderate head size; (3) pure and mixed Mediterranean derivatives; (4) brachycephalic (broad and short-headed, with a cephalic index of over 80) Mediterranean derivatives, probably mixed.

A Russian, N.N. Cheboksarov, on the other hand, divides (1951) the Europeans into only two principal races, with local variations: (1) south European, or Indo-Mediterranean, including the Mediterraneo-Balkanics, the Atlanto-Pontics, and the east Europeans; (2) north European, comprising the Atlanto-Baltics and the Balts of the White Sea.

More recently (1969), an Englishman, John Geipel, has argued the impossibility of establishing a racial classification of Europeans that can be related to definite geographic areas. The dispersal of distinct physical types is, he asserts, so wide that it is impossible even approximately to identify racially homogenous groups.

Prehistoric cultures. Agriculture and the technical, economic, and social developments associated with it first appeared in Europe in the context of Neolithic culture. The first rudimentary origins of agropastoral techniques appeared in the Balkans toward the end of the 7th millennium BC, but, until the beginning of the 2nd millennium, most of the continent was inhabited, for the most part, by gatherers, hunters, and fishermen of a Mesolithic culture stage. Numerous isolated agropastoral communities were in existence as early as 4500 BC, however, from the Lower Danube to the Atlantic. Throughout this period, new waves of migrants from the Near East were arriving in Europe, sometimes via North Africa and the Iberian Peninsula.

Domestication of new types of plants and animals and the introduction of new labour techniques, architecture, and pottery marked the progressive stages in the development of this early European culture. Europe was then covered with dense forests, but the slash-and-burn technique, common among Amerindian primitive agriculturalists and in medieval Europe, was apparently not applied; rather, the first European farmers tended to sow in woodland glades. In the Balkans, the first Neolithic



Presumed locations of the major identified cultures and agropastoral societies of Europe from the 6th to 2nd millennium BC.

houses, around 6000 BC, were small, rectangular, single-roomed, mud-wall constructions. It was among these Balkan people that the earliest distinctive, identifiable European culture—termed Starčevo-Körös—emerged. Based on Near Eastern and Cretan Neolithic traditions, its architecture was poor, and what is known of its culture from clay and pottery figures indicates an earth-mother-goddess cult and a matriarchal social organization.

Linear Pottery culture and its influence

During the 5th millennium, the now so-called Linear Pottery colonists, migrating from the southeast, built ordered villages of huge longhouses with massive timber framing, averaging about 100 by 25 feet (30 by 8 metres). The Linear Pottery culture spread through the river valleys of present north Hungary, Czechoslovakia, Poland, and Germany. Simultaneously with the middle period of this culture, an eastern European agropastoral group, the Funnel-neck Beaker culture, began to expand from the Dnepr River and in the Pontus area. Since the early 4th millennium, its influence has been strongly felt to the north on the Polish plateau as far as the mouth of the Vistula and, later, in the Baltic regions, Jutland, and the Danish islands. In the Middle Danube Valley, around 3800 BC, the Linear Pottery culture evolved into the so-called Note-Head Pottery culture, and between 3500 and 3000 BC the same area was occupied by the Dotted Pottery culture, which expanded as far as northeast France. Simultaneously, in the 4th and the 3rd millennium, agriculturalists settled in the western Mediterranean area and spread into France, Switzerland, and to the north Italian lakes (Chassey-Cortaillod cultures). Their settlements included the so-called Swiss Lake-dwellings, considered for a long time by specialists to have been built on wooden piles over open water. Recent researches have revealed, however, that they were situated on the shore and that their foundations simply served as a protection against ground dampness. At the same time, around 3100 BC, in the Atlantic and west Mediterranean littoral zones, appeared Megalithic cultures characterized by stone-chambered tombs (dolmens) and anthropomorphic stone blocks (menhirs), isolated or in ordered alignments. The orientation of these Megalithic monuments suggests a solar cult, the propagation of which was probably due to the activities of missionary migrants. Around 3000 BC another agrarian culture developed in the Dnepr Valley. Called the Tripolye culture, after the first site discovered near Kiev, it is characterized, like the Linear Pottery culture, by ordered villages of long rectangular houses but arranged in concentric circles. In the centre the cattle, the most valuable asset, were fenced in an enclosure.

Since linguists and ethnologists date the appearance of Indo-European languages in the Neolithic, the question arises as to which of the above described peoples might be identified as the first Indo-Europeans. One of the best known authorities on the problem, the Mexican P. Bosch-Gimpera, has identified the primitive Indo-Europeans as the bearers of the Linear Pottery, the Funnel-neck Beaker, and the Tripolye cultures and has argued that it is impossible to trace Indo-European ethnogenesis back to a single ethnical and geographical unit. The opinion of other scientists is strongly divided on the geographical location of the early Indo-Europeans.

The ethnogenesis of the other important European linguistic family, the Uralians (Finno-Ugrics and Samoyeds), gives rise to less debate: modern authorities agree that their native land is the central and northern part of the large east European plain, somewhere west of the Ural Mountains. A divergent opinion based on scientific evidence suggests an origin east of the Urals.

BIBLIOGRAPHY. ALAN G. OGILVIE, *Europe and Its Borderlands* (1957), is one of the best syntheses of Europe's human geography. The movements of linguistic majorities and minorities is clearly presented by ALBERT DAUZAT, *L'Europe linguistique* (1953); and GUY HERAUD, *Peuples et langues d'Europe* (1968). For a general survey of the ethnocultural structure of the whole continent, see SIGURD ERIXON, "West European Connections and Culture Relations," in *Folk Liv* (1938); M. KENNY (ed.), *Europe and Its Cultures*, a special issue of *Anthropological Quarterly* (1963); ANDRE VARAGNAC, *Civilisation traditionnelle et genres de vie* (1948); and GEZA DE ROHAN-CSERMAK, "La Notion de complexe ethnique européen," in *Ethnologia Europaea* (1967). The best summaries of ethnocultural features according to culture areas and provinces are published in German: GEORG BUSCHAN (ed.), *Illustrierte Völkerkunde*, 3rd ed., pt. 3 (1926); HUGO A. BERNATZIK (ed.), "Europa," in *Die grosse Völkerkunde*, vol. 1 (1939); and TORSTEN GEBHARD and JOSEF HANIKA (eds.), *IRO-Volkskunde: Europäische Länder* (1963). Europe's prehistory is described in several excellent handbooks, including GRAHAME CLARK, *Prehistoric Europe* (1952); VERE G. CHILDE, *The Prehistory of European Society* (1958); STUART PIGGOTT, *An-*

cient Europe (1965); and JAN FILIP (ed.), *Enzyklopädisches Handbuch zur Ur- und Frühgeschichte Europas*, 2 vol. (1966–69). For migratory movements, see VERE G. CHILDE, *Prehistoric Migrations in Europe* (1950); GEZA DE ROHAN-CSERMAK, "Le Principe du 'pont cultural' dans l'ethnologie européenne," in *Actas do Congr. Int. de Etnografia, Santo Tirso* (1963); and EUGENE M. KULISCHER, *Europe on the Move: War and Population Changes, 1917–47* (1948). Among the numerous works on physical anthropology CARLETON S. COON, *The Races of Europe* (1939); and JOHN GEIPEL, *The Europeans* (1969), may be profitably consulted.

(G.de R.-C.)

European Plain, Folk Cultures of the

The European plain is one of the most productive areas in the world and supports one of the greatest population densities. It covers a vast area. East to west it stretches from the Ural Mountains in the Soviet Union to the Atlantic shores of Ireland. In western Europe, it covers a territory that extends from the Pyrenees and the Alps in the south through Denmark and the southern part of Sweden in the north. The north–south spread of the plain is even greater in eastern Europe, where it extends from the Black Sea to the Arctic Ocean.

Landscape and climate of the European plain

Because it covers so much territory, the plain gives Europe the lowest average elevation of any continent. The flatness of this enormous lowland, however, is broken by hills, particularly in the west. Forests and woods also diversify the landscape, although present forests are no more than remnants of a thick mixed forest of oak, elm, ash, linden, and maple, which, since the Middle Ages, has given way to villages and fields in most places.

The climate on the whole is characterized by marked seasonal changes, with cold winters and warm summers. The west has a maritime climate very favourable to agriculture. It has enough rain in all seasons to keep fields green. Summers are warm, but not hot, and winters are cold, but not freezing. As one moves eastward into the zone of continental climate, rainfall is concentrated in the warmer months, and winters become extremely cold. Spring and fall nearly disappear as separate seasons, and the greenness of the summer gives place abruptly each year to the gray drabness of a frozen winter. Agriculture in eastern Europe tends to be more difficult and less productive than in the west.

A variety of languages is spoken on the plain. As in the rest of Europe, almost all belong to the Indo-European family. The one exception is Magyar (Hungarian), a Finno-Ugric language. Four major branches of Indo-European speech are represented. The Celtic branch is found in the form of Irish (Gaelic) still spoken in the western part of Ireland. The Germanic branch is represented by English on the British Isles and by Dutch, Flemish (in part of Belgium), German (including the dialect of Austria), Danish, and Swedish elsewhere. The major representative of the Romance branch is French, along with some inhabitants of the eastern plain who speak Romanian. In most of the east, however, people speak languages of the Slavic branch, of which Polish, Russian, Belorussian (White Russian), and Ukrainian are the most widespread, but also including Czech, Slovak, Slovene, Serbo-Croatian, and Bulgarian.

The European plain includes people as diverse in personality and culture as Irishmen, Russians, Hungarians and Swedes. In spite of important differences, many of these peoples traditionally shared underlying similarities that derived in part from a common pattern of village life and agricultural routine. This pattern was called the open-field system because several landholders owned unfenced plots in the same field.

Open-field communities covered large parts of England in a band running diagonally from the North Sea coast through the Midlands to the English Channel. Across the Channel, they covered major parts of France from the mouth of the Seine to the northernmost bend of the River Loire (particularly the Beauce, Champagne, and Picardy). In the north they were characteristic of Denmark and southern Sweden (Scandia), whereas in central Europe they covered most of Germany as well as the lowlands of Austria, Hungary, and Bulgaria. Eastward, open-field villages were typical of Poland and Great Russia.

TRADITIONAL CULTURE PATTERNS

Economic systems. *Settlement patterns and housing.* In the classic form of open-field husbandry, the land of a village was divided into three fields, and every landholder in a village owned parcels in each field. Use of the fields was rotated so that, in any given year, one was planted in winter wheat or rye, a second was planted in spring oats or barley, and the third field lay fallow to regain its fertility. Only the main fields were fenced in, and then only at times. The three-field system appears to have originated among the Franks when they were ruled by Charlemagne. Late in the 8th century, a number of imperial manors were reorganized on this principle. It seems probable that the Franks established still other such villages in conquered territory, particularly where they put new land under cultivation.

Patterns of village settlement

It took several centuries for the open-field village system to spread. In the 11th, 12th, and early 13th centuries, however, the population of Europe was growing rapidly. The greater part of western Europe, which until then still had a primeval-forest cover, came under the plow. When new villages were established, they were set up on the open-field plan. At the same time, many old villages appear to have been reorganized so that they, too, could be worked in what became the dominant pattern of the plain.

During the Middle Ages, then, a particular pattern of village settlement spread widely over the heart of Europe. It had certain widespread features. Often it focussed on a single street, though sometimes it centred on an open space or plaza. Along the street or around the open space, each landowner had his house.

Typically, the house was single-storied, with a gabled roof of straw, slate, or tile. Anciently, it probably was constructed of wood, but, as the forest thinned out, half-timbering became widespread, the frame of heavy beams filled in with wattle and daub, stone, adobe, or, the most expensive, ceramic brick. Where the forests were completely gone, masonry walls became the norm.

In the Middle Ages, indoor living centred on the hearth. This changed during the late Renaissance (16th century), when the living room was provided with glass windows and chimneyed fireplaces. Because smoke no longer lingered in the room as it sought its way out through cracks, crevices, or holes, interior ceilings could be constructed. The Renaissance room was easier to keep warm and had a new source of light in the daytime. Activities shifted from the hearth to a bench and table by the window. This pattern endured for centuries.

Part of the main building might function as a stall or barn, but often separate buildings were constructed, each serving a special purpose. Whether one building or several, however, they normally had the street or plaza to the front and a kitchen garden to the rear. The relatively small fenced-in garden was largely under the care of the housewife and provided vegetables for the family table.

Open-field villages

At the centre of the village, one generally would find a village pond from which people and livestock got their drinking water. Nearby, a place for village meetings might be indicated by a circle of stones or a large shady tree. Many villages, however, had their meetings on the steps of the church, which normally was located in this part of the village. The village commons, where livestock could be grazed, was usually located near the village if not in its centre. The same was true of small cottages to house landless labourers, the village poor.

As one looked across the plain, the buildings and church of a village stood out like an island in a sea of fields, each community with its fields separated from others by woods and untilled waste. The fields tended to form a crazy quilt, each patch cut into strips that were long and narrow (see Figure). In part, at least, the shape of fields was determined by the equipment used for plowing. Fields were cultivated with a wheeled plow. Wheels made it possible to construct a heavy implement

that supported a knifelike coulter to cut a trench and a deep-cutting moldboard to lift and turn the soil. One reason that medieval farmers were able to spread over the plain and to root out so much of the forest was that they possessed this plow capable of turning the heavy, moist soil. To pull such a plow required from two to six or even eight horses, with at least two people to assist, one to guide the plow and the other to manage the animals. The resultant rig was long and cumbersome and required long fields with plenty of turning room at each end in order to operate efficiently.

Patterns of production and technology. As noted earlier, only the main fields occasionally were fenced in. This saved expense and trouble, but it also had important implications for the farmer who practiced mixed farming, a technique that joined crop cultivation with animal husbandry. Under the mixed farming regime, livestock raised for meat and milk were fed in part by grazing on the commons or on hay harvested from natural meadows. But in part they fed on the stubble of harvested crops. In return, animals provided rich fertilizers for the soil, thus increasing the production of cereals for human consumption.

Open-field farming

The two types of production were mutually supporting. But cattle could not be turned loose to feed on the stubble of one man's strips if the crop on neighbouring strips had not yet been harvested. So long as individually owned holdings were not separately fenced, all harvests had to be brought in before any livestock could graze. This meant that all of the major decisions about cultivation and cattle raising had to be subject to communal sanctions. They had to be synchronized. All had to agree to plow and sow at the same time as well as to cultivate the same crop. Only in that way were they all able to bring in their harvests at about the same time.

The open-field system of land management, then, was associated with a relatively high development of communalism. Communal habits were further encouraged by use of the wheeled plow. Such a plow was expensive, and many farmers did not own one. It also required more horses than one man was likely to own. Villagers found it convenient to share horses and plows and to cooperate in their use.

Property and exchange systems. Men in open-field villages fostered habits of cooperation and sharing in their work. Their communalism was balanced, on the other hand, by a keen sense of individual responsibility and individual property ownership. Most villagers were not completely free, however, and much of the wealth that they produced was not theirs to use, whether individually or communally. A wealthy elite of landlords was legally entitled to part of what was produced. Throughout the plain, particularly in earlier centuries in the west and in the last century in the east, this relationship was shaped by the custom of serfdom.

The landlord and serfdom

The open-field village did not stand alone on the plain. Whether in the village or off by itself, a manor house usually provided separate, more elaborate accommodations for the local landlord. The landlord might also own strips in the fields. Often his fields were consolidated off to one side. Either way, he was entitled to have them worked by villagers, for, in addition to rents and dues of various sorts, the landlord was entitled to free labour by serfs who supplied their own tools. At times, the landlord's entitlement was unlimited. He could demand as much free labour as he needed. But even when limited, it was a difficult burden for peasants, for it required their services at precisely the time that their own fields needed to be worked.

Full serfdom largely disappeared during the late Middle Ages in western Europe. It still existed in the 18th century, but by that time most serfs were neither bound to the land nor subject to unlimited demands for labour. In Russia, serfdom was later to appear and was not officially abolished until 1861.

Villagers, then, lived under a complex system of property and exchange. Under private ownership, they possessed their houses, furnishings, clothing, tools, livestock, gardens, and strips in the three village fields. Under communal sanctions, they coordinated their labour, cooperated in plowing, shared rights to the church and cemetery, shared the village commons, and shared the village forest and waste, where they could gather firewood and graze pigs. Finally, under the law of serfdom, they might be obliged to contribute labour and the use of their tools without remuneration, in addition to making payments of land rents and other dues. Under forms of land tenure other than that of serfdom, they also customarily paid rents, dues, and taxes.

Social structure. *Local and territorial organization.* Some forms of tribal and clan organization existed far back in time, at least in some parts of the plain. But such groupings did not survive the Middle Ages. It seems likely that under the conditions of serfdom, when landlords manipulated peasant families at will, larger forms of social solidarity were destroyed.

Family and kinship patterns. The typical family of the plain was usually the small domestic (nuclear) family. There were exceptions. In parts of Germany, for example, the inheriting son was expected to continue to live with his parents, even after he married and had children. The result was a three-generational family known as a stem family. In Russia and other parts of eastern Europe, several sons might remain in the family after marriage to form a larger, so-called joint family.

Beyond the household of nuclear, stem, or joint family, wider kinship ties were important. Since relationships were traced bilaterally (through both the male and the female lines), every individual had a large number of relatives (the kindred). These ties could be especially strong when they were close in both genealogical and territorial terms. Yet, their importance was limited. Kindred solidarity found expression primarily in the ritual of funerals, weddings, and baptisms, when more distant relatives were invited to the festivities. The individual, however, could not normally expect significant economic help from distant relatives, and even married siblings severely limited the assistance they usually would give to one another. In the economic context, households had to be self-reliant.

Self-reliance of households

Ties of ritual kinship (godparenthood) were universally established at baptisms. Individuals considered it an honour to be asked to become godparents, and acceptance brought with it certain minor obligations, such as to provide gifts for the child. In general, however, people of the plain did not use the institution of godparenthood as a way to establish patron–client relationships or to build a network of ties with individuals from whom economic benefits might be expected.

Stratification. Social stratification existed on two levels in traditional Europe. On the one hand, villagers comprised a class of peasants who had a very different life-style from that of burghers (craftsmen and artisans) or the upper class. Not only did these people have different cultures, they also were ranked, with peasants regarded as belonging at the bottom of the scale.

Within each class, further ranking existed. Among peasants, landless labourers (cottagers) had a much lower standard of living than did landowners. This constituted a fundamental dichotomy in the social structure of the village. Within each of these two basic strata, further ranking was customary. But always, the major division was that which separated the landed from the landless.

Socialization and education. Socialization practices varied greatly from one place to another. Everywhere, children were welcomed, perhaps because everywhere children, and especially sons, added to the work force of the family when they got older. Children also provided support for their aging parents.

Child care was highly variable. The swaddling of infants was widespread but varied as to whether the arms were bound or not and whether the bindings were tight or relatively loose. Because infant mortality was high, child rearing was surrounded with mystical beliefs and practices, particularly during and just after birth. The mother, for example, was often not allowed to leave the dwelling until 40 days had passed, after which she formally was readmitted to the village congregation in a

ceremony presided over by the priest, the so-called rite of churching. The baby itself was baptized shortly after birth, and this normally provided the occasion for a family celebration.

The life of the young

Peasants in most of the plain were uneducated and illiterate. There were exceptions. In some villages, church schools had existed for centuries, so that at least some village children learned to read, write, and do sums. In Denmark, schools could be found in most villages as early as the 18th century. Even where schools were not normally attended, a child generally was taught the catechism prior to his confirmation (Protestant) or first Communion (Catholic). The main education of every peasant child, however, was in the apprenticeship that he did on the farm.

Children learned by doing. As young as seven or eight years of age, they were given chores commensurate with their abilities; they might spend their days tending geese, sheep, or cows, for example. It was customary, though, to send young teen-agers to work as servants or hired hands on other farms, in town, or on manorial estates. In this way, they learned something of how other people lived, though on the whole they remained markedly parochial in mentality.

Religious beliefs and aesthetic systems. The peoples of the plain were Christians. They varied greatly as Orthodox Catholics, Roman Catholics, and Protestants, yet they remained similar in sharing some knowledge of biblical stories and homilies. Everywhere they shared some features of the Christian calendar, including Sundays as a day of rest, and Christmas and Easter, especially, as major annual holidays. Being Christian also meant that village solidarity was increased by the habit of meeting in church as a congregation. Village business often was conducted on the steps of the church or inside. The priest or minister tended to be a man of leadership and high status in the community.

Pre-Christian beliefs survived throughout the centuries. Even though it was contrary to Christian belief, villagers continued to rely on magical potions, omens, and rites to cure disease, help crops, or dispel bad fortune. Christian and pagan beliefs tended to blend, as in the custom of using holy water or the sacred Host as part of a magical substance concocted to improve fertility or cure illness.

Some folk art originated locally, but much of it was built on aristocratic or urban styles. Yet, folk art remained distinctive, because modifications were made during the slow process of borrowing. Peasant styles in the Middle Ages, for example, tended to reflect concepts of Gothic art as these were reproduced by village craftsmen. In the late 16th and early 17th centuries, when peasants were unusually prosperous and open to innovation, elements of Renaissance art largely replaced Gothic elements that still survived in the countryside. Subsequently, one can trace influences of later art styles in painting and woodwork design. Yet, 18th- and 19th-century folk art retained its basic Renaissance inspiration.

General character. On the whole, the folk culture of the plain was that of peasants resident in open-field villages. People varied greatly from one place to another, yet everywhere they shared certain fundamental assumptions as Christians. These included Christian teachings that supported the low status of peasants on the ground that a man's place in life was ordained by God. This apparently made it easier for the lowly to accept their lot, particularly since they were assured rewards in heaven if they were faithful to their calling, just as the landlord would be punished if he were evil.

> O let us love our occupations,
> Bless the squire and his relations,
> Live upon our daily rations,
> And always know our proper stations.

Attitudes and outlook

Peoples of the plain were superstitious. Although they lived in a relatively productive area, there were times of bad harvests, epidemic diseases, and warfare when the peasants were helpless and without defense. Perhaps for this reason they supplemented reliance on hard work and an agrarian technology with belief in miracles and magical interventions.

Open-field villagers lived by an ethic of communalism. They were accustomed to subordinate their wishes to decisions of village ("town") meetings. Yet, a communal orientation was balanced by a keen sense of individual integrity. Each family had the ultimate responsibility for its own affairs, and, though families contributed to cooperative ventures, they did not do so at the cost of compromising their fundamental status as independent social units.

Finally, countrymen of the plain were down-to-earth villagers in orientation. They lived out their lives within the narrow confines of a village and its locality. Often, their personal experience extended only as far as the nearest small market town. They were parochial in the sense that the world they knew was essentially the world of their own parish. And within that world, they were absorbed by the demands of agriculture. Cultivation was not an occupation for them but a way of life. The activities and interests that filled their days, as well as the values that gave meaning to their lives, were shaped by a massive preoccupation with livestock and fields. The folk culture of the plain was shaped by this preoccupation with the soil and the particular form it took under an open-field system and a peasant form of Christianity.

EVOLUTION OF THE CULTURES TODAY

Heritage of integrating and disintegrating factors. The folk culture of the plain was never static. In clothing, art styles, dialect, and other aspects of custom, minor changes were normal. Yet, at times, changes of greater magnitude took place, and this especially was so during the 18th and 19th centuries. It is so now.

Enclosure. During the 18th and 19th centuries, folk life was thoroughly changed by the consolidation of farm plots and the division of communal land. The intent of consolidation was to remove the difficulties of land fragmentation. Each peasant owned strips in various parts of each of the three main fields. He might possess anywhere from 20 to 100 or more small plots. To work them entailed much wasted energy, since a man had to spend time going from one plot to another. The need for access paths also wasted space that could otherwise have been put to the plow.

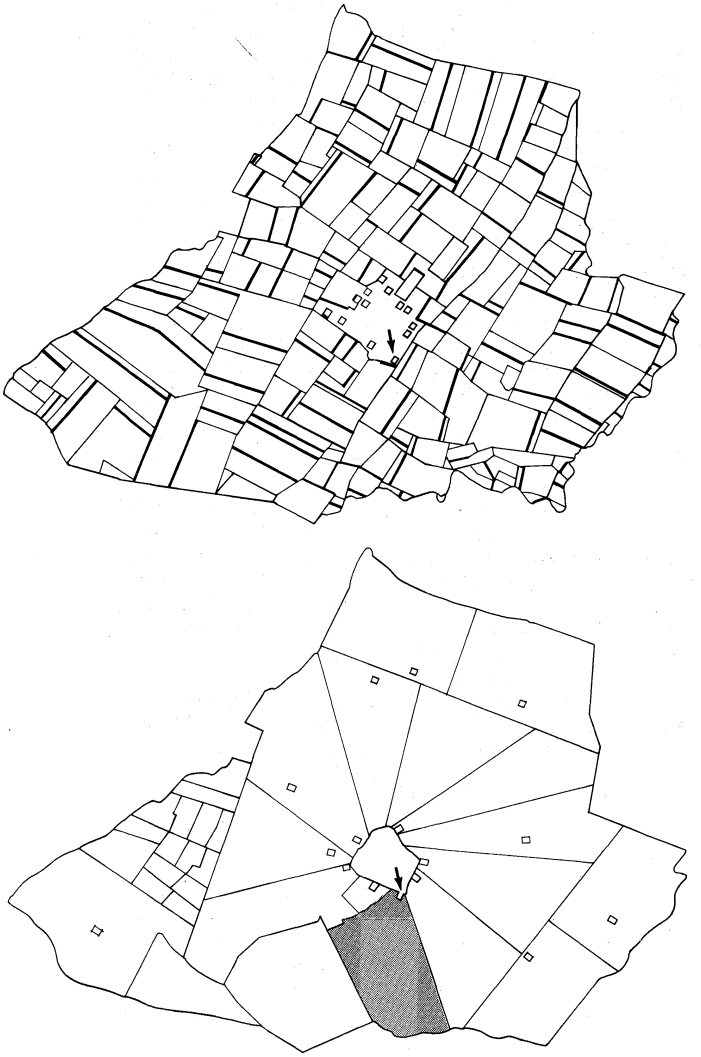
Villagers resisted consolidation. They were aware of the advantages it offered, but they feared the possible disadvantages. The scattering of farm plots usually meant that a peasant had some good land as well as some poor land. Scattering also provided some insurance against catastrophic damage by the weather. A hailstorm, for example, might destroy the crop on some plots but spare others, so the entire harvest was not lost. Consolidation, it was argued, would remove this insurance against the weather. It also might leave a man with fields of poorer quality than he already had. Or, he might be assigned a larger field or two at the margin of village territory, far removed from his house and the community.

In places, it took a century or more to overcome this aversion to consolidate. Legislation made it possible for a minority, perhaps no more than the local landlord and his allies, to force the change. At the same time, communal land was divided up for private ownership among landholders, including the local gentry. This move proved disastrous for smallholders and landless labourers who depended for a major part of their subsistence on the right to graze livestock, for they did not share in the division. Many became paupers. Others found work in new factories.

The move to consolidate fields and divide the commons is termed enclosure, because its visible effect was to put fences around fields as each man enclosed his own property. On the whole, the result was beneficial for landowners. With the opportunity to work their fields individually, they became more open to innovation. The movement prepared the way for the adoption of new kinds of seed, new methods of land use, and new farm machinery. Each family could manage its land more efficiently, but social life and ethos changed.

Results of enclosure

With enclosure, communalism declined dramatically. Each family tended to operate independently of others.



(Top) A village before enclosure and consolidation. Dark lines are scattered strips of farm at arrow. (Bottom) The same village after enclosure. The farm at arrow now has its fields consolidated rather than fragmented.
From H. Thorpe, "The influence of inclosure on the form and pattern of rural settlement in Denmark," *Transaction and Papers*, pub. no. 17 (1951)

The ethic of communalism disappeared, and when 19th-century reformers attempted to persuade farmers to participate in the cooperative movement, they found the farmers reluctant to commit themselves to new group arrangements. Cooperatives now are widespread in western Europe, but they were slow to come.

Communal solidarity was undermined not only by the end of open-field communalism but also by the appearance of a new settlement pattern. Farmers with holdings at the margins of village territory moved their homes to their fields. On the plain today, the territory between villages now commonly is scattered with individual homesteads, each isolated on its own land.

The question of enclosure was clearly decided in England by the end of the 18th century. On the Continent enclosure got under way later and was finished during the 19th century. The movement lagged even further in eastern Europe. Villages in Russia operated under a form of open-field communalism known as the *mir* until the October Revolution of 1917. During the 1920s, the period of the so-called New Economic Policy (NEP), most Russian farming was under a regime of small family farms. Then, beginning in 1928, Joseph Stalin enforced a massive program of collectivization, and within a few years all farming was under one of two forms of socialist farm, the collective (*Kolkhoz*) or the state industrial farm (*sovkhoz*).

Other parts of the east European plain developed much as did western Europe during the period between the two world wars. After 1945, when these nations became satellites of the Soviet Union, they were pressed to convert to socialist forms of farming. By 1962, this was accomplished throughout the plain, with but one exception. In Poland, where today only 13 percent of arable land is in the socialist sector, most of the land is under a regime of small family farms.

Indirect industrialization. By the latter half of the 19th century, a new form of massive change began to take place as an indirect result of industrialization. New products replaced the products of folk arts and crafts. Countrymen of the plain began, for example, to acquire factory-loomed cloth and ready-made clothing to replace homespun, hand-sewn garments. By the end of the century, peasant styles of clothing had been replaced by new urban modes.

Effects of modernization

Cast-iron cookstoves and factory-produced petroleum lamps were widely adopted in these decades. New sources of light and heat were associated with more individual freedom within the family, as evening activities no longer tended to locate the whole family around the fireplace and the table with its oil lamp. Other rooms could be heated and lighted. People stayed up later in the evening, as the old custom of going to bed with the sun came to an end. Since these developments were associated with massive efforts to bring modern schooling to villages, daily activities came to include evening hours in which children did their lessons and parents might read a book or paper as well as knit or do minor repairs on equipment.

An openness to change in the latter 19th and early 20th centuries found expression in part in the modernization of farm technology. In most areas, the old wheeled plow had been replaced by improved implements. Now these too were replaced by still better steel plows and by early forms of machinery for harvesting and threshing grain. In the last 50 years, tractors have replaced horses as the main source of energy. New crops and changed methods have left almost nothing of the old folk economy behind. Subsistence agriculture has been replaced by commercial production, and, with that, commercial attitudes have become widespread.

Current cultural conditions. Although the eastern part of the plain remains old-fashioned in many ways, the western part since the early 1950s has moved importantly toward still one more new style of life. Recent decades have seen urban centres grow into the surrounding countryside. Modern transportation has made it easy for farmers to get regularly to town. In many places, members of farming families, released now from working on the land by the effectiveness of modern machinery, find jobs in town, but without moving from the farm. They commute. Conversely, urbanites find that they can live in villages and work in town. Where this has occurred, the centuries-old distinction between urban and rural cultures (or subcultures) has been obliterated. Even where developments have not gone that far, to the extent that the farmer is no longer parochial, the old distinction is broken down. Folk culture on the plain disappeared in the latter 19th century as an indirect result of industrialization. In recent decades, even the subculture of farmers has tended to disappear as farmers and townsmen have merged.

BIBLIOGRAPHY. LYNN T. WHITE, JR., *Medieval Technology and Social Change* (1962); and ROBERT T. ANDERSON, *Traditional Europe* (1971), provide general information on historical periods, though neither deals exclusively with the plain. The best general work that includes some material on the modern plain is S.H. FRANKLIN, *The European Peasantry: The Final Phase* (1969). England is the most written about in English. GEORGE CASPAR HOMANS, *English Villagers of the Thirteenth Century* (1941 and 1960); and GEORGE G. COULTON, *The Medieval Village* (1925), offer classic accounts of life in open-field villages; modern villages are described in VICTOR BONHAM-CARTER, *The English Village* (1952); and RONALD FRANKENBERG, *Communities in Britain: Social Life in Town and Country* (1966). For the continent, ROBERT T. and BARBARA GALLATIN ANDERSON, *Bus Stop for Paris: The Transformation of a French Village* (1965), describes an open-field community and the changes that took place with urbaniza-

tion. The best work in English on Germany is a chapter in Franklin's book cited above, while for Denmark the most useful remains PETER MICHELSEN and HOLGER RASMUSSEN, *Danish Peasant Culture* (1955). As concerns eastern Europe, the transformation of Russian open-field villages into collective farms is documented in STEPHEN P. and ETHEL DUNN, *The Peasants of Central Russia* (1967); and SULA BENET (ed. and trans.), *The Village of Viriatino: An Ethnographic Study of a Russian Village from Before the Revolution to the Present* (1970; orig. pub. in Russian, 1958), but since both books depend upon official Soviet sources they are somewhat romanticized. EDIT FEL and TAMAS HOFER, *Proper Peasants: Traditional Life in a Hungarian Village* (1969), is thoroughly objective, and includes a brief section on collectivization. Also thoroughly objective and well documented is WILLIAM I. THOMAS and FLORIAN ZNANIECKI, *The Polish Peasant in Europe and America,* 2nd ed., 2 vol. (1972).

(R.T.A.)

Eusebius of Caesarea

The most important 4th-century historian of the Christian Church, Eusebius of Caesarea, lived in that momentous period in Christian history during which toleration was attained for Christianity through the conversion of the Roman emperor Constantine I (died 337) and the doctrine of the incarnation (God made flesh in the Person of Christ) was authoritatively defined at the Council of Nicaea (325). He not only recounted these events but he preserved for posterity a knowledge of some of the personages, events, and movements of Christianity from its beginning until the 4th century. While bishop of Caesarea Palestinae he was involved in the Arian controversy, a dispute over the relationship of Christ as Son to God the Father, and therefore took a relatively active part in the Council of Nicaea.

Early career

He was baptized and ordained at Caesarea, which had become a centre of Christian scholarship through the long residence (*c.* 232–254) there of Origen, the former head of the Catechetical school of Alexandria. Alexandrian learning, doctrinal views, and theological methods that stemmed from Origen were mediated to Eusebius through the teachings of the learned presbyter Pamphilus, to whom he was bound by ties of respect and affection and from whom he derived the name "Eusebius Pamphili" (the son or servant of Pamphilus). Eusebius was an enthusiastic disciple and collaborator.

In 303 the greatest persecution of the church was undertaken by Diocletian (reigned 284–305) and his fellow emperors. In such a widespread persecution it was natural that the Christians of a provincial capital such as Caesarea should suffer, and Eusebius later commemorated them in his *Martyrs of Palestine.* The most poignant event was the long imprisonment of Pamphilus, ending in his martyrdom in 310. Eusebius may himself have been imprisoned at Caesarea or, later, in Egypt. Long afterward he was accused of having secured release by some act of recantation, but such accusations were widespread, and it is unlikely that a willing traitor would have become bishop of Caesarea so soon after persecution ended.

The work of the scholars of the Christian school at Caesarea extended into all fields of Christian writing. They corrected manuscripts of Scripture, an activity that extended even into the period of Pamphilus' imprisonment. They were alive to current theological trends in writing a *Defense of Origen,* who was now subject to attack from various quarters. Eusebius himself wrote a lengthy refutation of the Neoplatonist philosopher Porphyry's attack on Christianity (written after 271), and also against Hierocles, governor of Bithynia, a prominent official and persecutor, who had made a comparison of the Neo-Pythagorean philosopher and reputed wonder-worker Apollonius of Tyana (1st century AD) with Christ. Throughout his life he also produced commentaries on the Bible and works explaining the parallels and discrepancies in the Gospels. His method of exegesis (interpretive criticism) was partly literal and partly allegorical, with a tendency to seek where possible messianic interpretations.

But for subsequent centuries his fame was to rest on his *Ecclesiastical History* (probably begun during the persecution and revised several times between 312 and 324). Here he was conscious of being a pioneer, as indeed he was, for the writing of church history would have been exceedingly difficult before the settled conditions of the late 3rd century and the availability in one place of an adequate library. Eusebius is therefore a chief primary source. He produced what may be called, at best, a fully documented history, and, at worst, collections of passages from his sources. He had already compiled his *Chronicle* (later revised and then expanded by Jerome), an epitome of universal history, and he carried this annalistic method over into his *Ecclesiastical History*, constantly interrupting his narrative to insert the accession of Roman emperors and of the bishops of the four great sees (Alexandria, Antioch, Jerusalem, and Rome). He enlarged his work in successive editions to cover events down to 324, the year before the Council of Nicaea. Eusebius, however, was not a great historian. His treatment of heresy, for example, is inadequate, and he knew next to nothing about the Western Church. His historical works are really apologetic, showing by facts how the church had vindicated itself against heretics and heathens. Of more direct apologetic import were his vast *Praeparatio* ("Preparation") and *Demonstratio evangelica* ("Demonstration of the Gospel"). In the former he refuted pagan mythology, oracles, and astrology, expounded the Jewish scriptures, and argued that whatever was best in Greek thought coincided with or was derived from Jewish thought. In the course of this work he quoted Plato over 250 times and made some use of Neoplatonic writings. The *Demonstratio* dealt with the fulfillment of Hebrew prophecy in Christ.

Election as bishop

The duties of bishop of the metropolitan see of Palestine, assumed by Eusebius in *c.* 313, must have been onerous, and there is little wonder that his literary output slackened. Moreover, the period after the persecution of Diocletian and his successors—which ended in 313—was one of reconstruction, during which multitudes sought admission to the church. He was in Tyre about 316, preaching at the dedication of a new church. Paulinus of Tyre was one of his closest friends; another was Theodotus, bishop of Laodicea in Syria, to whom he dedicated his *Praeparatio* and *Demonstratio.*

When (about 318) the theological views of Arius, a priest of Alexandria, became the subject of controversy because he taught the subordination of the Son to the Father, Eusebius was soon involved; he had already discussed the subjects at issue, for example, in the *Demonstratio.* Expelled from Alexandria for heresy, Arius sought and found sympathy at Caesarea, and, in fact, proclaimed Eusebius as a leading supporter. Eusebius did not wholeheartedly support either Arius or Alexander, bishop of Alexandria from 313 to 328, whose views appeared to tend toward Sabellianism (a heresy that taught that God was manifested in progressive modes). He wrote to Alexander, claiming that Arius had been misrepresented, and he also urged Arius to return to communion with his bishop. But events were moving fast, and at a strongly anti-Arian synod at Antioch, about January 325, Eusebius and two of his allies, Theodotus of Laodicea and Narcissus of Neronias in Cilicia, were provisionally excommunicated for Arian views. When the Council of Nicaea, called by Constantine, met later in the year, Eusebius had to explain himself, and did so on the basis of the baptismal creed of the Church of Caesarea. He was exonerated with the explicit approval of the Emperor. Perhaps Eusebius never forgot that, and though he at first denounced the term *homoousios* ("of one substance") as the key word in the Creed of Nicaea in expressing the relation of the Father to the Son, once more the Emperor's influence, and his own desire for peace, caused him to accept it.

Eusebius and Constantine seem to have met only twice, at Nicaea in 325 and ten years later at Constantine's *tricennalia* (30th anniversary of accession). The years that followed the Council of Nicaea showed how much the Emperor was bent on unity, and the true supporters of

Relations with imperial and ecclesiastical authorities

Nicaea soon found themselves forced into the position of dissidents. Eusebius took part in the expulsion of Eustathius of Antioch (*c.* 337), Athanasius of Alexandria (335), and Marcellus of Ancyra (*c.* 336). But he refused to accept the position of bishop of Antioch, a refusal for which Constantine praised him. He was present, and may have presided, at the Synod of Tyre in 335, where Athanasius was condemned (though not on doctrinal grounds). Summoned, with others, to Constantinople when Athanasius appealed to the Emperor, he did not fail to continue in the Emperor's favour and delivered an oration on his sovereign's *tricennalia*—in which he developed a Christian theory of the empire, to meet the changed conditions of the new age. His ideas on the relation of God, the empire, and the church were based on the view that the emperor ruled by God's grace and was analogous to earlier deified rulers. This view was to collapse when the empire and a large part of the church came into collision under the Emperor's son, Constantius II (337–361). After Constantine's death (337) Eusebius wrote his *Life of Constantine*, a panegyric which possesses some historical value, chiefly because of its use of primary sources. Eusebius was not simply a servile flatterer; he once rebuked Constantia, the Emperor's half sister, for her desire to possess a picture reputed to be of Christ, but she had little political influence.

About 336 Marcellus of Ancyra, a leading supporter of Nicaea, was exiled for supposed Sabellianism. Eusebius and Marcellus had long been hostile toward each other, and Eusebius attacked Marcellus and defended various friends in his "Against Marcellus" and "On the Theology of the Church." These works show that he was still not a defender of the doctrine of Nicaea, but he had moved nearer to that position. Eusebius died about 340.

Acacius, his pupil and successor at Caesarea, wrote a life of Eusebius, which is not extant. But if Acacius and another pupil, Eusebius of Emesa, can be taken to represent their master's theology, it is of a semi-Arian type. Later generations were puzzled by his services to Christian scholarship coupled with his Arian leanings. His only wholehearted supporter was the church historian Socrates (*c.* 380–*c.* 445). Eventually, the seventh ecumenical council (787), at Nicaea, condemned him, finding him double-minded and unstable in all his ways.

Evans, Oliver

Oliver Evans was one of the most versatile geniuses of the Industrial Revolution, yet one of the least known in modern times. He pioneered the high-pressure steam engine, an improvement on the inventions of Newcomen and Watt that made steam power widely applicable in industry and transportation; and he created the first continuous production line, an innovation 50 years or more ahead of its time.

Born in Newport, Delaware, September 13, 1755, 21 years before the American Declaration of Independence, Evans was apprenticed to a wheelwright at 16. Observing the trick of a blacksmith's boy who used the propellant force of steam in a gun, he began to investigate ways to harness steam for propulsion. Before he could successfully pursue this line of research, however, he became involved with a number of other industrial problems. Carding, or combing, fibres to prepare them for spinning was a laborious process constituting a bottleneck in the newly mechanized production of textiles. To speed this operation Evans invented a machine that cut and mounted 1,000 wire teeth per minute on leather, the teeth serving as an improved carding device.

Evans, portrait by W.G. Jackman, 19th century. In the Metropolitan Museum of Art, New York.

Work on automated production

In 1784, at the age of 29, he attacked another major industrial production problem, the age-old process of grinding grain. Building a factory outside Philadelphia, and adapting five machines, including conveyors, elevators, and weighing scales, he created a production line in which all movement throughout the mill was automatic. Labour was required only to set the mill in motion; power was supplied by waterwheels, and grain was fed in at one end, passed by a system of conveyors and chutes through the stages of milling and refining, emerging at the other end as finished flour. The system, which reduced costs by 50 percent according to Evans' calculations, was widely copied in United States flour milling.

When Evans applied for patent protection, first to state governments (1787) and later to the new United States Patent Office (1790), he added a third invention, his high-pressure steam engine. He continued to work on this for the next several years, envisioning both a stationary engine for industrial purposes and an engine for land and water transport. In 1801 he built in Philadelphia a stationary engine that turned a rotary crusher to produce pulverized limestone for agricultural purposes. The engine that became associated with his name was an original adaptation of the existing steam engine; Evans placed both the cylinder and the crankshaft at the same end of the beam instead of at opposite ends, as had been done previously. This greatly reduced the weight of the beam. An ingenious linkage, which became world famous as the Evans straight-line linkage, made the new arrangement feasible. He saw at once the potential of such an engine for road transportation but was unable to persuade the authorities to permit its use on the Pennsylvania Turnpike—not unnaturally, since it might well have frightened the horses, which at that time provided the main form of transport. Within a few years he had engines doing several other kinds of work, including sowing grain, driving sawmills and boring machines, and powering a dredge to clear the Philadelphia water frontage. Completed by June 1805, his new type of steam-engine scow, called the Orukter Amphibolos, or Amphibious Digger, was 30 feet (nine metres) long by 12 feet (four and seven-tenths metres) wide. In its machinery it embodied the chain of buckets principle of his automatic

flour mill. Equipped with wheels, it ran on land as well as on water, making it the first powered road vehicle to operate in the United States.

Building of steam engines

In 1806 Evans began to develop his noted Mars Works, where, over the next ten years, he made more than 100 steam engines that were used with screw presses for processing cotton, tobacco, and paper. The Navy Yard in Washington bought one of Evans' engines, and when the War of 1812 broke out Evans and a partner proposed to build a powerful steam warship with a large gun at the bow, thus anticipating John Ericsson's "Monitor" of 50 years later; but the proposal was not accepted.

Evans' last great work, completed in 1817, was a 24-horsepower high-pressure engine for a waterworks. He died on April 15, 1819, shortly after a disastrous fire that destroyed his Mars Works, including his valuable patterns and molds.

His *Young Mill-Wright and Miller's Guide*, which he had written back in 1792, continued to sell and had gone through 15 editions by 1860. In another work, *The Abortion of the Young Steam Engineer's Guide* (1805), he forecast the need for government subsidization of technological advances.

Vested interests in horses, poor roads, steep gradients, inadequate springing, and an inadequate technology of materials hindered the adoption of his ideas for steam engines on roads; and also because of the slowness of later manufacturers to make use of his innovative manufacturing techniques, Evans was long a somewhat neglected figure. More recently, however, in the allocation of priorities for the development of the high-pressure steam engine, the simultaneity of Evans' work with that of the British genius Richard Trevithick has been established, and historians have accorded proper credit for his pioneering of the assembly line.

BIBLIOGRAPHY. GREVILLE and DOROTHY BATHE, *Oliver Evans: A Chronicle of Early American Engineering* (1935), a massively authoritative study that is not likely to be superseded, since it is based on meticulous historical research, with copious references; SIEGFRIED GIEDION, *Mechanization Takes Command: A Contribution to Anonymous History* (1948), a stimulating impressionistic account of the development of mechanization from Evans' day to the end of World War II, providing a framework in which Evans' ideas can be assessed; as does H.W. DICKINSON, "The Steam Engine to 1830," in CHARLES SINGER *et al.* (eds.), *A History of Technology*, vol. 4, pp. 168–198 (1958), the most recent synoptic view of the steam engine, which places Evans in context with his English and European contemporaries; G. DOORMAN, "Dredging," in the same volume, pp. 628–643, synthesizes the expert studies on this subject with a most helpful bibliography.

Evaporites

Evaporites are mineral deposits that form by the precipitation of salts in restricted water bodies such as inland seas, semi-isolated coastal waters, lagoons, and terrestrial playa lakes. When such water bodies are subject to evaporation losses that equal or exceed the water supplied by rainfall, runoff, groundwater flow, or the open sea, the salts in solution become concentrated and, by definition, the salinity increases. Ultimately a saline brine will form and salts will begin to precipitate from the brine. Because evaporation is the principal cause of the salt concentration and precipitation, the individual minerals and the deposits as a whole—whether marine or nonmarine in origin—are termed evaporites, after the process.

Sequence of precipitation from seawater

The precipitation of salts from a brine is governed chiefly by the solubilities of individual salts and by the brine temperature and composition. The first investigation of the order of salt precipitation from seawater was undertaken by the French chemist J. Usiglio, who evaporated a water sample from the Mediterranean Sea in 1849 and periodically analyzed the mineral precipitates and residual brine. When the sample was reduced to about 50 percent of its original volume, calcium carbonate ($CaCO_3$) began to precipitate. When reduced to about 15 to 20 percent of the original volume, calcium sulfate ($CaSO_4$) began to precipitate. Only after reduction to 10 percent of the original volume did sodium chloride (NaCl) precipitate; further evaporation led to the separation of magnesium sulfate ($MgSO_4$) and magnesium chloride ($MgCl_2$), followed by sodium bromide (NaBr) and potassium chloride (KCl).

Usiglio's results are roughly in accord with the sequence of minerals observed in some evaporite deposits. An occurrence of calcite ($CaCO_3$), gypsum ($CaSO_4 \cdot 2H_2O$) or anhydrite ($CaSO_4$), halite (NaCl), and a small quantity of magnesium, sodium, or potassium salts is not unrepresentative. But the deposition of evaporites in nature is not nearly so simple a process as the continuous evaporation of a seawater sample in the laboratory. Changes of temperature, salinity, and brine composition in nature may occur for a wide variety of reasons; such changes may lead to the re-solution (or alteration) of previously deposited minerals or to the formation of new and different ones. Hence, evaporite deposits may consist of repetitive sequences of only two or three common minerals such as calcite, anhydrite, and halite, or of an enormously complex array of 30 or more individual mineral types.

More than 80 minerals have been identified in evaporites of marine origin. These are principally carbonates, sulfates, and chlorides, with some borates, silicates, and other mineral groups. Evaporites formed in nonmarine environments may contain many of the same mineral species, but, as a generalization, they exhibit still greater diversity. This is because the composition of seawater is everywhere more nearly constant than the waters that feed playa lakes, which reflect the vagaries of neighbouring source areas. Borates, nitrates, and sulfocarbonates occur more often in nonmarine evaporites.

Evaporites occur in strata of every geological system, beginning with the Cambrian Period, 570,000,000 years ago. They are widespread, occurring on every continent, but a gradual restriction toward the Equator is evident from consideration of their distribution through time. This fact, combined with the need for high evaporation rates, has led many authorities to believe that evaporites are good paleoclimatic indicators—*i.e.*, that their occurrence signifies the existence of a generally arid climate at the time of their formation.

Sites of modern deposition

Areas of modern evaporite formation tend to sustain this view; noteworthy occurrences include: Great Salt Lake, the Death Valley salt pan, and many other playa lakes in the western United States, Chile, Australia, and other arid areas; Kara-Bogaz-Gol Gulf in the eastern part of the Caspian Sea; coastal lagoons along the margins of the Persian Gulf; the Rann of Kutch in India; Lake Larnaca, Cyprus; Lake Assal, Afars and Issas, formerly French Somaliland; the Dead Sea, between Israel and Jordan; and parts of the Red Sea. In each of these cases, the climate is generally arid, evaporation rates are high, and water salinities are about seven to ten times that of normal seawater, except in the rainy season.

In addition to their possible paleoclimatic significance, evaporites are of much interest for paleogeographic reasons; this stems from the occurrence of thick deposits in nature. It has long been known, for example, that evaporation of a column of seawater 100 metres (330 feet) in height would lead to deposition of a salt bed only 150 centimetres (60 inches) thick. Moreover, only four centimetres (1.5 inches) of this salt would be gypsum (or anhydrite), a mineral that is present in beds whose aggregate thickness is as great as 500 metres (1,600 feet) or more in some sequences. The quantities and depths of water required to produce 500 metres of anhydrite are so vast that it has long been obvious that some resupply mechanism must be involved.

A "bar theory" of evaporate deposition was set forth in 1864 to explain these thick evaporite deposits. Briefly stated, this theory, and its subsequent refinements, simply assumes the existence of an offshore bar that restricts free circulation between the open sea and a coastal lagoon area. The bar would permit inflow of seawater to the lagoon, however, to replenish the water lost through evaporation and the salt lost through precipitation. The principal notion involved is the constant resupply of saline water, which eliminates the need for an initial water body that is nearly oceanic in size.

The paleogeographic or environmental setting is still subject to debate, however. Aside from clearly continental playa deposits, the association of some evaporites with coral-reef deposits, red beds, or fluvial structures suggests shallow-water or terrestrial environments. Indeed, there are many authorities who would interpret most deposits as originating in this way. Others, however, argue for deepwater basins, and still a third idea involves a two-layer aqueous system in which a lower brine layer is exposed intermittently to evaporation.

Importance to man

Evaporites are of considerable importance to man. They are the source for the world's supply of common salt (halite), gypsum, and much potash and magnesium. Borates and nitrates of economic importance also are derived from evaporite deposits. In addition, salt beds that are confined by the weight of overlying sedimentary rocks eventually tend to rise upward through this overburden, forming salt domes. These salt structures are intimately related to petroleum and natural gas occurrences in many parts of the world because they trap or block the subsurface migration of oil and gas and cause its accumulation.

The low permeability of salt, which makes it an effective seal against petroleum, is useful in other ways. Caverns in salt are almost perfectly dry, and it has been suggested that liquefied petroleum gas could be efficiently stored in artificial caverns in salt. Such caverns also might be used for the storage of certain radioactive wastes.

This article treats the general characteristics of evaporite minerals and mineral equilibria, the several theories of origin with regard to depositional environments, and the occurrence and distribution of evaporites in the geological record. For further information on carbonate minerals and rocks, see LIMESTONES AND DOLOMITES and CARBONATE MINERALS. For data on the composition and geochemistry of seawater, see OCEANS AND SEAS and GEOCHEMICAL EQUILIBRIA AT LOW TEMPERATURES AND PRESSURES. The several environments that are related to the occurrence of evaporites are further treated in the articles LAGOONS; PLAYAS, PANS, AND SALINE FLATS; CORAL ISLANDS, CORAL REEFS, AND ATOLLS; PALEOGEOGRAPHY; and SEDIMENTARY FACIES. See also SALT; SALT DOMES; and the several articles on saline water bodies—*e.g.*, RED SEA.

EVAPORITE MINERALOGY

Classification of evaporite minerals

Evaporite mineralogy appears formidable to the uninitiated because of the large number of mineral species involved and the unfamiliar ring of their names and chemical formulas. Examination of some relatively common evaporite minerals, however, reveals that a somewhat restricted set of constituents is present (see the Table). The minerals are categorized in four principal groups: carbonates, sulfates, chlorides, and borates and nitrates. The four principal cations (positively charged ions) associated with these groups are sodium, calcium, potassium, and magnesium, which are, of course, the principal salts in seawater. The Table also reveals that several pairs of mineral species are distinguished solely by reason of different numbers of water molecules contained in their crystal structure. Gypsum and anhydrite; vanthoffite and bloedite; and colemanite and inyoite are paired examples of this fact.

Having said this, it must be admitted that variety is one of the hallmarks of evaporite mineralogy. In addition to the minerals listed in the Table there are perhaps another 70 species that have been identified in marine and nonmarine deposits. They include some fluorides (fluorite and sellaite), iron oxides (magnetite, hematite, and limonite), silicate minerals (quartz, opal, and talc), clay minerals (kaolinite, illite, and sepiolite), phosphates (goyazite), sulfides (pyrite), and even native elements (sulfur).

Some Relatively Common Evaporite Minerals*

	formula
Carbonates	
Calcite	$CaCO_3$
Aragonite	$CaCO_3$
Magnesite	$MgCO_3$
Dolomite	$CaCO_3 \cdot MgCO_3$
Natron	$Na_2CO_3 \cdot 10H_2O$
Trona	$Na_2CO_3 \cdot NaHCO_3 \cdot 2H_2O$
Nahcolite	$NaHCO_3$
Pirssonite	$Na_2CO_3 \cdot CaCO_3 \cdot 2H_2O$
Gaylussite	$Na_2CO_3 \cdot CaCO_3 \cdot 5H_2O$
Sulfates	
Anhydrite	$CaSO_4$
Gypsum	$CaSO_4 \cdot 2H_2O$
Glauberite	$CaSO_4 \cdot Na_2SO_4$
Thenardite	Na_2SO_4
Mirabilite	$Na_2SO_4 \cdot 10H_2O$
Aphthitalite	$(K,Na)_3Na(SO_4)_2$
Vanthoffite	$3Na_2SO_4 \cdot MgSO_4$
Bloedite	$Na_2SO_4 \cdot MgSO_4 \cdot 4H_2O$
Loeweite	$6Na_2SO_4 \cdot 7MgSO_4 \cdot 15H_2O$
Kieserite	$MgSO_4 \cdot H_2O$
Hexahydrite	$MgSO_4 \cdot 6H_2O$
Epsomite	$MgSO_4 \cdot 7H_2O$
Langbeinite	$K_2SO_4 \cdot 2MgSO_4$
Leonite	$K_2SO_4 \cdot MgSO_4 \cdot 4H_2O$
Picromerite	$K_2SO_4 \cdot MgSO_4 \cdot 6H_2O$
Polyhalite	$K_2SO_4 \cdot MgSO_4 \cdot 2CaSO_4 \cdot 2H_2O$
Celestite	$SrSO_4$
Barite	$BaSO_4$
Chlorides	
Halite	$NaCl$
Sylvite	KCl
Bischofite	$MgCl_2 \cdot 6H_2O$
Carnallite	$KCl \cdot MgCl_2 \cdot 6H_2O$
Kainite	$4KCl \cdot 4MgSO_4 \cdot 11H_2O$
Borates and nitrates	
Colemanite	$Ca_2B_6O_{11} \cdot 5H_2O$
Inyoite	$Ca_2B_6O_{11} \cdot 13H_2O$
Priceite	$Ca_4B_{10}O_{19} \cdot 7H_2O$
Kernite	$Na_2B_4O_7 \cdot 5H_2O$
Borax	$Na_2B_4O_7 \cdot 10H_2O$
Ulexite	$NaCaB_5O_9 \cdot 8H_2O$
Searlesite	$Na_2O \cdot B_2O_3 \cdot 4SiO_2 \cdot 2H_2O$
Boracite	$Mg_3B_7O_{13}Cl$
Niter	KNO_3
Soda niter	$NaNO_3$

*The formulas are written as shown for reasons of convenience and ease of distinguishing the cationic and anionic elements and groups involved. Dolomite, for example, is commonly expressed chemically as $CaMg(CO_3)_2$, rather than the form listed above.

Mineral equilibria. The reasons for this impressive mineral diversity can best be understood in terms of the geochemical relations that exist between evaporate minerals and the mother liquor, or brine, from which they precipitate. Usiglio's work clearly showed that calcite and gypsum are the first minerals to precipitate from seawater in the normal course of evaporation. After reduction to 10 percent of the original volume, sodium chloride begins to precipitate from solution, and magnesium chloride, magnesium sulfate, potassium chloride, and a host of other salts do not precipitate from solution until a volume reduction to about 3 percent is attained. Interpretation of the salts associated with this residual hypersaline brine can best be accomplished by considering the geochemical system: sodium–potassium–magnesium–chloride–sulfate–water. The complexities of such a six-component system are legion, but simplification is possible. Much work has been based on consideration of the three-component system, magnesium–potassium–sulfate, when this system is in equilibrium with a solution that is saturated with respect to sodium chloride (*i.e.*, essentially the conditions that exist when sodium chloride begins to precipitate from seawater).

The magnesium–potassium–sulfate system

The geochemical relations among mineral species in equilibrium with the magnesium–potassium–sulfate system (and the associated sodium–chloride solution) are portrayed on the triangular Jänecke-type diagram in Figure 1. The diagram was devised by the German chemist Ernst Jänecke, who studied the geochemical relations of the Braunschweig salt deposits in the early 1900s. Essentially, the area bounded by the triangle represents all possible compositional variations of the three chemical end-members, or components (magnesium, potassium, and sulfate), that add up to 100 percent. The apex designated K_2^{++} (potassium ion), for example, represents 100 percent potassium and no magnesium or sulfate. If a vertical line were drawn from the K_2^{++} apex to the base of the triangle, the point of intersection would represent the composition 50 percent magnesium, 50 percent sulfate, and no potassium. Similar relations prevail for the other corners and

edges. Thus, each edge of the Jänecke diagram is actually a scale reflecting all possible mixtures of the two pure components at its ends; a point located precisely in the centre represents the tripartite composition: one-third magnesium, one-third potassium, and one-third sulfate.

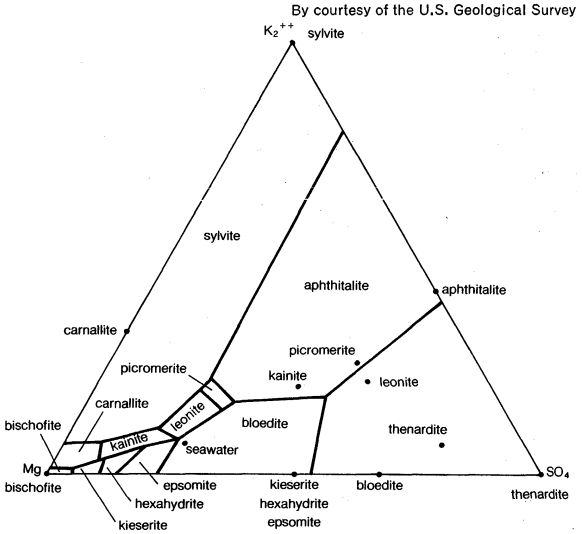

Figure 1: Stability fields of evaporite minerals at 25° C in the system magnesium–potassium–sulfate (see text).

The dots on the diagram indicate mineral compositions, and sylvite (KCl; no magnesium or sulfate), thenardite (Na_2SO_4; no magnesium or potassium), and bischofite ($MgCl_2 \cdot 6H_2O$; no potassium or sulfate) are, accordingly, the mineral end-members of this system; they are plotted at the corners of the triangle. Minerals such as kainite ($4KCl \cdot 4MgSO_4 \cdot 11H_2O$), which contain some of each of the components, are plotted in the triangle interior as dictated by their compositions.

Temperature dependence of stability fields

Finally, it is important to note that the areas given to a particular mineral species cover a much wider range of compositions than those indicated by the plotted dots on the diagram. Thenardite is plotted in the sulfate corner because, as noted above, it contains no potassium or magnesium. The large area labelled thenardite in the lower right part of the diagram refers to the stability field of this sodium sulfate at 25° C (77° F). At any solution composition that falls within this area, thenardite will begin to precipitate at the stated temperature. The lines that bound the thenardite field represent experimentally determined transitions (thermodynamic equilibria) between thenardite and aphthitalite on the one hand, and thenardite and bloedite on the other. These stability boundaries refer, in a gross compositional sense, to the limiting concentrations of potassium and magnesium that can be associated with the precipitation of thenardite from solution.

When precipitation of any mineral species occurs, the overall brine composition changes because some components will have been removed from solution. Figure 1 shows the compositional location of seawater; it falls within the stability field of bloedite. This means that bloedite, a hydrated sodium and magnesium sulfate, will be the first of the minerals to precipitate upon evaporation of seawater at 25° C (77° F). Removal of some sulfate and sodium from solution shifts the composition of the brine, and, in consequence, the next mineral that will precipitate is epsomite. Continued evaporation at this temperature results in the further mineral succession: kainite, hexahydrite, kieserite, carnallite, and, ultimately, to the precipitation of bischofite. This sequence has been experimentally demonstrated. Many authorities believe, however, that bischofite is formed by diagenesis in evaporite deposits (that is, by alteration of previously formed minerals) because solutions rich in the required magnesium chloride are most uncommon in nature.

The temperature dependence of geochemical reactions involving evaporites and brines is great, and it should be emphasized that the minerals, stability fields, and evaporative succession cited above hold only at a temperature of 25° C (77° F). The Dutch chemist Jacobus Henricus van't Hoff devoted many years of research to a systematic examination of mineral equilibria related to the Stassfurt salt deposits in Germany. He might well be called the father of experimental study of evaporites, and among his many fundamental discoveries was the change in mineral assemblage to be anticipated with increasing temperature. The interval from 25° to 37° C (77° to 99° F) was characterized by van't Hoff as one marked by the disappearance of picromerite, epsomite, and hexahydrite—each of which appears on the stability fields (25° C) shown in Figure 1. The temperature interval from 37° to 55° C (99° to 131° F) is associated with the appearance of langbeinite, loeweite, and vanthoffite; and a third temperature interval, from 55° to 83° C (131° to 181° F), is one in which bloedite, leonite, and kainite disappear.

Typical dehydration reactions

Some typical dehydration (water loss) reactions that indicate both the temperature dependence of evaporite assemblages and the cause of much mineral speciation include the following:

$$\underset{\text{mirabilite}}{Na_2SO_4 \cdot 10H_2O} \rightleftharpoons \underset{\text{thenardite}}{Na_2SO_4} + \underset{\text{water}}{10H_2O},$$

which occurs at 18° C (65° F) in the presence of halite;

$$\underset{\text{picromerite}}{K_2SO_4 \cdot MgSO_4 \cdot 6H_2O} \rightleftharpoons \underset{\text{leonite}}{K_2SO_4 \cdot 2MgSO_4 \cdot 4H_2O} + \underset{\text{water}}{2H_2O},$$

which occurs at 26° C in the presence of halite, bloedite, and aphthitalite;

$$\underset{\text{hexahydrite}}{MgSO_4 \cdot 6H_2O} \rightleftharpoons \underset{\text{kieserite}}{MgSO_4 \cdot H_2O} + \underset{\text{water}}{5H_2O},$$

which occurs at 35.5° C in the presence of halite and bloedite;

$$\underset{\text{bloedite}}{Na_2SO_4 \cdot MgSO_4 \cdot 4H_2O} + \underset{\text{thenardite}}{2Na_2SO_4} \rightleftharpoons \underset{\text{vanthoffite}}{3Na_2SO_4 \cdot MgSO_4} + \underset{\text{water}}{4H_2O},$$

which occurs at 46° C (115° F) in the presence of halite and aphthitalite; and

$$\underset{\text{kainite}}{4KCl \cdot 4MgSO_4 \cdot 11H_2O} \rightleftharpoons \underset{\text{kieserite}}{4MgSO_4 \cdot H_2O} + \underset{\text{sylvite}}{4KCl} + \underset{\text{water}}{7H_2O},$$

which occurs at 83° C (181° F) in the presence of halite.

Each of the above reactions occurs only at the temperatures stated and in the presence of the minerals indicated; being reversible dehydration reactions, they are characterized principally by the loss (or gain) of water molecules as shown.

Jänecke diagrams for temperatures as high as 350° C (650° F) have been prepared. They are similar to the diagram of Figure 1, but the minerals present and the area of their stability fields vary because of the temperature dependence noted above. At 110° C (230° F), for example, the stability field of thenardite is increased and occupies much of the right side of the triangle. The other principal mineral species present at 110° C are aphthitalite, sylvite, langbeinite, kieserite, and vanthoffite; small areas represent the stability fields of loeweite, carnallite, and bischofite. Several of these mineral species are, of course, absent from the 25° C diagram, and seawater is in equilibrium with vanthoffite instead of bloedite at the elevated temperature of 110° C.

Knowledge of these mineral relations and equilibria is of great aid in efforts to understand and interpret the origin of evaporites. The presence of certain high temperature species in a particular deposit is obviously of paleo-environmental significance. Similarly, the presence of some of the rarer potassium or magnesium chlorides, for example, is of significance because it indicates either (1) the existence of environmental opportunity for evaporation to proceed nearly to completion or (2) the occurrence of post-depositional alteration of an original evap-

orite assemblage, perhaps by percolation of brines within a groundwater circulation system. In either case, the history of deposition is clarified.

Mineral characteristics. The physical properties of the several mineral groups involved are treated elsewhere; see, for example, the article CARBONATE MINERALS. In general, the most distinctive physical characteristic of evaporite minerals and mineral sequences (aside from salt or bitter taste) is colour. A wide variety of colours has been noted, and some are rather readily explained in terms of inclusions: carbonaceous matter lends black and brown tones; finely disseminated clays produce shades of gray; iron oxides such as hematite are associated with reds and reddish browns; and the presence of small amounts of iron chloride is thought to be the cause of some yellows.

Colour in evaporites

Many investigations of colour in evaporites have been directed toward explanation of blue, violet, and yellow colours in halite, violet in anhydrite and langbeinite, and other evaporite colours that are known or thought to be produced by inclusion of radioactive trace elements. Uranium, thorium, and potassium-40 are among the suggested causes, and a relationship between mineral colour and helium content has been demonstrated in some cases. The helium may be derived from brine inclusions that were trapped when the minerals were first formed. In other instances, however, minerals with equally high helium contents are uncoloured. Hence, colour in evaporite minerals—indeed, in minerals in general—remains somewhat enigmatic. It is a source of intrinsic beauty as well as speculation, however, because the brilliant white of many evaporite beds contrasts markedly with the coloured deposits of some of the minerals mentioned here.

ORIGIN OF EVAPORITES

The origin of evaporites is rather simple in the sense that all deposits are derived by evaporation of water bodies. Beyond this, complexities arise because the variability of conditions in nature can give rise to the great mineral diversity already noted, and because a number of possible environments of deposition are involved. The purposes of this article are not compatible with extensive discussion of the technical arguments on evaporite origin. The topic will here be treated in terms of the principal environments of deposition that are known to exist: namely, the nonmarine closed-basin or playa environment; the shallow-water tidal flat and coastal lagoon; and the deep-basin environment with restricting sill or bar. An alternate hypothesis treating evaporite deposition from layered solutions will be appended in order to indicate some trends of modern thought on the question of origin.

The nonmarine environment. Evaporite deposition in the nonmarine environment occurs in closed lakes—those without outlet—in arid or semi-arid regions. Such lakes form in closed interior basins or shallow depressions on land where drainage is internal and runoff does not reach the sea. If water depths are shallow or, more typically, somewhat ephemeral, the term playa or playa lake is commonly used.

Hydrology of closed lakes

Hydrologic inflow to closed lakes consists principally of precipitation and surface runoff, both of which are small in amount and variable in occurrence in arid regions. Groundwater flow and discharge from springs may also provide water input in some cases, but evaporation rates are high and are always considerably in excess of precipitation and surface runoff. When sporadic or seasonal storms occur, they give rise to a sudden surge in water inflow. Because the closed lake lacks an outlet, it can respond to such circumstances only by increasing its surface area and water depth. Subsequent evaporation will reduce the volume of water present to the prestorm or normal amount; fluctuation of the lake level, therefore, is characteristic of the environment.

Changing lake levels and water volumes give rise in turn to fluctuating salinity values. Salinity is a measure of the total salt content, commonly expressed in units of parts per thousand and represented by the symbol ‰. The values reported for some closed lakes are as high as those existing anywhere on Earth; some examples are: Lake Assal, Afars and Issas, formerly French Somaliland (325 ‰); Elton Lake, Soviet Union (300 ‰); Tuz Gölü, Turkey (250 ‰); Dead Sea, Israel and Jordan (270 ‰); Deep Springs Lake, California (310 ‰); and Lake Eyre, Australia (240 ‰). By way of contrast, the salinity of normal seawater is about 35 ‰ and that of the most saline seawater does not exceed closed-lake values (salinity in the Kara-Bogaz-Gol Gulf of the Caspian Sea is 310 ‰; salinity in the Atlantis II Deep and the Discovery Deep, both in the Red Sea, is 257 ‰). It must be emphasized, however, that salinites are highly variable in closed lakes. Influx of fresh water from storm runoff has produced temporary salinity values as low as 40 ‰ in Lake Eyre and 22 ‰ in Deep Springs Lake, for example.

The salinity variations described can affect equilibrium relations between brine and minerals and lead to much solution and reprecipitation of evaporites in the nonmarine environment. Nevertheless, there is often a striking resemblance between the mineral zonation exhibited by sediments of playa lakes and that which would occur if the natural brines were allowed to evaporate in the laboratory. Indeed, such zonation can be said to be one of the hallmarks of the nonmarine environment. A particularly fine example is shown in Figure 2, the result of a study of evaporites in Deep Springs Lake, California.

Areal zonation of minerals

The relatively flat basin containing this playa lake receives about 125 millimetres (five inches) of precipitation per year, whereas the mean annual evaporation is approximately 1,250 millimetres (50 inches) per year. Water composition reflects the lithologies (rock types) that exist within the drainage basin, and the saline brine of this particular playa lake consists essentially of sodium sulfo-carbonate, with lesser amounts of calcium, magnesium, potassium, and chloride. The areal variation of evaporites from the playa margin to its centre is as follows: calcite, dolomite, gaylussite, and thenardite, surrounding a central zone of burkeite. The composition of the latter mineral, which characterizes the central salt pan, is

$$Na_6(SO_4)_2CO_3.$$

The areal variation shown in Figure 2 is precisely what would be expected of a sequence of mineral precipitates under the prevailing conditions.

Many of the same minerals are present in the neighbouring Death Valley salt pan, where a more complete carbonate–sulfate–chloride areal variation has been demonstrated. The particular mineral suite present in the nonmarine environment is quite variable, however; water composition always varies to some degree with rock type and composition, and the evaporites present may vary from basin to basin, even within the same general region.

The chloride stage of precipitation in Deep Springs Lake is represented by a vertical sequence of evaporite minerals within salt crusts and polygons. Halite and sylvite overlie thenardite, burkeite, trona, and one or two other minerals at depth, but the overall relationship in vertical layering is not nearly so consistent as is areal variation. This is true of closed lakes generally, because the fluctuating water levels combine with very flat topography (note ground elevations shown in Figure 2) to produce extensive shoreline changes. Such changes may have caused considerable variation in brine composition over any fixed point through time, and vertical sequences are, of course, always representative of these variations or changing environmental conditions.

The shallow marine environment. Evaporite deposition in the shallow marine environment (sometimes termed the salina) occurs in desert coastal areas, particularly along the margins of such semi-restricted water bodies as the Red Sea, Persian Gulf, and Gulf of California. Restriction is, in general, one of the critical requirements for evaporite deposition because free and unlimited mixing with the open sea would easily overcome the high evaporation rates of arid areas and dilute these waters to near-normal salinity. The semi-restriction referred to cannot, in fact, prevent a great deal of dilution by mixing; coastal physiography is the principal factor involved in brine production.

Evaporite formation along the coast of the United Arab Emirates

The United Arab Emirates (formerly the Trucial Coast) of the Arabian Peninsula provide an excellent and much-studied example of this environment. A fringing network of offshore islands between Qatar and Abu Dhabi serves as a barrier for coastal lagoons, within which the waters of the Persian Gulf are further restricted. Salinity values are about 70 ‰, or twice that of normal seawater. One of the largest of the lagoons off the United Arab Emirates is Khawr al-Bazm, and the lagoon and its associated islands constitute the outermost of three distinct but contiguous elements of the shallow marine environment (Figure 3). The second element is the algal flat, an intertidal zone in the vicinity of the high-water mark, and the third element is the coastal salt flat, or sabkha, a supratidal zone that is inundated by seawater only occasionally.

The lagoonal sediments are largely carbonate sands and muds, rich in coral fragments and other bioclastic grains. It is thought that blue-green algae play an important role in the alteration of the carbonate sediments and in inducing precipitation of aragonite rather than calcite in many instances. They are also instrumental in creating the algal-mat area; the mats trap such carbonate sediment and tend to be preserved as distinctive strata within vertical sedimentary sequences. Evaporite formation is largely restricted to the coastal sabkha, however.

The sabkha along the coast attains widths of eight to ten kilometres (five to six miles), and temperature and salinity values more nearly resemble those of continental playas than those of the adjacent lagoon, Khawr al-Bazm. Evaporation of groundwater influx and occasional storm-generated floodwaters has produced an interstitial brine (*i.e.*, within the pore space of the sabkha sediments) about one metre below the sabkha surface. The salinity of this brine may be as great as 350 ‰ in places, and evaporite precipitation, largely in the form of gypsum and anhydrite, occurs within the interstices of the sabkha sediments (Figure 3). Alteration and replacement (diagenesis) of the original sediments also occur by reaction with the interstitial brine. Dolomite, produced in a variety of ways, is fairly common, and halite occurs in the salt crusts of the sabkha surface. Other evaporites present include celestite and huntite; the latter is a relatively rare carbonate of calcium and magnesium.

Shoreline regression and mineral variation

Several kinds of vertical mineral variations occur in this environment, but an areal variation is particularly worthy of note. Data from Baja California and the Persian Gulf suggest that shoreline regression is occurring at the rate of one to two metres per year, which means that a sabkha as wide as 100 to 200 kilometres (60 to 120 miles) could be formed in as little as 100,000 years—a short time span in the geological sense. Whether this occurs without interruption depends upon a number of factors; however, with regard to the areal variation of minerals, gypsum belts will move progressively seaward through time, and the width of belts of anhydrite—which

forms by dehydration of gypsum under certain conditions—will increase. The sabkha mineral belts always tend to parallel the associated coastal lagoons. When these evaporites are found in the geological record, they provide evidence of the former location of land and sea and of the trends of former shorelines.

The deep-basin environment. There is no doubt that some evaporites in the geological record were deposited under shallow-water conditions that closely resembled those of the modern Khawr al-Bazm. The great thickness of evaporites in some ancient deposits (*e.g.*, approximately 1,200 metres [3,900 feet] thick in the German Zechstein deposits) poses difficulty for the salina model, however. The basic problem is that rates of land subsidence in areas of salt deposition would necessarily have to equal known rates of evaporite accumulation. The required subsidence seems geologically unreasonable in many instances, and a deepwater model provides a more plausible alternative in such cases.

The deep-basin model from the initial to permanent stages

As in all instances of evaporite formation—including nonmarine formation—evaporation must generally exceed precipitation and surface runoff in the deep-basin model. The principal physiographic requirement is the presence of a barrier sill to prevent unlimited mixing of water within the basin with that of the open sea. This physical configuration is quite similar to that of the Mediterranean Sea, most of the Norwegian fjords, and the Red Sea proper.

Figure 4 illustrates the probable sequence of events. In the formative stage (Figure 4A), incoming seawater of density 1.02 grams per cubic centimetre (subsequently abbreviated here as g/cm³) gives rise to water of density 1.025 g/cm³ within the basin because of surface evaporation. Toward the landward margin of the basin, the density further increases, and the circulation caused by the sinking of denser water is as shown. Conditions in the Mediterranean Sea today closely resemble those depicted here for the formative stage.

The continual sinking of dense brines formed at the surface ultimately displaces all of the waters of normal or near-normal density within the basin, and stagnant bottom water, lacking oxygen, is formed. This is the euxinic stage (Figure 4B), in which normal carbonate deposition ceases and is replaced by the accumulation of dark, sulfide-rich, organic muds. Bottom-water densities attain values of about 1.08 g/cm³ and marine life generally perishes.

Continued surface evaporation will lead to precipitation of the first evaporite mineral, gypsum, when densities of about 1.10 g/cm³ are attained in the distal parts of the basin. This is termed the ephemeral stage (Figure 4C) because the gypsum crystals will redissolve as they sink toward the bottom through water of lesser density (1.08 g/cm³) that is not yet fully saturated with respect to calcium sulfate.

The permanent evaporite stage is finally reached when very dense water fills the entire basin to the depth of the sill (Figure 4D). At the density shown (1.25 g/cm³), gypsum, anhydrite, and halite could accumulate on the basin bottom without the occurrence of re-solution. Depending upon the salinity (density) variations that occur through time, a variety of evaporite minerals and mineral sequences could be deposited under the conditions here associated with the permanent stage of development.

Preservation of deposits

Evaporite deposition in the deep-basin environment is therefore limited chiefly by basin depth; the great thicknesses of many known deposits can be accounted for by this model. With regard to the ultimate fate and degree of preservation of deep-basin evaporites after basin filling, several alternatives are possible. Figure 4E shows one such alternative. The deep basin has been completely filled and salt flat or salina-like conditions prevail at the surface. Normal sedimentation, associated with shoreline shifts of the shallow marine environment, will preserve the thick evaporite deposit.

If sea level should fall or if the basin and its sill should rise because of uplift of the Earth's crust, the influx of seawater will be effectively cut off and the deep-basin evaporites easily preserved (Figure 4F). The thick salt deposits of the Ethiopian Danakil Depression may reflect this postulated condition.

Finally, climatic change may interrupt basin filling during the permanent stage. Even in the instance of much freshwater inflow (Figure 4G), the combined effect of the immediately overlying saline brine and the basinward transport of land-derived sediments will be to prevent re-solution and thus preserve the evaporites.

Deposition from layered solutions. It has recently been argued that some evaporites in the geological record accumulate at times and places for which there is no independent evidence of persistently arid climates. Because density stratification is known to exist in some form in all lakes and seas, a simple two-layer aqueous system has been proposed as fundamental to evaporite formation. Basically, the system consists of a dense layer of brine overlain by a relatively dilute water layer and separated from it by a pycnocline—*i.e.*, a boundary across which diffusion of salt is slow. The existence of pycnoclines in nature has been demonstrated; in fact, a permanent pycnocline was established in the Dead Sea about 1,500 years ago.

Laboratory work has demonstrated that evaporite deposition can occur in a two-layer system. This is not a drastically different concept, and several of the stages depicted in Figure 4 are quite similar to it, involving as they do water layers of lesser density and salinity that overlie denser brines. Two aspects of the two-layer system should be noted here, however. First, it is postulated that the brine layer below the pycnocline is sustained and

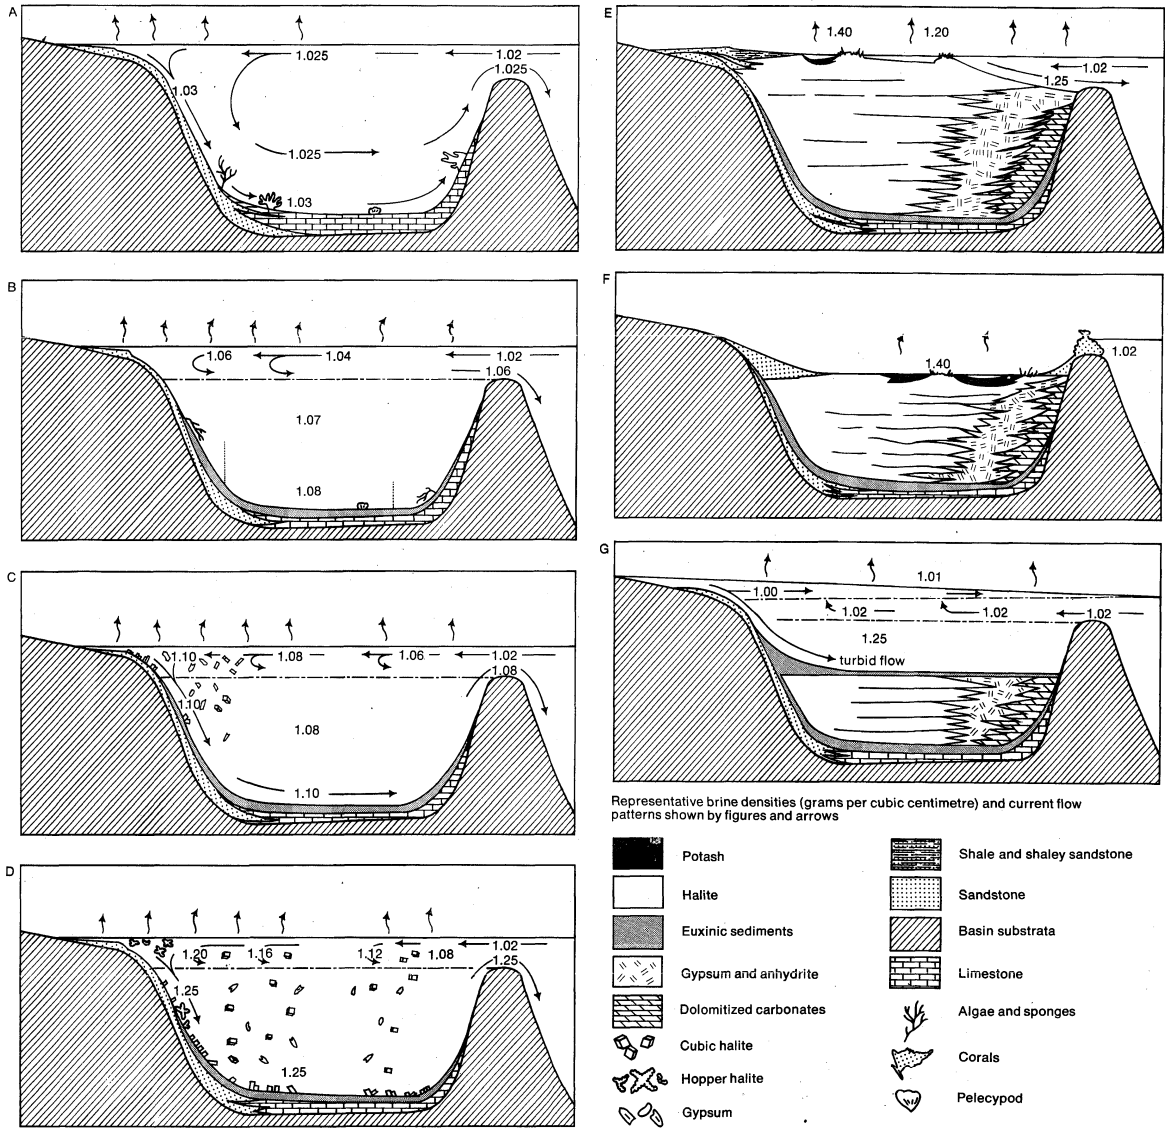

Figure 4: *Model of deepwater evaporite deposition.*

From R. Schmalz, "Deep Water Evaporite Deposition: A Genetic Model" (1969); American Association of Petroleum Geologists

replenished by the inflow of saline water derived from the entire drainage area. That is, evaporation over the immediate site of evaporite deposition need not be continuous; local or seasonal changes of climate can be accommodated without effect on the brine layer. Second, inclusion of the entire drainage area reduces the vast quantity of water per unit area that is customarily thought to be evaporated during evaporite deposition.

Brine exposure by seiches

The most tortuous facet of the two-layer hypothesis is a requirement that the brine below the pycnocline be intermittently exposed and subjected to surface evaporation to induce evaporite precipitation. Proponents cite the possibility of surface winds and internal seiches of sufficient amplitude and duration to "pile up" the dilute surface waters, expose the brine to evaporation for periods as long as weeks, and thus permit precipitation of evaporites over the entire basin surface. Internal seiches of Lake Baikal have a period of 30 to 40 days and an amplitude of 150 metres (500 feet) or more; this observation certainly strengthens the plausibility of the two-layer hypothesis.

In conclusion, it can only be added that each of the environments of deposition discussed in this article exists today and that each has been responsible for the formation of some evaporites in the geological past. Evaporites have originated in marine and nonmarine environments, in shallow water and in deep basins, and under arid and somewhat fluctuating climatic conditions. One of the principal virtues of the two-layer model is that it indicates a mechanism whereby the latter circumstances can be accomplished.

DISTRIBUTION IN SPACE AND TIME

Evaporites occur in strata of every geological age, from Cambrian (500,000,000 to 570,000,000 years ago) to Holocene time (the last 10,000 years, approximately). Space limitations preclude description of the mineralogy and stratigraphy of individual deposists; treatment here will be confined to the gross aspects of evaporite distribution and the implications that have been drawn from this distribution.

Evaporites in the geological record

Some of the oldest deposits occur in the Canadian Arctic Archipelago and on the Siberian Platform; Cambrian evaporites in the region of the upper Lena River constitute one of the world's greatest accumulations. This high-latitude occurrence in the Northern Hemisphere persisted through Devonian time (345,000,000 to 395,000,000 years ago), when evaporites were deposited in an enormous zone between northern Greenland and the Rocky Mountains. Devonian evaporites in Alberta and British Columbia are associated with coral reefs and oil and gas fields. Evaporites also were deposited in the northeastern

and north central United States, the Gulf of Mexico region, and in Tethys, the ancient east–west seaway between Europe and Africa that extended across southern Asia, during this general time span of more than 200,000,000 years.

Deposits of Carboniferous age (280,000,000 to 345,000,000 years ago) are not as abundant in the highest northern latitudes, and some of the principal occurrences are in the maritime areas of eastern Canada, and in England and Ireland. Carboniferous evaporites also occur in Brazil; this marks the earliest time of deposition in the Southern Hemisphere.

Evaporite deposition was at a maximum during the Permian Period (225,000,000 to 280,000,000 years ago), and some of the world's most famous deposits are of Permian age. The Arctic Archipelago again became a site of evaporite formation, and deposition occurred in eastern Greenland, Spitsbergen, over much of western Europe, and in the Ural Mountains. The upper Kama Basin in the Urals is thought to contain potash reserves that are several times greater than those in the German Stassfurt evaporites. Other noteworthy Permian deposits occur in the southwestern United States, western Canada, and in the Southern Hemisphere, where evaporites in Australia, South America, and Africa formed at latitudes as far from the Equator as 25° S.

During the Triassic Period (190,000,000 to 225,000,000 years ago) the principal sites of deposition were in western Europe and North Africa, in a broad belt extending approximately from Senegal to Libya. Evaporites of Triassic age also occur in western North America, in east Africa, and in scattered localities in the vicinity of the Persian Gulf, southern Asia, and South America. Some deposits formed in eastern Greenland, but no evaporites were formed in latitudes above 55° N after Triassic time.

Evaporite deposition during Jurassic (136,000,000 to 190,000,000 years ago) and Cretaceous (65,000,000 to 136,000,000 years ago) time was relatively restricted. Occurrences of note include a broad swath of deposits around the Gulf of Mexico, over much of the Arabian Peninsula, and in Argentina and Bolivia. During the Tertiary Period (2,500,000 to 65,000,000 years ago) the areas of evaporite deposition were further restricted. Evaporites formed principally in the Mediterranean region, the Red Sea and Persian Gulf, and in the Gulf of California and the Gulf of Mexico off the Yucatán Peninsula. The glacial conditions of the Pleistocene Epoch eliminated these depositional sites, which have been partly restored under Holocene or modern climates.

Climatic change and continental drift

It seems clear that evaporites were deposited over a much wider latitudinal range in the past, and that evaporite maximums have varied inversely with known glacial maximums through geological time. Combined with the fact that modern limits of evaporite formation are essentially determined by climate, most authorities agree that the distribution of evaporites through time closely reflects worldwide climatic change, specifically coinciding with periods of warmth and aridity. It might be argued that evaporite deposition from the two-layer system described earlier obviates the climatic link; however, Arctic evaporites are associated with coral reefs and plant remains that are independent indicators of much warmer conditions at high northern latitudes.

Because the general zone of evaporite deposition has remained symmetrical about the present rotational axis of the Earth (during the several latitudinal expansions and contractions that have occurred), this poses some constraints on the theory of continental drift. The movement of continents in an east–west direction (*e.g.*, the separation of Europe and North America by sea-floor spreading in the North Atlantic) can be accommodated, but the data on evaporite distribution would appear to conflict with north–south motions. In addition, the relatively sparse occurrence of evaporites in the Southern Hemisphere is most readily explained in terms of the present distribution of land and sea—that is, by the essential oceanic character of the Southern Hemisphere. This is incompatible with the postulated existence of a former great southern landmass that included Antarctica.

Most earth scientists are firm in the belief that continental drift and sea-floor spreading are realities rather than hypotheses, and, indeed, the paleomagnetic and other data from the ocean floors appear to be most convincing. There are, however, a few kinds of geological data that can be reconciled with predrift reconstructions of the Earth's crust only with difficulty. The distribution of evaporites in space and time must be considered in this category, thus providing a fascinating problem of Earth history.

BIBLIOGRAPHY. There are no books in English that treat all aspects of evaporites, but H. BORCHERT, *Ozeane Salzlagerstätten* (1959; Eng. trans. with new material by R.O. MUIR, *Salt Deposits*, 1964), presents a thorough description of mineral stability relations; and J. BRAUNSTEIN and G.D. O'BRIEN (eds.), *Diapirism and Diapirs* (1968), covers salt deposits in all parts of the world that are related to salt domes and piercement structures. Several elementary texts on geochemistry provide abbreviated but basic treatment from the chemical point of view. In this vein are E.T. DEGENS, *Geochemistry of Sediments* (1965); K.B. KRAUSKOPF, *Introduction to Geochemistry* (1967); and B.H. MASON, *Principles of Geochemistry*, 3rd ed. (1966). The relation of evaporites to other chemically precipitated rocks and to the geological record is covered in F.J. PETTIJOHN, *Sedimentary Rocks*, 2nd ed. (1957).

The interested reader must pursue the more specialized technical literature to gain further insight to the subject, however. Basic articles, each of which provides additional references within its bibliography, include: F.H. STEWART, "Marine Evaporites," *Prof. Pap. U.S. Geol. Surv.* 440-Y (1963); H.P. EUGSTER and G.I. SMITH, "Mineral Equilibria in Searles Lake Evaporites, California," *J. Petrology*, 6:473–522 (1965); O. BRAITSCH, "The Temperature of Evaporite Formation," in A.E.M. NAIRN (ed.), *Problems in Paleoclimatology* (1964); B.F. JONES, "The Hydrology and Mineralogy of Deep Springs Lake, Inyo County, California," *Prof. Pap. U.S. Geol. Surv.* 502-A (1965); C.B. HUNT *et al.*, "Hydrologic Basin, Death Valley, California," *Prof. Pap. U.S. Geol. Surv.* 494-B (1966); R. GREEN, "Palaeoclimatic Significance of Evaporites," in A.E.M. NAIRN (ed.), *Descriptive Palaeoclimatology* (1961); and A. LERMAN, "Model of Chemical Evolution of a Chloride Lake: The Dead Sea," *Geochim. Cosmochim. Acta*, 31:2309–2330 (1967). Worthy of special consideration is the entire issue of the *American Association of Petroleum Geologists Bulletin* of April 1969, which is devoted to the theme of evaporites and petroleum, and which covers the several concepts of evaporite formation in a variety of environmental settings; H.P. EUGSTER, "The Beginnings of Experimental Petrology," *Science*, 173:481–489 (1971), which presents a detailed description of the experimental work of van't Hoff on evaporite equilibria; and A.A. MEYERHOFF, "Continental Drift," 2 pt., *J. Geol.*, 78:1–51, 406–444 (1970), which include treatment of evaporite distribution in the geological record.

(L.K.L.)

Everest, Mount

Mount Everest, a peak on the crest of the Himalayan range in Asia, is the highest mountain on earth. It rises above the Himalayas, on the undemarcated Nepal–Tibet border, in the approximate position of 28° N, 87° E. Three barren ridges—the Southeast, Northeast, and West—culminate in two summits at 29,028 feet (8,848 metres; Everest) and 28,700 feet (8,748 metres; South Peak). The mountain can be seen directly from its northeastern side, where it rises about 12,000 feet above the Tibetan Plateau. The lesser peaks of Changtse (north; 24,780 feet), Khumbutse (northwest; 21,785 feet), Nuptse (southwest; 25,726 feet), and Lhotse (south; 27,923 feet), which rise around its base, hide the summit from Nepal (for details of the range of which it forms a part, see HIMALAYAN MOUNTAIN RANGES).

Formation of the Great Himalayan mountain ranges began during the Miocene Epoch (7,000,000 to 26,000,000 years ago), as a result of the shock produced by the convergence of the Indian subcontinent and the Tibetan Plateau. The Kāthmāndu and Khumbu nappes (faulted, overturned rock folds) were squeezed upward and folded upon each other in successive stages, creating a primitive mountain chain. A general uplifting of the northern land mass added further elevation. The whole was again overlaid by a further folding of the nappes, which resulted in the formation of Mt. Everest during the Mahabarat Phase of the Pleistocene Epoch (which lasted from about

10,000 to about 2,500,000 years ago). Its layers of limestone from the Permo-Carboniferous Period (which lasted from 225,000,000 to 345,000,000 years ago), separated by other paracrystalline sediments (sediments that were later metamorphosed), were laid down in synclinal stratification (*i.e.*, folded together with strata dipping inward). Formative forces are still evident in a continuing uplifting, which is counteracted by erosion.

The summit of Everest reaches up two-thirds of the way through the earth's atmosphere to the upper layers, where oxygen is thin. Lack of oxygen, powerful winds, and extremely cold temperatures preclude the development of any plant or animal life on the upper slopes. Precipitation falls, during the summer monsoon only, as snow, which lies in powdery drifts. Because these drifts are above the evaporation line, the large basins of névé (partially compacted granular snow), which usually feed glaciers, do not form. Everest's glaciers are consequently fed only by frequent avalanches. The ice sheets on the flanks of the mountain, separated from each other by the main ridges, cover the slopes down to the mountain's base but are slowly retreating because of gradual climatic change. The summit itself is relatively free of snow cover in the winter months, due to the force of northwest gale winds.

Individual glaciers are the Kangshung Glacier (east); the East, main, and West Rongbuk glaciers (north and northwest); the Pumori Glacier (northwest); the Khumbu Glacier (west and south); and the West Cwm, an enclosed valley of ice between Everest and the Lhotse-Nuptse Ridge.

The mountain's drainage pattern radiates southwest, north, and east. The Khumbu Glacier melts into the Lobujya Khola of Nepal, a river flowing southward as the Imja Khola to its confluence with the Dudh Kosi River. Two Tibetan rivers—the Rong Chu and Karma Chu—originate on Everest's slopes as the Pumori and Rongbuk glaciers and as the Kangshung Glacier, respectively. The Rong Chu and Dudh Kosi river valleys form the northern and southern access routes to the summit.

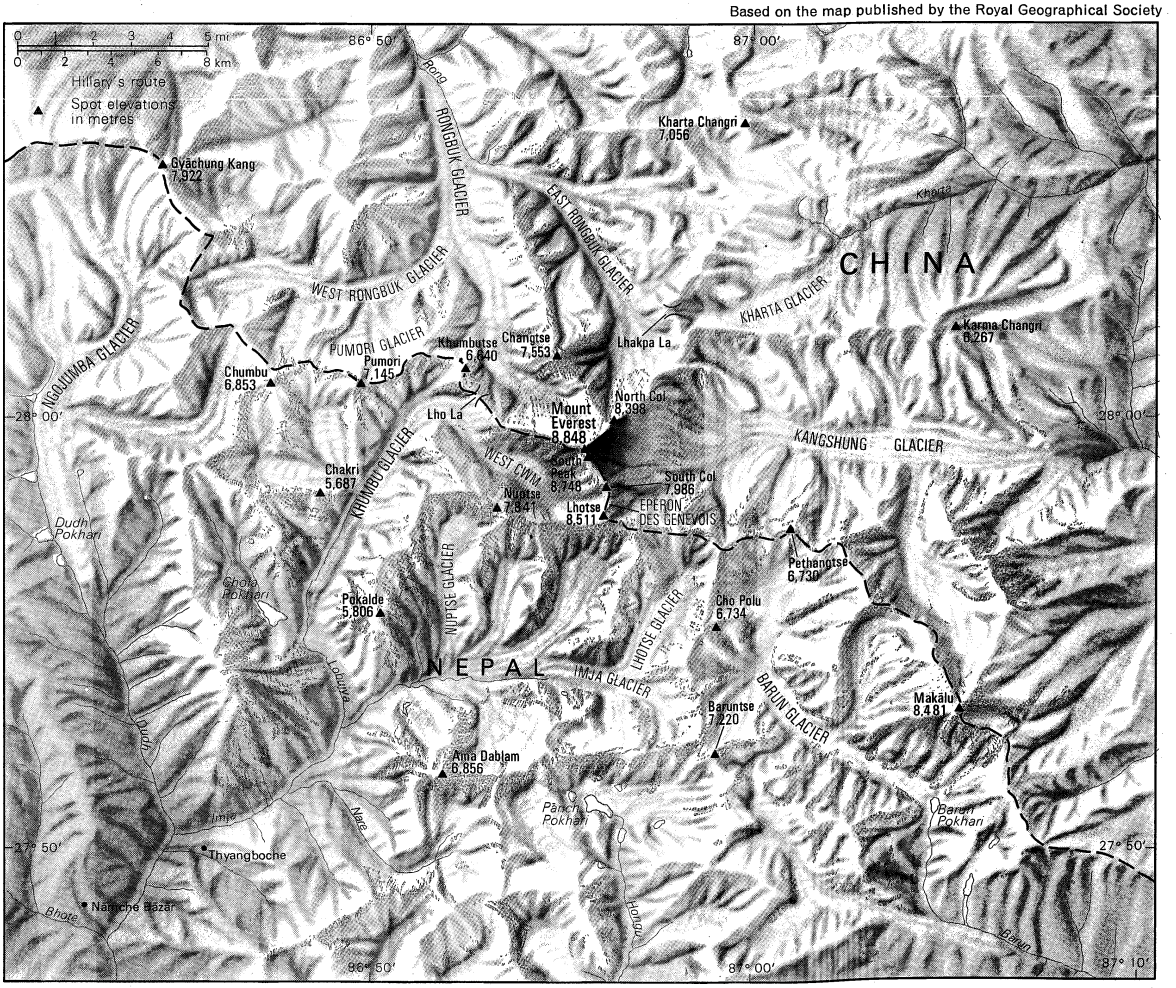
Peoples of the Everest area

Although Mt. Everest itself is void of life, the associated Khumbu Valley is inhabited by the Sherpas, a group of the Bhutia peoples of the Himalayas. Their villages are situated at 12,000 to 13,000 feet and are scattered from the Tibetan border, to the east, to the banks of the Bhote Khose River, to the west. An agricultural people with little cultivable land at their disposal, the Sherpas follow a semi-nomadic life style in their search for open pasturage. Summer grazing is sought as high as 16,000 feet, while winter refuge is taken at lower altitudes on sheltered ledges or on riverbanks. The main crops grown are potatoes and various grains; the yak is raised for its milk, meat, and fur. Many of the men supplement their income by engaging in the transmontane traffic between Nepal and Tibet.

Living in close proximity to the world's highest mountains, the Sherpas traditionally treated the Himalayas with respect—building Buddhist monasteries at their base, placing prayer flags on the slopes, and establishing sanctuaries for the wildlife of the valleys, such as musk deer, monal pheasant, and Himalayan partridge. Spirits and demons were said to live on the high peaks, and the Yeti (the so-called Abominable Snowman) was reputed to roam the lower slopes. Since 1951, when scientific mountain climbing expeditions began to arrive, Sherpas have often taken up employment as porters and have shown a bent for mountaineering.

Because of its commanding size and height, Everest was known in the Tibetan language as Chomolungma, "Goddess Mother of the World." Its identity as the highest point on the earth's surface was not recognized, however, until 1852 when the governmental Survey of India estab-

Based on the map published by the Royal Geographical Society



Mount Everest region.

lished that fact. In 1865 the mountain—previously referred to as Peak XV—was renamed for a British official, Sir George Everest, who was surveyor general of India from 1823 to 1843. Controversy over the exact altitude of the summit developed because of variations due to snow level, gravity deviation, and light refraction. The figure currently accepted—29,028 feet (plus or minus a fraction)—was established by the Survey of India between 1952 and 1955.

Attempts to climb Everest began with the opening of the Tibetan route in 1920. Seven successive attempts on the Northeast Ridge (1921–38), as well as three missions up the Southeast Ridge (1951–52), failed because of the combined difficulties caused by cold arid air, high winds, difficult terrain, and high altitude.

Everest was finally surmounted in 1953, as the result of efforts by an expedition sponsored by the Royal Geographical Society and the Joint Himalayan Committee of the Alpine Club. Open- and closed-circuit oxygen systems, especially insulated boots and clothing, and portable radio equipment were used by the climbers. Eight camps were established on the route that was taken up the Khumbu Icefall and Glacier, the West Cwm, and the face of Lhotse to the South Col, a rocky ridge at 26,200 feet. From there, on May 29, 1953, Edmund (later Sir Edmund) Hillary of New Zealand and Tenzing Norgay of Nepal ascended the Southeast Ridge, past South Peak, to the summit. Since then, four expeditions sponsored by different nations—Swiss (1956), American (1963), Indian (1965), and Japanese (1970)—have scaled the peak. The Japanese party was the first to include a woman.

In 1965 the government of Nepal closed the route to Everest; the ban was, however, lifted in 1968.

Everglades

Known to the Indians as Pa-hay-okee, "Grassy Waters," the Everglades is a great marsh encompassing nearly 4,000 square miles (10,000 square kilometres) at the southern tip of Florida. Through it, water moves slowly from the lip of Lake Okeechobee to mangrove swamps bordering the Gulf of Mexico and the Florida Bay on the west. On the east the marsh reaches near the narrow, sandy belt that includes the Greater Miami metropolitan area, while on the south Everglades National Park borders Florida Bay at the bottom of the peninsula.

Location

During the 20th century, men have had considerable success in exploiting the rich soil of the Everglades. The region has been the subject of constant conflict between various interests, however, and the delicate ecological balance of the marsh has been threatened constantly by human attempts to manage or transform its resources.

Natural environment. *Natural cover.* The glades occupy a shallow limestone-floored basin that slopes imperceptibly southward at about one-fifth of a foot per mile. Much of it is covered with saw grass (a sedge, the edges of which are covered with minute sharp teeth), which grows to a height of 10 to 15 feet (3 to 5 metres). Where undisturbed, it creates a surface of monotonous sameness. Open water is sometimes found; and there are numerous low islands, or "hammocks," on which a profusion of trees and shrubs grow, including palms, pines, live oaks, cypresses, saw palmettos, and other tropical species. The organic soils, which have been formed from the decay of lush vegetation, range from discontinuous shallow patches to accumulations of peat and muck 8 to 14 feet thick near Lake Okeechobee. The best soils are deep mucks found in a narrow zone along the lakeshore, where a dense tangle of custard apple, or papaw, and moonflower (a morning glory) once grew.

Climate. The climate of the glades is tropical savanna or subtropical and is influenced strongly by the southeast trade winds. Monthly mean temperatures range from 63° F (17.2° C) to 82° F (27.8° C), though winter frosts occur on rare occasions. Rainfall averages over 55 inches (1,400 millimetres) annually, with 75 percent coming between June and October. In winter and spring the glades can be so dry that water disappears into the underlying porous rock.

Wildlife. The mild climate and usual abundance of water provide an environment for myriad birds, particularly such wading birds as herons, egrets, and ibis, as well as for many species of snakes, turtles, and, best known of all, alligators. The "hammocks" served as shelter for deer, wildcats, panthers, bears, smaller mammals, and numerous reptiles. Drainage in the glades has altered the habitats of many species, extending them, as in the case of deer, but shrinking them for water-dependent creatures. An integral part of the ecosystem is a rich variety of insect life.

The Indian inhabitants. The vast areas of open saw grass were used only as passage for dugout canoes and as hunting and fishing territory. The "hammocks," however, were sometimes settled or used as garden sites. Mounds in the vicinity of Belle Glade indicate long-time occupance there. Calusa peoples penetrated from the Gulf Coast, but little colonization within the glades resulted. Adversely affected by European contacts, the Calusa were largely gone by 1800, although the amalgam of refugee Indian groups that became known as Seminole may have absorbed the last vestiges of the Calusa during the early 19th century.

Adaptation to Everglades living

The Seminole found sanctuary in the swamps and marshes because the white man did not covet the glades at the time, and they adapted in several ways. They developed the "chikee," a dwelling without walls, made of a log framework with a thatched roof over a raised platform, that assured maximum ventilation. They wore few clothes and greased their bodies against insect attack. Compromising between agriculture and a gathering economy, they planted corn, beans, melons, and squashes on patches of higher ground, but gathered nuts, greens, and palmetto hearts. The bulbous roots of the coontie plant were the source of a starchy flour, and hunting and fishing provided much of their sustenance.

Of the 1,000 or more Seminole in Florida in the 1970s, scarcely 200 lived within the Everglades. Some lived along the Tamiami Trail or other highways and sold goods or services to travellers and sportsmen. Several villages were open to tourists for a fee, and some were established for that purpose. A few worked as farmhands, at least part of the year, in the Okeechobee farming districts. Though generally these people long resisted cultural change, its impact was revealed in the 1970s in varying degrees.

Development of the Everglades. After the Seminole Indian Wars, which occurred sporadically from 1817 to 1858, interest in the Everglades centred upon exploitation of its wildlife, especially the heron and egret for their feathers and the alligator for its hide. Drastic reductions in wildlife numbers led to legislation after 1920 that protected "plume birds"; more recently, alligator hunting was similarly restricted.

Drainage remained the principal focus of engineering in the glades for many years. The Central and Southern Florida Flood Control District, established in 1947, has emphasized water control. The storage capacity of Lake Okeechobee has been increased behind a larger levee, three diked water-conservancy areas have been constructed along the eastern edge of the glades, and all are linked with an enlarged canal system and a battery of pumping stations.

Agricultural exploitation

A system of canals and lateral ditches to control Lake Okeechobee has converted about 500,000 acres (200,000 hectares) of glades land, about one-fifth of the total, to agricultural use. Muck soils were being cultivated by 1900, but early attempts to farm peat lands were unsuccessful. The discovery, in 1927, that the addition of chemical trace elements made the peat soils amazingly

productive and the development of subsoil channelling were key factors in the growth of the Everglades farming district, which, as the major supplier of many garden vegetables for Northern markets, has come to be known as the "Vegetable Kingdom." Two or three crops a year are grown, and land values are extremely high. Sugarcane growing and milling are also important. Though farms are large and highly mechanized, many labourers are needed during the winter and spring harvests; about 90 percent of the migratory labour used is Negro.

To stabilize the farming economy and utilize sugar-mill wastes, beef cattle first became important in the 1950s. Succulent grasses were planted in carefully drained and fenced pastures, and frequent spraying was necessary to combat insects.

In addition to agriculturally oriented activities, sport fishing has been facilitated by highway construction, and Everglades National Park, established in 1947 to protect wildlife habitats in the central and southern glades, attracts increasing numbers of visitors. A boon for the conservationists is the fact that oil drillers have found brine so troublesome a by-product that large-scale exploitation has been abandoned.

Prospects. On the other hand, reclamation of land in the Everglades has accentuated problems of drought during dry periods, such as that in 1970–71, yet has proved inadequate in times of abundant water. In fact, the entire regional climate may have been altered by removal of water and its stabilizing effects. Numerous muck and saw-grass fires have had disastrous effects, particularly upon wildlife habitats. The drainage of organic soils has caused sinking, and cultivation has led to accelerated oxidation of soils and to wind erosion. The average loss of topsoil from combined causes is about one foot per year, and the rate during the first years of cultivation is even higher. Subsoil drainage becomes impossible in soils less than three feet deep, and, unless new factors are introduced, it is estimated that by the year 2000 about 85 percent of the glades farmland will have become uncultivable.

Problems of ecological balance

Water control is complicated by conflicting demands: the farmer wants both irrigation and drainage; the wildlife manager needs optimum water levels for the diverse ecosystems of plants and animals, including those of Everglades National Park; and Miamians require fresh water. Conflicts of interest also arise when there are proposals for construction of an oil pipeline, an interstate highway, a jetport to serve Miami, or the exploitation of glades petroleum. The total impact of such developments upon the fragile environment of the Everglades is being more carefully weighed than in the past.
