Occasionally a fertilized egg fails to reach the uterus, implanting and beginning to develop elsewhere. This outcome is called an ectopic or extra-uterine pregnancy. The commonest ectopic site is the uterine tube, but the peritoneum lining the abdominal cavity and even the interior of the ovary are also involved, though rarely. The unsuitability of all these sites for continued development usually leads to early death and resorption of the embryo.

Placentation. The irregular strands of invasive syncytial trophoblast constitute a first stage in the formation of true villi (which form part of the placenta and are briefly described below). Primitive connective tissue soon lines the interior of the blastocyst wall, and this complex (trophoblast and connective tissue) is then named the chorion. Connective tissue promptly grows into the trophoblastic strands, and blood vessels develop in the tissue. The result is the production of many chorionic villi, each resembling a tiny, branching bush (Figure 1J, Ka).

In the fourth week of development, the essential arrangements have been established that make possible those physiological exchanges between mother and fetus that characterize the remainder of pregnancy. The deepest embedded portion of the chorionic wall becomes the so-called chorionic plate of the developing placenta. From the plate extend the main stems of chorionic villi, which give off progressively subdividing branches (Figure 1N, O). In general, the side branches are free, whereas apical ones tend to attach to the maternal tissue and serve as anchors. The villous trees occupy a labyrinthine space between the villi that was created by erosion of the uterine lining. Trophoblast not only covers the chorionic plate and its villi but also spreads like a carpet over the eroded surface of the maternal tissue.

Tapped uterine arteries open into the trophoblast-lined intervillous space, their blood bathing the branches and twigs of the villous trees as it circulates among them. This blood drains from the intervillous space through similarly tapped veins. Arterial blood of the embryo, and later fetus, passes through vessels of the umbilical cord to the chorionic plate. Thence it is distributed to the villous stems, branches, and twigs through vessels in their connective-tissue cores. Return of this blood to the fetus is by a reverse route.

The circulation of maternal blood through the intervillous space is wholly separate from fetal blood coursing through the chorion and its villi. Communication between the two is solely by diffusive interchange. The barrier between the two circulations consists of the trophoblastic covering of villi, the connective tissue of the villous cores, and the thin lining of the capillaries that are contained in the villous cores. The placenta serves the fetus in several ways, most of which involve interchanges of materials carried in the bloodstreams of the mother and fetus. These functions are of the following kinds: (1) nutrition, (2) respiration, (3) excretion, (4) barrier action (*e.g.*, prevention of intrusions by bacteria), and (5) synthesis of hormones, certain foodstuffs, and enzymes. For some functional details and for a description of the mature, expelled placenta, see PREGNANCY.

Functions of the placenta

EXTRA-EMBRYONIC MEMBRANES

The way in which the encapsulating membrane of the blastocyst becomes the chorion, and the most deeply embedded part of it becomes the fetal placenta, has already been described. There are still other important extra-embryonic membranes that develop from those portions of the inner cell mass of the blastocyst that are not directly involved in becoming an embryo.

Yolk sac. Cells split off from the inner cell mass of the blastocyst and fashion themselves into a primitive yolk

sac (Figure 1J, Ka). The roof of the sac then folds into a tubular gut, whereas the remainder becomes a vascularized bag that attains the size of a small pea (Figure 1M). In other vertebrates, such as amphibians and birds, the yolk sac is large and contains a store of nutritive yolk. But in man and other true mammals there is practically none. A slender neck, the yolk stalk, soon connects the rapidly elongating gut with the fast growing yolk sac proper. The stalk detaches from the intestine early in the second month, but the shrunken sac commonly persists and can be found in the expelled afterbirth.

Amnion. A cleft separates the outermost cells of the inner cell mass of the blastocyst from the remainder, which then becomes the embryonic disk (Figure 1H). The split-off, thin upper layer is the amnion, which remains attached to the periphery of the embryonic disk. As the disk folds into a cylindrical embryo, the amniotic margin follows the underfolding, and its line of union becomes limited to the ventral (frontward) body wall, where the umbilical cord attaches (Figure 1P, Q). The amnion becomes a tough, transparent, nonvascular membrane that gradually fills the chorionic sac and then fuses with it (Figure 1N, O). At the end of the third month of pregnancy, the nonplacental extent of this nearly exposed double membrane comes into contact with the lining of the uterus elsewhere. Fusion then obliterates the uterine cavity, which has been undergoing progressive reduction in size. For the remainder of pregnancy the only cavity within the uterus is that of the fluid-filled amniotic sac.

Clear, watery fluid fills the amniotic sac. The embryo is suspended in this fluid and thus can maintain its shape and mold its body form without hindrance. Throughout pregnancy the amniotic sac serves as a water cushion, absorbing jolts, equalizing pressures, and permitting the fetus to change posture. At childbirth it acts as a fluid wedge that helps dilate the neck of the uterus. When the sac ruptures, about a quart of fluid escapes as the "waters." If the sac does not rupture or if it covers the head at birth, it is known as a caul.

Allantois. The allantois, a tube of endoderm (the innermost germ layer), grows out of the early yolk sac in a region that soon becomes the hindgut. The tube extends into a bridge of mesoderm (the middle germ layer) that connects embryo with chorion and will become incorporated into the umbilical cord (Figure 1P, Q). The human allantoic tube is tiny and never becomes a large sac with important functions, as it does in reptiles, birds, and many other mammals. In the second month it ceases to grow, and it soon is obliterated. Blood vessels, however, develop early in its mesodermal sheath, and these spread into the chorion and vascularize it. Throughout pregnancy they will keep the embryo in close relationship with the mother's uterine circulation.

Umbilical cord. As the ventral body wall closes in, the yolk stalk and allantois are brought together, along with their mesodermal sheaths and blood vessels (Figure 1P, Q). Enclosing everything is a wrapping of amnion. In this manner a cylindrical structure, the umbilical cord, comes to connect the embryo with the placenta (Figure 1N, O). It will serve the embryo and fetus as a physiological lifeline throughout the period of pregnancy. The mature cord is about 1.3 centimetres (0.5 inch) in diameter, and it attains an average length of nearly 50 centimetres (two feet).

GASTRULATION

Formation of the three primary germ layers

The inner cell mass, attached to the deep pole of the implanted blastocyst, is sometimes called the embryoblast, since it supplies the materials used in the formation of an embryo. The cellular mass flattens and enters into the process of gastrulation, through which the three primary germ layers segregate and the gastrula stage, the next advance after the blastula, begins to take form. First, cells facing the cavity of the blastocyst arrange into a layer named the endoderm (Figure 1H, I). The thick residual layer, temporarily designated as epiblast, is the source of a definitive uppermost sheet, the ectoderm, and an intermediate layer, the mesoderm. In this second phase of gastrulation, some cells of the epiblast migrate to the midline position, then turn downward and emerge beneath as mesoderm. Such cells continue to spread laterally, right and left, between the endoderm and the residue of epiblast, which is now definitive ectoderm (Figure 1Kb).

The site where the migratory mesodermal cells leave the epiblast is an elongated, crowded seam known as the primitive streak (Figure 1Ka). Similar migrating cells produce a thick knob at one end of the primitive streak. Their continued forward movement from this so-called primitive knot produces a dense band that becomes the rodlike notochord.

The germ layers are not segregated sheets whose cells have predetermined, limited capacities and inflexibly fixed fates in carrying out organ-building activities. Rather, the layers represent advantageously located assembly grounds out of which the component parts of the embryo emerge normally, according to a master constructional plan that assigns different parts to definite spatial positions and local sites. Thus, although the germ layers have developmental potencies in excess of their normal developmental fates, their ordinary participation in organ forming does not deviate from a definite, standard program.

The derivatives of the primary germ layers can best be presented in tabular form. In naming the germ-layer origin of an organ, only the principal functional tissue is designated. In a few instances, such as the suprarenal (adrenal) glands and the teeth, a compound organ has important parts of different origin.

Table 1: Derivatives of Primary Germ Layers

ectoderm	mesoderm	endoderm
epidermis	epithelium of:	epithelium of:
cutaneous derivatives	circulatory system	pharynx
epithelium of:	spleen; lymph nodes	thyroid; thymus
mouth; oral glands	urogenital system	parathyroid
nasal passages	body cavities	digestive tube;
sense passages	connective tissues;	liver; pancreas
central nervous system	blood; bone marrow	larynx; trachea; lungs
peripheral nervous system	muscular tissues	urinary bladder; urethra
hypophysis;	skeletal tissues	vestibule; vagina
suprarenal medulla	suprarenal cortex	

GROWTH AND DIFFERENTIATION

Growth. Growth is an increase in size, or bulk. Cell multiplication is fundamental to an increase in bulk but does not, by itself, result in growth. It merely produces more units to participate in subsequent growing. Growth is accomplished in several ways: (1) Most important is synthesis, by which new living matter, protoplasm, is created from available foodstuffs. (2) Another method utilizes water uptake; a human embryo of the early weeks is nearly 98 percent water, while an adult is 70 percent fluid. (3) A third method of growth is by intercellular deposition; cells manufacture and extrude such nonliving substances as jelly, fibres, and the ground substance of cartilage and bone. Through these activities a newborn baby is several thousand million times heavier than the zygote from which it came.

Ways in which growth is accomplished; abnormal growth patterns

It is obvious that uniform growth throughout the substance of a developing organism would merely produce a spherical cellular mass. Local diversities in form and proportions result from differential rates of growth that operate in different regions and at different times. The particular program of starting times and growth rates, both externally and internally in the human embryo, constitutes its characteristic growth pattern. Abnormal growth occurs occasionally, and growth may be excessive or deficient. Also, such departures may be general or local, symmetrical or asymmetrical. General gigantism usually starts before birth, and the oversized baby continues to grow at an accelerated rate. On the other hand, an existing hereditary predisposition may not be aroused into action until some time during childhood. In a reverse manner, general dwarfism may exist before birth, the individual continuing to grow slowly and stopping at the usual time. Another type is normal in size at birth,

grows normally for a while, and then comes to a premature arrest. See also DEVELOPMENT, HUMAN; BIRTH DEFECTS AND CONGENITAL DISORDERS.

Differentiation. In a developing organism, differentiation implies increasing structural and chemical complexity. One kind of differentiation concerns changes in gross shape and organization. Such activities, related to molding the body and its integral parts into form and pattern, comprise the processes called morphogenesis. The processes of morphogenesis are relatively simple mechanical acts: (1) cell migration; (2) cell aggregation, forming masses, cords, and sheets; (3) localized growth or retardation, resulting in enlargements or constrictions; (4) fusion; (5) splitting, including separation of single sheets into separate layers, formation of cavities in cell masses, and forking of cords; (6) folding, including circumscribed folds that produce inpocketings and outpocketings; (7) bending, which, like folding, results from unequal growth.

Morphogenesis and histogenesis

A second kind of differentiation refers to progressive changes occurring in the substance and structure of cells, whereby different kinds of tissues are created. These changes, and the synthetic processes underlying them, constitute histogenesis. The zygote contains all the essential factors for development, but they exist solely as an encoded set of instructions localized in the genes of chromosomes and bearing no direct physical relationship to the future characteristics of the developing embryo. During histogenesis these instructional blueprints are decoded and transformed, through cytoplasmic syntheses, into the several types and subtypes of tissues that are the structural and functional units of organs. At first, the cells of each germ layer lack an identifiable shape and are similar in chemical composition, but an invisible type of chemical differentiation soon enters. After the elaboration of specific enzyme patterns and syntheses, certain groups of cells progressively assume distinctive characters that permit their fates to be recognized. Such early stages in definite lines of differentiation of cells are often designated by the suffix "-blast" (*e.g.*, myoblast; neuroblast).

The emerging cell types are discrete entities, without intermediates; for example, a transitional form between a muscle cell and a nerve cell is never seen. Neither can different, local parts of a cell carry out different types of tissue specialization, such as nerve at one end and muscle at the other end; nor can a cell, once fully committed to a particular type of specialization, abandon it and adopt a new course.

"Dedifferentiation"; the four types of tissue

Under certain conditions, differentiated cells may reverse their course and return to a simpler state. Thus, under a changed environment, cartilage may lose its matrix, and its cells may come to resemble the more primitive tissue from which it arose. Nevertheless, despite such reversal and apparent simplification ("dedifferentiation"), these cells retain their former histological specificity. Under suitable environmental conditions they can differentiate again but can only regain their previous definitive characteristics as cartilage cells.

The final result of histogenesis is the production of groups of cells similar in structure and function. Each specialized group constitutes a fundamental tissue. There are four main types of such tissues: (1) Each of the three germ layers gives rise to sheetlike epithelia, which cover surfaces, line cavities, and are frequently glandular. (2) Ectoderm also forms the nervous tissues. (3) Mesoderm also produces the muscular tissues. (4) It also differentiates into blood and the fibrous connective tissues (including two further specialized types, cartilage and bone).

THE ACQUISITION OF EXTERNAL FORM

At the end of the second week, the embryonic region is a nearly circular plate within its well-embedded, differentiating chorionic sac (Figure 1I). This embryonic disk consists of two layers (epiblast and endoderm), with a third layer (mesoderm) just starting to spread between them. A hollow, dome-shaped amnion sac attaches to the margin of the upper layer of the disk, and a hollow yolk sac is similarly continuous with the lower layer. A broad cellular bridge attaches the complex to the chorion.

Early in the third week the embryonic disk has enlarged and become pear-shaped in outline, and a well-formed primitive streak occupies the midline of its caudal (hind) half, which is narrower. Cells from the epiblast are passing through the streak and spreading laterally in both directions beneath the uppermost layer, now ectoderm (Figure 1Ka, Kb). In this way the embryonic disk becomes three layered, and the gastrula stage of development comes to an end. At the middle of the week a thickening, the head process, is extending forward from a knoblike primitive knot located at the head end of the primitive streak. These linear thickenings define the median plane of the future embryo and thus divide the embryonic disk into precise right and left halves.

Toward the end of the week the disk elongates and becomes slipper shaped in outline; a slight constriction demarcates it from the attached yolk sac. Growth has lengthened the region ahead of the now receding primitive streak. Here, in the midline, the ectoderm bears a definite gutter-like formation called the neural groove; it is the first indication of the future central nervous system. Beneath the groove the mesodermal head process presently rounds into an axial rod, the notochord, that serves as a temporary "backbone." By the end of the third week a head fold, paired lateral body folds, and a tail fold become prominent, demarcating a somewhat cylindrical embryo from the still broadly attached yolk sac (Figure 1L). The neural folds, flanking the neural groove, converge and begin to meet midway of their lengths, thereby producing a neural tube at that level. Mesoderm, alongside the notochord, begins to subdivide into paired blocks called somites, and the outlines of the somites show externally. From them, muscles and vertebrae will differentiate later. This stage, when the embryo is fashioning a neural tube, is often designated as a neurula.

In the fourth week the embryo goes beyond the external characteristics of vertebrates in general and becomes recognizable as a mammal. The week is marked by profound changes, during which the embryo acquires its general body plan. There is an increase in total length from about two to five millimetres, but size is quite variable among smaller specimens. Better correlated with the degree of development is the number of mesodermal somites, which attain their full number of about 42 during the fourth week. Some of the head of an early embryo arises from the embryonic disk in front of the primitive knot. But as the primitive streak shortens and its caudal retreat continues, such structures as the neural tube and notochord are added progressively in the wake of that retreat, and additional somite pairs also appear in steady succession.

Factors in formation of early embryo

The most important manoeuvre in the establishment of general body form is the transformation of the flat embryonic disk into a roughly cylindrical early embryo, which is attached to the yolk sac by a slender yolk stalk (Figure 1M). Three factors cooperate in producing this change: (1) There is more rapid expansion of both the embryonic area and the yolk sac than in the region joining the two. The enlarging embryonic area at first buckles upward and then overlaps the more slowly growing margin. Since growth is particularly rapid at the future head end and tail end, the embryo becomes elongate. (2) In conjunction with this overgrowth there is important underfolding, again most pronounced at the front and hind ends. Underfolding is produced by differential elongation in the regions of the brain and tail bud. Conspicuous is the change in the future cardiac (heart) and foregut region, which swings beneath the brain as on a hinge. (3) A certain amount of true constriction, through growth, purses all of these parts at the site of the future umbilicus.

Throughout the entire period when the body and its parts are being laid down, developmental advances tend to appear first at the head end and then progress tailward. For this reason, many structures that extend along the body for a distance show a gradation in development. The size advantage gained initially by the head end of the embryo is relinquished very slowly. Even in an infant the relatively large head and long arms are striking. A further tendency toward progressively graded development

occurs from the middorsal line in a lateral (sideward) and then ventral (frontward) direction. All such relations are the visible expressions of stages in growth and differentiation.

Early in the fourth week the cylindrical shape of the embryo is plain, even though the folding-off process is far from complete (Figure 1M). The neural tube is still open near both ends, and at the head end the broader neural folds indicate the future brain and even its three primary divisions. A pronounced bulge beneath the brain region denotes where the heart is forming precociously in order to institute a necessary, prompt circulation through the placenta.

During the middle and late days of the fourth week there are marked advances (Figure 2A). Accelerated growth along the dorsal region bends the total body length progressively until the embryo assumes a striking C-shape, with the tips of the head and tail not far apart. Continued growth and underfolding close in much of the ventral side of the embryo, so that a free head and upper trunk, and a lower trunk and a prominent tail, are easily recognizable. Forebrain, midbrain, and hindbrain can be identified, largely because of a sharp bend in the midbrain. Local outgrowths from each side of the forebrain produce stalked eye cups, and a pair of inpocketings of the ectoderm alongside the hindbrain sink beneath the surface as otic vesicles, forerunners of the inner ears. Bulges indicative of the heart and liver are prominent. Formations called branchial arches, reminiscent of the gill arches of fishes and aquatic amphibians, become conspicuous in the future jaw–neck region. Paired swellings ("buds") off the trunk foretell the locations of the upper and lower limbs.

Changes in the fifth to eighth weeks

A five-week embryo is about eight millimetres (about ⅓ inch) long (Figure 2B, C), whereas at six weeks the length is about 13 millimetres (Figure 2D). New external features are olfactory pits at the tips of the bent head. An umbilical cord becomes a definite entity, its proximal end occupying a low position on the abdominal wall. The sharply bent head joins the rest of the body at an acute angle. The first pair of branchial arches branch Y-fashion into maxillary and mandibular processes (primitive upper and lower jaws). The external ears are forming around the paired grooves located between each half of the

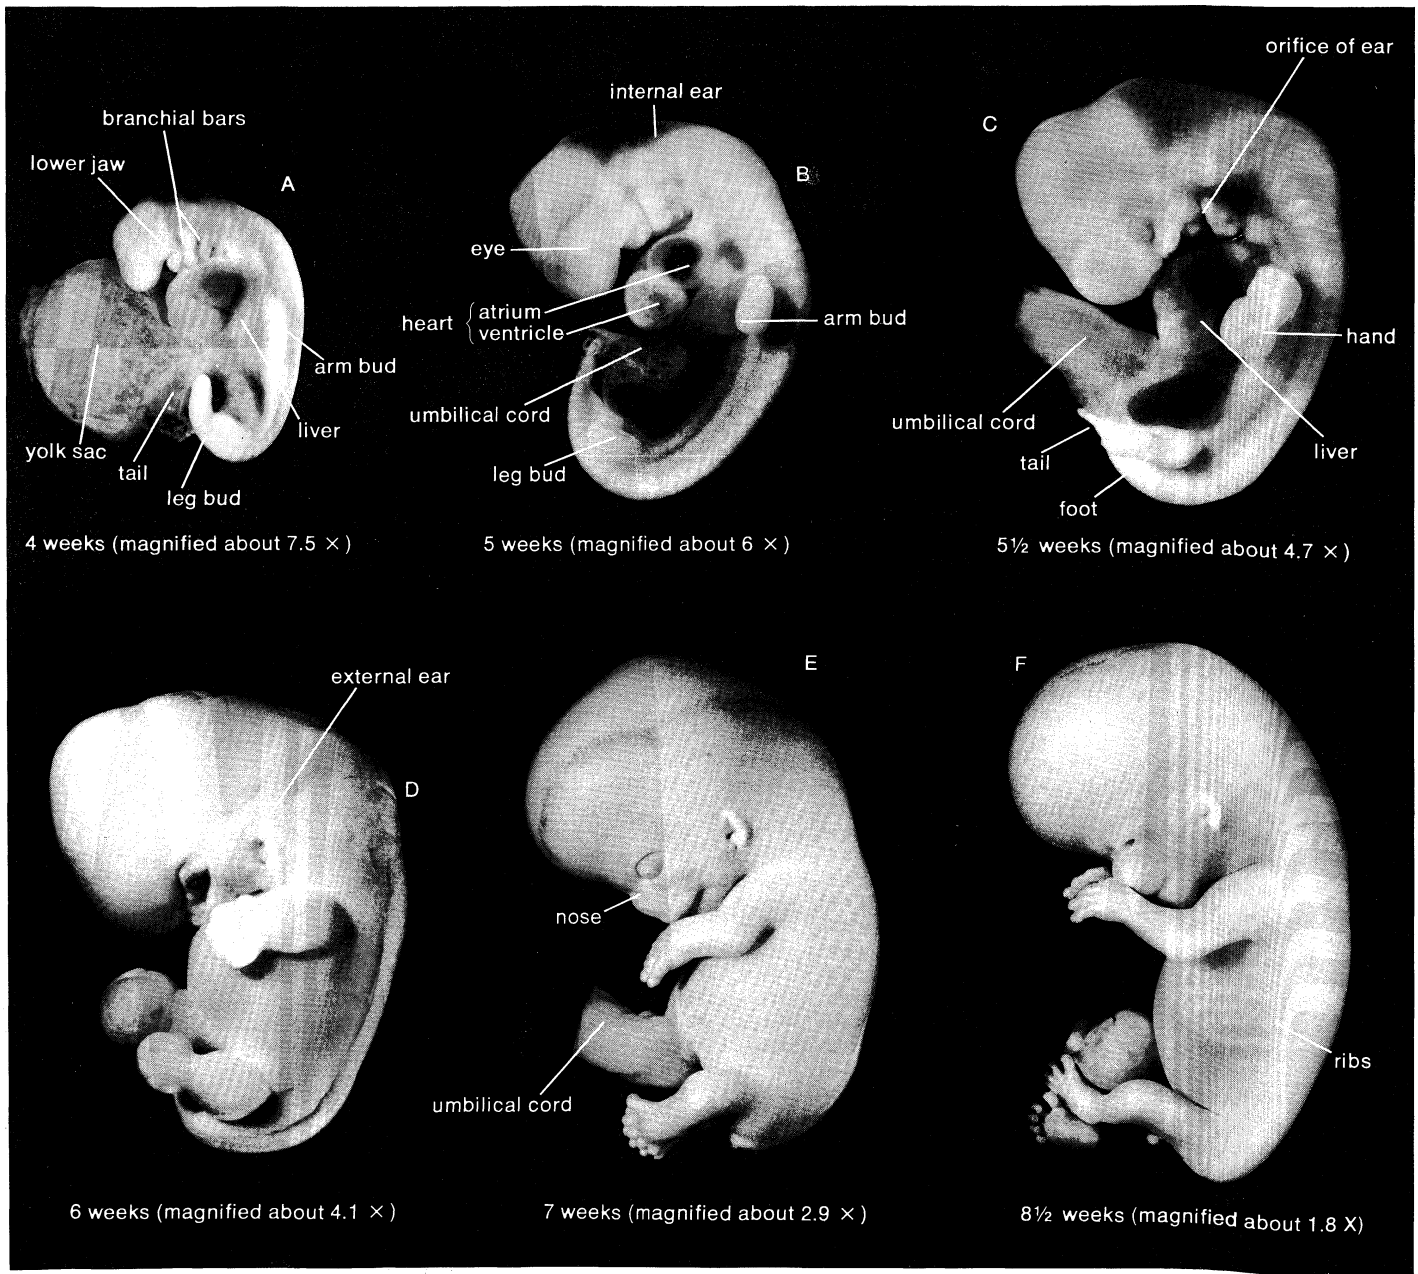

Figure 2: Human embryos from four to 8½ weeks.

mandible and each second branchial arch. The heart, which was previously the chief ventral prominence, now shares this distinction with the rapidly growing liver. Limb buds have elongated markedly and become flattened at their outer ends. A constriction on each bud separates a paddle-like hand plate or foot plate from a cylindrical segment attached to the body wall. Predictably, the upper limbs are somewhat further advanced than the lower pair.

In the latter weeks of the second month, developmental changes advance from those that distinguish primates to a state that is recognizably human (Figure 2E). At the end of the second month (30 millimetres', or 1.2 inches', length) the stage of the embryo ends; henceforth, until birth, "fetus" is the preferred term.

In the seventh and eighth weeks the head becomes more erect and the previously curved trunk becomes straighter (Figure 2E, F). The heart and liver, which earlier dominated the shape of the ventral body, yield to a more evenly rounded chest–abdomen region. The tail, which at an earlier time was one fifth of the embryo's length, becomes inconspicuous both through actual regression and through concealment by the growing buttocks. The face rapidly acquires a fairly human appearance; eyes, ears, and jaws are prominent. The eyes, previously located on the sides of the head, become directed forward; the nose lacks a bridge and so is of the "pug" type, with the nostrils directed forward instead of downward. A mandibular branch of each Y-shaped branchial arch combines with its mate to form the lower jaw. The maxillary branch on each side joins an elevation on the medial (inner) side of the corresponding nostril to produce the more complicated upper jaw. Branchial arches, other than those forming the jaws and external ears, are effaced through incorporation into an emerging, recognizable neck. Limbs become jointed, and the earlier hand plates and foot plates differentiate terminal digits. Primitive external genitalia appear, but in a nondistinctive, sexless condition.

Almost all of the internal organs are well laid down at the end of eight weeks, when the embryo is little more than 25 millimetres (one inch) long. The characteristic external features are established, and subsequent growth merely modifies existing proportions without adding new structure. Similarly, the chief changes undergone by internal organs and parts are those of growth and tissue specialization. At eight weeks the neuromuscular mechanism attains a degree of perfection that permits some response to delicate stimulation.

Development from the third month to birth

During the third month the young fetus clearly resembles a human being, although the head is disproportionately large (Figure 1O). The previous protrusion of much of the intestine into the umbilical cord is reduced through the return of its loops into the abdomen. The ears rise to eye level and the eyelids fuse shut. Nails begin forming; ossification (bone-forming) centres appear in most of the future bones; and the sex of external genitalia becomes recognizable. (In this paragraph, and in the next two, the months are lunar months, of 28 days).

At four months individual differences between the faces of fetuses become distinguishable. The face is broad but the eyes are now less widely separated. The umbilical cord attaches higher on the abdominal wall; this location is above an expanding region between the cord and the pubis (front bones of the pelvis) that scarcely existed previously.

At five months downy hairs (lanugo) cover the body, and some head hairs appear. The skin is less transparent. Fetal movements ("quickening") are felt by the mother. At six months eyebrows and eyelashes are clearly present. The body is lean, but its proportions have improved. The skin is wrinkled. At seven months the fetus resembles a dried-up old person. Its reddish, wrinkled skin is smeared with a greasy substance (vernix caseosa). The eyelids reopen. At eight months fat is depositing beneath the skin. The testes begin to invade the scrotum. At nine months the dull redness of the skin fades, and wrinkles smooth out. The body and limbs become better rounded.

At full term (38 weeks) the body is plump and proportions are improved, although the head is large and the lower limbs are still slightly shorter than the upper limbs. The skin has lost its coat of lanugo hair, but it is still smeared with vernix caseosa. Nails project beyond the finger tips and to the tips of toes. The umbilical cord now attaches to the centre of the abdomen. The testes of males are usually in the scrotum; the greater lips of the female external genitalia, which previously gaped, are now in contact. Cranial bones meet except at some angular junctions, or "soft spots."

The average time of delivery is 280 days from the beginning of the last menstrual period, whereas the duration of pregnancy (age of the baby) is about 266 days (38 weeks). Pregnancy may extend to 300 days, or even more, in which case the baby tends to be heavier. Premature babies born under 27 weeks of age rarely survive, whereas those more than 30 weeks old usually do survive. For the events of delivery, see PARTURITION, HUMAN.

Table 2: Age, Size, and Weight

age from date of conception (calendar months)	sitting height		weight	
	mm	in.	g	lb
Two	28	1	2.25	.75 oz
Three	75	3	25	1 oz
Four	135	5.3	170	6 oz
Five	185	7.3	440	14 oz
Six	225	9	820	1.75 lb
Seven	270	10.6	1,380	3 lb
Eight	310	12.2	2,220	5 lb
Nine	360	14.2	3,150	7 lb

Abnormal development

MULTIPLE BIRTHS

It is both unusual and abnormal for the human species to produce more than one offspring at a time. "Twins" and "twinning" are used as general terms to designate any number of multiple births, since the same basic principles apply.

Fraternal and identical twins

Fraternal twins stem from multiple ovulations in the same cycle. Each oocyte develops singly in a separate follicle, is shed and fertilized individually, develops within its own chorionic sac, and forms an individual placenta. In some instances, two blastocysts implant close together and the expanding placentas meet and fuse. In such double placentas, however, the two blood circulations rarely communicate. The word dizygotic technically designates two-egg twins. Such pairs obviously are independent in sex determination and bear no more resemblance (other than that due to their identical age) than do other children of the same parents. Properly speaking, they are merely littermates. Nearly three-fourths of all American twins are dizygotic, whereas the Japanese ratio is only one-fourth. A tendency toward such multiple births exists in some family lines.

Wholly different are those true twins who are always of the same sex and are strikingly similar in physical, functional, and mental traits. Such close identity is enforced by their derivation from a single ovulated and fertilized egg, and hence by their acquisition of identical chromosomal constitutions. This twin type is appropriately designated as monozygotic. Three-fourths of such pairs develop within a common chorionic sac and accordingly share a common placenta; one-fourth have individual sacs and placentas. The latter condition results from a mishap before implantation, when the cleavage cells separate into two groups and then become individually implanting blastocysts. There is no discernible hereditary tendency toward the production of monozygotic twins.

Several atypical processes involving the inner cell mass or embryonic plate can produce separate embryos within a single sac: (1) The inner cells of a blastocyst may segregate into two inner cell masses. (2) Somewhat later in time, two embryonic axes may become established on a single embryonic disk. (3) A single axis may subdivide by fission or budding. (4) Duplication of any sort may combine with secondary subdivision; the famous Dionne

quintuplets are believed to have followed this sequence, which is also normal for the regular quadruplets of the Texas armadillo.

The abnormal nature of monozygotic twinning is emphasized when the two individuals are conjoined as a "double monster." The degree of union varies from slight to extensive, and the possession of a single or double set of internal organs depends on the intimacy of fusion at any particular level. Union occurs by the heads, upper trunks, or lower trunks; the joining may be by the dorsal, lateral, or ventral surfaces. Sometimes there is a marked disparity in the size of the two components, and in such instances the smaller twin is called a parasite. Conjoining results from divergent growth at the front or hind end of the emerging primitive axis of an embryo, or at both ends.

FETAL DEVIATIONS

Human embryos are subject to disease, abnormal development, and abnormal growth. Decline and death can occur at any stage of embryonic and fetal life, but since most deaths occur in the first two or three weeks of development they usually escape notice. Probably little more than half of all zygotes reach full-term birth. Most abnormalities resulting from faulty development originate within the first seven weeks of pregnancy, before the prospective mother is surely aware of her condition. Abnormalities that do occur in living infants tend toward the milder types, since the severe mishaps commonly terminate development before birth.

Deep-rooted folklore maintains that a pregnant woman may "mark" her baby through incurring physical injuries or becoming subjected to horrors or repulsive sights. Since there are no nervous connections between mother and fetus, such beliefs lack a foundation. Moreover, practically all of the alleged causative experiences occur long after the "related" abnormalities have been established in the embryo.

Defective health of the mother can, in some instances, become a cause of the physical impairment or death of a fetus. Certain infectious diseases, for example, may result in fetal injury; such related causative organisms can be a virus (German measles), a spirochetal micro-organism (syphilis), or a protozoon parasite (toxoplasmosis). Also, placental disorders, malformations of the mother's reproductive organs, and inadequate functioning of her endocrines may provide an unfavourable environment for normal development. Birth itself imposes the risk of oxygen deficiency or other injury; either may result in some malfunctioning of the brain.

TERATOLOGY

Incidence, causation, and types of abnormality

Teratology is concerned with all features of abnormal generation and development of the embryo (embryogenesis) and their end products. The incidence of defective development is high. One infant in 14 that survive the neonatal period bears an abnormality of some kind and degree, and half of these babies have more than one malformation. Internal, concealed defects are more numerous than external ones, and some defects do not become apparent until childhood. One baby in 40 is born with a structural defect that needs treatment. Some types of abnormality are commoner in males (*e.g.*, pyloric stenosis, the narrowing of the opening between the stomach and the intestine), while other types predominate in females (*e.g.*, dislocated hip). Besides the obvious derangements of a gross nature, there are other aberrations at a submicroscopic, molecular level that are called inborn errors of metabolism. In these an enzyme deficiency blocks the normal course of intermediary metabolism and results in abnormal chemical functioning. Such errors involve proteins, carbohydrates, lipids, and pigments. The abnormal products may be stored or excreted. For some other information on teratology, see BIRTH DEFECTS AND CONGENITAL DISORDERS.

Important among causes of abnormalities are hereditary factors. Such include gene mutations, which may become Mendelian dominants (*e.g.*, fused fingers, which need be inherited from only one parent to appear in the offspring), recessives (*e.g.*, albinism, which does not become evident unless its gene is inherited from both parents), or sex-linked factors (*e.g.*, hemophilia, which becomes manifest in males). Besides the heritable defects, whose possibilities of recurrence can be estimated, there are many genetic results that are due to chance, are not passed on, and do not occur in other offspring. An unequal distribution of chromosomes during meiosis, leading to abnormal assortments, occurs in somatic (nonsex) chromosomes (*e.g.*, mongolism) and in sex chromosomes (*e.g.*, Klinefelter's syndrome).

Environmental factors, both external and internal, are also important. Among physical agents, mechanical pressures or blows are no longer considered to be significant because of the protection supplied by the uterus and the fluid-filled amniotic sac. On the other hand, irradiation is a wholly effective physical agency, as experiments (and atomic bombing) have amply proved. Various chemical agents, used experimentally on pregnant animals, are highly teratogenetic (productive of physical defects within the uterus), and at least one drug (thalidomide) has demonstrated its potency on human embryos. Deficiencies of some fetal hormones are associated causally with gross bodily defects (*e.g.*, male hormone and false hermaphroditism, a condition in which the gonads are of one sex but some appearances suggest the other). Similarly, hormonal excess can be productive (*e.g.*, growth-promoting hormone and gigantism). Vitamin deficiencies are effective experimentally but are not factors in ordinary substandard maternal diets. The role of infectious agents has been mentioned previously. Immunity incompatibilities may exist between mother and fetus (*e.g.*, Rh blood factor and fetal hemolysis, the release of hemoglobin from red blood cells).

There appear to be several ways in which teratogenetic agents can affect susceptible embryonic cells. But whatever the manner of interference may be, the final result is probably either cell impairment or death or a changed rate of growth. Either of these measures puts local development out of step with adjoining parts and upsets the coordinated schedule of development.

Development of organs

ECTODERMAL DERIVATIVES

Origin of the skin

Integumentary system. The skin has a double origin. Its superficial layer, or epidermis, develops from ectoderm. The initial single-layered sheet of epithelial cells becomes multilayered by proliferation, and cells nearer the surface differentiate a horny substance. Pigment granules appear in the basal layer, at least, of all races. The epidermis of the palm and sole becomes thicker and more specialized than elsewhere. Cast-off superficial cells and downy hairs mingle with a greasy glandular secretion and smear the skin in the late fetal months; the pasty mass is called vernix caseosa. The deep layer of the skin, or dermis, is a fibrous anchoring bed differentiated from mesoderm. In the later fetal months the plane of union between epidermis and dermis becomes wavy. The permanently ridged patterns are notable at the surface of the palm and sole.

Nails, hairs, and skin glands

Nails develop in pocket-like folds of the skin near the tips of digits. During the fifth month specialized horny material differentiates in proliferating ectodermal cells. The resulting nail plate is pushed forward as new plate substance is added in the fold. Fingernails reach the finger tips one month before birth. Hairs, produced only by mammals, begin forming in the third month as cylindrical pegs that grow downward from the epidermis into the dermis. Cells at the base of the peg proliferate and produce a horny, pigmented thread that moves progressively upward in the axis of the original cylinder. This first crop of hairs is a downy coat named lanugo. It is prominent by the fifth month but is mostly cast off before birth. Unlike nails, hairs are shed and replaced periodically throughout life.

Sebaceous glands develop into tiny bags, each growing out from the epithelial sheath that surrounds a hair. Their cells proliferate, disintegrate, and release an oily secretion. Sweat glands at first resemble hair pegs, but

the deep end of each soon coils. In the seventh month an axial cavity appears and later is continued through the epidermis. The mammary glands, peculiar to mammals, are specialized sweat glands. In the sixth week a thickened band of ectoderm extends between the bases of the upper and lower limb buds. In the pectoral (chest) region only, gland buds grow rootlike into the primitive connective tissue beneath. During the fifth month 15 to 20 solid cords foretell the future ducts of each gland. These later canalize and open into a pit that after birth elevates into a nipple. Until late childhood the mammary glands are identical in both sexes.

Mouth and anus. *Mouth.* The mouth is a derivative of the stomodeum, an external pit bounded by the overjutting primitive nasal region and the early upper and lower jaw projections. Its floor is a thin membrane, where ectoderm and endoderm fuse. Midway in the fourth week this membrane ruptures, making continuous the primitive ectodermal mouth and endodermal pharynx (throat). Lips and cheeks arise when ectodermal bands grow into the mesoderm and then split into two sheets. Teeth have a compound and relatively complicated origin, in which the cap of enamel develops from ectoderm, whereas the main mass of a tooth, the dentin, and the encrusting cementum about the root differentiate from mesoderm. For details, see TEETH AND GUMS, HUMAN. The salivary glands arise as ectodermal buds that branch, bushlike, into the deeper mesoderm. Berrylike endings become the secretory acini (small sacs), while the rest of the canalized system serves as ducts. The palate is described in relation to the nasal passages. A tiny pocket detaches from the ectodermal roof of the stomodeum and becomes the anterior, or frontward, lobe of the hypophysis, also called the pituitary. The anterior lobe fuses with the neural lobe of the gland (see below).

Anus. A double-layered, oval membrane separates the endodermal hindgut from an ectodermal pit, called the proctodeum, the site of the future anal canal and its orifice, the anus. Rupture at eight weeks creates a communication between the definitive anus and the rectum.

Origin, histogenesis, and morphogenesis of central nervous system

Central nervous system. Both the brain and the spinal cord arise from an elongate thickening of the ectoderm that occupies the midline region of the embryonic disk. The sides of this neural plate elevate as neural folds, which then bound a gutter-like neural groove (Figure 1L). Further growth causes the folds to meet and fuse, thereby creating a neural tube. The many-layered wall of this tube differentiates into three concentric zones, first indicated in embryos of five weeks. The innermost zone, bordering the central canal, becomes a layer composed of long cells called ependymal cells, which are supportive in function. The middle zone becomes the gray substance, a layer characterized by nerve cells. The outermost zone becomes the white substance, a layer packed with nerve fibres. The neural tube also is demarcated internally by a pair of longitudinal grooves into dorsal and ventral halves. The dorsal half is a region associated with sensory functioning and the ventral half with motor functioning.

The gray substance contains primitive stem cells, many of which differentiate into neuroblasts. Each neuroblast becomes a neuron, or a mature nerve cell, with numerous short branching processes, the dendrons, and with a single long process, the axon. The white substance lacks neuroblasts but contains closely packed axons, many with fatty sheaths that produce the whitish appearance. The primitive stem cells of the neural tube also give rise to nonnervous cells called neuroglia cells, with barrier and other functions.

Brain. The head end of the neural plate becomes expansive even as it closes into a tube. This brain region continues to surpass in size the remainder, or spinal cord region. Three enlargements are prominent, the forebrain, midbrain, and hindbrain. The forebrain promptly gives rise to two secondary expansions, called the telencephalon and the diencephalon. The midbrain, which remains single, is called the mesencephalon. The hindbrain produces two secondary expansions called the metencephalon and the myelencephalon.

The telencephalon outpouches, right and left, into paired cerebral hemispheres, which overgrow and conceal much of the remainder of the brain before birth. Late in fetal life the surface of the cerebrum becomes covered with folds separated by deep grooves. The superficial gray cortex is acquired by the migration of immature nerve cells, or neuroblasts, from their primary intermediate position in the neural wall. The diencephalon is preponderantly gray substance, but its roof buds off the pineal body, which is not nervous tissue, and its floor sprouts the stalk and neural (posterior) lobe of the pituitary. The mesencephalon largely retains its early tubular shape. The metencephalon develops dorsally into the imposing cerebellum, with hemispheres that secondarily gain convolutions clothed with a gray cortex. The myelencephalon is transitional into the simpler spinal cord. Roof regions of the telencephalon, diencephalon, and myelencephalon differentiate vascular choroid plexuses (including portions of the pia matter, or innermost brain covering, that project into the ventricles, or cavities, of the brain), which secrete cerebrospinal fluid.

Spinal cord. For a time the spinal cord portion of the neural tube tapers gradually to an ending at the tip of the spine. In the fourth month it thickens at levels where nerve plexuses, or networks, supply the upper and lower limbs; these are called the cervical and lumbosacral enlargements. At this time the spine begins to elongate faster than the spinal cord. As a result, the caudal (hind) end of the anchored cord becomes progressively stretched into a slender, nonnervous strand known as the terminal filament. Midway in the seventh month the functional spinal cord ends at a level corresponding to the midpoint of the kidneys. Both the brain and the spinal cord are covered with a fibrous covering, the dura mater, and a vascular membrane, the pia-arachnoid. These coverings differentiate from local, neighbouring mesoderm.

Histogenesis of peripheral nervous system

Peripheral nervous system. In general, each craniospinal nerve has a dorsal (posterior) root that bears a ganglion (mass of nerve tissue) containing sensory nerve cells and their fibres, and a ventral (anterior) root that contains motor nerve fibres but no nerve cells. Ganglion cells differentiate from cells of the neural crest, which is at first a cellular band pinched off from the region where each neural fold continues into ordinary ectoderm. Each of these paired bands breaks up into a series of lumps, spaced in agreement with the segmentally arranged mesodermal somites. Neuroblasts within these primordial ganglia develop a single stem and hence are called unipolar. From this common stem one nerve process, or projection, grows back into the adjacent sensory half of the neural tube; another projection grows in the opposite direction, helping to complete the dorsal root of a nerve. Neuroblasts of motor neurons arise in the ventral half of the gray substance of the neural tube. They sprout numerous short, freely branching projections, the dendrons, and one long, little-branching projection, the axon; such a neuron is called multipolar. These motor fibres grow out of the neural tube and constitute a ventral root. As early as the fifth week they are joined by sensory fibres of the dorsal root and continue as a nerve trunk.

Cells of the neural crest are versatile and differentiate into things other than sensory neurons. Among these variants are cells that encapsulate ganglion cells and others that become neurolemma cells, which follow the peripherally growing nerve fibres and ensheath them. The neurolemma cells cover some nerve fibres with a sheath of fatty substance called myelin.

Spinal nerves. Spinal nerves are sensorimotor nerves, with dorsal and ventral roots, as already described. A network called a brachial plexus arises in relation to each upper limb and a lumbosacral plexus in relation to each lower limb. The spine, elongating faster than the spinal cord, drags nerve roots downward, since each nerve must continue to emerge between the same two vertebrae. Because of their appearance, the obliquely coursing nerve roots are named the cauda equina, the Latin term for horse's tail.

Cranial nerves. Cranial nerves V, VII, IX, and X arise in relation to embryonic branchial arches but have origins similar to the spinal nerves. The olfactory nerves

(cranial nerve I) are unique in that their cell bodies lie in the olfactory epithelium (the surface membrane lining the upper parts of the nasal passages), each sending a nerve fibre back to the brain. The so-called optic nerves (II) are not true nerves but only tracts that connect the retina (a dislocated portion of the brain) with the brain proper. Nerves III, IV, VI, and XII are pure motor nerves that correspond to the ventral roots of spinal nerves. The acoustic nerves (VIII) are pure sensory nerves, each with a ganglion that subdivides for auditory functions and functions having to do with equilibrium and posture; they correspond to dorsal roots. Nerves X and XI are a composite of which XI is a motor component.

Autonomic nervous system. The autonomic nervous system is made up of two divisions, the sympathetic and the parasympathetic nervous systems; it controls such involuntary actions as constriction of blood vessels. Some

Origins of autonomic nervous system

cells of the neural crests migrate and form paired segmental masses alongside the aorta, a principal blood vessel. Part of the cells become efferent multipolar ganglion cells (cells whose fibres carry impulses outward from ganglions, or aggregates of nerve cells) and others merely encapsulate the ganglion cells. These autonomic ganglia link into longitudinal sympathetic trunks. Some of the neuroblasts migrate farther and assemble as collateral ganglia—ganglia not linked into longitudinal trunks. Still others migrate near, or within, the visceral organs that they will innervate and produce terminal ganglia. These ganglia are characteristic of the parasympathetic system.

Some cells of certain primitive collateral ganglia leave and invade the amassing mesodermal cortex of each adrenal gland. Consolidating in the centre, they become the endocrine cells of the medulla.

Sense organs. *Olfactory organ.* Paired thickenings of ectoderm near the tip of the head infold and produce olfactory pits. These expand into sacs in which only a relatively small area becomes olfactory in function (Figure 2E). Some epithelial cells in these regions remain as inert supporting elements. Others become spindle-shaped olfactory cells. One end of each olfactory cell projects receptive olfactory hairs beyond the free surface of the epithelium. From the other end a nerve fibre grows back and makes a connection within the brain.

Gustatory organ. Most taste buds arise on the tongue. Each bud, a barrel-shaped specialization within the epithelium that clothes certain lingual papillae (small projections on the tongue), is a cluster of tall cells, some of which have differentiated into taste cells whose free ends bear receptive gustatory hairs. Sensory nerve fibres end at the surface of such cells. Other tall cells are presumably inertly supportive in function.

Origins of eye and ear

Eye. The earliest indication of an eye is an optic vesicle (sac) bulging from each side of the forebrain (Figure 2B, C). It quickly becomes an indented optic cup, connected to the brain by a slender optic stalk. Most of the cup will become the retina, but its rim represents the epithelial part of the insensitive ciliary body and iris. The thicker inner layer of the cup becomes the neural layer of the retina, and by the sixth month three strata of neurons are recognizable in it: (1) visual cells, each bearing either a photoreceptive rod or a cone at one end; (2) bipolar cells, intermediate in position; (3) ganglion cells, which sprout axons that grow back through the optic stalk and make connections within the brain. The thin outer layer of the cup remains a simple epithelium whose cells gain pigment and make up the pigment epithelium of the retina.

The lens arises as a thickening of the ectoderm adjacent to the optic cup. It inpockets to form a lens vesicle and then detaches. The cells of its back wall become tall, transparent lens fibres. Mesoderm surrounding the optic cup specializes into two accessory coats. The outer coat, the tough, white sclera, is continuous with the transparent cornea. The inner coat, the vascular choroid, continues as the vascular and muscular ciliary body and the vascularized tissue of the iris. The eyelids are folds of adjacent skin; from the inside of each upper lid several lacrimal glands bud out (see EYE AND VISION, HUMAN).

Ear. The projecting part (auricle) of the external ear develops from hillocks on the first and second branchial arches (Figure 2C–E). The ectodermal groove between those arches deepens and becomes the external auditory canal. The auditory tube and tympanic cavity—the cavity at the inner side of the eardrum—are expansions of the endodermal pouch located between the first and second branchial arches. The area where ectodermal groove and endodermal pouch come in contact is the site of the future eardrum. The chain of three auditory ossicles (small bones) that stretches across the tympanic cavity is a derivative of the first and second arches.

The epithelium of the internal ear is at first a thickening of ectoderm at a level midway of the hindbrain (Figure 2B). This plate inpockets and pinches off as a closed sac, the otocyst. Its ventral part elongates and coils to resemble a snail's shell, thereby forming the cochlear duct, or seat of the organ of hearing. A middle region of the otocyst becomes chambers known as the utricle and saccule, related to the sense of balance. The dorsal part of the otocyst remodels drastically into three semicircular ducts, related to the sense of rotation. Fibres of the acoustic nerve grow among specialized receptive cells differentiated in certain regions of these three divisions.

MESODERMAL DERIVATIVES

Skeletal system. Except for part of the skull, all bones pass through three stages of development: membranous, cartilaginous, and osseous. The earliest ossification centres appear in the eighth week, but some do not arise until childhood years and even into adolescence.

Axial skeleton. The ventromedial walls (the walls toward the front and the midline) of the paired somites break down, and their cells migrate toward the axial notochord and surround it. Differentiation and growth of these segmental masses produce the jointed vertebrae. Ribs also grow out of each primitive vertebral mass, but they become long only in the thoracic region. Here their ventral ends join the sternum, which arises independently by the fusion of a pair of bars.

The skull has three components, different in origin. Its basal region is an ancient heritage whose bones pass through the three typical stages of development. By contrast, the sides and roof of the skull develop directly from membranous primordia, or rudiments. The jaws are derivatives of the first pair of cartilaginous branchial arches but develop as membrane bone. Ventral ends of the second to fifth arches contribute the cartilages of the larynx and the hyoid bone (a bone of horseshoe shape at the base of the tongue). Dorsal ends of the first and second arches become the three auditory ossicles (the small bones in the middle ear).

Development of the bones of the arms and legs; the joints

Appendicular skeleton. The limb bones develop in three stages from axial condensations in the local mesoderm. The shoulder and pelvic supports are comparable sets, as are the bones of the arms and legs.

Articulations. Some type of joint exists wherever bones meet. Joints that allow little or no movement consist of connective tissue, cartilage, or bone. Movable joints arise as fluid-filled clefts in mesoderm, which condenses peripherally into a fibrous capsule.

Muscular system. Much of each somite differentiates into myoblasts (primitive muscle cells) that become voluntary muscle fibres. Aggregations of such fibres become muscles of the neck and trunk. Muscles of the head, and some of the neck muscles, originate from mesoderm of branchial arches. Muscles of the limbs seemingly arise directly from local mesoderm. In general, muscle primordia may fuse into composites, split into subdivisions, or migrate away from their sites of origin. During these changes they retain their original nerve supply. Regardless of differences in source of origin, all voluntary muscle fibres are of the same striated type (marked by dark and light stripes). Spontaneous movements begin to occur in embryos about ten weeks old. In general, involuntary muscle differentiates from mesoderm surrounding hollow organs; only the cardiac muscle type is striated.

Vascular system. All hollow organs, including arteries, veins, and lymphatics, are lined with epithelium—

the principal functional tissue—and are ensheathed with muscular and fibrous coats.

Blood vessels. Primitive blood vessels arise in the mesoderm as tiny clefts bordered by flat endothelial cells. Growth and coalescence produce networks, out of which favoured channels persist as definite vessels, while others decline and disappear. A bilaterally symmetrical system of vessels is well represented in embryos four weeks old. This early plan is profoundly altered and made somewhat asymmetrical during the second month by fusions, atrophies, emergence of new vessels, and rerouting of older ones. The alterations reflect adjustments to changing form and pattern within the developing organ systems of the body.

Arteries cranial to the heart (headward of the heart) are mostly products of the paired aortic arches, which course axially within the branchial arches, thus interconnecting the ventral aorta with paired dorsal aortas. The third pair of aortic arches becomes the common carotids; the fourth pair, the aortic arch and brachiocephalic; the fifth pair, the pulmonary arteries and ductus arteriosus. The dorsal aortas fuse into the single descending aorta, which bears three sets of paired, segmental branches. The dorsal set becomes the subclavian, intercostal, and lumbar arteries. The lateral set becomes arteries to the diaphragm, the adrenal glands, the kidneys, and the sex glands. The ventral set becomes the celiac, mesenteric, and umbilical arteries. Axial arteries to both sets of limb buds emerge from an original plexus, but they undergo drastic alteration and extensive replacement.

The primitive veins are symmetrically bilateral. They consist of vitelline veins from the yolk sac, umbilical veins from the placenta, and precardinal and postcardinal veins from the cranial and caudal regions (the regions toward the head and toward the tail) of the body. Drastic transformations occur in all of these, and new pairs of veins (subcardinals and supracardinals) arise also, caudal to the heart. From the vitellines come chiefly the portal and hepatic veins. The left umbilical becomes the main return from the placenta by making a diagonal channel, the ductus venosus, through the liver to the heart. The precardinal veins change their names to the internal jugulars, but near the heart an interconnection permits both to drain into a common stem, then called the superior vena cava. Caudal to the heart, the postcardinals virtually disappear, and all blood return shifts to the right side as a new compound vessel, the inferior vena cava, becomes dominant. Pulmonary veins open into the left atrium. Veins from the limb buds organize from an early peripheral border vein.

Lymphatic vessels. The lymph vessels develop independently in close association with veins. Linkages produce the thoracic duct, which is the main drainage return for lymph. Masses of lymphocytes accumulate about lymphatic vessels and organize as lymph nodes. The spleen has somewhat similar tissue, but its channels are supplied with blood.

Origins of the heart

Heart. Fusion combines two endothelial tubes, and these are surrounded by a mantle of mesoderm that will become the muscular and fibrous coats of the heart. At three weeks the heart is a straight tube that is beginning to beat (Figure 1M). Starting at the head end, four regions can be recognized: bulbus, ventricle, atrium, and sinus venosus. Since the heart is anchored at both ends, rapid elongation forces it to bend. In doing this, the sinus–atrium and bulbus–ventricle reverse their original relations. Further development concerns the transformation of a single-chambered heart into one with four chambers.

The atrium becomes subdivided by the growth of two incomplete partitions, or septa, placed close together and each covering the defect in the other. The ventricle also subdivides, but by a single, complete partition. A canal, connecting atria and ventricles, becomes two canals. The bulbus is absorbed into the right ventricle, and its continuation (the truncus) subdivides lengthwise, forming the aorta and the pulmonary artery. The right horn of the sinus venosus is absorbed into the right atrium, together with the superior and inferior venae cavae, which originally drained into the sinus. The transverse portion of the sinus persists as the coronary sinus. The pulmonary veins retain their early drainage into the left atrium. Important valves develop and ensure flow within the heart from atria to ventricles, and outward from the ventricles into the aorta and the pulmonary artery.

Birth initiates breathing, and the abandonment of the placental circulation follows. These changes entail a drastic rerouting of blood through the heart. As a result, the two atrial septa fuse and no longer permit blood to pass from the right atrium to the left atrium. Blood in the pulmonary artery no longer virtually bypasses the lungs; previously it had passed to the aorta directly through a shunt offered by the ductus arteriosus. As a sequel to these changes, the abandoned umbilical arteries, umbilical vein, ductus venosus, and ductus arteriosus all collapse and become fibrous cords.

Urinary system. Vertebrates have made three experiments in kidney production: the pronephros, or earliest type; the mesonephros, or intermediate kidney; and the metanephros, or permanent kidney. All arise from the cellular plates called nephrotomes that connect somites with the mesodermal sheets that bound the body cavity. The vestigial pronephros is represented solely by several pairs of tubules; they join separately formed excretory ducts that grow downward and enter the cloaca, the common outlet for urine, genital products, and for intestinal wastes. Next tailward arise some 40 pairs of nephric (kidney) tubules that constitute the mesonephros; these tubules join the same excretory ducts, hereafter called the mesonephric ducts. The two sets of mesonephric tubules serve as functioning kidneys until the tenth week.

Origins of the kidney, urinary bladder, and urethra

Each permanent kidney, or metanephros, develops still farther tailward. A so-called ureteric primordium buds off each mesonephric duct, near its hind end. The ureteric stem elongates and expands terminally, thereby forming the renal pelvis and calices; continued bushlike branching produces collecting ducts. The early ureteric bud invades a mass of nephrotome tissue. The branching collecting ducts progressively break this tissue up into tiny lumps, each of which becomes a long secretory tubule, or nephron, and joins a nearby terminal twig of the duct system. Continued proliferation of ducts and nephric tissue produces over a million urine-producing tubules in each kidney.

The blind caudal end of the endodermal hindgut absorbs the stem of each mesonephric duct, whereupon the remainder of the duct and the ureter acquire separate openings into the hindgut. This expanded region of the gut, now a potential receptacle for feces, urine, and reproductive products, is known as a cloaca. It next subdivides into a rectum behind and a urogenital sinus in front. The sinus, in turn, will specialize into the urinary bladder and the urethra. The prostate gland develops as multiple buds from the urethra, close to the bladder.

Origins of sex glands and ducts and external genitalia

Genital system. The genital organs begin to develop in the second month, but for a time sex is not grossly distinguishable. Also, a double set of male and female ducts arise, and not until later does the unneeded set decline. Hence, this period is commonly called the indifferent stage.

Gonads. Sex glands develop in a pair of longitudinal ridges located alongside the mesentery, the anchoring fold of membrane to the gut. The primordial sex cells appear first in the cloacal wall, from which they migrate upward in the gut, pass through its mesentery, and finally invade the genital ridges, where they proliferate. The testes are the earliest type of gonad to organize. They begin by developing testis cords and a testis capsule. The cords radiate from one focal point at the periphery, and thin fibrous partitions segregate groups of the cords within wedge-shaped compartments. These cords do not gain channels and become semen-producing tubules until near the time of puberty. The ovaries organize somewhat tardily by differentiating an outer portion, the cortex, and a central portion, the medulla. The cortex contains the primordial sex cells; these become surrounded by a layer of ordinary cells, thereby forming primary ovarian follicles. The further advance of these follicles and that of the

testis tubules have been described earlier. Both the testes and the ovaries undergo relative shifts from their early sites to lower positions in the body. But only the testes make a bodily descent; this is into the scrotum.

Genital ducts. In the male, a few mesonephric tubules on each side do not degenerate but link up with the neighbouring testis tubules. The converted mesonephric tubules and the retained mesonephric ducts become the male sex ducts. Near their terminations they outpouch seminal vesicles and then open into the urethra. In the female, a pair of ducts develops from the epithelium clothing the mesonephric ridges. These ducts, known as the uterine tubes, mostly parallel the courses of the mesonephric ducts, but at their lower ends they unite into a common tube that becomes the uterus and vagina.

External genitalia. Both sexes develop a genital tubercle (*i.e.*, a knob) and a pair of urogenital folds flanked by a pair of genital swellings. At three months these rudiments begin to assume male or female characteristics. In the male, the tubercle and the united urogenital folds combine as the penis, thereby continuing the urethra to its end; the genital swellings shift toward the anus, fuse, and become the scrotum. In the female, the tubercle remains small, as the clitoris; it does not contain the urethra. The urogenital folds remain unclosed as the lesser vulvar lips and are flanked by the unshifted and unfused genital swellings, or greater lips.

Coelom. The lateral mesoderm, beyond the somites and nephrotomes, splits into two layers: the somatic layer and, underlying the somatic layer, the splanchnic layer. The intervening space is the coelom. As the embryo's body folds off, its coelom becomes a single closed cavity. In it can be recognized, regionally, a provisional pericardial cavity (cavity for the heart), two pleural canals (for the lungs), and a peritoneal cavity (for the abdominal contents). A thick plate of mesoderm, the transverse septum, constitutes a partial partition just ahead of the developing liver. Two pairs of membranes grow out from the septum. One set separates the pericardial cavity from the two pleural cavities; these membranes later expand into the pericardium and enclose the heart. The other pair of membranes separates the pleural cavities from the peritoneal cavity of the abdomen. The definitive diaphragm is a composite partition, much of which is furnished by the transverse septum; lesser contributions are from the lateral body walls and the paired membranes that separated the pleural and peritoneal cavities.

Origins of the body cavities

ENDODERMAL DERIVATIVES

Pharynx. The tongue is a product of four branchial arches, whose ventral ends merge in its midplane. Papillae elevate from the surface, and taste buds arise as specializations within the covering epithelium of some of them. Pharyngeal pouches are early lateral expansions of the local endoderm, alternating with the branchial arches. The first pair elongate as the auditory tubes and tympanic cavities. The second pair mark the site of the tonsils. The third pair give rise to the halves of the thymus, and the third and fourth pairs produce the two sets of parathyroid glands. The thyroid gland buds off the pharyngeal floor in the midplane and at the level of the second branchial arches.

Development of the esophagus, stomach, and intestines

Digestive tube. As the embryo folds off, the endoderm is rolled in as the foregut and hindgut. Continued growth progressively closes both the midbody and the midgut (Figure 1P, Q). The esophagus remains as a simple, straight tube. The stomach grows faster on its dorsal side, thereby forming the bulging greater curvature; the stomach also rotates 90° so that its original dorsal and ventral borders come to lie left and right. The intestine elongates faster than the trunk, so that its loops find temporary room by pushing into the umbilical cord. Later, the loops return, completing a rotation that gives the characteristic final placement of the small and large intestines.

When the gut folds into a tube it is suspended by a sheetlike dorsal mesentery, or membranous fold. In the region of the stomach it forms an expansive pouch, the omental bursa. Secondary fusions of the bursa and of some of the rest of the mesentery with the body wall produce lines of attachment from stomach to rectum inclusive, different from the original midplane course. Such fusions also anchor firmly some parts of the tract. A ventral mesentery, beneath the gut, exists only in the region of the stomach and liver.

Major glands. The liver arises as a ventral outgrowth of the foregut that invades the early transverse septum. Although rapid growth causes it to bulge prominently away from this septum, it remains attached to the septum and hence to the definitive diaphragm. The differentiating glandular tissue takes the form of plates bathed by blood channels. The stem of the original liver bud becomes the common bile duct, whereas a secondary outgrowth produces the cystic duct and the gallbladder.

The pancreas takes its origin from a larger dorsal bud and a smaller ventral bud, both off the foregut. The two merge and their ducts communicate, but in man it is the lesser, ventral duct that becomes the stem outlet. Secretory acini are berrylike endings of the branching ducts. Pancreatic islets arise as special sprouts from the ducts; these differentiate into endocrine tissue that secretes insulin.

Nose, larynx, trachea, and lungs

Respiratory system. *Nasal cavity.* The first part of the respiratory system is ectodermal in origin. The olfactory sacs (see above *Sense organs*) become continuous secondarily with a passage captured from the primitive mouth cavity. This addition is produced by a horizontal partition, the palate. It arises from a pair of shelflike folds that grow out from the halves of the primitive upper jaw and then unite. The final nasal passage extends from the nostrils to the back of the pharynx.

Larynx, trachea, and lungs. A hollow lung bud grows off the floor of the endodermal pharynx, just caudal (tailward) to the pharyngeal pouches and in the midline. It has the form of a tube with an expanded end. The entrance to this tube is the glottis, and the region about it becomes the larynx. The tube proper represents the trachea. Its terminal expansion divides into two branches, and these tubes elongate as the primary bronchi. Continued growth and budding produce two side branches from the right bronchus and one from the left. These branches and the blind ends of the two parent bronchi indicate the future plan of the lungs, with three right lobes and two left lobes. Continued branchings, through the sixth month, produce bronchioles of different orders. In the final months the smaller ducts and early respiratory alveoli (air sacs) appear, the lungs losing their previous glandular appearance and also becoming highly vascular. Until breathing distends the lungs, these organs remain relatively small.

(L.B.A.)

Emerson, Ralph Waldo

Essayist, major poet, lecturer whose voice and rhetoric sustained the faith of thousands in the lecture circuits be-

tween 1834 and the U.S. Civil War, cultural middleman through whom the aesthetic and philosophical currents of Europe and Asia passed to America, Emerson led his countrymen during the burst of literary glory known as the American renaissance (1835–65), serving as catalyst for such writers as Henry David Thoreau, Walt Whitman, Nathaniel Hawthorne, and Emily Dickinson. As a principal spokesman for Transcendentalism, the American tributary of European Romanticism, he gave direction to a warm, intuitional, religious, aesthetic, philosophical, and ethical movement that stressed a theoretical and practical way of life and combined ancient classical humanism with varieties of Oriental supernaturalism to support belief in an oversoul and in the "infinitude" (spiritual potential) of every man. Among his bequests to the 20th century, in which, according to one critic of awakening Emerson scholarship, he continues "the least limited, the most permanently suggestive" of American literary artists, are a controlled optimism with an awareness of the tragic; a Western or Yankee mysticism; poetry with a uniquely American quality; and the ideal of a vital, skeptical mind heroically affirming its individuality.

Principal spokesman for Transcendentalism

Early life and works. Ralph Waldo Emerson was born in Boston, Massachusetts, on May 25, 1803, to the Rev. William Emerson, a Unitarian clergyman and minister of the First Church, friend to the arts in the lean years following the American Revolution, and a founder of the Anthology Club of Boston. The club was a literary society out of which came the Boston Athenaeum, the *Monthly Anthology and Boston Review* (1803–11), and, eventually, the *North American Review*. Through his father, Emerson inherited the profession of divinity, which had attracted all his ancestors in direct line from Puritan days. The family of his mother, Ruth Haskins, was strongly Anglican, her father, John Haskins, being a communicant of King's Chapel, Boston, and both father and daughter loved the Anglican *Book of Common Prayer* and memorized its principal offices so that phrases from it sprang up naturally in their daily conversation. When John Haskins died, Emerson, then 11, wrote a short elegy beginning, "See the calm exit of the aged saint. . . ." Among Emerson's principal teachers, in later years, were Anglican writers and thinkers like Ralph Cudworth, Robert Leighton, Jeremy Taylor, and Samuel Taylor Coleridge—a fact that possibly explains some ambivalences.

On May 12, 1811, William Emerson died, leaving Ralph (aged nine) largely to the intellectual care of Mary Moody Emerson, his spinster aunt, who took her duties seriously, declaring that her brother's children "were born to be educated." In 1812 Emerson entered the Boston Public Latin School, where his juvenile verses were encouraged and his literary gifts recognized. In 1817, at the age of 14, he entered Harvard College, where he began his journals, which, when eventually published without abridgment, may prove to be the most remarkable record of the "march of Mind" or intellectual and moral progress to appear in America. Perhaps a little too young to earn distinction under the college marking system, he nonetheless developed intellectually and emotionally, graduating in August 1821, to enter school teaching while preparing for part-time study in the Harvard Divinity School. Though Emerson was licensed to preach in the Unitarian community in 1826, fatigue from his strenuous reading program and incipient lung disease required a sojourn in Georgia and Florida. Ordained to the Unitarian ministry at the Second Church, Boston, on March 11, 1829, he began concentrating on weekly sermons in which are to be found the great themes later developed in his famous essays. At this time he was reading the works of the Swedish philosopher and religious writer Emanuel Swedenborg; Sampson Reed, a Boston Swedenborgian writer; the poets Coleridge and Wordsworth; the French prelate François de Salignac de la Mothe Fénelon, who effectively proclaimed for him the majesty of the moral law within. Passages in these sermons may be considered first drafts for a number of his later poems, the prose style being intensely lyrical. In the pulpit he gained experience in the rhetoric which was to be employed with distinction on the lecture platform throughout his life.

Ordination to the Unitarian ministry

On September 30, 1829, as surviving love letters and his journals indicate, he entered into the most vital emotional experience of his life by marrying Ellen Louisa Tucker of New Hampshire. When she died of tuberculosis on February 8, 1831, his grief drove him to question his beliefs and his profession, turning him hopefully to other religious sects for evidence of vital truth—especially to Methodists, Quakers, and Swedenborgians of the Boston area. A period of agonized meditation in the White Mountains produced "Gnothi Seauton" (written in July 1831), an impassioned creed hymn, or meditation, in free verse on the witness of the oversoul in the heart of man and on the compensations by which it governed man's morality. From this point onward Unitarianism had little appeal, and his sermon opposing the asserted anachronism of the Lord's Supper (September 9, 1832), drawn from Quaker sources, was more an excuse for abandoning the ministry than a sufficient cause. His resignation having been reluctantly accepted, he sailed for Europe on Christmas Day in quest of spiritual communion with the three Romantic writers whom he had been studying with excitement. (His account of the meetings with Wordsworth, Coleridge, and Thomas Carlyle is given in *English Traits*.) His startled recognition of occult relationships between himself and natural objects in the Muséum Nationale d'Histoire Naturelle in Paris gave particularity to his already developing theory (suggested by Swedenborg and Coleridge) of a spiritual correspondence between man and nature, and it encouraged his browsing in available popular science books. When he returned to Concord in October 1833, he drew upon these and current literary studies for his first public lectures. Sparkling with wit, anecdote, proverbs, and his early Romanticism, his lectures offered a liberal education to his first Boston hearers and introduced a diffused and easily absorbed Transcendentalism in a style midway between the pedagogy employed in the sermons and the highly intricate prose of his essays.

Meeting with Wordsworth, Coleridge, and Carlyle

Emerson, lithograph by Leopold Grozelier, 1859.

Mature life and works. The death of his brother Edward Bliss, in the fall of 1834, was another blow that tested his optimism. In November, he took up permanent residence in Concord, which largely through his fame became the mecca of American Romanticism. By the end of the year, he had reached maturity as a poet, as evidenced in lyrics such as "Rhodora," "Xenophanes," "Each and All," and "The Snow-Storm." By June 1835, he had organized the wisdom from his principal sources, which he had made his own, into a cogent Transcendental credo or "Statement of the First Philosophy," which was a preparation for his first book. He had, meanwhile, married the slightly older Lydia Jackson ("Lidian") of Plymouth, Massachusetts, on September 14, 1835, and had lost another brother, Charles Chauncy, on May 9, 1836.

A complex classic—and his first major challenge to the

wasteland of his day—was *Nature* (1836), which may be classed with Whitman's "Song of Myself," Thoreau's *Walden*, Wordsworth's *Prelude*, and T.S. Eliot's *Four Quartets* as compressed and objectified personal experience, credal statement, confession, and prophecy combined. A prose lyric, it identifies the levels of nature's rich ministry to man in the conduct of his life and his quest for salvation, her role being analogous to Jesus' in the Christian dispensation. Influenced by ancient writers on the perennial philosophy (such as Plato and Plotinus) and moderns (such as Coleridge, Swedenborg and Goethe), it provides a compendium of Romantic doctrine and the highest point in Emerson's idealism, which was to be tempered but not compromised as, in middle life, he grew more aware of the limitations of man and society. The clarity of its structure reflects the instructional or programmatic character of the earlier lectures and sermons from which he drew many passages. All his later writings look back to this little book as their master plan and are variations of its themes. In this same year (1836), almost as if to illustrate the doctrines expressed at the end of *Nature*, his son Waldo was born and lovingly studied in terms of Romantic theories, infancy being defined as "the perpetual Messiah, which comes into the arms of fallen men, and pleads with them to return to paradise." (Emerson's other children were Ellen [1839], Edith [1841], and Edward Waldo [1844].

Theme of "The American Scholar"

His second challenge, "The American Scholar" (August 31, 1837), directed to the Harvard intelligentsia, under the auspices of Phi Beta Kappa, warned against pedantry, imitation of others, traditionalism, and scholarship unrelated to life, reminding the audience that since true wisdom flows from above by divine influx, the primary agency for acquiring it or (to use Plato's imagery) "unlocking" or "awakening" it in each man was the midwife nature. Books recording the great traditions of the past he considered of secondary importance, relegating them to the scholar's "idle times." To these channels of truth he added action, or full participation in human life. The address was a deliberate declaration of literary independence from England and an unconscious apology for his new vocation as artist and teacher on the lecture platform. His third major challenge (July 15, 1838) was the "Address at Divinity College," Harvard University, directed against a lifeless Christian tradition, especially Unitarianism as he had known it. Developing themes from "Gnothi Seauton" and emphasizing the "impersoneity" of the Transcendental and indwelling divinity, he dismissed religious institutions and the divinity of Jesus as dodges or failures to encounter deity directly through the moral principle or intuited sentiment of virtue. Since God so incarnates himself, men are differenced from Jesus and other spiritual leaders only in degree of reception and awareness. Alienated because of this impiety or infidelity, he now had few opportunities to preach in churches, and for many years Harvard had nothing to do with him; but young disciples joined the members of the informal Transcendental Club (founded in 1836) and encouraged him. In "Uriel" (written 1839), a parable of the difficulty in announcing or transmitting new truth and of society's inevitable resistance to its great philosophers and religious leaders, he apparently had in mind the career of Coleridge, who had suffered ignominy and rustication; but he used imagery suggesting the divinity school setting and unconsciously identified himself with the great English poet and critic.

Publication of *The Dial*

In July 1840, he helped launch *The Dial*, first edited by Margaret Fuller and later by himself, providing a publishing outlet for the new ideas which the Transcendentalists were trying to present to America. Though short-lived, it accomplished many of its purposes, providing the rallying point for the younger members of the school. Out of his continuing lecture series, meanwhile, Emerson gathered his *Essays* into two volumes (1841 and 1844), which became the basis of his international fame, linking him with other contributors to this genre such as Cicero, Plutarch, Michel de Montaigne, and Francis Bacon. In "History," the concept is interpreted not as a chronology of outward events but as an inner or existential awareness of reality, the record of the indwelling deity, or mind, as it manifests itself in the human condition. "Self-Reliance" (that is, God-reliance) celebrates the same divine intuitive principle in man, the voice of duty, which makes imitation of others or conformity to traditions a spiritual suicide. Nonconformity must be the rule of genius; intuition, its preservation. "Compensation" harks back to "Gnothi Seauton" in charting the instantaneous judgments from God or from the world that operate within man as he behaves, no element of chance being possible in the spiritual universe. One pays, rewards, and cheats himself. "Friendship" owes much to the Swedenborgian doctrines of influx and of the "association of spirits," the rule being that spiritual "like only can know or understand like." Human relationships like marriage gain little from arbitrary regulation or commitment. Without spiritual reciprocity no union can exist and no growth in character. "The Poet" predicted a bard who would choose America in the large for his theme and not the nightingales and skylarks of England. In his indigenous verse not metres "but a metre-making argument" would be apparent. Such a poet would be the complete man, receiving the greatest flow of power and truth and expressing in words his intuitions of eternal beauty. In "Politics," Emerson's doctrine of the God-reliant individual is related to government, which is best when it governs least and should expire altogether when it produces the wise man.

The death of little Waldo on January 27, 1842, clouded Emerson's middle years until his grief was partly relieved in "Threnody," one of the great elegies in the language. His earliest idealism, according to which all things seemed possible to man in union with the divine principle, began to accommodate itself to limitation, or fate. His later works show increasing acquiescence under the state of things, less reliance on the self, greater respect for society, and an awareness of the ambiguities and incompleteness of genius, which, at best, could only represent the divine completeness. His collected *Poems* (1846) were supplemented by others in *May-Day* (1867), the two volumes establishing his reputation as a major American poet. The first served as a visiting card in England when he returned there to lecture in 1847–48, helping him to establish friendships with younger poets, who were, perhaps, the first to appreciate such lyrics as "Mithradates," "Hamatreya," "The Humble-Bee," "Give All to Love," "Merlin," "The Apology," and "Bacchus"—to name only a few. While abroad this second time he was able to speak in behalf of Thoreau and Bronson Alcott, the Transcendentalist teacher and writer, and to invite like-minded Englishmen to the American shores.

Representative Men drew upon lectures and evaluations of his reading to praise the "uses" of men of genius without differencing them (except in degree) from ordinary men. Great men serve the human race directly by offering health, eternal youth, magical power, and prophecy; but they are not themselves original forces. Plato, the philosopher; Swedenborg, the mystic; Montaigne, the skeptic; William Shakespeare, the poet; Napoleon Bonaparte, the man of the world; and Goethe, the writer—these are the great servants of the race. *English Traits* (1856) is a character analysis of a people from which he himself stemmed and attests his admiration for the traditions of his forebears in spite of his strong declarations of independence.

Humanism of *The Conduct of Life*

The Conduct of Life (1860), Emerson's most mature work, reveals a developed humanism together with a full awareness of man's limitations, or partial development, in an evolutionary universe—man's freedom (resulting from the Spirit acting through his will) and "Fate" (one's boundaries established by time, space, environment and inheritance) both operating. Rich in the texture of human experience, it may be considered as partly confession. "Power" is achieved through the will, its value depending upon the kind of will exercised. "Wealth" is a good, especially if earned and spent by a "genius" ever enlarging its spiritual awareness. "Culture" (melioration) evaluates the popular procedures in getting an education, warns against what is called "success," and defines the title as

the process of correcting a man's imbalances or modulating the violence of his master tones. "Behavior" mounts from a consideration of manners that are deliberately acquired (thereby making society possible) to the unconscious flowering of character through self-reliance (God-reliance), which lies at the basis of love, friendship, and power. "Worship" (religion), the zenith of the cultural process, rests not upon history or dead traditions but upon the ever-living moral sense, discussed earlier in "Gnothi Seauton." "Considerations by the Way," which shows familiarity with Charles Darwin's ideas launched in the *Origin of Species* (1859), stresses goodness emerging from evil; the necessity of living with the witless, the unfit, the undeveloped; courage to be one's best through it all; and the importance of love, friendship, and service in the ascent of character. "Beauty" is ultimately a revelation of the moral sentiment whether it appears in outer form, human behaviour, or expression of thought. In "Illusions," he shifted his vision from the chaotic human scene already discussed with great psychological penetration and relegated it to what the Hindus call *māyā*, pointing to the super-realities (the "gods" on their thrones), sustaining the phenomenal universe, speaking in the moral sentiment, and beckoning mortals upward to their sphere. The majestic peroration contrasts with the sparkling wit, humour, metaphor, irony, and skepticism of the whole work.

His "Thoreau" (1862) brought together with some reservations his positive thoughts concerning the enigmatic disciple and in so many ways Emerson's teacher, who had died on May 6 and whose significance as a major American stylist possessing great charisma was to surpass all 19th-century expectations. Emerson had foreshadowed his brilliant protégé in "Woodnotes" (1840), much as he had predicted Whitman in "The Poet" (1844). He had praised Thoreau to the young versifiers in England and had seemed to commend his experimental return to nature at Walden Pond in the *Conduct of Life;* but his last word was scarcely prophetic of Thoreau's permanent place in the literature of the world.

Later life and works. The outbreak of the Civil War, which ushered in a period of Realism in American letters and threatened to end Transcendentalism as a literary force, found Emerson supporting the Union and abolition. He celebrated the Emancipation Proclamation in the "Boston Hymn" (1863) and followed that with "Voluntaries," lyric meditations on the black race, to which he promised recognition at last and for which the costly battle sacrifices were justified. These poems, in tone and movement, differ from earlier lyrics of the middle period, especially his Oriental pieces, such as "Hamatreya," "Saadi," and "Maia" (gathered into *Poems*), as well as "Brahma" and translations from the Persian (by way of a German text) in *May-Day*. "Terminus" acknowledged the limits and boundaries of his own life; "Days" stressed the illusoriness of human existence and the difficulty of knowing what to choose in it. *Society and Solitude* (1870), the last book he himself put together, had much great prose but revealed decreased powers.

Emerson's letters

Perhaps more significant for biography than either the published *Works* or *Journals* was the correspondence—nearly 5,000 letters written by and to him, much of it yet ungathered. At the centre are his communications with relatives, illustrating his affectionate concern and responsiveness; then with neighbours; with the Transcendentalists; with the larger literary fellowship, including Henry Wadsworth Longfellow, William Cullen Bryant, James Russell Lowell, and Whitman, at home, and Carlyle, Walter Savage Landor, John Stuart Mill, and Coventry Patmore abroad. Throughout all these letters his dignity, humour, frankness, courtesy, and wisdom are patent.

When, on July 24, 1872, the upper floors of Emerson's Concord home were destroyed by fire, neighbours saved his manuscripts and books, joining with his many friends throughout the country to raise money for a third trip abroad—to England, France, Italy, and Egypt, the farthest point being the isle of Philae, the supposed resting place of the god Osiris. Welcomed by the press wherever he went, he was met by friends all along the route. Meanwhile, in Concord, his house was restored and a major ovation planned for his return in May 1873.

He continued to make occasional public appearances—most of them near home—accompanied by his daughter Ellen. Between 1879 and 1880, he graced with his presence and an occasional lecture the new Concord School of Philosophy and Literature, founded by Bronson Alcott, his lifelong friend. He died on April 27, 1882, in his 80th year.

Relevance to the mid-20th-century world

Although the once-sharp outlines of Emerson's Transcendentalism were blurred as it became absorbed into the complex American mystical tradition, though the spiritual basis of his individualism has yielded largely to modern existentialisms, and though his recommended cultivation of the inner world of mind tends to be ignored in a collectivist and materialistic society, his humanistic ideals nevertheless are felt to remain fresh, the great problems that engaged him continue to challenge, and his attempted solutions command historic respect. As a writer of majestic prose he has few equals. His significance as a major poet is enlarging. His relevance to the mid-20th-century world is observable in ethical movements, the resurgence of youth, a revived Unitarianism, modern academic skepticism, religious tolerance, and concern with the world of the psyche. The proverbial and anecdotal quality of his writing has made him the most quoted American in the 20th-century press. Translated into dozens of languages, abroad he still represents the America of high goals, character values, and opportunities of which the immigrant dreams. Nineteenth- and 20th-century world figures such as the philosopher Nietzsche in Germany, the philosopher and writer Miguel de Unamuno in Spain, the poet, dramatist, and essayist Maurice Maeterlinck in Belgium, and the philosopher Henri Bergson in France have unhesitatingly confessed indebtedness to him, and the end is not yet.

MAJOR WORKS

POETRY: *Poems* (1846), including "The Sphinx," "Threnody," "The Problem," "The Rhodora," "Woodnotes," "Give All to Love," and "Bacchus"; *May-Day, and Other Pieces* (1867), including "Brahma" and "Terminus."

ESSAYS AND ADDRESSES: *Nature* (1836); "The American Scholar" (1837); "Divinity School Address (first published 1838, published under this title, 1903); *Essays: First Series* (1841); *Essays: Second Series* (1844); *Addresses and Lectures* (1849); *Representative Men: Seven Lectures* (1849, dated 1850); *English Traits* (1856); *The Conduct of Life* (1860); *Society and Solitude* (1870); *Letters and Social Aims* (1876); *Lectures and Biographical Sketches* (1884); *Miscellanies* (1884); *Natural History of Intellect* (1893); *Uncollected Writings* (1912); *Uncollected Lectures* (1932).

OTHER PROSE: *Journals*, 10 vol. (1909–14); *The Letters of Ralph Waldo Emerson*, 6 vol. (1939).

COLLECTIONS: *Journals and Miscellaneous Notebooks*, ed. by William H. Gilman *et al.*, 20 vol. (1960–); *Early Lectures*, ed. by Stephen E. Whicher and Robert E. Spiller, 3 vol. (1959–72); *The Collected Works* (1971–).

BIBLIOGRAPHY. RALPH L. RUSK, *The Life of Ralph Waldo Emerson* (1949), factually the latest and most complete biography, but it doesn't quite capture the many sides of the creative artist and man; OLIVER WENDELL HOLMES, *Ralph Waldo Emerson* (1885), a sympathetic study by a contemporary and a literary man; JAMES ELLIOT CABOT, *A Memoir of Ralph Waldo Emerson*, 2 vol. (1887), important because written by Emerson's literary executor; FREDERIC IVES CARPENTER, *Emerson Handbook* (1953), out of date but still useful; JONATHAN BISHOP, *Emerson on the Soul* (1964), perhaps the most radical interpretation of Emerson, employing close reading and new critical approaches; KENNETH WALTER CAMERON, *Emerson the Essayist*, new ed. (1971), basic for any discussion of intellectual backgrounds; *Index-Concordance to Emerson's Sermons, with Homiletical Papers*, 2 vol. (1963), the appendixes anticipate the kinds of evidence the sermons will eventually provide when they are completely edited; *Young Emerson's Transcendental Vision* (1971), indispensable for an understanding of "Gnothi Seauton," "The Statement of the First Philosophy," and *Nature* (1836); *Ralph Waldo Emerson's Reading: A Corrected Edition with Photographs of Literary Concord, Emerson, and His Family* (1962), especially valuable for the photographs; "Early Background for Emerson's 'The Problem,'" *Emerson Society Quarterly*, 27:37–46 (1962); ERIC W. CARLSON and J. LASLEY DAMERON

(eds.), *Emerson's Relevance Today* (1971); ARTHUR CHRISTY, *The Orient in American Transcendentalism* (1932); EDWARD WALDO EMERSON, *Emerson in Concord: A Memoir* (1889), a moving account of Emerson's home life and participation in Concord affairs, written by his son; MAURICE GONNAUD, *Individu et Société dans l'oeuvre de Ralph Waldo Emerson: Essai de biographie spirituelle* (1964), a study of Emerson by a perceptive Frenchman; LEYLA GOREN, *Elements of Brahmanism in the Transcendentalism of Emerson* (1959); DAVID GREENE HASKINS, *Ralph Waldo Emerson: His Maternal Ancestors, with Some Reminiscences of Him* (1887), sets forth the important dimension of Ruth Emerson's family; VIVIAN C. HOPKINS, *Spires of Form: A Study of Emerson's Aesthetic Theory* (1951), discusses Emerson's employment of Romantic organicism; LEONARD NEUFELDT, "The Vital Mind: Emerson's Epistemology," *Philological Quarterly*, 50:253–270 (1971); SHERMAN PAUL, *Emerson's Angle of Vision: Man and Nature in American Experience* (1952), a discussion of the Law of Correspondence, which lies at the core of Emerson's epistemology; HENRY POMMER, *Emerson's First Marriage* (1967); CARL F. STRAUCH, "The Year of Emerson's Poetic Maturity: 1834," *Philological Quarterly*, 34:353–377 (1955)—all Professor Strauch's articles are important in studying Emerson's poetry; HYATT H. WAGGONER, *American Poets, from the Puritans to the Present* (1968), Emerson is seen as a major poet, central in the development of American verse; STEPHEN E. WHICHER, *Freedom and Fate: An Inner Life of Ralph Waldo Emerson*, 2nd ed. (1971), portrays the modifications of Emerson's idealism.

(K.W.C.)

Emotion

In modern scientific usage, the term emotion has multidimensional referents that include: verbally expressible subjective experiences; concomitant internal physiologic changes; and observable motor behaviour (*e.g.*, facial expression, gesture, posture). These fundamental aspects are richly documented in human oral, written, and artistic traditions.

Emotional processes thus are characteristically complex, and in the early 1970s there was no theoretical frame that accounted for all aspects without contradiction. There are difficulties even in framing a simple definition.

THE NATURE OF EMOTION

While emotion may have subjective dimensions, not every inner experience is called an emotion. Emotions are characterized by visceral change; yet, not every alteration in blood pressure or perspiration is held to be emotional. Such manifestations may reflect adaptation to environmental temperature. People often weep when they say they are sad; yet, such responses can occur when there is local irritation of the eye, or even when the weeper reports happiness. A definition of emotion would have to qualify the relevant phenomena, to note conditions that bring them about, and perhaps to specify their consequences. Such a definition would rest on well-defined mechanisms of emotion that remain to be empirically established, providing grounds for theoretical controversy. Only by mid-20th century had approaches to emotion become relatively comprehensive. Earlier literature shows a variety of limited concepts that differ considerably in language, and in cultural and scientific traditions. Terms that continue to generate misunderstanding include: affect, sentiment, feeling, mood, and passion.

Terms used to define emotion

Affect is frequently used as a synonym for emotion; similar considerations apply to the concept of sentiment. Some use the term feeling to describe experiences that arise in the absence of immediate external stimuli. For example, one may feel sad for no apparent reason (presumably from unobserved changes within the body). Mood also has been defined as being dominantly determined internally, and as having relatively low intensity and brief duration.

The German term *Gefühl* indicates feeling and emotion in a positive, desirable sense. In French, *émotion* seems to refer to sudden, intense, rather negative states of excitement, the positive counterpart of which is *passion*; while *sentiment* is the most general concept, although mainly used in literature. In English, emotion is the most general term, feeling usually being limited to pleasant–unpleasant contexts. Other words connote explicit pathological manifestations (*e.g.*, depression, mania, apathy, anxiety, phobia, fury).

Terminological problems wane as objective (*e.g.*, physiologic) emotional indicators are discovered. With the appearance of each new book in psychology, the term emotion seems less likely to arise; authors seldom devote an independent chapter to the topic, tending to focus on the language of motivation. After the 1940s it seemed that the concept of emotion might dissolve in the complexities of motivational phenomena. There is, however, a common etymological origin for the words emotion and motivation, both being related to the Latin *movere*, "to move."

These semantic changes reflect major developments in research. Investigation into so-called emotional phenomena increasingly is being directed toward objective biological evidence. Nevertheless, the immediate, subjective experiences that people live through (*e.g.*, joy, hate) are undeniably essential to what are called emotional phenomena. An influential theoretician wrote in 1960: "Whether we like it or not, emotion is a 'mentalistic' phenomenon. If its character of experience is excluded, there is not much that remains to be discussed." While investigators may neglect this introspective aspect for temporary, strategic purposes (as in objective motivational studies), the subjective flavour is inescapable. Indeed, experimenters who turned away from introspective analysis of "felt," spontaneous emotion, enriched understanding of experiential qualities beyond that of traditional psychologists who focussed on the content of awareness.

INITIAL CONCEPTIONS OF EMOTION

Experimental analysis of introspective reports. Psychology as an experimental discipline developed during the second half of the 19th century. Its goal was to relate objectively definable, physically measurable environmental changes to the content of consciousness as it was available to self-observation (introspection). Wilhelm Wundt (1832–1920), called the father of experimental psychology, based his theory of emotion on an analysis of introspective reports of feelings (*Gefühlston*) generated by sensory stimuli. He concluded that emotions are describable in terms of three dimensions represented by pairs of contrasting words. Wundt's most fundamental dimension (*Lust–Unlust*) recurs in modern work as pleasant–unpleasant; another is translated as tension–release (*Spannung–Lösung*); and a third as excitement–relaxation (*Erregung–Beruhigung*). Only the first seems to have endured well; historically it is the oldest, being based on antecedents often identified as hedonic (see MOTIVATION). The other two, however, also touch on factors that reappear in empirical emotion research.

Wundt reported that near the sensory threshold, one perceives any stimulus in an emotionally neutral way; that, at higher intensities, pleasant and eventually unpleasant emotional qualities appear. Partial evidence for such a relationship later was reported, mainly in terms of taste (gustatory) stimuli (in studies of spontaneous food selection, through introspective reports, and by evidence of neural activity in gustatory experiments with humans and laboratory animals). Sensory and hedonic (pleasant–unpleasant) intensity in tasting salt solutions are not related in a straight-line fashion. When sensory intensity is smoothly varied, hedonic intensity abruptly changes at different levels of salt concentration.

Hedonic theories of emotion

The relation of stimulus intensity to affective quality appeared in more complex forms in later hedonic theories of emotion that added other cognitive factors. The effect of intensity in these theories is seen to depend on the perceiver's level of adaptation (or on his expectation of the stimulus effect). It is held that a relatively small discrepancy from anticipated stimulus intensity creates a pleasant effect, and that larger discrepancies are unpleasant; reduction of the discrepancy is said to lead to positive emotional experience, its persistence producing negative affect.

Evolutionary conceptions of emotion. Charles Darwin's *Expression of the Emotions in Man and Animals* (1872) had a profound influence in systematizing emo-

tion research. In his principle of "serviceable" association of habits, he suggested that emotional expressions are evolutionary remnants of previous adaptive behaviour, persisting (even uselessly) in a mild form (*e.g.*, snarling as a sign of aggression). In his principle of antithesis, concerning the multiplicity of emotional expression, he posited that "habitual actions" serviceable to "certain states of the mind" were replaced by contrary (antithetical) movement patterns that automatically tend to appear during the "opposite state of mind," even if they have no adaptive function. Darwin was suggesting that even "useless" emotional expression (and, consequently, its subjective correlates) derives from adaptive functions. Darwin's influence clearly can be seen in a later trend that dealt with emotions as a group of behaviour-controlling *processes* rather than as "mental" entities.

Patterns of emotional expression. In keeping with his initiative, some of Darwin's contemporaries began a continuing research effort toward understanding and classifying facial expressions and other movements that reflect emotional activity. A belief in universal patterns in human emotional expression is neither new nor entirely unfounded. Comic and tragic masks in European and Asian theatre provide ancient evidence.

In such research, statistical analysis is made of posed or active emotional mimicry by subjects; specific facial expressions are depicted in drawings, paintings, and photographs; and expressive behaviour is directly observed and evaluated. Some data provide cross-cultural comparisons, or concern emotional expression in the blind and among people of different ages.

Facial expression

Although partially validating some fundamental expressions (such as laughing or weeping) these investigations have not offered convincing evidence that mimicry in itself is a dependable indicator of subjective emotional states. Judgments of observers are clearly suspect.

Systematic analysis of criteria for evaluating emotional expression led U.S. psychologist Robert S. Woodworth (1869–1962) to devise a six-part scale: (1) love, happiness, mirth; (2) surprise; (3) fear, suffering; (4) anger, determination; (5) disgust; (6) contempt. Studies based on this scale led to a model that incorporated three emotional dimensions: pleasant–unpleasant, attention–rejection, and intensity. Such models are of uncertain value because of differences in cultural influence, in individual facial anatomy and muscular mobility (*e.g.*, deadpan), in tendency to dissimulate (*e.g.*, the false smile), and in emotional expression at different age levels.

Nevertheless, observation of the blind and studies of electrical stimulation to the brain among laboratory animals demonstrate distinct patterns of mimicry, gesture, posture, and vocalization in fundamental emotional phenomena (such as those interpreted as fear and anger). Among newborn infants (humans and anthropoid apes) indications of general excitement are about all that can be observed. Specific emotional expression (*e.g.*, smiling) first appears about the third month among human infants. Mimicry later becomes more differentiated, and it is characteristic of children aged three to five to recognize and readily produce mimicry related to joy; but they tend to have real difficulty with expressions of surprise and contempt. Emotionally expressive mimicry by blind adults is relatively poor, demonstrating that emotional expression is learned as well as genetically mediated.

Mimicry in infants and blind people

Efforts to interpret gestures, postural reactions, and vocalizations that accompany facial expressions still rest heavily on everyday observations with only limited scientific evidence available. It has been suggested that behind every interpretation one makes of emotional expression in others there lies a complicated, unreliable, intuitive act; just how unreliable such estimates can be is well demonstrated by prejudice and social misunderstanding.

Despite modest progress, efforts to classify emotional activity on the basis of expressive movements cannot be considered successful. Such activity is not as homogeneous as the simplified, abstract language of classification might suggest. Traditional terms based on manifest behaviour barely begin to reflect the transient, contradictory nature of emotional activity. The common confusion was in error; neurophysiological evidence suggests that such experiences may alternate quite rapidly.

THE PHYSIOLOGY OF EMOTION

Emotion as bodily sensation: James–Lange theory. William James (1842–1910) stated that his own theory of emotion would be as difficult to verify as to refute: "The best thing I can say for it is, that in writing it, I have almost persuaded *myself* it may be true!"

Evidence from studies of perceiving and of brain function (as well as his own introspections) led James to conclude that emotions are perceptions of changes within the body itself: ". . . the bodily changes follow directly the *perception* of the exciting fact . . . our feeling of the same changes as they occur *is* the emotion." According to James: "An object falls on a sense-organ and is apperceived by the appropriate cortical centre; or else the latter, excited in some other way, gives rise to an idea of the same object. Quick as a flash, the reflex currents pass down through their preordained channels, alter the condition of muscle, skin and viscus; and these alterations, apperceived like the original object, in as many specific portions of the cortex, combine with it in consciousness and transform it from an object-simply-apprehended into an object-emotionally-felt."

This abstract formulation may not convey the unexpected, shocking effect it had on everyday thinking. In its already classic popularization it meant that one does not run from an unexpected encounter with a bear out of fear; one is frightened *because* of running away.

James supported his postulate with excellent examples of major sensory impressions that evoke changes mediated by the autonomic nervous system (*e.g.*, blushing) evident even to naïve observers. A Danish physician, Carl Georg Lange (1834–1900), stressed changes in the circulatory system in his own version of the theory. It seemed to both James and Lange that emotional qualities were the result of perceived changes in bodily activity that followed sensory impressions. An enduring line of research has indeed emerged from this theory.

Visceral and chemical patterns. Beyond the James–Lange theory, elucidation of the structure and function of the autonomic nervous system marked a major contribution to the study of visceral correlates of subjective emotional states. Clear evidence was found of neural control over most viscera through the two autonomic divisions: sympathetic and parasympathetic. The sympathetic division functions through thoracic and lumbar spinal nerves; parasympathetic activity is mediated by brainstem structures (cranial nerves) and those of the sacral region of the spinal cord. In some organs the two have opposite effects (*e.g.*, heart rate is slowed by the parasympathetic and accelerated by the sympathetic). Its diffuse connections, however, make the sympathetic division more suited for general effects, while the parasympathetic tends to mediate selective, localized activity. Both systems can inhibit and excite; for example, sympathetic effects usually are to inhibit digestive function and selectively to dilate or to constrict blood vessels.

U.S. physiologist Walter B. Cannon (1871–1945) drew attention to the close relationship between emotional activity and sympathetic function. According to his emergency theory of emotion, the sympathetic division of the autonomic nervous system helps the organism face stress. A cat that faces an aggressive dog responds with increased heart rate and breathes more rapidly. In the cat's eyes, pupils dilate and blinking (nictitating) membranes retract; digestive function is inhibited; hair stands up; perspiration appears on the pads of the feet; the number of red cells in the circulating blood increases through contraction of the spleen; adrenal-gland activity is stimulated; glucose is mobilized into the bloodstream from glycogen storage in the liver. These symptoms all reflect sympathetic activation; Cannon's classical suggestion (1915) was that they increase resistance to stress and enhance defensive abilities (fight or flight).

Cannon's emergency theory

Nevertheless, a growing experimental literature indicates that Cannon's focus on the sympathetic division was too narrow. Among humans and other animals parasympathetic emotional effects also appear. Defecation and urination by frightened soldiers are under parasympathetic control. Among monkeys and human infants, a sudden auditory stimulus may produce parasympathetic penile erections, besides eliciting a distinctive, generalized bodily reaction (startle response).

Blood-sugar levels increase in response to sympathetic adrenal activation in rats after sudden, loud noise, and in cats frightened by a dog. Yet, after surgical removal of the adrenal glands, the same stimuli trigger pancreatic insulin secretion to decrease blood-sugar levels. This effect can be abolished by cutting the animal's (parasympathetic) vagus nerve (that initiates insulin production). Clearly, both autonomic sectors are active in marked emotional states. This and similar evidence casts doubt on Cannon's notions that sympathetic (or adrenaline) effects are the hallmark of emotional arousal and that they always are adaptive. Excessive elevation in heart rate, for example, will produce a maladaptive decrease in the volume of discharged blood. While adrenaline optimally mobilizes sugar stored in the liver as glycogen to decrease muscle fatigue, in larger doses it actually decreases blood flow in the functioning muscle.

Adrenal function

Emotional activity clearly shows characteristic combinations of sympathetic–parasympathetic effects. The earlier assertion that such visceral changes are essentially quantitative, and therefore unsuitable for distinguishing emotional qualities, has become less tenable. Bodily evidence of fear (or anxiety) gives promise of being discriminable through rigorously controlled psychophysiological experiments; electronic devices permit remarkably complex observation, and improved methods of hormone detection and quantification have become available.

During intense fear one's face usually is pale; it flushes during anger. Similarly, in chronic cases of gastric ulcer, when the lining of the stomach was observed directly, gastric secretion was inhibited during fear and the mucous membrane blanched; when the patient seemed angry or happy, the lining flushed. Similar findings have been reported for nasal and vaginal membranes.

The sympathetically controlled medulla (core) of the adrenal gland produces the hormones epinephrine (adrenaline) and norepinephrine (noradrenaline). Each hormone has different cardiovascular effects; from these it has been shown that people who exhibit fear react by secreting epinephrine; when they manifest anger or hostility, they produce norepinephrine. This is supported by findings that the adrenal glands of aggressive predators (such as dogs and cats) contain norepinephrine, while the fearful rabbit's contains epinephrine.

Monkeys under sudden, marked stress (apparently uncertainty or fear) showed increased blood-plasma levels of both hormones from the adrenal medulla, and of other substances (17-hydroxycorticosteroids) produced by the gland's cortex. When a monkey was prepared by a warning signal, however, epinephrine level remained normal, corticosteroids decreased and norepinephrine increased. Stimuli that elicted no signs of fear or anxiety tended to decrease blood pressure and pulse rate (parasympathetic effects). In other research, a quantitative relationship was reported between peripheral vasoconstriction (narrowing of blood vessels) and estimated degree of anxiety.

Serotonin, a substance found in many parts of the body, may have immediate emotional effects. An increase of serotonin that follows introduction of its biochemical precursor into the brain generates signs of ecstasy and euphoria. Drugs that imitate the effects of serotonin have analogous chemical structures and produce excitement, hallucination, and agitation; drugs that are serotonin antagonists tend to generate feelings of depression. Psilocybin (found in certain mushrooms), used in Yucatán for centuries to induce trance states, and LSD (lysergic acid diethylamide) are serotonin-like. Antagonists include the tranquillizers reserpine and chlorpromazine. Many hormones (*e.g.*, sex hormones and thyroxine) have significant influence on emotional function (see also HALLUCINOGEN).

Serotonin

Physiological detection of emotion. *The galvanic skin response (GSR).* A most sensitive indicator of sympathetic activity level is the galvanic skin response (GSR), also known as the psychogalvanic reflex (PGR), or the electrodermal reflex (EDR). The fluctuating electrical resistance (or conductivity) of any part of the body may be measured through electrodes on the skin (*e.g.*, on the palm and back of the hand). GSR fluctuations occur in response to such influences as frightening stimuli and are usually quick and transient; there also are more-or-less regular, slow changes during the course of a day. GSR latency (time lag) and voltage have not proved reliable indicators of specific emotional qualities, probably because they are too sensitive. Stimuli perceived as pleasant or as unpleasant can change GSR. In problem-solving tasks, subjects first tend to show elevated GSR activity; this decreases as tension dissipates with learning. Such changes usually are attributed to the subject's general level of physiological activity or to his degree of attention, as well as to his emotional intensity. Used with other indicators, the GSR has been helpful in studying emotional arousal or mood. Its doubtful use in lie detection presumably depends on sympathetic changes that accompany feelings of guilt (see below *Lie detection*).

Respiratory signs. Although respiration is partly under the control of autonomic brainstem centres, it also can be voluntarily influenced. Respiratory patterns once were expected to discriminate among what were thought to be primary emotional processes: enjoyment, pain, anger, astonishment (surprise), fear, and disgust. These hopefully were to be reflected in the changing inspiration/expiration ratio (I/E), based on the time the subject took to inhale and to exhale. It also was thought that specific I/E ratios could indicate lying as well, but well-controlled experiments dimmed most of these hopes. Weeping, however, can be differentiated by its sobbing interruption of inhalation, and in laughing, exhalation is spasmodic. Both patterns are observed as involuntary symptoms among those with injuries in the nervous system.

Muscle tone. Muscle tone, the degree to which a group of muscles is contracted, is another peripheral and general indicator of excitement, fear, and anxiety. Neck muscles exhibit particularly characteristic electrical changes (muscle potentials).

The startle reflex to unexpected, intense auditory stimulation usually is considered to be an emotional phenomenon. This complicated response involves skeletal muscles (particularly flexors) and viscera. First there is blinking (with a latency of about .04 of a second after stimulation); next the skeletal muscles react after a lag of about 0.1 of a second; after about one second, more complex signs appear (*e.g.*, GSR, blood pressure elevates, pulse rate quickens). In this hierarchy of latencies, some theorists see a distinctive sequence of the central nervous system.

Startle reflex

Lie detection. Word-association techniques have been used in criminal interrogation combined with physiological indicators of emotion. One is asked to respond to a number of words (some related to the given crime) with the first word he thinks of each time. Emotional tension elicited by critical words is assumed to be indicated by verbal hesitation and by such indicators as respiration, blood pressure, and GSR. Forms of a device (polygraph) are commercially available for such recordings. Most experts judge accuracy to depend heavily on the interrogator's experience and to be subject to serious error.

Soviet psychologist A.R. Luria suggested in 1932 that involuntary finger movements reflect emotional aspects of lying more sensitively than does word association. In the Luria method, one presses a key that registers pressure at each of his verbal associations. The pressure pattern is supposed to reflect increased muscle tension during emotional conflict.

Value of peripheral phenomena in classifying emotional states. Peripheral signs fail to give unequivocal support for the James–Lange hypothesis. Most visceral and chemical (humoral) indicators simply reflect a quantitative,

general level of emotional tension (although there are hormonal and vasomotor signs characteristic of fear–anxiety and joy–anger–resentment). The viscera and central nervous system also have routine regulatory functions that can cancel each other. Despite use of the polygraph to record complex peripheral responses simultaneously, chances are poor for developing emotional classifications based on visceral responses alone.

Further caution is indicated by work showing that the brain can mediate conditioning of visceral reflexes more precisely than once was assumed (particularly in autonomic change). Indeed, highly specific visceral and vascular reactions (as in high blood pressure) have been controlled experimentally by conditioning.

Cognitive effects on response to adrenaline

Apparently contradictory evidence regarding the James–Lange theory also comes from response to injections of such agents as adrenaline. Earlier experimenters reported genuine emotional effects in only a fraction of such cases. Carefully designed later experiments with humans suggested that the emotion-mobilizing effect of epinephrine varies considerably with the subject's cognitive state. (Some of the experimental subjects who watched live filmed slapstick antics were informed of the bodily experiences to be expected from their epinephrine injections; others were not.) It was concluded that the expectations of the individual are decisive in experiencing emotional qualities induced by epinephrine. Injection is not necessarily equivalent to normal physiological excitement, however; and adrenaline has central effects (in the brain and spinal cord) as well as peripheral influence.

INSTINCT AND BEHAVIOUR

Instinct theories. Darwin's view that emotionally expressive activities are evolutionary remnants and James's notion that emotion is organic sensation supported efforts to interpret these functions as instinctive. Instincts are defined as genetically fixed patterns of activity, and it is critical to differentiate them from acquired behaviour. While British psychologist William McDougall (1871–1938) attempted to specify an appropriate emotion for every instinct, his list has shrunk considerably in modern versions. One of these reduces the array to the following: incorporation, rejection, destruction, protection, reproduction, deprivation, orientation, and exploration. In this model, emotional intensity is said to vary within these eight qualitative dimensions. Such speculative models neglect the quantitative effects of cognitive, energizing factors in emotion. For similar reasons the concept of instinct came on hard times in the first half of the 20th century.

About that time a distinct research movement (ethology) was developing in Europe. Avoiding the speculative aspects of earlier instinct theories, ethologists provided evidence for instinctive behaviour among animals in the wild. Their strict empirical data pointed to instinctive functions not clearly manifested under rigid laboratory conditions. A territorial instinct, for example, seems well supported and could help account for such emotional behaviour as aggression, fighting, courage, cowardice, and pride. Austrian ethologist Konrad Lorenz assumed a close relationship between emotion and instinct, seeking evidence of human instincts in verbal reports of emotional experience. Uncertainty in such an undertaking stems from evidence that instinctive behaviour in humans is greatly modified by learning. Ethologists seem to face the formidable problem of distinguishing these two factors in every individual case. Nevertheless, unless all human behaviour results strictly from learning, instinctive tendencies merit attention.

Psychoanalytic theorists (S. Freud, C.G. Jung) assumed a close relationship between instincts and emotions, but failed to provide a systematically complete account. Their influential, but indirect, effect on research efforts is discussed under MOTIVATION.

The behavioral approach to the study of emotion. Such extreme behaviourists as U.S. psychologist John B. Watson (1878–1958) held that subjective aspects are to be disregarded; that only objective emotional behaviour is measurable and, therefore, significant. Instinctive behaviour was viewed as an unconditioned chain of activity, fundamental emotional reactions being described as unconditioned reflexes. An impressive finding of behaviouristic research was that emotional behaviour could be conditioned to appear on signal. Watson named fear, rage, and love as the basic emotions, and showed how readily they could be elicited from children, rabbits, or other animals by a conditioned (initially neutral) auditory or visual stimulus.

Emotions as conditionable reflexes

Among more sophisticated, later representatives of behaviourism, emotional intensity gained a central position. The U.S. neobehaviourist B.F. Skinner in 1953 wrote: "We define an emotion—insofar as we wish to do so—as a particular state of strength or weakness in one or more responses induced by any one of a class of operations."

MOTIVATION AND EMOTION

By the 1930s the term instinct was largely being replaced by the language of drive and motivation, so much so that it was being asked whether what was coming in the back door had not just been thrown out the window. With the word motivation, psychologists indeed faced some of the earlier difficulties they had with the notion of instinct. Laboratory studies indicated that stimulus and response were separated by a relatively unobservable process that itself is a condition of learning. This intervening process (represented by such words as hunger, thirst, fear, or sexual desire) was not considered a special problem by classical reflexologists who saw it in terms of complex, unconditioned chains of instinctive reflexes. As a subjective emotional experience, it was held by behaviourists to be unworthy of attention. Yet, when instrumental or operant conditioning to rewards and punishments came to be widely studied, what had been called instinct seemed to loom as central problems once more.

The concept of drive. Drive (motivation is a more general synonym) was defined as a characteristic state of excitement that appears under physioloigcal (homeostatic) imbalance. An organism deficient in some nutrient, for example, shows specific food-seeking activities. Drive states were defined as intervening variables (or hypothetical constructs) to be inferred from observable antecedents (*e.g.*, food deprivation) and consequences (*e.g.*, food seeking). Consequences were held to be systematically manipulable through antecedents, and the critical factor in instrumental learning (or reinforcement) was believed to have been found in drive reduction. Evidence was offered to show that originally indifferent stimuli, if consistently presented when reinforcement occurs, can become reinforcing and drive-inducing (incentive, cue) factors themselves. Attention was thus focussed on the role of learning in establishing central motivational states that influence behaviour generally. The motivational process was conceived in the 1970s as a complex of neural and humoral changes that reflect learned tendencies; the concept seemed to be widening to include specific anatomic–functional endowments of the central nervous system. This superficial description is intended to aid in understanding a growing debate that began in the mid-1930s with the question of emotions, appeared to reach a peak in the early 1950s, but still continued on into the 1970s.

Drive states

Energy and emotion. To some psychologists most of the empirical and assumed characteristics of motivation coincided with those of emotion. Elizabeth Duffy, a pioneer in motivational interpretations in the U.S., argued convincingly that the concept of emotion was no longer justified in a scientific context. She held that definitions of emotion describe nothing qualitatively different from other activities or response patterns, and that so-called emotional activity was simply a quantitative change in the energy level of the organism. Duffy interpreted the associated subjective experiences merely as the conscious aspect of adaptive function, noting that "emotion" is: ". . . the individual's response to situations which promise well or ill for the attainment of his goals." She held that relatively slow, mild, and consistent

Emotion as change in energy level

changes in energy level produce subjective states corresponding to the old notion of "mood," and that rapid, intense changes generate "emotion." She noted that energy level (including its introspective aspects) varies along a continuum so that there is no fixed point at which a "nonemotional" level suddenly becomes "emotional."

The last notion seems most significant and enduring. Essentially, it denies that emotion is an independent psychic entity, suggesting that it is not even a special quality that appears at a definite level of physiological intensity. On the whole, Duffy convinced many investigators that "emotion" is not to be separated from motivation; that the objective, experimental approachability of the latter should provide a sufficient basis for dispensing with the concept of emotion.

It is difficult, however, to understand Duffy's discussion of the conscious aspects of adaptative responses: "I think it will be agreed that the individual does not experience 'emotion' except in situations which are of significance to him." This apparently means that, if the environment does not create "significant" energy change, there is no "emotion." But it can be argued that the energy factor is not a state but an active process, even if it tends toward equilibrium; and that, consequently, in its integrated form, an emotional base is always given. It is difficult to understand how people can indifferently experience stimuli that do not generate perceptible equilibrium changes, since such changes should not be perceived at all. If perceptible changes are imagined that do not have a motivating consequence (*e.g.*, what William James called "cold" perceptions), Duffy's postulated continuum is broken, and emotional quality could be said to emerge only at a special point in the continuum. At any rate, Duffy gave no definite answers to such questions. The problem they present remained unsolved by the efforts of U.S. psychologist Robert W. Leeper to challenge the traditional belief that emotional activity is disruptive.

Emotion as disruptive

Organizing and disorganizing emotional effects. Leeper's work created stormy debates, since it seemed to contradict folk wisdom and obvious, everyday evidence of disorganizing effects on behaviour during fright or blind anger. Leeper argued that the essential function of emotion is to be sought in its *organizing* effects. Many of his critics held that emotion can be either organizing or disorganizing, depending on the situation. They seemed to be rapping on an open door, however, since Leeper himself already had considered the reorganization necessary for adaptation to be a simultaneous disorganization of earlier, inadequate behaviour. He emphasized that disorganization is not the *essence* of emotion. His critics seemed to miss the point, since Leeper's argument was with any approach that ripped subjective activity apart by offering cognitive, affective, and conative distinctions. The interpretation of emotions as disruptive endorses the view that human emotion (affective) is only a weakness, deriving from a brute animal heritage that is pitted against rationality (cognitive) and will (conative).

Despite the attractiveness of arguments of the sort offered by Leeper, experimental efforts to apply the motivational interpretation of emotions seem to be returning to the traditional view that was under challenge. Early in his work Leeper himself emphasized so-called higher, secondary, generally emotional factors, rather than motives deriving from homeostatic biological processes; his later writings showed this tendency even more.

In a brilliant psychological analysis of Sir Ernest Henry Shackleton's South Pole expedition, he argued similarly in favour of the decisive superiority of higher motivations (*e.g.*, achievement) against primary biological drives. He offered the critical conclusion that ". . . emotional processes basically and fundamentally are perceptual processes."

The richness and differentiation of perceptual function indeed sheds light on the variety of flexibility of human emotions. What is of theoretical concern is that the perceptual conception offered by Leeper seems inconsistent with the emotional-motivational continuum he (and Duffy) so unflaggingly defended. When he wrote of "motivationally neutral perception," he seemed to be arguing for discontinuity; clearly, he endorsed the possibility of unmotivated or emotionless perception. The possibility that this may be a return of the concept of "cold" (William James) highlights the critical and consistently recurring problem of perceptual function in emotion.

PERCEPTION AND EMOTION

Objections to the James-Lange theory. Although his emergency theory supported James's hypothesis that emotion is organic sensation, Cannon later categorically rejected that hypothesis: "(1) Total separation of the viscera from the central nervous system does not impair emotional behavior. (2) The same visceral changes occur in very different emotional states and in nonemotional states. (3) The viscera are relatively insensitive structures. (4) Visceral changes are too slow to be a source of emotional feeling. (5) Artificial induction of the visceral changes typical of strong emotions does not produce them."

Though it seemed that these critical statements of Cannon's would end the debate on the James–Lange theory, James's prophecy that it would be as difficult to reject as to verify his hypothesis was to prove stubbornly viable. British Nobelist C.S. Sherrington (1857–1952) had presented impressive experimental support for Cannon's first, apparently most telling, objection. Despite such measures as surgical severing of the spinal cord (at the neck) and of the parasympathetic vagus nerve, ostensibly "isolated" heads of laboratory animals consistently continued to show a full range of emotional expression.

It was argued that laboratory animals cannot give introspective reports. People with severed spinal cords, however, report a full range of emotional experience.

The impact, however, is considerably reduced when it is realized that visceral impulses still can reach the brain via intact cranial nerves. Humoral (chemical) information also continues to be carried by blood from lower parts of the body (although this represents a relatively sluggish process).

Cannon's principal objection to the James–Lange theory is that animals without peripheral feedback will respond emotionally only to stimuli to which they had earlier learned to respond. Theoretically, once emotional expression is conditioned, visceral impulses are no longer necessary; but this assumption has defied experimental verification.

Even if there is no absolute correlation between visceral–somatic activity patterns and specifically experienced emotional qualities, the possibility of some relationship cannot be excluded with certainty. In summary, most of Cannon's arguments seem questionable; however, consider now his statement that visceral alterations are too sluggish to be an immediate source of subjective emotional experience.

At the turn of the century, attempts to measure the speed of visceral responses indeed indicated that they proceeded too slowly to be held responsible for subjectively "felt" emotions. But there was considerable reluctance to reject the James–Lange theory on these grounds since the accuracy of introspective accounts was not trusted. There is, however, one consideration of the time factor that avoids this difficulty, once and for all showing that peripheral theories of the genesis of emotions have become untenable.

"Cold" and emotionally "coloured" perception

James's abstract description of neural mechanisms tends to oversimplify and harden emotional processes into states. If the events he described be reconsidered, this time with special attention to the time factor, the environmental stimulus that initiates definite changes in the brain cortex then becomes the first event. This cortical activity represents what James called a "cold" perception, subjectively an awareness of the stimulus devoid of affect, though the existence of such a discrete state has been challenged. Next, the pattern of neural excitation was held to flow from the cortex to other parts of the body (the periphery) to produce an appropriate bodily (somatic) response. Secondary impulses feeding back

from somatic receptors to reach initially excited parts of the cortex were said to lend emotional "colouring." James was asserting separate perceptions rather than an essentially unified process: a "cold" perception that reflects external stimulus relationships, followed by an emotionally "coloured" perception.

In itself, the assumption of a "cold" perception contradicts James's repeated statements, in other contexts, that perceiving cannot be deprived of emotional elements. The contradiction might be resolved by asserting that the final form of perception develops in two phases. A much more serious objection arises, however, when it is asked if the environmental stimulus excites an initially indifferent, quiescent cortex. Clearly, the cortex is affected by a constant stream of impulses coming from other parts of the body. It can justly be asked whether this continuing process does not "colour" the effect of every incoming environmental impulse. This is possible, but obviously would not fulfill the requirements of James's hypothesis, since it involves visceral responses to other, earlier stimuli. It could also be imagined that any residual cortical excitement would always be erased by the immediate environmental stimulus, but this would wipe out traces of any equally significant earlier stimulus, change the experience to a "cold" perception, and leave "emotional gaps" in the perceptual process. By this assumption, emotional components could not develop during any rapid sequence of incoming stimuli. The only alternative to this would seem to be that the environmental impulse is emotionally "coloured" immediately on arrival, perhaps because the incoming impulse interacts with earlier cortical processes that reflect continuing visceral–somatic states, or because the environmental impulse on its way to its specific cortical projection area may stimulate brain tissues that represent the viscera. It can be assumed that the initial impulse can travel either toward the cortex or toward the periphery. The peripheral flow would elicit characteristic visceral–somatic responses while the other would stimulate the cortex with minimal delay to lend "colouring" to the already activated sensory projection area. Even if this makes two perceptions plausible, both would be emotionally "coloured." The dominant bodily activity at the moment the environmental impulse directly stimulates the cortex "colours" the effect of that impulse, while the second lends "colour" by altering the peripheral response. This happens much faster than James assumed, since the development of peripheral reverberations *de novo* is not needed. These assumptions coincide with empirical measurements that show subjective emotional response to precede induced visceral change.

Cannon's thalamic theory. Many points of the interpretation just given have been experimentally verified. The interpretation failed to gain explicit expression in Cannon's time when much less was known about expressive emotional patterns and about visceral representation in the central nervous system. Nevertheless, Cannon's (1927) thalamic theory of emotion rested on similar considerations. (The thalamus is the prominent structure of the diencephalon; a major relay centre, it integrates the periphery, other subcortical regions, and the cortex.)

Experimental and clinical observations had led to the conclusion that the integration of fundamental emotional processes is mediated by subcortical brain structures. By the end of the 19th century it had been found that animals surgically deprived of cerebral cortex can show marked emotional symptoms (*e.g.*, anger, attack). Particular attention had been drawn to the human thalamus by emotional aberrations associated with circulatory disturbances or tumours there. Unilateral thalamic injuries were known to intensify sensitivity on the same side of the body, heightening both pleasant and unpleasant sensory experiences and disturbing emotional expression (*e.g.*, producing involuntary crying and laughing). In view of such evidence, the anatomical position of the thalamus and its extensive cortical connections persuaded Cannon to concentrate on this centre in seeking the central integration of emotion. Specifically, he posited that environmentally produced impulses moving toward the cortex simultaneously excite appropriate thalamic regions. Those resulting thalamic impulses that flowed to the cortex were said to provide the perceptual "colouring," the other thalamic impulses serving to excite visceral and somatic expressive emotional patterns. A significant element of Cannon's theory (especially attractive to psychologists) is that of inhibition of the thalamus by the cortex to control the emotional component (unless followed by an appropriately intense external stimulus).

Criticism of Cannon's theory

In addition to enthusiastic support, Cannon drew criticism that largely objected to selecting the thalamus as the centre of emotional activity. Critics observed that many expressive symptoms attributed to the thalamus (*e.g.*, compulsive crying and laughing) can be produced by injuries to other points in the nervous system. Besides, most people with such injuries reported no subjective emotional experiences appropriate to the symptoms; for example, one might cry without feeling sad. The existence of a portion of the neural pathways postulated by Cannon was also contested. Accurate on many points, these objections were not so much to Cannon's general theory as to the anatomical bases he specified. Cannon's basic hypothesis can be considered a precursor of activation theory in which subjective and expressed emotions clearly were held to be integrated by the central nervous system. In this sense, Cannon's theory continues to be endorsed.

ACTIVATION THEORY

Pathologies such as brainstem lesions in human encephalitis (producing disorders of wakefulness and sleep) and emotional symptoms associated with circulatory disorders and subcortical tumours served to draw attention to the integrative role of the midbrain. Improved stereotactic devices for accurately placing electrodes and cannulas deep into the brain made it possible to study these regions in freely active animals. Permitting focal electrical and chemical stimulation, circumscribed tissue destruction, and detection of spontaneous, local electrical activity in the brain, these methods in the 1930s began an avalanche of discoveries.

Sleep and wakefulness were found to have readily distinguishable spontaneous electrical patterns in the brain. People in deep sleep, for example, tend to show a high-voltage, slow pattern; during relaxed wakefulness lower amplitude (or voltage) and more rhythmic, higher frequency is characteristic. Among cats with their cerebrospinal axes severed at different points, such electroencephalographic indicators show that intact pathways connecting the mesencephalic brainstem to anterior brain structures are indispensable for wakefulness.

Electroencephalography

Local electrical stimulation has established that the brainstem's central, netlike structure of gray matter (reticular formation) is responsible for wakefulness (rather than sensory pathways on the edges of the mesencephalon). Stimulation of the reticular formation in slightly anesthetized animals induces throughout the cortex fast, low-voltage waves (so-called desynchronized activity) characteristic of wakefulness. Selective destruction of the reticular region results in enduring sleeplike coma.

Reticular electrical activity indicates that many pathways to the cortex send collateral fibres into the reticular formation. Collateral impulses in the netlike structure contribute to diffuse reticular excitement that passes via the thalamus to activate the whole cortex. The abbreviation ARAS (for ascending reticular activating system) has taken firm root in the investigative literature.

Wakefulness thus arises not only from direct cortical stimulation by specific sense receptors but also from reticular function that integrates receptor effects to influence the entire cortex. On this basis inferences have been made about emotion: (1) The functional continuum associated with the ARAS includes all organized psychological processes from sleeping to extreme states of excitement; consequently, it includes emotion. (2) The basic functions of the ARAS (activation, arousal) coincide with those considered most typical of emotion in motivational theories. Consequently, this continuum of activation also

is a motivational-emotional continuum. (3) Impulses arising from both the internal and external environment act to excite the ARAS, and the activating effect of the ARAS is a precondition for the integrative function of the cortex. It follows that even the most elementary perceptual effect is emotionally "coloured" from its very inception.

These three considerations are the basis of the activation theory of emotion developed by U.S. psychologist Donald B. Lindsley (1951), according to whom activation is a continuum along which degrees of intensity may be measured alternatively as visceral–somatic responses (peripheral effects) or as central electroencephalographic responses. At one end of the intensity continuum are the first arousing, orienting reactions of attention; the other extreme is characterized by major signs of emotion.

Activation theory has been well-supported and extended by experimental evidence. For example, the activation effect, once believed to be restricted to the reticular formation, involves other parts of the brain, including several structures of the limbic system (see below *The limbic system*).

Autonomic function in homeostasis

Anatomically the activating mechanism embraces the autonomic nervous system (also called the vegetative system), characterized as controlling the stability (homeostasis) of the internal milieu. Autonomic function is under the influence of neural impulses from the viscera and also of humoral factors such as metabolic waste products and hormones. Beyond homeostasis, these factors have general activating, arousing effects as well. At the same time, autonomic function affects the readiness of skeletal muscles to react. Complicated stimulating and inhibiting effects on this musculature arise chiefly from a specific portion of the spinal outflow (the so-called gamma-fibre loop). Apart from this, sharp patterns of emotional expression can be elicited from the activation system, particularly the hypothalamus.

Postulated effects of activation on discriminative cortical function have been verified. Mild reticular electrical stimulation reduces the time required by monkeys to discriminate among briefly flashed pictures. Stimulation of specific points on the cortex can result in diffuse reticular activation, although the cortex on the whole tends to inhibit reticular function. The latter mechanism amounts to a negative feedback loop from the reticular system to the cortex and back. This regulatory effect indeed could correspond to the cortical inhibition postulated by Cannon.

Objections to the activation theory of emotion stem from considerations already known to its author when he wrote: ". . . activation theory appears to account for the extremes, but leaves intermediate and mixed states relatively unexplained as yet." Activation theory indeed fails to explain individual emotional qualities, tending to clarify negative rather than positive emotions. The notion of moderate activation as pleasant and of intense activation as unpleasant seems simplistic since both negative and positive emotions show extremely wide ranges in level of excitement.

Despite criticisms of activation theory, it is still argued that the basis for individual emotional qualities should be sought in the details of the activation system. Nevertheless, some psychologists assign primary, determining emotional function to cognitive factors.

REGULATORY THEORY: EMOTION AS RELATED TO HOMEOSTATIC MECHANISMS

Hypothalamic activity. Below the thalamus, the hypothalamus forms part of the walls and floor of a brain cavity, the third ventricle. This relatively small hypothalamic structure is a complex receptor area, remarkably reflecting the state of the internal milieu by reacting to humoral and neural stimuli. It functions homeostatically through its dangling pituitary (the so-called master endocrine gland) and through its efferent neural connections; *e.g.*, helping to regulate blood circulation, body temperature, fat metabolism, and sexual function. Hypothalamic impairment can severely and chronically disturb such functions. This bit of brain also is a substrate for marked emotional expression (*e.g.*, fear, anger). The question of a connection between hypothalamic regulatory and emotional function seems fundamental.

The striking evidence is that every apparently distinct regulatory function is mediated by a structurally discrete, functionally contrasting pair of hypothalamic subcentres. This parallels lower brainstem organization (as in opposing effects on respiration and blood pressure). Stimulation and destruction of disparate hypothalamic centres have contradictory effects. Frontal hypothalamic stimulation primarily yields parasympathetic activity called trophotrop (constructive or protective) visceral functions. These include temperature regulation (heat-reducing mechanisms). Posterior hypothalamic stimulation tends to mobilize sympathetic or ergotrop (energy-consuming) visceral effects such as heat production. Destruction of any of these centres disturbs or abolishes their function; with frontal hypothalamic injury, animals are defenseless against overheating and, with posterior damage, against chilling.

Trophotrop and ergotrop effects

Lateral hypothalamic stimulation induces even well-fed animals to eat voraciously; stimulation of the ventromedial region will make the hungriest animal stop eating or chronically reject food. Reciprocally, lateral electrosurgical destruction abolishes feeding to the point of death from starvation. Ventromedial destruction has produced overeating (hyperphagia), in animals such as rats, cats, or monkeys, which become grotesquely obese.

The hypothesis that emotional qualities are interdependent with these regulating processes is supported by evidence that the posterior hypothalamus also is essential in integrating manifestations of anger and aggression. Injury to many cortical and subcortical areas (*e.g.*, the amygdala) can produce similar phenomena; however, the central significance of the hypothalamus clearly has been confirmed.

"Sham rage"

Anger reactions following hypothalamic injury or stimulation once were labelled "sham rage" (implying transient expressive movement devoid of subjective emotional quality). Yet, animals with such symptoms make goal-directed attacks on appropriate environmental stimuli. It is further demonstrable that hypothalamic stimulation promotes potentially goal-oriented reflex activity (*e.g.*, biting) triggered only by appropriate receptors (*e.g.*, when the region of the mouth served by the trigeminal nerve is denervated, no biting accompanies the other aggressive symptoms).

Manifestations of escape, defense, anger, and attack have been elicited from a contiguous region running from the amygdala through the hypothalamus to the mesencephalon; one worker concluded that brain tissues responsible for escape form a concentric zone that surrounds the region of tissue that produces signs of attack. This spatial configuration suggests a reciprocal, functional relationship that is strikingly demonstrable. When movement is restrained during electrical stimulation of an animal's escape zone, the original effect is transformed into clearly contrasting signs of angry aggression.

The fundamental emotional role of the human hypothalamus emerges during neurosurgery and in hypothalamic disease. Mechanical manipulation or electrical stimulation of the patient's hypothalamus generates violently aggressive or euphoric outbursts.

Recall definitions of drive and motivation as intervening variables inferrable from antecedents and consequences. Yet electrical stimulation of the hypothalamus has identical motivational effects to those ordinarily observed. In a genuine sense identification of the neurological substrate lends such intervening variables more than mere hypothetical validity. Instrumental conditioning by direct brain stimulation does effect enduring motivational changes; they are not simply transient expressive movements.

The motivational effects of such stimulation have been known since the 1950s. Reinforcement in learning escape and avoidance reactions is provided by allowing animals to switch off escape-inducing brain stimulation. After a few successful trials, animals learn to manipulate the

switch in an instrumental response to a warning stimulus or to brain stimulation itself. Animals that have been conditioned only by warning signals will execute learned avoidance and feeding responses in a coordinated fashion when the hypothalamus alone is stimulated, without the warning (conditioned) stimuli.

Brain stimulation as reinforcement

The phenomenon of self-stimulation through electrodes implanted in the brain was discovered in work originally designed to investigate motivational effects. By pressing a bar or pedal, a rat can stimulate implanted parts of its own brain. For some brain loci, continuous, enthusiastic pressing is observed and for other locations, systematic avoidance of the pedal is noted, suggesting emotionally rewarding and punishing effects. The method seems to hold promise for quantitatively mapping (in terms of pressing rate) the two fundamental emotional qualities in the brain. (For example, the number of times an animal presses to interrupt a continuous punishing stimulus can be recorded.)

Reward and punishment centres in the brain

It already has been shown that rewarding and punishing effects are mediated through relatively well-defined and distinct regions. Reward primarily seems to involve the medial forebrain bundle running from the lateral hypothalamus to the brainstem, punishment being associated with the medial hypothalamus; these effects seem to overlap in some regions. Both effects can be elicited elsewhere (amygdala, hippocampus, thalamus, mesencephalic tegmentum), although data for precise localization often have been contradictory.

Despite this evidence for central emotional mechanisms, unanswered questions remain. If pedal pressing in self-stimulation really is equivalent to fundamental positive and negative emotional qualities, it is not clear how this is related to more common forms of emotional expression (*e.g.*, eating, sex). Nor is it known whether all of them are aspects of the same process or are intrinsically independent functions that simply overlap anatomically. A general underlying process seems to be at work in evidence that self-stimulation quantitatively changes with traditional efforts to manipulate drive level (*e.g.*, administration of hormones, castration, increased feeding or food deprivation). Yet, while self-stimulation or consummatory behaviour (*e.g.*, feeding) can be elicited from identical brain loci, the thresholds for these effects seldom coincide. Surprisingly, positive self-stimulation can be elicited from the same brain loci that induce marked anger reactions; the signs of anger do not interfere with self-stimulation.

Such data neither exclude nor endorse the possibility that reward and punishment in self-stimulation correspond to the excitement and inhibition of homeostasis. Though it might, for example, be implied that the motivation for food is emotionally positive and that food avoidance is emotionally negative (or vice versa); this would seem to be improbable since injury of the ventromedial hypothalamus increases food intake (with eventual obesity) only if food is easily obtained. When food-getting requires great effort, the animal will fast. In later stages following such injury, experimental animals become quite fastidious, chronically rejecting tasteless food and losing weight. Observations of this sort suggest that destruction of a subcentre assumed responsible for inhibiting food intake (a centre of satiation) does not increase but reduces the motivation of the animal to eat. (Perhaps the initially excessive consumption of easily accessible food is mediated by some feeding mechanism at a lower neural level.) A fundamental contradiction also seems to emerge from evidence that rewarding self-stimulation more or less coincides (at times is identical) with loci that prompt the animal to eat; on the other hand, areas that inhibit food intake (coinciding with satiation centres) have negative effects on self-stimulation. The subjectively critical problem is that the animal tends to stimulate a brain area that induces signs of hunger (from an introspective human point of view, a negative emotional state) rather than stimulating regions connected with satiation. It is not known why an animal will stimulate itself at a point in the brain that unfailingly produces signs of anger.

These discrepancies suggest that emotional-motivational qualities are not exclusive products of functionally independent subcentres representing contrasting effects; they seem to be integrated resultants of some kind of interaction among neural structures. The following data seem to support this interpretation.

Behavioral effects indicate that the initial, rewarding effect of stimulation of some hypothalamic regions gradually becomes punitive if stimulation is prolonged. Thus, and depending on the predetermined duration of stimulation, animals can be taught systematically both to connect and to disconnect themselves with two opposed pedals. Whatever the mechanism for such changes from positive to negative reinforcement, it decisively involves the intensity of stimulation. Under relatively mild hypothalamic stimulation animals rapidly learn to avoid a vicinity that will switch them off; with high intensity, approach to the switch-off zone also is learned quickly. Animals behave as if they want to sustain mild excitement and to stop intense stimulation. Mild stimulation seems to be emotionally positive, while intense excitement appears negative. While this adds little to the observation that activation theory fails to account for positive emotional qualities of great intensity, what follows may hold genuine promise.

In the experiments just summarized, bodily movements from brain stimulation were recorded simultaneously with electroencephalographic data. Positive or negative emotional effects were found to be related both to the direction of induced movement and to electrical activity in the hippocampus. (Functionally, the cortical region called the hippocampus has a close and ancient evolutionary relationship with the hypothalamus.) Bodily movement toward the side opposite the stimulated hemisphere, associated with slow-wave activity in the hippocampus, signalled an effect the animal appeared reluctant to interrupt; that is, seemed to experience as emotionally positive. Movement or withdrawal toward the side of the stimulated hemisphere, combined with fast activity of a low amplitude (desynchronization) in the hippocampus, characterized an effect the animal consistently switched off, apparently experiencing it as emotionally negative.

Hippocampal indicators of emotional quality

Bodily movement and hippocampal electroencephalographic activity jointly provide an exceptionally flexible indicator of motivational-emotional effects. Systematic variation of the intensity of brain stimulation reveals that an initially positive emotional effect will increase with stimulus intensity or with time only to a given limit; it then progressively decreases and even may reverse. Analysis of movements and electroencephalographic responses invariably has suggested that an effect becomes emotionally negative in direct ratio to the degree with which the originally produced movement tendency is restrained or inhibited. This is the basis for the generalization that, in terms of its mechanism, negative emotion is synonymous with such inhibition. In this sense the process of negative emotion is not a homogeneous neural mechanism but a composite of simultaneous excitement and inhibition. In psychological terms, this corresponds literally to tension, as clearly is indicated by the aftereffects. At the moment brain stimulation is interrupted, the function that was progressively inhibited during stimulation erupts as an aftereffect. This brief but intense effect (in neurophysiology it is called a rebound response) is equivalent to emotionally positive activity according to the movement–hippocampal signs. When the rebound is repeatedly experienced in the same part of the laboratory, the animal will learn to approach that particular place. This evidence that sudden release of inhibited function tends to facilitate learning touches on a controversial aspect of the relationship between motivation and learning.

Excitement and inhibition

At any rate, these data illuminate the question of how the mechanism that generates intense, positive emotional activity is to be conceived: it seems to be one of liberation from inhibition. The movement–hippocampal indicators of this positive emotional quality in rebound are just as intense as the preceding signs of negative emotion, an observation that seems to relieve the inadequacy of

activation theory of accounting only for weak positive emotions.

It may be objected that the signs of positive emotion in rebound are either short-lived or contingent on previously existing negative emotional activity. It is also debatable whether the simple notion of liberation from inhibition does full justice to subjective experience of intense positive emotion. There is, however, evidence on which an account of the development of prolonged, intense, positive activity may be based. It has been established that long-lasting homeostatic conditions ("tuning states") of internal equilibrium can result from humoral and neuronal autonomic mechanisms (sympathetic or parasympathetic). It seems quite possible that the intensity and cyclic characteristics of homeostatic tuning correspond to introspective emotional qualities. Prolonged equilibrium seems to be an appropriate correlate of moods; rapid fluctuation being associated with such classically labelled emotional qualities as fright, surprise, and anger.

By this conception of emotion as a product of regulatory neurophysiology, the isolation of fundamental emotional qualities is to be sought in the dynamics of excitement and inhibition. Efforts to specify regulatory changes that produce any given emotional quality face the technical problem of concomitant measurement and identification of appropriate behaviour and of relevant neural activity.

Determinants of emotional quality

Perhaps emotional qualities also are determined by the adaptive purpose served by different regulatory functions. Although homeostatic processes that support life rest on identical principles, emotionally they are introspected as qualitatively different. The same regulatory mechanism (in identical phase and intensity) may mediate one's approach to a loved person or to a dish of favourite food; yet, romantic and epicurean appetites are perceived differently. Their distinction clearly rests on perceptual learning, itself already shown to depend on regulatory dynamics. Interaction and overlap of systems that regulate such behaviour as feeding and mating further complicate the study of emotional qualities since underlying mechanisms may not be separable.

At any rate, research into the regulation of motivation has simply provided an endorsement of the old, fundamentally two-dimensional (positive–negative) hedonic theory, all other qualities being held derivative. Nevertheless, the motivational approach has delineated indicators that seem to resolve once-puzzling discrepancies.

It bears repeating that in research limited to such peripheral autonomic indicators as vascular and hormonal changes, only two emotional qualities have been consistently separable. These indicators lump fear, anxiety, and similar states; then they paradoxically group extreme pleasure (joy) with a set of hardly agreeable subjective experiences such as anger, rage, and resentment. (Efforts to distinguish joy from anger in facial expression also produce confusion.) Added to this is the apparently paradoxical observation that an anger-producing hypothalamic locus also encourages self-stimulation.

Joy (emotionally positive) and such experiences as anger (traditionally regarded as negative) could be empirically confused through inadequate objective indicators if their underlying mechanisms overlapped too much. Indeed, overlap in terms of compressed sequence over time is observed during electrical stimulation of the hypothalamus. Evoked anger and attack consistently are preceded by signs of fear that last from a fraction of a second to a few seconds (depending on the stimulation). Somatic symptoms of fear are accompanied by hippocampal activity characteristic of negative emotion. Signs of anger and attack appearing as rebound (at the moment stimulation is switched off) or as an eruptive transition during stimulation are consistently associated with the slow, high-amplitude hippocampal activity (theta waves) characteristic of *positive* emotional states. According to the hippocampal indicator, rage and attack are to be interpreted as *positive* emotional reactions that arise as liberations from inhibition. This interpretation is buttressed by the observation that rage and attack have a typical motor pattern of approach (in contrast to withdrawal in fear and defense).

Thus, it seems less paradoxical that self-stimulation and anger go together. These experiments serve to illustrate the postulate that regulatory changes at different levels of intensity correspond to different emotional qualities. In these terms, rage is a positive counterpart of panic-like fear, emerging during a period of relatively intense homeostatic-motivational activity.

Rage and attack as positive emotions

Negative emotional-motivational neural signs among laboratory animals generally arise in situations that interfere with effort or tendency to approach a goal. The psychological terms frustration and conflict coincide by definition with such neuronal interpretations of negative emotions; namely, they also signify inhibition of the approach tendency. On the other hand, aggressive behaviour seems emotionally positive on the basis of regulatory indicators. Aggressive human personality changes, among the most common consequences of conflict and frustration, can also be conceived as the enduring symptoms of liberation from inhibition. Negative emotional aspects of what are called repression and regression might be interpreted as activities in which inhibition has become dominant.

The limbic system. Hypothalamic mechanisms fall far short of exhausting the emotional substrate. The hypothalamus mediates the most fundamental homoeostatic bases for survival of individual and species (*e.g.*, internally influenced metabolic function). These primitive, built-in, motivational-regulatory mechanisms permit wider possibilities for classifying emotion than seemed possible when activation theory first was developed. They also draw attention as archaic evolutionary sources of emotion. Learning processes, however, also become crucial in regulating motivation. Through learning, initially indifferent external stimuli become motivating and provide a basis for new learning. The individual gradually learns a complicated hierarchy of cognitive signs and relationships that have emotional significance beyond that of processes that serve physiological survival. Clearly, the hypothalamus alone is structurally insufficient for evaluating complex cognitive emotional influences or for integrating their ramifications in visceral response. Nevertheless, it is unlikely that complicated cognitive emotional processes are independent of or fundamentally different from hypothalamic mechanisms.

The influence of cognitive learning

Similar considerations led to a theory in the 1930s that attributed cognitive aspects of emotion to higher forebrain structures in close anatomic relationship with the hypothalamus. These were depicted primarily as perceiving emotion, contrasting the hypothalamus as a structure for its expression. The forebrain locus central to the theory is the cingulate gyrus (ridge) on the medial cortical surface. It is older in evolution than the brain's neocortex and simpler in structure. Through intermediate relay centres (hippocampus, mammillary bodies, anterior thalamus) the gyrus connects the hypothalamus with higher structures for emotional representation. This speculative emphasis on the cingulate gyrus directed attention to the integrative complex of brain structures now known as the limbic system. (Comparative anatomy also provides important impetus.) The term limbic system is used loosely to include all rhinencephalic structures once identified with the sense of smell (olfaction); *e.g.*, the hippocampus, amygdala, septum, cingulate gyrus, portions of the temporal lobe, and medial nuclei of the thalamus. The name rhinencephalon ("nose brain") now is used as a synonym for limbic system, since it has been found to have at most a secondary relationship to the primary olfactory brain.

In contrast to the neocortex, limbic structures have prominent vegetative (autonomic) influence. This is powerfully consistent with evidence that emotional processes are mediated by neural systems that also regulate the internal milieu. Such evidence prompted the suggestion of the term visceral brain (in lieu of rhinencephalon or limbic system), stressing the role of hippocampal structures and of the amygdala over that of the cingulate gyrus. (The amygdala is a complex of subcortical nuclei that

The limbic system or the visceral brain

connect with the temporal neocortex.) It was theorized that these structures are agencies for sensory and motor emotional function (analogous to neocortical sensory and motor projections that interact with the environment).

Emotional–cognitive unity clearly emerges in the frequent finding that hippocampal injury (laboratory animals and humans) also produces serious disorders in learning and remembering. Presumably this hippocampal mechanism participates in analyzing environmental data related to physiological survival, integrating them with the regulatory activity of the hypothalamus.

Injuries to various parts of the limbic system have a significant influence on emotional lability. Massive damage involving temporal lobe and amygdala tends to tame aggressive animals, producing oral and hypersexual tendencies. Such injury damps the effects of frightening stimuli and tends seriously to reduce readiness to react socially. More selective lesions, however, may increase aggressive tendencies. At earlier stages of their evolution (as in many extant species) limbic structures are closely related to olfactory function. It has been observed that the sense of smell among ancestors of man must have been critical (*e.g.*, in acquiring food, in detecting an enemy or sexual partner).

Such motivational polarities of the hypothalamus as starvation–gluttony appear for the limbic system but are much less clear and barely definable anatomically. Perhaps the emotional functions of the limbic system will become clearer after its regulatory functions have been more thoroughly explored.

The frontal lobes. Even the frontal lobes, last part of the human neocortex to evolve, seem to be special structures for emotional integration. Once called the "silent" lobes, they now are known to have substantial visceral–autonomic representation, transmitting visceral impulses through several subcortical systems (*e.g.*, the hypothalamus).

Lobectomy and lobotomy

Among lower primates, it long has been known that experimentally produced signs of fear and anxiety disappear with removal of the frontal lobes. Innovators adapted such findings to humans for the relief of otherwise intractable anxieties and psychotic depression. Instead of removing the lobes (lobectomy), surgeons cut the connections between the frontal cortex and subcortical structures; the operation is called a lobotomy. With encouraging initial successes, lobotomies were performed on thousands of people. In some cases the method was modified to destroy small bits of cortex or thalamic relay centres for the frontal lobe.

This therapeutic method largely belongs to the past; effects of lobotomy tend to be transient and difficult to predict; psychotropic drugs are more reliable and entail less risk; and lobotomy has produced more or less serious psychological damage (*e.g.*, distractibility, intellectual deficit). However, lobotomy can reduce or abolish emotional concomitants of severely painful bodily conditions. After frontal pathways are interrupted, the patient can sense pain but no longer reacts with signs of emotional distress.

This phenomenon clearly bears on emotional function and raises the question of how painful experiences arise. It may be observed (in terms of regulatory theory) that brain structures substantially regulate the impulses they receive from so-called pain receptors. Classically, the experience called pain was considered as an elementary sensory function tied to such receptors. More recent work suggests that the experiences involve at least two interacting regulatory mechanisms. One is a so-called gate-control mechanism of the spinal cord that modulates (inhibits and facilitates) receptor impulses directed toward the brain. Such impulses may evoke painful experience if they are realized in the brain. They are assumed to be realized only if a second mechanism in the hierarchy (that regulates motivational intensity as discussed above in relation to hypothalamic function) functions in appropriate phase. Theoretically, pain relief through frontal-lobe removal could be related to such a motivational control mechanism.

Injury to the frontal lobe most consistently results in disinhibition; rage manifested by decorticate dogs long has been interpreted as liberation of subcortical centres from inhibition by the cortex. Hierarchically arranged inhibiting functions are found on every level of the nervous system, and the activity at any level may be inferred to be the result of integrated interaction with structures farther along the neuraxis. Cortical tissues seem to integrate and interact with subcortical and spinal structures. In this way the organism can make appropriately selective somatic and visceral responses as it learns the complexities of the environment. This continuing process of selection and shifting at higher levels modifies, retards, and inhibits the responses of the more primitive regulatory apparatus.

Disturbances that accompany injuries at the widest variety of levels of neural structures that integrate emotion-motivation demonstrate that all human reactions (from primitive homeostatic responses to cognitive judgments) are emotional. Destruction or impairment of structures that mediate the emotional component does not result in "cold" cognitive function but in impaired cognitive function. The cognitive (as well as visceral) interests of the organism seem always to be emotionally expressed; indeed, such a unity of function seems to have served the very survival of the human species.

Empiricism

In its most general sense, Empiricism is the name applied to the attitude that beliefs are to be accepted and acted upon only if they first have been confirmed by actual experience—a definition that accords with the derivation of the name from the Greek word *empeiria*, "experience."

More specifically, Empiricism comprises a pair of closely related, but still distinct, philosophical doctrines—one pertaining to concepts and the other to propositions:

Empiricism of concepts and of beliefs

1. The first of these doctrines, a theory of meaning, holds that words (*e.g.*, the word substance) can be understood or the concepts requisite for any articulate thought possessed only if they are connected by their users with things that they have experienced or could experience (*e.g.*, pieces of wood, or the gases in a gasoline engine).

2. The second doctrine, a philosophical theory of knowledge, views beliefs, or at least some vital classes of beliefs (*e.g.*, that Jane is kind), as depending ultimately and necessarily on experience for justification (Jane is seen performing acts of kindness).

It is not obvious, however, that either of these two doctrines strictly implies the other. Several recognized Empiricists have admitted that there are a priori propositions but have denied that there are a priori concepts. The reverse disconnection between the two forms of Empiricism, however, has no obvious exponents, since there are hardly any philosophers who totally deny a priori propositions and certainly none who would at the same time accept a priori concepts.

As stressing experience, Empiricism is thus opposed to the claims of authority, intuition, imaginative conjecture, and abstract, theoretical, or systematic reasoning as sources of reliable belief. Its most fundamental antithesis is with the latter (*i.e.*, with Rationalism, also called intel-

lectualism or apriorism). A Rationalist theory of meaning asserts that there are concepts not derived from or correlated with experienceable features of the world, such as "cause," "identity," or "perfect circle," and that these concepts are a priori (Latin "from the former") in the traditional sense of being part of the mind's innate or natural equipment—as opposed to being a posteriori (Latin "from the latter"), or grounded in the experience of facts. On the other hand, a Rationalist theory of knowledge holds that there are beliefs that are a priori (*i.e.*, that depend for their justification upon thought alone), such as the belief that everything must have a sufficient reason or that a process cannot exist by itself but must occur within some substance. Such beliefs can arise either from intellectual intuition, the direct apprehension of self-evident truth, or from purely deductive reasoning.

VARIOUS MEANINGS OF EMPIRICISM

Broader senses. In both everyday attitudes and philosophical theories, the experiences referred to are principally those arising from stimulation of the sense organs, in particular those of sight and touch. Most philosophical Empiricists, however, have maintained that sensation is not the only provider of experience, admitting as empirical the awareness of mental states in introspection or reflection, such as feelings of pain or of fear, often metaphorically described as present to the "inner sense." It is a controversial question whether still further types of experience, such as moral, aesthetic, or religious experience, ought to be acknowledged as empirical.

Two other viewpoints related to but not the same as Empiricism are the Pragmatism of the American philosopher and psychologist William James, an aspect of which was Radical Empiricism, and Logical Positivism, also called Logical Empiricism (see POSITIVISM AND LOGICAL EMPIRICISM). Though these philosophies are, indeed, empirical, each has a distinctive focus that warrants its treatment as a separate movement. Pragmatism stresses the involvement of ideas in practical experience and action, whereas Logical Empiricism is more concerned with scientific experience.

Popular and medical Empiricism

When describing an everyday attitude, the word Empiricism sometimes conveys an unfavourable implication of ignorance of or indifference to relevant theory. Thus, to call a doctor an "Empiric" has been to call him a quack —a usage traceable to a sect of medical men who were opposed to the elaborate medical, and in some views metaphysical, theories of Galen, a prominent Greek physician of the 2nd century AD, theories which dominated medicine until the 17th century. The medical Empiricists opposed to Galen preferred to rely on treatments of observed clinical effectiveness, without inquiring into the mechanisms sought by therapeutic theory. But "Empiricism," detached from this medical association, may also be used, more favourably, to describe a hard-headed refusal to be swayed by anything but the facts that the thinker has observed for himself, a blunt resistance to received opinion or precarious chains of abstract reasoning.

Stricter senses. As a more strictly defined movement, Empiricism reflects certain fundamental distinctions and occurs in varying degrees.

Fundamental distinctions. If the blurring of the distinction between concepts and propositions has confused discussions of Empiricism, another influence at least equally vexing is that which, embodied in the traditional terminology of the debate, contrasts the empirical not with the a priori but with the innate. Since logical problems are easily confused with psychological problems, it is difficult to disentangle the question of the causal origin of man's concepts and beliefs from that of their meaning and justification.

Innate versus a priori

A concept, such as "Five," is said to be innate if a man's possession of it is causally independent of his experience —*e.g.*, of groupings of five objects. A concept, such as "Ought," is a priori, on the other hand, if the logical conditions of its application (or those of the word expressing it) do not include any reference to experienceable states of affairs (thus "Ought" cannot be defined in terms of facts alone). Similarly, a belief is innate if its acceptance is causally independent of the believer's experience; and it is a priori if its justification is logically independent of experience. Propositions could be innate without being a priori: for example, the baby's empirical belief that its mother's breast will nourish it.

Some colour is lent to the confusion of the a priori and the innate by the fact that most empirical concepts are actually acquired through the technique of ostensive definition, in which a concept (such as "long") is conveyed by introducing instances of it (several long pencils) into the experience of the learner. But it is not in virtue of their mode of acquisition that concepts are empirical; it is the way in which they are applied, once they are possessed, that qualifies them as such. Even if a man were born with an instinctive capacity to use the word blue and never had to learn how to use it, it would still be an empirical concept if the occasion for its use were always his sense experience of a blue object. Furthermore, the fact that men learn, postnatally, to use the word cause does not prove that it expresses an empirical concept if its application to something always implies more than the sense which experience of that kind of thing presents to the mind.

Another supposedly identical but in fact more or less irrelevant property of concepts and beliefs is that of the universality of their possession or acceptance—that a priori or innate concepts must be the common possession of all men and that such beliefs must be accepted by everyone. There may be, in fact, some basis for inferring universality from innateness, since many innate characteristics such as the fear of loud noises appear to be common to the whole species.

Formal versus categorial

Two main kinds of concept have been held to be a priori and thus nonempirical. First, there are certain formal concepts of logic and of mathematics that reflect the basic structure of discourse: "not," "and," "or," "if," "all," "some," "existence," "unity," "number," "successor," "infinity." Secondly, there are categorial concepts, such as "substance," "cause," "mind," and "God," so-called after the "categories of thought" as listed by Aristotle and Kant, which the mind imposes upon the given data of experience.

A very large variety of different types of proposition has been held to be a priori. Few would deny this status to such definitional truisms or obvious tautologies as "all hairless heads are bald" or "a rose is a rose." There are also the truths of logic, of mathematics, and of metaphysics—whether transcendent, such as the existence of God or things-in-themselves (lying behind appearances), or immanent and thus discernible within reality, such as the principles (presupposed by much natural science) of conservation, causality, and sufficient reason. Some have held that the basic principles of ethics or the causal laws of nature are a priori. Empiricism maintains, however, that some of these are a priori.

Degrees of Empiricism. Empiricism, whether concerned with meaning or knowledge, can be held with varying degrees of strength. On this basis, absolute, substantive, and partial Empiricisms can be distinguished.

Absolute Empiricists hold that there are no a priori concepts, either formal or categorial, and no a priori propositions. Absolute Empiricism about knowledge is less common than that about concepts, and nearly all philosophers admit that at least obvious tautologies and definitional truisms are a priori; but many would add that these represent a degenerate case.

Substantive Empiricism

A more moderate form of Empiricism is that of the substantive Empiricists, who are unconvinced by attempts that have been made to interpret formal concepts empirically and who therefore concede that formal concepts are a priori but deny that categorial concepts, such as "substance," "cause," and "God," are a priori. In this view, formal concepts would be no longer semantical, pertaining to the relation of words to things; they would be, instead, merely descriptive or purely syntactical, pertaining to the relations between ideas. On this basis

"God," for example, would not be an entity alongside other entities but a device for arranging a man's factual beliefs about the world; the concept "God" would thus play a structural and not an informative role.

The parallel point of view about knowledge assumes that the truth of logical and mathematical propositions is determined, as is that of definitional truisms, by the relationships between meanings that are established prior to experience. The truth often espoused by moralists, for example, that one is truly obliged to rescue a man from drowning only if it is possible to do so is a matter of meanings and not of facts about the world. On this view, all propositions that, in contrast to the foregoing example, are in any way substantially informative about the world are empirical. Even if there are a priori propositions, they are all formal or verbal or conceptual in nature, and their necessary truth derives simply from the meanings that man has attached to the words he uses. A priori knowledge is useful because it makes explicit the hidden implications of substantive, factual assertions. But a priori propositions do not themselves express genuinely new knowledge about the world; they are factually empty, "true in all possible worlds." Thus "All bachelors are unmarried" merely gives explicit recognition to the commitment to describe as unmarried anyone who has been described as a bachelor; but it does not add anything new.

Substantive Empiricism about knowledge, which is fundamental to most contemporary Analytical philosophy, regards all a priori propositions as being more-or-less concealed tautologies, or, in Kantian terms, as being analytic. If a person's "duty" is thus defined as that which he should always do, the statement "A person should always do his duty" then becomes "A person should always do what he should always do." Deductive reasoning is conceived accordingly as a way of bringing this concealed tautological status to light. That such extrication is nearly always required means that a priori knowledge is far from trivial.

For the substantive Empiricist, truisms and the propositions of logic and mathematics exhaust the domain of the a priori. Science, on the other hand—from the fundamental assumptions about the structure of the universe to the singular items of evidence used to confirm its theories—is regarded as empirical throughout. The propositions of ethics and those of metaphysics, which deals with the nature of Being as such (for example, "Only that which is not subject to change is real"), are either disguised tautologies or empirical statements or only pseudo-propositions; *i.e.*, combinations of words that, despite their grammatical respectability, cannot be taken as true or false assertions at all.

Partial Empiricism

The least thoroughgoing type of Empiricism here distinguished, ranking third in degree, can be termed partial Empiricism. Many philosophers hold that other concepts besides the formal are a priori and that there are substantially informative propositions about the world that are nevertheless not empirical. The theses of transcendental, or Kantian, metaphysics and those of theology, the general scientific principles of conservation and causality, the basic principles of morality, and the causal laws of nature have all been held to be at once synthetic and a priori—substantial and yet establishable by reasoning alone without recourse to experience. In all versions of this view, however, there remain a great many straightforwardly empirical concepts and propositions: ordinary singular propositions about matters of fact and the concepts that figure in them are held to fall in the empirical domain.

HISTORY OF EMPIRICISM

In ancient philosophy. So-called common sense is inarticulately empiricist; and philosophy, in seeking to correct it, has to start from a rationalistic position. Philosophical Empiricism is thus always critical, a resistance to the pretensions of a more speculative philosophy. The ground was prepared for Plato, the greatest of Rationalist philosophers, by three earlier bodies of thought: the Ionian cosmologies of the 6th century BC—so-called from their concentration along the western coast of Asia Minor—with their distinction between sensible appearance and a reality accessible only to pure reason; the philosophy of Parmenides (early 5th century BC), the important early monist, in which purely rational argument is used to prove that the world is really an unchanging unity; and Pythagoreanism (*q.v.*), which, holding that the world is really made of numbers, took mathematics to be the repository of ultimate truth.

The first Empiricists in Western philosophy were the Sophists, who rejected such Rationalist speculation about the world as a whole and took man and society to be the proper objects of philosophical inquiry. Invoking skeptical arguments to undermine the claims of pure reason, they posed a challenge that invited the reaction that comprised Plato's philosophy (see below, *Criticism and evaluation*).

Plato and to a lesser extent Aristotle were both Rationalists. But Aristotle's successors in the ancient Greek schools of Stoicism and Epicureanism (*qq.v.*) advanced an explicitly Empiricist account of the formation of man's concepts or ideas. For the Stoics the human mind is at birth a clean slate, which comes to be stocked with ideas by the sensory impingement of the material world upon it. Yet they also held that there are some ideas or beliefs, the "common notions," present to the minds of all men; and these soon came to be conceived in a nonempirical way. The Empiricism of the Epicureans, however, was more pronounced and consistent. For them man's concepts are memory images, the mental residues of previous sense experience; and knowledge is as empirical as the ideas of which it is composed.

In medieval philosophy. Most medieval philosophers after St. Augustine (see below, *Criticism and Evaluation*) took an Empiricist position, at least about concepts, even if they recognized much substantial but nonempirical knowledge. The standard formulation of this age was: "There is nothing in the intellect that was not previously in the senses." Thus St. Thomas Aquinas (1225–74) altogether rejected innate ideas. Both soul and body participate in perception, and all of man's ideas are abstracted by the intellect from what is given to the senses. Man's ideas of unseen things, like God and angels, are derived by analogy from the seen.

The 13th-century scientist Roger Bacon emphasized empirical knowledge of the natural world and anticipated the polymath Renaissance philosopher of science Francis Bacon (1561–1626) in preferring observation to deductive reasoning as a source of knowledge. The Empiricism of the 14th-century Franciscan Nominalist William of Ockham was more systematic. All knowledge of what exists in nature, he held, comes from the senses, though there is, to be sure, "abstractive knowledge" of necessary truths; but this is hypothetical and does not imply the existence of anything. His more extreme followers extended his line of reasoning toward a radical Empiricism, in which causation is not a rationally intelligible connection but merely an observed regular sequence.

The Empiricism of William of Ockham

In modern philosophy. In the earlier and unsystematically speculative phases of Renaissance philosophy, the claims of Aristotelian logic to yield substantial knowledge were attacked by several 16th-century logicians, and, in the same century, the role of observation was stressed. One mildly skeptical Christian thinker, Pierre Gassendi (1592–1655), advanced a deliberate revival of the empirical doctrines of Epicurus. But the most important defender of Empiricism was Francis Bacon, who, though he did not deny the existence of a priori knowledge, claimed that, in effect, the only knowledge that is worth having (as contributing to the relief of man's estate) is empirically based knowledge of the natural world, which should be pursued by the systematic, indeed almost mechanical, arrangement of the findings of observation and is best undertaken in the cooperative and impersonal style of modern scientific research. Bacon was, indeed, the first to formulate the principles of scientific induction.

A Materialist and Nominalist, Thomas Hobbes (1588–1679), combined an extreme Empiricism about concepts, which he saw as the outcome of material impacts on the

bodily senses, with an extreme Rationalism about knowledge, of which, like Plato, he took geometry to be the paradigm. For him all genuine knowledge is a priori, a matter of rigorous deduction from definitions. The senses provide ideas; but all knowledge comes from "reckoning," from deductive calculations carried out on the names that the thinker has assigned to them. True knowledge is thus not merely a priori but also analytic. Yet it all concerns material and sensible existences: everything that exists is a body.

Locke's Empiricism

The most elaborate and influential presentation of Empiricism was made by John Locke (1632–1704), an early Enlightenment philosopher, in the first two books of his *Essay Concerning Human Understanding* (1690). All knowledge, he held, comes from sensation or from reflection, by which he meant the introspective awareness of the workings of man's own mind. Locke confused the two issues of the nature of concepts and the justification of beliefs. His Book I, though titled "Innate Ideas," is largely devoted to refuting innate knowledge. And even so, he later admitted that much substantial knowledge—in particular, that of mathematics and morals—is a priori. He argued that infants know nothing; that if men are said to know innately what they are capable of coming to know, then all knowledge is, trivially, innate; and that no beliefs whatever are universally accepted. Locke was more consistent about the empirical character of all man's concepts and displayed in detail the ways in which simple ideas can be combined to form complex ideas of what has not in fact been experienced. One group of dubiously empirical concepts—those of unity, existence, and number—he took to be derived both from sensation and from reflection. But he allowed one a priori concept—that of substance—which the mind adds, seemingly from its own resources, to its conception of any regularly associated group of perceptible qualities.

Bishop George Berkeley (1685–1753), a theistic Idealist and opponent of Materialism, applied Locke's Empiricism about concepts to refute Locke's account of man's knowledge of the external world. He drew and embraced the inevitable conclusion that material things are simply collections of perceived ideas, a position that ultimately leads to phenomenalism; *i.e.*, to the view that reality is nothing but sensations. He accounted for the continuity and orderliness of the world by supposing that its reality is upheld in the perceptions of an unsleeping God. The theory of spiritual substance involved in Berkeley's position seems to be vulnerable, however, to most of the same objections as those that he posed against Locke.

The Scottish Skeptical philosopher David Hume (1711–76) fully elaborated Locke's Empiricism and used it reductively to argue that there can be no more to man's concepts of body, mind, and causal connection than what occurs in the experiences that he has of them. For Hume all necessary truth is formal or conceptual, determined by the relations of identity and exclusion that hold between ideas.

Voltaire imported Locke's philosophy into France; and its Empiricism, in a very stark form, is the basis of sensationalism, in which all of the constituents of human mental life are analyzed in terms of sensations alone.

A genuinely original and clarifying attempt to resolve the controversy between Empiricists and their opponents was made in the critical philosophy of Immanuel Kant (1724–1804), drawing upon Leibniz and Hume. With the dictum that, although all knowledge begins with experience it does not all arise from experience, he established a clear distinction between the innate and the a priori. He held that there are a priori concepts, or categories—substance and cause being the most important—and also substantial or synthetic a priori truths. Although not derived from experience, the latter apply to experience. A priori concepts and propositions do not relate to a reality that transcends experience; they reflect, instead, the mind's way of organizing the amorphous mass of sense impressions that flow in upon it.

Lockean Empiricism prevailed in 19th-century England until the turn to Hegel occurred in the last quarter of the century. To be sure, the Scottish philosophers who followed Hume but avoided his Skeptical conclusions insisted that man does have substantial a priori knowledge. But the philosophy of John Stuart Mill (1806–73), logician, economist, and Utilitarian moralist, is thoroughly Empiricist. He held that all knowledge worth having, including mathematics, is empirical. The apparent necessity of mathematics, according to Mill, is the result of the unique massiveness of its empirical confirmation. All real knowledge for Mill is inductive and empirical; and deduction is sterile. On similar lines, the philosopher of evolution Herbert Spencer (1820–1903) offered another explanation of the apparent necessity of some of man's beliefs: they are the well-attested empirical beliefs of his ancestors from whom he has inherited them, an evolutionary revival of the doctrine of innateness. Two important mathematicians and pioneers in the philosophy of modern physics, W.K. Clifford (1845–79) and Karl Pearson (1857–1936), defended radically Empiricist philosophies of science, anticipating the Logical Empiricism of the 20th century.

J.S. Mill and Positivism

In contemporary philosophy. The most influential Empiricist of the 20th century was the great British philosopher and logician Bertrand Russell (1872–1970), who at first was Lockean in his theory of knowledge—admitting both synthetic a priori knowledge and concepts of unobservable entities. Ludwig Wittgenstein (1889–1951), the influential pioneer of the school of Linguistic Analysis, convinced Russell that the truths of logic and mathematics are analytic; and Russell then came to believe, with Hume, that the task of philosophy is to analyze all concepts in terms of what can be directly present to the senses. In this spirit, he tried to show that even the concepts of formal logic are ultimately empirical though the experience that supplies them may be introspective instead of sensory.

Doctrines developed through the collaboration of Russell and Wittgenstein yielded the Logical Positivism of the German philosopher Rudolf Carnap (1891–1970) and of the Vienna Circle, a discussion group in which that philosophy was worked out. The Empiricism of Logical Positivism is especially evident in its restatement of the fundamental thesis of Hume's philosophy in a form known as "the verification principle," which recognizes as meaningful and synthetic only those sentences that are in principle verifiable by reference to sense experience.

CRITICISM AND EVALUATION

The earliest expressions of Empiricism in ancient Greek philosophy were those of the Sophists. In reaction to them Plato presented the Rationalistic view that man has only "opinion" about changing, perceptible, existing things in space and time; that "knowledge" can be had only of timeless, necessary truths; and that the objects of knowledge—the unchanging and imperceptible forms or universals (such as "Bed," "Man," etc.)—are the truly real. The circles and triangles of geometrical "knowledge," in this view, are quite different in their perfect exactness from the approximately circular and triangular things present to man's senses. In the *Phaedo*, Plato expounded a theory of literally innate ideas; man, for example, has a conception of exact "equality," which, since it could not have been supplied by the senses, must have been acquired by the soul before it was embodied.

The critique of Plato and Aristotle

Aristotle agreed with Plato that knowledge is of the universal but held that such universal forms should not be conceived as "separated" from the matter embodying them. This belief does not make Aristotle an Empiricist, although he was certainly a less extreme Rationalist than Plato. Aristotle took the Rationalist view that every science or body of knowledge must resemble Euclidean geometry in consisting of deductions from first principles that are self-evidently and necessarily true and that, although the senses acquaint man with the sensible forms of things, he cannot have knowledge of them unless reason is brought into play to acquaint him with their intelligible forms as well.

The Stoic view of "common notions," or beliefs that are held by all men—a Rationalistic element in an otherwise

Empirical school of thought—was expanded in the early medieval period by the Christian Platonist St. Augustine (AD 354–430), a thoroughgoing Rationalist. The Stoic common notions, he held, are truths that God has implanted in the human mind by direct illumination.

Though the early modern expression of Empiricism in the 17th century by Francis Bacon heralded the scientific age, its influence was lessened by his failure to appreciate the revolutionary use of mathematics that comprised the genius of Galileo's new physics and, even more fundamentally, by his underestimation of the need for imaginative conjecture in the formation of scientific hypotheses to restrict the overwhelming number of facts that would otherwise have to be handled. In contrast to the views of Bacon, his contemporary, the philosopher and mathematician René Descartes (1596–1650), one of the principal founders of modern thought, developed a comprehensive Rationalism that was more immediately influential. For him all clear and distinct ideas, and in particular those of philosophy and of geometrical physics, are innate; sense experience is at most the agency that elicits ideas already present in the mind; in principle, all knowledge is a priori and demonstrable by pure reasoning, but in practice, because of man's finite intellect, it is necessary to rely on experience to confirm propositions for which rational proof is beyond reach. In England, innate ideas and knowledge were defended by Edward Lord Herbert of Cherbury (1582–1648), precursor of Deism, and by a school of Puritan Humanists known as the Cambridge Platonists. The case for innate ideas, however, is hard to establish; there can be in the nature of the case little actual evidence that one can possess concepts before he has had some relevant experience.

In the second half of the 17th century, the Empiricist views of John Locke were similarly controverted by a systematic thinker and man of affairs, G.W. Leibniz, who examined Locke's views in minute detail in his book *Nouveaux essais sur l'entendement humain* (1704, published 1765; Eng. trans., *New Essays*, 1916), arguing that ideas can be virtually innate in a less trivial sense than Locke allowed. Interpreting Locke's notion of reflection as reasoning rather than as introspection, Leibniz supposed that Locke was more of a Rationalist than he really was.

In contemporary philosophy, there are thinkers who, though broadly sympathetic to Positivism, have voiced reservations about its more specifically Empiricist elements. One important philosopher of science, Karl Popper (1902–), has rejected the inductivism that views the growth of empirical knowledge as the result of a mechanical routine of generalization. To him it is falsifiability by experience that makes a statement empirical. An American philosopher and logician, W.V. Quine (1908–), critical of the Logical Empiricists' frequent recourse to the concept of meaning, has rejected the sharp distinction that has been made between analytic and factual truths, on which most of contemporary Empiricism rests. For him, both man's concepts and his beliefs are the joint outcome of experience and conventional decision, and he denies that the role of the two factors can be readily distinguished.

The theory of knowledge has been the central discipline in philosophy since the 17th century, and its most basic issue is that between Empiricism and Rationalism, an issue that is still being actively debated. On the one hand, the idea that science rests on substantial but nonempirical presuppositions has been put in question by the fact that in some areas it seems to get along without them: without conservation in cosmology, without causality in quantum physics. On the other hand, the traditional theory of the innate powers of the mind has been reanimated by the considerations underlying the theory of language offered by Noam Chomsky, a generative grammarian, who holds that language learning is too rapid and too universal to be attributed entirely to an empirical process of conditioning. The basic strength of Empiricism consists in its recognition that man's concepts and beliefs apply to a world outside himself, and that it is by way of his senses that this world acts upon him. The question, however, of just how much the mind itself contributes to the task of processing its sensory input is one that no simple argument can answer.

(A.M.Q.)

Employment and Unemployment

Work satisfies many needs. For the individual it satisfies the need to exercise his faculties and to participate in the collective work of society. It also gives him a claim upon the social product, enabling him to support himself and his family. From the standpoint of the community work is necessary for survival and civilization.

Throughout most of history, man has had to wrest a living from the soil, for the longest period with little more than his bare hands. Without technology, the earth can be made to yield only a meagre existence, and the population dependent upon it is inexorably limited by starvation. Everything man consumes comes from the efforts he has made to transform nature; even the simplest foods, such as wheat, potatoes, or tree fruits, have been created by artificial selection and must constantly be defended from the competition of natural plants. It has been estimated that if mankind were to disappear from the face of the earth, wheat would give way in less than a quarter of a century to various wild grasses and the same fate would befall other crops, fruit trees, and domestic animals.

CHANGING CHARACTER OF THE LABOUR FORCE

In traditional societies, in which the productivity of agricultural labour is very low, virtually the entire population must be employed in farming. As a country develops, it becomes able to feed its people more easily, so that a smaller proportion need be employed in farming. When productivity reaches a certain point the demand for primary goods (agricultural products) drops in relation to the demand for other goods such as clothing, shelter, and manufactured products. The production of these so-called secondary goods ultimately becomes organized in factories and expands dramatically. As the demand for other manufactured goods grows and remains high, employment in the secondary sector remains high as well. There is also a third, or tertiary, sector of employment comprising the service trades, teaching, administration, scientific research, medical care, art, tourism, and other pursuits that are not carried on in factories. As technical progress in this sector is slight, compared to that in the primary and secondary sectors, its activities require a large number of people. In countries with high living standards, demand for products of the tertiary sector keeps increasing; hence employment in that sector increases more rapidly than in the others.

Effects of industrialization on the labour force

The radical nature of the employment changes that occur in the course of economic development can be seen from the statistics of employment in the primary, secondary, and tertiary sectors. It is estimated that in France in 1800 some 80 percent of the working population were employed in agriculture, whereas in 1970 the figure was only about 13 percent. In the United States in 1820 about 72 percent of the working population were employed in agriculture; by 1970 the proportion had fallen

to 4 percent. This meant, of course, that a great shift occurred in the labour force, from primary production into secondary and tertiary production. The most remarkable expansion (in terms of employment) took place in the tertiary sector. In France in 1800 that sector employed only 10 percent of the workers, while in 1970 it accounted for about 47 percent. Tertiary employment in the United States rose from 15 percent of the working population in 1820 to 65 percent in 1970. The examples in the Table show how other countries compare with

France and the U.S. in this respect. In India or Turkey today, as in France or the United States in the early 1800s, it is still necessary for three people out of four to work in agriculture in order to maintain the population at a low level of subsistence. This does not mean that there is no room for a tertiary sector even in very poor countries; there are always festivals and holidays (in India, funerals) that call for activities not related to feeding the population; there are the arts; and, of course, there are the irreducible needs of administration and law enforcement.

TECHNOLOGY AND UNEMPLOYMENT

The great shrinkage of employment in the primary sector is one of the most important phenomena of modern history. Men who abandon the soil must change not only their means of livelihood but their residence and their way of life as well, and all in the course of a single lifetime. This migration from a peasant culture to an urban industrial one has involved many millions of people. For a long time the migration went chiefly toward the factories; as recently as 1930 it was still possible to imagine that the world of the future would be one immense factory. Now it is clear that although the output of the factories has continued to increase, factory employment has not. Employment in the secondary sector in the United States reached its peak in the period from 1920 to 1970, at about one-third of the labour force, and since then the expansion has been in the tertiary sector. Technological progress would have led to unemployment, or to much-reduced working hours, had it not been for the expanding tertiary sector.

Ever since the time of the Industrial Revolution, men have feared that new machinery would lead to unemployment. Such a fear is a natural reflex of the man who sees a machine replacing him in his work. This often led to violent attacks upon machines, as in England in the 18th and early 19th centuries. It now appears that the fear of technological unemployment is exaggerated.

Two kinds of technological progress

To understand the effect of technological progress on employment it is necessary to distinguish between two kinds of such progress. There is, first, what may be called intensive progress, involving an increase in the efficiency with which man exploits nature: in agriculture, for example, all of the techniques that make it possible to extract products from the soil in a shorter period of time per worker. Intensive progress obviously results in a reduced need for workers. But there is another kind of progress that one may call extensive progress, which enlarges the exploitation of nature. Thus, the discovery of raw materials enlarges the framework of the economy, and the industrial development based upon it brings about the creation of new kinds of employment. The invention of a new product, such as the automobile or the radio, has the same effect. In France it has been estimated that more than 1,000,000 persons make their livings from the automobile, whether as factory workers, garage mechanics, or drivers.

Intensive progress allows man to satisfy his existing needs with less labour; extensive progress, on the other hand, satisfies needs that either did not exist or were not satisfied previously, and, consequently, creates new jobs. But the two kinds of progress do not automatically balance each other. In an economy that is not highly developed, technological progress in agriculture may allow the population to consume more food. In a more developed economy, one in which standards of living are already high, the same progress will not lead to increased food consumption; the end result may be glut, with lower farm prices and unemployed agricultural workers. In a period of general technological progress, employment is likely to be unstable because of the necessity for production to adapt itself to the changing demands of the market.

The consumption of primary, or agricultural, goods eventually reaches a point of saturation. The consumption of manufactured products passes through a phase of increase and then one of relative decline, except when new products appear on the market that have the extensive effect described above. It is the tertiary sector, however, that absorbs most of the manpower freed by technological progress in the other sectors. Employment as a whole does not, over the long run, decline because of technological progress. It is easy to show that in wealthy countries neither the size of the work force nor the length of the work week has had any tendency to decline in the last 50 years. There have been economic crises resulting in unemployment, but the unemployment was eventually absorbed. A dynamic economy requires that labour be mobile enough to move out of sectors in which technological progress has reduced the need for manpower and into sectors in which labour is in short supply. This migration is not pleasant for those who are caught up in it, since it is inevitably accompanied by some degree of unemployment or underemployment.

MEASURING UNEMPLOYMENT

The condition of unemployment seems simple enough: it is being without a job. But for the statistician unemployment is difficult to define precisely. The definition used in compiling the statistics of the United States and other de-

veloped countries treats as unemployed anyone who is capable of working and is actively seeking work but is unable to find it. Before a person can be unemployed in this sense he must be an active member of the labour force in search of a job. Students and housewives perform work, but they are not considered to be employed unless they are paid; by the same token they are not considered unemployed unless they are actively seeking gainful jobs. Any person who, because of handicap or discouragement, has not tried to find work—even if only to the extent of registering at a public employment office—will not be counted in the statistics of unemployment. There is a category of young people leaving schools or universities, who do not find jobs commensurate with their education; in some countries the government recognizes them as unemployed and tries to assist them.

Underemployment. Outside of the very clear category of unemployment, there is a whole gamut of degrees of nonemployment and underemployment. Until recently, unemployment was not distinguished from nonemployment with any degree of clarity. Numerous persons were not employed or, more often, were underemployed—that is, working here and there at one thing or another for a space of hours or days or months without a precise contract. A period of inclement weather would put day labourers out of work, and they received no aid of any kind. In the rural sectors of many countries today there appear to be considerable numbers of persons who may be called underemployed because they do not have full-time work even though they are part of the labour force.

Measurement of part-time unemployment is not too difficult and is done in a number of countries. In 1964, when the Swedish unemployment rate was 1.6 percent, involuntary part-time unemployment accounted for another 1.4 percent. Italy classifies as underemployed those persons who have worked fewer than 33 hours in the survey week. When the Italian unemployment rate was 3.4 percent in 1964, such persons accounted for another 1.7 percent. In West Germany, persons working up to 25 hours per week who desire more hours are classified as unemployed. In the United States, involuntary part-time workers averaged 2,443,000 in 1970 as compared with an average of 4,088,000 fully unemployed. In Japan only 590,000 persons (about one percent of the labour force) were counted as unemployed in 1968, but 1,496,000 employed wished to find part-time employment and 1,768,000 were seeking regular jobs.

Concealed unemployment

In modern industrial societies the statistics of employment sometimes conceal substantial amounts of unemployment or underemployment. This is because the unemployed may be brought into factories where they are not needed and have insufficient work to do. If the economy is a competitive one, each firm or enterprise will have an incentive to keep its operations efficient enough so that it makes a profit, and this will tend to prevent the hiring and maintaining of surplus workers. But where enterprises are subsidized or owned by the state, it is necessary to develop administrative and political controls to assure that work is carried on efficiently and in the interest of the public. These controls do not work as well in enforcing efficiency as those of a profit-making economy; they are often biased, erratic, or subject to the interference of pressure groups, politicians, or bureaucrats. In the Communist countries of Europe there has been much discussion, since the 1950s, of the problem of running socialized enterprises efficiently; the planners and economists of those countries have conceded that enterprises that are not subject to the pressures of the market have more difficulty than others in adjusting their production to the needs of consumers, and consequently in working out optimal plans and raising the efficiency of their labour force. It is possible to reduce unemployment and underemployment on a national scale, even to the point of an apparent shortage of labour, while at the same time permitting a considerable amount of misemployment and its accompanying inefficiency.

Rates of unemployment. During the Great Depression of the 1930s, unemployment in the Western capitalist countries reached very high rates. In the United States, the proportion of unemployed as counted by the government statistics reached 25 percent of the labour force in 1933. In Sweden unemployment reached 25 percent twice—in 1921 and 1931. In Great Britain the rate was above 15 percent in those two years. Since World War II, unemployment rates have been far below catastrophic levels. They have been higher in the United States than in other industrial countries: in the 1960s unemployment in the U.S. ranged between a high point of 6.7 percent in 1961 and 3.5 percent in 1969. In Sweden, from 1960 to 1970 unemployment remained below 2.2 percent. In Great Britain, from 1957 to 1970, the highest figure was 2.5 percent. In France, in the same period, unemployment exceeded 2 percent only once. (The figures are not precisely comparable as between countries because of differences in the way in which unemployment is measured.) In the Federal Republic of Germany and in Switzerland unemployment was so low as to be negligible, and the three countries imported large quantities of manpower, net immigration in 10 years amounting to about 3,000,000 persons in West Germany, 2,500,000 in France, and 500,000 in Switzerland. In Japan, unemployment moved downward from 1.8 percent in 1955 to less than one percent throughout most of the 1960s.

Varying incidences of unemployment

Even when the overall rate of unemployment is low, it remains a serious social problem because its incidence is not the same for all categories of workers. While some may be only temporarily out of work or passing from one job to another, others may be unemployed for long periods of time. The statistics published by most countries do not distinguish among categories of unemployed workers. The United States Bureau of Labor Statistics, however, has studied the incidence of unemployment quite thoroughly. Its figures show that women have more unemployment than men, young people more than adults, and persons without education or special skills more than educated persons. Thus, in 1964, when the overall rate of unemployment was 5.2 percent, the rate for men with less than five years of schooling was 9.4 percent. The difference in the rates had been much less in 1950, suggesting that employment opportunities for those with little education had declined. Blacks in the United States suffer more severely from unemployment than do whites. In 1970 the jobless rate for black teenagers was 30.1 percent as compared to 13.6 percent for white teen-agers; the rate for black men was 7.3 percent as compared to 4.0 percent for white men; and the rate for black women was 9.3 percent as compared to 5.4 percent for white women.

The most damaging unemployment, from a personal or family point of view, is that which persists for a long time. In 1970, about 16 percent of all U.S. unemployed had been out of work 15 weeks or more, and 6 percent for 27 weeks or more. Middle-aged workers and blacks were disproportionately represented among the long-term unemployed.

In all of the industrially developed countries, governments now collect increasing quantities of information on the labour force. Concise statistics, however, cannot adequately portray the whole spectrum of employment problems. Some workers remain in the same occupation, the same business, and even the same firm for decades, while others change jobs frequently. Some work at more than one job at a time. Some have seasonal jobs. Some work only a few hours a month, while others may work 60 or 65 hours a week. Some pass through a number of jobs searching for the one that is agreeable and pays well. A substantial number of persons cannot be easily classified as inside or outside of the labour force. Many who are outside the active labour force might be drawn in if jobs were obtainable or if help were available to assist them in qualifying for jobs. This sort of hidden unemployment may be more serious than overt unemployment if personal and social handicaps are combined with a shortage of work opportunity.

GOVERNMENT EFFORTS TO INCREASE EMPLOYMENT

Since World War II the governments of most industrial countries have become committed to a program of re-

ducing unemployment and underemployment. The constitution of France explicitly charges the state with assuring full employment. Similar goals have been affirmed with varying degrees of concreteness in other countries. The Charter of the United Nations makes full employment a major objective of its members.

Approaches to employment policy

Governments have followed various policies in pursuit of full employment. One general approach is to try to improve the supply of manpower. Another is to alleviate the effects of unemployment and underemployment. A third approach seeks to maintain economic activity at a high level through monetary and fiscal policies. Finally, there is the method of economic planning tried out in France, where the government planning commission sets targets for the various sectors of the economy that are linked to forecasts of manpower, in the belief that the difficult and complex problems of employment and unemployment cannot be separated from other problems of economic and social development (see ECONOMIC PLANNING).

Manpower policies. The first consistent efforts to deal with the instability of employment caused by technical and economic progress involved providing information on the state of the labour market and on the qualifications of those seeking work. This was done in the hope of directing job seekers more efficiently to existing jobs or of helping them to prepare themselves for the occupations and careers in which manpower seemed likely to be needed. Public employment services developed, particularly in the 1930s, that sought to direct applicants more efficiently to existing jobs or to help them prepare for occupations and careers in which manpower seemed likely to be needed. Most large industrial nations now have such agencies, designed to bring together the two sides of the labour market. Information leads to guidance and guidance to education and training, or retraining. The rapid progress of technology in recent times has required a perceptible raising of the qualifications of workers: skilled labourers have increased relatively to the unskilled, technicians relatively to skilled labourers, and engineers relatively to technicians. Governments have therefore endeavoured to provide or subsidize training programs for those who could benefit from them.

Often unemployment is a regional matter. Attempts have been made to mitigate it through regional development programs in a number of countries.

Ameliorative policies. All of the developed countries try to soften the impact of unemployment through unemployment compensation and other forms of social insurance. In some cases, governments seek to induce employers to retrain workers for new jobs rather than lay them off.

The maintenance of aggregate demand. The use of monetary and fiscal policies to keep the economy functioning at a high level of employment has been undertaken in a number of countries since the Depression of the 1930s (see FISCAL AND MONETARY POLICY). In periods of recession or of growing unemployment the government may increase aggregate demand by expanding the money supply or by increasing its own spending. This approach had some success in the United States during the 1960s, when a major income tax reduction, tax incentives for business investment, and a great increase in federal expenditures for both war and nonwar purposes brought the unemployment rate down to 3.5 percent in 1969. In the years that followed, however, the country was faced with serious inflation; in the effort to stabilize prices it had to incur rising unemployment.

National economic planning. The problems of unemployment and underemployment cannot be divorced from other problems of economic and social development. In the 1950s and 1960s the French government undertook national planning on a broad scale and succeeded in maintaining rapid economic growth, full employment, and a stable currency. The French experiment compared favourably with experience in Britain, where fiscal and monetary measures failed to overcome a persistent stagnation of the economy, and with the U.S. experience of inflation and recurring unemployment. It seemed likely that employment policies in most industrial countries would be oriented in the future toward a context much broader than that of placement bureaus, labour mobility, and fiscal and monetary policy.

Indications of a new, more comprehensive approach to problems of unemployment might be seen in the studies of the United States economic commissions and of the Organization for Economic Co-operation and Development. A report by the OECD, *The Growth of Production 1960–1980: Experience, Perspectives and Problems of Economic Policy* (1970), made estimates of employment for a number of countries in 1980, based on forecasts of general economic development. It is likely that this approach to economic planning will become the general tendency in all industrial countries in the future. It will also, one may hope, cease to be tied to a specialized discipline of econometrics. The speed with which society is evolving, the variety of possible ways of life, and the unforeseeable changes in the human condition make it increasingly necessary to view economic phenomena as only part of civilization, inseparable from the rest.

BIBLIOGRAPHY. Among the most important general works on employment and unemployment in modern industrial society are: JOHN MAYNARD KEYNES, *The General Theory of Employment, Interest and Money* (1936); and WILLIAM HENRY BEVERIDGE, *Full Employment in a Free Society* (1944). The distinctive French approach to employment forecasting is set forth in the *Rapports généraux de la commission de la main-d'oeuvre* of the COMMISSARIAT GENERAL DU PLAN, available only in French.

The specialized literature is enormous. Notable examples include: the publications of the INTERNATIONAL LABOUR ORGANIZATION, particularly its *Manpower Aspects of Recent Economic Developments in Europe* (1969); the publications of the ORGANIZATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT in the "Reviews of Manpower and Social Policies" series; and in *Employment and Earnings*, a monthly report issued by the UNITED STATES BUREAU OF LABOR STATISTICS.

Some recent works on the changing structure of the labour force include: SOLOMON BARKIN (ed.), *Technical Change and Manpower Planning: Coordination at Enterprise Level* (1967), consisting of 28 case studies dealing with 8 countries; VICTOR FUCHS, *The Service Economy* (1968), an analysis of the expanding tertiary sector in the United States; A.J. JAFFE and J.N. FROOMKIN, *Technology and Jobs: Automation in Perspective* (1968); and REID HUNTER and FRANCIS M. BODDY, *Labour Problems of Technological Change* (1970), a thorough study of the British situation.

(J.Fo.)

Enamelwork

Enamel, in art, is a vitreous glaze or combination of vitreous glazes fused on a metallic surface. The general term enamels is applied to metal objects that have this material as the principal decoration.

Enamels have been used to decorate the surface of metal objects, perhaps originally as a substitute for the more costly process of inlaying with precious or semiprecious stones but later as a decorative medium in their own right. Whereas painting on metal has a short life and, even when new, is overshadowed by the brilliance of the polished metal, enamelling provided the craftsman with a means of giving to the surface of metal a durable, coloured, decorative finish. With the painted enamels of the Renaissance and the portrait miniatures of the 17th century, the technique reached its most ambitious and artistic form; for here the craftsman attempted to create his version of an oil painting, using a metal sheet instead of a canvas and enamels instead of oil paints. While this medium undoubtedly has its limitations—few painted-enamel plaques of the Renaissance, for example, are much more than one foot square—it may be claimed that, whereas oil paints on canvas will fade and darken, the colours of enamels are permanent. Nevertheless, relatively few creative artists of distinction have chosen to work in this medium; thus, its prime function has tended to be purely decorative.

Few types of metal object have not, at some period, been enriched with enamelled decoration. Throughout history, jewelry has been made more colourful by the application of enamels. Similarly, arms and armour, horse trappings, and even domestic items, such as mirrors

Objects typically decorated with enamelwork

and hanging bowls, were embellished with enamel decoration. Throughout the Middle Ages, both secular and ecclesiastical objects, such as chalices, cups, reliquaries, caskets, crosiers (a staff carried by bishops and abbots as a symbol of office), and spoons, were elaborately enamelled. With the advent of painted enamels in the Renaissance, tableware was completely covered with enamel, and painted-enamel panels were used to decorate the ceilings and walls of rooms in the châteaus of France. Following upon the invention of the domestic table clock and of the watch in the 16th century, enamelling became one of the most popular forms of decoration for the dials and cases; by the 18th century, items of the drawing room, such as snuffboxes, etuis (cases for small articles like scissors and needles), tea caddies, candlesticks, scent bottles, and thimbles, were frequently made of enamel.

Among the objects decorated with enamels in east Asia are vases, incense vessels, teapots, suits of armour, and sliding doors.

This article treats the material, techniques, and history of enamelwork.

MATERIALS AND TECHNIQUES

Enamel is a comparatively soft glass, a compound of flint or sand, red lead, and soda or potash. These materials are melted together, producing an almost clear glass, with a slightly bluish or greenish tinge; this substance is known as flux or frit—or, in France, *fondant*. The degree of hardness of the flux depends on the proportions of the components in the mix. Enamels are termed hard when the temperature required to fuse them is very high; the harder the enamel is, the better it will withstand atmospheric agencies, which in soft enamels first produce a decomposition of the surface and ultimately cause the breakup of the whole enamel. Soft enamels require less heat to fire them and consequently are more convenient to use, but they do not wear so well, especially if subjected to friction.

Clear flux is the base from which coloured enamels are made, the colouring agent being a metallic oxide, which is introduced into the flux when the latter is in a molten state. The brilliance of an enamel depends on the perfect combination of its components and on maintaining an equal temperature throughout its fusion in the crucible. The colour of many enamels is achieved by a change in the proportion of the components of the flux rather than by a change in quantity of the oxide. For example, turquoise-blue enamel can be obtained from the black oxide of copper by using a comparatively high proportion of carbonate of soda; in the same way, a yellowish-green enamel can be obtained from the same black oxide by increasing the proportionate amount of red lead.

Clear flux is also used to make opaque enamels; the addition of calx, a mixture of tin and lead calcined, renders translucent enamels opaque. White enamel is produced by adding stannic and arsenious acids to the flux, the quantity of the acid affecting the density, or opacity, of the enamel.

Preparation of the enamel

The heated enamel, after being thoroughly stirred, is usually poured out onto a slab and allowed to solidify into cakes of approximately four to five inches (10 to 13 centimetres) in diameter. For use, each cake must be pulverized into a fine powder with a pestle and mortar; the powder then has to be subjected to a series of washings in distilled water until all the floury particles are removed. The metal, on which the powdered enamel is to be spread, is cleansed by immersion in acid and water. All trace of the acid is then removed by washing and by drying in warm oak sawdust. After the wet powder has been spread on the metal, it is allowed to dry in front of the furnace before it is carefully introduced into the muffle of the furnace (a compartment protected from the flame), where it is heated to the point at which it fuses and adheres to its metal base. The firing of enamel takes only a few minutes, and the object is then withdrawn and allowed to cool.

The various techniques practiced by craftsmen in the past differ mainly in the methods employed in preparing the metal to receive the powdered enamel.

Cloisonné. In the cloisonné technique, thin strips of metal are bent and curved to follow the outline of a decorative pattern; they are then attached, usually soldered, to the surface of the metal object, forming miniature walls that meet and create little cells between them. Into these cells, the powdered enamel is laid and fused. After it has cooled, the surface can be polished to remove imperfections and to add to the brilliance. The cloisonné technique is particularly suited to objects made of gold, such as jewelry.

Champlevé. This process is the opposite of the cloisonné technique: instead of building up on the surface of the metal object, the surface is gouged away, creating troughs and channels separated by thin ridges of metal that form the outline of the design. The troughs are filled with powdered enamel and fused. The champlevé technique requires a thick metal base and therefore is used on copper and other base metals.

Basse-taille. This technique is a sophisticated extension of the champlevé method, for again the metal surface has to be cut away and filled with enamel, but here there are two major differences. First, within the area that has been cut away to receive the enamel, a design or figural composition is chased (chiselled), or sometimes engraved, in low relief. Because the highest point of the relief is below the general surface of the surrounding metal, the enamel, which is level on its outer surface, lies in varying thicknesses over the modelled surfaces of the low relief. Second, because the coloured enamels used in this technique are translucent, the composition of the low relief shows through; and, since the metal used is normally gold or silver, the light is reflected back through the translucent enamelling, adding a brilliant tonal quality to the enamel, just as sunlight enhances the beauty of a stained-glass window. The effect of the reflected light varies according to the thickness of the enamel lying over the undulating surfaces of the low relief; consequently, an impression of plasticity and of three-dimensional modelling is created by the subtle variations in tonal strengths of the enamel colours, which range from bright highlights to the rich tones of the deep recesses.

Stained-glass window in miniature

Plique-à-jour. The plique-à-jour technique is designed to produce an effect of a stained glass window in miniature through the use of translucent enamels. The technique is exactly the same as cloisonné enamelling except that the strips of metal forming the cells are only temporarily attached—not soldered—to a metal base to which the enamel will not stick. After the enamel is fused and sufficiently annealed, the metal sheet, usually aluminum–bronze, is removed with a few light taps,

leaving a network of metal strips filled with enamel "windows." The enamels can be carefully polished to enhance their appearance.

Encrusted enamelling (émail en ronde bosse). Encrusted enamelling is the term used to describe the technique of enamelling the irregular surfaces of objects or figures in the round or in very high relief. Both opaque and translucent enamels are applied to these small-scale sculptural objects, which are usually made of gold. The great technical problem is to devise methods of supporting and protecting these objects during the firing. Frequently, plaster of paris is used to envelop parts of the object, leaving exposed only those parts on which enamel is to be applied and fused.

"Goldenes Rössel," gold shrine with encrusted enamelling, French, *c.* 1403. Given to Charles VI of France by his queen, Isabella of Bavaria. In the pilgrimage church of Altötting, West Germany. Height 62 cm.

Painted enamels. This technique differs fundamentally from the preceding five in that the various coloured enamels are not separated from each other by metal strips or ridges. Although these enamels are still applied in their wet, powdered state, the adjacent patch of coloured enamel is first allowed to dry to avoid one running into the other and so blurring the outline between them.

The metal generally used in this technique is copper. It is cut with shears into a plate of the size required and slightly domed with a burnisher or hammer, after which it is cleaned with acid and water. The enamel is laid equally over the whole surface both back and front, and then the object is fired. The first coat of enamel being fixed, the design is delineated by drawing with a needle through a layer of wet white enamel or any other that is opaque and most advantageous for subsequent coloration.

Grisaille enamels

In the case of grisaille enamels, the white is mixed with water, turpentine, spike oil of lavender, or essential oil of petroleum and painted over a dark-enamel ground. Light areas of the design are painted thickly; gray areas, thinly to allow the dark ground to tone the white pigment. The technique creates a strong contrast between light and shade, creating an impression of low relief. The scenes in grisaille are sometimes rendered more subtly by hatching, executed with a pointed tool or needle to reveal the dark enamel beneath.

In coloured painted enamels, enamel colours are spread over the grisaille treatment; when fired, parts of the surface are heightened by touches of gold, usually painted in thin lines, like hatchings. Other parts can be made more brilliant by the use of foil, over which the transparent enamels are placed and then fired.

HISTORY

Ancient Western. The origins of the art of enamelling are uncertain. While there is archaeological evidence that glass was being made from the 3rd millennium BC in western Asia and from the 15th century BC glass vessels were undoubtedly being made in Egypt, there is no proof that enamelling on metal was practiced in either Asia Minor or Egypt until after the time of Alexander the Great (died 323 BC).

Mycenaean enamelling

Perhaps the origins of the art are to be found on Mycenaean metalwork of the 13th to 11th centuries BC. Six gold rings, excavated from a Mycenaean tomb of the 13th century BC at Kouklia (near Old Paphos), in Cyprus, are decorated with a cloisonné technique that suggests an intermediary stage between inlay and true enamelling. Scientific examination has shown that the different coloured enamels were not in the form of powder when they were inserted into the cloisons before being fired and fused together; rather they were in the form of fragments of coloured glass. Unfortunately, no report exists of any scientific examination of a more accomplished example of Mycenaean enamelling—the decoration on the gold sceptre found in a royal tomb at Kourion Kaloriziki, in Cyprus—but it is generally believed that this is true enamelling and datable to the 11th century BC.

If true enamelling existed in Mycenaean work, it would be reasonable to expect the technique to have been inherited by the Greeks and transmitted by them to the rest of Europe, perhaps by way of the colonies on the north shore of the Black Sea and in the south of Italy. Unfortunately, however, there is a long gap between the Mycenaean enamels and the Greek gold jewelry of the 6th–3rd centuries BC, which is sparingly enamelled, often having no more than touches of blue and white enamel enclosed by thin gold wire openwork (filigree).

Until recently the most ancient examples of enamelling outside Mycenaean art were said to be on ornaments discovered in a cemetery in the Kuban, close to the Caucasus, variously dated between the 9th and 7th centuries BC; but the most important of these Kuban enamels, the famous Maikop belt buckle (the Hermitage, Leningrad) depicting a griffin attacking a horse, is now regarded by Russian experts as a forgery. Consequently, the earliest enamelling from south Russia may date from the 3rd or 2nd century BC.

Celtic enamel decoration

A slightly earlier date is given to a number of excavated bronze objects of western European origin, which are said to bear the remains of cloisonné enamel decoration. Until this early Celtic material has been scientifically examined and proved to be true enamel as distinct from inlaid coral, cut stone (chiefly lapis), or coloured glass applied cold, theories about it remain open to question. At the present time it is a matter of conjecture what link, if any, may have existed between the enamellers in south Russia and those Celtic craftsmen who by the 3rd century BC, if not earlier, were using red enamel in place of coral inlay.

During the Roman period, enamelling—both cloisonné and champlevé on bronze—was carried on almost entirely in those old Celtic areas that had become the northern provinces of the Roman Empire. It may well be to these provincial works that a passage from the works of the Greek philosopher Philostratus, 2nd century AD, refers. The author, describing a boar hunt at which the riders appear with horse trappings ornamented in bright colours, writes:

> It is said that the barbarians in the ocean [*i.e.*, the Celtic tribes] pour these colours into bronze moulds, that the colours become as hard as stone, preserving the designs.

This is a fair description of the process of champlevé enamel and suggests that the technique, in use in the British Isles, was not practiced at the time in Greece or

Italy. Enamelled horse trappings such as Philostratus describes have been found in many places in the British Isles. This type of Celtic enamelling of the Roman period lived on in northwest Europe, particularly in Ireland, until as late as the 12th century. Some of its more striking effects seem to be derived from Roman glassmaking practices, particularly its use of millefiori glass, a mosaic of very thin glass rods of different colours and shapes fused together and then cut into thin sections, which the Celtic craftsmen fused into a ground of coloured enamel.

Medieval. *Byzantine.* The most dramatic development in the history of enamelling took place in the Byzantine Empire between the 6th and 12th centuries, a period during which only the cloisonné technique—almost exclusively executed on gold—was in use. At their zenith in the 10–11th centuries, Byzantine enamellers created delicate, highly expressive miniature scenes in a great range of colours that shine like jewels. The masterpiece of this period is the altar screen "Pala d'Oro" in St. Mark's, Venice, believed to have been brought from Constantinople to Venice about 1105. The quality of Byzantine enamelling began to decline in the late 12th century.

Islāmic. There is no direct evidence that enamelling on metal was practiced at any Islāmic centre in western Asia. Those scholars who would argue that the technique of Byzantine gold-cloisonné enamelling originated in Syria before the 7th century AD can point to just one object, which, only on inconclusive stylistic considerations, may be associated with Umayyad Syria rather than with Byzantium. Only one other enamelled object has survived with strong Islāmic connections: a dish with an Arabic inscription referring to an Artuqid Prince, who reigned AD 1114–44. The enamel technique is cloisonné, but with bronze wires soldered onto a copper base. As no other examples have been found and as the inscription in Arabic indicates an imperfect knowledge of the language, it may be the work of a Byzantine craftsman working in the Artuqid kingdom.

Western European. As early as the 7th century, according to some scholars, Byzantine work was being copied by Lombard craftsmen in northern Italy; later it was imitated in Sicily and other parts of Italy—even perhaps in England, where the famous Alfred Jewel, made to the order of the English king Alfred the Great in the 9th century AD, shows strong Byzantine influence. In the Ottonian period (AD 936–1002), gold-cloisonné enamelling seems to have flourished in eastern France, and in the Rhineland, particularly among the goldsmiths working at Essen and in the workshops of Archbishop Egbert (AD 937–993) at Trier.

In western Europe cloisonné enamelling was abandoned in the 12th century, in favour of the champlevé technique executed on a base metal such as copper or bronze. This revival may have taken place first in Spain, in the valleys of the Rhine and the Meuse, or in France at Limoges; but, by the middle of the century, expert craftsmen in these centres—and in England—had established it as one of the foremost mediums for artistic expression in the Romanesque style. In the Mosan school, the famous 12th-century enamellers Godefroid de Claire at Liège and Nicholas of Verdun created champlevé enamelwork of unprecedented merit. The best work from Limoges was executed at the turn of the 12–13th century; thereafter, the output was commercialized and standards fell steadily throughout the 13th and 14th centuries.

Basse-taille enamelling

In the late 13th century, gold and silver objects were again decorated with enamel but in a new technique, basse-taille enamelling. The earliest surviving dated example was made in Italy in 1290. Throughout the following century, Italian goldsmiths, particularly from Siena and Florence, produced pictorial masterpieces in this medium. The technique was especially favoured in Spain and France. No more accomplished example has survived than the "Royal Gold Cup" (British Museum), commissioned by the brother of the French king Charles V about 1380. The sides and the cover have scenes depicting the life and martyrdom of St. Agnes in the most glowing rich colours and elegant draftsmanship of the period. The great era of basse-taille enamelling ended with the Renaissance, though it remained popular in Spain and southern Germany, chiefly in Augsburg, to the middle of the 17th century.

Plique-à-jour and encrusted enamelling

15th century to the present: European. Under the patronage of the courts of France and Burgundy in the late 14th and first half of the 15th centuries, goldsmiths devised new and more audacious methods of enamelling. Using translucent coloured enamels, they created the effect of stained-glass windows in miniature by the technique known as plique-à-jour. One of the loveliest pieces is the silver-gilt Merode beaker of Flemish or Burgundian origin, probably *c.* 1430–40, decorated with two bands of enamels set in tiny windows with Gothic tracery (Victoria and Albert Museum, London). Employing another technique, encrusted enamelling, they created both large-scale three-dimensional compositions and miniature work to be worn as jewelry. Among the finest and earliest surviving examples is the Reliquary of the Holy Thorn (in the Waddesdon bequest in the British Museum): the Holy Thorn, set in a gem, is surrounded by the Last

Judgment scene, in which all the figures (20) are enamelled, many of them being executed wholly in the round. The taste for this type of enamelled goldsmith work spread to all the courts of Europe; and, although the style changed several times, first from Gothic to Renaissance and then to Baroque, the essential extravagant toy-like quality remained. Of all the Renaissance goldsmiths who moved from court to court, and, through these movements, helping to create an international style, only Benvenuto Cellini wrote (*c.* 1560) a technical treatise on the subject.

Although the technique of painted enamels was probably first evolved by Flemish craftsmen about 1425–50 for the Burgundian court and perhaps developed by Venetian and north Italian enamellers between 1450 and 1500, the supremacy of the Limoges workshops was established by the beginning of the 16th century. For the next 100 years, French Mannerist art found talented expression in this medium, and, enjoying court patronage, the best Limoges enamellers strove to compete with other artists in decorating the rooms of royal palaces. Painting in grisaille was finally introduced at Limoges by about 1530–40.

Miniature painting in enamel colours

A new dimension was given to painted enamelwork about 1620–30 by a French goldsmith, Jean I Toutin of Chateaudun, and some rival craftsmen in Blois. Their achievement was to invent a highly skillful method for fine miniature painting in enamel colours on a white-enamel ground. Since the technique was admirably suited to the current enthusiasm for portrait miniatures, artists of distinction, such as Jean Pettitot, were employed by Charles I of England and the French kings to work in this medium.

With equal artistic skill, other French enamellers decorated items of jewelry, especially watchcases; and, by the second half of the 17th century, this craft had become centred on Geneva, where it continued to flourish into the 19th century. In England, particularly in the Midlands, the Continental style of painted enamelled "toys" was copied and produced on a large scale, but the technique of transfer printing on enamel was invented in England and brought to perfection at the Battersea (London) factory during 1753–56. The design was applied to the white-enamel ground by transferring to paper, and then to the surface to be decorated, an impression from an engraved metal plate that had been brushed with enamel colours. Throughout the 17th and 18th centuries, enamellers used the technique of fine miniature painting in enamels in Germany, Holland, England, and Russia in order to produce the "toys" of the fashionable world of society.

The technique called *en résille sur verre* flourished for only about 40 years (*c.* 1600–40), and few examples have survived. Yet it required an exceptional degree of skill. The technique consists of cutting the design in a medallion of glass, usually coloured, lining the incisions with gold and filling them with variously coloured enamels. The exponents of this kind of enamelling were mainly French.

Although surviving examples are rare, there is a distinctive group of brass objects, mainly candlesticks and andirons, which have green, blue, or white opaque enamelling. These objects were made in 17th-century England (perhaps in Sussex).

Almost all of the early enamelling techniques have continued to be used by goldsmiths in modern times—from the Parisian makers of gold snuffboxes in the 18th century to Carl Fabergé at the beginning of the 20th century. Art Nouveau jewellers, such as René Lalique, and modern artists, such as Georges Braque, Georges Rouault, and Gerda Flockinger, have kept alive the craft of enamelling and added to the multiplicity of its ingenious effects. (H.Ta.)

China. Enamels do not appear to have reached China until long after they were found throughout Europe. All authorities are agreed as to the Western origin of the art, which in all probability was introduced into China by traders or by travelling craftsmen. Although by the 5th century AD the Chinese were informed as to the production of glass—an essential material for the making of enamels—and were already highly skilled in the working of bronzes and other metals, there is no evidence that the art of enamelling was practiced before the T'ang dynasty (618–907). There is in the Shōsō-in (principal storehouse) at Nara, in Japan, a silver mirror, the back of which is decorated in cloisonné. It is generally agreed that the mirror is of Chinese origin, dating from the T'ang dynasty, as is certainly the case with many other

Earliest known enamelwork

objects in the collection. At present, this is the only known Chinese enamelled ware made before the 14th century; but it can be safely assumed from this piece that the art of cloisonné was developed to a respectable height in the T'ang dynasty. It appears that cloisonné work was well established in China at the end of the 14th century and that Byzantine work of similar character was also so well known as to invite comparison with the native product. The former may well have served as an example for Chinese craftsmen. As one scholar points out:

> The workmanship presents occasionally . . . striking resemblances with certain enamels of the Byzantine school; the mixture of different enamels inside the wall of the same cell, the employment of gold incrustations in the treatment of the fingers and the hands, etc.

Active trade and cultural intercourse between the Near East and China during the Yüan (Mongol) dynasty must have been the reason for this revival of enamelwork, which then flourished through the Ming and Ch'ing dynasties (1368–1644 and 1644–1911, respectively).

Chinese enamels fall into three categories—cloisonné, champlevé, and painted. In none does the technique vary appreciably from that employed in Western countries.

Cloisonné. The earliest example of cloisonné enamel that can be authentically associated with east Asia is the silver mirror in the Shōsō-in mentioned above. Its cloisonné back is decorated in a design of a six-petalled blossom in three layers, the tips of the outer rows of petals forming 12 points of the mirror. The piece is regarded as a T'ang dynasty work. Apart from this, the sequence of known Chinese enamels begins in the Yüan period, and the earliest recorded marks belong to the reign of the last emperor of that dynasty (1333–67). The great period of production is certainly that of the Ming dynasty, which followed.

Ming enamels

The mark most commonly found within this period is that of the Ching-t'ai reign (1449–57). The Ming enamels, bold in design with fine depth and purity of colour, were never surpassed in later epochs. The two shades of blue, a dark-lapis-lazuli tone and a pale sky blue with a very slight tinge of green, are particularly excellent. The red is of dark-coral tint, and the yellow full-bodied and pure. Greens derived from copper are sparingly used. Black and white are the least successful, the former shallow and dull, the latter clouded and muddy. As fine as the Ming enamels are, however, there is an imperfection of technique, close examination revealing minute pitting in the enamels, which was caused by inadequate packing of the material, and some lack of polish in the surface. These technical defects, however, do not appreciably detract from the great artistic value of the Ming enamels.

A great revival of art industries took place under the patronage of the emperor K'ang-hsi (1661–1722), who, in 1680, established a series of imperial factories. He commissioned sets of incense vessels of cloisonné enamel for presentation to the numerous Buddhist temples founded under his auspices in the neighbourhood of Peking, as well as other objects for the honorific gifts that were characteristic of his enlightened reign. The enamels produced during his time are marked by an improvement in technical quality as compared with those of the Ming period; to a considerable extent they also retained the finer qualities of the Ming wares. In many cases the forms of ancient bronze vessels were revived and enriched with enamels.

The style of this reign persisted during that of K'ang-hsi's successor, Yung-cheng (1723–35), while the long rule of Ch'ien-lung (1736–96) was marked, in enamel as in the case of many other industrial arts, by a further perfection of technique but by a loss of much of the vigour of design and breadth of execution that distinguished the products of earlier periods. Modern enamels, although they are primarily imitations of older work, are more hurriedly made and therefore not so well finished as the older work.

Champlevé. Some of the most ancient enamel examples extant belong to this class, and examples in which both champlevé and cloisonné are employed are not uncommon.

Although the opaque enamels were more common, Chinese artisans occasionally used translucent enamels on a silver or gold base. The cloisonné back of the silver mirror in the Shōsō-in, for example, is decorated with transparent enamels, but important pieces such as this are rare. This technique more often appears in Chinese jewelry.

Painted enamels. The painted enamels of China, generally known, from the principal seat of their manufacture, as Canton enamels, are practically identical in technique with the Limoges and other painted enamels of

Canton enamels

Europe. Specimens of the latter are known to have been taken to China by the missionaries of the late 17th and 18th centuries; they not only exercised direct influence on the Chinese ware but also, in some cases, were copied. Representations of European subjects, copies of engravings and armorial decorations, are also found. Painted enamels are termed by the Chinese *yang-tz'u* ("foreign porcelain"), the palette of colours used being the same as with enamelled porcelain, whose decoration under foreign influence is called *yang-ts'ai* ("foreign colours"). A ground of opaque enamel, generally white, is laid on the copper, and on this the colours are superimposed and fired. The best period of this art was the 18th century. Although imitations have continued to be made, nothing of real quality in this style was produced after the termination of the reign of Ch'ien-lung in 1796. The method has always been looked upon by the Chinese as alien in taste; in fact, a great part of the Canton enamels were made for export, not only on European commission but also for clients in India, Persia, and several other Asian countries.

Japan. The art of enamelling in Japan may date back to the 7th century. One enamelled metal piece, discovered in a tomb near Nara, which probably dates from the 7th century, seems to be of Japanese origin. The civic Taihō code, compiled in the 8th century, provides one official to be in charge of founding metals and "painted glass decoration." Subsequently, however, this art seems almost to die out until the 17th century. When Dōnin Hirata I (1591–1646) succeeded in making enamelled wares, having learned the technique from Koreans, his art was highly appreciated by Tokugawa Ieyasu, then the shogun of Japan, under whose patronage Hirata worked in Kyōto. There is a suit of armour with enamelled metal fittings ascribed to him, as well as enamelled metal fittings decorating sliding doors and lintels in the Katsura Palace, Kyōto. His family continued the trade until the late 19th century, making use, on a small scale, of both the cloisonné and champlevé methods. There was no further development of importance until Kaji Tsunekichi (1803–83) and his pupils established in Nagoya an important and successful manufacture of cloisonné, which obtained a considerable vogue, especially among foreigners.

While Kaji used brass cloisons and opaque enamel colours only, his successors used silver cloisons and succeeded in making both transparent and translucent enamels. They further modified the cloisonné process with remarkable ingenuity and produced work of great interest. First, they reproduced in minutely detailed cloisonné work realistic pictures, of trees and flowers, for example. This effort led them in the 1880s to produce lineless cloisonné enamels, which have all the beauty and brilliance of true cloisonné, with thick layers of enamel colours, but which, showing no trace of cloisons, permit a gradation of colours as in the less clear and brilliant painted enamels. The effect was achieved by taking off the cloisons before each firing, the process being repeated at least three times. The artists working for the factory of Namikawa Sōsuke of Tokyo in the late 19th century were most successful in this technique. Another Namikawa of Kyōto worked in true cloisonné. The factory of Jubei Ando of Nagoya has produced more variations. These developments have carried the art of enamel very far from the old traditions; while the skill and ingenuity of technique they evince may be appreciated, there is a danger of losing the artistry peculiar to the art of enamelling.

Encyclopaedia

For over 2,000 years encyclopaedias have existed as summaries of extant scholarship in forms comprehensible to their readers. The word encyclopaedia, of Greek origin (*enkyklopaideia*), at first meant a circle or a complete system of learning; that is, an all-round education. When Rabelais used the term in French for the first time in *Pantagruel* (chapter 20), he was still talking of education. Paul Scalich, a German writer and compiler, was the first to use the word to describe a book in the title of his *Encyclopaedia; seu, orbis disciplinarum, tam sacrarum quam prophanum epistemon* . . . ("Encyclopaedia; or Knowledge of the World of Disciplines, Not Only Sacred but Profane . . ."), issued at Basel in 1559. The many encyclopaedias that had been published prior to this time had either been given fanciful titles (*Hortus deliciarum*, "Garden of Delights") or had been simply called "dictionary." The word dictionary has been widely used as a name for encyclopaedias, and Scalich's pioneer use of "encyclopaedia" did not find general acceptance until Denis Diderot made it fashionable with his historic French encyclopaedia, although "cyclopaedia" was then becoming fairly popular as an alternative term. Even today a modern encyclopaedia still may be called a dictionary, but no good dictionary has ever been called an encyclopaedia.

Encyclopaedia as a complete system of learning

The meaning of the word encyclopaedia has changed considerably during its long history. Today most people envisage an encyclopaedia as a multivolume compendium of all available knowledge, complete with maps and a very detailed index, as well as numerous adjuncts such as bibliographies, illustrations, diagrams, lists of abbreviations and foreign expressions, gazetteers, and so on. They expect it to include biographies of the great men and women of the present as well as those of the

past, and they take it for granted that the alphabetically arranged contents will have been written in their own language by many people and will have been edited by a highly skilled and scholarly staff. Yet not one of these ingredients has remained the same throughout the ages. Encyclopaedias have come in all sizes from a single 200-page volume written by one man to giant sets of 100 volumes or more. The degree of coverage of knowledge has varied according to the time and country of publication. Illustrations, atlases, and bibliographies have been omitted from many encyclopaedias, and for a long time it was not thought fitting to include biographies of living persons. Indexes are a late addition, and most of the early ones were useless. Alphabetical arrangement was as strongly opposed as the use of any language but Latin, at least in the first 1,000 years of publication in the West, and skilled group editorship has a history of scarcely 200 years.

In this article the word encyclopaedia has been taken to include not only the great general encyclopaedias of the past and the present but all types of works that claim to provide in an orderly arrangement the essence of "all that is known" on a subject or a group of subjects. This includes dictionaries of philosophy and of American history as well as volumes such as *The World Almanac*, which is really a kind of encyclopaedia of current information.

Encyclopaedias as reflections of the development of scholarship

An outline of the scope and history of encyclopaedias is essentially a guide to the story of the development of scholarship, for encyclopaedias stand out as landmarks throughout the centuries, recording much of what was known at the time of publication. Many homes have no encyclopaedia at all, very few have more than one, yet in the past 2,000 years at least 2,000 encyclopaedias have been issued in various parts of the world, and some of these have had many editions. No library has copies of them all; if it were possible to collect them they would occupy some two miles of shelf space. But they are worth preserving—even those that appear to be hopelessly out of date—for they contain many contributions by a large number of the world's leaders and scholars.

This article is outlined as follows:

I. The nature of encyclopaedias
II. Encyclopaedias in general
    The role of encyclopaedias
    Editing and publishing
III. The kinds of encyclopaedias
    General encyclopaedias
    Encyclopaedic dictionaries
    The modern encyclopaedia
    Encyclopaedias for special interests
    Children's encyclopaedias
    Specialized encyclopaedias
    Encyclopaedias of countries and regions
IV. History of encyclopaedias
    Encyclopaedias in the West
    Encyclopaedias in the East
    Aims and effects of encyclopaedias

I. The nature of encyclopaedias

In the *Speculum majus* ("The Greater Mirror"; completed 1244), one of the most important of all encyclopaedias, the French medieval scholar Vincent of Beauvais maintained not only that his work should be perused but that the ideas it recorded should be taken to heart and imitated. Alluding to a secondary sense of the word *speculum* ("mirror"), he implied that his book showed the world what it is and what it should become. This theme, that encyclopaedias can contribute significantly to the improvement of mankind, recurs constantly throughout their long history. A Catalan ecclesiastic and scholastic philosopher, Ramon Llull, regarded the 13th-century encyclopaedias, together with language and grammar, as instruments for the pursuit of truth. Domenico Bandini, an Italian humanist, planned his *Fons memorabilium universi* ("The Source of Noteworthy Facts of the Universe") at the beginning of the 15th century to provide accurate information on any subject to educated men who lacked books and to give edifying lessons to guide them in their lives. Francis Bacon believed that the intellect of the 17th-century individual could be refined by contact with the intellect of the ideal man. Another Englishman, the poet and critic Samuel Taylor Coleridge, was well aware of this point of view and said in his "Preliminary Treatise on Method" (1817) that in the *Encyclopaedia Metropolitana*, which he proposed to create, "our great objects are to exhibit the Arts and Sciences in their Philosophical harmony; to teach Philosophy in union with Morals; and to sustain Morality by Revealed Religion." He added that he intended to convey methodically "the pure and unsophisticated knowledge of the past . . . to aid the progress of the future." The Society for the Diffusion of Useful Knowledge declared in *The Penny Cyclopaedia* (1833–43) that, although most encyclopaedias attempted to form systems of knowledge, their own would in addition endeavour to "give such general views of all great branches of knowledge, as may help to the formation of just ideas on their extent and relative importance, and to point out the best sources of complete information."

In *De disciplinis* ("On the Disciplines"; 1531) the Spanish humanist Juan Luis Vives emphasized the encyclopaedia's role in the pursuit of truth. In Germany of the early 19th century the encyclopaedia was expected to provide the right or necessary knowledge for good society. Probably the boldest claim was that of Alexander Aitchison, that his new *Encyclopaedia Perthensis* (1796–1806) was intended to supersede the use of all other English books of reference.

Greek and Roman concepts

All these ideas were a far cry from the Greek concept, deriving from Plato, that in order to think better it is necessary to know all, and from the Roman attitude of the advisability of acquiring all useful knowledge in order to carry out one's tasks in life competently. The present concept of the encyclopaedia as an essential starting point from which one can embark on a voyage of discovery, or as a point of basic reference on which one can always rely, is little more than two centuries old.

The prose form has usually been accepted as the only suitable vehicle for the presentation of the text of an encyclopaedia, though the *Mappemonde*, or *L'Image du monde* ("The Image of the World"; 1246)—attributed by some to Gautier de Metz, a French poet and priest, and by others to a Flemish theologian, Gossouin—was written in French octosyllabic verse; and Jean de Magnon planned his never-completed *Science universelle* (1663) to comprise 200,000 lines of heroic verse. Even as late as 1783, the French poet André de Chénier was planning to condense Diderot's *Encyclopédie* into a poem in the Lucretian style. It has also been generally accepted that an encyclopaedia should adopt a straightforward, factual approach. Even so, the Latin writer Martianus Capella wrote his *Liber de nuptiis Mercurii et Philologiae* ("Book Concerning the Nuptials of Mercury and Philology"; *c.* 410–429) in an elaborate allegory in which the seven bridesmaids represented the seven liberal arts. Domenico Bandini similarly divided his encyclopaedia into five parts in honour of Christ's wounds, while Alfonso de la Torre, in his *Visiõ delectable* ("Delightful Vision"; *c.* 1435), adopted the allegorical approach of a child receiving instruction from a series of maidens named Grammar, Logic, Rhetoric, and so on.

The alphabetically arranged encyclopaedia has a history of less than 1,000 years, most of the encyclopaedias issued before the introduction of printing into Europe having been arranged in a methodical or classified form. The early compilers of encyclopaedias held with Samuel Taylor Coleridge that "To call a huge unconnected miscellany of the *omne scibile*, in an arrangement determined by the accident of initial letters, an encyclopaedia, is the impudent ignorance of your Presbyterian bookmakers!" Today several encyclopaedias still retain the classified form of arrangement.

There has never been any general agreement on the way in which the contents of an encyclopaedia should be arranged. In Roman times the approach was usually practical, with everyday topics such as astronomy and geography coming first, while the fine arts were relegated to the end of the work. The Roman statesman and writer

Cassiodorus, however, in his 6th-century *Institutiones*, began with the Scriptures and the church and gave only brief attention to such subjects as arithmetic and geometry. St. Isidore of Seville, educated in the classical tradition, redressed the balance in the next century in his *Etymologiarum sive originum libri XX* ("Twenty Books on Origins, or Etymologies"), commonly called *Etymologiae*, giving pride of place to the liberal arts and medicine, the Bible and the church coming later, but still preceding such subjects as agriculture and warfare, shipping and furniture. The earliest recorded Arabic encyclopaedia, compiled by the Arab philologist and historian Ibn Qutayba, had a completely different approach, beginning with power, war, and nobility, and ending with food and women. A later Persian encyclopaedia, compiled in 975–997 by the Persian scholar and statesman al-Khwārizmī, started with jurisprudence and scholastic philosophy, the more practical matters of medicine, geometry, and mechanics being relegated to a second group labelled "foreign knowledge." The general trend in classification in the Middle Ages is exemplified by Vincent of Beauvais's *Speculum majus*, which was arranged in three sections: "Naturale"—God, the creation, man; "Doctrinale"—language, ethics, crafts, medicine; "Historiale"—world history. The encyclopaedists were, however, still uncertain of the logical sequence of subjects, and although there were many who started with theological matters, there were just as many who preferred to put practical topics first.

A turning point came with Francis Bacon's plan for his uncompleted *Instauratio magna* ("Great Instauration"; 1620) in which he eschewed the endless controversies in favour of a three-section structure, including "External Nature" (covering such topics as astronomy, meteorology, geography, and species of minerals, vegetables, and animals), "Man" (covering anatomy, physiology, structure and powers, and actions), and "Man's Action on Nature" (including medicine, chemistry, the visual arts, the senses, the emotions, the intellectual faculties, architecture, transport, printing, agriculture, navigation, arithmetic, and numerous other subjects).

Various arrangements of the contents of encyclopaedias

In his plan Bacon had achieved more than a thoroughly scientific and acceptable arrangement of the contents of an encyclopaedia; he had ensured that the encyclopaedists would have a comprehensive outline of the scope of human knowledge that would operate as a checklist and prevent their omitting whole fields of human thought and endeavour. Bacon had so profoundly altered the editorial policy of encyclopaedists that even 130 years later Diderot gratefully acknowledged his debt in the prospectus (1750) of *L'Encyclopédie*. Because every later encyclopaedia was influenced by Diderot's work, the guidance of Bacon still plays its part today.

Coleridge, who was very much impressed by Bacon's scheme, in 1817 drew up a rather different table of arrangement for the *Encyclopaedia Metropolitana*. It comprised five main classes: Pure Sciences—Formal (philology, logic, mathematics) and Real (metaphysics, morals, theology); Mixed and Applied Sciences—Mixed (mechanics, hydrostatics, pneumatics, optics, astronomy) and Applied (experimental philosophy, the fine arts, the useful arts, natural history, application of natural history); Biographical and Historical, chronologically arranged; Miscellaneous and Lexicographical, a gazetteer, and a philosophical and etymological lexicon. The fifth class was to be an analytical index.

Influence of Coleridge's classification

Although Coleridge's classification was altered by the publisher, and although the *Metropolitana* was an impressive failure, the ideas for it had a lasting influence. Even though nearly all encyclopaedias today are arranged alphabetically, the classifications of Bacon and Coleridge still enable editors to plan their work with regard to an assumed hierarchy of the various branches of human knowledge.

The concept of alphabetical order was well known to both the Greeks and Romans, but the latter made little use of it. Neither the Greeks nor the Romans employed if for encyclopaedia arrangement, with the exception of Sextus Pompeius Festus in his 2nd-century *De verborum significatu* ("On the Meaning of Words"). St. Isidore's encyclopaedia was classified, but it included an alphabetically arranged etymological dictionary. The 10th- or 11th-century encyclopaedic dictionary known as *Suidas* was the first such work to be completely arranged alphabetically, but it had no influence on succeeding encyclopaedias, although glossaries, when included, were so arranged. Bandini's *Fons memorabilium universi* ("The Source of Noteworthy Facts of the Universe"), though classified, used separate alphabetical orders for more

Engraved title page from the first edition of Francis Bacon's *Instauratio magna*, published in London, 1620.

than a quarter of its sections, and the Italian Domenico Nani Mirabelli's *Polyanthea nova* ("The New Polyanthea"; 1503) was arranged in one alphabetical sequence. These were rare exceptions, however; the real breakthrough came only with the considerable number of encyclopaedic Latin-language dictionaries that appeared in the early 16th century, the best known of which is a series of publications by the French printer Charles Estienne. The last of the great Latin-language encyclopaedias arranged in alphabetical order was *Encyclopaedia* (1630) by the German Protestant theologian and philosopher Johann Heinrich Alsted. The publication of *Le Grand Dictionnaire historique* ("The Great Historical Dictionary"; 1674) of Louis Moréri, a French Roman Catholic priest and scholar, confirmed public preference both for the vernacular and the alphabetically arranged encyclopaedia; this choice was emphasized by the success of the posthumous *Dictionnaire universel* (1690) by the French lexicographer Antoine Furetière.

From time to time important attempts have been made to reestablish the idea of the superiority of the classified encyclopaedia. Coleridge saw the encyclopaedia as a vehicle for enabling man to think methodically. He felt that his philosophical arrangement would "present the circle of knowledge in its harmony" and give a "unity of design and of elucidation." He did agree that his appended gazetteer and English dictionary would best be arranged alphabetically for ease of reference. By then, however, alphabetical arrangement had too strong a hold, and it was not until 1935 that a new major classified encyclopaedia began to appear—the *Encyclopédie française* ("French Encyclopaedia"), founded by Anatole de Monzie. The Dutch *Eerste nederlandse systematisch ingerichte encyclopaedie* ("First Dutch Systematic and Comprehensive Encyclopaedia"; 1946–52) has a classification that is in almost reverse order of that of the *Encyclopédie française*, but it is clear that behind both works lies a philosophical concept of the order and main divisions of knowledge that is influenced by both Bacon and Coleridge. The Spanish *Enciclopedia labor* (1955–60) and the *Oxford Junior Encyclopaedia* (1948–56) follow systems of arrangement that are closer to the French than to the Dutch example.

Role of the trivium and quadrivium

From the earliest times it had been held that the trivium (grammar, logic, rhetoric) and the quadrivium (geometry, arithmetic, astronomy, music) were essential ingredients in any encyclopaedia. Even as late as 1435 Alfonso de la Torre began his *Visiõ delectable* in almost that exact order, and only when he had laid these foundations did he proceed to the problems of science, philosophy, theology, law, and politics. Thus the seven liberal arts were regarded by the early encyclopaedists as the very mathematics of human knowledge, without a knowledge of which it would be foolish to proceed. This idea survived to a certain extent in Coleridge's classification; he stated that grammar and logic provide the rules of speech and reasoning, while mathematics opens mankind to truths that are applicable to external existence.

When Louis Shores became editor in chief of *Collier's Encyclopedia* in 1962, he said that he considered the encyclopaedia to be "one of the few generalizing influences in a world of over-specialization. It serves to recall that knowledge has unity." This echoes the view of the English novelist H.G. Wells, that the encyclopaedia should not be "a miscellany, but a concentration, a clarification and a synthesis." The Austrian sociologist Otto Neurath in the same year suggested that the proposed new international encyclopaedia of unified science should be constructed like an onion, the different layers enclosing the "heart"—comprising in this case the foundations of the unity of science.

This modern emphasis on the unity of knowledge and the interdependence of its parts shows that encyclopaedists today are keenly aware of their educational role and that although the use of alphabetical arrangement may conceal the framework of classification, that framework is nevertheless an integral part of any good encyclopaedia (displayed in this encyclopaedia in the first volume as the *Outline of Contents*).

II. Encyclopaedias in general

THE ROLE OF ENCYCLOPAEDIAS

Of the various types of reference works—who's whos, dictionaries, atlases, gazetteers, directories, and so forth—the encyclopaedia is the only one that can be termed self-contained. Each of the rest conveys some information concerning every item it deals with, but only the encyclopaedia attempts to give a comprehensive summary of what is known of each topic considered. To this end it employs many features that can help in its task, including illustrations, maps, diagrams, charts, and statistical tables. It also frequently incorporates other types of reference works. Several modern encyclopaedias, from the time of Abraham Rees's *New Cyclopaedia* (1802–20) and the *Encyclopédie méthodique* ("Systematic Encyclopaedia"; 1782–1832) onward, have included a world atlas and a gazetteer, and language dictionaries have been an intermittent feature of encyclopaedias for most of their history.

Most modern encyclopaedias since the *Universal-Lexicon* (1732–50) of the Leipzig bookseller Johann Heinrich Zedler have included biographical material concerning living persons. The first edition of *Encyclopædia Britannica* (1768–1771) had no biographical material at all.

Treatment of biographical material

In their treatment of this kind of information they differ, however, from the form of reference work that limits itself to the provision of salient facts without comment. Similarly, with dictionary material, some encyclopaedias—such as the great Spanish "Espasa" (1905 to date)—provide foreign-language equivalents as well.

An English lexicographer, Henry Watson Fowler, wrote in the preface to the first edition (1911) of *The Concise Oxford Dictionary of Current English* that a dictionary is concerned with the uses of words and phrases and with giving information about the things for which they stand only so far as current use of the words depends upon knowledge of those things. The emphasis in an encyclopaedia is much more on the nature of the things for which the words and phrases stand. Thus the encyclopaedic dictionary, whose history extends as far back as the 10th- or 11th-century *Suidas*, forms a convenient bridge between the dictionary and the encyclopaedia, in that it combines the essential features of both, embellishing them where necessary with pictures or diagrams, at the same time that it reduces most entries to a few lines that can provide a rapid but accurate introduction to the subject.

Interrelations. An encyclopaedia does not come into being by itself. Each encyclopaedia builds on the experience and contents of its predecessors. In many cases the debt is acknowledged: the German publisher Friedrich Arnold Brockhaus bought up the bankrupt encyclopaedia of Gotthelf Renatus Löbel in 1808 and converted it into his famous *Conversations-Lexikon;* but Jesuits adapted Antoine Furetière's *Dictionnaire universel* without acknowledgment in their *Dictionnaire de Trévoux* (1704). Classical writers made many references to their predecessors' efforts and often incorporated whole passages from other encyclopaedias. Of all the many examples, the *Cyclopaedia* (1728) of the English encyclopaedist Ephraim Chambers has been outstanding in its influence, for Diderot's and Rees's encyclopaedias would have been very different if Chambers had not demonstrated what a modern encyclopaedia could be. In turn, the publication of *Encyclopædia Britannica* was stimulated by the issue of *L'Encyclopédie.* Almost every subsequent move in encyclopaedia making is thus directly traceable to Chambers' pioneer work.

Readership. Encyclopaedia makers have usually envisaged the particular public they addressed. Cassiodorus wrote for the "instruction of simple and unpolished brothers"; the Roman statesman Cato wrote for the guidance of his son; Gregor Reisch, prior of the Carthusian monastery of Freiburg, addressed himself to "Ingenuous Youth"; the Franciscan encyclopaedist Bartholomaeus Anglicus wrote for *ordinary* people; the German professor Johann Christoph Wagenseil wrote for children; and Herrad of Landsberg, abbess of Hohenburg, wrote for her nuns. *Encyclopædia Britannica* is designed for the use of the curious and intelligent layman. The editor of *The Columbia Encyclopedia* in 1935 tried to provide a work compact enough and simply enough written to serve as a guide to the "young Abraham Lincoln." The Jesuit Michael Pexenfelder (1670) made his intended audience clear enough by writing his *Apparatus Eruditionis* ("Apparatus of Learning") in the form of a series of conversations between teacher and pupil. St. Isidore addressed himself to the needs not only of his former pupils in the episcopal school but also to all the priests and monks for whom he was responsible. At the same time, he tried to provide the newly converted population of Spain with a national culture that would enable it to hold its own in the Byzantine world.

Contributors. In sympathy with such ends, many scholars have contributed to encyclopaedias. Not all their contributions are known because, until recently, it was not the custom to sign articles. Even today there is what amounts to partial concealment in that articles are often initialled only, and, although a key is provided, few readers look up the writer's identity. It is known, however, that the English encyclopaedist John Harris enlisted the help of such scientists as John Ray and Sir Isaac Newton in his *Lexicon Technicum* (1704) and that Rees's *New Cyclopaedia* (1802–20) included articles on music by the English organist and music historian Charles Burney and on botany by the English botanist Sir J.E. Smith. Illustrious Frenchmen such as Voltaire, Rousseau, Condorcet, Montesquieu, and Georges Boulanger contributed to *L'Encyclopédie;* the writer and statesman Thomas Macaulay, the Russian-born jurist and medieval historian Sir Paul Vinogradoff, and the Czech statesman Tomáš Masaryk to the *Britannica;* the Scottish physicist Sir David Brewster and the Danish physicist Hans Christian Oersted to *The Edinburgh Encyclopaedia* (1808–30); the English astronomer Sir William Herschel and the English mathematician and mechanical genius Charles Babbage to the *Metropolitana;* the Russian Communist leader Lenin to the "Granat" encyclopaedia; and the dictator Benito Mussolini to the *Enciclopedia italiana.*

Language. The language of Western encyclopaedias was almost exclusively Latin up to the time of the first printed works. As with most scholarly writings, the use of Latin was advantageous because it made works available internationally on a wide scale and thus promoted unlimited sharing of information. On the other hand, it made the contents of encyclopaedias inaccessible to the great majority of people. Consequently, there was from the early days on a movement to translate the more important encyclopaedias into various vernaculars. Honorius Inclusus' *Imago mundi* ("Image of the World"; *c.* 1122) was rendered into French, Italian, and Spanish; Bartholomaeus Anglicus' *De proprietatibus rerum* ("On the Characteristics of Things"; 1220–40) into English; the Dominican friar Thomas de Cantimpré's *De natura rerum* ("On the Nature of Things"; *c.* 1228–44) into Flemish and German; and Vincent of Beauvais's *Speculum majus* ("The Greater Mirror") into French, Spanish, German, Dutch, and Catalan. In later years the more successful encyclopaedias were translated from one vernacular into another. Moréri's encyclopaedia, *Le Grand Dictionnaire historique,* was translated into both English and German. The German *Brockhaus* appeared in a Russian translation (1890–1907), and the French *Petit Larousse* had several foreign-language editions. Nevertheless, an encyclopaedia, however successful in its own country, may find acceptance in another country far from easy, because each nation appears to have its own very individual concept of what an encyclopaedia should comprise.

Translations of Latin encyclopaedias

The contemporary world. Encyclopaedias have often reflected fairly accurately the civilization in which they appeared; that this was deliberate is shown by the frequency with which the earlier compilers included such words as *speculum* ("mirror"), *imago* ("image"), and so forth in their titles. Thus as early as the 2nd century the Greek sophist Julius Pollux was already defining current technical terms in his *Onomastikon.* In the 13th century Vincent of Beauvais quoted the ideas of both pagan and Christian philosophers freely and without differentiation, for their statements often agreed on questions of morals. In doing so, he reflected the rapidly widening horizons of a period that saw the founding of so many universities. Bartholomaeus Anglicus devoted a considerable part of his work to psychology and medicine. "Theophilus" (thought to be Roger of Helmarshausen, a Benedictine monk) as early as the 12th century gave a clear and practical account in his *De diversis artibus* ("On Diverse Arts") of contemporary processes used in painting, glassmaking and decoration, metalworking, bone carving, and the working of precious stones, even listing the necessary tools and conditions for successful operations. Pierre Bayle, a French philosopher and critic, showed in his *Dictionnaire historique et critique* ("Historical and Critical Dictionary"; 1697) how the scientific renaissance of the previous 40 years had revolutionized contemporary thought. To every detail he applied a mercilessly scientific and inquiring mind that challenged the assumptions and blind reverence for authority that had characterized most of his predecessors.

Treatment of practical matters in encyclopaedias

At that point in history, much attention was being paid to practical matters: the statesman Jean-Baptiste Colbert himself directed the French Académie des Sciences (1675) to produce a work that eventually appeared as the *Description et perfection des arts et métiers* ("Description and Perfection of the Arts and Crafts"; 1761). The German Meyer's *Grosses Conversations-Lexicon* from the first edition (1840–55) onward paid particular attention to scientific and technical developments, and the *Encyclopedia Americana,* aided by the *Scientific American,* strengthened its coverage in this area from 1911 onward. From its first edition the *Encyclopædia Britannica* included practical articles on topics such as bookkeeping and aspects of farming. Similarly, Abraham Rees had been including articles on subjects such as candlemaking and coachbuilding earlier in the century. The outstanding example of a completely contemporary encyclopaedia was, of course, *L'Encyclopédie,* in which the philosopher Denis Diderot and the mathematician and philosopher Jean Le Rond d'Alembert and their friends set out to reject much of the heritage of the past in favour of the scientific discoveries and the more advanced thought of their own age. Their decision in this respect was both intellectually and commercially successful; since that time every edition of any good ency-

clopaedia has the additional merit of being a valuable source for the thought and attitudes of the world for which it was published.

Encyclopaedias and politics. All great encyclopaedia makers have tried to be truthful and to present a balanced picture of civilization as they knew it, although it is probable that no encyclopaedia is totally unbiassed. A great encyclopaedia is inevitably a sign of national maturity and, as such, will pay tribute to the ideals of its country and its times. The first Hungarian encyclopaedia, János Apáczai Csere's *Magyar encyclopaedia* (1653–55), was mostly a summary of what was available in foreign works, but the *Révai nagy lexikona* ("Révai's Great Lexicon"; 1911–35) was a handsome tribute to Hungary's emergence as a country in its own right, just as the *Enciklopedija Jugoslavije* (1955–) is a prestige work that does full justice to the advances made by Yugoslavia in the mid-20th century. The supreme example of an encyclopaedia that set out to present the best possible image of its people and the wealth and stature of their culture is undoubtedly the *Enciclopedia italiana* (1929–39). Mussolini's contribution of an article on Fascism indicates the extent to which the work might be regarded as an ideological tool, but, in fact, the bulk of its contents is admirably international and objective in approach. The various Soviet encyclopaedias already occupy many feet of shelf space, and the later editions each devote one complete volume to the Soviet Union in all its aspects. Though successive editions have been notable for the obvious political factors that have been responsible for the inclusion and exclusion of entries for famous nationals according to the current state of their acceptance or condemnation by the existing regime, many critics have felt that the newest edition, the first volume of which was issued in 1970, is more mature than any of the others in this regard.

Opposition to encyclopaedias

Political censorship is not the only form of oppression in the world of encyclopaedias. Antoine Furetière, on issuing his prospectus (1675) for his *Dictionnaire universel*, found his privilege to publish cancelled by the French government at the request of the Académie Française, which accused him of plagiarizing their own dictionary. The Leipzig book trade, fearing that publication of Johann Heinrich Zedler's huge *Universal-Lexikon* (1732–50) might put them out of business, made such difficulties that Zedler thought it best to issue his work in Halle. Diderot, the editor, and André-François Le Breton, the publisher, faced such opposition from both church and state in their publication of *L'Encyclopédie* (1751–65) that many of the volumes were secretly printed, and the last ten were issued with a false imprint. In the early part of the 19th century, *Brockhaus* was condemned by the Austrian censor, and in 1950 its 11th edition was branded as reactionary by the East German government.

The reader's needs. People look to encyclopaedias to give them an adequate introduction to a topic that interests them. Many expect the encyclopaedia to omit nothing and to include consideration of all controversial aspects of a subject. Encyclopaedia makers of the past assumed that there was a large public willing to read through an entire encyclopaedia if it was not too large. In the 18th century, for example, there was a good market for pocket-size compendia for the traveller, or for the courtier to browse in as he waited for an audience. Thus, although most encyclopaedias are multivolume works, there are many small works ranging from the *Didascalion* of the scholastic philosopher and mystic theologian Hugh of Saint-Victor (*c.* 1128), through Gregor Reisch's *Margarita philosophica* (1496) and the French writer Pons-Augustin Alletz' *Petite Encyclopédie* (1766), to C.T. Watkins' *Portable Cyclopaedia* (1817). The last was issued by a remarkable publisher, Sir Richard Phillips, who realized the great demand for pocket-size compendia and drove a thriving trade in issuing a number of these; he is thought to have written large sections of these himself.

Royalty and encyclopaedias. Most of the classic Chinese encyclopaedias owe their existence to the patronage of emperors. In the West, the Roman scholar Pliny dedicated his *Historia naturalis* ("Natural History") to the emperor Titus; Julius Pollux dedicated his *Onomastikon* to his former pupil, the Roman emperor Commodus, while the Byzantine philosopher and politician Michael Psellus dedicated his *De omnifaria doctrina* ("On All Sorts of Teaching") to his former pupil the emperor Michael VII Ducas, ruler of the Eastern Roman Empire. Gervase of Tilbury, an English ecclesiastic, compiled his *Otia imperialia* ("Imperial Pastimes") for the Holy Roman emperor Otto IV, and Alfonso de la Torre prepared his *Visiõ delectable* for Prince Carlos of Viana. St. Isidore dedicated his encyclopaedia to the Visigothic king Sisebut, and the French king Louis IX patronized Vincent of Beauvais's *Speculum majus*. Nor did kings eschew the work of compiling encyclopaedias. The emperor Constantine VII of the Eastern Roman Empire was responsible for a series of encyclopaedias, and Alfonso X of Spain organized the making of the *Grande e general estoria* ("Great and General History").

Contents and authority. The extent to which readers have been dependent on editorial decisions concerning not only what to include but also what to exclude has yet to be explored in detail. For example, Vincent of Beauvais rarely mentioned the pagan and Christian legends that were so popular in his day. The anonymous compiler of the scholarly *Compendium philosophiae* ("Compendium of Philosophy"; *c.* 1316) was careful to omit the credulous tales that appeared in contemporary bestiaries. For many centuries it was not considered right to include biographies of men and women who were still alive. And the early Romans, such as Cato the Censor, rejected much of Greek theoretical knowledge, regarding it as a dangerous foreign influence and believing with the Stoics that wisdom consisted in living according to nature's precepts.

Editorial censorship

Whatever the compiler did decide to include had a far-reaching influence. Pliny's vast *Historia naturalis* has survived intact because for so many centuries it symbolized human knowledge, and even the "old wives' tales" it injudiciously included were unquestioningly copied into many later encyclopaedias. The influence of St. Isidore's work can be traced in writings as late as Sir John Mandeville's travels (published in French between 1357 and 1371) and the English poet John Gower's 14th-century *Confessio amantis* ("A Lover's Confession"). Honorius' *Imago mundi* is known to have influenced some of the German medieval chronicles and the Norse saga of Olaf Tryggvason. The main source of classics such as the *Roman de la rose*, the Alexander romances, Archbishop Giovanni da Colonna's *Liber de viris illustribus* ("Book Concerning Illustrious Men"), and the recorded lives of the saints can be traced to the *Speculum majus*. The direct and indirect influence of the critical encyclopaedias of Pierre Bayle and Denis Diderot is, of course, incalculable.

The problem of keeping encyclopaedias up-to-date is very much of a preoccupation of contemporary publishers. The more important encyclopaedias maintain large permanent staffs to scrutinize newspapers and periodicals as well as books in an effort to ensure that the latest theories and discoveries are incorporated and that outmoded information and exploded "facts" give place to more precise and accurate material. The possibilities of utilizing the computer to this end have been studied intensively.

EDITING AND PUBLISHING

One-volume encyclopaedias

There always have been and there still are a number of successful one-volume encyclopaedias. Current outstanding examples include *The Columbia Encyclopedia*, the *Petit Larousse*, and *Hutchinson's New Twentieth Century Encyclopaedia*. Some booksellers and publishers nevertheless confirm that there is, however unreasonably, a certain amount of public prejudice against the single-volume form, and that most people prefer a multivolume work. Throughout the entire history of encyclopaedias there has been much disagreement on the correct number of volumes. Many of the Chinese encyclopaedias have been very much larger than any Western work. Pliny's

Historia naturalis comprised about 2,500 chapters, Zedler's *Universal-Lexicon* was planned for 12 volumes and eventually filled 64; the publishers of *L'Encyclopédie* were faced with a lawsuit (1768–78) for producing a 26-volume encyclopaedia instead of the ten volumes they had promised; and Johann Samuel Ersch and Johann Gottfried Gruber's German *Allgemeine Encyclopädie* ("General Encyclopaedia") had already reached 167 volumes at the time of its discontinuance. Today, although the major Soviet encyclopaedia consists of more than 50 volumes, most encyclopaedias appear to favour a size between 20 and 30 volumes, occupying between three and four feet of shelf space. Thus the modern encyclopaedia appears smaller than its 19th-century counterpart, but, in fact, the content may be greater because the thick matt paper of Victorian times has been replaced by a thinner paper capable of reproducing coloured and black and white halftone illustrations with sharp definition.

The length of encyclopaedia articles is a feature on which there has been a lasting difference of opinion. Most of the great encyclopaedias of the past, and many of the present, devote considerable space to any topic of major importance. As early as the turn of the 19th century, however, it was recognized that an alternative method of treatment would be to break up the larger subjects into a number of specific aspects and distribute them among the appropriate parts of the alphabetical sequence. Thus, an article on broadcasting could be limited to broad aspects, separate entries being made for radio, television, and so on. Supporters of this system argue that cross-references enable such articles to be linked up; opponents say that cross-references are not always followed up and that the fragmentation of the subject enforces much repetition of basic information. Nevertheless, *Brockhaus*, *Meyer*, *Larousse*, and many other encyclopaedias of the *Konversationslexikon* type exist today and have a strong following.

Authorship by one individual

The first encyclopaedia makers had no doubts concerning their ability to compile their works single-handedly. Cassiodorus, Honorius Inclusus (or Solitarius), and Vincent of Beauvais fully justified this attitude, though their task was largely that of the anthologist. Vincent and many other encyclopaedists employed both scribes and scholars to help them in their work, but once the encyclopaedia reached the stage of independent writing it was clear that the editorial task was going to become more complex. Even so, some of the later pocket encyclopaedias—such as the English bookseller John Dunton's mediocre *Ladies' Dictionary* (1694), *An Universal History of Arts and Sciences* (1745) by the French-born Englishman Chevalier Denis de Coëtlogon, and the popular *Allgemeines Lexicon* (1721) by the Prussian scholar Johann Theodor Jablonski—were substantially or almost wholly the work of a single author; such items are, however, negligible.

John Harris, an English theologian and scientist, may have been one of the first to enlist the aid of experts, such as the naturalist John Ray and Sir Isaac Newton, in compiling his *Lexicon Technicum* ("Technical Lexicon"; 1704). Johann Heinrich Zedler, in his *Universal-Lexicon* (1732–50), went further by enlisting the help of two general editors, supported by nine specialist editors, the result being a gigantic work of great accuracy. The French *Encyclopédie*, the largest encyclopaedia issued at that time, inevitably had many contributors, although the French writer Voltaire said that Diderot's collaborator, the Chevalier Louis de Jaucourt (aided by secretaries), contributed about three-quarters of the articles in that work. The pattern for future encyclopaedias was established: for any substantial work it would be necessary not only to have contributions from the experts of the day, but it would also be essential to have subject editors who could supervise the coverage and content in each area of knowledge. With little alteration, this system prevails today.

Encyclopaedia adjuncts. The readers of modern encyclopaedias are rarely aware of the numerous aids that have been provided to make their search for information so easy and efficient. Only when recourse is had to one of the older encyclopaedias does the reader become conscious of the advances that have been made. In former days it was often difficult to distinguish between one article and the next, because distinctive headings or inset titles or the use of boldface was rare. Nor was the necessity for running titles or alphabetical notations at the head of the pages fully appreciated. Even more troublesome was the problem of the arrangement of entries for several persons of the same name; reference to the older encyclopaedias under such headings as "Henry," "Charles," "John," or "Louis"—names held by both princes and religious potentates—will show how little the art of acceptable arrangement was understood.

Arrangement of articles

Cross-references and bibliographies. Cross-references are an essential feature of the modern encyclopaedia; they date back at least as far as Bandini's *Fons memorabilium universi*, but it was Brockhaus who introduced an ingenious system of using arrows instead of the words "see also." *The Columbia Encyclopaedia* achieves the same effect by printing in small capital letters the words under which additional information can be found. Other features of interest in the modern encyclopaedia include the devotion of each volume to a letter of the alphabet (*Compton's Encyclopaedia* formerly followed this system), or the indication of the division between letters by thumb-indexing or by the insertion of a thicker sheet of distinctively coloured paper. The bibliographies in established encyclopaedias for individual articles are usually the result of careful editorial consultation with the writer and with librarians.

Indexes. Undoubtedly the major adjunct of the modern encyclopaedia is its index. As early as 1614 the bishop of Petina, Antonio Zara, included an index of a kind in his *Anatomia ingeniorum et scientiarum* ("Anatomy of Talents and Sciences"). A Greek professor at Basel, Johann Jacob Hoffman, added an index to his *Lexicon universale* of 1677; *L'Encyclopédie* was completed by a two-volume "Table analytique et raisonnée" for the entire 33 volumes of text, supplements, and plates; and the *Britannica* included individual indexes to the lengthier articles in its 2nd edition (1778–84) and provided its first separate index volume for the 7th edition (1830–42). The nature of good indexing was still far from being fully understood, however, and it was only later in the 19th century that really good encyclopaedia indexes were prepared. In the 20-century encyclopaedias that provide indexes—and there are many that do not—the reader is invariably advised to read the guides to their use because the index is a sophisticated tool that, by the aid of a few simple typographical devices and editorial conventions, is able to offer a wealth of information in one alphabetical sequence.

Illustrative material. The use of illustrations in encyclopaedias goes back almost certainly to St. Isidore's time. One of the most beautiful examples of an illustrated encyclopaedia was the abbess Herrad's 12th-century *Hortus deliciarum*. In many earlier encyclopaedias the illustrations were often more decorative than useful, but from the end of the 17th century the better encyclopaedias began to include engraved plates of great accuracy and some of great beauty. *L'Encyclopédie* is particularly distinguished for its superb volume of plates—they have even been reprinted in the 20th century. In modern times the trend has been toward more lavish illustration of encyclopaedias, including elaborate coloured anatomical plates with superimposed layers, and specially inset small coloured halftones, as well as marginal line drawings. Since 1950 a form of encyclopaedia has begun to appear that comprises large numbers of coloured illustrations with a somewhat subordinated text.

Early illustrated encyclopaedias

The level of writing. The American editor Franklin H. Hooper, undaunted by his own lack of scholarship, took a notable part in ensuring that the articles of the 11th edition of *Encyclopædia Britannica* were kept within the mental range of the average man. The problem of the encyclopaedist has always been to strike the right mean between too learned and too simplified an approach. The Roman Cassiodorus wrote his encyclopaedia to pro-

vide a bridge between his unlettered monks and the scholarly books he had preserved for their use. Hugh of Saint-Victor, the theologian and philosopher, achieved one of the best approaches in his charming *Didascalion* (*c.* 1128), in which he used an elegant and simple style that everyone could appreciate. The abbess Herrad, knowing her audience, described in didactic fashion the history of the world (with emphasis on biblical stories) and its content, with commentaries and beautifully coloured miniatures designed to help and edify the simple nuns in her charge. The master of Dante, Brunetto Latini, wanted to reach the Italian cultured and mercantile classes with his *Li livres dou trésor* ("Treasure Books"; *c.* 1264) and therefore used a concise and accurate style that evoked an immediate and general welcome. Gregor Reisch managed to cover the whole university course of the day in his very pleasing and brief *Margarita philosophica*, which correctly interpreted the taste of the younger generation at the end of the 15th century.

Until the 17th century there had been a great many encyclopaedias written by clerics for clerics, and further examples continued to be published. After that time, more popular works began to be published as well, particularly in France, where such palatable compilations as the Sieur Saunier's *Encyclopédie des beaux esprits* ("Encyclopaedia of Great Minds"; 1657) had an immediate success. The philosopher Pierre Bayle in his *Dictionnaire historique et critique* (1697) first introduced the lay reader to the necessity of reading more critically; in this his work constituted a forerunner of *L'Encyclopédie*, with its challenges to so many undiscriminating assumptions about religion and politics, history and government. On the other hand, the contemporary *Dictionnaire universel* of the Jesuit fathers of Trévoux had a popularity among the orthodox that caused it to run through six editions and gradually to increase its size from three to eight volumes between 1704 and 1771.

Encyclopaedias for clerics and lay readers

Supplementary material. The idea of keeping encyclopaedias up-to-date by means of supplements, yearbooks, and so on, is well over 200 years old. In 1753 a two-volume supplement to the 7th edition of Ephraim Chambers' *Cyclopaedia* was compiled by George Lewis Scott, a tutor to the English royal family. Charles-Joseph Panckoucke, a publisher, issued a four-volume supplement to *L'Encyclopédie* (1776–77), in spite of Diderot's refusal to edit it. The *Britannica* included a 200-page appendix in the last volume of the 2nd edition (1784) and issued a two-volume supplement to the 3rd edition (1801; reprinted 1803). *Brockhaus* broke new ground by issuing in monthly parts (1857–64) a yearbook to the 10th edition (1851–55), which, on the commencement of the issue of the 11th edition, changed its name to *Unsere Zeit* ("Our Times") and doubled its frequency (1865–74). In 1907 Larousse began publication of the *Larousse mensuel illustré* ("Monthly Illustrated Larousse"). *The New International Encyclopaedia* issued a yearbook from 1908 (retrospective to 1903), and the *Britannica* issued one yearbook in 1913 and recommenced with the *Britannica Book of the Year* in 1938. The publication of supplements has a much longer history in China, but the system on which they operated was very different from that of the West (see below). Nowadays yearbooks are a common feature of encyclopaedias of standing in the U.S. and other countries. In the main, they are more effective in recording the events and discoveries of each year than they are in keeping the main articles up-to-date, but they perform an essential duty in informing their readers of much that is not reported or that is only inadequately reported in the press; at the same time, they provide a more reasoned assessment and perspective than the daily newspapers and the weekly commentaries can usually achieve.

Some of the leading encyclopaedias offer additional services that are not too widely known. The modern encyclopaedia is a complex work of reference, and the reader needs expert guidance if he is to get the best from its contents. To this end, small subject guides are sometimes issued, which, in narrative form, outline the whole field and bring each topic into perspective, drawing attention to the appropriate articles that will throw further light on the matter. As a means of self-education, some of these outlines maintain a high standard and are an invaluable adjunct to the encyclopaedia. Another feature offered by established encyclopaedias is an inquiry service. An inquiry on a point concerning which the encyclopaedia has not provided the reader with sufficient information gives him access to the files that the encyclopaedia maintains. In addition, the encyclopaedia will refer the more difficult inquiries to its specialist editors or contributors, or it may contact the appropriate specialized libraries, rather than return an inadequate answer to the reader. This particular service is of value to both the encyclopaedia's readers and to its staff, because, on the one hand, it gives the user the reassurance that he has an extra and very lively resource on which to draw for information, and on the other, it keeps the editorial staff in contact with the changing interests of readers and helps to underline omissions and deficiencies in the current edition.

Research services

Other supplementary material sometimes issued by encyclopaedias ranges from ten-year illustrated surveys of events to sets of books that have had a major impact on mankind. Although few publishers include dictionaries as an integral part of their encyclopaedia, they frequently supply a well-known, independently compiled work as part of their service. It is an increasingly common custom, however, for a modern encyclopaedia to incorporate an atlas and a gazetteer, often in the last volume.

Problems of encyclopaedias. *Authorship.* In using a reputable encyclopaedia the reader is inclined to accept the authenticity of any article he happens to read. Subconsciously he is aware that the highly organized body of scholars listed at the beginning of the work must inevitably have ensured the severe scrutiny of all material. Nevertheless, in recent years editors of encyclopaedias have tended more and more to commission signed articles by well-known experts. One of the most famous examples of this was the *Britannica*'s commissioning of articles for its 1922 supplement from some of the most famous men and women of the day: "Belgium" by the Belgian historian Henri Pirenne; "Anton Ivanovich Denikin" by the Russian-born jurist and historian Sir Paul Vinogradoff; "Drama" by St. John Ervine, the Irish playwright and novelist; "Czechoslovakia" by the Czech statesman Tomáš Masaryk; and "Russian Army" by Gen. Yuri Danilov. This created a new dimension in encyclopaedias, for it introduced a personal element on a scale previously seen only in the columns of *L'Encyclopédie*.

There is, in fact, a difference in the treatment of a subject written by a politician such as Masaryk and by an academic historian of distinction. Each writer has something important to offer, and the results will be very different.

Length restrictions. The restrictions imposed by the space available for any particular article are of great consequence. If an expert is asked to contribute an article on his own field, his first reaction is often one of dismay at the comparatively small amount of space that can be allotted to it. Writing articles for encyclopaedias is an art of its own; within a limited space so much must be compressed—nothing important can be omitted, nothing trivial should be included. Most experts would agree that it is easier to write a book than an encyclopaedia article. They would also consider it simpler to write an article for a periodical, because encyclopaedia writing is teamwork in which each article is edited in relation to others closely connected by subject. If a writer makes a statement that is partly qualified or totally contradicted in another article, the contributions of both writers must be scrutinized by the editorial staff, whose job it is to effect some kind of eventual agreement. Truth can be viewed from many standpoints, and references to any controversy may produce problems demanding all the skill and tact of the editors to resolve, particularly when the reputation of the writer is at stake in a signed article.

Revision and updating. The revision and updating of an encyclopaedia is one of the greatest challenges to its

makers, and one to which many ingenious, if admittedly partial, solutions have been found. Louis Moréri set the example in his rapid incorporation of new information in each succeeding issue of his widely used *Grand Dictionnaire historique* ("The Great Historical Dictionary"; 1674). When the German publisher Friedrich Arnold Brockhaus first issued his great encyclopaedia he was forced by an unexpectedly large public demand to issue edition after edition in quick succession (some of them even overlapped). In all of these he took great pride in providing the latest information, personally supervising much of the revision of individual articles. Moreover, he provided special supplements incorporating these revisions for purchasers of each edition, so that they did not have to buy the next in order to keep up-to-date. Modern encyclopaedias of standing use rather different systems, such as yearbooks, to achieve the same objective.

Revision of an article, at first glance, may appear to be a relatively easy task, including such processes as the insertion of death dates for recently deceased persons. A good editor realizes that this is not such a simple matter. On the death of a person of note the press takes the opportunity to reassess his contribution to society. Very often new facts come to light at that time—such as a long but concealed struggle against severe ill health—that materially affect what has been written. Similarly, a single scientific or archaeological discovery may alter to some extent all existing theories on the subject. In such cases the editor cannot achieve revision by the addition of a sentence at the end of an article; rather, he must consider partial or even complete rewriting. With the pace of modern research, this is an ever-present problem with which only a highly organized and scholarly editorial staff can adequately cope.

Conditions for complete revision

Up to about 1930 encyclopaedias achieved revision by issuing new editions every few years and by filling the gaps with supplements of yearbooks. This was a very unsatisfactory procedure that resulted in good editorial teams being largely dispersed when an edition had been issued, with the consequent difficulty of reassembling them when a new edition had been authorized. The insecurity of such a system caused the permanent loss of many very skilled personnel. A turning point came when the *Britannica* introduced the system of continuous revision that is now the practice of most major encyclopaedias in a number of countries. Continuous revision implies that each article is subject to review as new facts come to light and new developments take place. Apart from biographical and historical articles, the major revisions occur more often in scientific and technological articles than in those on the humanities. On the average, a good system of continuous revision results in the revision of about 10 percent of the text of an encyclopaedia in any one year, and probably every article will have been rewritten at least once in ten years. To do this, a permanent editorial staff is necessary. The increasing sales of encyclopaedias and growing public reliance on the accuracy of their contents has enabled publishers to assume this responsibility of continuous revision; an additional advantage has been gained in that a permanent staff gives much thought to further improvements in the course of its work.

The most apparent answer to problems of revision, the looseleaf encyclopaedia, has never proved a publishing success, in spite of the obvious advantages of being able to substitute new for outdated information. *Nelson's Perpetual Loose-Leaf Encyclopaedia* (2nd edition, 1920) was eventually discontinued, but the great *Encyclopédie française* (1935–66) has retained both the looseleaf form and the issue of revised volumes.

Controversy and bias. All major encyclopaedias throughout the ages have been accused of bias; *L'Encyclopédie* was full of such articles, and the early issues of the *Britannica* had many as well, but the views of the writers were well known, and their slanted opinions lent a colour to their words that many a modern encyclopaedia article lacks. Modern editors make every effort to eliminate any hint of bias in the writings of their contributors, but their task is difficult. For example, an account of the Korean War would vary according to whether it was written by a North or South Korean, a Chinese or an American writer.

Efforts to eliminate bias

Similarly, the inclusion of a map showing the frontiers between two or more nations may give rise to vigorous controversy if the nations involved were to dispute any part of the boundaries as shown. The illustration of a painting with an attribution to one artist may draw strong protests from art critics who do not agree with the writer. Controversy today has grown rapidly on many subjects that were not in dispute a few years ago.

Unauthorized copying. One of the problems that beset encyclopaedists is the unauthorized copying of material. Pirated editions of whole encyclopaedias were a normal feature of publishing up to the mid-19th century, but this rarely occurs nowadays, as a result of the international copyright convention, though in the 1950s unauthorized photo-offset versions of the *Britannica* were being printed in pirated editions in Taiwan. The illegal copying of individual articles in whole or in part still happens. Established encyclopaedias maintain a constant watch to avoid the inadvertent "borrowing" or plagiarizing of the contents of other encyclopaedias, and they take special care to avoid "adaptations" from foreign-language encyclopaedias. This is a very different attitude from that of the writer Temple Henry Croker, who, in his preface to *The Complete Dictionary of Arts and Sciences* (1764–66), impudently claimed: "We will venture to promise, that everything valuable in Mr. Chambers' Cyclopedia, and the other works of that Kind, particularly the Encyclopédie . . ., shall be contained in this Dictionary."

Modern encyclopaedias also take legal action in instances in which unscrupulous copying is openly undertaken. Knowledge is, of course, universal property, but its gathering and presentation in the form of an encyclopaedia is the property of its makers, in the same way that any other book is.

III. The kinds of encyclopaedias

GENERAL ENCYCLOPAEDIAS

Within the last 2,000 years, it is possible to perceive a pattern in encyclopaedia production that closely corresponds with the changing social needs of each age. The outstanding circumstances that governed the policy and production of encyclopaedias for the first 15 centuries were that comparatively few people were able to read and, stemming partly from this and partly from the cost of materials and workmanship, that copies of any lengthy work were very expensive. Only when printing was introduced into Europe did the cost of production drop by any large amount; this development in turn helped to stimulate the growth of readership. A notable feature at the time of the early printing press was the sudden growth in the popularity of some of the older encyclopaedias as a result of the tendency to ensure a ready market by printing works of which many manuscript copies were in circulation.

Influence of printing

During the first 16 centuries of their publication the great majority of encyclopaedias comprised great anthologies of the most significant writings on as many subjects as possible. These excerpts were arranged in an order that was constantly varying according to the individual compiler's concept of the hierarchies of human knowledge; some of these classification systems were more suitable than others, but none was completely successful in meeting the tastes of the reading public because there was no general agreement on the essential order of ideas. Although the compiler exercised considerable latitude in his choice of items to include in his encyclopaedia, he often restricted comment to a minimum, so that the reader was free to form his own opinion of what was offered. On the other hand, the informed guidance that the modern established encyclopaedia can offer was, in this way, less available to the reader. In addition, because the compiler selected his material from what had already been written, the gaze of the reader was being turned to the past, and, although he could enjoy the heritage of the preceding cultures, he was not being put in

touch with as much of the contemporary world as he might have desired.

Around the 10th or 11th century, a new type of encyclopaedia began to emerge, probably stimulated by the growing number of language dictionaries that, starting well before printing was used, grew ever more numerous once they could be produced by this method. Many of the early dictionaries were little more than enlarged glossaries, but from the time of *Suidas* onward, there began to appear a type of dictionary—now called encyclopaedic—that added to the definition and etymology of a word a description of the functions of the thing or idea it named. In some dictionaries, such as those of the Estiennes, a French family of bookdealers and printers, this description might in some cases be of considerable length. Thus the compilers of the new form of encyclopaedia that emerged in the 16th and 17th centuries inevitably thought in terms of arranging their entries in alphabetical order, because the dictionaries had already familiarized the reading public with this system. It needed only the success of a single encyclopaedia, such as Moréri's *Grand Dictionnaire historique*, to prove to publishers in general that this was a formula with considerable promise.

The last half of the 18th century was an era of such upheaval in man's concept of the world that the time was ripe for further experiments in the form of the encyclopaedia. The French encyclopaedists Diderot and d'Alembert and their band of contributors broke no new ground in the physical format and arrangement of the encyclopaedia, but their work inspired the intelligentsia of other nations to produce really good encyclopaedias of their own. It is no coincidence that both the German *Brockhaus* and the Scottish *Britannica* appeared with policies so different from all that had gone before that no publisher of any new encyclopaedia could afford to ignore their new pattern. Their formula was so good that the modern encyclopaedia is simply a vastly improved elaboration of their method of arrangement and organization. The compilers of both encyclopaedias had taken the best ideas from the anthologies and miscellanies of the early period of encyclopaedia making and from the later stage of encyclopaedic dictionaries. Realizing that the reading public would not tolerate the omission of some subjects and the unequal treatment of others, they prepared works in which at least a few lines were devoted to almost every conceivable topic, and for more important subjects a full account was provided, written by an expert, if possible.

Formulas of *Brockhaus* and *Britannica*

The three periods of the history of encyclopaedias—(1) to 1600, (2) 1601–1799, and (3) 1800 onward—are very unequal. They are, moreover, to a certain extent misleading, for the different forms of the encyclopaedia overlapped at each turning point for some years, and today there are still some important survivals from the two earlier periods. One can study and compare what each of the three main types of encyclopaedia has had to offer by opening the *Encyclopédie française*, *Webster's Third New International Dictionary*, and the *Encyclopædia Britannica* at the places in which each describes the same subject. The *Encyclopédie française* will provide one or more well-written treatises on the subject by writers of note. This is exactly what the encyclopaedias of the earliest period offered; and in both the old and the contemporary encyclopaedia the reader is left free to form his own opinion after reading what the experts have to say. *Webster's*, a one-volume work, of course provides much less, but it also gives much more, because it adds definitions and, often, explanatory drawings or diagrams to an admirably concise text that tells the reader much in a very few lines. This is exactly what the encyclopaedic dictionaries of Louis Moréri, Antoine Furetière, and others were offering in the 17th and 18th centuries. The *Britannica*'s contribution is distinct from those of the other two in that it provides a synthesis of what is known on the subject to date, and attempts to assess its current position. The comparison of these three examples gives only an approximate idea of the nature of the encyclopaedia in each of its three main stages, but it also helps to remind the reader of today that ideas concerning the form of an encyclopaedia have changed greatly throughout the centuries.

The encyclopaedias of the period before 1600 apparently were designed for a small group of people, who had much the same educational background as well as similar interests and opportunities to pursue them. In general, they had a common outlook on both religious and secular matters. Moreover, although they were citizens of many different countries, they were united by their knowledge and use of Latin, the international language.

Background of readers before 1600

The Eastern Roman emperor Constantine VII Porphyrogenitus (905–959) tried to plant firmly in the hearts of the most worthy of his contemporaries both knowledge and experience of the past. His were troubled times, and he felt justified in using much of his enforced leisure (he came to the throne in 911 but was not allowed to rule until 945) to provide for the administrators and emissaries of his court the most useful extracts from the writings of a very catholic selection of authors, including the patriarch of Constantinople John of Antioch (Johannes Scholasticus), the Roman historian Appian, the Greek historian Polybius, the Greek philosopher Socrates, the 5th-century Byzantine historian Zosimus, and many others. One of the unexpected by-products of this industry was the preservation of a large number of writings, a service that some of the other medieval encyclopaedias also performed.

An advantage of the encyclopaedists of the first period (*i.e.*, before 1600) was that each of them either knew or could visualize his reading public, a point that encouraged a minimum of commentary and moralizing. In a way, they were performing the duties of a personal librarian in that they drew their readers' attention to innumerable passages that they believed might be useful to them in their work or their private lives. The possibility of achieving even more was fully appreciated: the English scholar Alexander Neckham, in his early-13th-century *De naturis rerum* ("On the Natures of Things") hoped that by the imparting of knowledge he might help to lift or lighten man's spirit, and to this end he tried to maintain a simple and admirably clear text. Neckham's near-contemporary Bartholomaeus Anglicus similarly set himself in his *De proprietatibus rerum* ("On the Characteristics of Things") to bring to his readers' attention the nature and properties of the things and ideas on which the early Christian Fathers and the philosophers had expatiated, but he forbore to comment on their writings, leaving his readers to form their own judgments. The anonymous compiler of the *Compendium philosophiae* ("Compendium of Philosophy"; *c.* 1316) believed the knowledge of truth to be the supreme and final perfection of mankind; thus he never moralized on the contents of his encyclopaedia, its cumulative effect thereby being the more impressive.

Within the early period of the history of encyclopaedias a number of stages can be distinguished that make each group of works of great importance in any study of the development of scholarship and the spread of learning throughout the West. Encyclopaedias of classical times reached their culmination in Pliny's *Historia naturalis*, which was issued in the time of the Roman emperor Titus (AD 39–81). Not one of the encyclopaedias of Pliny or his predecessors paid much attention to religion; if it was discussed the approach was antiquarian, the gods of the different nations ruled by Rome being named and described in a dispassionate spirit that reflected both the tolerance and the noninvolvement of the Romans in these matters. The emphasis instead was on government, geography, zoology, medicine, history, and practical matters. The theories of the various philosophers were outlined impartially, no indication being given of any personal preference. This objective approach adopted by the Romans in their encyclopaedias was not achieved again until the 19th century.

Encyclopaedias of classical times

By the time of the Roman philosopher Boethius and the statesman Cassiodorus (*i.e.*, the 5th and 6th centuries AD), the position concerning objectivity had changed. Like Pliny and the Roman statesman Cato, Cassiodorus

had been an administrator, but while his predecessors had been engaged in interpreting and epitomizing the knowledge of the ancient world for the benefit of their own people, Cassiodorus realized the necessity for providing a new interpretation of this knowledge for the Goths, the new masters of Italy. In the next 700 years the impact of Christianity brought a new phase in Western encyclopaedia making, just as the impact of Islām is clearly visible in the Arabic encyclopaedias of the same period. Although religion is not always given pride of place in the encyclopaedias of those times, it pervades the whole of their contents. Thus Cassiodorus' division of his encyclopaedia into two main sections—divine and human—is made even more interesting by his inclusion of cosmography, the liberal arts, and medicine in the first section. Although the compilers of the encyclopaedias of this period could envisage in theory a perfectly logical arrangement for their encyclopaedias by starting with the creation and working downward to the smallest and least significant of God's creations, in practice they found this very difficult to apply, and the result was often only superficially scientific. Moreover, the inclusion of such topics as astrology and magic was surprisingly prevalent and only began to disappear after the publication of *Liber floridus* ("The Flowering Book"; *c.* 1120), by Lambert, a canon of Saint-Omer, a work that discarded practical matters in favour of metaphysical discussion.

Use of the vernacular

The third stage in the development of encyclopaedias came with the introduction of vernacular editions, such as the *Mappemonde* and *Li livres dou trésor*, and the reflection of the impact of Greek philosophical works (in translation) in the middle of the 13th century. In this era there was an increasing number of lay encyclopaedists—*e.g.*, Latini, Bandini, de la Torre—and the subject coverage changed to give more space and importance to the practical matters that interested the rising mercantile class. At the same time, theology no longer dominated the classification schemes. Humanism reached its full expression in the Spanish philosopher Juan Luis Vives' *De disciplinis* (1531), in which all the compiler's arguments were grounded on nature and made no appeal to religious authority. The printing press had eliminated one of the most vexatious problems: the introduction or perpetuation of textual errors by the manuscript copyists. At the same time, the wider circulation of encyclopaedias through the unrestricted sales of printed copies brought about a situation in which the compilers could no longer envisage their reading public and accordingly adjusted their approach to their largely unknown audience.

ENCYCLOPAEDIC DICTIONARIES

The period spanning the 17th and 18th centuries is characterized by the flourishing of the encyclopaedic dictionaries that were pioneered by the Estienne family in France in the 16th century. During these two centuries this form of encyclopaedia adopted two different policies. On the one hand there was the encyclopaedia, such as those of the Germans Johann Theodor Jablonski and Johann Heinrich Zedler, that paid particular attention to the fields of history and biography. On the other, there was a new form of encyclopaedia—if the exception of the 12th-century *De diversis artibus* be set aside—that devoted itself to the arts and sciences. The first type can therefore be said to be retrospective in approach, while the arts and sciences encyclopaedia was clearly identifiable with contemporary matters.

None of these divisions is actually clear-cut, for many traditional encyclopaedias continued to be compiled throughout the period, and not all the historical-biographical encyclopaedias ignored the arts and sciences or contemporary people and events. Nevertheless, the issue of Antoine Furetière's encyclopaedia and the immediate follow-up by *Le Dictionnaire des arts et des sciences* (1694) by the writer Thomas Corneille (the younger brother of the playwright Pierre Corneille) were sufficient to indicate the growing public interest in a more modern form of encyclopaedia. This indication was confirmed by the successful publication of John Harris' *Lexicon Technicum* (1704), which the author described as "an universal English dictionary of arts and sciences: explaining not only the terms of art, but the arts themselves." It is significant that Harris omitted such subjects as theology, biography, and geography. The Englishman Ephraim Chambers went even further in describing his internationally influential *Cyclopaedia* (1728) as

> an universal dictionary of arts and sciences; containing an explication of the terms, and an account of the things signified thereby, in the several arts, both liberal and mechanical, and the several sciences, human and divine, compiled from the best authors.

Ideal contents as viewed in the 18th century

No century has seen more public discussion of the nature of the encyclopaedia than the 18th; at the same time, there was much uncertainty concerning its ideal contents. The fine Italian encyclopaedia of Gianfrancesco Pivati (the secretary of the Academy of Sciences at Venice), the *Nuovo dizionario scientifico e curioso, sacro-profano* ("New Scientific and Curious, Sacred-Profane Dictionary"; 1746–51), avoided the subject of history, whereas the German writer Philipp Balthasar Sinold von Schütz's *Reales Staats- und Zeitungs-Lexicon* ("Lexicon of Government and News"; 1704) concentrated on geography, theology, politics, and contemporary history and had to be supplemented by the German economist Paul Jacob Marperger's *Curieuses Natur-, Kunst-, Berg-, Gewerk- und Handlungslexikon* (1712), which covered the sciences, art, and commerce.

The introduction of the arts and sciences type of encyclopaedia inevitably hastened the use of specialist contributors, for it widened the total subject field considerably. "Hübner" (as Sinold von Schütz's encyclopaedia was known from the writer of the preface) employed many contributors, and it is known from the draft prospectus of the British writer Oliver Goldsmith that an encyclopaedia he projected was to have included comprehensive specialist articles by the lexicographer Samuel Johnson, the statesman Edmund Burke, the portrait painter Sir Joshua Reynolds, the historian Edward Gibbon, the economist Adam Smith, and others. The remarkable progress made in this period can easily be judged when one compares the encyclopaedia *Lucubrationes* (1541), in which the author, Joachim Sterck van Ringelbergh, found it necessary to include a "miscellaneous" section (which he amusingly dubbed "Chaos"), with the approach of Johann Georg Krünitz, a German physician and philosopher, in his highly organized, modern *Oekonomisch-technologische Encyklopädie* ("Economic-Technological Encyclopaedia"; 1773–1858) with its 242 volumes.

THE MODERN ENCYCLOPAEDIA

The period of the encyclopaedic dictionary was brilliant, but it gradually became apparent that, in abandoning the systematic encyclopaedia of the earlier period in favour of the quick reference dictionary form, quite as much had been lost as had been gained. The comparatively brief entries in the encyclopaedic dictionary had, by accident of the alphabet, fragmented knowledge to such an extent that users received only a disjointed knowledge of the things in which they were interested. Nor had the willful and extremely individualistic effort of the French encyclopaedists Diderot and d'Alembert done more than confuse the issue, for they had bent the principles of encyclopaedia making to their own purposes. It is therefore remarkable that the initial solution to the problem should have been found by Andrew Bell (1726–1809), Colin Macfarquhar (*c.* 1745–93), and William Smellie (1740–95), three Scotsmen who were responsible for the first edition (1768–71) of *Encyclopædia Britannica*. Aware of the shortcomings of *L'Encyclopédie*, they devised a new plan. Their encyclopaedia was to include about 45 principal subjects (distinguished by titles printed across the whole page), supported by another 30 lengthy articles, the whole being contained within one alphabetical sequence interspersed with numerous brief entries enhanced by references, where appropriate, to the principal subjects. Some of the princi-

Plan of the first *Encyclopaedia Britannica*

pal articles, notably those on medical subjects, extended to well over 100 pages each. The three collaborators had thus incorporated the comprehensive treatment of important subjects accorded by the earliest form of encyclopaedias and had supplemented this with the attraction of the brief informative notices of minor topics that had been the chief feature of the encyclopaedic dictionary. The key to their success was, however, their retention of the single alphabetical sequence.

Meanwhile, Renatus Gotthelf Löbel was planning to compile an encyclopaedia that could supersede "Hübner." It was Sinold von Schütz who, in the 4th edition of "Hübner," had introduced the word *Conversations-Lexikon* into the title, and it was Löbel who decided to give it pride of place in his new encyclopaedia. The *Konversationslexikon* was designed to provide the rapidly growing German bourgeoisie with the background knowledge considered essential for entry into the polite society of the day. When Brockhaus took over Löbel's bankrupt and incomplete encyclopaedia, he saw the value and appeal of this evocative word and retained it (in various spellings) for many years afterward. Löbel's and Brockhaus' solution to the problem of the form of the modern encyclopaedia was not the same as the *Britannica*'s; it is interesting to note that whereas the *Britannica* model has widely prevailed throughout the English-speaking world, *Brockhaus* has been the model for most of the encyclopaedias prepared in countries in which English is not widely spoken.

Format of the *Konversationslexikon*

Brockhaus, throughout its existence, has faithfully followed a system in which the whole of knowledge has been analyzed into very specific topics. These topics are arranged alphabetically and, under each heading, condensed entries convey the essential information. By ingenious cross-references, entries are linked with other entries under which further information can be found, thus avoiding the inclusion of an index. There is no difficulty in distinguishing encyclopaedias of the *Konversationslexikon* form from encyclopaedic dictionaries. The former are usually of considerable size (*Der grosse Brockhaus*, 1928–35, included 200,000 articles by over 1,000 authors) and possess elaborate cross-reference schemes. Moreover, whenever a really important subject occurs, considerable space is allowed, though the same principle of concentrated text is followed. The *Ready Reference and Index* of this encyclopaedia reflects elements of the *Brockhaus* model but departs from it by offering indexing to longer articles of the circle of learning.

Although the *Britannica* and *Brockhaus* examples eventually became the models for 19th- and 20th-century encyclopaedias, there have been many survivals from the previous periods. Ersch and Gruber's enormous *Allgemeine Encyclopädie* ("General Encyclopaedia"; 1818–89) has been cited as a true example of the medieval "summa"—it is famed for including the longest article in any encyclopaedia, that on Greece, which fills 3,668 pages in volumes 80–87. The *Encyclopédie française* is an even later example of this form and, as Samuel Taylor Coleridge planned it, the *Encyclopaedia Metropolitana* could have proved the supreme example of this type of treatment. The encyclopaedic dictionary has never died; at the very time when *Brockhaus* and the *Britannica* were building their markets, Noah Webster was developing his dictionary's reputation for reliability into a household expression in the U.S.

ENCYCLOPAEDIAS FOR SPECIAL INTERESTS

Most encyclopaedias have been compiled from a purely scholarly point of view and have had no particular ax to grind, though nearly all have been inhibited to a certain extent by the interests and policies of the milieu in which they made their appearance. There are, however, several encyclopaedias that have deliberately been planned for a special purpose. One that is unique and continues to be of the greatest value to historians is the work of the 16th-century Spanish Franciscan Fray Bernardino de Sahagún, who spent much of his life in missionary work in Mexico. Sahagún was ordered to write in Nahuatl the information needed by his colleagues for the conversion of the Indians. The result, the *Historia general de las cosas de Nueva España* ("General History of the Matters of New Spain") is a magnificent record of the Aztec culture as recounted by the Indians of south central Mexico. The arrangement of this work, written in pictorial language as well as in Spanish, follows the familiar medieval pattern and resembles most closely that of Bartholomaeus Anglicus (Sahagún may have been familiar with a recent translation of Bartholomaeus' encyclopaedia). *Historia* is one of the most remarkable encyclopaedias ever compiled, and it has also a special importance for students of language.

Many of both the Arabic and Chinese classical encyclopaedias were compiled with the object of helping civil-service candidates in their studies and of providing administrators with the cultural background needed for their work. Their interest to historians of the two cultures can well be understood, for their arrangement and contents throw useful light on the concepts of administration and justice (to name only two aspects) in the Chinese and Islāmic worlds during the 7th to 15th centuries.

Older Arabic and Chinese encyclopaedias

Of the Western medieval encyclopaedias, the most interesting in this respect is the *De naturis rerum* (*c.* 1228–44) of the Dominican friar Thomas de Cantimpré. His aim was that of St. Augustine: to unite in a single volume the whole of human knowledge concerning the nature of things, particularly the nature of animals, with a view toward utilizing it as an introduction to theology. To achieve this he devoted the first part of his work to mankind, zoology, botany, and geology. He then compiled a much smaller section on cosmology. An additional section on astronomy followed later. Although it was a comparatively unorganized and ill-balanced work, the popular nature of this encyclopaedia, with its stories of magic and allegorical creatures, ensured its widespread success over two centuries.

Religion and politics were the main motives for writing encyclopaedias with a special purpose. Louis Moréri made no secret of his intention to produce an encyclopaedia that would defend the teaching and policies of the Roman Catholic Church. Antoine Furetière and Pierre Bayle, on the other hand, represented the philosophers, and their anticlerical bias was more in tune with the skeptical minds of the age. Nevertheless, there was still a strong orthodox following in France, as the long-continuing demand for the *Dictionnaire universel* of the Jesuit fathers of Trévoux demonstrated, and this encyclopaedia was as firmly in defense of Catholicism as *L'Encyclopédie* was critical of it.

Diderot and d'Alembert's encyclopaedia had originally been intended by its publisher to be no more than an adaptation of Ephraim Chambers' *Cyclopaedia*. The outcome was a giant reference work that criticized the government, satirized the Calvinist clergy of Geneva, championed the Age of Reason, and supported an atheistic materialism. To the more rigid members of the French Establishment, the encyclopaedia was a monster. But the more worldly had no objection to a work whose succeeding volumes were each an audacious source of scandal.

Even Pierre-Athanase Larousse, the French encyclopaedist, was not impartial. His finest encyclopaedia, the *Grand Dictionnaire universel du XIX^e^ siècle* ("Great Universal Dictionary of the 19th Century"; 1865–90), one of the most influential of the century, was deliberately anticlerical in policy. And Herder, in the heart of Catholic Germany, produced a counterweight to the Protestant *Brockhaus* in his *Konversations-Lexikon* (1853–57), which adopted a distinctive Catholic viewpoint. This excellent encyclopaedia was early recognized for its general impartiality, scholarship, and accuracy. In the long run, both "Herder" and *Brockhaus* gradually eliminated their sectarian inclinations, and the current editions are both of high standard.

Objectivity in encyclopaedias

CHILDREN'S ENCYCLOPAEDIAS

Before the 19th century, only Johann Wagenseil (1633–1705) produced an encyclopaedia for children—the *Pera*

Librorum Juvenilium ("Collection of Juvenile Books"; 1695). Larousse issued an interesting *Petite Encyclopédie du jeune âge* ("Small Children's Encyclopaedia") in 1853, but the next, *Encyclopédie Larousse des enfants* ("Larousse Encyclopaedia for Children"), did not appear until 1957. The first of the modern children's encyclopaedias was, however, a long-standing favourite. Prepared by the English writer and editor Arthur Mee (1875–1943), it was called *The Children's Encyclopaedia* (1910) in Great Britain and *The Book of Knowledge* (1912) in the U.S. The contents comprised a series of vividly written and profusely illustrated articles; because the system of article arrangement was obscure, much of the success of the work as a reference tool resulted from its splendidly contrived index, which even now remains a model of its kind. Arthur Mee later produced a completely pictorial encyclopaedia, *I See All* (1928–30), that comprised thousands of small illustrations, each accompanied by only a few words of text. Librarians still treasure it for its reference value, even if it is no longer used by children. In 1917–18 a completely new children's encyclopaedia was published, *The World Book Encyclopedia*, which the title page described as "organized knowledge in story and picture." A success from the start, it issued enlarged editions in quick succession. In 1925 a volume devoted to reading courses and study units was added, but the index was abandoned in favour of innumerable cross-references in the text. Annual supplements were also provided from 1922 onward. In 1961 a Braille edition in 145 volumes was issued; most of the illustrations were eliminated in this, but many of the diagrams and graphs were retained and in many cases the captions for the pictures were incorporated in the text. In 1964 a separate 30-volume set in a special large type was published for the use of the partially blind.

World War I put a halt to the idea of issuing a *Britannica Junior*, and the first edition was not published until 1934. It was based on *Weedon's Modern Encyclopedia*, whose copyright had been bought by Britannica. Renamed *Britannica Junior Encyclopædia* in 1963, it was specifically designed for children under 12. One of its features is its ready-reference index volume, which combines short fact entries with indexing to longer general articles. In 1960 a British *Children's Britannica* was issued, and was subsequently supplemented by yearbooks.

Compton's Encyclopedia

In 1894 Frank E. Compton sold a U.S. school encyclopaedia, the *Students Cyclopedia*, from door to door to pay his way through college. This later became the *New Students Reference Work*, which Compton finally bought. While continuing to publish this, Compton designed a completely new and, for those times, revolutionary work, which first appeared in 1922 as *Compton's Pictured Encyclopedia*. In due course, the system of continuous revision was introduced, close cooperation with educational and library advisers was fostered, and contributions from well-known authors were encouraged. In 1971 *Compton's*, by then published by Encyclopædia Britannica, Inc., introduced a new type of encyclopaedia for younger children just beginning to read, called *Compton's Young Children's Precyclopedia*, with 16 volumes, in which all the illustrations are coloured and supported by a brief but informative text.

Unlike *World Book*, *Compton's*, and the *Britannica Junior Encyclopædia*, the *Oxford Junior Encyclopaedia* (intended for children of 11 upward) is systematically arranged. Each of the 12 text volumes is devoted to a broad subject field: mankind, natural history, the universe, communications, great lives, farming and fisheries, industry and commerce, engineering, recreations, law and order, the home, and the arts. The 13th volume is an index, which includes a special section of ready-reference material. The contents of each volume are arranged alphabetically (with cross-references), and there are many illustrations.

SPECIALIZED ENCYCLOPAEDIAS

The alternative title of the 12th-century *Speculum universale* ("Universal Mirror") of a French preacher, Raoul Ardent (a follower of Gilbert de La Porrée, a French theologian), was the *Summa de vitiis et virtutibus* ("Summa [Exposition] of Faults and Virtues"). The title gives the clue of Raoul's intent, which was to provide a modern authoritative account of the Christian attitude to the world. His plan was different from that of other encyclopaedists, for he limited his work to the discussion (in this order) of theology, Christ and the redemption, the practical and ascetic life, thought, prayer, ethics, the four cardinal virtues, human conduct, and the four senses. This work could, in fact, be termed the first of the specialized encyclopaedias.

Apart from isolated examples such as this, and the technical encyclopaedia of Roger of Helmarshausen, the specialized encyclopaedia did not really make an appearance until the 18th century. The stimulus was probably provided by the increasing number of encyclopaedias that included the arts and sciences to such a point that some of them included little else. In any classified encyclopaedia the individual classes do, of course, constitute a kind of specialized encyclopaedia, but such a work falls far short of the real thing in that it is not sufficiently self-contained to stand on its own. It was inevitable, as the boundaries of knowledge contained in encyclopaedias grew greater, that there would be at least some attempts to produce specialized works of this kind; the French publishers Panckoucke and Agasse did something of this nature in their rearrangement of the contents of Diderot's *Encyclopédie* as a series of 196 volumes of separate dictionaries covering 41 subjects. The idea might have taken hold had it not been for insuperable difficulties caused by the French Revolution.

First specialized encyclopaedia on biography

The first real effort toward a specialized encyclopaedia had come some years earlier, and the subject field that it treated was biography. The *Allgemeines Gelehrten-Lexicon* ("General Scholarly Lexicon"; 1750–51) was compiled by Christian Gottlieb Jöcher, a German biographer, and issued by Gleditsch, the publisher of both "Hübner" and Marperger and the opponent of Zedler's encyclopaedia. Jöcher's work was continued by the German philologist Johann Cristoph Adelung and others and is still of value today. The field of international biography is not a simple one to tackle, and there were only two further efforts of note: J.C.F. Hoefer (1811–78) compiled the *Nouvelle Biographie générale* ("New General Biography"; 1852–66) and J.F. Michaud (1767–1839) was responsible for the *Biographie universelle*. These two great works were to a certain extent competitive; this helped to improve their coverage and content; they are still heavily used in all research libraries. After their publication, the task of recording biographical information on a universal scale reverted to the general encyclopaedias.

Developments in the field of specialized encyclopaedias correspond closely to other developments in the world of scholarship. It is, for example, no accident that so much attention should be paid to the subject of chemistry at a time when L.F.F. von Crell was issuing his series of abstract journals on chemistry. The English scientist and inventor William Nicholson (1753–1815) was first in the field with his *Dictionary of Chemistry* (1795), published by Sir Richard Phillips (who later issued C.T. Watkin's *Portable Cyclopaedia*). On this was based Andrew Ure's *Dictionary of Chemistry*, which was for a long time the standard reference work on the subject in Great Britain. In 1807 the German chemist Martin Heinrich Klaproth issued his *Chemisches Wörterbuch* ("Chemical Dictionary"), but a more important event was the publication of the *Handbuch der theoretischen Chemie* ("Handbook of Theoretical Chemistry"; 1817–19) by the German scientist Leopold Gmelin, a work of such excellence that it still appears in new editions from the Gmelin-Institut. Heinrich Rose, a German chemist, issued his *Ausführliches Handbuch der analytischen Chemie* ("Complete Handbook of Analytic Chemistry") in 1851, and the first edition of the famous Liebig, Poggendorff, and Wöhler's *Handwörterbuch der reinen und angewandten Chemie* ("Handbook of Pure and Applied Chemistry") was issued in 1837; its second edition (1856–65) was expanded to nine volumes. This work was continued by Hermann Fehling's *Neues Handwörterbuch der Chemie* ("New

Pocket Dictionary of Chemistry"; 1871–1930). The French counterpart, C.A. Wurtz's *Dictionnaire de chimie pure et appliquée* ("Dictionary of Pure and Applied Chemistry"; 1869–1908), became the standard work of its day. The Russian-born chemist Friedrich Konrad Beilstein first issued his *Handbuch der organischen Chemie* ("Handbook of Organic Chemistry") in Hamburg, Germany, in 1880–83; it is the most extensive work of its kind today. The French chemist Edmond Frémy's *Encyclopédie chimique* ("Chemical Encyclopaedia") appeared in 1882–99, and *A Dictionary of Applied Chemistry*, edited by Sir Thomas Edward Thorpe, the English chemist, was first issued in 1890–93. Twentieth-century standard works include Fritz Ullmann's *Enzyklopädie der technischen Chemie* ("Encyclopaedia of Applied Chemistry"; 1914–23), Victor Grignard's *Traité de chimie organique* ("Treatise on Organic Chemistry"; 1935), *Elsevier's Encyclopaedia of Organic Chemistry* (1940), the *Encyclopedia of Chemical Technology* (1947–56)—known by the names of its principal editors as "Kirk-Othmer"—Waldemar Koglin's *Kurzes Handbuch der Chemie* ("Short Handbook of Chemistry"; 1951), and the indispensable *Handbook of Chemistry and Physics*.

Specialized encyclopaedias of chemistry

The impressive run of encyclopaedias and handbooks of chemistry over so long a period is paralleled only in the field of music, in which the *Musikalisches Lexikon* ("Musical Lexicon"; 1732) of the German composer and music lexicographer Johann Gottfried Walther began the trend and was supplemented by the very successful *Historisch-biographisches Lexicon der Tonkünstler* ("Historical and Biographical Lexicon of Musicians"; 1790–92) of the German organist and music historian Ernst Ludwig Gerber. The *Biographie universelle des musiciens et bibliographie générale de la musique* ("Universal Biography of Musicians and General Bibliography of Music"; 1835–44) was compiled by the director of the Brussels Conservatoire, the Belgian composer François-Joseph Fétis, almost coinciding with the equally voluminous *Encyklopädie der gesammten musikalischen Wissenschaften* ("Encyclopaedia of Collected Musical Knowledge") of Gustav Schilling, a German lexicographer and historian of music. A pupil of Mendelssohn, Hermann Mendel, founded the *Musikalisches Conversations-Lexikon* (1870), which was completed by August Reissmann, who also edited the musicologist and composer Auguste Gathy's *Musikalisches Conversationslexikon* (1871). The great *Encyclopédie de la musique et dictionnaire du Conservatoire* (1913–31) was begun by the French writer on music Albert Lavignac and continued by Lionel de La Laurencie, but the third part, a dictionary of names and subjects covered in the preceding parts, was never issued. Walter Willson Cobbett compiled the *Cyclopedic Survey of Chamber Music* (1929–30), and the English writer on music Sir George Grove first issued his *Dictionary of Music and Musicians* in 1879–89. The German music historian Hugo Riemann compiled his standard *Musik-lexikon* in 1882, and the comprehensive *Musik in Geschichte und Gegenwart* ("Music of the Past and Present") began publication in 1949.

The publication of the German philosopher G.W.F. Hegel's *Encyklopädie der philosophischen Wissenschaften* ("Encyclopaedia of Philosophical Knowledge"; 1817) was of more than subject importance in that it was a compendium of the author's philosophical system in three parts; Logic, Nature, Mind. It influenced many editors of general encyclopaedias during the rest of the century. The standard work in this field has for many years been the *Dictionary of Philosophy and Psychology* edited by the American psychologist James Mark Baldwin, though the publication of *The Encyclopedia of Philosophy* (1967) provided a substantial work more in line with modern tastes. Other works in this area include the Centro di Studi Filosofici di Gallarate's *Enciclopedia filosofica* (1957), the French philosopher André Lalande's *Vocabulaire technique et critique de la philosophie* ("Technical and Critical Vocabulary of Philosophy", first issued 1902–12), and the Austrian writer Rudolph Eisler's *Wörterbuch der philosophischen Begriffe* ("Dictionary of Philosophical Concepts").

Encyclopaedias of philosophy

The Architectural Publication Society began issuing its *Dictionary of Architecture* as early as 1852, but it took 40 years to complete. A more modern work is *Wasmuths Lexikon der Baukunst* ("Wasmuth's Lexicon of Architecture"; 1929–37). Further material is included in the *Encyclopedia of World Art* (1959–68), the *Reallexikon für Antike und Christentum* ("Encyclopaedia for Antiquity and Christianity"; 1950–), and the *Enciclopedia dell'arte antica, classica e orientale* ("Encyclopaedia of Ancient, Classical, and Oriental Art"; 1958–66).

The words "Pauly-Wissowa" are very familiar to a great number of people. August von Pauly (1796–1845), the German classical philologist, began issuing his *Real-Encyclopädie der classischen Altertumswissenschaft* ("Encyclopaedia of Classical Antiquities") in 1839. The new edition was begun by another German classical philologist, George Wissowa, in 1893. This enormous work on classical studies has no equal in any part of the world, though it can be supplemented in some areas by the encyclopaedic series *Handbuch der Altertumswissenschaft* ("Handbook of Antiquities") begun in 1887.

The Swiss theologian J.J. Herzog (1805–82) gave religion its first great encyclopaedia with his *Real-Encyklopädie für protestantische Theologie und Kirche* ("Encyclopaedia of the Protestant Church and Theology"; 1854–68). Philip Schaff (1819–93), a Swiss-born U.S. church historian, prepared the abridged English edition (1882–84) from which *The New Schaff-Herzog Encyclopedia of Religious Knowledge* stems. James Hastings, a Scottish clergyman, was responsible for no fewer than four encyclopaedic works in this field: *A Dictionary of the Bible* (1898–1904); *A Dictionary of Christ and the Gospels* (1906–08); *Encyclopaedia of Religion and Ethics* (1908–26), still of great importance; and *Dictionary of the Apostolic Church* (1915–18). An even more significant series is the *Encyclopédie des sciences ecclésiastiques* ("Encyclopaedia of the Ecclesiastical Sciences"), which will take many decades to complete. It comprises: *Dictionnaire de la Bible* (1907–); *Dictionnaire de théologie catholique* (1909–); *Dictionnaire d'archéologie chrétienne et de liturgie* (1928–53); *Dictionnaire d'histoire et de géographie ecclésiastiques* (1929–); and *Dictionnaire de droit canonique* ("Dictionary of Canon Law"; 1935–). Other important works are *The Catholic Encyclopedia* (1907–18), which has not been completely superseded by the *New Catholic Encyclopedia* (1967); the finely illustrated *Enciclopedia cattolica* (1948–54); *Die Religion in Geschichte und Gegenwart* ("Religion in the Past and Present"; 1909–13); and the *Lexikon für Theologie und Kirche* ("Lexicon of Theology and the Church"; 1930–38). Two recently published encyclopaedias of religion include *The Encyclopaedia of Islam* (1960–) and the *Encyclopaedia Judaica* (1971–72).

It was not until the 1860s that three of the most useful handbooks now in daily use began to appear. *The Statesman's Year-Book*, important for its statistical and political information, began publication in 1864. In 1868 the English publisher Joseph Whitaker first issued his *Whitaker's Almanack*, and the *World Almanack* started in the same year. The *Chicago Daily News Almanac* appeared from 1885 to 1946, and the *Information Please Almanac* began in 1947. Herder's *Staatslexikon* ("Lexicon of Political Science") was first published in 1889–97; this compendium was soon followed by the *Dictionary of Political Economy* (1894) by the English banker and economist Sir Robert Palgrave. In 1930–35 the *Encyclopaedia of the Social Sciences* was published; an immediate success, it is often referred to as "Seligman" after the name of its chief editor. The new *International Encyclopedia of the Social Sciences* (1968) did not supersede it in every respect. In a similar fashion, the *Handwörterbuch der Sozialwissenschaften* ("Pocket Dictionary of the Social Sciences"; 1952–) supplemented rather than superseded the standard *Handwörterbuch der Staatswissenschaften* ("Pocket Dictionary of Political Science," 4th ed.; 1923–39).

Almanacs and handbooks of social and political science

In the field of literature, if Isaac Disraeli's *Curiosities of Literature* (1791) is ruled out, the first important handbook is the *Dictionary of Phrase and Fable* (1870) by the

English clergyman and schoolmaster Ebenezer Cobham Brewer (1810–97), supplemented with Brewer's *Reader's Handbook* (1879). Other important works include the *Dizionario letterario Bompiani degli autori* ("Bompiani's Literary Dictionary of Authors"; 1956–57), the *Dizionario letterario Bompiani delle opere* ("Bompiani's Literary Dictionary of Works"; 1947–50), *Cassell's Encyclopaedia of Literature* (1953), and the Oxford "companions" to American, English, and French literature. In the last quarter of the 19th century, three major specialized encyclopaedias were issued: *Dictionnaire de botanique* ("Dictionary of Botany"; 1876–92) of the French naturalist and physician Henri Baillon, the *Lexikon der gesamten Technik* ("Lexicon of Collected Technology"; 1894–99) of the German engineer Otto Lueger, and the Berlin Academy's *Enzyklopädie der mathematische Wissenschaften* ("Encyclopaedia of Mathematical Sciences"; 1898–1935). The last was shortly followed by the important but incomplete *Encyclopédie des sciences mathématiques pures et appliquées* ("Encyclopaedia of Theoretical and Applied Mathematical Sciences"; 1904–14).

Physics never received the degree of attention that the encyclopaedists accorded to chemistry and chemical engineering. The standard *Dictionary of Applied Physics* of the English physicist Sir Richard Glazebrook was first issued 1922–23. The *Handbuch der Physik* ("Handbook of Physics") was also issued during those years; the second edition (1955) is often referred to by the name of its editor, Siegfried Flügge. The most recent work is the *Encyclopaedic Dictionary of Physics* (1961–64), edited by James Thewlis.

In medicine the pioneer *British Encyclopaedia of Medical Practice* (1936–39) has been followed by *The Encyclopaedia of General Practice* (1963).

Other important encyclopaedias and handbooks issued in recent years include *The Encyclopedia of Photography* (1949), the superbly illustrated and well-documented *Enciclopedia dello spettacolo* ("Encyclopaedia of the Stage"; 1954–62), which includes all forms of staged entertainment; the *Dictionnaire du cinéma et de la télévision* ("Dictionary of the Cinema and Television"; 1965–); the *McGraw-Hill Encyclopedia of Science and Technology* (1960), and the *Encyclopedia of Library and Information Science* (1968–).

ENCYCLOPAEDIAS OF COUNTRIES AND REGIONS

A special kind of encyclopaedia dealing with a single country or region began to appear in the late 19th century. Sometimes it is possible to distinguish by a subtle form of titling those national encyclopaedias that deal with the world scene from those that concentrate chiefly on their own country. Thus the "Ruritanian Encyclopaedia" can usually be taken to be a work produced in Ruritania that takes a world view, while the "Encyclopaedia of Ruritania" probably deals mainly with Ruritania and the surrounding areas. There are no rules in this matter, and this method of differentiating between the two kinds can only be regarded as an imprecise way of identifying the kind of encyclopaedia in the first instance.

The encyclopaedias of geography are of particular use in this field because they cover in detail many islands, small cities, and other features that are only dealt with in the briefest fashion elsewhere. Of the modern geographical encyclopaedias the following are of especial importance: *Westermanns Lexikon der Geographie* (1968–); *Meyers Kontinente und Meere* ("Meyer's Continents and Seas"; 1968–); the Russian *Kratkaya geograficheskaya entsiklopedya* ("Short Geographical Encyclopaedia"; 1960–66); and the *Länderlexikon* ("Geographical Dictionary"; 1953–60), of which a new edition began to be issued in the early 1970s. These encyclopaedias have an additional value as sources of maps and illustrations that would be difficult to find elsewhere. The main modern encyclopaedias dealing with continents, regions, and countries are:

Encyclopaedias of continents, regions, and countries

Africa: *Encyclopaedia of Southern Africa* (1961); *Deutsches Kolonial-Lexikon* (1920); *Encyclopédie coloniale et maritime* (1941–); *Grande encyclopédie de la Belgique et du Congo* (1938–52).

Australasia: *The Australian Encyclopaedia* (1958); *Encyclopaedia of Australia* (1968); *The Modern Encyclopaedia of Australia and New Zealand* (1964); *An Encyclopaedia of New Zealand* (1966).

Central and South America: *Diccionario enciclopédico de las Américas* (1947); *Verbo: enciclopédia luso-brasileira de cultura* (1963–); *Diccionario enciclopédico del Peru* (1967); *Enciclopedia Yucatanense* (1944–47); *Enciclopedia de México* (1966–); *Diccionario histórico-enciclopédico de la Republica de El Salvador* (1927–); *Diccionario geográfico, estadístico, histórico, de la isla de Cuba* (1863–66); *Gran enciclopédia argentina* (1956–64); *Encyclopedie van de Nederlandse Antillen* (1969); *Encyclopaedie van Nederlandsch West-Indië* (1914–17); *Enciclopédia larense* (1941).

Europe: *Flandria nostra* (1957–60); *Magyar életrajzi lexikon* (1967–69); *Encyclopaedia of Ireland* (1968); *Latvijas PSR mazā enciklopēdija* (1967–); *Latvju enciklopēdija* (1950–55); *Mažoji lietuviškoji tarybinė enciklopedija* (1966); *Norge* (1963); *Enciclopedia României* (1938–43); *Encyclopédie polonaise* (1916–20); *Sverige: land och folk* (1966); *Ukraine: A Concise Encyclopaedia* (1963–); *Narodna enciklopedija srpsko-hrvatsko-slovenačka* (1925–29).

Middle East: *Eretz-Yisra'el: Entziqlopedia Ṭopografit-Hisṭorit* (1946–55).

North America: *Encyclopedia Canadiana* (1957–58).

IV. History of encyclopaedias

ENCYCLOPAEDIAS IN THE WEST

Early development. The first fragments of an encyclopaedia to have survived are the work of Speusippus (died 339/338 BC), a nephew of Plato's. Speusippus conveyed his uncle's ideas in a series of writings on natural history, mathematics, philosophy, and so forth. Aristotle's wide-ranging lectures at the Lyceum were equally influential, and he and Plato appear to have been the originators of the encyclopaedia as a means of providing a comprehensive cultural background.

The Greek approach was to record the spoken word. The Romans, on the other hand, aimed to epitomize existing knowledge in readable form. Their first known effort is the *Praecepta ad filium* ("Advice to His Son"; *c.* 183 BC), a series of letters (now lost) written by the Roman consul Cato the Censor to his son. Cato's intention was to provide a summary of useful information that could help in the process of living and in guiding and helping one's fellow men. A more substantial attempt was made by the learned Latin writer Marcus Terentius Varro in his *Disciplinarum libri IX* ("Nine Books of Disciplines"), his *Rerum divinarum et humanarum antiquitates* ("The Antiquities of Things Divine and Human"), and his *Imagines*, which together covered the liberal arts, human efforts, the gods, and biographies of the Greeks and Romans.

Pliny's *Historia naturalis*

The most important Roman contribution was the *Historia naturalis* of Pliny the Elder, a vast work constituting a kind of classified anthology of information. Although undiscriminating in its record of fact and fancy, it was nevertheless very influential; the Latin grammarian and writer Gaius Julius Solinus drew nearly 90 percent of his 3rd-century *Collectanea rerum memorabilium* ("Collection of Memorabilia") from Pliny, and the *Historia naturalis* served as a major source for other encyclopaedias for at least the next 1,500 years. Even today it is still an important record for details of Roman sculpture and painting.

The statesman Cassiodorus, when he withdrew to the Vivarium in 551, dedicated this monastery to sacred and classical learning. His *Institutiones divinarum et saecularium litterarum* ("Institutes of Divine and Secular Literature") seems to have been designed to preserve knowledge in times that were largely inimical to it. In his encyclopaedia, Cassiodorus drew a clear distinction between the sacred and the profane, but the first Christian encyclopaedia to be compiled for the benefit of the newly converted Spanish population followed a different

scheme. St. Isidore (*c.* 560–636) considered the liberal arts and secular learning to be the true basis of a Christian's education. His *Etymologiae* therefore paid much attention to practical matters and even included an etymological dictionary. This was in line with the thought of St. Jerome—on whose encyclopaedic *Chronicon* and *De viris illustribus* St. Isidore had drawn—who, in common with the early Christian Fathers, was eager to provide a basis for a Christian interpretation and organization of knowledge. This concept was much later to be renewed by the Catalan ecclesiastic Ramon Llull.

The development of the encyclopaedia during the next 500 years, though of social interest, was undistinguished from the point of view of scholarship. Rabanus Maurus (*c.* 776–856), one of the English scholar Alcuin's favourite pupils, compiled *De universo* ("On the Universe"), which, in spite of its being an unintelligent plagiarism of St. Isidore's work, had a lasting popularity and influence throughout the medieval period. A series of encyclopaedias of special subjects—undistinguished anthologies of classical and Christian writings on history, jurisprudence, agriculture, medicine, veterinary surgery, and zoology—was organized by the Byzantine emperor Constantine VII Porphyrogenitus (905–959). Michael Psellus (1018–96), a tutor of a later emperor, contributed a more interesting work, *De omnifaria doctrina*, in the form of questions and answers on both the humanities and science. At this time there was a growing influence on metropolitan and secular learning. In an attempt to counterbalance it, the brief but charming *Didascalion* of Hugh of Saint-Victor (*c.* 1096–1141), which paid much attention to practical matters as well as to the liberal arts, was soundly based on a profound classification of knowledge that influenced many later encyclopaedias. About this time an encyclopaedic dictionary known as *Suidas* broke with tradition by adopting alphabetical order for its contents. This had no effect on the plan of later encyclopaedias, but its contents included so much useful information that it has retained its importance as a source throughout the succeeding centuries.

Adoption of the alphabetical order in *Suidas*

The *Liber floridus* (*c.* 1120) of Lambert of Saint-Omer is an unoriginal miscellany, but it has an interest of its own in that it discards practical matters in favour of metaphysical discussion and pays special attention to such subjects as magic and astrology. Lambert had been influenced by the Pseudo-Dionysian writings, one aspect of the contemporary revival of learning that was to reach its climax in the next century. The greatest achievement of the 12th century was the *Imago mundi* of Honorius Inclusus. Honorius produced his "mirror of the world" for Christian, later abbot of St. Jacob, and drew on a far wider range of authorities than any of his predecessors. The arrangement of the first section on geography, astrology, and astronomy was sound; it started with the creation and worked down to individual countries and cities. This was followed by a "chronicle," and a third section provided a brief list of important events since the fall of Satan. Honorius accurately foresaw his book's fate: innumerable copies, unauthorized plagiarisms, incessant criticism, and incompetent additions for at least 200 years.

Probably the first encyclopaedia to be compiled by a woman, the *Hortus deliciarum* of the abbess Herrad (died 1195), comprised a magnificent illuminated manuscript with 636 miniatures, intended to help and edify the nuns in her charge. Bartholomaeus Anglicus based his *De proprietatibus rerum* (1220–40) on the works of St. Isidore and Pliny. It was designed for ordinary people and became Europe's most popular encyclopaedia for the next three centuries. But the outstanding achievement of the Middle Ages was the *Speculum majus* of Vincent of Beauvais. Vincent was not an original writer but he was industrious, and his work comprised nearly 10,000 chapters in 80 books; no encyclopaedia rivalled it in size until the middle of the 18th century. The work was very well balanced, almost equal space being allotted to the three sections. The "Naturale" dealt with God and man, the creation, and natural history. For this Vincent drew not only on Latin writings but also on Greek, Arabic, and Hebrew, which were at that time (through translations) making a very considerable impact on the thinking of the West. The "Doctrinale" covered practical matters as well as the scholastic heritage of the age. The "Historiale" included a summary of the first two sections and a history of the world from the creation to the times of St. Louis. A fourth section, "Morale," based principally on St. Thomas Aquinas, was added after Vincent's death. The influence of the *Speculum majus* was immediate and lasting. Translations were made into several languages, and complete reprints appeared as late as 1863–79. One of its many values is that it is a source for extracts from many documents of which no other parts have survived. Another is its detailed history of the second quarter of the 13th century.

Vincent's was the last major work of its kind. Later encyclopaedists began to compile for a wider public than the very limited world of religious communities. The first breakaway from Latin came with *Li livres dou trésor* ("Treasure Books") of Brunetto Latini (*c.* 1220–95), the master of Dante, and the Florentine poet and philosopher Guido Cavalcanti. Latini wanted to reach the mercantile and cultured classes of Italy; he therefore used French, their common language. The arrangement of his work was similar to Vincent's but his approach was concise. The language, the brevity, and the accuracy of his encyclopaedia had an immediate and wide appeal. A friend of Petrarch's, Pierre Bersuire, based his *Reductorium, repertorium et dictionarium morale utriusque testamenti* ("Moral Abridgment, Catalogue and Dictionary of Each Testament"; *c.* 1340) on Bartholomaeus' *De proprietatibus rerum*. In contrast to Latini's work, this was a return to the traditional, with its moralizings on the Bible, Ovid's *Metamorphoses*, and natural history, but it had a considerable success when printing was introduced, being issued 12 times by 1526.

Brunetto Latini's breakaway from Latin

One of the most delightful of all encyclopaedias is the little *Margarita philosophica* that Gregor Reisch (died 1525) wrote for young people. In some 200 pages he contrived to cover in a very pleasing style the whole university course of the day, both the trivium and the quadrivium. The arrival of humanism is reflected in the *De disciplinis* of Juan Luis Vives, a pioneer in psychology and philosophical method; Vives grounded all his arguments on nature and made no appeal to religious authority. With the writing of the anonymous *Compendium philosophiae* (*c.* 1300) the concept of the modern scientific encyclopaedia was reached at last. It was the first encyclopaedia to adopt an inquiring and impartial attitude to the things described, and the old wives' tales that had filled so many pages of encyclopaedias from the time of Pliny onward were replaced by the latest scientific discoveries.

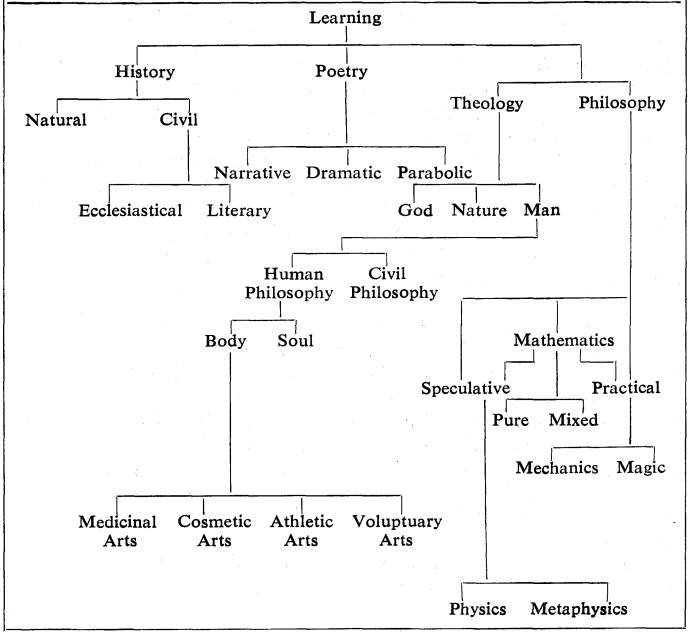
The first indigenous French encyclopaedia, the popular *Dictionarium historicum, geographicum et poeticum* ("Historical, Geographical, and Poetic Dictionary") of Charles Estienne (1504–64) was not published until 1553. For encyclopaedias in their own language, the French still had to rely on translations of the encyclopaedias of other nations, such as *Les diverses leçons* ("The Various Lessons"; 1552) of Pedro Mexia, a mediocre Spanish historian whose haphazard compilation was enormously popular in the 16th and 17th centuries.

The development of the modern encyclopaedia—17th and 18th centuries. Francis Bacon's purpose in writing the *Instauratio magna* was "to commence a total reconstruction of sciences, arts, and all human knowledge, raised upon the proper foundations" in order to restore or cultivate a just and legitimate familiarity between things and the mind. Only a small part of this enormous work was ever completed, but the author had planned 130 sections divided into three main sections: external nature, man, and man's action on nature. From its proposed contents Bacon's intention was clearly to compile an encyclopaedia thoroughly scientific in character—"a thing infinite and beyond the powers of man"—that he himself recognized to be revolutionary in character. His most important contribution was, however, the devising of a new and thoroughly sound classification of knowledge that bears a remarkable resemblance to the classifi-

Bacon's influential classification

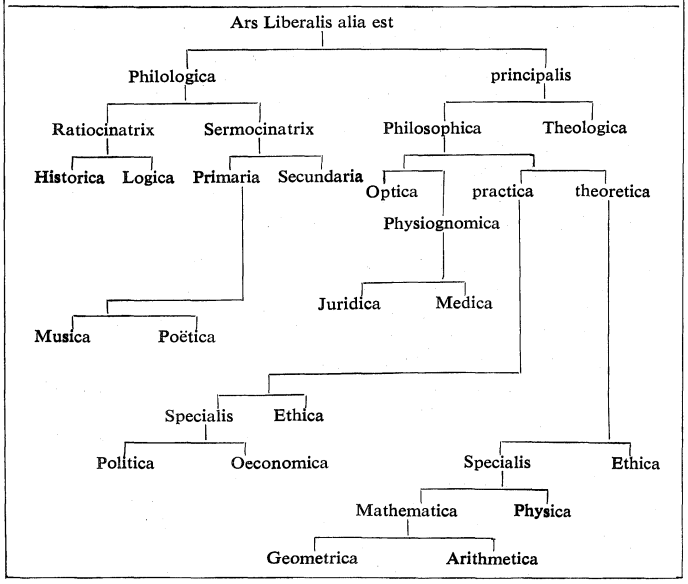
cation put forward by Matthias Martini in his *Idea Methodica* (1606). Although Bacon was apparently unaware of this work, both philosophers were probably working from the same basic Platonic precepts. The results were profound: Diderot made a point of acknowledging the assistance Bacon's analysis of the structure of human knowledge had afforded him in planning the contents of *L'Encyclopédie*, and Samuel Taylor Coleridge hailed "the coinciding precepts of the Athenian Verulam and the British Plato."

Table 1: Francis Bacon's Classification of Knowledge



Only two more Latin encyclopaedias of any importance followed. Antonio Zara, bishop of Petina, compiled the *Anatomia Ingeniorum et Scientiarum* ("Anatomy of Arts and Sciences"; 1614), which was chiefly remarkable for the inclusion of an index. And Johann Heinrich Alsted, who, like Martini, came from Herborn, compiled an *Encyclopaedia* (1630) whose arrangement corresponds broadly to the main outlines of Matthias' classification of human knowledge.

Table 2: Matthias Martini's Classification of Human Knowledge



Zara's and Alsted's encyclopaedias were systematically arranged. The turning point came with Louis Moréri's alphabetically arranged *Grand Dictionnaire historique* (1674), which was especially strong in geographical and biographical material. Its success was immediate; six editions were issued by 1691, each incorporating much new contemporary information. English editions followed in 1694, 1701, and (a supplement) 1705. Other encyclopaedias in England, Germany, Switzerland, and The Netherlands acknowledged its inspiration. The alphabetically arranged encyclopaedia in the vernacular had almost won the day, in spite of the German scholar Daniel George Morhof's modest success with his ill-balanced *Polyhistor Literarius, Philosophicus, et Practicus* ("Literary, Philosophical, and Practical History"; 1688–1708).

Furetière's modern *Dictionnaire universel*

If there was any doubt concerning the more popular form of the encyclopaedia, the issue of Antoine Furetière's *Dictionnaire universel des arts et sciences* (1690) confirmed the true nature of public taste. Furetière not only compiled a fine encyclopaedic dictionary, but he emphasized the arts and the sciences, thus reflecting the rapidly growing public interest in modern culture, science, and technology. If confirmation were still needed, the Académie Française's commissioning of Thomas Corneille to compile *Le Dictionnaire des arts et des sciences* (1694), with its thorough and authoritative treatment of these new encyclopaedic features, demonstrated that even the more conservative scholars were by now keenly aware that a new spirit had arisen. The period of the clerical encyclopaedia had ended, as the Franciscan friar Vincenzo Maria Coronelli found when his *Biblioteca Universale Sacro-Profano* (1701–06) ceased publication at volume 7 of a projected 45.

Pierre Bayle, in his *Dictionnaire historique et critique* (1697), achieved a most remarkable tour de force. Although his encyclopaedia purported to be an updating of the information in Moréri, the entries were largely unexceptionable. The real originality of his work lies in the profuse and scholarly footnotes and the commentaries that at times were an amazing mixture of skepticism, blasphemy, and ribaldry. Bayle challenged orthodox ideas; his brilliant mind spared nothing. This approach heralded that of Diderot, and the distinguished writers who revised later editions—Prosper Marchand and Pierre Desmaizeaux—continued in the same style.

The *Lexicon Technicum* (1704) of John Harris represented the powerful impact of the work of the Royal Society (founded 1660). Here was all the equipment of the modern encyclopaedia: excellent engraved plates, clear practical text, bibliographies appended to the more important articles. So far, England had had to make do with translations of French encyclopaedias. Harris' emphasis on the need to include scientific and technical subjects helped to reverse the trend. This process was completed by the issue of Ephraim Chambers' *Cyclopaedia* (1728). Like Harris, Chambers omitted people in favour of more information on the arts and sciences, and he paid more attention to clear expositions of ancient and modern philosophical systems. His admirably cross-referenced work is universally recognized as the father of the modern encyclopaedia.

The French were well aware of these developments. By 1744 five editions of Chambers' *Cyclopaedia* had been issued. The Paris publisher André Le Breton saw a ready market for a translation. The first proposals were a failure, however, and Diderot was enlisted to plan what at that time was still essentially a translation on a much broader basis. Under the hands of Diderot and d'Alembert the concept changed. *L'Encyclopédie* (1751–65) was a philosophical undertaking carried out on a gigantic scale, and much of the writing was of a high standard. To the orthodox, it appeared that the project had got out of hand, but there were 2,000 subscribers to the first volume, and the subsequent scandals over the irreverent, authority-challenging articles only added to the number of purchasers. The equivocal attitude of high dignitaries in both church and court and the growing public dislike of the encyclopaedia's chief critics—the Jesuits—led to a complex situation in which official disapproval and sub-

Diderot's monumental *Encyclopédie*

stantial private encouragement caused the production and fortunes of *L'Encyclopédie* and its producers to lurch dangerously from one crisis to another. Curiously, Diderot did nothing to further the physical development of the encyclopaedia; his contribution was to fire men's minds with a willful guidance that conformed to the country's increasingly revolutionary spirit. As Voltaire said: "this vast and immortal work seems to reproach mankind's brief lifespan."

The shortcomings of *L'Encyclopédie* were obvious. The essential ingredients of an encyclopaedia, the entries on every conceivable subject, had been sacrificed to make place for lengthy polemics on the controversial topics of the day. The *Encyclopædia Britannica* was intended to improve on this, and, with all its shortcomings, the first edition (1768–71) did exactly that. The achievement of its editors was the more remarkable in that there were already several English encyclopaedias on the market. The Scottish encyclopaedia, however, reflected the taste of the day better than any of its competitors, for it was a completely new work and not just a remaking of Chambers and Harris. There was much to criticize in the first edition, but the second (1777–84; dated 1778–83) was greatly improved, and succeeding issues of the *Britannica* made steady progress.

Meanwhile, Germany, at first largely dependent on translations of foreign encyclopaedias, had produced the scholarly "Hübner" (1704)—the first of the *Konversationslexikon* type—in a form that appealed to the rapidly growing middle class of the country, who welcomed encyclopaedias designed to provide them with an adequate cultural background for polite society. Johann Theodor Jablonski's illustrated *Allgemeines Lexicon* (1721) continued in this same style, and there were similar works compiled by the Swiss theologian and philologist Jakob Christoph Iselin and Antonius Moratori (1727). Johann Heinrich Zedler's huge *Grosses vollständiges Universal-Lexicon* ("The Great Comprehensive Universal Lexicon"; 1732–50) was in the older tradition but is important for its accuracy and its biographical and bibliographical material. An attempt to produce a German type of *L'Encyclopédie* in 1778–1807 was, however, a failure. Friedrich Arnold Brockhaus recognized the real need of the German people. Reworking Renatus Gotthelf Löbel's bankrupt encyclopaedia, he produced his first *Konversations-Lexikon* (1796–1811), thereby setting the pattern for at least half of all succeeding encyclopaedias throughout the western world. Brief, well-designed articles tightly packed with facts, comprehensive coverage, and a reputation for accuracy and up-to-dateness were the ingredients for one of the most successful of encyclopaedias.

Brockhaus' *Konversations-Lexicon*

The 19th century. Having served a long apprenticeship as a reviser of Chambers' *Cyclopaedia*, Abraham Rees at last produced a completely original and finely illustrated work, *The New Cyclopaedia* (1802–20), the only serious rival to the *Britannica* in a generation that saw some dozen "new" encyclopaedias rise and fall. What might have been the greatest encyclopaedia of the century, the *Encyclopaedia Metropolitana* (1817–45), failed miserably because of the early withdrawal of its designer, Samuel Taylor Coleridge, and subsequent financial troubles; but from it came the most notable contribution to the philosophy of encyclopaedia making since Bacon—Coleridge's profound "Treatise on Method" (1817).

To the principal influences on the compilation of encyclopaedias—Bacon, Diderot, the *Britannica*, and *Brockhaus*—must be added that of the Frenchman Pierre Larousse. His completely original approach to encyclopaedia making has given the series of encyclopaedias that bear his name a unique reputation. Emphasis throughout has been on readability; style has never been sacrificed to conciseness, and the successive editors of *Larousse* have paid very close attention to the changing public taste among French readers concerning the presentation of information.

The advent of Noah Webster was fully as epoch-making as that of Brockhaus and Larousse. Webster's informative *American Dictionary of the English Language* (1828) was encyclopaedic in character, but he avoided the long entries for the more important subjects that were such a feature of *Larousse*. Webster's approach appealed to the American taste and captured a huge market that has only increased with the years.

Brockhaus soon faced opposition, for his encyclopaedia was stronger on the humanities than on scientific and technical subjects. Joseph Meyer's *Der grosse Conversations-Lexikon* (1840–52) rectified this imbalance and was the first of a highly successful series that competed vigorously with *Brockhaus* for 100 years. In addition, Herder's *Conversations-Lexikon* (1853–57) and its subsequent editions provided the Catholic counterbalance in a country where Protestants and Catholics were almost equal in numbers.

The market for encyclopaedias in 19th-century Great Britain seemed inexhaustible, but many publishers lost money by putting out works that failed to capture the public's fancy. An exception was *Chambers's Encyclopaedia* (1860–68), which was unconnected with Ephraim Chambers' classic. Influenced by childhood access to a copy of the *Britannica*, Robert Chambers and his brother William compiled an original work, *Chambers's Encyclopaedia*, that took the *Konversationslexikon* form and thus found a new market that has continued to the present day.

Chambers's Encyclopaedia in England

In the first half of the 19th century there was increasing activity in other countries. Poland produced the *Encyklopedia Powszechna* (1858–68), known as "Orgelbrand" after its publisher. The Hungarians had followed the Bohemian *Slovník naučný* ("Scientific Dictionary"; 1860–90) with the *Egyetemes magyar encyclopaedia* ("Universal Hungarian Encyclopaedia"; 1861–76). The Russians had produced half an encyclopaedia, V.N. Tatishchev's *Leksikon rossyskoy* ("Russian lexicon"), in 1793, and then issued A. Starchevsky's *Spravochny entsiklopedichesky slovar* ("Encyclopaedic Reference Dictionary"; 1847–55) on the *Brockhaus* model. More important was the famous *Entsiklopedichesky slovar* ("Encyclopaedic Dictionary"; 1895), which became known as "Granat" after the Granat Russian Bibliographical Institute that produced it. A later edition (1910–48) of "Granat," in 58 volumes, is not exported from the Soviet Union. Modelled on the *Britannica*, this edition contained many important articles, such as Lenin's contribution on "Marx" and on "The Russian 19th-Century Agrarian Problem." Successive ideological changes in Russian society caused many changes in the text of "Granat," and it remains one of the most inaccessible of all Russian encyclopaedias outside the Soviet Union.

Larousse did not go unchallenged. Inspired by the French politician Ferdinand-Camille Dreyfus, *La Grande Encyclopédie* (1886–1902) provided France with a superb, authoritative, and comprehensive work, well documented, and of excellent scholarship throughout; it is still in use today. In Denmark the century ended with the issue of no fewer than three new good multivolume encyclopaedias: *Allers* (1892–99), *Hagerups* (1892–1900), and *Salmonsens* (1893–1911), a situation without parallel in the history of encyclopaedias. During the course of the century practically every feature of the modern encyclopaedia had been introduced, and editorial standards had at times risen to a height that modern editors can only envy.

The 20th century. In 1890–1906 a Russian edition of *Brockhaus*, which subsequently had considerable success, was issued from the St. Petersburg office of *Brockhaus*. In contrast, S.N. Yushakov designed his *Bolshaya entsiklopedya* ("The Great Encyclopaedia"; 1900–09) on the "Meyer" model. After "Granat" the next important encyclopaedia was the 65-volume *Bolshaya sovetskaya entsiklopedya* ("The Great Soviet Encyclopaedia"; 1926–47), which was eventually discredited; the second edition (1949–58) had a Marxist-Leninist approach but was less biassed on nonpolitical subjects. It represented almost the whole of the Soviet Union's cultural resources: 8,000 scholars contributed articles, and the appended bibliographies were truly international in scope. One complete

Russian encyclopaedias

volume was devoted to the Soviet Union. The yearbooks that supplemented this encyclopaedia were very well produced and maintained the high standards of the original work.

There has also been a series of editions of the much smaller *Malaya sovetskaya entsiklopedya* ("The Little Soviet Encyclopaedia"), first issued in 1928–31.

In the U.S., the first edition of the *New International Encyclopaedia* was issued in 1902–04 and was subsequently supplemented by yearbooks. *The Encyclopedia Americana*, which traces its ancestry back to an English-language adaptation (1829–33) of the 7th edition of *Brockhaus*, took on new strength in 1902 when the editor of *Scientific American*, Frederick C. Beach, was appointed editor of the *Americana*. It has enjoyed growing success through its policy of following the continuous revision system, and yearbooks have supplemented it from 1923 onward. In 1950–51 a completely new American work, *Collier's Encyclopedia*, appeared in 20 volumes, and subsequent editions have been supplemented by yearbooks since 1960. *Collier's* is noted for its large number of illustrations and maps.

The "Espasa," the *Enciclopedia universal ilustrada europeo-americana* (1905–70), is not only a great encyclopaedia, but—like the *Enciclopedia italiana*—it eschews revision in favour of a series of sizable supplements. Physically, it is the largest current encyclopaedia in the world. One complete volume is devoted to Spain and is separately revised and reissued from time to time. A smaller encyclopaedia, the *Diccionario Salvat* (first issued in 1907–13), is revised at frequent intervals. Another major Spanish encyclopaedia, the *Enciclopedia labor* (1955–60), is remarkable for devoting each volume to a major subject field, an index volume providing the key to the total contents. This encyclopaedia is valuable for the attention it pays to every part of the Spanish-speaking world.

Italian encyclopaedias

One of the most important of all encyclopaedias, the *Enciclopedia italiana* (1929–39), is famous for its lavish production, its superb illustrations, and its lengthy, scholarly, and well-documented articles. Even its defense of Fascist ideology is not allowed to impinge on the general impartiality of the text. Supplements have been issued since World War II. The postwar *Dizionario enciclopedico italiano* (1955–63), issued by the same publishers, is a much smaller but well-illustrated work. In Germany, the three giants of the German encyclopaedia world—*Brockhaus*, "Meyer," "Herder"—continue to produce new editions, unchallenged by any new encyclopaedia of comparable scope.

In spite of the continuing popularity of *Larousse*, France has produced three other encyclopaedias of note in the 20th century. The *Encyclopédie française* (1935–66) is an outstanding collection of monographs by well-known scholars and specialists, arranged in classified form and issued in looseleaf binders, supplemented by a continuously revised index. The *Encyclopédie de la Pléiade* (1955–) is an encyclopaedic series, each work (some in more than one volume) being a self-contained treatment of a broad subject field written in narrative form. One of the most interesting new encyclopaedias is the *Encyclopaedia Universalis* (1968–), edited by Claude Grégory and owned by the French Book Club and Encyclopædia Britannica, Inc. This work, inspired by *L'Encyclopédie*, eschews the inclusion of minor items in favour of extensive and very well-illustrated articles on important subjects, and it pays special attention to modern science and technology. Of the 20 volumes planned, volumes 17–19 will constitute a "thesaurus" of fact entries and index, and volume 20 will be devoted to an exposition of the classifications used in constructing the encyclopaedia and to further elaborations.

Most countries have issued at least one good encyclopaedia, among which should be mentioned:

Bulgaria: *Kratka bŭlgarska entsiklopediia* (1963–).

Czechoslovakia: *Ottův slovník naučný* (1888–1909); *Masarykův slovník naučný* (1925–33); *Nový velký ilustrovaný slovník naučný* (1929–34); *Komenského slovník naučný* (1937–38); *Příruční slovník naučný* (1962-67).

Denmark: *Gyldendals Nye leksikon* (first issued 1931–32); *Raunkjaers konversations leksikon* (1948–57); *Gyldendals store opslagsbog* (1967–70).

Estonian S.S.R.: *Eesti nõukogude entsüklopeedia* (1968–).

Finland: *Otavan iso tietosanakirja/Encyclopaedia fennica* (1960–65); *Nuorten tieto* (1963–); *Fokus: Otavan kertovasti kuvitettu tietosanakirja* (1963–).

Greece: *Megalē hellenikē enkyklopaideia* (1926–34); *Eleutheroudakē enkyklopaidikon leksikon* (1927–31).

Hungary: *Révai nagy lexikona* (1911–35); *Új magyar lexikon* (1959–62); *Új idők lexikona* (1936–42).

The Netherlands: *Eerste nederlandse systematisch ingerichte encyclopaedie* ("ENSIE"; 1946–52); *Grote Winkler Prins encyclopedie* (1966– ; the latest in an outstanding series of "Winkler Prins" encyclopaedias starting in 1870–82); *Algemene nederlandse systematisch ingerichte encyclopedie* ("ANSIE"; 1955–); *Oosthoeks encyclopedie* (1968– ; the latest edition of a series starting in 1916–23).

Norway: *Aschehougs Konversasjons leksikon* (1970– ; the latest in a series started in 1907–13); *Norsk konversasjonsleksikon* (first published 1931–34); *Norsk allkunnebok* (1948–61).

Poland: *Wielka Encyklopedia Powszechna PWN* (1962–).

Romania: the Romanian Academy's *Dictionar enciclopedic român* (1962–66).

Sweden: *Bonniers konversations lexikon* (first published 1922–32); *Focus uppslagsbok* (1958–60).

Turkey: *Türk ansiklopedisi* (1946– ; first called *Inönü ansiklopedisi*).

Yugoslavia: *Enciklopedija Jugoslavije* (1955–); *Enciklopedija leksikografskog zavoda* (first published 1955); *Pomorska Enciklopedija* (1954–64); *Hrvatska enciklopedija* (1941–45; unfinished, A–El only).

Lithuania (published in Boston): *Lietuvių enciklopedija* (1953–69).

ENCYCLOPAEDIAS IN THE EAST

China. The contribution from the East to the history of encyclopaedias is distinctive and covers a longer period than that of the West. The Chinese have produced encyclopaedias for approximately 2,000 years, but traditionally they differ from the modern Western encyclopaedia in that they are mainly anthologies of significant literature with some elements of the dictionary. Compiled by scholars of eminence, they have been revised rather than replaced over hundreds of years. In the main, they followed a classified form of arrangement; very often their chief use was to aid candidates for the civil service. The first known Chinese encyclopaedia, the *Huang-lan* ("Emperor's Mirror"), was prepared by order of the emperor in about AD 220. No part of this work has survived. Part of the *Pien-chu* ("Stringed Pearls of Literature"), prepared around 600, is still extant. About 620 the *I-wen lei-chü* ("Anthology of Art and Literature") was prepared by Ou-yang Hsün (557–641) in 100 chapters divided into 47 sections. The *Pei-t'ang shu-ch'ao* ("Extracts for Books") of Yü Shih-nan (558–638) was more substantial and paid particular attention to details of the organization of public administration. An annotated edition, edited by K'ung Kuang-t'ao, was published in 1880.

The earliest Chinese encyclopaedia

The *Ch'u-hsüeh chi* ("Entry into Learning") was a modest work compiled about 700 by Hsü Chien (659–729) and his colleagues. A more important book was the *T'ung-tien* ("Comprehensive Statutes") compiled by Tu Yu (735–812), a writer on government and economics. Completed in about 801, it contained nine sections: economics, examinations and degrees, government, rites and ceremonies, music, the army, law, political geography, national defense. In 1273 it was supplemented by Ma Tuan-lin's enormous and highly regarded *Wen hsien t'ung k'ao* ("General Study of the Literary Remains"), which included a good bibliography. Supplements to this work were published in the 17th, 18th, and 20th centuries. Under the order of the second Sung emperor, Sung T'ai Tsung, the statesman Li Fang organized the

compilation of the vast *T'ai-p'ing yü-lan* ("Emperor's Mirror"), which included extracts from many works of literary and scientific standing that are no longer extant. In 1568–72 the *T'ai-p'ing yü-lan* was revised and reprinted from movable type; a new edition revised by Yüan Yüan appeared in 1812. The *Ts'e-fu yüan-kuei* (*c.* 1013), particularly strong in historical and biographical subjects, was almost as large as the *T'ai-p'ing yü-lan.*

The historian Cheng Ch'iao (1108–66) compiled the *T'ung chih* ("General Treatises"), an original work with a strong personal contribution; the printed edition (1747) was in 118 volumes. One of the richest and most important of all Chinese encyclopaedias, the *Yü-hai* ("Sea of Jade"), was compiled about 1267 by the renowned Sung scholar Wang Ying-lin (1223–92) and was reprinted in 240 volumes in 1738.

World's largest encyclopaedia

What was probably the largest encyclopaedia ever compiled, the *Yung-lo ta-tien* ("Great Handbook"), was issued at the beginning of the 15th century. Unfortunately, only a very small part of its 22,937 chapters has survived; these were published in 1963. A number of small encyclopaedias were issued in the 16th century, but the next important event was the publication of the small but profusely illustrated *San ts'ai t'u-hui* (1607), compiled by Wang Ch'i and his son Wang Ssu-i. In 1704–11 the Chinese literary encyclopaedia *P'ei-wen yün-fu* was compiled by order of the emperor K'ang-hsi; this was supplemented by the *Yün fu shi I* (1720). Other works ordered by the emperor include the *Pien-tzu lei-pien* (1726) and the *Tzu shih ching hua* (1727). In 1726 the huge *Ku-chin t'u-shu chi-ch'eng* ("Collection of Pictures and Writings") was published by order of the emperor. Edited by the scholar Ch'en Meng-lei, it filled over 750,000 pages and attempted to embody the whole of the Chinese cultural heritage.

At the turn of the century, a number of encyclopaedias were issued. Wang Chi's *Shih wu yüan hui*, which covered well over 2,000 topics, was compiled in 1796. Lu Feng-tso's *Hsiao chih lu* (1804) is particularly valuable for its attention to technical terms, which previous works had ignored. Ch'en Wei's *Ching Chuan II* (1804) concentrated on history and the great Chinese classics, whereas Wang Ch'eng-lieh's *Ch'i ming chi shu* (1806) is stronger in biographical material. Tai Chao-ch'un compiled the *Ssu shu wu ching lei tien chi ch'eng* (1887), a historical work for the use of civil-service candidates. Wei Sung's *I shih chi shih* (1888) had actually been compiled 65 years previously, but it paid far more attention to practical matters. The *Chiu T'ung T'ung* (1902) of Liu K'o-i was in large measure a reassembly of material in the older encyclopaedias in a more efficient classification. A more important work of the period is the largely historical and biographical *Erh shih ssu shih chiu t'ung cheng tien lei yao ho pien* (1902). The *Ch'ing ch'ao hsü wen hsien t'ung k'ao* (1905), compiled by Liu Chin Tsao, was revised and enlarged in 400 volumes in 1921. It includes contemporary material on fiscal, administrative, and industrial affairs and gives some attention to technical matters. Lu Erh-k'uei's *Tz'u-yüan* (1915), with a supplement issued in 1931, was the first really modern Chinese encyclopaedia and set the style for nearly all later works of this nature.

Japan. In the Edo, or Tokugawa, era (1603–1867) there appeared a kind of encyclopaedia that consisted of extracts of major works in Japanese and Chinese. *Koji-ruien* (51 volumes, 1879–1914) and *Nihon-hyakka-daijiten*, or the "Great Japanese Encyclopaedia" (10 volumes, 1908–19) were somewhat more akin to modern encyclopaedias but were mostly compilations of scientific works. More complete general encyclopaedias appeared in the Showa period (1926–); *Dai-hyakka* (28 volumes, 1931–35), *Kokumin-hyakka* (15 volumes, 1934–37), *Sekai-dai-hyakka* (24 volumes, 1955–68), and *Japonica* (19 volumes, 1967–72) are examples of well-compiled works. In 1972 the *Britannica International Encyclopaedia* (28 volumes when completed) began publication. Unlike most of the formerly published Japanese encyclopaedias, which featured simple short entries, this work consisted of systematic long entries, supplemented with shorter "fact index" entries.

The Arab world. The early encyclopaedias written in Arabic can be roughly divided into two classes: those designed for people who wished to be well informed and to make full use of their cultural heritage, and those for the rapidly growing number of official administrators. The latter type of encyclopaedia originated when the Arabs established their rule through so many parts of the Mediterranean region. The first true encyclopaedia was the work of Ibn Qutayba (828–889), a teacher and philologist, who dealt with his topics by quoting traditional aphorisms, historical examples, and old Arabic poems. The arrangement and contents of his *Kitāb ʿUyūn al-Akhbār* ("The Best Traditions") set the pattern for many later encyclopaedias. The ten books were arranged in the following order: power, war, nobility, character, learning and eloquence, asceticism, friendship, prayers, food, women. Ibn ʿAbd Rabbih of Córdoba improved on Ibn Qutayba's work in his *ʿIqd* ("The Jewelled Necklace") by including more contemporary items of note.

Work of Ibn Qutayba

What has often mistakenly been referred to as the first encyclopaedia, the *Mafātīḥ al-ʿUlūm* ("Key to the Sciences"), was compiled in 975–997 by the Persian scholar and statesman al-Khwārizmī, who was well aware of the content of the more important Greek writings. He divided his work into two sections: indigenous knowledge (jurisprudence, scholastic philosophy, grammar, secretarial duties, prosody and poetic art, history) and foreign knowledge (philosophy, logic, medicine, arithmetic, geometry, astronomy, music, mechanics, alchemy). The Ikhwān aṣ-Ṣafāʾ ("Sincere Brethren"), a religious or political party founded at Basra in the 10th century, published the *Rasāʾil Ikhwān aṣ-Ṣafāʾ*, a remarkable work that consisted of 52 pamphlets written by five authors, comprising all the knowledge available in their milieu. The work included (1) mathematics, geography, music, logic, and ethics; (2) the natural sciences and philosophy; (3) metaphysics; and (4) religion, astrology, and magic. A complete edition was published in 1887–89.

The Egyptian historian and civil servant an-Nuwairi (1272–1332) compiled one of the best known encyclopaedias of the Mamlūk period, the *Nihāyat al-ʿarab fī funūn al-adab* ("The Aim of the Intelligent in the Art of Letters"), a work of almost 9,000 pages. It comprised: (1) geography, astronomy, meteorology, chronology, geology; (2) man (anatomy, folklore, conduct, politics); (3) zoology; (4) botany; (5) history. A complete edition was issued in 1923. The *Masālik al-abṣār* ("Sight-Seeing Journeys") of al-ʿUmarī (1301–48) was chiefly strong on history, geography, and poetry. A third Egyptian, al-Kalkashandī (died 1418), compiled a more important and well-organized encyclopaedia, *Ṣubḥ al-aʿshā*, that covered geography, political history, natural history, zoology, mineralogy, cosmography, and time measurement. Ibshīhī (flourished 1440) compiled a very individual encyclopaedia, the *Mustatraf* ("Spiritual Discoveries"), that covered the Islāmic religion, conduct, law, spiritual qualities, work, natural history, music, food, and medicine. At the turn of the Arab fortunes, Ibshīhī had recapitulated all that was best in their culture.

15th- and 16th-century Arabic encyclopaedias

The Persian lawyer ad-Dauwānī (1427–1501) published a kind of encyclopaedia, entitled *Unmūdag al-ʿūlūm*, that consisted of documented questions and answers and technical inventions on a very wide range of subjects. As-Sīrazī (died 1542) soon issued a refutation to it, the *Maqālatar radd ʿalā unmūdag al-ʿulum al-Galā lija.* The *Magmaʾ multaqat az-zuhūr birauḍa min al-manẓūm wal mantur* (1524) of al-Ḥanafī comprised an encyclopaedic survey and description of the various branches of knowledge, with an appendix containing an alphabetical list of the names of God. In Lebanon, Buṭrus al-Bustānī and his sons compiled the *Dāʾirat al-maʿārif* (1876–1900). A second edition (1923–25) was prepared by Muḥammad Farid Wajdi, and a third edition was begun by Fu'ād Afrām al-Bustānī in 1956. In 1955 Albert Rihani issued the one-volume *al-Mawsūʿat al-ʾarabīyah.*

Other areas. Other important encyclopaedias from the East include:

Burmese: the Burma Translation Society's *Myanma swezon kyan/Encyclopaedia Burmanica* (1954–).

Hebrew: *ha-Entziqlopedia ha-'Ivrit* (*Encyclopaedia Hebraica* 1949–); *Entziqlopedia tevel u-melo'a* (1962–); *Entziqlopedia kelalit Massadah* (1958–60).
Indonesian: *Ensiklopedia Indonesia* (1954).
Sinhalese: *Sinhalese Encyclopedia* (1963–).

AIMS AND EFFECTS OF ENCYCLOPAEDIAS

For much of their existence encyclopaedias have tried to be all things to all men. The effort has been magnificent, the results uncertain. No one can know what specific influence an encyclopaedia may have had on the thoughts and actions of any particular individual. One can be sure, however, that no one can look at an encyclopaedia without reacting in some way to its contents. The most ordinary effect is to remind the reader how little he knows of the world around him. This may produce in him a feeling that he is content to leave the situation as it is; it is far more likely to stimulate him at least to make some temporary effort to improve his understanding, and out of this may develop further studies that may interest him for a lifetime.

While trying to be a source for all that the reader wants, encyclopaedias have nevertheless omitted some things throughout their history. For a long time biographical information concerning living people was not thought suitable for inclusion. Humour and satire have always been found out of place; they date a work or become incomprehensible after a time. Up until the 19th century, "do-it-yourself" items were hardly ever more than a sporadic feature of any encyclopaedia, but nowadays many encyclopaedias cover a bewildering mass of facts and explanations. There are, however, still numerous aspects of ordinary life that are not considered part of encyclopaedic information. For example, it is extremely doubtful that an encyclopaedia will describe the kinds of clothing that are advisable for a visit to a foreign land, the precautions to be taken, the local customs to observe. Rightly or wrongly, this type of information is regarded as the preserve of the travel guide.

Even in this age, the editorial policies of most encyclopaedias have drawn a line between domestic needs—such as food recipes, touring routes, postal charges—and public concerns—such as population statistics, historical facts, explanations of scientific phenomena and technical inventions.

BIBLIOGRAPHY. There are two short and very readable introductions to the subject: JAMES M. WELLS, *The Circle of Knowledge: Encyclopaedias Past and Present* (1968), a well-illustrated guide issued in connection with a Newberry Library exhibition; and S.H. STEINBERG, "Encyclopaedias," *Signature*, New Series, no. 12, pp. 3–22 (1951), which is a brilliant conspectus of the whole field of encyclopaedia history. R.L. COLLISON, *Encyclopaedias: Their History Throughout the Ages*, 2nd ed. (1966), lists and describes in one chronological sequence encyclopaedias from both East and West, and pays particular attention to *L'Encyclopédie*, *Brockhaus*, the *Britannica*, the *Metropolitana*, and *Larousse*. It also includes a reprint (pp. 238–295) of SAMUEL TAYLOR COLERIDGE'S philosophical essay on the design of encyclopaedias, the "Treatise on Method." FRITZ SAXL, "Illustrated Mediaeval Encyclopaedias," in his *Lectures*, vol. 1, pp. 228–254, and vol. 2, plates 155–174 (1957), is an important and original contribution to the subject, the 20 illustrations being especially interesting. The *Journal of World History* devoted one complete issue (vol. 9, no. 3, 1966) to an international symposium on encyclopaedias, special attention being paid to St. Isidore, Hugh of Saint-Victor, Raoul Ardent, Vincent of Beauvais, Sahagún, *L'Encyclopédie*, the *Metropolitana*, the *Britannica*, *L'Encyclopédie française*, and Arabic and Chinese encyclopaedias of the classical period. A.J. WALFORD (ed.), *Guide to Reference Material*, 2nd ed., vol. 3, pp. 83–107 (1970); and CONSTANCE M. WINCHELL, *Guide to Reference Books*, 8th ed., pp. 81–91 (1967), and their supplements, both provide scholarly evaluations of the principal current English- and foreign-language encyclopaedias. GERT A. ZISCHKA, *Index Lexicorum* (1959), is important both for its excellent summary of the history of the encyclopaedia and for its extensive bibliography of past and present encyclopaedias. "The Uses of Encyclopaedias: Past, Present, and Future," in the *American Behavioral Scientist*, 6:3–40 (1962), is a stimulating symposium with contributions by Livio C. Stecchini, Jacques Barzun, Harry S. Ashmore, W.T. Couch, Charles Van Doren, Francis X. Sutton, David L. Sills, Carl F. Stover, and Alfred de Grazia. HERMAN KOGAN, *The Great EB* (1958), is a well-written and fascinating account of the *Britannica* and its history, but it is also valuable for the light it throws on the more practical problems and techniques of the encyclopaedia world in general. S. PADRAIG WALSH, *Anglo-American General Encyclopedias* (1968), is a dictionary of English-language encyclopaedias issued during the period 1703–1967, and has helpful evaluative notes. In 1969 the REFERENCE AND SUBSCRIPTION BOOKS REVIEW COMMITTEE OF THE AMERICAN LIBRARY ASSOCIATION issued "Purchasing a General Encyclopaedia," a pamphlet suggesting 12 criteria for evaluating the quality and usefulness of any encyclopaedia, and containing the committee's recommendations concerning a number of named encyclopaedias. In each encyclopaedia the entry under the word "Encyclopaedia" or "Encyclopedia" will usually (but not invariably) provide information concerning its own history, and often gives very useful information on the history of encyclopaedias in general. Additional details may often be found in the encyclopaedia's general introduction, which is usually printed in the first volume.

(R.L.C.)

Endocrine System, Human

The human endocrine system is made up of a large number of glandular tissues that have in common the fact that they secrete directly into the blood stream "chemical messengers" that regulate and integrate body functions. These chemical messengers, or hormones, usually but not invariably act on tissues some distance away from the cells that secrete them. One function of the endocrine system is the regulation of reproduction and closely associated phenomena. Other functions resemble those of the nervous system in that they help individuals cope with changes in their environment. Both hormonal and neural messages are specific. Nerve impulses pass along their axons (see NERVE IMPULSE). Hormones, on the other hand, enter the general circulation and are spread to all or almost all of the tissues in the body. Only certain tissues, however, are "programmed" to respond to a given hormone. Endocrine messages thus owe their specificity to the ability of those particular tissues to "understand" them.

This article is divided into the following major sections:

The nature of the human endocrine system and its hormones
The glands and tissues comprising the system
- The testes
- The ovaries
- The thyroid gland
- The adrenal glands
- The pituitary gland
- The structure and endocrine functions of the hypothalamus
- The pancreatic islets
- The parathyroid glands
- The gastrointestinal mucosa
- The thymus
- The pineal body
- The kidneys
- Other possible hormones and endocrine organs

The endocrine systems of animals other than man are dealt with in the article ENDOCRINE SYSTEMS. For a detailed description of the secretions of those systems, see the article HORMONE.

The nature of the human endocrine system and its hormones

Many known tissues secrete hormones in humans; probably still others are as yet undiscovered. The principal endocrine glands and tissues are shown in Figure 1, and the known or suspected endocrine tissues in humans, their hormones, and the chemical nature of these secretions are summarized in Table 1. Some hormones are tropic hormones that act on other endocrine cells. Four of the anterior pituitary hormones, for example, are tropic hormones, and through them the pituitary regulates the secretions of the adrenal cortex, the thyroid, and the sex glands.

Many hormones are proteins and polypeptides—*i.e.*, complex chains of amino acids. The structure of most if not all of these hormones varies from one animal species to another. In mammals the differences are usually so

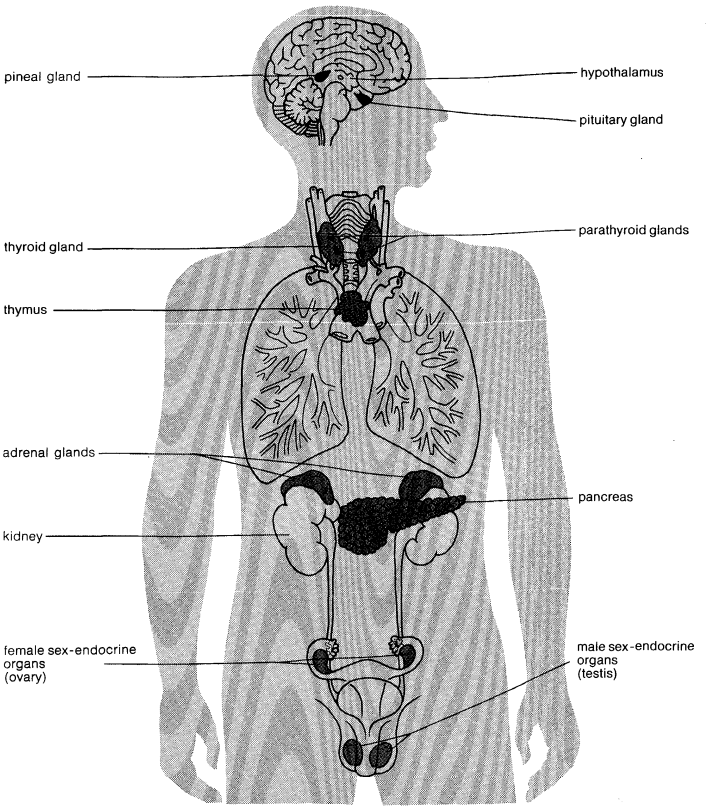


Figure 1: The human endocrine glands.

slight that the protein hormones of one species are generally, but not always, active in others. The structural differences are detected by the antibody-forming mechanism, however, and antihormone antibodies develop over a period of time. In human diabetics treated for prolonged periods with insulins of animal origin, for example, this can become a serious problem.

Neural control of the endocrine system

A large segment of the endocrine system is under nervous system control. Changes in the external or internal environment initiate changes in the sense organs that monitor these environments. Impulses set up in the nerve fibres from these receptors travel to areas of the brain where they make connections that activate effector mechanisms. The effectors available to the nervous system include somatic, smooth, and cardiac muscles, and glands.

The somatic muscles are the voluntary muscles responsible for moving, speaking and breathing. The smooth and cardiac muscles are responsible for visceral functions (*e.g.*, the peristaltic movements of the digestive tract are brought about by smooth muscle; only the heart contains cardiac muscle). Some of the gland cells are endocrine; *i.e.*, they secrete hormones directly into the bloodstream. The endocrine glands that are at least in part under neural control include the adrenal medulla, the juxtaglomerular cells of the kidneys, the beta cells in the islets of the pancreas, and the pituitary gland. These glands will all be described in the paragraphs that follow. Because the pituitary secretes at least ten hormones, of which four are hormones tropic to other endocrine glands, its regulatory effects are extremely widespread.

The nature of neural control varies from gland to gland. In the case of the adrenal medulla, the secretory cells are innervated by nerve cells. In the case of the juxtaglomerular cells, the regulatory effect appears to be mediated by circulating epinephrine (adrenalin), the hormone secreted by the adrenal medulla, as well as by a direct innervation of the secretory cells. The regulation of pituitary secretion is largely a function of the hypothalamus, the portion of the brain that lies immediately above the pituitary gland. In the anterior pituitary, the gland cells are regulated by hormones called "releasing factors" and "inhibiting factors" secreted by nerve cells in the hypothalamus into the portal hypophysial vessels, a collection of special blood channels that run directly from the hypothalamus to the anterior lobe of the pituitary. The posterior pituitary hormones are secreted directly into the general circulation from the endings of neurons whose cell bodies are located in the hypothalamus. Intermediate lobe hormones apparently are secreted from innervated gland cells and possibly are regulated by humoral agents from the hypothalamus as well.

Secretion of hormones by such neurons is not unique. Most, possibly all, neurons secrete chemical substances at their endings. In some cases, these substances act locally to produce excitation in the nerve or muscle cell on which the particular neuron ends; in other cases, the secreted material enters the blood or lymph circulation.

Neuroendocrine control of endocrine function is important in that it regulates the secretions of a large part of the endocrine system in accordance with the needs of the individual.

Feedback control

Another mechanism that regulates endocrine secretion is known as feedback control. Negative feedback is important. The secretion of parathyroid hormone is an example of negative feedback: parathyroid hormone increases blood-plasma calcium levels, and increased plasma calcium acts directly on the parathyroid gland cells to inhibit parathyroid secretion. If an extraneous factor increases plasma calcium, the secretion of parathyroid hormone is decreased and the rise in calcium is counteracted. A similar negative feedback plays a regulatory role in the interaction between the pituitary gland and some of the endocrine organs on which its hormones exert tropic effects. Adrenocorticotropic hormone (ACTH) from the pituitary, for example, increases the secretion of cortisol, a hormone of the adrenal cortex; and cortisol feeds back in a negative fashion to inhibit ACTH secretion.

Positive feedback also occurs in a few special circumstances in the endocrine system when a change in the substance regulated feeds back to change endocrine functions in a way that accentuates, rather than counteracts,

Table 1: The Human Endocrine System

gland or tissue	hormone	chemical nature
Testis	testosterone	steroid
Ovary	17β-estradiol	steroid
	progesterone	steroid
	relaxin	polypeptide
Thyroid gland	thyroxine	amino acid
	triiodothyronine	amino acid
	calcitonin	polypeptide
Adrenal gland		
Medulla	epinephrine	amine
	norepinephrine	amine
Cortex	cortisol	steroid
	corticosterone	steroid
	aldosterone	steroid
	androgens	steroid
	estrogens	steroid
Pituitary gland		
Anterior lobe	adrenocorticotropin (ACTH, corticotropin)	polypeptide (mw = 4,567)*
	growth hormone (GH, STH, somatotropin)	protein (mw = 21,734)*
	thyrotropin (TSH, thyroid-stimulating hormone)	glycoprotein (mw ≈ 25,000)*
	follicle-stimulating hormone (FSH)	glycoprotein (mw ≈ 30,000)*
	luteinizing hormone (LH, interstitial cell stimulating hormone ICSH)	glycoprotein (mw = 26,000)*
	prolactin (luteotropic hormone, LTH, lactogenic hormone, manmatropin)	protein (mw = ?)
Posterior lobe	oxytocin	polypeptide (mw = 1,007)*
	vasopressin (ADH, antidiuretic hormone)	polypeptide (mw = 1,228)*
Intermediate lobe tissue	α-melanocyte-stimulating† hormone (α-MSH)	polypeptide (mw = 1,823)* (not secreted?)
	β-melanocyte-stimulating† hormone (β-MSH)	polypeptide (mw = 2,734)*
Hypothalamus	corticotropin releasing factor (CRF)	polypeptide?
	growth hormone releasing factor (GRF)	polypeptide?
	thyrotropin releasing factor (TRF)	polypeptide
	follicle-stimulating hormone releasing factor (FSHRF)	polypeptide?
	luteinizing hormone releasing factor (LHRF)	polypeptide
	prolactin inhibiting factor (PIF)	polypeptide?
Pancreatic islets	glucagon	polypeptide
	insulin	polypeptide
	gastrin	polypeptide
Parathyroid gland	parathyroid hormone	polypeptide
Gastrointestinal mucosa		
Stomach	gastrin I	polypeptide
	gastrin II	polypeptide
Duodenum	cholecystokinin-pancreozymin (CCK)	polypeptide
	secretin	polypeptide
	intestinal glucagon (GLI)	polypeptide?
Small intestine	villikinin	—
	enterocrinin	—
Thymus	thymosin	polypeptide
Pineal	melatonin	amine (not secreted?)
Kidneys	renin	protein
	renal erythropoietic factor (REF)	protein?
Placenta	human chorionic gonadotropin (HCG)	glycoprotein
	human chorionic somatomammotropin (HCS)	protein
	renin	protein
	estrogens	steroids
	androgens	steroids
	progesterone	steroid

*Molecular weight (mw) in daltons. †Intermediate lobe hormones referred to collectively as melanotropin or intermedin.

the change. It is apparent that such control must be short-lived or self-limiting.

An example of positive feedback that includes a neuroendocrine link is the regulation of the posterior pituitary hormone oxytocin secretion during the delivery of a baby. This hormone acts on the uterus to increase its contractions. As the baby's head begins to dilate the neck of the uterus and to descend into the birth canal, nerve impulses from these regions pass up the spinal cord to the brain, where they stimulate oxytocin secretion from the posterior pituitary. The oxytocin in turn increases the force of uterine contractions, pushing the baby's head further along and causing greater sensory stimulation with increased oxytocin secretion. The resulting crescendo of oxytocin secretion is not primarily responsible for delivery but does aid parturition. The process ceases, of course, with the expulsion of the baby from the mother's body. Positive feedback is probably also involved in the secretion of the hormones responsible for ovulation.

The negative feedback component in the control of the secretion of some hormones is indirect. This is particularly true of hormones that are under hypothalamic control. Hormones secreted by the ovaries and testes, for example, exert a negative feedback effect primarily on the hypothalamus, with a secondary decrease in the secretion of the pituitary hormones that regulate ovarian and testicular hormone secretion. In the case of ACTH and thyroid stimulating, or thyrotropic, hormone (TSH), the target organ hormones appear to feed back on both the hypothalamus and the anterior pituitary gland. In addition, evidence has been found that the pituitary tropic hormones may feed back on the hypothalamus to either inhibit or stimulate the secretion of the corresponding hypothalamic releasing or inhibiting factors. This type of feedback has been dubbed "short-loop feedback." It has also been suggested that there is also a "minifeedback" in which releasing and inhibiting factors actually exert an inhibitory effect on their own secretion.

Protein binding of hormones

Another feature of general interest in the endocrine system is the binding or linking of a number of hormones to proteins in the circulation. Protein-bound hormones, generally believed to be physiologically inactive, exist in equilibrium with the free, active form of the hormone. Hormones that are protein bound include those of the thyroid and steroid secretions of the adrenal cortex, testes, and ovaries. The degree of binding varies. In the case of the adrenocortical hormones, there is relatively little binding of aldosterone, but bound cortisol accounts for about 96 percent of the total circulating cortisol. Practically all (99 percent) of the circulating thyroxine is bound. The function of the large circulating pools of bound, inactive hormones is uncertain, but it seems likely that they provide reservoirs of readily available hormones, as an extra safeguard against a dangerous drop in the amount of circulating free hormone.

Because there are so many hormones and their effects are extremely varied, it might be expected that the molecular mechanisms by which they exert their actions would be equally varied. Research, however, has demonstrated that there are two mechanisms of action common to a large number of hormones. One is by way of the cellular apparatus that regulates protein synthesis (genetic code), and the other via the intracellular formation of the nucleotide cyclic adenosine-3,5-monophosphate (cyclic AMP).

Evidence that some hormones act through the mechanism of the genetic code first came from experiments on insects. Deoxyribonucleic acid (DNA) in the nucleus of all cells contains the "instructions" for the formation of all the proteins that the cell can make. Parts of the genetic message are copied by messenger ribonucleic acid (mRNA), which then migrates to the ribosomes in the cytoplasm, where it supervises the formation of the proteins from amino acids (see also GENETICS; PROTEIN). The protein synthetic mechanism is the key to the function of the cell, since the synthesized proteins include the enzymes necessary to catalyze all of the cell's chemical reactions. All steroid hormones and a number of protein hormones appear to act in ways that lead to increased formation of DNA-dependent mRNA and consequently to synthesis of key enzymes. Thus, the hormones cause the expression of portions of the genetic message that are coded in the cell nucleus but that, in the absence of the hormones, are retained there in a repressed state.

Portions of the genetic message are transcribed in response to a given hormone only in certain cells, those said to be sensitive to the hormone. This specificity appears to be imparted by the presence in the sensitive, but not in the other, cells of a specific receptor protein that binds the hormone.

Cyclic AMP

An even more interesting feature of the action of hormones, and particularly of protein and polypeptide hormones, on cells is the generation of cyclic AMP, which is capable of initiating a variety of changes that mimic the actions of particular hormones. Cyclic AMP is formed from adenosine triphosphate (ATP) in a reaction catalyzed by the enzyme adenyl cyclase (see also METABOLISM) and is inactivated by a reaction catalyzed by the enzyme phosphodiesterase. Adenyl cyclase is found in the membranes of cells and consequently can be activated by chemicals that contact the outside of the cells without penetrating them. This had led to the hypothesis that some hormones act on their target cells by activating adenyl cyclase, and the intracellular cyclic AMP thus generated acts as a "second messenger" to bring about the hormone's action. The hypothesis is an attractive one because it explains how high molecular weight protein hormones can act without entering cells; it is difficult to visualize how such large molecules could enter cells without disrupting their membranes.

Since many hormones appear to act via cyclic AMP, but each of the hormones has its own characteristic actions, a given hormone must activate adenyl cyclase only in the membranes of its target cells. The basis of such specificity is not known, but it could be related to the presence of hormone-specific receptors in the cell membranes.

In certain instances, both the cyclic AMP second messenger system and DNA-dependent mRNA synthesis appear to be involved in the action of a single hormone. There is now evidence, however, that in some cases intracellular cyclic AMP initiates the expression of the portion of the genetic message that is responsible for the action of the hormone.

The second messenger system is frequently involved when the target tissue of a particular hormone is another endocrine gland. Cyclic AMP, thus, appears to be involved in the secretion of the kidney hormone renin in response to epinephrine and norepinephrine, the adrenocortical hormones in response to adrenocorticotropic hormone, the hormones of the corpus luteum of the ovary in response to luteinizing hormone (LH), the thyroid hormones in response to thyroid-stimulating hormone, and some of the hormones of the anterior pituitary in response to the hypothalamic releasing factors. The role of cyclic AMP in the secretory process is the subject of much current research.

The secretory process: emeiocytosis

There appear to be additional features common to the secretory process in various endocrine cells. Protein and polypeptide hormones, like other proteins and polypeptides, are formed in the endoplasmic reticulum (see CELL AND CELL DIVISION). In the cellular Golgi apparatus, the hormones are condensed into granules, and each granule is surrounded by a membrane. The granular particles thus formed are secreted by a process of emeiocytosis (literally, "cell vomiting"). The hormone granules move to the edge of the secretory cell, their membranes fuse with the cell membrane, and the area of fushion then degenerates, leaving the hormone granules outside the cell and the cell membrane intact. The process is the reverse of pinocytosis, in which substances are engulfed by protoplasmic extension of the cell and taken into its interior. A typical example of emeiocytosis is the secretion of the polypeptide hormone insulin. Epinephrine and norepinephrine are apparently bound to protein and stored in similar membrane-lined granules, then secreted by emeiocytosis.

Steroid-secreting cells have a prominent smooth endoplasmic reticulum that seems to play an important part in the formation of their secretions. Emeiocytosis is not involved in this secretory process. Steroids, however, are soluble in membrane constituents and probably can cross cell membranes with relative ease by dissolving in them.

Once released, the hormones must generally pass through the basement membranes of the particular endocrine cell and of the endothelial cells that form the wall of the blood capillaries. In most endocrine glands the endothelium itself is thinned out so that there are gaps, or fenestrae, between cells closed only by a thin, homogeneous membrane. This fenestrated endothelium is also found in the intestine and kidneys, where large amounts of substances are transported across the capillary walls. For some reason, however, such endothelium is absent in the testes.

In the following sections, each of the human endocrine glands is described. Each gland's location, structure, blood supply and innervation are considered; the nature, action and metabolism of its secretions are summarized; and the regulation of its secretion is reviewed.

The glands and tissues comprising the system

THE TESTES

The testes are the male gonads (see REPRODUCTIVE SYSTEM, HUMAN). They have two functions: they produce spermatozoa, the male germ cells, and they secrete testosterone, the hormone primarily responsible for male sex characteristics. The first function is the gametogenic function, and the second is the endocrine function. Testosterone and other hormones that produce masculinization are referred to collectively as androgens.

The testes are located in the scrotum, the wrinkled bag of skin at the base of the penis. In this location, the testes are kept cooler than the tissues in the interior of the body. The process of forming sperm cells proceeds best at a temperature several degrees below body temperature; if the testes were in the abdomen, sperm formation would reduce to the point of sterility.

The testes develop during embryologic life from structures in the abdomen, and when they later migrate to the scrotum they take their blood vessels with them. The internal spermatic arteries that bring blood to the testes are branches of the aorta. The spermatic veins empty into the renal vein on the left side of the body and the inferior vena cava on the right. The nerves are branches of the sympathetic and pelvic autonomic plexuses.

The spermatozoa are produced in the testes in a series of long, folded and coiled tubes called the seminiferous tubules. The tubules drain into a network of ducts in the epididymis, a large structure that lies along the side of the testes. The ducts in the epididymis coalesce to form the vas deferens. This latter duct passes into the abdomen and conducts sperm to the urethra, the urinary passage from the bladder to the tip of the penis.

Testosterone. Between the seminiferous tubules in the testes are nests of cells that secrete testosterone. These cells, which contain lipid granules, are called the interstitial cells of Leydig. Testosterone is a steroid that contains 19 carbon atoms. Steroid hormones are derived from the cyclopentanoperhydrophenanthrene nucleus. They are formed in the body from cholesterol. The male sex hormones secreted by the testes and adrenals are

Leydig cells

From Israel S. Kleiner and James M. Orten, *Biochemistry*, 7th ed. (1966); The C.V. Mosby Co., St. Louis

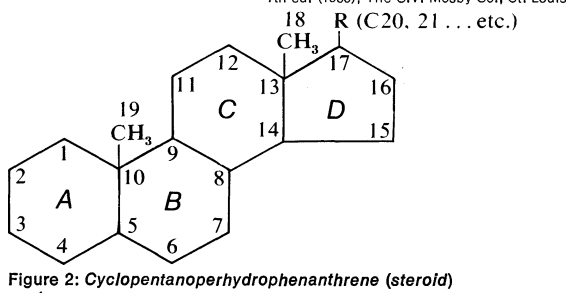

Figure 2: *Cyclopentanoperhydrophenanthrene (steroid) nucleus.*
The rings are lettered (*A*, *B*, *C*, *D*), and the carbon positions numbered. R denotes an aliphatic (nonringed hydrocarbon) side chain. Hormonal activity is altered to a large extent by additions or modifications at the 3, 11, and 17 positions (see text).

mostly carbon-19 steroids in that they contain 19 carbon atoms, while the adrenocortical steroids are mostly carbon-21 steroids that have a carbon-2 side chain on the *D* ring. Steroid formation is similar in all steroid-producing glands, and the pathways are comparable from gland to gland, the end product being determined by the particular enzymes in a given gland (see also STEROIDS).

The actions of testosterone. The actions of testosterone and of other androgens are primarily responsible for the characteristics associated with maleness. They stimulate the growth of the beard and increase the length of the larynx, producing deepening of the voice. They are protein anabolic; *i.e.*, they promote the formation of more protein in the body. They are thus responsible for the formation of the broad-shouldered, well-muscled body of the male. They also have a number of other effects, including apparent effects upon behaviour. The behavioral effects are difficult to quantitate, but testosterone does appear to promote aggressive, boisterous behaviour and to stimulate interest in sexual activity.

About 70 percent of the circulating testosterone is bound to a gonadal steroid-binding protein in the plasma, while the remaining testosterone in the circulation is in the free form. Its half-life in the circulation (time required for one-half a given amount to disappear from the circulation) is 90 minutes. The hormone is converted to various derivatives, most of which have an oxygen atom, usually contained in a keto group, attached to the *D* ring of the steroid molecule in position number 17. These compounds are therefore called 17-ketosteroids and are measured in the urine as an index of the endocrine function of the testes; 17-ketosteroids, however, are also formed from adrenal cortical hormones.

Control of testicular function

Both the gametogenic and the endocrine functions of the testes are under the control of the anterior lobe of the pituitary gland. The anterior pituitary hormone that regulates spermatogenesis is the follicle-stimulating hormone (FSH), and the anterior pituitary hormone that regulates testosterone secretion is LH. The secretion of FSH and LH is in turn under hypothalamic control, via follicle-stimulating and luteinizing hormones releasing factors, releasing factors secreted by the hypothalamus.

In the adult male, testosterone appears to be secreted at a steady rate and spermatogenesis is a steady, nonfluctuating process. Testicular function depends, therefore, on the maintenance of steady secretion of luteinizing hormone and follicle-stimulating hormone. Negative feedback control provides such stability. Luteinizing hormone secretion is under negative feedback control via testosterone. Luteinizing hormone stimulates testosterone secretion, and the circulating testosterone in turn inhibits LH secretion. The site at which the feedback occurs is probably the hypothalamus rather than the pituitary, and the testosterone appears to act by inhibiting the secretion of luteinizing hormone releasing factor, the hypothalamic factor which regulates the secretion of LH. Follicle-stimulating hormone stimulates spermatogenesis, and the secretion of it also appears to be under feedback control, since the secretion of this hormone increases if the testes are removed. The nature of the feedback inhibitor, however, has not yet been determined. It is thought probable that it is not testosterone, because in certain diseases FSH secretion is increased while testosterone secretion is normal. There is evidence that the testes produce a substance of unknown chemical nature called "inhibin," that suppresses follicle-stimulating hormone secretion.

THE OVARIES

The ovaries are the female gonads (see REPRODUCTIVE SYSTEM, HUMAN). They produce the female germ cells, or ova, and they secrete three hormones, estradiol, progesterone, and relaxin. In the adult female, each ovary is

Ovarian morphology

an irregularly ovoid almond-sized structure located in each side of the abdominal cavity at the edge of the pelvis. The ovaries receive their arterial blood supply from the ovarian arteries, branches of the aorta which are comparable to the internal spermatic arteries in the male. They join with the uterine artery. The ovarian veins, like the internal spermatic veins, drain into the inferior vena cava on the right and the left renal vein on the left. The nerves come from surrounding autonomic nervous system plexuses. The ovaries are located close to the fluted ends of the fallopian, or uterine, tubes, hollow conduits which pass on either side from the ovary to the uterus. The uterus, which in the nonpregnant woman resembles in size and shape an inverted pear, opens into the vagina through its opening, the cervix. The vagina, in turn, opens to the exterior.

The menstrual cycle. The theme of reproductive function in the mature female is the cyclicity of the menstrual cycle. This is in marked contrast to the male, in which the pattern is one of steady hormone secretion and germ cell production. In the female, cyclic changes in the ovary produce cyclic changes in the uterus, which culminate approximately every 28 days in menstruation (see also MENSTRUATION). The ovarian changes are, in turn, the product of sequential, orderly secretion of a number of anterior pituitary hormones under the control of a "biological clock" in the brain.

In the ovary of a young woman who has reached sexual maturity there are approximately 500,000 structures called primordial follicles. Each of these contains a primitive germ cell or ovum that had partially developed, then became dormant at the time of birth. At about the time each menstrual cycle ends, one of these follicles begins to enlarge. The hormone primarily responsible for the enlargement is follicle-stimulating hormone from the anterior lobe of the pituitary. If a woman receives injections of FSH, many follicles are usually stimulated, and women treated in this way frequently give birth to more than one baby. Indeed sextuplets, septuplets, and even nontuplets have been reported. The reason why follicle-stimulating hormone from the woman's own pituitary usually stimulates only one follicle, while exogenous FSH stimulates many, is unknown. The final maturation of the follicles requires both follicle-stimulating hormone and luteinizing hormone from the pituitary.

On approximately the 14th day of the menstrual cycle there is a sudden burst of luteinizing hormone and follicle-stimulating hormone secretion, and in response to the LH the mature (graafian) follicle ruptures. This rupture is the process of ovulation. The ovum is extruded from the follicle into the abdominal cavity and is usually promptly caught up in the folds around the opening of the adjacent fallopian tube. It is transported toward the uterus, largely by the action of the hairlike cilia that project from the cells lining the tube. If fertilization does not occur, the ovum passes through the uterus and out the vagina to the exterior.

The ruptured follicle fills promptly with blood, which clots to form what is called a corpus hemorrhagicum. The cells lining the corpus hemorrhagicum are stimulated, and yellowish, lipid-rich luteal cells rapidly grow into the clot. The ball of luteal cells thus formed is called the corpus luteum. In humans, the corpus luteum is

The corpus luteum

maintained by luteinizing hormone from the pituitary gland for 10–12 days. It then begins to degenerate, its function regresses, and menstruation begins. The whole process from initial stimulation of the follicle to advance regression of the corpus luteum normally takes approximately 28 days.

During the first part of the menstrual cycle, the inner lining of the uterus, known as the endometrium, grows thicker. In the endometrium the uterine glands, which are exocrine (*i.e.*, do not secrete directly into the bloodstream), become longer but remain relatively straight and secrete little. The endometrium during this stage is said to be in the proliferative phase of the cycle.

After ovulation, the uterine glands become coiled and begin to secrete mucus. The endometrium is said to be in the progestational stage of the cycle. Its glycogen content increases, and it becomes more succulent and edematous. If fertilization and implantation of the fertilized ovum in the uterus do not occur, the endometrium begins to break down as the corpus luteum regresses. Bleeding occurs, and the endometrium is sloughed except for a thin layer near the uterine muscle. The blood and sloughed endometrial tissue constitute the menstrual flow. Menstruation stops after an average of five days because the spiral arteries that supply the endometrium constrict and cut off the blood flow.

Ovarian hormones. The ovaries secrete three hormones: estradiol, progesterone, and relaxin.

Estradiol. Estradiol is an estrogen (estrogen is a generic term for the feminizing, or female, hormones) secreted

by the inner lining, or theca interna, of the follicle, and by the luteal cells. It is a steroid that is in equilibrium in the body with two closely related estrogens, estrone and estriol, and is synthesized from cholesterol in the body by way of testosterone. Most synthetic estrogens have similar structures, although some, such as stilbestrol, do not. Estrogens are responsible for "femininity" and for the growth of the endometrium during the proliferative phase of the menstrual cycle; along with other hormones, they also promote breast development, affect follicle-stimulating and luteinizing hormone secretion in a feedback fashion; and, in many laboratory mammals, act on the brain to stimulate sexual behaviour. Secreted estrogens are about 30 percent bound to protein in the circulation. Estradiol, estrone, and estriol are all excreted in the urine.

Progesterone. Progesterone is formed by the luteal cells of the corpus luteum. A small amount is also secreted by the adrenal gland in both men and women, and it is an important intermediate in the biosynthesis of other steroids. Further details of its biosynthesis are considered in the section on the adrenal cortex. Circulating progesterone is largely bound to albumin and to a globulin. It has a half-life in the circulation of only five minutes and is metabolized, principally in the liver, to pregnanediol, which in turn is conjugated to glucuronic acid and excreted.

Progesterone actions

The main action of progesterone is on the uterus, where, in concert with estrogens, it causes the previously discussed changes in the endometrium during the latter half of the menstrual cycle. Progesterone stimulates breast enlargement by promoting the development of the milk sacs. It is also thermogenic (*i.e.*, raises body temperature) and is responsible for the temperature elevation that occurs immediately after ovulation, a clinical sign that is obviously of value in family planning.

Progesterone also inhibits luteinizing hormone secretion and, when administered throughout the cycle, can prevent the increase in LH secretion that normally produces ovulation. Many derivatives of progesterone have been used for this purpose, and several contraceptive pills are a mixture of a synthetic progestational agent and a small amount of estrogen.

Relaxin. Relaxin is a polypeptide or a group of polypeptides apparently secreted by the corpus luteum. Relaxin softens the pelvic ligaments, permitting the birth canal to enlarge. It is presumably secreted at the time of delivery, but the mechanisms of its formation, secretion, and metabolism are as yet unresolved.

The cyclic pattern of reproductive functioning. The secretion of estrogen and progesterone and their interaction with the pituitary and the hypothalamus to produce the cyclic pattern of reproductive functioning in women is complex.

In the absence of fertilization. Estrogen secretion increases sharply just before ovulation, and there is a second rise in estrogen secretion in the middle of the progestational part of the cycle. Progesterone secretion is low throughout the first half of the cycle and increases only after ovulation. The secretion of estrogen from the developing follicle and the corpus luteum is stimulated by follicle-stimulating hormone in the presence of luteinizing hormone, and estrogen feeds back to inhibit FSH secretion. Progesterone secretion by the corpus luteum is dependent upon LH from the anterior lobe of the pituitary gland, and progesterone inhibits LH secretion. A sharp rise in estrogen levels can also stimulate LH secretion. The FSH level in the blood is slightly elevated early in the menstrual cycle and falls off while the LH level stays constant until midcycle. About the 14th day of the cycle, there is a sharp increase in the circulating levels of LH and FSH, the former being greater than the latter. Thereafter the levels of both hormones fall, reaching their lowest points during the cycle. The rise in LH secretion produces ovulation, while the significance of the rise in FSH secretion is still uncertain. (A more detailed description of the cycle is given in the article MENSTRUATION.)

The secretion of follicle-stimulating hormone and luteinizing hormone is controlled by the hypothalamus through follicle-stimulating hormone releasing factor and luteinizing hormone releasing factor. There is considerable experimental evidence from female animals for the existence of two brain centres to regulate gonadotropic hormone secretion. One centre in the base of the hypothalamus maintains basal levels of FSH and LH secretion, while the other in the superior and anterior hypothalamus is responsible for the bursts of luteinizing hormone secretion that produce ovulation.

Hypothalamic control

It is possible to advance a hypothesis of the way steroids and gonadotropic hormones interact to produce the menstrual cycle: the slightly elevated follicle-stimulating and luteinizing hormone levels early in the cycle lead to follicular maturation, and as the follicle matures there is a sharp increase in estrogen secretion. This estrogen peak in the relative absence of progesterone stimulates the secretion of LH and presumably FSH by positive feedback, with the production of ovulation. The corpus luteum then secretes progesterone and estrogen, and these hormones acting together depress by negative feedback the levels of FSH and LH secretion. When the corpus luteum regresses, estrogen and progesterone secretion declines, and the rise in FSH and LH secretion initiates a new cycle. The hypothesis is, however, admittedly tenuous.

The preceding paragraphs have detailed the endocrine events occurring in the menstrual cycle in the absence of pregnancy. If the ovulated ovum becomes fertilized, the events are different (see PREGNANCY; EMBRYOLOGY, HUMAN), primarily because of hormones secreted by the placenta.

Fertilization and pregnancy. Fertilization usually occurs in the midportion of the fallopian tube. The fertilized ovum, which begins to divide at once, enters the uterus and implants in the endometrium, usually on the posterior superior wall of the uterus. The developing embryo, now called a blastocyst, becomes surrounded by the chorion, a tissue made up largely of syncytiotrophoblasts. The syncytiotrophoblast is comprised of masses of multinucleate protoplasm without clear cell boundaries and is capable of eroding the endometrial tissue to make room for the developing fetus. The outside layer of cells of the blastocyst becomes the trophoblast. Later in pregnancy, the trophoblast becomes organized into the mature placenta. By this time, the syncytiotrophoblast is located on the surface of the villi and is underlain by the cytotrophoblast, a layer of trophoblast cells with distinct boundaries that divide and add to the mass of syncytiotrophoblast by fusing with it (see also EMBRYOLOGY, HUMAN).

The secretions of the placenta. Early in pregnancy, the placenta secretes large amounts of a gonadotropic hormone called human chorionic gonadotropin (HCG). The action of this hormone maintains the corpus luteum, which fails to regress and becomes known as the corpus luteum of pregnancy. No menstruation occurs because progesterone and estrogen secretion from the corpus luteum remains high, and no new follicles develop because these high levels of estrogen and progesterone inhibit the secretion of follicle-stimulating and luteinizing hormone from the pregnant woman's own pituitary.

Human chorionic gonadotropin

Human chorionic gonadotropin is secreted in greatest quantities in early pregnancy, but appreciable amounts continue to be secreted until delivery. The placenta also secretes progesterone and estrogen in increasing amounts throughout pregnancy. Ovariectomy before the third month of pregnancy causes abortion, whereas it has no effect later because the placental hormones maintain the pregnancy. In addition, the placenta secretes renin (a kidney hormone, discussed later) and human chorionic somatomammotropin (HCS), a protein hormone with lactogenic (milk-stimulating) and growth-promoting activity. Thus the placenta is a remarkable endocrine organ in its own right. The performance of the placenta is all the more amazing in view of the fact that all of the placental hormones seem to be secreted by the amorphous syncytiotrophoblast.

Lactation. After delivery of the baby, lactation begins. Breast development, both at puberty and during preg-

nancy, appears to depend on the balanced action of several hormones, but estrogens and progesterone play the principal roles. Prolactin (luteotropic hormone of the anterior pituitary gland) causes the developed breast to secrete milk, and the secretion is apparently increased following delivery, especially after suckling. The mechanism responsible for holding lactation in check during pregnancy and for initiating it after the baby is born, however, is poorly understood.

THE THYROID GLAND

The thyroid gland plays a key role in the regulation of metabolism (see also METABOLISM). It secretes two similar hormones, thyroxine and triiodothyronine. These hormones increase oxygen consumption by most of the cells in the body. In man and other mammals, the thyroid also secretes calcitonin, a plasma-calcium-lowering hormone.

Thyroid morphology

The thyroid gland, located just below the larynx at the base of the neck, is made up of two lobes of tissue connected by a narrow isthmus. It is derived embryologically from the floor of the pharynx, and a remnant of tissue, the thyroglossal duct, sometimes extends from the thyroid to the base of the tongue in the adult. The gland is supplied by two main pairs of arteries, one pair from the external carotid arteries in the neck to the superior poles of the gland and one from the subclavian arteries in the chest to the inferior poles. The thyroid veins drain into the neighbouring large veins of the neck and chest. Like all other endocrine glands, the thyroid is a vascular tissue and has a copious blood supply. Sympathetic nerve fibres pass from the cervical sympathetic ganglia to the gland, and parasympathetic fibres enter it from the vagus nerve. Afferent nerves that relay sensory information from the thyroid to the central nervous system enter the laryngeal nerves. It is probable, however, that the only function of thyroid innervation is regulation of its blood flow.

Thyroid tissue is organized into follicles in which balls of thyroid cells surround a central cavity. The follicles contain a gelatinous pink material, the colloid, in which thyroid hormones are stored bound to a protein called thyroglobulin. The structure of these cells varies with their state of activity. When the gland is inactive for a long time, the cells become flattened; when it is very active, they become square or even rectangular (columnar). Under the electron microscope, these cells show structural details which help to explain their functions. They are underlain by a basement membrane but are in close contact with the capillary blood vessels. The capillaries, like those of other endocrine glands and some other tissues, have gaps or fenestrae between the endothelial cells that make up their walls. At these fenestrae, there is only a thin membrane between the interstitial fluid and the blood, and the fenestrae are presumably the sites of easy transfer of substances into and out of the capillaries. The inner borders of the cells have multiple fine extensions, called microvilli, which project into the colloid.

The hormones of the thyroid. The hormones secreted by the thyroid gland include thyroxine, an amino acid containing four iodine atoms, and its triiodinated derivative, triiodothyronine. The raw materials necessary to form these hormones are iodine and tyrosine, an amino acid normally found in the diet. Their synthesis occurs at the border between the cells and the colloid by successive iodination and condensation of tyrosine residues attached to the thyroglobulin in the colloid. The iodine is actively pumped out of the body fluids into the thyroid cells, and it and the thyroglobulin are secreted into the colloid by the thyroid cells. In addition the thyroid cells remove the hormone from the thyroglobulin and secrete it into the blood stream.

Calcitonin

The thyroid also contains parafollicular or clear cells, which secrete the calcium-lowering hormone calcitonin. Most of these cells are found, as their name implies, in the spaces between the follicles. The parafollicular cells in mammals are homologous to the cells of the ultimobranchial bodies, which are separate endocrine organs in nonmammalian vertebrates. The function of calcitonin is discussed in detail below in the section on the parathyroid glands.

Iodine transport and hormone synthesis. In the body, inorganic iodine circulates in the form of I^-, the iodide ion. In the thyroid, iodine is actively transported from an area of low concentration (the extracellular fluid) to one of high concentration (the interior of the thyroid cell). It is also transported against an electrical gradient. Since the interior of the cell is 50–90 millivolts negative to the exterior, and the iodide ion is negatively charged, the negative ion is moving toward, instead of away from, negativity. The energy for this active transport comes from the chemical adenosine triphosphate (ATP) and related energy-rich phosphate compounds. The transport mechanism is also called the "iodide pump" and the "iodide-concentrating" or "trapping" mechanism. Once the iodide is in the cells, it normally is promptly converted to iodine and bound to the tyrosine residues on the thyroglobulin in the colloid. If this binding is prevented by a drug such as thiouracil, the avidity of the transport mechanism can be seen. The normal ratio of thyroid to plasma iodide is approximately 25:1, but in the presence of thiouracil it may reach 250:1.

Because iodide is concentrated and bound in the thyroid gland, radioactive iodine can be conveniently used for the diagnosis and treatment of certain thyroid diseases. Radioactive iodide is handled by the gland in the same way as other iodides. The magnitude of iodide uptake and binding, therefore, can be quantitated in patients suspected of having thyroid disease by administering an isotope of iodine, then monitoring thyroid radioactivity with a gamma radiation detector placed over the thyroid gland. An uptake curve is plotted and compared with a typical curve for iodine uptake in a normal human. The minute amounts of radioactivity used for diagnostic purposes have no known significant effect on thyroid function, but when large doses of radioactive iodine are administered, radioactivity concentrations in the gland may become sufficient to damage and even kill the thyroid cells. Thus radioactive iodine is of value in the treatment of some cases of hyperthyroidism and thyroid cancer.

As previously mentioned, the thyroid hormones are formed in the colloid by the progressive and orderly addition of iodine atoms to tyrosine residues on the molecules of thyroglobulin in the colloid. This reaction is followed by condensation of two of the iodinated residues to form thyroxine or triiodothyronine. Iodinated products other than thyroxine and triiodothyronine are also formed, but they are de-iodinated by enzymes in the thyroid tissue and their iodine re-used.

In addition to transporting the raw materials for thyroid hormone synthesis to the colloid, the thyroid cells remove triiodothyronine and thyroxine from the colloid and secrete it into the bloodstream. The removal process involves ingestion of bits of colloid by pinocytosis. Inside the cells, the thyroxine and triiodothyronine are detached from the thyroglobulin, presumably through the action of enzymes that are stored within the cells in structures called lysosomes. The hormones then move into the capillaries, apparently by simple diffusion.

Circulating thyroxine bound to protein

In the circulation, thyroxine is bound to plasma proteins. Triiodothyronine is also bound but to a lesser extent. Free thyroxine and triiodothyronine are physiologically active while the bound forms are not. Most of the thyroxine is bound to a circulating globulin called thyroxine-binding globulin, or TBG. Some is also bound to another protein, thyroxine-binding prealbumin, TBPA. In all, more than 99 percent of the thyroxine in the circulation is bound. The total bound and free thyroxine, however, are in equilibrium, and as free thyroxine is removed from the circulation by processes such as entry into cells, it is promptly replaced by thyroxine from the bound pool. Thus the large reservoir of bound thyroxine apparently serves to stabilize the free thyroxine level.

The thyroid hormones are metabolized by removal of iodine (de-iodination) and by combining with glucuronic acid or sulfate (conjugation). The former process occurs in all tissues, while the latter occurs principally in the liver and the kidneys. The half-life of thyroxine is comparatively long (six to seven days); the half-life of triiodothyronine is much shorter

Effects of thyroid hormones. The thyroid hormones have a number of different effects, but their primary action in adults is a stimulation of the oxygen consumption of cells. The stimulation occurs in most organs in the body, the only prominent exceptions being the brain, spleen, and testes. Secondary to the stimulation of metabolism, there is increased appetite, weight loss, often a slight rise in body temperature, and various other effects. The hormones also lower circulating cholesterol levels, an effect for which they have been used therapeutically. They are necessary for normal growth and development of children, and their deficiency is associated with dwarfism and mental retardation. The hormones appear to exert their effects primarily via DNA and RNA. Details of the actions of these hormones are considered in the articles HORMONE; ENDOCRINE SYSTEM DISEASES AND DISORDERS. The effect of a single dose of thyroxine on oxygen consumption is slow in onset and prolonged, lasting many days. The effect of triiodothyromine is much more rapid and pronounced, possibly because this hormone is less firmly bound to plasma protein than thyroxine and has a much shorter half-life.

Control of thyroid secretion

The secretion of thyroxine and triiodothyronine is under the control of thyroid-stimulating hormone from the anterior lobe of the pituitary gland. In the absence of pituitary, the thyroid continues to function, but at a low level. Conversely, injection of TSH causes a pronounced stimulation of thyroid function and increased secretion of thyroxine and triiodothyronine. Its exact site of action remains uncertain; it seems to stimulate almost all aspects of thyroid function, including iodide transport, oxidation to iodine, and iodine binding to tyrosine, as well as ingestion of colloid by the cells. The key to all these actions, however, appears to be stimulation by TSH of the formation of cyclic adenosine monophosphate in the thyroid. How this reaction leads to the others is unknown.

Thyroid-stimulating hormone secretion is controlled in part by the hypothalamus by way of the thyrotropin releasing factor secreted into the portal hypophysial vessels. Free thyroxine and triiodothyronine feed back to inhibit TSH secretion. The main site at which the thyroid hormones exert their inhibitory effect is the anterior pituitary itself. There may be an additional negative feedback of thyroid hormones at the hypothalamic level as well. It is still convenient, and probably accurate, to visualize the regulation of TSH secretion in terms of a closed-loop negative feedback system that maintains a stable day-to-day level of thyroid function and an open loop mechanism, via the nervous system and thyrotropin releasing factor, which can override the feedback control. One condition which probably works via this override system is environmental temperature; exposure to a cold environment promptly increases TSH secretion, at least in infants, whereas exposure to warmth decreases it. Psychological stimuli may also effect TSH secretion via the hypothalamus, but current evidence indicates that such stimuli do not exert major effects on thyroid function.

THE ADRENAL GLANDS

Man has two adrenal, or suprarenal, glands, one at the upper end of each kidney. Each gland is made up of an inner medulla, which secretes the hormones epinephrine and norepinephrine, and an outer cortex, which secretes steroid hormones. The cortex, in turn, is made up of an outer zona glomerulosa, which secretes the salt-regulating steroid aldosterone; and an inner zona fasciculata and zona reticularis, which secrete the other adrenal cortical hormones.

Structure. The cortical cells contain considerable quantities of lipids. The cells of the zona glomerulosa are arranged in balls, while the zona fasciculata is made up of straight cords of cells, and the zona reticularis is made up of cells arranged in an irregular net. Under the electron microscope, the adrenocortical cells are seen to contain the structures typical of steroid-secreting cells. There is a prominent smooth endoplasmic reticulum.

The medulla contains granulated secretory cells arranged in short cords or clumps. These cells, like certain other cells in the body, stain intensely with potassium bichromate and hence are called chromaffin cells. They contain dense-core granules surrounded by membranes. These granules contain epinephrine or norepinephrine bound to ATP and a protein. Morphologically, they resemble protein-secreting cells. There appear to be separate norepinephrine-secreting and epinephrine-secreting cells, the norepinephrine-secreting cells containing granules that are more dense than those of the epinephrine-secreting cells.

Blood supply of the adrenals

The adrenal glands are supplied by a large number of arterial twigs from the inferior phrenic arteries, the aorta, and the renal arteries, the major arteries in the vicinity. For the most part, these arteries form a plexus, or network, on the surface of the gland, and from it, broad, thin-walled sinusoids drain blood through the three zones of the cortex to the medulla. The capillaries of the medulla drain to a central vein. This vein drains into the vena cava on the right and the left renal vein on the left. Some arteries from the capsular plexus pass directly to the medulla. The adrenal medulla thus has a dual blood supply; some blood reaches it directly via the arteries from the capsule, but much of the blood that reaches it has first passed through the cortex. This arrangement may have functional significance; the activity of the enzyme responsible for the formation of epinephrine is increased by high concentrations of adrenal cortical hormones (see below), and it has been argued that formation of epinephrine depends on the medulla being perfused with blood from the cortex.

Innervation of the adrenal medulla

The adrenal medulla is formed from primitive neural tissue in the embryo and is densely innervated. The adrenal medullary cells, homologous to the nerve cells of the sympathetic chain, are also innervated by nerve cells that have their cell bodies in the central nervous system (preganglionic neurons). In the sympathetic ganglia, these neurons innervate postganglionic neurons that in turn innervate the viscera, while in the adrenal medulla they innervate cells that secrete directly into the bloodstream. The preganglionic neurons in both instances are cholinergic; *i.e.*, the chemical mediator liberated by the nerve endings is acetylcholine. The nerve fibres that innervate the adrenal medulla have their cell bodies primarily in the lateral gray column of the mid- and lower thoracic segments of the spinal cord and reach the adrenal via splanchnic nerves and the celiac and renal sympathetic plexuses.

Adrenal cortical hormones. The adrenal cortical hormones are steroids; *i.e.*, compounds that, as noted in the section on the testes, contain the cyclopentanoperhydrophenanthrene nucleus. They are conveniently divided on a functional basis into: (1) mineralocorticoids, hormones that have their major action on the excretion of sodium and potassium; (2) glucocorticoids, hormones that affect the metabolism of glucose, other carbohydrates, and protein; and (3) sex hormones, including both androgens and estrogens, that have the same functions as the gonadal steroids discussed previously. The mineralocorticoids and glucocorticoids are carbon-21 steroids (with a side chain on carbon atom 21), while the sex hormones are mostly carbon-19 steroids.

The adrenocortical hormones are synthesized from cholesterol, which in turn is formed from acetate. The cholesterol is converted to pregnenolone. The adrenocortical hormones are then formed by rearrangement of the A ring of the steroid nucleus and the addition of hydroxyl (−OH) groups in various positions. Each step is catalyzed by a particular enzyme or enzyme complex. By way of the so-called mineralocorticoid pathway, pregnenolone is converted to corticosterone and then to aldosterone. Pregnenolone and progesterone are also converted to their 17-hydroxy derivatives by the addition of an −OH group in the 17 position (17-α-hydroxylation). Via the 17-hydroxycorticoid pathway, they are then converted to cortisol, or, alternatively, the side chain in position 17 is split off and the androgens dehydroepiandrosterone and Δ-4-androstene-3,17-dione are formed. Appreciable quantities of these androgens are secreted, but

they are also converted to testosterone, and some of the testosterone appears to be converted to estradiol.

The enzymes involved in steroid biosynthesis are of considerable interest because different disease states caused by isolated congenital deficiency of each of the enzymes have now been described. In addition, drugs have been discovered that can inhibit individual enzymes in the biosynthetic scheme.

Mineralocorticoids. Hormones with mineralocorticoid activity increase the reabsorption of sodium by the kidney and decrease the net reabsorption of potassium so that sodium is retained in the body and potassium is lost from it. Mineralocorticoids also affect sodium and potassium metabolism through actions on other organs, but their principal effect is on the kidney.

Aldosterone is the most active mineralocorticoid secreted by the adrenal cortex. Corticosterone and deoxycorticosterone have appreciable mineralocorticoid activity, but when secreted in normal amounts, they contribute relatively little to the regulation of sodium and potassium balance. Thus aldosterone, even though its normal secretion rate is only 50–200 micrograms (millionths of a gram) per day, is the principal mineralocorticoid.

About 60 percent of the secreted aldosterone is bound to circulating proteins, mostly to albumin. It has a biological half-life of approximately 35 minutes and is metabolized in the liver and kidneys, principally by conjugation (in the 3 or 18 position) to glucuronic acid. The glucuronic acid derivatives are then excreted in the urine.

Secretion of aldosterone

The secretion of aldosterone is affected by adrenocorticotropin from the anterior lobe of the pituitary gland but is also regulated by angiotensin II, a peptide formed in the bloodstream, and by the plasma levels of sodium and potassium. Angiotensin II formation is in turn regulated by the rate at which renin is secreted by the kidneys (described later). ACTH has a marked effect on glucocorticoid secretion, but relatively large amounts are normally required to increase aldosterone secretion. On the other hand, small amounts of angiotensin increase aldosterone secretion. Larger amounts produce significant increases in glucocorticoid output as well, but even extremely large doses do not increase glucocorticoid output as much as ACTH does. A rise in plasma potassium or a fall in plasma sodium produces an increase in aldosterone secretion through a direct effect on the adrenal cortex.

Table 2: Major Stimuli That Alter Aldosterone Secretion*

	ACTH secretion	renin secretion	plasma potassium	plasma sodium
Surgery, physical trauma	+	NC or +†	NC	NC
Anxiety	+	NC or +†	NC	NC
Hemorrhage	+	+	NC	NC
Low sodium intake	NC	+	NC or +‡	NC or −‡
Standing	NC	+	NC	NC
Secondary hyperaldosteronism (some cases of heart failure, liver cirrhosis, nephrosis)	NC	+	NC	NC
High potassium intake	NC	NC or −	+	NC

*+ = increase; − = decrease; NC = no change. †Due to increased sympathetic activity. ‡Plasma sodium and potassium change only when sodium restriction is prolonged.

The major stimuli known to increase aldosterone secretion are summarized in Table 2. Stimuli, such as physical or mental stress, that increase aldosterone secretion by way of ACTH also increase glucocorticoid secretion. The increase in aldosterone secretion produced by ACTH is temporary; aldosterone output subsequently declines even if ACTH secretion remains elevated. Other factors stimulate aldosterone secretion selectively without increasing ACTH output. The increases produced by these stimuli are mediated, for the most part, via the renin-angiotensin system, although the increase produced by a high potassium diet appears to be direct. Stimuli that probably act by way of the renin-angiotensin system include a low sodium intake, bleeding, standing, and various disease states (such as nephrosis and cirrhosis) that increase aldosterone secretion. The way in which a low-sodium diet stimulates renin secretion is unknown. Other stimuli may act by decreasing blood pressure in the kidney. The aldosterone in turn causes sodium retention. Water is retained with the sodium, extracellular fluid volume is expanded, and blood pressure rises, shutting off the stimulus to aldosterone secretion. This feedback control mechanism by way of extracellular fluid volume is probably significant in the regulation of aldosterone secretion.

The role of plasma sodium and potassium, on the other hand, is less important, at least in the day-by-day regulation of aldosterone secretion. In experimental animals, relatively large changes in plasma sodium and potassium are required to produce a rapid change in aldosterone secretion. Although the increase in aldosterone brought about by a high potassium diet is probably due to a direct action of potassium on the adrenal, the plasma sodium and potassium mechanism appears to be primarily a homeostatic "backup" not normally involved in a major way in the regulation of aldosterone secretion.

There is some evidence that as yet uncharacterized factors, in addition to ACTH, the renin-angiotensin system, and plasma sodium and potassium, also affect aldosterone secretion.

Glucocorticoids. Glucocorticoids influence glucose metabolism principally by (1) exerting an anti-insulin effect, and (2) increasing the formation of glucose from amino acids and other noncarbohydrate precursors in the liver, a process known as gluconeogenesis. They also cause extensive protein breakdown, however, and have widespread additional effects in the body. In large amounts, but probably not in quantities normally secreted, they can counteract allergic and other types of inflammatory reactions. It is on this basis they have been used in the treatment of asthma, rheumatoid arthritis, and various skin diseases.

Cortisol

The principal glucocorticoid in man is cortisol. Corticosterone also has appreciable glucocorticoid activity, but normally there is less of it in the circulation. The other secreted hormones account for only a small portion of the glucocorticoid activity in the body fluids. Cortisol and corticosterone are secreted in much larger quantities than aldosterone. Under resting conditions in normal adult humans, the 24-hour cortisol output is about 20 milligrams (thousandths of a gram) and the corticosterone output about three milligrams. Cortisol is bound in the circulation to a plasma protein called transcortin, or corticosteroid-binding globulin, which is synthesized in the liver. A small amount is also bound to plasma albumin. The normal morning value for circulating cortisol is approximately 12 micrograms per 100 millilitres (thousandths of a litre) of plasma. Approximately 96 percent of this is bound and only 4 percent free. Corticosterone is similarly bound, but not to as great a degree; the normal morning value for corticosterone is 0.6 microgram per 100 millilitres of plasma, and only 90 percent of this is bound. Bound hormones are not as available for metabolism, so the half-life of cortisol in the circulation is 60–90 minutes, while the half-life of corticosterone is approximately 50 minutes.

The amount of transcortin in the circulation obviously affects the equilibrium between free and bound cortisol and corticosterone. If the amount of circulating transcortin increases, more glucocorticoids are bound. The bound glucocorticoids, unlike the free, appear to be physiologically inactive. The decrease in free glucocorticoids, however, stimulates adrenocorticotropin secretion, causing more glucocorticoids to be secreted, and a new equilibrium is reached in which the free glucocorticoid level is restored to normal.

Cortisol is removed from the circulation primarily in the liver. Some of the cortisol is reduced to form tetrahydrocortisol, which is then conjugated to glucuronic acid to form tetrahydrocortisol glucuronide. Some of the cortisol is converted to 17-ketosteroids, and some is converted to cortisone. The cortisone is, in turn, reduced and conjugated. Cortisone, then, an active glucocorticoid and well-known for its extensive use in the treatment of allergic and related diseases, is not a physiologically significant secretion of the adrenal cortex but is instead

primarily a liver metabolite of cortisol. The glucuronic acid derivatives of cortisol and cortisone are readily soluble in water, and are excreted in large quantities in the urine. Smaller amounts of other metabolites and of free cortisol are also excreted. The metabolism of corticosterone is similar to that of cortisol, except that it is not converted to cortisone.

One of the body's notable reactions to injury or threatened injury is an increase in glucocorticoid secretion. This increase is of great importance; in its absence even relatively minor injuries can be fatal. The multitude of noxious and potentially noxious stimuli that increase glucocorticoid secretion are generally lumped together under the term "stress." There is in addition a regular diurnal fluctuation in resting levels of glucocorticoid secretion. Both stress-induced and diurnal variations are caused by fluctuations in the secretion of adrenocorticotropin from the pituitary.

Regulation of glucocorticoid secretion

The regulation of glucocorticoid secretion is almost exclusively under the control of ACTH from the pituitary gland, and, although certain other factors including angiotensin II can increase glucocorticoid secretion, it appears that under all but the most extreme conditions, these latter factors play no physiological role. In the absence of stress, adrenocorticotropin is secreted in irregular spurts throughout the day, but the number and size of these spurts is greater in the early morning hours while the subject is still asleep. The circulating glucocorticoid level follows the adrenocorticotropin level, with a general downward trend throughout the waking hours.

The secretion of adrenocorticotropin is inhibited by cortisol and other glucocorticoids from the adrenal, and this negative feedback control provides stability to the system. The site at which the cortisol feeds back to inhibit ACTH secretion is probably the pituitary, but there may be an additional feedback on the hypothalamus or some other part of the brain. The increases in adrenocorticotropin secretion produced by most stimuli are mediated by way of the nervous system. Neural stimuli converge on the ventral portion of the hypothalamus, where they affect the production of the corticotropin releasing factor (CRF). By way of the portal hypophysial vessels the CRF enters the anterior pituitary, where it regulates the secretion of adrenocorticotropin. The neural impulses responsible for the increases in adrenocorticotropin secretion produced by physical stress probably ascend to the hypothalamus through the reticular formation, the ancient core of the brain (see also NERVOUS SYSTEM, HUMAN). Some drugs may act directly on the hypothalamus. Psychological stimuli act via the limbic system, that part of the central nervous system in the temporal lobes of the brain concerned with the genesis and expression of emotion. The "biological clock" responsible for the diurnal variation in adrenocorticotropin secretion also appears to be located in the temporal lobes. It also appears that there are neural pathways that inhibit ACTH secretion. The physiological role of the inhibitory pathways, however, is presently unknown.

Sex hormones. The adrenal sex hormones are normally supplemental to the gonadal sex hormones and have relatively little effect on their own. The adrenal androgens, however, particularly dehydroepiandrosterone, play a role in the growth of pubic and axillary hair in women. Secreted in excess, they can produce marked masculinization. The secretion of the adrenal sex hormones, like that of the glucocorticoids, is apparently controlled primarily by adrenocorticotropin. Gonadotropins do not appear to play any role. The androgens are excreted for the most part as 17-ketosteroids.

Adrenal medullary hormones. The adrenal medullary hormones are norepinephrine and epinephrine. Norepinephrine is formed by decarboxylation and successive hydroxylation of the amino acid tyrosine. Tyrosine is taken up by adrenal medullary cells and converted to dihydoxyphenylalanine (dopa). Dopa is then decarboxylated to the corresponding amine, dopamine. Dopamine, norepinephrine, and epinephrine are all amines (organic compounds structurally related to ammonia), and because of their structure they are frequently referred to collectively as catecholamines (structurally related to phenol alcohols). Dopamine enters the dense-core granules in the cells and is hydroxylated to form norepinephrine. The reactions to this point are identical to those occurring in the norepinephrine-secreting adrenergic neurons in the brain and sympathetic nervous system. In adrenal medullary cells that secrete epinephrine, however, there is an additional reaction. This reaction, the methylation of norepinephrine to form epinephrine, is catalyzed by the enzyme phenethanolamine-N-methyl transferase (PNMT). There is evidence that PNMT formation requires a milieu in which the glucocorticoid concentration is high. Such a milieu is provided only in the adrenal medulla, since as noted above, the medulla is perfused with blood that has first passed through the adrenal cortex. This may explain why appreciable amounts of PNMT activity, and consequently of epinephrine synthesis, are found only in the adrenal medulla.

Synthesis of norepinephrine and epinephrine

The actions of epinephrine and norepinephrine are generally similar, but there are certain important exceptions to this generalization. Both amines increase the force of contraction of the heart, break down fats and thus increase the level of circulating free fatty acids, raise the metabolic rate, and increase alertness by an action on the brain. Norepinephrine, however, causes a rise in blood pressure because it causes constriction of all blood vessels—except possibly the coronary vessels supplying the heart. Epinephrine causes constriction in many vascular beds, but it dilates the blood vessels in the skeletal muscles and the liver. The net effect on the peripheral resistance against which the heart must pump is, therefore, relatively small, and there is little change in mean blood pressure. Epinephrine breaks down the glycogen in the liver (glycogenolysis) with a consequent outpouring of glucose from the liver into the circulation. Norepinephrine has little glycogenolytic activity.

Circulating epinephrine and norepinephrine have short half-lives. They are inactivated primarily by O-methylation to form the inactive compounds metanephrine and normetanephrine. The enzyme catalyzing O-methylation is catechol-O-methyltransferase (COMT). Some of the normetanephrine and metanephrine are then oxidized to 3-methoxy-4-hydroxy mandelic acid (VMA). Intracellular catecholamines, on the other hand, are subject to oxidation before secretion because of the presence in the mitochondria of the enzyme monoamine oxidase (MAO). The inactive oxidation products enter the circulation and are converted to VMA by COMT. Other metabolites are formed in small amounts. About 2 percent of the secreted catecholamines appears unaltered in the urine; about 35 percent is excreted as metanephrine and normetanephrine and 35 percent as VMA.

In humans, epinephrine makes up 80 percent of the total catecholamine secretion of the adrenal medulla. The remaining 20 percent is norepinephrine, although it is possible that traces of dopamine are also secreted. Norepinephrine also reaches the circulation from sympathetic nerve endings, so the normal resting plasma norepinephrine level is about 0.4 nanogram (1 nanogram = 10^{-9} gram) per millilitre while the epinephrine level is 0.1 nanogram per millilitre or less.

Stimuli for medullary secretion

The stimuli that increase adrenal medullary secretion are, in general, those that increase sympathetic discharge. These include most, but not necessarily all, of the stressful stimuli that increase ACTH secretion. The sympathetic discharge, because it prepares the animal to meet emergency situations, is sometimes called the "fight or flight reaction." Among the stimuli that increase adrenal medullary secretion are low blood sugar, oxygen lack, and cold. A decline in blood pressure also initiates increased secretion. Control of the gland is almost completely neural, via the preganglionic nerve fibres that innervate the adrenal medullary cells. The adrenal medulla is one of the few endocrine tissues in which the gland cells are directly innervated by secreto-motor nerve fibres. There is some evidence for selective secretion of either epinephrine or norepinephrine from the adrenal medulla under certain circumstances, but most stimuli provoke a proportionate increase in the secretion of both

hormones. The response to bleeding is probably mediated via the pressure-sensing carotid and aortic receptors in the arteries (see BLOOD CIRCULATION, HUMAN), and the receptors that initiate the responses to low blood sugar, oxygen lack, and cold are probably neural elements in the central nervous system or the peripheral tissues. It is notable that there is only indirect negative feedback control in the adrenal medullary system, and catecholamines do not appear to act directly to inhibit their own secretion.

THE PITUITARY GLAND

The pituitary gland is located deep in the head at the top of the nasal cavity in a hollow, the sella turcica, in the base of the skull. It is connected to the overlying hypothalamus by a stalk. Except where it is pierced by the pituitary stalk, the sella is covered by a fold of dural membrane, the tentorium, or diaphragma sella. The pituitary is formed during embryonic development by the union of a ball of cells that breaks off from the roof of the mouth (Rathke's pouch) with a projection from the base of the brain. This accounts for the formation of an anterior, an intermediate, and a posterior lobe. In a number of mammalian species, however, the intermediate lobe tissue is rudimentary, and in humans it is intermingled with the tissue of the anterior lobe.

The anterior pituitary and its hormones. The anterior pituitary receives few if any nerve fibres from the hypothalamus. In man and some other mammalian species, it also lacks any appreciable direct blood supply; instead, almost all the blood reaching it first perfuses the base of the brain and is transported to the pituitary by the portal hypophysial vessels. These vessels drain a primary network of capillary loops in the median eminence of the hypothalamus and adjacent upper portion of the pituitary stalk. They pass down the stalk to the anterior lobe, where they supply the gland cells. The primary network from which the portal vessels arise is formed by branches from the carotid and other neighbouring arteries. The blood supply to the anterior pituitary is thus a true portal system since it begins and ends in capillaries without going through the heart. The blood from the anterior pituitary drains into the neighbouring cavernous sinus, a venous sinus that, in turn, drains into the jugular veins and thence into the heart.

Morphology of the anterior lobe

The anterior lobe is divided into two parts: (1) the pars tuberalis, the thin layer of tissue on the pituitary stalk through which the portal vessels run; and (2) the pars distalis, the main secretory portion of the gland. The cells of the pars tuberalis are not well differentiated, but in the pars distalis are found various types of secretory cells, including some intermediate lobe cells. The anterior lobe cells generally have been divided, on the basis of their staining characteristics, into acidophils (staining with acid dyes), basophils (staining with basic dyes), and chromophobes (staining poorly with either type of dye). More refined techniques and electron microscopy, however, have shown that, at least in some species, there are six distinct cell types, one for each of the six anterior lobe hormones. This is probably also true in man, although all six cell types have not as yet been absolutely identified.

The anterior lobe of the pituitary secretes six polypeptide or protein hormones; adrenocorticotropic hormone (ACTH), growth hormone (GH), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), and prolactin. The human anterior pituitary also contains the intermediate lobe hormones, α- and β-melanocyte stimulating hormone (α- and β-MSH). ACTH is a simple polypeptide. Growth hormone and prolactin are simple proteins, while TSH, FSH, and LH are glycoproteins that contain carbohydrates such as fucose. The hormones are synthesized, as are other proteins, in the rough endoplasmic reticulum and stored in membrane-lined granules in the cells. Secretion involves the previously considered process of emeiocytosis —the movement of these granules to the cell membrane; the membrane around the granule then fusing with the cell membrane, and the area of fusion breaking down, leaving the secretory granule on the outside of the cell and the membrane intact.

The tropic hormones. ACTH, TSH, FSH, and LH are tropic hormones in the sense that they act to regulate other endocrine glands, whereas growth hormone and prolactin act directly on non-endocrine tissues. The details of the functions of the tropic hormones are treated in the sections on the particular glands they regulate.

Growth hormone. GH promotes protein synthesis and plays an important role in growth. Dwarfism results from its absence. Of the variety of causes of dwarfism, many are associated with skeletal and other deformities. In congenital isolated growth hormone deficiency, the body proportions are normal except for short stature, and sexual function is preserved. Charles Stratton, the "midget" whom P.T. Barnum, the famed circus entrepreneur, exhibited under the name General Tom Thumb, was in all probability an example of isolated growth hormone deficiency.

Growth hormone is also secreted in adults; in fact, the rate of growth hormone secretion in adults is about as high as it is in children. It exerts an anti-insulin effect and also acts to mobilize free fatty acids from fat depots. Its actions are discussed in more detail in HORMONE; ENDOCRINE SYSTEM DISEASES AND DISORDERS.

Control of GH secretion

Growth hormone secretion is controlled by growth hormone releasing factor (GRF) from the hypothalamus. Resting plasma growth hormone levels are normally zero to three nanograms per millilitre. The half-life of the hormone in the circulation is 20–30 minutes, and it is metabolized, at least in part, in the liver. Growth hormone secretion is increased during sleep, but the cause and the significance of this increase remain obscure. The growth hormone-stimulating action of the pancreatic hormone glucagon may help the body combat a low blood sugar. Other GH-secreting stimuli generally fall into one of three categories: (1) stressful stimuli, (2) stimuli that increase circulating amino acid levels, and (3) conditions such as low blood sugar and fasting in which there is a deficiency, or at least a threatened deficiency, of fuel to be burned to meet the body's energy needs.

Growth hormone has no target endocrine gland, and hence no direct negative feedback control via a target organ hormone. There is evidence, however, that growth hormone feeds back to inhibit its own secretion, presumably by an action at the hypothalamic level. Growth hormone secretion is thus regulated in part by short-loop feedback. The receptors responsive to blood glucose and amino acid levels are presumably in the brain, but their exact location has not been established.

Prolactin. The only proved function of prolactin in mammals is stimulation of the synthesis of milk in the breast. Its function in males, despite a great deal of speculation, is unknown. The action of prolactin on the breast requires the presence of other hormones, including estrogens, progesterone, and adrenocortical hormones. Prolactin secretion is increased after parturition when milk is being formed for the newborn infant. In abnormal states, however, prolactin can also produce milk secretion in virgin women and even in men. In laboratory mammals, prolactin secretion is increased by suckling. There is a sharp increase in circulating prolactin along with the increase in circulating LH and FSH at the time of ovulation, but during the rest of the sexual cycle and during pregnancy, the levels are low. There is no reason to believe that the pattern of prolactin secretion in humans is different, but proof that it is similar must await the development of a method for measuring prolactin in man.

One of the reasons that methods for measurement of prolactin have not been successful is the difficulty in separating human prolactin from human growth hormone. The similarity between the two hormones is so great that it has been postulated that they are identical. The growth hormone-like and prolactin-like activities released by human pituitary cells in tissue culture, however, are not always parallel, and female dwarfs with congenital growth hormone deficiency lactate normally

and have prolactin-like activity in their blood when they nurse their babies. Thus, it appears that the two hormones are separate, although human prolactin has not as yet been isolated or characterized.

Control of prolactin secretion

Prolactin secretion is under inhibitory control by the hypothalamus, and severance of the portal vessels by cutting the pituitary stalk or transplanting the pituitary leads to increased prolactin secretion. Section of the pituitary stalk can bring about lactation in nonpregnant women. A prolactin inhibiting factor (PIF) has been extracted from the hypothalamus, and there is some evidence that there may be a prolactin stimulating factor as well. There is also evidence that prolactin feeds back in a short-loop fashion to inhibit its own secretion.

Intermediate lobe and its hormones. Two intermediate lobe hormones, α-MSH (α-melanocyte-stimulating hormone) and β-MSH, are found in the pituitaries of mammals (see HORMONE). The first is a polypeptide containing 13 amino acid residues that has the same structure in a variety of mammals and probably in man. The structure of β-MSH varies from species to species; in humans, it is a polypeptide containing 22 amino acid residues. β-MSH is found in human blood, but α-MSH has not been detected in any of the body fluids. Little is known about the metabolism and excretion of these compounds.

Functions of the intermediate lobe hormones

Intermediate lobe hormones stimulate melanophores, cells that contain motile granules in the skin of reptiles, fish, and amphibia. When the granules are aggregated in the centre of these cells, they are relatively clear, and the skin of the animal assumes a light colour; when the granules spread throughout the cells, the skin becomes dark. In many animals, the secretion of intermediate lobe hormone plays an important role in protective changes in skin coloration. There are no melanophores, however, in the skin of mammals. Melanocyte-stimulating hormones can produce some darkening of the human skin by increasing the formation of dark pigments, but this does not occur under normal conditions. Many other functions have been hypothesized for α- and β-MSH in humans, but there is insufficient evidence to consider any of them as established. It is known that the β-MSH level in the circulation tends to parallel that of ACTH, being high when cortisol secretion is low and low following administration of adrenocortical hormones. ACTH has some MSH activity because it contains a sequence of amino acids that is also found in the latter. In certain diseases, high levels of β-MSH in the blood are associated with increased pigmentation of the skin. These are also diseases in which the rate of ACTH secretion is high, but the ACTH is not present in sufficient quantities to produce the pigmentation by itself.

In some animal species, the intermediate lobe appears to be under direct neural control via nerve fibres from the hypothalamus that inhibit its secretion. The existence in the hypothalamus of two factors that influence MSH secretion has been claimed—one an MSH-inhibiting factor (MIF) and the other an MSH-releasing factor (MRF), but the role that these factors play, if any, in the regulation of MSH secretion is uncertain.

The posterior pituitary and its hormones. The posterior lobe of the pituitary gland secretes two hormones: vasopressin and oxytocin. Each is a small polypeptide.

The posterior pituitary is embryologically and functionally a part of the brain (many of the neurological structures considered here are described in the article NERVOUS SYSTEM, HUMAN). It is made up primarily of nerve fibres that end around blood vessels. These nerve fibres are the axons of nerve cells that have their cell bodies in two prominent nuclei of the hypothalamus, the supraoptic and paraventricular nuclei. The blood vessels that supply the posterior lobe come from nearby arteries, and the venous drainage, like that of the anterior lobe, is into the nearby cavernous sinus.

The posterior lobe hormones are formed in the neurons of the supraoptic and paraventricular nuclei and released from the endings of their axons into the capillaries of the posterior lobe. These capillaries have fenestrated endothelial linings. Release is triggered by nerve impulses that travel along these neurons to their endings. The axons from the supraoptic nuclei, whose principal secretion is vasopressin, end mainly in the posterior lobe; the axons from the paraventricular nuclei, which secrete mainly oxytocin, have an appreciable number of endings in the stalk and median eminence as well. Under the electron microscope, the endings of the neurons are found to contain many granules that are 1000–1500 angstrom (1 angstrom = 10^{-10} metre) units in diameter. These granules are probably collections of oxytocin or vasopressin bound to several small proteins called neurophysins. It is still uncertain how the hormones pass from the nerve endings into the blood vessels, although it may be by emeiocytosis or by dissolution of the granules.

Herring bodies

The supraoptic and paraventricular neurons contain globules of a material that takes on certain specific stains (*e.g.*, the Gomori stain). In mammals, they are the only neurons that stain in this fashion. The stained globules, called Herring bodies, are apparently aggregations of carrier-bound posterior pituitary hormones, and the material is known as "neurosecretory." If the axons of the supraoptic and paraventricular nuclei are cut, neurosecretory material disappears beyond the cut and accumulates just proximal to it. Thus it appears that oxytocin and vasopressin are manufactured in the cell bodies of the neurons and transported along the axons to their endings. Most, if not all, neurons secrete chemical agents at their axon terminals, and there is evidence that many of these secreted chemical agents are synthesized in part in the cell bodies of the neurons and carried along their axons to the endings.

Vasopressin. Vasopressin is the antidiuretic hormone. It acts primarily on the walls of the terminal portions of the kidney tubules, causing an increase in water reabsorption. This makes the urine more concentrated and consequently dilutes the body fluids. Vasopressin plays an important role in maintaining the body's water and electrolyte balance. The hormone acts by way of cyclic adenosine monophosphate. It has a half-life in the circulation of only three minutes and is metabolized in the liver and kidneys.

Oxytocin. Oxytocin acts on muscle-like cells (myoepithelial cells) in the walls of the ducts of the breast. Contraction of these cells squeezes milk out of the ducts and consequently out of the nipples to the exterior. Oxytocin also induces contractions of the uterine muscle, but this action is strong only in the estrogen-dominated uterus; *i.e.*, when the estrogen blood-level is high. Oxytocin aids in parturition and may also assist the movement of sperm up the female genital tract after sexual intercourse. The half-life of oxytocin in the circulation is approximately the same as that of vasopressin, and it is metabolized for the most part in the kidneys.

The regulation of vasopressin and oxytocin secretion is considered in the paragraphs that follow.

THE STRUCTURE AND ENDOCRINE FUNCTIONS OF THE HYPOTHALAMUS

The hypothalamus is not only a major regulator of endocrine secretion, it is also an endocrine gland in its own right, as its nerve cells secrete blood-borne factors that regulate anterior pituitary activity, water balance, and milk secretion. It forms the anterior end of the stem of the brain. It is bounded on each side by the temporal lobes of the cerebral cortex, above by the thalamus, and behind by the midbrain. The bottom portion of the hypothalamus is called the tuber cinereum, and its midportion, from which the portal hypophysial vessels originate, is the median eminence of the tuber cinereum.

Morphology of the hypothalamus

The hypothalamus contains many nuclei that regulate a variety of endocrine and vegetative, or involuntary, functions. The supraoptic and paraventricular nuclei, the large-celled nuclei that regulate posterior pituitary secretion, are mentioned above. The axons of the cells in these nuclei pass to the median eminence and posterior pituitary, forming the hypothalamo-pituitary tract. In the median eminence are many nerve endings closely associated with the primary plexus of the portal hypophysial vessels. It is probable that most of these endings secrete the releasing and inhibiting factors that regulate

anterior pituitary secretion. The major factors are summarized in Table 1. There may also be a growth hormone inhibiting factor (GHIF) and a prolactin stimulating factor (PSF). Thyrotropin releasing factor (TRF) has been isolated and synthesized; it is a tripeptide containing three amino acid residues. The other factors are probably polypeptides, but their exact structure has not been determined. At least some of them appear to act via cyclic AMP, but the details of their actions and metabolism are unknown.

There are few cell bodies in the median eminence; therefore, most of the neurons that secrete the factors affecting anterior pituitary function must have their cell bodies located elsewhere. The neurons concerned with gonadotropic hormone secretion appear, for the most part, to have their cell bodies in the arcuate nucleus near the ventromedial nucleus. The neurons concerned with the regulation of thyroid-stimulating hormone secretion have their cell bodies in the anterior hypothalamus. The locations of the cell bodies of the other neurons that secrete releasing and inhibiting factors are unknown.

The regulation of growth hormone and vasopressin secretion

The control of growth hormone secretion is an example of the regulation of anterior pituitary secretion mediated by the hypothalamus. The major factors that increase the secretion of this hormone are energy deficiencies, stressful stimuli, and certain amino acids. Presumably these stimuli all act on the nervous system in different ways, but the net effect of them all is stimulation of the neurons that secrete growth hormone releasing factor (GRF). This factor is liberated from the endings of these neurons into the portal vessels and passes by this route to the anterior pituitary where it stimulates release of growth hormone.

The control of the secretion of vasopressin is an example of the type of neuroendocrine reflex that controls posterior pituitary secretion. Vasopressin secretion is increased when the osmolality, or osmotic pressure, of the blood plasma increases; *i.e.*, when plasma becomes more concentrated. It is also increased by a decrease in the circulating blood volume, by pain, and by certain drugs.

Osmotic control is mediated through cells in the hypothalamus that are sensitive to changes in the osmolality of the body fluids. When the pressure increases, these cells bring about an increase in the rate of discharge of the supraoptic neurons and the amount of vasopressin released from their endings is increased. The vasopressin acts on the kidneys, causing water retention and thus diluting the body fluids back toward their original osmolality. With the return of normal osmotic pressure the stimulus to increased vasopressin secretion is abolished. Conversely, a fall in plasma osmolality decreases the discharge rate in the supraoptic neurons; less vasopressin is secreted; less water is reabsorbed in the kidney; and water is lost in the urine until the plasma osmolality is again restored to normal. Thus the osmoreceptor-vasopressin mechanism is a feedback mechanism, which, in the absence of complicating factors, constantly operates to maintain the plasma osmolality at a normal level.

Vasopressin secretion is also increased by a decrease in blood volume and decreased by an increase in blood volume. This type of control of vasopressin is mediated through pressure-change receptors in the large arteries, veins and heart. When blood volume is increased, venous pressure rises. This initiates increased discharge in the nerves from the pressure sensors in the large veins and the atria of the heart. When the increase in blood volume is marked, arterial blood pressure also rises and there is increased discharge from the arterial pressure sensors in the carotid sinus and arch of the aorta as well. The increased discharge inhibits vasopressin secretion. Conversely, when blood volume is decreased, as it is, for instance, after severe bleeding, the rate of discharge from the pressure receptors decreases and vasopressin secretion is increased.

The supraoptic neurons are nerve cells as well as endocrine cells. It is, therefore, not surprising that they also respond to painful stimuli with increased discharge, and to certain drugs that act on the brain. The main control of vasopressin secretion normally is osmotic, but when the other mechanisms are activated they interact with the osmotic stimuli in complex but predictable patterns.

Regulation of oxytocin secretion

The regulation of oxytocin secretion is another example of neuroendocrine integration. A prime stimulus to oxytocin secretion is the infant suckling at the breast. The touch receptors, stimulated by the baby's mouth, initiate impulses which ascend the spinal cord and brainstem to the paraventricular nuclei. The paraventricular neurons become excited, and oxytocin is secreted into the bloodstream at their endings in the median eminence and posterior lobe. The oxytocin causes the mammary ducts to contract, and milk pours out into the waiting mouth of the infant.

Oxytocin also plays a role in the delivery of the baby at the end of pregnancy. The hormone apparently does not initiate labour, but once the uterus starts to contract, the pressure of the infant's head against the tissues initiates nerve impulses that ascend to the paraventricular nuclei. Oxytocin secretion is increased, and the hormone strengthens the contractions of the uterus, aiding the process of labour. There is also evidence that, at least in some species, oxytocin liberated by nerve impulses from the genital region during copulation can increase sperm transport through the nonpregnant uterus. Spermatozoa move up the genital tract more rapidly than can be accounted for by their own swimming motion, and contractions of the uterus appear to propel them along. It is uncertain, however, whether oxytocin aids sperm transport in humans.

The regulation of pituitary secretion is not the only endocrine function of the hypothalamus. It also exerts a minor effect on insulin secretion via the vagus nerves, and increases adrenal medullary secretion. Available evidence indicates that the hypothalamus mediates the increase in epinephrine and norepinephrine secretion seen during such emotional states as anger and fright.

THE PANCREATIC ISLETS

The pancreas is both an exocrine and an endocrine gland. Its exocrine secretion is a juice rich in digestive enzymes that is secreted by way of the pancreatic ducts into the duodenum. Its endocrine secretions are released into the blood stream from the islets of Langerhans, collections of secretory cells scattered throughout the pancreas. The islet cells secrete the polypeptide hormones insulin and glucagon, and they may also secrete the polypeptide hormone gastrin.

Structure. The pancreas stretches across the upper abdomen (see also DIGESTIVE SYSTEM, HUMAN). Its head is on the right side of the body closely applied to the

From W. Bloom and D.W. Fawcett, *A Textbook of Histology*, 9th ed. (1968); W.B. Saunders Company

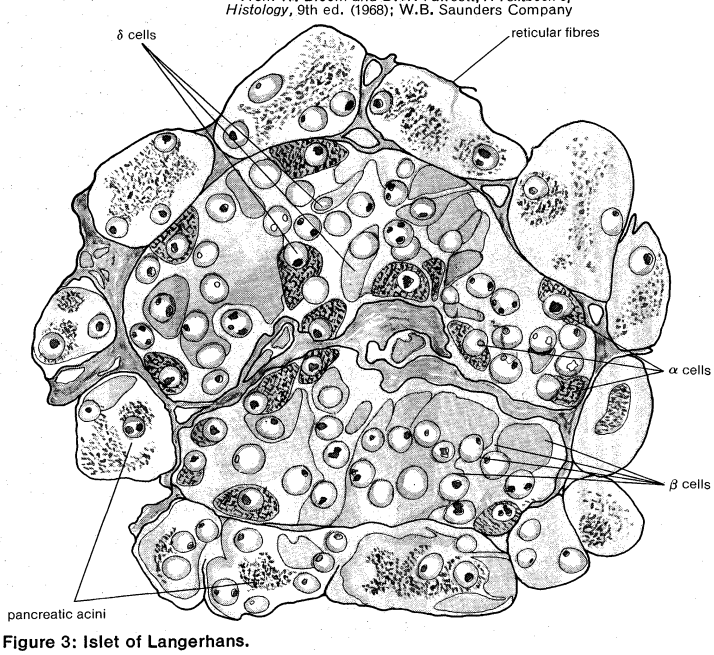

Figure 3: Islet of Langerhans.

duodenum, while its tail reaches almost to the spleen in the left upper corner of the abdominal cavity.

The pancreas receives its blood supply from several major abdominal arteries: the splenic, hepatic, and superior mesenteric. Its effluent blood drains by way of the splenic and superior mesenteric veins to the hepatic portal vein, and thence to the liver. The hepatic portal system is a system of blood vessels that arises in the intestine and other viscera and ends in the liver. Blood from the liver passes by way of the hepatic veins to the general circulation. The hormones of the pancreas (and the gastrointestinal tract) are unlike other hormones in that they are secreted into the hepatic portal system, and consequently the liver is exposed to higher concentrations of these hormones than are other tissues in the body. This fact may have physiological significance, since glucagon and insulin exert an effect on liver cells.

Unmyelinated sympathetic nerve fibres enter the pancreas, mainly from the celiac plexus. Myelinated parasympathetic branches of the vagus nerves also penetrate the gland. Most of these fibres end around the acinar cells that produce the pancreatic exocrine secretion, but some unmyelinated fibres are occasionally seen in close apposition to granulated endocrine cells in the islets. Stimulation of the right vagus nerve increases insulin secretion in animals, and norepinephrine, the mediator at sympathetic nerve endings, exerts both excitatory and inhibitory effects on insulin secretion, the details of which are considered later.

The islets are round or ovoid structures approximately 100 millionths of a metre in diameter. There are approximately 1,000,000 islets in the pancreas of an adult human, and islet tissue makes up about 1 percent of the total weight of the organ. The islets are diffusely distributed throughout the pancreas, but they are somewhat more numerous in the tail than in the head. Each islet contains granulated cells which, on the basis of their staining characteristics, are divided into alpha, beta, and delta, or D, cells. The alpha cells secrete glucagon, the beta cells secrete insulin, and the delta cells probably secrete gastrin. Approximately 70 percent of the islet cells are beta cells, while 25 percent are alpha cells and 5 percent are delta cells.

Carbohydrate metabolism

Islet cell hormones. In considering the functions of the endocrine portion of the pancreas, it is necessary to refer to a number of steps in intermediary metabolism, and especially to two steps involved in the metabolism of the principal sugar in the body, glucose. The details of intermediary metabolism are treated in the article METABOLISM but for convenience a brief summary is presented here.

The products of the digestion of dietary carbohydrates are sugars containing five or six carbon atoms, of which glucose is the most abundant. The products of protein digestion are amino acids, and those of fat digestion are fatty acids and glycerol. Glucose and other simple sugars, amino acids, and fatty acids are absorbed into the bloodstream from the intestine and metabolized in the liver and other parts of the body. Glucose enters cells, and the intracellular glucose either polymerizes to the storage form of carbohydrate, glycogen, or breaks down in orderly steps to a substance called pyruvate. In the absence of oxygen, the pyruvate is converted to lactate, while in the presence of oxygen, it enters the so-called Krebs cycle and is burned to carbon dioxide and hydrogen ions. The hydrogen ions are then oxidized to water, and coupled with this oxidation is the formation of large amounts of the energy-rich phosphate compound, adenosine triphosphate (ATP). ATP provides a ready storehouse of energy for the various energy-requiring processes in the body. Fatty acids are converted to acetylcoenzyme A, and the acetylcoenzyme A enters the Krebs cycle. Amino acids are converted to several intermediates in the metabolic pathways for glucose, and are burned in a similar fashion. It should be noted that glucose, amino acids, and fat can also be formed from intermediates in the Krebs cycle or related small molecules. Little fat is converted to glucose, but large amounts of glucose are converted to fat and there is active formation of glucose from noncarbohydrate substances, particularly from amino acids, by a process known as gluconeogenesis.

Insulin synthesis

Beta cell hormone: insulin. Insulin is synthesized and secreted by the beta cells of the islets. Like other proteins and polypeptides, it is synthesized in the endoplasmic reticulum of the cells. It then moves to the Golgi apparatus, where packets of newly synthesized insulin acquire a surrounding membrane. It is stored in membrane-lined secretory granules. The insulin in the secretory granules is in round or rhombic aggregates in which the insulin is apparently polymerized or complexed with zinc. When the insulin is secreted, the granules move to the periphery of the cell and discharge their contents by the process of emeiocytosis, leaving the cell membrane intact. Once outside the cell, the insulin apparently moves by diffusion across the basement membrane of the beta cell, across the basement membrane of the adjacent capillary endothelium, and through the fenestrated endothelium of the capillary wall into the blood system.

Human insulin is a polypeptide containing 51 amino acid residues. It is made up of two chains (the A and B chains) linked by sulfur-sulfur (disulfide) bridges. Most mammalian insulins differ from one another by only one to four amino acid residues. These differences are generally not great enough to reduce biological activity, but they are great enough to make the insulins antigenic when injected in other species; *i.e.*, they stimulate the formation of anti-insulin antibodies.

Insulin is formed as a single polypeptide chain that is then folded, permitting the disulfide bonds to be formed. The folded molecule, known as proinsulin, is then subjected to peptide chain cleavage, which splits off the amino acid chain connecting the A and B chains. The connecting peptide remains in the beta granules and is secreted along with the insulin. Neither the connecting peptide nor proinsulin have appreciable biological activity. (For a more detailed discussion of amino acid linkages and protein structure, see PROTEIN.)

The half-life of insulin in the circulation is about 30 minutes. It is degraded in almost all the tissues of the body, but most actively in the liver and kidneys.

Functions of insulin

Insulin increases the entry of glucose into muscle and other cells in the body, resulting in a decline in the glucose level in the blood. The mechanism by which this increased entry is effected is unknown, but the widespread metabolic effects of insulin can be explained largely by its fundamental action on glucose entry into cells. It seems clear, however, that insulin has a number of fundamental actions that are independent of its effect on glucose transport. These additional actions include increased movement of amino acids into cells, an increase in the difference in electrical potential across certain cell membranes, and inhibition of hormone-sensitive lipase, the enzyme in adipose tissue that catalyzes the breakdown of fats to fatty acids. The action on amino acid transport fosters protein synthesis and growth; the action on the membrane potential aids entry of potassium into cells; and the action on adipose tissue inhibits release of free fatty acids into the circulation.

The consequences of the increased entry of glucose into cells produced by insulin include not only a decline in blood sugar but a variety of other metabolic changes that are best understood by cataloging the defects that are observed in the presence of insulin deficiency. The sum of these defects is the picture known in humans as diabetes mellitus. This common, but serious, endocrine disorder is discussed in detail in the article ENDOCRINE SYSTEM DISEASES AND DISORDERS; the abnormalities associated with it are only summarized here. During insulin deficiency the blood sugar rises, and there is increased excretion of glucose in the urine. This leads to loss of water from the body and thirst and dehydration. The lack of glucose inside cells activates mechanisms that increase the breakdown of fats and proteins. Products of this breakdown are burned for energy. There is increased appetite caused by inhibition of the appetite-inhibiting cells in the brain. The accumulation of free fatty acids to increased formation of acetoacetic acid and β-hydroxybutyric acid, and their partial excretion in the lungs, giv-

ing rise to "acetone breath." These two acid ketone bodies are the cause of the ketosis seen in the disease. Furthermore, when these ketone bodies are produced in excess of the ability of the body to buffer them, the acidity of the body fluids increases to a serious degree. If untreated, the acidosis is fatal.

All these abnormalities are reversed by insulin. Providing intracellular glucose shuts off the excess fat catabolism, stops the marked production of glucose from amino acids, and permits the normal body defenses to restore acid–base balance to normal.

Large amounts of insulin depress the blood glucose to subnormal levels (hypoglycemia). Glucose is an obligatory fuel for the brain and consequently hypoglycemia is associated with disordered brain function. The symptoms start with nervousness and tremulousness and can progress to convulsions, coma, and death.

Regulation of insulin secretion

Since insulin is of pivotal importance to normal metabolism, it is not surprising that its secretion is regulated by a number of different factors. The primary regulation is by way of a direct feedback of glucose on the insulin-secreting cells. The resting, relatively low level of insulin secretion is increased by a rise in the circulating glucose and decreased by a fall. The glucose must enter the beta cells and be partially metabolized to exert its stimulatory effect. Some event during the metabolism of the glucose apparently leads to increased formation of cyclic AMP, which, in turn, stimulates insulin secretion. Insulin secretion is also increased by certain amino acids and by β-keto acids such as acetoacetic acid. Insulin decreases circulating amino acid levels by increasing their entry into muscle, and decreases β-keto acid levels because it combats ketone body formation. In addition, insulin secretion is increased by stimulation of the right vagus nerve in animals, but the physiological and pathological significance of this factor is uncertain. A variety of other factors affect insulin secretion, but most of them either affect glucose metabolism or cyclic AMP. Normal secretion also requires the presence of adequate quantities of calcium and potassium ions.

There is considerable evidence that agents that stimulate α-adrenergic receptors inhibit cyclic AMP formation, and those that stimulate β-adrenergic receptors stimulate cyclic AMP formation. Alpha-adrenergic stimulating agents inhibit insulin secretion, and β-adrenergic stimulating agents increase insulin secretion. Epinephrine has both α and β actions, so this catecholamine both inhibits and stimulates insulin secretion. The inhibitory effect usually predominates. Norepinephrine exerts a similar predominately inhibitory effect. Insulin secretion is also increased by sulfonylurea compounds such as tolbutamide, and these drugs may act by stimulating cyclic AMP formation in the islets. Tolbutamide and related oral hypoglycemic agents have seen extensive use in the treatment of diabetes, but their efficacy has been questioned. They work only in relatively mild diabetes in which pancreatic islets are still functioning, since the hypoglycemic effect is due to their ability to stimulate insulin secretion.

Another important group of agents that stimulate insulin secretion are the gastrointestinal hormones, which are secreted when food enters the stomach and small intestine. Their properties are considered below. Stimulation of insulin secretion is produced by gastrin, cholecystokinin-pancreozymin (CCK), secretin, and probably glucagon-like immunoreactive factor (GLI) found in the intestinal lining. Pancreatic glucagon also stimulates insulin secretion. It is not established which of the "gut factors" is the physiological stimulus to insulin secretion after meals, but it has been determined that glucose and amino acids in the intestine increase insulin secretion. Furthermore, the increases in insulin secretion produced by glucose or amino acids are greater when these substances are given by mouth than when they are given intravenously. The increase in insulin secretion produced by food in the gastrointestinal tract has physiological value, since it promotes a more rapid and complete utilization of the products of digestion, once they are absorbed.

The increase in insulin secretion produced by a glucose load is biphasic: an initial short-lived increase that apparently represents release of preformed hormone, followed by a slowly developing, prolonged release that appears to represent release of newly synthesized hormone as well. The first component is blocked by agents that block activation of cyclic AMP, while the second is blocked by antibiotics that inhibit protein synthesis.

In summary, insulin secretion is increased by increased amounts of glucose and amino acids in the intestine and in the blood. The hormone acts to increase the entry of glucose and amino acids into the cells, promoting their metabolism and utilization. Insulin secretion thus rises after meals and insulin has been appropriately called the "hormone of abundance."

Alpha cell hormone: glucagon. Glucagon is secreted by the alpha cells of the islets. These cells contain uniform, dense secretion granules. Hormone synthesis and secretion in these cells is presumably similar to that of insulin in the beta cells, but it has not been studied in as great detail.

The structure of porcine glucagon is known. It is a simple polypeptide containing 29 amino acid residues. The structure of glucagon in other species, including man, probably differs by varying numbers of amino acids but is basically similar.

A substance similar to glucagon is found in the walls of the stomach and small intestine. This intestinal glucagon cross-reacts with pancreatic glucagon in immunoassays and hence has been called glucagon-like immunoreactive factor (GLI), but it now appears that it is not identical to pancreatic glucagon.

Pancreatic glucagon is metabolized rapidly, with a half-life that is even shorter than the 30-minute half-life of insulin in man. Glucagon is presumably metabolized to a large extent in the liver, but the details of its metabolism and excretion are unknown.

Functions of glucagon

Glucagon acts on the liver to increase the breakdown of glycogen (glycogenolysis). The glucose thus formed enters the bloodstream and the blood glucose level rises. Glucagon also increases the formation of glucose from amino acids (gluconeogenesis). Its action on the liver is mediated by cyclic AMP. An additional action of both pancreatic glucagon and GLI is stimulation of insulin secretion.

The secretion of glucagon is increased by a decline in blood glucose and decreased by an increase in blood glucose, presumably by a direct effect on the secretory cells. In this respect, it differs from GLI; the secretion of GLI is increased by glucose in the intestinal tract, and GLI may be one of the "gut factors" that increases insulin secretion. The secretion of pancreatic glucagon is increased during fasting, and it seems probable that pancreatic glucagon is a "hormone of fasting" which helps keep the blood glucose from falling to dangerously low levels during starvation.

Glucagon secretion is also increased by amino acids. Because amino acids increase the secretion of both insulin and glucagon, it has been suggested that after a protein meal the insulin fosters the utilization of the amino acids while the glucagon prevents the hypoglycemia which the insulin would otherwise produce.

Delta cell hormone: pancreatic gastrin. Tumours made up of delta cells secrete excessively large amounts of gastrin and normal delta cells contain gastrin, the hormone that is also secreted by the gastric mucosa and increases gastric acid secretion. The delta cell tumours produce a disease in humans called the Zollinger-Ellison syndrome, which is characterized by severe, intractable ulcers of the stomach and duodenum due to the excess acid secretion. The role of pancreatic gastrin in normal physiology, however, is unknown.

THE PARATHYROID GLANDS

There are usually four parathyroid glands, two behind each lateral lobe of the thyroid gland. Their number and location, however, may vary considerably. They receive blood from local branches of the thyroid artery and drain into branches of the thyroid veins. A few nonmyelinated nerve fibres accompany the blood vessels.

Each parathyroid gland is well vascularized and disk-shaped, measuring approximately three by six by two millimetres. Each contains many small cells called chief cells, which secrete parathyroid hormone. There are also smaller numbers of large, granulated cells containing many mitochondria; these are called oxyphil cells, and their function is unknown.

The structure of bovine and porcine parathyroid hormone is known. Bovine parathyroid hormone is a simple peptide containing 84 amino acid residues. Human parathyroid hormone has a similar amino acid composition, but its exact structure is not yet known. It appears to have a relatively short half-life, but little is known about its metabolism and excretion.

Parathyroid hormone and calcium metabolism. Two hormones, parathyroid hormone and calcitonin, are primarily involved in the maintenance of a normal concentration of calcium, and specifically of ionized calcium, in the body fluids. The former hormone, which raises plasma calcium, is secreted by the parathyroid glands, while the latter, which lowers it, comes from the thyroid. The stability of the plasma calcium concentration is essential for a wide variety of body functions, including particularly the maintenance of normal nerve and muscle excitability. Long-term changes in plasma calcium bring about alterations in the structure of the bones.

Calcium enters the body through the gastrointestinal tract and leaves it in large part through the kidneys. The principal calcium storage site is the bones, which contain large quantities of calcium salts. Hormones and other calcium regulating factors, in consequence, act on the gastrointestinal tract, the kidneys and the bones. The total amount of calcium in the body of an adult human is about 1,110 grams (2.4 pounds). The normal concentration in circulating plasma is approximately 10 milligrams per 100 millilitres (5 milliequivalents per litre). There is normally an approximate reciprocal relationship between the calcium and the phosphate in the body. Whenever the product of the calcium concentration and the phosphate concentration in the body fluids exceeds a value called the solubility product, calcium phosphate precipitates. Local changes which alter the calcium or phosphate concentration may be part of the process by which bone calcifies. The details of the calcification process, however, are not known.

Role of vitamin D in calcium metabolism

In addition to the parathyroid hormone and calcitonin, vitamin D plays an important role in the regulation of calcium metabolism. This vitamin is formed in the body from dietary precursors by the action of sunlight on the skin (see also VITAMIN). It is converted to compounds which act mainly to facilitate the transport of calcium across the intestinal mucosal cells into the circulating body fluids.

A low plasma calcium level leads to hypocalcemic tetany, a condition in which there are spasms of the skeletal muscles. These are especially marked in the extremities and the larynx, and if untreated, laryngeal spasm eventually obstructs the airway and leads to death by suffocation. A high level of plasma calcium causes irritability, mental symptoms, and kidney stones as a result of calcium salt precipitation in the urinary tract.

Parathyroid hormone functions in a variety of ways to increase plasma calcium. It acts on the skeleton to increase the amount of calcium moving from the bones to the body fluids. Its action is by way of cyclic AMP, but the exact molecular mechanism responsible for the increased bone dissolution is not known. In addition, parathyroid hormone augments the action of vitamin D in facilitating transport of calcium out of the intestinal lumen into the circulating body fluids. It also acts on the kidney to increase phosphate excretion. This tends to lower plasma phosphate, and secondarily, because of the reciprocal relation between calcium and phosphate, to elevate plasma calcium.

Parathyroid secretion is regulated directly by a negative feedback effect of calcium on the parathyroid gland itself. A rise in plasma calcium inhibits, and a fall stimulates, parathyroid hormone secretion. The gland thus provides an excellent example of simple negative feedback control of the secretion of an endocrine gland. Changes in plasma magnesium appear to exert parallel effects, but the major regulation is apparently via calcium feedback.

The role of calcitonin. The cells responsible for the secretion of calcitonin have been described previously in the discussion of the thyroid gland. These parafollicular cells are found between the thyroid follicles in humans and other mammals, but in birds, fish, and other non-mammalian vertebrates they are collected into a pair of separate glands, the ultimobranchial bodies.

Human calcitonin is a polypeptide with a ring of amino acids at one end closed by the disulfide bonds of two half-cystine residues. Little is known about its metabolism or excretion. It acts on bone to counteract the effect of parathyroid hormone, possibly through an anti-cyclic AMP action. It not only lowers the plasma calcium, but it also lowers the plasma phosphate.

The regulation of calcitonin secretion appears to be mediated by a direct negative feedback of calcium on the cells secreting the hormone. In this case, a rise in calcium stimulates and a fall inhibits calcitonin secretion.

The exact physiological role of calcitonin is uncertain. Although the effects of its injection can be demonstrated in man, there is very little derangement of calcium metabolism after thyroidectomy. On the other hand, when the parathyroid glands are removed, plasma calcium drops and the individual develops hypocalcemic tetany, which, if untreated, is fatal.

THE GASTROINTESTINAL MUCOSA

The hormones secreted by cells in the mucosa, or lining, of the stomach and small intestine are of historical as well as current interest, since the whole "chemical messenger" concept stemmed from work on one of them. Six gastrointestinal hormones are listed in Table 1 (counting gastrin I and II as a single hormone). The first three of these are well established, and the first two have been synthesized. The fourth probably exists as a separate hormone, and the fifth and sixth are hypothesized to explain effects that appear to be hormonally mediated and cannot be explained by actions or interactions of the other four. These interactions are extensive, and, although gastrointestinal hormones in addition to these six may exist, it does not seem necessary at present to postulate their existence.

The cells secreting gastrin are modified epithelial cells embedded for the most part in the walls of the gastric juice-secreting pyloric glands in the distal portion (antrum) of the stomach. The identity of the cells secreting the other hormones is not known.

Hormones. *Gastrin.* Gastrin is secreted primarily from the mucosa of the antral portion of the stomach, although small amounts may also be secreted by cells in the mucosa of the small intestine (intestinal gastrin). In humans and in all other species examined gastrin is a mixture of approximately equal amounts of two components, gastrin I and gastrin II. Each contains the same 17 amino acid residues, but gastrin II has a sulfate ($-SO_3H$) group on the tyrosine residue in position 12, while gastrin I lacks this sulfate group. The physiological activities of these two gastrins are approximately equal. A tetrapeptide containing amino acid residues 14–17 of gastrin has all the activity of gastrin, although the total activity is about 10 percent of the parent compound. Other polypeptides also have gastrin activity.

Action of gastrin

The principal action of gastrin is to increase gastric secretion of acid and the proteolytic digestive enzyme, pepsin, but it also increases the movements of the stomach (gastric mobility) and has a variety of other actions. Gastrin is secreted when the antrum of the stomach is distended and when the mucosa is bathed by alcohol, protein, or the products of protein digestion. Stimulation of the vagus nerve to the stomach also stimulates gastrin secretion, and vagal stimulation acts directly to increase gastric acid secretion and motility. Thus, there is a neuroendocrine link between the vagus nerve and gastrin secretion, and the actions of the neural

and endocrine mechanism abet and supplement each other. Gastrin has been measured in the circulating blood of humans by radio-immunoassay, but very little is known about its metabolism and excretion.

Secretin. In England in 1902, two physiologists, W.M. Bayliss and E.H. Starling, first demonstrated that the excitatory effect of food in the small intestine on pancreatic secretion was due to a blood-borne factor. In subsequent experiments, they extracted a substance from the duodenal mucosa which they called secretin. They appreciated, however, that the significance of their discovery went far beyond secretin itself. They suggested that other cells in the body might secrete "chemical messengers" that entered the circulation and acted on tissues some distance away, and they coined the term hormone to categorize these substances. The list of "chemical messengers" has now grown to more than 50, and the whole science of modern endocrinology attests to the correctness of the hypothesis advanced by Bayliss and Starling on the basis of their work with secretin.

Secretin is secreted by the duodenal mucosa when the mucosa is bathed with acid or the products of protein digestion. It has a number of effects, the principal one being an action on the pancreas to cause the secretion of a dilute pancreatic juice rich in bicarbonate. The structure of porcine secretin is known. It is different from gastrin and CCK, and it resembles pancreatic glucagon; indeed, 14 amino acid residues occupy the same positions in the two hormones. Little is known as yet about the metabolism or excretion of secretin.

Cholecystokinin-pancreozymin (CCK). Experiments some years ago demonstrated that there was a hormonally mediated contraction of the gallbladder when food, particularly fat, was placed in the duodenum, and that there was, as well, a hormonally mediated increase in the secretion of an enzyme-rich pancreatic juice produced by food in the duodenum. It was initially thought that a gastrointestinal hormone called cholecystokinin was responsible for the gallbladder contraction and another hormone called pancreozymin responsible for the increased pancreatic secretion. It has since been proved that a single gastrointestinal hormone is responsible for both actions, and this hormone has been named cholecystokinin-pancreozymin (CCK). This hormone has other actions as well, including some gastrin activity.

The chemistry of CCK

The amino acid composition of porcine CCK is known, but the exact sequence of its 33 amino acids has not yet been determined. It is chemically similar to gastrin, and, like gastrin, contains a sulfated tyrosine residue near the C-terminal end of the molecule. As yet, little is known about its metabolism and excretion.

It is interesting that a polypeptide with a structure and actions that resemble both gastrin and CCK has been isolated from the skin of an Australian frog. This material, caerulein, is being used to produce gallbladder contraction in humans.

Intestinal glucagon. Another apparent gastrointestinal hormone is a factor in the intestinal mucosa which closely resembles pancreatic glucagon. This intestinal glucagon cross-reacts with glucagon in some immunoassays, but although its exact structure is unknown, it appears to differ from pancreatic glucagon. Because of its immune reactions, it has been called glucagon-like immunoreactive factor, or GLI. Its concentration in blood appears to rise after a meal. Its properties apparently resemble those of secretin and pancreatic glucagon.

Other gastrointestinal hormones. The interactions between the gastrointestinal hormones mentioned above offer an explanation for various responses that were thought to be mediated by other gastrointestinal hormones. For example, it was postulated that a hormone called enterogastrone was secreted from the intestinal mucosa and acted on the stomach to inhibit gastric secretion and emptying. It now appears that this inhibition is caused principally by the action of secretin. On the other hand, two effects presumably mediated by hormones remain unexplained, and there may be separate hormones from the intestinal mucosa that are responsible for them. One is the increased contractions of the intestinal villi when food is in the intestine, and the postulated hormone in this case is called villikinin. The other is the increased intestinal gland secretion when food is in the intestine, and the postulated hormone is called enterocrinin. Proof of the existence of these hormones awaits their isolation and chemical identification.

Cross-reactions. Although gastrin, CCK, and secretin both have a principal action, it is now clear that there are also extensive cross-reactions among these three gastrointestinal hormones and presumably with GLI as well. Gastrin, CCK, and secretin all stimulate insulin secretion; in addition, gastrin and CCK each stimulate gastric acid and pepsin secretion, gastric and intestinal motility, pancreatic secretion of enzymes and bicarbonate ions, liver secretion of bicarbonate ions, contraction of the gallbladder, and secretion of certain mucus-secreting glands in the duodenum. Secretin inhibits gastric acid secretion and gastric and intestinal motility, but otherwise its actions resemble those of gastrin and CCK. Insofar as they have been tested, the actions of pancreatic glucagon, and presumably those of intestinal glucagon as well, resemble those of secretin. In addition, the various gastrointestinal hormones synergize with, and also antagonize, one another, so that the pattern of gastrointestinal responses depends not only on single hormones but on interactions between the various hormones.

THE THYMUS

The thymus is a lymphoid organ located behind the sternum in the chest. It is made up of an outer cortex densely packed with lymphocytes and an inner medulla containing more widely scattered lymphocytes and cells arranged in clusters (Hassall's corpuscles). The arterial supply to the organ comes from branches of the mammary and thyroid arteries, and the veins drain into the innominate and thyroid veins. The few nerve fibres that enter the gland probably regulate the calibre of its blood vessels.

The thymus is large in fetal life and infancy and undergoes gradual involution with advancing age. The Hassall's corpuscles may be remnants of the branchial pouches from which the thymus arose during embryonic development. Adrenocortical hormones cause lymphoid tissue to atrophy, and since the thymus is a lymphoid organ, its size decreases markedly in individuals subjected to stress. In patients who have died after prolonged, severe infection, for example, the thymus is markedly atrophic. On the other hand, the thymus is relatively large in individuals in whom death has been sudden and not preceded by prolonged illness.

The thymus and cellular immunity

The thymus is known to be the key to the production of the lymphocytes responsible for cellular immunity. There are two types of immunity: humoral immunity, mediated by circulating antibodies, and cellular immunity, which is delayed in onset (see IMMUNITY). Cellular immune responses include the delayed hypersensitivity reactions responsible for such phenomena as rejection of skin, kidney, and heart grafts or transplants from other individuals (homografts). Early in life, the lymph nodes become populated with lymphocytes capable of mediating this type of response. It appears that the lymphocytes are affected by a thymic hormone. In animals, removal of the thymus in early life prevents the rejection of tissue grafts from other animals, and in thymectomized animals thymic grafts in tissue chambers with pores too small to permit passage of cells restore the ability to develop delayed hypersensitivity reactions. Cell-free extracts of thymic tissue accelerate the rejection of skin grafts and increase the number of circulating lymphocytes. The hormonal factor involved seems to be a polypeptide of relatively low molecular weight and has been called thymosin. The details of its formation and function remain to be determined.

THE PINEAL BODY

The pineal body properly belongs in the list of organs with suspected rather than proved endocrine functions. It is located deep between the cerebral hemispheres of

the brain at the top of the midbrain. The pineal contains neuroglia and cells which look as if they might be secretory. The gland is large in children and begins to involute before puberty. With advancing age in humans, small deposits of calcium and magnesium phosphate and carbonate (pineal sand) accumulate, making the structure visible on X-rays of the skull. The pineal receives a sympathetic nerve supply by way of sympathetic fibres that ascend through the sympathetic cervical ganglia from the chest. It receives blood from arterial vessels in the vicinity, and its effluent blood drains through the vein of Galen to dural venous sinuses in the skull.

Postulated functions of the pineal

Numerous endocrine and other functions have been attributed to the pineal, but most of the postulated functions have failed to withstand the test of time and experimental verification. Among the postulated functions in this category are a role in maintaining mental health and secretion of a factor or factors regulating adrenocortical secretion of aldosterone. Pineal tumours are sometimes associated with precocious sexual development and early puberty in boys, and this observation plus some suggestive data in animals indicates that the pineal may be involved in the regulation of gonadal function.

The postulated pineal hormone is melatonin, one of a variety of substances containing the indole ring that are found in the pineal. The pineal manufactures melatonin from 5-hydroxytryptamine (serotonin). Injected melatonin is metabolized to 5-methoxytryptamine, 5-methoxyindoleacetic acid, and 6-hydroxymelatonin, but the fate of endogenous melatonin is unknown. Melatonin lightens the skin of tadpoles, and there is some evidence that it exerts an antigonadotrophic effect in rats, slowing the onset of puberty.

The enzyme responsible for the synthesis of melatonin from 5-hydroxytryptamine is hydroxyindole-*o*-methyltransferase. In the rat, the activity of this enzyme in the pineal undergoes marked diurnal fluctuation, being high during the hours of darkness and low during the hours of light. The changes in enzyme activity have been shown to be neurally mediated and are prevented by cutting the sympathetic nerve fibres to the pineal. Light can alter reproductive cycles in the rat, and it has been suggested that the modifications are brought about, at least in part, through the action of melatonin. Melatonin, however, has not yet been detected in the blood of the rat or the human. In addition, the precocious puberty produced in humans by pineal tumours could well be due to pressure on the hypothalamus. Therefore, it cannot be stated, at least at the present time, that any endocrine function has been established for the pineal body in humans.

THE KIDNEYS

In addition to their excretory function and their role in the regulation of acid–base balance, the kidneys secrete at least two hormones. One of these, renin, acts on a protein in the blood to form a peptide which increases blood pressure and stimulates adrenocortical secretion of aldosterone. The other, the renal erythropoietic factor, stimulates the formation of a protein which increases red blood cell production in the bone marrow.

Kidney hormones. *Renin.* Renin is secreted by the juxtaglomerular cells. These granulated cells are located in the wall of each afferent arteriole, the arterial blood vessel that enters the renal glomerulus. The tubule from each glomerulus doubles back and touches the afferent arteriole at its junction with the glomerulus from which the tubule arose. At this point of contact, the tubular lining is thickened to form the structure known as the macula densa. Juxtaglomerular cells are most prominent and renin content is highest in the afferent arterioles of glomeruli in the outer part of the renal cortex, but renin is found throughout the renal cortex. There are large numbers of unmyelinated adrenergic sympathetic nerve fibres in close association with the juxtaglomerular cells, and some of the fibres appear to end on these cells. Thus, the juxtaglomerular cells appear to be innervated gland cells.

Renin is a protein with a molecular weight of approximately 50,000. It has not been obtained in pure form and its structure is unknown. Like other protein hormones in other endocrine cells, it is stored in granules in the juxtaglomerular cells. Secretion probably occurs by the process of emeiocytosis. Some renin appears to be produced by organs other than the kidney. Appreciable amounts are found in the pregnant uterus, and even in nonpregnant women and in men there are small but measurable amounts of renin in the circulation after removal of both kidneys. The physiological role of this extrarenal renin appears to be negligible.

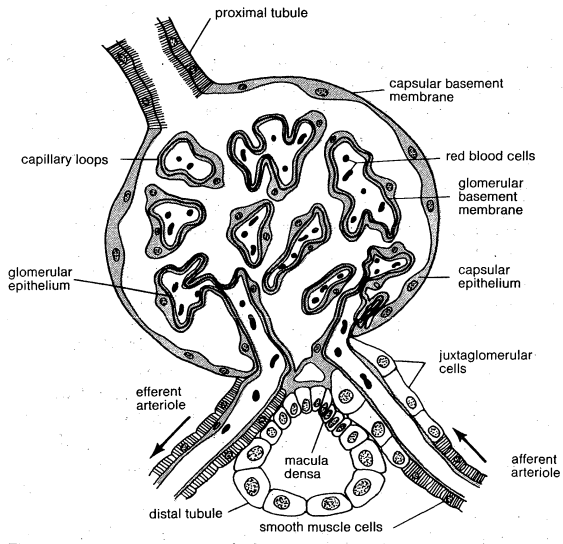

Figure 4: Diagram of a renal glomerulus showing the juxtaglomerular cells and the macula densa in relation to other structures of the kidney.

Renin-angiotensin system

Renin is different from other hormones in that it does not act on a tissue but on a protein in blood. This protein, called angiotensinogen, is formed in the liver, and is a globulin with molecular weight of approximately 58,000. From it renin splits off a decapeptide, angiotensin I. The angiotensin I is in turn converted to angiotensin II, a polypeptide containing eight amino acid residues, by removal of the dipeptide, histidyl-leucine, from the C-terminal end. The conversion is catalyzed by converting enzyme. There is some converting enzyme in plasma, but most of the conversion of angiotensin I to angiotensin II occurs in the lungs. The pulmonary conversion is efficient; it takes a red blood cell less than one second to traverse the pulmonary capillaries, yet during passage through the lungs, conversion of angiotensin I to angiotensin II is about 50 percent complete. It is notable that angiotensinogen can be called a "prohormone" and the liver called an endocrine gland, since angiotensinogen is converted in the blood by the sequential action of renin and converting enzyme into the physiologically active peptide angiotensin II.

Angiotensin II has several actions in the body. It acts on the vascular smooth muscle to produce constriction of small arteries and arterioles. This increases the resistance against which the heart must pump, and the blood pressure rises. Angiotensin II also stimulates the secretion of the sodium-retaining hormone aldosterone from the adrenal cortex. In addition, it may stimulate thirst by an action on the brain and may act on the brain to increase blood pressure by way of increased discharge of the sympathetic nervous system. Its action on blood pressure depends on the sodium and water balance of the individual; when the individual is salt depleted, its pressor activity is low while its aldosterone stimulating activity is maintained or even increased.

The angiotensin II in the circulation is rapidly metabolized, in part by enzymes in the blood, but also to a large degree by a poorly understood mechanism in peripheral vascular beds that appears to remove the peptides from the circulation. Its half-life in humans is less than one minute. Renin has a somewhat longer half-life, about 30–

60 minutes, and is metabolized for the most part in the liver.

Theories of renin secretion

The regulation of renin secretion has been the subject of much research and debate. Three theories have been advanced to explain how the stimuli affecting renin secretion activate the juxtaglomerular cells. A renal baroreceptor theory holds that the rate of renin secretion is inversely proportional to the degree of stretch of the juxtaglomerular cells. A so-called macula densa theory holds that the rate of renin secretion is inversely proportional to the rate at which sodium is transported from the urine to the blood across the macula densa cells. A neural theory holds that the sympathetic nervous system regulates renin via a direct secretomotor nerve supply to the juxtaglomerular cells.

The renal baroreceptor theory was advanced to explain why renin secretion is increased when there is a decline in blood pressure and decreased when the blood pressure rises. The higher the blood pressure, the more the walls of the arteries and arterioles, and hence the juxtaglomerular cells, are stretched.

The macula densa theory was advanced to explain the frequent inverse correlation between the rate of renin secretion and the rate at which sodium is excreted in the urine. According to this view, the macula densa is a sensor that monitors changes in the composition of the urine in the tubules. When the amount of sodium reaching the macula densa is low, or when sodium transport across the macula densa is inhibited by drugs such as diuretics, renin secretion increases.

It has been proved that stimulation of the sympathetic nervous system increases renin secretion, via both the renal sympathetic nerves and the circulating epinephrine from the adrenal medulla. These effects of sympathetic stimulation could be mediated by stretch of the juxtaglomerular cells or by way of induced changes in sodium excretion monitored by the macula densa. The juxtaglomerular cells appear to be innervated, and there is evidence that norepinephrine and epinephrine act directly on the juxtaglomerular cells to increase renin secretion. There is also evidence that cyclic AMP is involved in the secretory process.

These theories are not mutually exclusive. In addition, none of the theories can explain all the experimental data, and it appears that there must be more than one mechanism regulating renin secretion. The operation of renin, angiotensin I and II, and aldosterone in a negative feedback system that helps defend the volume of the body fluids has been described in the section concerning the adrenal glands. The renin-angiotensin system is also responsible for certain forms of high blood pressure in humans. The role of angiotensin in the regulation of normal blood pressure appears to be related to its effect on aldosterone secretion rather than its direct blood pressure-elevating action. Its possible role in the regulation of thirst remains to be determined.

Erythropoietin

Renal erythropoietic factor. It has been known for some time that the formation of red blood cells in the bone marrow is under hormonal control. The hormone involved is called erythropoietin. It is a glycoprotein with a molecular weight of approximately 60,000. It was thought for some time that the kidney secreted erythropoietin, but there is now reason to believe that the kidney secretes instead a substance that acts on or with a substance produced by the liver to produce erythropoietin in the circulation. The substance secreted by the kidney has been called renal erythropoietic factor (REF). Erythropoietin increases red blood cell production by stimulating the conversion of primitive precursor cells in the bone marrow into pro-erythroblasts, bone marrow cells that subsequently mature and are released into the circulation as red blood cells. The half-life of erythropoietin is approximately five hours, and it appears to be inactivated primarily in the liver.

There are apparent similarities between the renin-angiotensin system and the REF-erythropoietin system. It is clear, however, that the two systems are separate. Angiotensin II has no erythropoietic effect, and erythropoietin has no effect on blood pressure or aldosterone secretion.

The amount of erythropoietin in the circulation is increased when the number of red blood cells in the circulation is reduced, as by bleeding, and is decreased when the number of red blood cells is greater than normal; thus, erythropoietin, like so many other hormones, is under negative feedback control. Erythropoietin is also increased in persons who ascend to high altitudes or have their oxygen intake reduced with resulting oxygen lack in the tissues. The part of the kidney that secretes the REF and how its secretion is stimulated is unknown.

It is to be noted that, in humans and some other animal species, erythropoietin remains in the circulation after nephrectomy, and its circulating level can even be increased somewhat by oxygen deficiency and other stimuli. Consequently, it seems probable that the kidney is not the only source of REF. Some renin is also found in the circulation after the kidneys are removed (nephrectomy), but the amounts are physiologically insignificant.

Other kidney factors. In addition to renin and REF, the kidney may secrete a substance that lowers blood pressure. There is some reason to believe that this substance is a prostaglandin. Prostaglandins are unsaturated fatty acids that have widespread but incompletely understood actions in the body. Other investigators have argued that a protein blood pressure-lowering agent is secreted by the kidney. The nature, and even the existence, of a renal blood pressure-lowering factor is uncertain, and only future research can settle the question of whether additional hormones are secreted by the kidney.

Prostaglandins

OTHER POSSIBLE HORMONES AND ENDOCRINE ORGANS

It seems unlikely that the hormones treated above are all the chemical messengers in the human body, and it will be surprising if future research does not lead to the discovery of additional hormones. There are already several indications that as yet unisolated hormones exist. For instance, the level of circulating granulated white blood cells appears to be controlled by a humoral factor that has been tentatively named granulopoietin. The source of this substance is unknown. There is some evidence that the carotid body secretes a hormone that is involved in the control of red blood cell production but that is different from erythropoietin. There have been repeated reports of a humoral factor, sometimes called "third factor," that decreases sodium reabsorption in the proximal tubule portion of the nephrons in the kidney. This "hormone" has not been isolated nor has its source been elucidated, and many investigators have argued that it does not exist. These are but a few examples of current research pointing to the possible existence of other endocrine products and endocrine glands in experimental animals and man.

BIBLIOGRAPHY. The standard endocrinology textbooks are R.H. WILLIAMS (ed.), *Textbook of Endocrinology*, 4th ed. (1968); and C.D. TURNER and J.T. BAGNARA, *General Endocrinology*, 5th ed. (1971). Williams' text is oriented toward human disease, and the coverage of endocrine abnormalities in man is exhaustive. In Turner and Bagnara the emphasis is on comparative endocrinology with much material on birds, reptiles, and fish. A basic text, short and to the point, is C.T. SAWIN, *The Hormones* (1969). There is a concise review of the fundamentals of endocrine physiology in W.F. GANONG, *Review of Medical Physiology*, 5th ed. (1971).

There are numerous publications dealing with various specialized aspects of endocrinology. The subject of brain-endocrine interactions is covered in detail in *Neuroendocrinology*, ed. by L. MARTINI and W.F. GANONG, 2 vol. (1966–67). The same editors have published two subsequent volumes, *Frontiers in Neuroendocrinology* (1969) and *Frontiers in Neuroendocrinology* (1971). *The Pituitary Gland*, ed. by G.W. HARRIS and B.T. DONOVAN (1966), is an exhaustive three-volume reference work. Modern short volumes on various glands include: R.J. WURTMAN, J. AXELROD, and D.E. KELLY, *The Pineal* (1968); R.J. WURTMAN, *Catecholamines* (1966); S.S. LAZARUS and B.W. VOLK, *The Pancreas in Human and Experimental Diabetes* (1962); T. SYMINGTON, *Functional Pathology of the Human Adrenal Gland* (1969); and P. RHODES, *Reproductive Physiology for Medical Students* (1969).

Valuable surveys of currently active areas of endocrine research are published in the series of annual volumes called *Recent Progress in Hormone Research.*

(W.F.G.)

Endocrine System Diseases and Disorders

Endocrine glands secrete hormones that enter the bloodstream directly and influence biochemical processes within target glands or tissues. Details of the structure and function of human endocrine glands and biosynthesis of the hormones they produce are given in the article ENDOCRINE SYSTEM, HUMAN; the nature and activities of hormones—from plants up through the animal kingdom to vertebrates—are presented in HORMONE; and endocrine systems for all animals, on a comparative basis, are covered in ENDOCRINE SYSTEMS. Most of the recognized hormones are composed of amino acid chains or steroids and increase or decrease the rate of biochemical processes within the cells or tissues. Mediators between the hormone and the target cell include the chemicals adenyl cyclase, cyclic adenosine monophosphate (AMP), and other such "messengers." Products of biochemical activity within cells provide feedback signals that serve to maintain endocrine activity within the physiologic range.

Long-recognized endocrine tissues in the so-called higher centres lie within the hypothalamus, a portion of the brain located above the pituitary gland, to which it is connected by the pituitary stalk. Releasor or inhibitor hormones produced in the hypothalamus reach the anterior pituitary via the stalk and, in turn, regulate the manufacture and secretion of hormones. The latter control growth and other metabolic events (growth hormone, or GH), thyroid function (thyroid-stimulating hormone, or TSH), adrenocortical activity (adrenocorticotropin, or ACTH), gonadal maturation and production of sex hormones, ova, and spermatozoa (follicle-stimulating hormone, or FSH, and luteinizing hormone, or LH), lactation (lactogenic hormone, or prolactin), and activity of the pigment- (melanin) producing cells (melanocyte-stimulating hormone, or MSH).

Hormones of the anterior pituitary gland

This article is divided into the following sections:

I. The pituitary
  - Diseases and disorders of the anterior pituitary
  - Diseases and disorders of the posterior pituitary

II. The thyroid
  - Excesses of thyroid hormones
  - Deficiencies of thyroid hormones
  - Inflammatory disorders: thyroiditis
  - Tumours
  - Associated disorders

III. The parathyroids
  - Excesses of parathyroid hormone
  - Deficiencies of parathyroid hormone

IV. The adrenals
  - Adrenal cortex
  - Adrenal medulla

V. The gonads
  - Premature development
  - Disorders of the testes
  - Chromosomal disorders
  - Intersexes
  - Other disorders of the ovary
  - Tumours
  - The breast in endocrine disorders

VI. The pancreas: diabetes mellitus
  - Classification of diabetes mellitus
  - Occurrence of diabetes
  - Cause and treatment of diabetes

VII. Other endocrine glands
  - The pineal gland
  - The thymus

I. The pituitary

DISEASES AND DISORDERS OF THE ANTERIOR PITUITARY

Excesses of pituitary secretions. *Acromegaly.* Excesses of growth hormone secreted by a particular type of pituitary tumour—usually one made up largely of cells that take on an eosin stain (eosinophilic adenoma)—produce undue growth of the skeleton and soft tissues. If this occurs in a child, gigantism results; if in an adult, the overgrowth is confined to the bones of the jaw, hands, feet, eyebrow ridges, and the soft tissues. Such persons develop more or less characteristic physical features, with coarsening of the face; thickening—and at times infolding—of the scalp; large hands, feet, and digits; and enlargement of the heart, liver, and other internal organs.

Acromegalic individuals are likely to develop congestive heart failure, particularly when blood pressure becomes high. Muscle weakness is frequent because muscle overgrowth produced by growth hormone decreases their capacity for work. At times excessive overgrowth of bone edges involves the joints and produces pain. The bones may become thin and porous—a condition known as osteoporosis.

Signs and symptoms of acromegaly

Expansion of the tumour within the pituitary can lead to losses of the follicle-stimulating and luteinizing hormones of this gland and to decreases in libido, potency, menstruation, and fertility. Increased metabolism with high basal metabolic rate readings, usually unrelated to any laboratory evidence of thyroid overactivity, is frequent in active acromegaly. Occasionally, however, thyroid overactivity or underactivity may coexist with acromegaly. The thyroid underactivity could result from losses of pituitary TSH and the overactivity from TSH production by the pituitary tumour. Each of these, however, could occur without causal relationship to the acromegaly. Secondary adrenocortical insufficiency does not appear unless the tumour destroys the ACTH-secreting cells of the pituitary. Indeed, adrenal hyperplasia may be present. Undue facial and other hirsutism may develop in women for reasons that are not clear. Diabetes mellitus appears in 20 to 40 percent of acromegalic individuals because excesses of growth hormone block the action of insulin. If the pituitary tumour enlarges, it can produce visual field defects, blindness or paralysis of the eye muscles, and can injure the posterior pituitary gland or the hypothalamus. Also, hemorrhage into the tumour can produce sudden loss of vision.

Occasionally, acromegalic persons, both male and female, develop a milk-like secretion from the breasts (galactorrhea), probably because growth hormone chemically resembles human lactogenic hormone, or prolactin, which induces lactation. Such galactorrhea, however, could also result from injury to the hypothalamus with loss of the prolactin inhibitor, which prevents pituitary secretion of prolactin.

Acromegaly can be a feature of the so-called Zollinger–Ellison syndrome, in which tumours of the parathyroids, pancreatic islets, thyroid, or adrenal glands may also be present.

An abnormal elevation of serum growth hormone that is not lowered by ingestion of glucose is the best index of active acromegaly or gigantism. Increases in serum inorganic phosphorus, new bone formation at the rib ends, and high levels of the amino acid hydroxyproline in the urine are indices of lesser value.

Treatment of acromegaly

Acromegaly may be treated by surgical removal of the pituitary tumour or destruction of it by X-ray irradiation or liquid nitrogen. Rarely, the pituitary tumour will cease to secrete growth hormone because of a spontaneous hemorrhage or blockade of the blood supply. Decreases in acromegalic manifestations and amelioration of diabetes mellitus have followed therapy with female hormones—estrogen or medroxyprogesterone—which reduce the secretion of growth hormone. For those treated by pituitary surgery, irradiation, or other measures and for those who spontaneously develop deficits of gonadal, thyroidal, or adrenocortical hormones, replacement hormone therapy is necessary.

Gigantism caused by excesses of growth hormone produced by a pituitary adenoma is different from gigantism associated with various types of cerebral injury (cerebral gigantism) or with fractional hypopituitarism (so-called fractional hypopituitarism with gigantism). Growth hormone levels are normal in the last two conditions, in each of which the gigantism may well result from excesses of lactogenic hormone.

Cushing's disease. Cushing's disease is adrenocortical overactivity chiefly, or entirely, of the cortisol-excess type resulting from an ACTH-secreting tumour—usually a basophilic (basic staining), and less often a chromophobe (nonstaining) adenoma or cancer of the anterior pituitary, frequently referred to as pituitary basophilism.

Cushing's syndrome is a more general term indicating that the adrenocortical steroid excesses that characterize

this disorder arise for reasons other than a pituitary tumour—*e.g.*, as a consequence of adrenocortical hyperplasia, adenoma, or cancer in association with cancers secreting ACTH-like polypeptides, and similar conditions. The most common cause today, however, is the administration of pharmacological dosages of cortisol (hydrocortisone) steroids.

The symptoms and signs in both Cushing's disease and syndrome are largely the same and are discussed later. Enlargement of the pituitary fossa or hyperpigmentation are not present, however, in untreated Cushing's syndrome arising in the adrenal cortices.

Causes of hypopituitarism

Deficiencies of pituitary secretions. *Simmonds–Sheehan syndrome.* Hypopituitarism may appear as a consequence of pituitary destruction (infarction) following extensive blood loss and circulatory collapse during delivery of pregnancy (Sheehan's syndrome); it may also result from blood clots, tumour, abscess, syphilis, tuberculosis, or unknown causes (Simmonds' disease); or it may follow pituitary surgery or irradiation, injury to the hypothalamus, influenza, or prolonged cortisol steroid therapy. Destruction of the pituitary need not be complete, and hormonal deficits may be partial. Cachexia, or marked weight loss, is not an essential feature, and even obesity may be present. Wrinkling of the face and decreased sweat and sebaceous gland activity often appear. Pubic and axillary hair is lost, and eyebrows become sparse.

When all of the pituitary hormones (GH, TSH, ACTH, MSH, FSH, LH, and prolactin) are lost, panhypopituitarism is said to be present. Growth hormone deficits produce dwarfism and predispose to low blood-sugar levels. The loss of TSH results in secondary (*i.e.*, pituitary) myxedema or hypothyroidism, with cold intolerance, torpor, slow speech, anemia, low basal metabolic rate, low serum protein-bound iodine, diminished radioactive iodine uptake, and sometimes increased serum cholesterol.

The absence of ACTH results in secondary hypoadrenocorticism, with loss of cortisol secretion and accompanying pallor, weakness, low blood pressure, diminished blood sugar, decreased excretion of water loads, low plasma and urine steroids, losses of adrenal androgens and estrogens with resultant decreases in or absence of sex hair, and adrenal crises (see the section below on deficiencies of adrenocortical hormones). Coma and death may occur as a result of adrenal insufficiency and myxedema.

Loss of FSH and LH is followed by decreased and then absent libido and potentia, amenorrhea, atrophy of internal and external genitalia, absence of sperm and ova production, infertility, and diminished sex hair. Lactation cannot occur in the absence of prolactin.

Treatment consists of replacement of lost hormone secretions—*i.e.*, cortisol, thyroid hormone, and androgens or estrogens. These measures correct these particular hormone deficits but do not restore fertility, which is dependent on adequate supplies of FSH and LH.

Reasons for hypophysectomy

Hypophysectomy. Removal of the pituitary (hypophysectomy) and pituitary stalk section by surgery or destruction by radioactive implants, X-ray or proton beams, ultrasound waves, and coagulation with liquid nitrogen have been undertaken in treatment of cancer and of vision-threatening eye changes in diabetes mellitus.

Hypophysectomy in individuals with cancer of the breast or prostate that has spread to bone often relieves pain and reduces the size of the tumour. In diabetes mellitus, hypophysectomy may stay the course of blindness. Hemorrhages and new blood-vessel formation cease. A type of scar tissue (glial retinitis proliferans) persists when present, and blood clotting and leakage of blood from capillaries (micro-aneurysms) may continue, but visual acuity often improves. High blood pressure, when present, tends to fall. Kidney function, when reduced, is not benefitted. Insulin requirements usually decrease.

Persons with reduced or absent pituitary function must receive daily cortisol and usually thyroid hormones as well. Sex hormones are not ordinarily replaced in persons with cancer of the breast or prostate but may be used in the treatment of diabetic individuals.

Chromophobe adenoma. Chromophobe adenomas make up 60 to 95 percent of pituitary tumours and are the most common cause of enlargement of the sella turcica, the bone "cavity" occupied by the pituitary. Only rarely are these true cancers, and calcium deposits occur in only about 6 percent of the cases. Enlargement of the pituitary fossa may also occur, however, with extra-pituitary tumours in the brain, Hodgkin's disease, or extensions from cancer elsewhere in the body. The space normally occupied by the pituitary may also become enlarged during pregnancy, in myxedema or cretinism, by dilatation of a nearby artery following a localized hemorrhage, or as a result of increases in intracranial pressure.

Chromophobe adenomas are generally considered to be nonsecretory, but this is not always the case. Thus, Cushing's disease, acromegaly, thyrotoxicosis, and galactorrhea have been observed in persons with what appeared to be a chromophobe adenoma. With appropriate staining techniques, such chromophobe tumours often prove to consist of amphophils—cells that are capable of secretory activity. Inappropriately high amounts of vasopressin may also occur in the plasma and urine of individuals with a chromophobe adenoma, perhaps because the tumour is secreting this polypeptide or somehow the rate of its production is increased by the hypothalamus. The signs of this condition are retention of water and dilution of plasma sodium and chloride. The losses of pituitary FSH, LH, ACTH, lactogenic, or growth hormone encountered with chromophobe adenomas result from pressure exerted on the hormone-producing cells by the tumour within the gland, with consequent destruction of those pituitary cells.

As with acromegaly, the possibility of adenomas in other endocrine glands is suspected in anyone with a chromophobe tumour. These tend to be familial and have been observed in various combinations, such as the Zollinger–Ellison syndrome, with chromophobe or eosinophil pituitary adenoma, and in adenomas of the parathyroid, pancreas, and other glands in association with peptic ulcers or diarrhea.

Treatment of chromophobe adenoma

The operative mortality with surgical removal of a chromophobe adenoma ranges between 5 and 15 percent. The appearance of sudden blindness, however, in a person with a chromophobe adenoma is an indication that a hemorrhage has occurred in the tumour and is a signal for instant surgery with the hope of restoring vision. The relative ineffectiveness of irradiation in the treatment of chromophobe pituitary adenomas in the past has been partially cancelled by the use of higher voltages directed more precisely at the tumour. Though results with X-ray irradiation of the adenoma may equal those seen following surgical removal, better results may be obtained by combining the two forms of therapy; *i.e.*, operative removal followed by irradiation.

Hormonal deficits may precede, as already indicated, or follow pituitary surgery or irradiation, requiring maintenance on full replacement dosages of cortisol, thyroid, and male or female sex hormones. So-called pituitary coma appearing in a person with a treated or untreated chromophobe adenoma is usually responsive to massive dosages of cortisol steroids. Low blood-sugar levels and myxedema coma also require therapy when they occur in such individuals.

Craniopharyngioma. Craniopharyngiomas are brain tumours that arise from Rathke's pouch, an embryologic remnant located posterior to, and above, the pituitary. As the tumours grow they encroach on this gland and on the hypothalamus. They can occur at any age, with peak frequencies in the second, third, and fourth decades. The tumour is somewhat more common in males than in females. Calcium deposits within the tumour are not uncommon, and distortion or destruction of that portion of the base of the skull in which the pituitary is housed occurs in 30 to 90 percent of the cases.

Most individuals with a craniopharyngioma report disturbances of vision. Sleepiness and personality changes may also develop; headaches are common and may be accompanied by nausea and vomiting. Rarely, convulsions, fever, and one-sided muscle weakness may devel-

op. Delayed sexual maturation or losses of menstruation, libido, and potency frequently occur.

Severe weight loss and stunting (resulting from malnutrition, losses of growth hormone, or both) take place in approximately one out of four affected individuals. Alternatively, the person may become unduly overweight. Thus, up to one-half of the children meet the criteria for the Babinski–Fröhlich syndrome (hypothalamic injury with obesity and genital underdevelopment). Diabetes insipidus, pointing to damage of the hypothalamus, the supra-optic hypophyseal tract, or the posterior pituitary, appears in a minority. In addition to the deficits of pituitary gonadotropins, which affect sexual maturation and function, underfunction of the thyroid and adrenal cortices may appear as a consequence of the losses of hypothalamic TSH and ACTH releasors or of pituitary TSH and ACTH production.

POSTERIOR PITUITARY

Particular areas in the hypothalamus, the supra-optic nuclei, elaborate the polypeptide neurohormone vasopressin (antidiuretic hormone, or ADH). This substance moves down the supra-optic hypophyseal tract and is stored in the posterior pituitary gland.

The hypothalamus also produces oxytocin, the chief function of which is the stimulation of uterine contractions during labour.

Action of vasopressin

The absorption of water back into the body fluids occurs in the kidney during the formation of urine from the blood plasma. This process is dependent upon vasopressin. When body water must be conserved, vasopressin enhances the ability of the kidney tubules to reabsorb water and enables them to excrete urea, salts, and other metabolic end products in a small volume of concentrated urine. On the other hand, decreases in vasopressin, when excesses of body water are present, permit the excretion of the extra water as a dilute urine. When vasopressin is lacking or ineffective, excessively large volumes of body water are lost in urine. This is termed diabetes insipidus (a flowing through of a nonsweet—*i.e.*, sugar-free—urine). The thirst that develops then leads to an increased intake of aqueous fluids. When diabetes insipidus is present, any increase in the load of solutes to be excreted by the kidney increases the volume of urine. On the other hand, decreases in the solute load by starvation, salt restriction, and reduced liquid intake diminish the urine excesses.

Diabetes insipidus is to be differentiated from psychogenic thirst—*i.e.*, potomania, or a sensation of thirst unrelated to a shortage of water—in which the urine volumes are increased secondary to an increased water intake. Increased urine volumes mimicking diabetes insipidus may also occur in diabetes mellitus, in kidney disease, during discharge of excess body fluids, and in a number of other conditions.

Diabetes insipidus that results from injury to or destruction of the hypothalamic nucleus (where vasopressin is produced), the tract by which vasopressin is conveyed to the posterior pituitary gland, or the posterior pituitary (neurohypophysis; where it is stored), is called supra-optic hypophyseal diabetes insipidus, or SHDI. These conditions can be congenital, familial, or acquired defects produced by brain tumours, injury, or disease. When the supplies of vasopressin are adequate but the kidney tubules are unresponsive—either genetically or because of potassium depletion, high levels of serum calcium, or other disorders—nephrogenic diabetes insipidus (NDI) results. The genetic type is familial and may be fully or partly developed; it may be present in newborn infants and, if untreated, results in mental retardation or death by dehydration.

SHDI can be corrected by injections of vasopressin-like molecules of animal or synthetic origin; such treatment, however, is ineffective in the nephrogenic form of the disorder. In both types, reduction of the solute load presented for excretion to the kidneys or the administration of certain antidiuretic drugs that influence salt and water excretion by the kidneys reduces the volume of urine.

II. The thyroid

The thyroid gland, two shield-shaped structures joined by an isthmus overlying the larynx (Adam's apple) is the source of the two currently recognized thyroid hormones, tetraiodothyronine or thyroxine (T_4) and triiodothyronine (T_3), which participate in the overall control of energy utilization. The thyroid gland is also the site of production of thyrocalcitonin, a hormone secreted by the clear or C cells, which buffers against undue increases in serum calcium.

The thyroid hormones: thyroxine, triiodothyronine, and thyrocalcitonin

EXCESSES OF THYROID HORMONES

Hyperthyroidism. Overactivity of the thyroid gland (hyperthyroidism, thyrotoxicosis, or toxic goitre) with diffuse enlargement of the thyroid gland and excesses of thyroidal hormones (T_4 and T_3, or just T_3 alone) often accompanied by eye protrusion (exophthalmos, or Graves' disease) is an auto-immune disorder. It arises from long-acting thyroid stimulator (LATS), a gamma globulin probably produced as an antibody to thyroid tissue. LATS is unrelated to TSH. Toxic nodular goitre, or Plummer's disease, results from hyperfunction of thyroid adenomata, or tumours. It usually occurs without eye signs, but the eyes often appear larger because of a stare. Thyrotoxicosis may also result from an ovarian struma (a goitre-like, iodine-containing tumour) that secretes thyroid hormones; from a testis, placental, or other tumour that is secreting TSH-like material that stimulates the thyroid gland; or from ingestion of huge amounts of thyroid hormone.

Although hyperactive behaviour, thyroid enlargement, smooth and hot skin, excessive sweating, tremors, rapid pulse, and eye signs are the most frequent features of thyrotoxicosis, virtually any organ or tissue may be involved.

Thyrotoxicosis

Thus, with respect to the central nervous system, emotional and personality disturbances, abnormal brain waves and nerve–muscle transmission, or convulsions may occasionally develop in thyrotoxicosis. Rapid contraction and relaxation of tendon reflexes are frequent.

The circulatory changes in hyperthyroidism can be depicted as a sequence: increased heat production and heat loss, dilatation of blood vessels, decreased arterial tone, increased movement of blood, greater output of blood by the heart, and rise in blood pressure. Blood-plasma volume is probably increased, and extracellular fluid may be, also; insensible loss of fluid is clearly greater than normal. Heart disease associated with hyperthyroidism may be characterized by totally irregular heart action (atrial fibrillation) and congestive failure. These heart conditions are more common in older persons, affecting one-half or more of those over 40 years of age. They may occur, however, in younger individuals with apparently normal hearts. Angina pectoris, a constricting type of chest pain usually associated with a shortage of blood supply and oxygen in the heart muscle is common in thyrotoxicosis, but damage to the heart muscle in these cases is unusual. The elasticity of the lungs and the respiratory excursions may be decreased in hyperthyroidism. Blood flow through the kidneys and various kidney functions are often increased. The intake of food is greater, and food starts to leave the stomach sooner, but emptying of this organ takes longer than normal. The absorption and movement of food through the gut are generally accelerated, and diarrhea may develop. Liver glycogen stores are usually decreased, and infiltration with fat and cells may be present. Weakness of the eye muscles is frequent, and acute or chronic weakness of other muscles may develop. Also, intermittent weakness of the periodic paralysis type, or progressive decrease in muscle strength (myasthenia gravis) as the day goes on, can occur. Thinning of bone (osteoporosis), localized destruction of bone (osteitis fibrosa), and inadequate bone salt deposition (osteomalacia) may take place. In a few individuals, marked clubbing of the fingers, increases in periosteal or surface bone, and arthritic symptoms develop.

Endocrine glands other than the thyroid may be affected when excesses of thyroid hormones are present. Occasionally, urine volumes and thirst are excessive, probably

Effects of hyperthyroidism on other endocrine glands

because increased serum calcium interferes with the action of vasopressin, one of the hormones that regulate water excretion by the kidney. Growth hormone responses to low blood-sugar levels may be diminished. Skin pigmentation increases in some individuals because of increases in ACTH or MSH or in the responses to them. Alternatively, it is possible that the increased pigmentation results from the higher skin temperatures and the increased heat transfers. Adrenocortical function is increased when the thyroid is overactive. This compensates for the shortened survival time of hydrocortisone when thyroid hormone excesses are present. Blood pressure and pulse responses to adrenal medullary hormones of the adrenaline type (epinephrine and norepinephrine) are increased in hyperthyroidism. Loss of menstruation is common when thyroid overactivity is severe, but pregnancy can occur. During such pregnancies, the hyperthyroidism is frequently accentuated, the incidence of toxemia of pregnancy rises, and that of fetal mortality increases. Though, as mentioned, bone mass tends to decrease in hyperthyroidism as a result of thinning and localized destruction of bone, and perhaps deficits of bone salt, the serum inorganic phosphorus generally tends to increase slightly, and serum calcium may increase. When thyroid hormone supplies are excessive, insulin responses to sugar are generally normal, but the blood-sugar levels following glucose may be higher and more prolonged. The frequency of actual diabetes mellitus is increased, especially in older persons; pre-existent diabetes is made more severe, and insulin is probably destroyed more rapidly.

Laboratory diagnosis of hyperthyroidism. A diagnosis of thyroid overactivity is supported by increased oxygen consumption—*i.e.*, elevated basal metabolic rate (BMR) readings—and especially by increases in the levels of serum protein-bound iodine (PBI), butanol-extractable iodine (BEI), thyroxine (T_4) and triiodothyronine (T_3), and the thyroidal uptake of radioactive iodine. Indices of lesser value include the binding of radioactive T_3 to blood cells or resin in vitro, ankle reflex time, and miscellaneous other measurements. No single test is consistently infallible, and, hence, a battery of several is usually employed. Evaluation of the significance of such tests is aided by the history, physical findings, and the responses to therapy.

The BMR is above +15 percent in four-fifths or more instances of thyroid overactivity; it is normal in the rest. High BMR values, however, also occur in illnesses that do not affect thyroid function.

The serum PBI can be a reliable index of thyroid hormone excesses. A value above 7.5 or 8.0 gammas per 100 millilitres of blood serum uncontaminated by iodine compounds is virtually diagnostic. The serum PBI, however, is unduly high during an intake of inorganic or organic iodides; in estrogen excesses; during pregnancy or with use of many of the birth-control pills; in certain forms of goitrous cretinism; some cases of thyroiditis or hepatitis, porphyria, liver disease; during therapy with certain tranquillizer drugs; and after therapeutic dosages of radioactive iodine. The PBI may be below normal during T_3 therapy, when plasma thyroxine binding protein is deficient, or during treatment with androgens or diphenylhydantoin, an anti-epileptic drug. The BEI fails to differentiate organic iodides such as gallbladder and other dyes from circulating T_4 but is not affected by inorganic iodides. It is particularly useful in goitrous cretinism, in which iodinated tyrosines may be released into the circulation. Serum T_4 and T_3 measured by chromotographic techniques identify thyroid overactivity when the serum PBI and BEI fail to reflect the levels of thyroid hormones in the circulation.

The thyroidal uptake of radioactive iodine, when elevated above 40 percent at 24 hours, is also a highly reliable index of thyrotoxicosis. The uptake may be normal, however, despite the existence of an overactive thyroid, and high values occur in iodine deficiency and in certain types of thyroid failure. Refinements of the radioactive iodine uptake test prove useful in equivocal circumstances. Thus, high uptake rates that can be sharply reduced by perchlorate, thiocyanate, or related ions point to defective binding of the trapped iodine to thyroid protein, as in thyroiditis or as in the presence of thyroid blocking agents. Also, when the thyroid is overactive, the residual thyroidal radioactivity is generally low for one week following the test dose of the isotope, whereas it tends to be high in thyroid failure and iodine deficiency. Failure to suppress thyroidal iodine uptake by desiccated thyroid, T_4, or preferably by T_3, is also a useful indication of hyperthyroidism. A high conversion ratio—*i.e.*, the percentage of radioactive iodine present in blood plasma or serum as radioactive PBI two or more days after administration of the isotope—is characteristic of thyroid hyperfunction. It is not specific, however, because similar high values may occur in myxedema, thyroiditis, iodine deficiency, goitrous cretinism, nephrotic syndrome, and in children under the age of five. The removal of iodine from the circulation by the thyroid can be calculated easily and serve as an index of hyperthyroidism.

Diagnostic tests for hyperthyroidism

The binding of radioactive T_3 to a sample of blood or to resin correlates moderately well with the thyroid status. This test may be used when excesses of organic dyes interfere with thyroidal uptake, PBI, or BEI measurements. False low binding of T_3 to blood cells or resin, however, is produced during pregnancy by estrogen excesses because of increased binding of T_3 to the proteins of blood plasma. Also, false elevations in T_3 binding occur in a large variety of nonthyroidal disorders.

Though tendon reflexes are more rapid in hyperthyroidism, measurements of the Achilles reflex time may not demonstrate values outside the normal range.

Other indices employed in the past to support a diagnosis of hyperthyroidism are much less useful. Low serum cholesterol levels, for example, are not regularly present; galactose or xylose tolerance tests are not consistently abnormal; decreased ultrafiltrable magnesium levels have not proved to be a consistent indicator; but total magnesium and radiomagnesium studies are more useful. Under appropriate circumstances, the presence of creatine in the urine of adult males may be a clue to the existence of hyperthyroidism, but this also occurs in various muscle diseases.

A number of less specific and, therefore, nondiagnostic laboratory findings occur in hyperthyroidism. Thus, routine blood studies may reveal an increased lymphocyte percentage and a lowered red blood cell count. The latter is largely a reflection of an expanded blood-plasma volume, but the total red cell mass may also be diminished. In general, the blood sugar, urea, nonprotein nitrogen, and the serum electrolytes remain within normal limits in hyperthyroidism. As indicated earlier, the serum inorganic phosphorus may be slightly increased. Quite regularly, the serum proteins and especially the serum albumin tend to be low in thyroid overactivity, whereas gamma globulins and plasma mucoproteins may be increased. Occasionally, serum calcium may be increased, and calcium may be deposited in the kidneys. Rarely, the serum potassium may be low. The total potassium of the body may also be decreased. This is more likely to occur in men than in women. Chloride and sodium levels in sweat may be low. Urinary and fecal losses of calcium are generally increased in thyrotoxicosis.

Treatment of hyperthyroidism. The selection of a particular treatment for an overactive thyroid—*i.e.*, use of iodide–iodine solution or other thyroid blocking drugs, surgical removal, destruction by radioactive iodine, or a combination of all of these—is determined by a number of variables. These include the age and sex of the person, associated disorders, the size and shape (*e.g.*, it can be nodular or asymmetrical) of the gland, and the ability of the individual to cooperate.

Iodide–iodine treatment

Inorganic iodide and elemental iodine tend to suppress thyroid overfunction. The net result is the same whether one or the other is given. Iodide–iodine is probably more effective in diffuse than in nodular goitres. Their potency, however, is weak compared to that of blocking agents of the thiocyanate, thiouracil, and associated chemical type. Iodide–iodine therapy given as the sole treatment proves

effective in only about 20 percent of the patients. The response is prompt, however, appearing in a few days, and therefore more rapid than that obtained with most of the thyroid blocking drugs or with radioactive iodine. Excesses of iodide or iodine block the binding of this halide to protein within the gland, an effect that interferes with hormone synthesis. The latter presumably is also the basis for the origin of goitres and even of myxedema in persons receiving inorganic iodide, elemental iodine, or related agents for prolonged periods. On rare occasions, iodide–iodine administration in the usual dosages may produce or appear to produce an increase in the severity (exacerbation) of thyrotoxicosis. The notion that iodide–iodine solutions exert effects that last for only a limited period and then cease is erroneous. The action continues, but variations in the intensity of the underlying thyrotoxicosis may give that impression. Also, the view that iodide–iodine solutions interfere with the responses to thyroid blocking agents such as thiouracil is not correct, although they will block the effects of thiocyanate, nitrate, and perchlorate (see below). In fact, inorganic iodide hastens the response to propyl thiouracil and related drugs. Skin eruptions, fever, enlargement of the salivary glands, and respiratory symptoms as a result of increased pulmonary and bronchial secretions may occur during treatment with inorganic iodide or elemental iodine.

Two classes of thyroid blocking agents

In addition to iodide and iodine, there are, as previously mentioned, two general classes of thyroid blocking agents: (1) those that interfere with the "pump" that concentrates iodide in the thyroid cells (*e.g.*, thiocyanate, perchlorate, or nitrate) and (2) those that prevent the binding of iodine within the thyroid (*e.g.*, propylthiouracil with a thiocarbamide grouping). These two classes of thyroid blocking compounds ultimately produce hypothyroidism and a goitre. In the case of the thiocyanate group, the inhibition of the thyroid iodide pump and the subsequent effects can be entirely overcome by excesses of inorganic iodide. With the thiouracil drugs, inorganic iodide and elemental iodine minimize the size and blood supply of the gland but do not prevent or cancel the goitre. In animals, the goitre-producing effects of both classes of compounds can be entirely cancelled by giving thyroid hormones or by hypophysectomy, indicating that enlargement of the gland results from excesses of thyroid-stimulating hormone (TSH) produced by the anterior pituitary.

The thiocyanate drugs have had only limited use in the control of thyrotoxicosis but are of value in selected circumstances. The propylthiouracil and related drugs have been widely employed in the treatment of hyperthyroidism. Experience has been most extensive, and toxicity the lowest, in the case of propylthiouracil. Undesirable side effects have been less than 1 percent. Individuals with diffuse toxic goitres respond more readily than do those with toxic adenomas. During such therapy, hypothyroidism can be avoided by reduction of the dosage or, more simply, by taking full replacement dosages of desiccated thyroid, or equivalent amounts of synthetic thyroid hormones (T_4 and T_3).

Radioactive iodine therapy

Radioactive iodine (I-131) therapy is generally reserved for adults and for those who, at any age, are poor surgical risks, who do not wish to submit to surgical treatment, who have been operated upon previously, or in whom adequate long-term observation during treatment with thyroid blocking agents is not possible. The radioactive iodine is usually given in sessions spaced two or more months apart. The effects of a particular dosage of radioactive iodine may not be maximal for many weeks. Hence, the thyroid status is re-evaluated at intervals following radioactive iodine administration and a decision reached concerning further therapy. Such treatment with radioactive iodine will also reduce the size of disfiguring toxic goitres. Control of the hyperthyroidism with radioactive iodine treatment is more readily accomplished in diffuse toxic goitres than in nodular goitres. Replacement of thyroid hormones is usually prescribed when the hyperthyroidism begins to subside, thus preventing the development of post-treatment myxedema. Radioactive iodine cannot be administered beyond the tenth week of pregnancy because it destroys the fetal thyroid and produces cretinism.

Partial thyroidectomy after the hyperthyroidism has been controlled by thyroid blocking agents is often performed on younger thyrotoxic individuals in whom a permanent remission is desired and especially in those with symptoms produced by the enlarged thyroid. Treatment of hyperthyroidism by surgical removal of a part of the thyroid gland (*i.e.*, by subtotal thyroidectomy) has been brought to a high state of technical perfection. The operative mortality in many institutions is less than 1 percent, and surgical complications (*e.g.*, removal of parathyroid glands) are equally infrequent. To avoid possible shortages, thyroid hormones in replacement dosages are often prescribed following this surgical treatment.

Hyperthyroidism concurrent with pregnancy can be controlled with inorganic iodide or elemental iodine, with thyroid blocking agents alone, or with these agents followed by subtotal thyroidectomy. Every attempt is made to minimize suppression of fetal thyroid function by using the smallest possible dosages of blocking agents. As already noted, radioactive iodine cannot be administered beyond the tenth week of pregnancy because it will be concentrated in and destroy the fetal thyroid.

Thyroid overactivity in children occurs above the age of ten years about 80 percent of the time, but it may be present at birth. As in the adult population, the condition is more prevalent among females than males; weight loss occurs in most of the children, and nervousness, tremor, rapid heart action, and thyroid enlargement are almost always evident. Eye protrusion (exophthalmos) develops in about one-half the cases. The blood pressure may increase. If the overactivity of the thyroid has been present for six months or longer, the child may be unusually tall. In contrast to older age groups, however, exophthalmos is less severe, and the enlargement of the thyroid is diffuse rather than nodular.

Therapy is often confined to thyroid blocking agents of the propylthiouracil type, because in many children a permanent remission can be obtained after several years of treatment. To avoid recurrences and hypothyroidism, and perhaps to cancel or minimize any tendency to the development or progression of exophthalmos, full replacement dosages of thyroid hormones may be given with the propylthiouracil. Such a program prevents exacerbation of the thyroid overactivity and assures a constant normal level of circulating thyroid hormones. Partial surgical removal of the thyroid following production of a remission with thyroid blocking agents is an effective alternative. Treatment with radioactive iodine is generally not used in children because of the question of ultimate effects on the thyroid gland. When circumstances dictate this treatment, it is as effective as in adults.

Thyroid crises. Thyroid crises, or storms, are variably characterized by increases in heart rate, fever, nausea, vomiting, diarrhea, stupor, and coma. They occur spontaneously or following various diagnostic or treatment procedures in persons with incompletely controlled hyperthyroidism. Such thyroid storms can also be produced by taking large quantities of thyroid hormone. These are serious medical emergencies, and failure of the heart, kidneys, adrenals, or the liver and circulatory collapse and death may ensue.

Treatment of thyroid storms

Treatment is based on all potentially beneficial measures, since the mortality, though reduced from its previously high level of virtually 100 percent, may still be as high as 25 percent. Attention is therefore directed toward (1) blocking further release of thyroid hormones; (2) cancelling some of the effects of thyroid hormone excesses by such drugs as reserpine and guanethidine (tranquillizers and anti-hypertensive agents); (3) increasing the supply of protective cortisol-type steroids; (4) treatment of congestive heart failure, shock, dehydration, and electrolyte depletion; and (5) removal of the precipitating cause.

DEFICIENCIES OF THYROID HORMONES

Myxedema and hypothyroidism. The terms myxedema and hypothyroidism refer to thyroid underfunction in

adults or older children with resultant deficits of the two thyroid hormones, thyroxine (or T_4) and triiodothyronine (or T_3). Such underfunction may originate in the thyroid itself (primary type) or in the pituitary or hypothalamus, which control the thyroid (secondary type).

A rough, dry, and yellow skin, coarse scalp hair, and hoarse voice suggest that thyroid hormones may be deficient, but none of these signs need be present. Overweight is not necessarily a characteristic feature. Intellectual functions may become impaired, and personality changes or severe emotional illnesses, including so-called myxedema madness and coma, may appear. The nervous system may also be affected in other ways. Thus, disturbances of gait, of coordination, and of rapid movements may develop. Sensations may be altered and hearing can decrease. Tendon reflexes and brain waves are usually slowed.

Exophthalmos in association with myxedema occurs only in the primary type but is not always present. Drooping of the upper eye lids, often detectable only by measurements before and after thyroid replacement therapy, is frequent. Thyroid underactivity is also accompanied by a constriction of blood arterioles, increased resistance to blood flow, and prolonged circulation time. At times, the heart chambers may enlarge, the output of blood by the heart may decrease, and congestive heart failure may appear. The blood flow to the kidney and various kidney functions diminish, but not to critical degrees. Urinary bladder tone is decreased. In far-advanced thyroid underfunction, breathing may become shallow and slow and may result in carbon dioxide retention (respiratory acidosis) and coma. Body water and extracellular fluid volumes increase during prolonged shortages of T_4 and T_3, whereas the blood-plasma volume diminishes. Abnormal collections of fluid can appear in the extremities, in the abdomen, and in other body cavities. The secretion of gastric juice diminishes, the intestinal absorption of foodstuffs is delayed or reduced, and constipation is frequent. Skeletal muscles may become enlarged and firm as a result of thyroid hormone shortages and of relaxation of muscles after contraction becomes prolonged. The maturation of the skeleton may be affected. Thus, the normal fusion of the growing ends of the bone to the bone shaft may be delayed, and arthritic symptoms reversible by thyroid therapy can occur.

Effect of myxedema on other endocrine glands

Endocrine glands other than the thyroid may be affected by myxedema. Thus, excesses of the antidiuretic hormone (vasopressin) in myxedema may produce low blood sodium (hyponatremia). Other endocrine glands may be affected by the shortage of thyroid hormone: the gonadotropins, ACTH, and growth hormone may be decreased. Ovarian dysfunction in myxedema is different in the primary and secondary types. In the former, menstrual flow may be more frequent, prolonged, and excessive. In the latter, if associated losses of gonadotropins are present, the menses cease. In the male, sexual activity and sperm production decrease. Fertility is reduced in both sexes. Myxedema may also be responsible for delayed sexual maturation (which can be corrected by thyroid replacement), but sexual precocity can also occur. Adrenocortical function may become decreased in myxedema either because of loss of pituitary ACTH, a direct effect of hypometabolism on the adrenals, or as a consequence of decreased utilization of, and therefore decreased need for, cortisol. These are temporary changes. At times, the myxedema is accompanied by permanent primary hypofunction of the adrenal cortices (Addison's disease). This has been called Schmidt's syndrome. Also, circulatory responses to epinephrine (adrenaline) secreted by the adrenal medulla are decreased in hypothyroidism. Finally, it has been suggested that myxedema protects against the development of diabetes mellitus, but the two entities can and do occur together.

Laboratory diagnosis of myxedema. The laboratory diagnosis of primary or secondary myxedema requires the demonstration of decreased thyroid function with a resultant shortage of thyroid hormones. The more reliable of the readily available tests are based on the demonstration of a decreased thyroidal uptake of administered radioactive iodine and low level of T_4 in the blood serum. The T_4 can be measured as such or as the serum protein-bound iodine (PBI). Less reliable and often less readily available or more cumbersome indices include decreased oxygen consumption or basal metabolic rate (BMR), prolongation of the ankle reflex time, increased serum cholesterol, increased binding of radioactive T_3 to serum proteins, decreased conversion of radioactive iodine to radioactive thyroid hormones, increased secretion of inorganic iodide in the saliva, delayed absorption of glucose or other sugars from the gut, decreased creatine in serum and urine, and increased total or ultrafiltrable magnesium in serum. The laboratory differentiation of primary and secondary myxedema depends upon the administration of TSH of animal origin.

Use of routine laboratory tests

Routine laboratory tests may show nonspecific changes during shortages of thyroid hormone. Voltage may be low in heart tracings, for example, or anemia may develop; blood sugar and the serum sodium and inorganic phosphorus may be lowered, while serum cholesterol, calcium, total carbon dioxide content, total protein, gamma globulins, uric acid, and spinal fluid proteins may be raised. The fecal and urinary excretion of calcium is generally decreased; serum alkaline phosphatase tends to be low; and serum creatine phosphokinase is increased.

Therapy of hypothyroidism and myxedema. Desiccated thyroid of animal origin, a mixture of thyroid protein, T_4, T_3, and other iodine compounds, has been extensively employed in the therapy of primary or secondary myxedema. Synthetic thyroid hormones, such as sodium L-thyroxine (T_4) or sodium L-triiodothyronine (T_3), may also be used, but when used alone in full replacement amounts, T_4 produces undue rises in the serum PBI and T_4 values, and T_3 depresses them. These limitations are not encountered when mixtures of T_4 and T_3 in a ratio of approximately 4:1 are employed. In treating hypothyroidism or myxedema, particular care is taken to begin with small dosages, lest adrenocortical insufficiency, heart pain, myocardial infarction, or congestive heart failure be produced; dosage is increased in gradual increments until the full replacement dosages are reached. TSH derived from animals cannot be used to treat myxedema of pituitary origin, because, with continued administration, the human thyroid ceases to respond to this stimulus.

The rapid onset and offset of T_3 effects are of special value in the treatment of life-threatening myxedema coma, myxedema heart disease, or in preparing a hypothyroid person for emergency surgery. In such emergencies, the T_3 must be administered in substantial dosages at intervals of several hours, rather than in the small amounts previously described. The use of these relatively large dosages of triiodothyronine is generally accompanied by the administration of cortisol steroids.

Cretinism and juvenile myxedema. Cretinism is hypothyroidism or myxedema that begins before birth or during infancy or childhood and results in bodily stunting and intellectual retardation. Such thyroid underfunction may be primary in the thyroid or secondary to a deficit of pituitary TSH or hypothalamic TSH releasor. Enlargement of the thyroid (*i.e.*, goitres) may or may not be present in the primary type but is never present in the secondary type. Goitres represent an attempt to restore failing thyroid function to normal by greater output of TSH, which increases the size of the gland. The failure of thyroid function can result from a lack of inorganic iodide or elemental iodine in foods, or increased losses via feces, ingestion of certain foods containing thyroid blocking agents, inflammatory conditions of the thyroiditis type, exposure to radioactive iodine, and apparently spontaneous enzymatic defects. Currently recognized enzymatic defects within the thyroid that can result in a goitre consist of inability of the thyroid to: (1) trap iodide, (2) bind iodine to thyroid protein, (3) deiodinate iodotyrosines, (4) couple iodotyrosines to form T_3 and T_4, and (5) produce and release normal thyroid hormones.

Symptoms and signs of infantile cretinism that appear at birth or several weeks thereafter include: poor ap-

petite, breathing difficulties, low body temperature, dry and thickened skin, and decreased vigour and activity.

Symptoms and signs of cretinism

During the first three to five months of age, the following signs may be indicative of cretinism: delayed union of skull bones, torpid behaviour, slow nursing, spells of choking and cyanosis (*e.g.*, turning blue of the skin) during feeding, excessive sleepiness, hoarseness, constipation, a pallid, cold, gray-mottled or yellow-tinged skin, enlargement of the tongue, umbilical herniation, flabby musculature, a pulse rate of less than 100, or rectal temperatures of 98° F (37° C) or lower. When cretinism develops in the later months of the first year of life or subsequently, any of the above may occur as well as delay or reversal of such activities as sitting, crawling, walking, talking, or head lifting. Also, delays in teething, failure to grow in length at a normal rate, excessive body and facial hair, increased neck or hip fat, or a low pulse pressure may be present. In cretins who remain undiagnosed during the early years of life, the fully developed picture becomes evident. This consists of intolerance to cold, decreased sweating, shortened stature, infantile body proportions with short legs and arms, depression of the bridge of the nose, enlargement of the tongue, retarded behaviour, thin, dry, and scaling skin with "dirty" knees and elbows, slow relaxation of tendon reflexes, and the other symptoms and signs mentioned previously.

Juvenile hypothyroidism and myxedema differ from cretinism in that thyroid hormone supplies, growth, and intellectual development have been normal during infancy and early childhood. Such juvenile hypothyroidism can be spontaneous or may follow surgical removal of the thyroid gland. The shortage of thyroid hormones results in dryness of the skin, delayed eruption and deformation of the teeth, increased dental cavities, excessive body and facial hair, brittle scalp hair, and increased muscle size. Growth may be retarded, but body proportions are not infantile. Although intellectual performance may be decreased, it is not so profound as in cretinism, and, more importantly, it is fully reversible. Sexual maturation may be retarded; occasionally, sexual precocity develops.

Among the nonspecific laboratory indices that may be suggestive of cretinism, juvenile hypothyroidism, or myxedema are the following: anemia, increased blood sedimentation rate, high serum calcium after a calcium load, low serum inorganic phosphorus, low fasting blood sugar, low serum alkaline phosphatase, carotene in the plasma, prolongation of the jaundice of newborns (this jaundice, present in about 70 percent of newborns, usually disappears in about 10 days), decreased urine creatine, lengthening of the Q-T interval of the electrocardiogram, abnormal brain waves, low BMR values, prolonged contraction and relaxation of tendon jerks, delayed skeletal maturation and abnormal X-ray patterns of conversion of cartilage to bone with the development of epiphyseal dysgenesis, and enlargement of the pituitary fossa.

Diagnosis of thyroid underfunction

The diagnosis is usually established by demonstration of low serum levels of PBI and thyroxine and reduced thyroidal uptake of radioactive iodine. In some of the enzymatic disorders, however, serum PBI may be normal or high because abnormal thyroid proteins are being produced and released, but the serum T_4 remains low. Also, thyroidal uptake of radioactive iodine may be misleadingly high at times, but appropriate tests can then establish that the normal conversion of such trapped iodine to thyroid hormones is not occurring.

Prompt diagnosis of thyroid underfunction is essential in infants and children. Adequate replacement with adult dosages of thyroid hormones will prevent further retardation of physical and intellectual development.

Women with a history of previous cretin births or those who have received radioactive iodine or thyroid blocking drugs during pregnancy may be treated with T_3 or other thyroid hormones in the hope of preventing cretinism.

Metabolic insufficiency. Low BMR readings without deficits of thyroid hormones have been described under a variety of terms including: hypometabolism without hypothyroidism, non-myxedematous hypometabolism, pseudohypothyroidism, euthyroid hypometabolism, or metabolic insufficiency.

It has been suggested that such persons suffer from fatigue early in the day, cold sensitivity, impaired intellectual activity, emotional depression, headache, pains and aches, decreased sexual activity, scanty menstruation, and infertility. Obesity, dry nails and hair, tenderness of the muscles, generalized puffiness or edema, slowing of the Achilles tendon reflex, and decreased sperm production or ovulation are stated to be frequent accompaniments. The thyroidal uptake of radioactive iodine and the levels of serum PBI and T_4, however, are within the normal range; serum cholesterol may be normal or elevated.

It has been suggested that therapy with desiccated thyroid or with T_4 in amounts ordinarily adequate to produce a remission in myxedema fails to restore the BMR to normal and does not relieve the above symptoms and signs. Observations that T_3 administration appeared to alleviate the condition have led to the suggestion that hypometabolism without hypothyroidism results from inadequate responses to T_4 or from inadequate conversion of T_4 to T_3.

INFLAMMATORY DISORDERS: THYROIDITIS

Thyroiditis, or inflammation of the thyroid gland, can be acute, subacute, or chronic, but this does not necessarily mean that each of these is a separate and distinct entity. Such a classification merely emphasizes the onset and duration of the symptoms and signs of thyroiditis and relates them to the microscopic appearance of the gland.

Acute, subacute, and chronic thyroiditis

Before the advent of agents for treating infections, acute thyroiditis generally represented a complication of a systemic infection such as typhoid fever or pneumonia. The infecting organism could usually be isolated from the blood or other sites as well as from the gland itself. The death rate was significant, although not necessarily related to the thyroiditis. In current experience, bacterial infection and abscess formation are unusual in acute thyroiditis, either because treatment with antibiotics and related drugs is started early or because the infective agent is frequently a virus. The manifestations of acute thyroiditis include fever, malaise, and pain in the front of the neck particularly on swallowing. The thyroidal uptake of radioactive iodide may be low and uneven, and serum protein-bound iodine (PBI) may be elevated. Despite the latter, circulating thyroxine, or T_4, is not increased. Acute thyroiditis responds promptly to adrenocortical steroid and antibacterial therapy. There is no indication for the use of thyroid blocking agents, unless true thyroid overactivity is present.

Subacute thyroiditis—*i.e.*, a lingering thyroiditis of insidious onset and duration—is correlated with a granulomatous change in the thyroid in which giant cells may be present. This condition has been termed pseudotuberculous, or De Quervain's thyroiditis. Nonspecific symptoms and signs such as fatigue, low-grade fever, and anemia are frequent. The origins of subacute thyroiditis are not established beyond the fact that auto-immunization may play a role. Such persons may, however, have a high level of antibody against the mumps virus, and the virus itself has been isolated from the thyroid glands. The serum PBI in subacute thyroiditis may be normal, low, or high, and the uptake of radioactive iodine by the thyroid is often uneven. Before the demonstration that desiccated thyroid and adrenocortical steroids in adequate amounts produce a remission, the local and systemic complaints of subacute thyroiditis lasted for months or even years.

Many but not all instances of chronic thyroiditis can fall into either the Hashimoto (struma lymphomatosa) type, in which the gland is heavily infiltrated with lymphocytes, or the Riedel (struma fibrosa) type, in which scar tissue replaces most of the gland. These microscopic differences and the natural history of the two forms of thyroiditis originally led to the suggestion that they are separate entities. At present the justifications for such categories seem less valid, since chronic thyroiditis may not meet the histological criteria for either the Hashimoto or Riedel types and must therefore be called nonspecific. Hashimoto's thyroiditis may be familial or hereditary. Disturbances of the thyroidal uptake of iodide

and of the serum PBI levels may be present in various combinations in chronic thyroiditis. Myxedema is especially likely to occur in the Hashimoto type. As with subacute thyroiditis, these chronic types decrease in size with pharmacological dosages of adrenocortical steroids and with replacement thyroid hormone therapy. Reversal of the Riedel type of fibrosis cannot be expected, but X-ray irradiation may reduce the size of the gland. Surgical removal of the enlarged and scarred gland may be necessary for relief of obstruction.

Thyroiditis as an auto-immune reaction

Antibodies to the thyroglobulin or to other components of the thyroid occur in the serum of individuals with subacute, Hashimoto, Riedel, and nonspecific thyroiditis. This suggests that the various types of thyroiditis represent an auto-immune reaction. A predisposition to auto-immunization in such patients is supported by the association of thyroiditis with Addison's disease, various collagen disorders, hemolytic anemia, pernicious anemia, and perhaps myasthenia gravis and cirrhosis, entities in which sensitization of the individual to his own tissues plays a role. Hence, a diagnosis of thyroiditis is supported by the demonstration of circulating antibodies to thyroglobulin or the thyroid gland, but these may also be present in other types of goitres, in thyroid overactivity, myxedema, cretinism, and cancer. Proof of thyroiditis, therefore, must be based on a microscopic examination of thyroid tissue.

TUMOURS

Tumours and cancers of the thyroid gland. Ninety percent of the noncancerous tumours (adenomas) of the thyroid are of the follicular type. The remainder fall into the embryonal, fetal, simple, colloid, Hürthle cell, or papillary types, or into an unclassified category. If the enlargement is nodular and goitre is not prevalent in that geographic area, the possibility of cancer is increased. Cancer of the thyroid makes up slightly more than 0.5 percent of all cancers and is responsible for slightly less than 0.5 percent of cancer deaths among adults.

Although it may affect children and the aged, cancer of the thyroid is largely a disease of middle life. As with all thyroid disorders, women are affected about twice as often as men, but observations on this point vary. Preexisting thyroid nodules and X-ray irradiation of the thymus, neck, face, and other nearby areas predispose to thyroid cancer. Cancer of the medullary type in association with another tumour arising in the adrenal medulla may occur in families. Medullary cancers arise from cells that produce thyrocalcitonin, a hormone that counteracts parathyroid hormone effects in bones.

Cancer of the thyroid is uncommon in childhood, making up about 4 to 6 percent of cancers in that age group. Females outnumber males in a ratio of 2:1. The peak rates in both sexes occur between the ages of seven and 14. A history of irradiation of the chest and neck area for enlargement of the thymus, acne, and other conditions is present in 20 percent or more of these cases. In children as in adults, papillary cancer of the thyroid is the most frequent; the follicular type is next in order, followed by the undifferentiated and the miscellaneous forms.

The most important symptoms and signs of thyroid cancer consist of discomfort on swallowing, anterior neck pain, and voice changes of recent origin, but none of these need be present. Also, although goitre occurs with most thyroidal cancers, the latter may exist in glands that appear grossly normal. Cancer of the thyroid, in general, spreads to the nearby lymph nodes and to the lungs, but such spread varies with the type of tumour. Extension to the skeleton, for example, occurs more often with the follicular than with the undifferentiated cancers and is rare with the papillary type.

Therapy. Localized cancers of the thyroid, particularly the papillary and follicular types, are usually removed by surgery. These well-differentiated cancers also respond well to follow-up local X-ray or to radioactive iodine administration. The undifferentiated cancers such as the small cell or giant cell types grow quickly, are more difficult to remove, do not take up radioactive iodide, and are less susceptible to external X-ray irradiation. In the miscellaneous groups, the epidermoid, the fibrosarcoma, the lymphoid, and the Hürthle cell types respond in part to surgery and to irradiation.

Persons with a history of a treated thyroid cancer are usually maintained indefinitely on full replacement dosages of desiccated thyroid or other thyroid hormones. This suppresses TSH and thereby minimizes recurrence and growth of the tumour. Five-year survival figures in thyroid cancer without regard to cell type or therapy range up to 60 percent. When the cell type is taken into account, survival is shortest in the undifferentiated—*i.e.* giant cell and small cell—cancers. The outlook is more favourable in most of the differentiated forms. Thus, five-year survivals in the papillary or the follicular type reach 70 to 90 percent or more, with the results generally better in the former. Hürthle cell cancers, because of their slow course, are believed to be relatively benign. In the other miscellaneous cancers of the thyroid, such as the epidermoid and the lymphoid, the fibrosarcomas, and the teratomas, survival usually reflects the statistics established for the individual cell types.

Survival after treatment of thyroid cancer

Prevention of cancer of the thyroid consists of limitation of X-ray of the neck and chest areas to procedures absolutely essential for diagnosis and remedial treatment, the removal of any goitres that are increasing in size or producing new symptoms, and the treatment of all noncancerous goitres, diffuse or nodular, with full replacement dosages of thyroid hormones for an indefinite period.

Cancers of nonthyroidal origin present elsewhere in the body can ultimately involve the thyroid gland. These are secondary cancers. The most common tumour that spreads to the thyroid gland from other sites is that originating in the bronchus, with cancers of the breast, stomach, lymph glands, larynx, cervix of the uterus, and esophagus next in order of frequency.

ASSOCIATED DISORDERS

Exophthalmos. Exophthalmos—*i.e.*, protrusion—and other abnormalities of the eye and surrounding structures occur in about one-half of the persons with thyroid overactivity, in a minority of those with thyroid underfunction, and, on rare occasions, in those whose thyroid function appears normal. Women are affected by exophthalmos about twice as often as men. Protrusion of the eyes, usually of a less severe degree, may also develop in Cushing's syndrome and in acromegaly. Spontaneous exophthalmos is to be differentiated from protrusion of the eye resulting from a tumour in the eye socket, clotting of blood in the venous channels within the skull, deformities of the eye socket, and from pseudoexophthalmos, in which the eyes only appear more prominent because of retracted eyelids. Such pseudoexophthalmos is common in individuals with an overactive thyroid and may occur in various illnesses such as asthma, congestive heart failure, and liver disease.

True exophthalmos may be divided into simple and malignant forms. In both, edema is frequent in the outer half of the upper lids (bulging), the lower lids, and adjacent areas. In simple exophthalmos, eye movements are grossly normal, but lid lag may be present, and conjunctival involvement is minimal or absent. Visual acuity is normal, and there is no double vision. In malignant exophthalmos, the eyes are more prominent, conjunctival swelling is marked, the eyes cannot be moved normally, and double vision is frequent; these various abnormalities are progressive, visual acuity becomes reduced, and the survival of the eyes is threatened.

Studies in humans and in experimental exophthalmos in animals have established that the protrusion of the eyes is produced by increases in the volume of tissues—muscles and cells—in the eye socket. Many theories have been advanced to explain the occurrence of exophthalmos in association with thyroid disorders. It has been suggested that exophthalmos is produced by the thyroid-stimulating hormone (TSH) or a closely related principle —*i.e.*, an exophthalmos-producing factor (EPF)—or a long-acting thyroid stimulator (LATS). As yet there is no

conclusive and consistent supporting evidence for any of these hypotheses.

Treatment with cortisol-type steroids often produces a decrease in exophthalmos of recent origin. Irradiation or removal of the pituitary or surgical removal of part of the wall of the eye socket have been successful in treating progressive exophthalmos.

Localized myxedema of the skin. In its usual form, localized myxedema is a firm swelling of the lower legs but may expand to a diffuse thickening of the skin of the legs and arms. The skin over the swelling resembles pigskin leather. It is usually accompanied by thyroid overactivity and exophthalmos but may first appear after hyperthyroidism has remitted or when post-treatment hypothyroidism has developed. Localized myxedema has been reported in thyrotoxicosis without exophthalmos and without thyroid disorder or eye abnormalities.

Features of localized myxedema

Microscopically, localized myxedema is characterized by features identical with, but more marked than, those seen in generalized myxedema. The viscid fluid causing the swelling is high in protein and acid mucopolysaccharides, including hyaluronic acid. Acid mucopolysaccharides may also be increased in unaffected portions of the skin. Localized myxedema probably results from excesses of thyroid-stimulating hormone (TSH) or related principles such as the exophthalmos-producing factor (EPF) or long-acting thyroid stimulator (LATS). As an alternative to the excess TSH, EPF, or LATS hypothesis, it has been suggested that sluggish venous blood brings about a release of hyaluronic acid from certain tissue cells with a production of edema.

Treatment of any underlying thyroid disease usually has no effect on the localized myxedema. The lesion itself is often asymptomatic and does not require therapy. If itching appears or cosmetic considerations are imperative, systemic treatment with ACTH or cortisone or localized injections of cortisol-type steroids can lead to the disappearance of localized myxedema. Success has been obtained with topical adrenal steroids and occlusion by wrapping. Injection of the enzyme hyaluronidase or of T_3 directly into the lesion or simple incision and drainage may produce partial relief. Some improvement after estrogen therapy has been reported. All forms of treatment have at times proved disappointing and surgical excision and grafting may be followed by recurrence.

Goitre. The word goitre refers to any enlargement of the thyroid. An enlarged thyroid gland, smooth or nodular, can represent, among other conditions, a nontoxic goitre, a failing or overactive thyroid, thyroiditis, a benign tumour, cancer, or involvement of this gland by tuberculosis, amyloidosis, or secondary cancer. In regions in which goitres are common, the frequency of thyroid overactivity, thyroiditis, and thyroid cancer is also increased.

Nontoxic goitres are thyroid enlargements that represent an attempt, usually successful, to restore the function of a failing gland to normal by increases in endogenous TSH. The prevalence of nontoxic goitre ranges from approximately 4 percent in the United States to as high as 85 percent in some parts of the world. The occasional cases are termed sporadic, and those that occur frequently in a particular area are called endemic. Nontoxic goitres representing a failing thyroid may result from (1) iodine–iodide deficiency, (2) marked iodine–iodide excesses, (3) defects of enzymes essential for thyroid hormone synthesis, (4) thiocyanate, perchlorate, and other agents that inhibit iodide trapping, (5) thyroid blocking compounds that interfere with the binding of iodine to protein—such as those with a thiocarbamide or related grouping, including propylthiouracil and methimazole—(6) partial destruction of the thyroid by radioactive iodine and other irradiation, (7) inflammatory disorders (thyroiditis), (8) increased urinary losses of iodide produced by high sodium chloride intake, or (9) increased fecal losses of thyroxine, as with high intake of soybeans. The possible role of variables other than iodine–iodide deficiency and environmental anti-thyroid agents in endemic goitre, including diet, water supplies, unsanitary conditions, infections, and ions such as calcium, tellurium, cobalt, fluoride, and cyanide, is incompletely defined. Heredity may play an important role in goitre, as in Pendred's syndrome (high-pitch deafness with goitre), perception deafness, and decreased binding of iodine to thyroid protein.

Causes of nontoxic goitres

Dietary and other iodine or iodide deficiency results in a shortage of thyroid hormones because this element is an essential component of T_3 and T_4. Blockade of thyroid hormone synthesis by excesses of inorganic iodide or elemental iodine is most likely to be encountered in individuals with conditions such as asthma, chronic bronchitis, or bronchiectasis who may be receiving large dosages of Lugol's solution or iodide salts. At one time that therapy was widely used, and it is possible that such goitres appeared only in susceptible individuals. The congenital (*i.e.*, inherited) and the acquired (dietary, drug inflammatory, or other origin) enzymatic defects interfere with the synthesis of thyroid hormones. Thus, any of the following may be decreased or absent: the trapping of iodine or iodide by the thyroid, the binding of trapped iodine to thyroidal tissues with iodination of tyrosine, the deiodination of excesses of monoiodotyrosine and diiodotyrosine, the coupling of iodinated tyrosines to form T_3 and T_4, or the formation of normal thyroglobulin. The rare defects in trapping are most often found among persons with a goitre and low thyroidal uptake of radioactive iodine. The binding defects are detectable by undue dumping of thyroidal radioactive iodine following potassium perchlorate or by thiocyanate administration. Thyroidal auto-immune antibodies are not a specific index of a nontoxic goitre due to thyroiditis, since they occur also in such conditions as colloid goitre, cancer, and thyroid overactivity.

Though, as indicated, most individuals with a goitre are euthyroid—*i.e.*, they secrete normal amounts of the hormone—this is not always true. In evaluating the status of the gland, the major indices of thyroid function (serum PBI and T_4 and thyroidal radioactive iodine uptake) and the minor indices (binding of T_3 to blood cells or resin, Achilles reflex time, lipid levels) must be obtained. Also, the possibility of a failing thyroid or of thyrotoxicosis should be investigated by the TSH stimulation and T_3 suppression tests, respectively.

Prevention and treatment of goitre

The prevention of goitre by administering elemental iodine or inorganic iodide is successful in the iodine deficiency type or in those that result from thiocyanate or other agents that interfere with the iodide trapping mechanisms. In goitres caused by thyroid blocking agents, such as the thiocarbamides, the administration of inorganic iodides or elemental iodine may slightly decrease the size of the gland and correct excessive vascularity. As indicated, however, marked excesses of iodide or iodine may themselves be goitrogenic, at least in certain individuals. On the other hand, desiccated thyroid in full maintenance dosages is highly effective in reducing the size of most nontoxic goitres that represent impending or actual thyroid failure. Long-standing large goitres with fibrosis may well be irreversible, however, even though the cause is removed, and those caused by cancer or tuberculosis will not respond. Also, such therapy is largely ineffective in diffuse toxic goitres because they result from LATS, a product of an auto-immune reaction to thyroid tissue.

III. The parathyroids

The parathyroids, usually four in number, are tiny glands located in the posterior part of the thyroid—either in the capsule or within the thyroid itself. They are the source of parathyroid hormone, a polypeptide that stimulates the removal of bone calcium and regulates the urinary excretion of inorganic phosphorus. Serum calcium and inorganic phosphorus levels are controlled in part by the level of parathyroid hormone. Thyrocalcitonin, a hormone elaborated by the clear cells of the thyroid, counteracts the effect of parathyroid hormone in bone and serves to reduce excesses of serum calcium to normal.

EXCESSES OF PARATHYROID HORMONE

Primary hyperparathyroidism. Primary hyperparathyroidism—excesses of parathyroid hormone without

recognized stimulus—can result from a noncancerous parathyroid adenoma, diffuse enlargement or hyperplasia of the parathyroids, or cancer of these glands, in this order of frequency. Most instances of primary hyperparathyroidism are diagnosed in persons between the ages of 30 and 70. The adenomas are multiple about 10 percent of the time, occurring predominately in females, whereas the sex distribution is about equal in adenomas of childhood and in the cancers. Parathyroid cancers, however, are rare. Increases in serum calcium and other manifestations of hyperparathyroidism have been observed with miscellaneous cancers of tissues unrelated to the parathyroid glands; such cancers produce a polypeptide with parathyroid hormone effects.

Signs and symptoms of hyperparathyroidism

The manifestations of primary hyperparathyroidism are often quite nonspecific; they may include loss of appetite, nausea, vomiting, constipation, fatigue, weight loss, and deafness of the conduction type. Personality changes, stupor, and coma may develop. Kidney stones and duodenal ulcers are common. Occasionally, acute and severe abdominal pain may appear as a result of pancreatitis. The blood pressure may increase and be followed by congestive heart failure or a cerebral hemorrhage. At times, far-advanced kidney failure may supervene.

Early in primary hyperparathyroidism, there is no X-ray evidence of bone change. With long-standing disease, bone density decreases, with loss of clarity of bone spicules or trabeculae first manifested in the shoulder blades and fingers. As the process of bone destruction (osteitis fibrosa) progresses, fractures, especially of the spine, may occur spontaneously or after minimal trauma. Rarely, increased forward curvature of the upper spine as a result of compression fractures of the vertebrae and pseudoclubbing of fingertips as a consequence of bone resorption may be present. Other X-ray findings may include deforming giant cell tumours of bone, calcification of soft tissues and cartilage, and loss of the lamina dura (the hard layer lining the alveoli) of the teeth. Conjunctival and eyelid deposits of calcium and band keratopathy may also appear, as they do whenever the serum calcium is above normal. The electrocardiogram and brain wave patterns may show changes indicative of high serum calcium levels.

High levels of serum calcium and low levels of inorganic phosphate are usually present in primary hyperparathyroidism. That disease, however, is not the sole cause of high serum calcium levels. The differential diagnosis, therefore, must include idiopathic (cause unknown) hypercalcemia of infancy, vitamin D poisoning, sarcoidosis, milk–alkali syndrome, cancers destructive of bone, tumours producing hypercalcemia, and the rare instances of hyperthroidism, myxedema, adrenocortical insufficiency, hypophosphatasia, and idiopathic osteoporosis associated with increases in serum calcium. In general, only the hypercalcemia of hyperparathyroidism fails to decrease after pharmacologic dosages of hydrocortisone and related steroids are administered in the so-called cortisone test; in the others, the serum calcium levels return to normal.

Serum alkaline phosphatase levels are increased in primary hyperparathyroidism only when bone involvement is extensive. Serum potassium and magnesium may be low. Increases in serum calcium impair the urinary excretion of hydrogen ions, and this may result in an alkaline urine. Other body fluids remain normal unless kidney failure supervenes.

Effect of hyperparathyroidism on urinary calcium

Urinary calcium is increased in hyperparathyroidism. This is most clearly demonstrated when the excretion of calcium in urine exceeds the daily intake of calcium and is one of the more reliable tests for hyperparathyroidism. Other indices employed in the diagnosis of this disorder include the urinary excretion of phosphorus in relation to urine creatinine, the effect of injections of parathyroid hormone or of calcium or phosphorus salts, the localization of the parathyroid tumour by its uptake of radioactive selenium, the demonstration of microscopic bone destruction by osteoclast cells, and the measurement of circulating levels of parathyroid hormone.

If stupor, coma, or a hypercalcemic parathyroid crisis occurs during primary hyperparathyroidism, the serum calcium can usually be lowered by administering phosphate, sulfate, or citrate salts. Therapy of primary hyperparathyroidism consists of the removal of the parathyroid tumour or tumours or of excess parathyroid tissue. In rare instances, emergency removal of the parathyroid tumour or glands has been necessary when hypercalcemic coma unresponsive to the usual measures has developed.

The possibility of a Zollinger–Ellison syndrome and variants thereof—comprising peptic ulcer, pancreatic islet tumour, adenomas of parathyroid and other endocrine glands such as the pituitary and adrenal, and other findings—is normally explored in any person in whom a parathyroid adenoma has been found. Hyperparathyroidism caused by a parathyroid adenoma without detected evidence of other endocrine adenomas may occur in brothers and sisters and in successive generations of the same family.

Secondary hyperparathyroidism. Chronic kidney failure (uremia) is the commonest cause of secondary hyperparathyroidism; *i.e.*, of excesses of parathyroid hormone traceable to a known cause. The increased secretion of parathyroid hormone results from the increase in serum inorganic phosphorus, the decrease in serum calcium, and the acidosis that develop in uremia. Under these circumstances, the absorption of calcium from the gut is impaired, and vitamin D is relatively ineffective. Parathyroid overactivity also occurs secondary to other types of chronic acidosis, rickets (osteomalacia), phosphate loading, and calcium deprivation.

Approximately one out of five persons with kidney failure and secondary hyperparathyroidism also shows X-ray evidence of bone destruction, and other bone lesions may also be present. Serum alkaline phosphatase levels are increased, and each parathyroid is increased in size—as differentiated from a primary parathyroid tumour or adenoma, in which usually only one gland is increased in size. Diffuse enlargement of more than one, or all, of the glands, however, can also be a cause of primary hyperparathyroidism. In some individuals with uremia, the secondary hyperparathyroidism raises the low serum calcium levels to or above the normal range. Under these circumstances, calcium is deposited in the soft tissues—especially in the kidney and, thus, further aggravates the kidney failure.

Restoration of normal calcium and phosphorus levels by means of an artificial kidney or by a kidney transplant can correct the secondary hyperparathyroidism. Surgical removal of the excess parathyroid tissue at times has been necessary in persons with renal failure, bone pain, repeated fractures, severe itching of the skin, and in those who develop high serum calcium levels after a kidney transplant.

DEFICIENCIES OF PARATHYROID HORMONE

Idiopathic and acquired hypoparathyroidism. In parathyroid underfunction—*i.e.* in hypoparathyroidism—the control of body calcium and phosphorus is disturbed. In one type of hypoparathyroidism, in which the parathyroid glands are absent, inorganic phosphorus is retained in the serum, which, at the same time, becomes deficient in ionized calcium. This condition frequently follows inadvertent removal of the parathyroids during thyroid surgery, occurs transiently after the excision of a parathyroid tumour, develops only rarely after treatment with radioactive iodine, may become manifest in infants born of hypoparathyroid, hyperparathyroid, or diabetic mothers, or has no identifiable cause.

Decreases in serum calcium can produce contractions and twitching of muscles (tetany), numbness and tingling, convulsions, cataracts, physical and mental retardation, malformation of the nails, faulty dentition, thin and dry hair, fungus infection (moniliasis), diarrhea, and, rarely, congestive heart failure. The tetany may first become manifest after an acute infection or following pregnancy or during lactation. Hypoparathyroidism may occur in various combinations with Addison's disease, pernicious anemia, fatty diarrhea, and moniliasis.

The diagnosis of hypoparathyroidism depends on the

demonstration of decreases in serum calcium and increases in serum inorganic phosphorus, both in the absence of kidney failure. The serum alkaline phosphatase levels are normal. Changes may be present in the electrocardiogram and brain wave tracings, but results of X-ray examination of the skeleton are usually normal. Calcification of the soft tissues or of the basal ganglia of the brain can occur. The individual with acquired or idiopathic hypoparathyroidism responds to injections of parathyroid hormone of animal origin by an exaggerated increase in the excretion of phosphorus in the urine.

Treatment of hypoparathyroidism

Treatment with vitamin D or related sterols (*e.g.*, dihydrotachysterol) and large amounts of calcium salts, such as calcium lactate, can restore serum calcium levels to normal. The drug probenecid, which increases the urinary excretion of phosphorus, may also be used. Diets low in phosphate and the oral administration of aluminum hydroxide gels, which remove phosphate via the gut, may be prescribed to decrease the serum phosphorus levels.

Pseudohypoparathyroidism. Pseudohypoparathyroidism is characterized by all of the features of hypoparathyroidism, such as tetany, convulsions, and cataracts, plus variable somatic and skeletal abnormalities. In pseudohypoparathyroidism, however, the parathyroid glands are present and may even be enlarged, but the tissues do not respond normally to parathyroid hormone. Body build, bone, and soft tissue abnormalities may be present in pseudohypoparathyroidism; these include a short, thickset body, round face, shortening of lateral digits of the hands and feet due to short metacarpal and metatarsal bones, and calcification of the brain basal ganglia and of subcutaneous tissues. The bone changes in pseudohypoparathyroidism are of the chondrodysplastic type and are not recognized to be causally related to the pseudohypoparathyroidism. Females are affected more often than are males by the condition.

Secondary hypothyroidism—*i.e.*, a shortage of thyroid hormones secondary to a lack of pituitary TSH—may also develop.

The criteria for the diagnosis of pseudohypoparathyroidism consist of low serum calcium levels and increased serum inorganic phosphorus without evidence of kidney failure or other disease, normal serum alkaline phosphate, and absent or diminished increase in urine phosphorus after injection of parathyroid extract (the Ellsworth–Howard test). Since injection of parathyroid extract either does not induce an increase in urine phosphorus or produces a poor response by comparison to that obtained in idiopathic or acquired hypoparathyroidism, it is evident that the kidneys are absolutely or relatively unresponsive to this hormone, meaning that an end-organ defect is present.

Therapy of pseudohypoparathyroidism is the same as that employed for idiopathic or acquired hypoparathyroidism—*i.e.*, vitamin D, dihydrotachysterol, calcium salts, low phosphate regimens, aluminum hydroxide gel to increase the fecal loss of phosphate, and probenecid to raise the urinary output of phosphate—but parathyroid hormone, of course, would be of no therapeutic value.

Pseudo-pseudohypoparathyroidism. Individuals who resemble those with pseudohypoparathyroidism in body build and skeletal abnormalities but whose serum calcium and phosphorus values are normal have been called pseudo-pseudohypoparathyroid. This term is confusing, and it is simpler to designate them as chondrodysplastic. The condition differs, however, from ordinary chondrodysplasia in that, as in pseudohypoparathyroidism, soft tissues such as those of the skin, feet, and ears may become calcified, and calcium deposits may be present in the brain. At times excrescences (exostoses) develop in various bones. This type of chondrodysplasia has also been observed in individuals with gonadal dysplasia of the Turner's syndrome type (see also GENETICS, HUMAN).

IV. The adrenals

ADRENAL CORTEX

The adrenal, or suprarenal, glands present at the upper ends of the kidneys produce two completely different sets of hormones. The outer layer, or cortex, is the source of several steroid hormones. The inner portion or medulla secretes amine (NH_2-type) hormones, substances of completely different chemical and physiological properties.

Zones of the adrenal cortex

The adrenal cortex can, in turn, be subdivided into three zones, depending on cell type and arrangement and, more importantly, on the basis of the steroid hormone produced by each of these layers. Thus, the outermost layer, or zona glomerulosa, is the production site of aldosterone, a potent mineral-regulating steroid. The middle, or zona fasciculata, secretes cortisol (hydrocortisone), a steroid hormone. Cortisol is essential for life; it influences the metabolism of foodstuffs, controls sodium, potassium, and chloride exchanges, and participates in a host of other processes. The innermost layer of the cortex, or zona reticularis, is the site of adrenal androgen and estrogen production. The activities of the middle and inner zones of the adrenal cortex are under the influence of ACTH of the anterior pituitary and, in turn, of the ACTH-releasor factor or corticotropin-releasor factor, or CRF, of the hypothalamus. Needs for additional amounts of cortisol evoke increases in CRF and, in turn, of ACTH; on the other hand, the administration of amounts of cortisol in excess of daily secretion suppresses CRF and ACTH. These fluctuations in CRF and ACTH in response to cortisol needs also affects adrenal androgen and estrogen production because, as mentioned, the zona reticularis is controlled by ACTH.

The control of aldosterone secretion from the outer layer of the adrenal centre is mediated largely through extra-hypothalamic and extra-pituitary sources such as the juxtaglomerular apparatus of the kidney (see ENDOCRINE SYSTEM, HUMAN), which elaborates the hormone renin. Renin, in turn, influences the production of substances called angiotensin I and II, and the latter evokes a secretion of aldosterone from the zona glomerulosa. Only under limited circumstances does this outer layer of the adrenal cortex respond to ACTH.

Excesses of adrenocortical hormones. *Cushing's syndrome.* Cushing's syndrome develops as a consequence of a prolonged excess of cortisol or related steroids. It may result from a basophilic tumour of the pituitary gland as originally suggested by Harvey Cushing, the surgeon who first described the condition, and is then called Cushing's disease or pituitary basophilism. Such pituitary tumours produce great excesses of adrenocorticotropin (ACTH), which increase the secretion of cortisol by the outer layer of adrenal cortex and result in hyperplasia (enlargement) of this portion of the adrenal gland. More often, however, spontaneous Cushing's syndrome results from enlargement of the outer layers of the adrenal glands without evidence that a pituitary tumour is present. Less often, a benign tumour (adenoma) or a cancer of the adrenal cortex causes a spontaneous Cushing's syndrome. In rare instances, other cancers—such as those of the lung, colon, or thyroid—produce ACTH, and Cushing's syndrome results. Cushing's syndrome can also be produced by the administration of sufficient amounts of ACTH of animal or laboratory origin or of synthetic cortisol-like steroids.

Bodily effects of Cushing's syndrome

The excesses of cortisol and related steroids that develop in the spontaneous or induced types of Cushing's disease or syndrome affect the following systems and tissues: *Central nervous system:* Serious emotional illnesses (psychoses) in 25 percent and less obvious emotional and personality changes in another 35 percent of the spontaneous instances of Cushing's syndrome; 15 percent, or higher, incidence of personality disturbances in the therapy-induced type. *Body build:* Obesity of the trunk, thin extremities, localized collections of fat (round and moonlike face, "buffalo hump" and supraclavicular —across the shoulder—pads) and increased prominence of the eyes (exophthalmos). *Skin and hair:* Redness of the face (caused by dilated capillaries), purple stretch marks at the hips and shoulders; and baldness or hirsutism in the female. *Lymphoid tissues and blood:* Decreased lymphoid tissue, low blood eosinophil and lymphocyte counts and increased numbers of blood polymorphonuclear leucocytes, possible changes in basophils, platelets,

and sedimentation rate, and shortened coagulation time (see also BLOOD, HUMAN). *Heart, blood vessels, and kidneys:* High blood pressure, increased heart size, possible congestive heart failure; kidney failure, usually, with longstanding disease. *Body fluids:* Sodium and chloride retention, potassium losses, and metabolic alkalosis; lowered concentrations of chloride and potassium in serum (effects are less marked or absent with certain of the newer synthetic cortisol derivatives); increased uric acid, calcium, phosphorus, and possibly magnesium, in the urine. *Gastrointestinal tract:* Abdominal discomfort; increased incidence of ulcers. *Liver:* Increased liver glycogen storage and variable increases in bile flow. *Pancreas:* Decreased volume and change in composition of pancreatic secretions, destruction (necrosis) of pancreatic fat. *Metabolism:* Losses of body nitrogen, blockade of insulin action, increased sugar formation from protein (gluconeogenesis), delayed glucose disposal and diminished response to insulin, and frank diabetes mellitus in 25 percent of spontaneous Cushing's syndromes. *Muscles and skeleton:* Muscle weakness, thinning of the bones (osteoporosis), and compression fractures in advanced stages of the disease.

Treatment and remission of Cushing's syndrome

Many of the manifestations of Cushing's syndrome disappear when the cause of the cortisol excesses is removed. If the cause is from ACTH or steroid treatment, remission occurs when treatment is discontinued. In the spontaneous types, partial or complete surgical removal of the overactive adrenal cortices, or of the ACTH-producing tumour of the pituitary, or cancer located in other tissues or organs, is followed by a remission of the symptoms and signs. Daily treatment with cortisol is essential if the adrenal cortices have been completely removed, but it may also be necessary after partial removal of these glands. Cushing's syndrome is also treated at times by irradiation of the pituitary with a proton beam, by implants of radioactive materials, or by administration of certain chemical agents that block cortisol production.

Normal adrenocortical function is not always the end result of successful therapy of Cushing's syndrome. Removal of a hyperfunctioning adenoma or cancer may leave the patient hypoadrenocortical—*i.e.*, short of adrenal steroids—because of persistent suppression of the remaining adrenal. Also, surgical removal of the entire pituitary or other induced forms of hypopituitarism are followed by deficient gonadal, thyroidal, and adrenocortical function. Most of these can be corrected by appropriate replacement therapy.

Even when the Cushing's syndrome and the untoward effects or side effects of treatment have been eradicated, however, some of the changes produced by the Cushing's syndrome may continue. This is true, for example, of the heart, blood vessel, kidney changes, and the osteoporosis. Finally, pituitary enlargement may follow adrenalectomy as a result of the growth of a previously present or newly developed pituitary tumour.

Primary aldosteronism. Aldosteronism refers to the presence of excess aldosterone, an adrenal steroid with potent mineral regulating and other effects, secreted by the adrenal glands. During good health, the time of day, the position of the body (*i.e.*, upright or horizontal), and the body's supplies of sodium and potassium affect the rate of secretion of aldosterone. Aldosterone secretion is higher during the day and in the upright position. Sodium loading or potassium restriction decreases the aldosterone secretion, whereas sodium depletion or potassium excess raises it. Under ordinary circumstances, the adrenal glands of healthy individuals secrete less than 300 micrograms (millionths of a gram) of aldosterone daily. About one-seventh of this amount appears in the urine, and plasma levels of this hormone are one microgram per litre or less. When these limits are consistently exceeded, either primary or secondary aldosteronism—*i.e.*, hyperaldosteronism—is considered to be present. Primary aldosteronism results from a benign tumour (adenoma) or a cancer of the adrenals and rarely from an unexplained increase in the size of the aldosterone-secreting layers of these glands. The secondary type represents excess aldosterone production in response to various disturbances in the body fluids and in the concentration and amount of sodium and of potassium in particular.

Bodily effects of primary aldosteronism

Primary aldosteronism produces the following manifestations: Weakness, disturbed sensations, and possible tetany; usually persistent high blood pressure (edema is rare); increased losses of potassium in urine; low levels of potassium and high levels of sodium in serum; increased fecal losses of potassium, calcium, and magnesium; inability to concentrate urine with resultant increased urine volumes; vacuole formation in kidney tubules of the type seen in potassium depletion; destruction of fibres; periodic paralysis of the low-potassium type; increased frequency of diabetes mellitus; decreased response to antidiuretic hormone with increased urine volume and increased thirst.

Primary aldosteronism is treated by surgical removal of the excess adrenocortical tissue. The effects of aldosterone excesses on blood pressure and body electrolytes can be cancelled by the drug spironolactone, which interferes with the action of aldosterone.

Secondary aldosteronism. Secondary aldosteronism is most commonly seen in association with congestive heart failure, cirrhosis-like kidney disorders, including the nephrotic syndrome, either as a result of the underlying disease or as a consequence of treatment with diet or medications that produce a shortage of sodium or an excess of potassium. Edema—*i.e.*, swelling of body tissues—is common. Edema that develops during the day in some women while walking about may also be a form of secondary aldosteronism and can be overcome by lying down.

Successful treatment of the heart, or of liver or kidney disorder, and cancellation of the electrolyte abnormalities that produced the secondary aldosteronism returns the supplies of the hormone to normal. Aldosterone antagonists, such as the spironolactones that block the action of the hormone in the kidney tubules, may eliminate the excess sodium and water and other abnormalities that characterize secondary aldosteronism.

Deficiencies of adrenocortical hormones. *Addison's disease.* Historically, the phrase Addison's disease has generally referred to those instances of spontaneous and gradual loss of adrenal steroid secretions that result from destruction of the adrenal cortices by such conditions as atrophy, tuberculosis, or other invasion by micro-organisms, and cancer. An equivalent degree of primary hypoadrenocorticism—*i.e.*, shortage of adrenocortical steroids—however, can result from surgical removal of the adrenals, suppression of adrenal function by prolonged steroid therapy, massive bleeding into the adrenals, or by toxic agents. Adrenocortical insufficiency involving decreased secretion of cortisol as a result of enzymatic abnormalities can also be a feature of the adrenogenital syndrome.

The microscopic findings in the causes (etiology) of Addison's disease appear to be changing: tuberculosis of the adrenals is decreasing, whereas the incidence of idiopathic atrophy is rising. The origins of the latter are not entirely clear. It is conceivable that in some instances specific agents or events, such as chemicals or hemorrhage, respectively, produced the destruction, but most cases of the atrophic type probably result from destruction of the adrenals by circulating antibodies. Addison's disease predominates in adults, becoming manifest most often in early or middle life, but it can also develop in children. Also, the simultaneous occurrence of a fungus infection—moniliasis—and of deficient parathyroid gland secretion in children with Addison's disease has been observed.

None of the manifestations of Addison's disease can be considered diagnostic as they also occur under other circumstances. Combinations of the following, however, point to the diagnosis: fatigue and weight loss; occurrence of increased pigmentation of skin and mucous membranes, especially at pressure points and in scars, dark brown freckles, and areas of depigmentation (vitiligo); variable decreases in body and sex hair; rarely, personality disturbances, or even psychosis; abnormal brain wave tracings; low blood pressure, decreases in

blood pressure on standing; small-sized heart, abnormal heart tracings; circulatory collapse during adrenocortical or Addisonian crises; loss of appetite; nausea and vomiting; increase in blood lymphocytes and eosinophils; depletion of sodium, chloride, and water; retention of potassium; metabolic acidosis; delays in excretion of water; reversibly impaired kidney function and retention of nitrogen as a result of decreased circulatory efficiency; abnormally low values of cortisol in plasma and of cortisol derivatives, 17-ketosteroids, aldosterone, and other adrenal steroids in urine—not corrected by injections of ACTH; decreased liver glycogen stores; unduly low blood-sugar levels in the fasting state or following sugar or insulin administration; inflammation of the thyroid (thyroiditis); associated hypoparathyroidism or diabetes mellitus; decreased steroid requirements during pregnancy.

Partial versus total Addison's disease

Addison's disease may be partial; *i.e.*, steroid secretions are adequate under nonstress situations but cannot be adequately increased during infection, surgery, and other stress because adrenocortical reserves have been lost. Fractional Addisonian-like deficiencies can also occur: loss of cortisol with adequate production of aldosterone and androgens, deficits of aldosterone with other steroids normal, and similar situations.

In total Addison's disease, there is a disturbance or complete loss of (1) maintenance of normal volumes and levels of body water and salts by means of adrenal mineral-regulating steroids, (2) control of metabolism by cortisol, and (3) contributions of adrenal androgens and estrogens to muscle strength, body build, and secondary sex characteristics. Thus, deficits in aldosterone, desoxycorticosterone (DOC), and perhaps of cortisol and related steroids result in inadequate kidney reabsorption and subsequent loss of sodium and chloride ions and water. The end result is potassium retention and circulatory collapse. Collapse or crisis as a consequence of cortisol deficits may, however, occur suddenly before any changes in body fluids become evident, because cortisol is essential for life and normal cell function. Moreover, shortages of cortisol affect the conversion of foodstuffs to glucose and the storage of glycogen. Thus, the formation of glucose from amino acids and glycerol is impaired, and the deposition of glycogen is reduced. At the same time, the blockade of insulin action that cortisol and related steroids exert on the tissues is lost. The blood sugar usually decreases to a moderate degree, but this may or may not produce symptoms. Finally, the loss of adrenal androgens deprives the female of her only significant source of these steroids, decreases sex hair and libido, and aggravates the loss of muscle strength. These changes are less significant in the male because of the continued contribution of androgens by the testes. The deficits of adrenal estrogens do not appear to be clinically significant in either sex.

The increased pigmentation of the skin and mucous membranes of Addisonian patients is attributable to losses of cortisol, desoxycorticosterone, and other steroids with subsequent stimulus (via feedback) to higher regulatory centres, including the pituitary and hypothalamus. This evokes an increased output of adrenocorticotropic hormone (ACTH) and melanocyte-stimulating hormone (MSH), each of which increases melanin pigment production. Aldosterone deficits do not play a role in the hyperpigmentation because, as previously mentioned, the secretion of this steroid is not primarily under the control of ACTH.

The above interrelations illustrate, however, the relative or possible roles of the various classes of adrenal steroids in homeostasis—*i.e.*, the overlap of aldosterone, DOC, and cortisol in the regulation of electrolytes and water; the major contribution of cortisol to intermediary metabolism; and the less significant role of aldosterone and the unimportance of DOC in this respect. The complexity of regulatory mechanisms is further evident in the control of water balance. Thus, in adrenocortical insufficiency, DOC can raise the kidney glomerular filtration rate (GFR) but cannot restore to normal the excretion of a water load; aldosterone also fails in the latter respect, but cortisol and related steroids do accomplish this. Similarly, overlapping of aldosterone, DOC, and cortisol is manifest in the regulation of sodium excretion.

Use of adrenal steroid secretion in diagnosis

Definite evidence of primary—*i.e.*, nonpituitary and nonhypothalamic—adrenocortical insufficiency must be based on the demonstration of the absence of, or restricted, ability of the adrenals to elaborate the chief classes of adrenal steroids under the impetus of adequate stimulation. In the case of cortisol and the androgenic and other precursors of the 17-ketosteroids of adrenal origin, ACTH administration provides a simple and adequate stimulus. (ACTH can also be used to test the adrenal output of estrogen, but this is not a useful test for Addison's disease). In usual practice, ACTH of animal or synthetic origin is injected, and the diagnosis of Addison's disease is established if plasma cortisol-like steroids or the various adrenal-steroid products present in urine do not increase. Aldosterone secreting capacity is tested by measuring the levels of this hormone in response to rigid restriction of sodium, potassium loading, or both, since, as already indicated, aldosterone secretion is not under significant ACTH control.

Other indices employed for the diagnosis of Addison's disease are less conclusive. Thus, sodium and chloride levels may be low in serum and high in sweat and in urine, while potassium is high in serum and low in sweat and urine. All three electrolytes, however, may be normal in these various body fluids. The excretion of water loads is generally delayed in adrenocortical failure, but false positive and, less often, false negative tests occur. Failure to demonstrate sodium conservation and the production of potassium accumulation by diets deliberately low in sodium or high in potassium is an extremely dangerous index of loss of mineral-regulating steroids and, therefore, is no longer used in detecting Addison's disease. Although low blood-sugar levels are usual in Addison's disease, they are not dangerously low, nor are they limited to this disorder; the same is true of the responses to glucose or insulin. Inconsistencies in circulating eosinophil and urinary uric acid–creatinine responses to ACTH render these indices virtually useless as criteria for diagnosis in individual patients.

In the past, sodium supplementation, potassium restriction, and between-meal feedings prolonged survival, but for only a few months, and it did not correct the weakness and fatigue of Addison's disease. Some persons lived for a decade or more, but these may well have had some residual ability to produce cortisol. The advent of desoxycorticosterone (DOC) solved the problem of sodium depletion and potassium retention but did not meet the need for cortisol. Stresses such as infections and surgical procedures still produced crises that often proved fatal. Adrenocortical extracts were employed in the treatment of such crises, but the quantities of steroids, and of cortisol in particular, thus administered were often too small. Expense prohibited use of these extracts for maintenance purposes.

Synthetic adrenal steroids for treatment and maintenance

The current availability of synthetic cortisol-like and related adrenal steroids has greatly simplified the maintenance and treatment of adrenocortical insufficiency. The usual programs are based upon cortisol in daily maintenance dosages, often supplemented by sodium- and potassium-regulating steroids, such as desoxycorticosterone or closely related 9-α-fluorohydrocortisone. In times of stress or in crisis, the dosages of cortisol are increased to quantities sufficient to avert or correct Addisonian crises.

Waterhouse–Friderichsen syndrome. The Waterhouse–Friderichsen syndrome consists of a fulminating infection, usually meningococcal, in the bloodstream (septicemia); hemorrhage; or clotting of the blood in the adrenal glands, in the skin, and in blood vessels in general; adrenocortical insufficiency; and circulatory collapse. Actual hemorrhage into the adrenal may not be present even in fatal cases, although adrenocortical destruction is usually evident. The syndrome is especially likely to occur in children.

The two major problems in this illness are adrenocortical insufficiency and the extensive hemorrhage and

clotting of blood in tissues. Treatment consists of massive dosages of cortisol (there is not an expert consensus on this point), sulfa drugs, fluids, and support of the blood pressure as needed.

Adrenalectomy. Removal of the adrenal or adrenals (adrenalectomy), partial or complete, is highly effective in the treatment of tumours of the adrenal cortex or medulla, in Cushing's syndrome, and in primary aldosteronism. It has also been successfully employed in attempts to prevent the growth of spreading cancer of the breast. In the past it was used, with questionable benefit, to treat prostate cancer, and with some effect in the control of hypertension unresponsive to drugs and none in the slowing or stopping of vision-threatening changes in the eyes of diabetic individuals.

Preoperative and postoperative care is based on the administration of adequate quantities of cortisol: 500 milligrams or more, or physiologically equivalent amounts of related steroids are given during the first day. These quantities are decreased on successive days. Ultimate maintenance dosages, when needed, are the same as those employed in other types of adrenocortical insufficiency.

Secondary hypoadrenocorticism. Decreases in or losses of pituitary adrenocorticotropic hormone (ACTH) as a consequence of nonfunction of the pituitary or the hypothalamus result in secondary hypoadrenocorticism and a shortage of adrenal steroids other than aldosterone.

Causes of secondary hypoadrenocorticism

This may result from destruction of the pituitary by a tumour, for example, or hemorrhage, surgery, or from damage to the ACTH-releasor areas of the hypothalamus. Such adrenocortical underfunction may also be a feature of myxedema with resultant depression of the pituitary. The most common form, however, is that induced by prolonged therapy with cortisol and related steroids. In theory, secondary hypoadrenocorticism is easily distinguished from the primary type by the absence of increases in urine and plasma steroids in the latter following ACTH injection. Responses to ACTH, however, may also be decreased or absent in long-standing secondary hypoadrenocorticism.

Patients with secondary hypoadrenocorticism do not show the pigmentary or sodium, chloride, and potassium symptoms of pituitary adrenocortical insufficiency of the Addison's disease or related type, but all the other manifestations may be present. In addition, patients with damage of the pituitary or hypothalamus will often have FSH, LH, TSH, or growth hormone deficits and, at times, diabetes insipidus, obesity, and other dysfunctions. ACTH in plasma or serum is difficult to measure, and such data are not readily available. Indirect evidence of ACTH deficiency may be obtained with the drug metyrapone, which blocks cortisol synthesis. In the normal person it evokes a rise both in ACTH and in certain easily measured plasma and urine steroids.

There is at present no satisfactory method of avoiding the adrenal suppression produced by large dosages of cortisol-type steroids taken for many months or years. The best preventive is the limitation of steroid therapy to intermittent courses of several days or administration of a single large dose of steroids every 48 hours. Also, intermittent injections of ACTH may serve to keep the adrenal cortices responsive until internal secretion of ACTH is resumed.

Therapy of secondary hypoadrenocorticism of the irreversible type consists of replacement dosages of cortisol with provision for increases during stress. Aldosterone or desoxycorticosterone (DOC) are not needed, either because endogenous production remains adequate despite losses of ACTH or because mineral regulation is effected by the cortisol. If gonadotropins and TSH have also been lost, androgens or estrogens and thyroid are given. Care is taken to meet the cortisol needs before administering thyroid hormones in myxedema and thereby avoid the possibility of an adrenocortical crisis.

Combined deficits and excesses of adrenocortical hormones. *Adrenogenital syndromes.* The phrase adrenogenital syndromes refers to specific disorders of the adrenal and either the ovaries or testes, often accompanied by abnormalities of the genital apparatus. The adrenogenital syndromes of infancy and childhood are characterized by compensated, impending, or actual deficits in the enzymatic synthesis of cortisol by the adrenals that are genetically determined, and by an associated excess of androgen production by the adrenal glands. The actual or impending shortage of cortisol evokes an increased secretion of adrenocorticotropic hormone (ACTH) by the pituitary, which increases cortisol production toward or to normal but simultaneously raises above normal the production of adrenal androgens.

Symptoms of the adrenogenital syndrome

The recognized symptoms and findings in the several types of adrenogenital syndromes stem from varying combinations of ACTH-induced androgenic excesses, deficits of cortisol, and the production of other steroids in disproportionate amounts.

Excesses of androgens in certain types of adrenogenital syndrome present before birth produce male-like genital changes (pseudohermaphroditism) in genetic females and excessive genital development with small testes in genetic males. Masculinization of body build then occurs in both sexes, and sex hair appears prematurely, but breast development and menses are absent. Body growth is accelerated, but the ultimate height is shortened. Acne may appear in both sexes, and facial hair increases in the females. In persons with the 3-β-hydroxyl dehydrogenase deficiency or those with defects in conversion of cholesterol to pregnenolone, the developmental and genital changes are variable. In the former, the newborn infant may die, and, in the latter, undescended testes have been noted. The 17-α-hydroxylase type of adrenogenital syndrome has been characterized by absence of menses, high blood pressure, and swelling of the extremities and other tissues.

The deficits of cortisol that occur in the adrenogenital syndrome produce pigmentation of skin and mucous membranes as a result of the excesses of ACTH. Life-threatening Addisonian or adrenocortical crises may occur with or without increases in serum potassium, decreases in serum sodium, acidosis, and kidney failure. Blood-sugar levels tend to be low; the disposal of sugar loads is accelerated; and the blood-sugar responses to insulin are increased. In addition to the cortisol shortages, actual or impending, present in all types of adrenogenital syndromes, the levels of other steroids are also altered. Another enzymatic defect of steroid production by the adrenals results in a shortage of aldosterone. This has not been associated with changes in the genitalia nor with a shortage of cortisol.

Treatment of adrenogenital syndromes

The adrenogenital syndromes are treated by replacement–displacement amounts, usually 20 to 30 milligrams per day on a maintenance basis, of cortisol. This results in the return of normal steroid patterns; *i.e.*, the shortage of cortisol is cancelled, and the excessive production of androgens and of steroids, which results in masculinization, high blood pressure, and related manifestations, ceases. The adrenocortical crises are treated as in Addison's disease. Therapy of amenorrhea requires estrogen administration. Plastic surgery on the genitals and reorientation of the individual's social sex are then undertaken after careful review of the psychological and emotional factors involved.

Adrenogenital syndromes can be mimicked by excesses of various steroids with actual or potential androgenic activity administered during pregnancy and resulting in abnormal development of the genitals prior to birth. Also, the administration to growing children of medications with male sex hormone produces changes in the body build, sex hair, and genitals of the type that develop spontaneously in the adrenogenital syndrome. In these, however, there are no subsequent developmental abnormalities of the type seen in the enzymatic forms of adrenogenital syndrome, such as accelerated body growth, retarded or accelerated sexual maturation, and others previously described. Also, the tendency to cortisol deficits and the abnormal steroid patterns encountered in the spontaneous adrenogenital syndrome are not present, and the urinary 17-ketosteroids are not elevated.

Adrenogenital syndromes may also be mimicked by

tumours of the adrenals, the testes, the ovary, or other tissues that can produce excesses of male sex hormone and thus modify the primary and secondary sex characteristics of males and females, while cortisol production and supplies are normal.

Finally, adrenogenital type changes of unexplained origin may be present at birth. Some of these are associated with gross abnormalities of the gastrointestinal and urinary tracts.

Adrenogenital syndrome in adults. Adrenogenital syndromes based on deficiency of certain hydroxylase enzymes may occur in adults. In each of these syndromes, the shortage of cortisol can result in an Addisonian crisis. Hypertension can be a feature of the 11-β-hydroxylase and the 17-α-hydroxylase types. Increases in body hair other than the scalp and masculinizing changes develop in the 21-β-hydroxylase and 11-β-hydroxylase disorders but not with 17-α-hydroxylase deficiency. Loss of menses occurs in all three.

Changes in blood serum content

The blood and serum solute changes, when present in the 11-β-hydroxylase and 21-β-hydroxylase types, are the same as those that occur in the childhood form. They may include low blood sugar and increased serum urea nitrogen, depletion of sodium, and increases in serum potassium. In the 17-α-hydroxylase type, an excess of desoxycorticosterone results in retention of sodium, losses of potassium and chloride, and increases in serum carbon dioxide. The plasma and urinary steroid patterns are identical with those observed in children. In all three forms, treatment consists of cortisol in replacement–displacement dosages, and estrogen is also given in the 17-α-hydroxylase type.

Increases in facial and body hair (hirsutism) may be present in females who do not have one of the recognized forms of adrenal or ovarian disorders—such as the adrenogenital syndrome, Cushing's syndrome, adrenal or ovarian tumour, or polycystic ovarian change—that increase androgen supplies and support hair growth. Some represent unrecognized disorders. In others, hirsutism may be a genetic trait or may result from undue sensitivity of hair follicles to ordinary supplies of androgen. In such hirsutism, a trial of cortisol-type steroids in small dosages may be undertaken. Estrogens or ovulation suppressants may also be effective.

ADRENAL MEDULLA

The adrenal medulla produces three simple amines or catecholamines: epinephrine or adrenaline, norepinephrine or noradrenaline, and isoproterenol, which, in addition to their endocrine functions, also serve as chemical mediators of autonomic nerve impulses in various organs.

Responses to epinephrine and norepinephrine

The responses to epinephrine and norepinephrine differ. The former produces a net dilatation of peripheral blood arterioles, decreases the diastolic blood pressure, and increases the pulse pressure (*i.e.*, the difference between the systolic and diastolic blood pressure readings), the pumping action of the heart, and the pulse rate. Norepinephrine induces constriction of peripheral vessels, increases the diastolic blood pressure, narrows the pulse pressure, decreases the output of blood by the heart, and slows the pulse rate.

Both epinephrine and norepinephrine raise the blood glucose by mobilizing glucose from liver and muscle glycogen and restricting the output of insulin by the pancreas. These two amines also mobilize fatty acids from body fat depots.

Isoproterenol is the most active of the amines that act almost exclusively on beta receptors: the heart, the smooth muscles of the bronchi, the blood vessels of skeletal muscle, and the alimentary canal. The hormone lowers peripheral vascular resistance, raises cardiac output, relaxes smooth muscle, and causes the release of free fatty acids. It causes less hyperglycemia (high blood sugar) than does epinephrine but has almost the same calorigenic value.

Pheochromocytomas are catecholamine-secreting tumours that develop in the adrenal medulla or at nerve endings. Those within the adrenal secrete epinephrine and norepinephrine. Those that arise from nerve endings produce only norepinephrine. They occur in the population at a rate of 1 per 1,000 and are more likely to involve the right adrenal. They may be large or small, are bilateral about 10 percent of the time, and one out of ten are cancers. The tumour may occur in locations outside the abdominal cavity; *e.g.*, the chest, the pelvis, or the urinary bladder. The possibility of a pheochromocytoma is especially likely in relatives of proved cases and in persons with conditions such as neurofibromatosis.

Transient or persistent elevation of the blood pressure is almost an invariable hallmark of the tumour, but the following may also be encountered: *General:* thin body build, pallor, and sweating; *central nervous system:* headache, nervousness, anxiety, personality change, convulsions, and eye ground (fundus) signs indicative of high blood pressure; *other heart and blood changes:* heart pain, shortage of breath, enlargement of the heart, congestive heart failure, cyanosis, and blood pressure decreases on assuming upright position (postural hypotension); *effects on urine and kidneys:* protein and sugar in the urine; kidney failure; *gastrointestinal:* abdominal pain, vomiting; *endocrine and metabolic:* increased water exchanges, diabetes mellitus, loss of subcutaneous fat, and elevated basal metabolic rate (BMR).

The availability of analytical technics or assays for the measurement of epinephrine and norepinephrine and their derivatives in urine and other body fluids has greatly facilitated the identification of such tumours. A diagnosis may also be made by various X-ray techniques, by provoking a rise in blood pressure by massage of the tumour area, or by the intravenous injection of test substances such as histamine when the blood pressure is not elevated. If the blood pressure is high, such drugs as phentolamine or piperoxan, which cancel the blood pressure rises produced by epinephrine or norepinephrine excesses, are injected and are used as screening tests for pheochromocytoma. Anesthesia, sedatives, drugs that lower the blood pressure, and kidney failure increase the incidence of false results with these screening tests.

Successful surgical removal of the tumour usually brings about a disappearance of all the reversible manifestations of a pheochromocytoma, but in some persons high blood pressure and diabetes mellitus persist. Cortisol steroids must be given during and following surgical procedures in which both adrenals are removed.

V. The gonads

PREMATURE DEVELOPMENT

True sexual precocity—*i.e.*, early maturation of ovaries and testes with production of ova before the age of nine years in girls, or sperm before ten years in boys—occurs without evident cause (constitutional or familial type) or as a manifestation of cerebral disease (cerebral type). In such true sexual precocity, the maturation of genital structures and body growth are also accelerated, and early reproduction is possible—*i.e.*, as early as the age of six years. After a period of accelerated growth, premature fusion of the growing ends of the bones, the epiphyses, occurs with ultimate stunting. The manifestations in the cerebral type are the same as those in constitutional or familial true sexual precocity. In addition, intracranial disease (brain tumour, for example, or fibrous dysplasia, abscess, encephalitis, or hydrocephalus) is present. Laboratory indices of ovarian or testicular function such as gonadotropin levels (the follicle-stimulating and the luteinizing hormones) and the excretion of male or female sex hormones reaches but does not exceed the range of values observed in normal young adults.

Causes of sexual pseudoprecocity

Sexual pseudoprecocity results from excesses of sex hormones (of androgens in boys and of estrogens in girls) from the adrenal cortex, testis, ovary, or from other sources, including extragonadal tumours. Such pseudoprecocity may also result from gonadotropin-secreting non-endocrine tumours of the liver or other tissues that stimulate androgen or estrogen production by the testes or ovaries. It can also be produced by the administration of androgens or estrogens.

Rare instances of sexual precocity or pseudoprecocity

have been observed in conjunction with insulin excesses, with dwarfism, and with hypothyroidism.

Sexual pseudoprecocity in boys as a consequence of excesses of male sex hormones occurs in the adrenogenital syndrome or with androgen-producing tumours of the adrenal or testis. Boys with a Cushing's syndrome caused by an adrenal tumour may also show this change. In all of these, enlargement of the penis, accelerated appearance of sexual characteristics—pubic and axillary hair, masculinization, faster body growth, and ultimate stunting—are present. The testes, however, are smaller than usual, a cardinal clinical sign, and do not produce spermatozoa. The urinary androgens and derivatives, such as the 17-ketosteroids, are elevated and may reach levels above the adult range, but follicle-stimulating and luteinizing hormones are low or absent.

Sexual pseudoprecocity in girls arises from increased supplies of female sex hormones secreted by tumours of the gonads or adrenals. The external manifestations of sexual maturation—breast formation and appearance of sex hair, for example—appear early, but the maturation and discharge of ova do not occur. Body growth and skeletal maturation are accelerated, but the final height attained is below normal. Estrogen levels are increased, while measurements of gonadotropin are below normal.

In some female infants or children, premature breast development (thelarche) may be the sole clinical manifestation of pseudoprecocity, with subsequent sexual maturation occurring at the appropriate time. Similarly, pubic and axillary hair can appear prematurely followed by normal sexual development at the usual time. Such precocious hair has been attributed to premature increases in adrenocortical secretions in the course of adrenarche (menstruation induced by adrenal activity).

Removal of the cause, if identifiable, is the first goal of therapy. In idiopathic complete sexual precocity, menstruation and other manifestations of premature sexual development may be held in abeyance or even made to regress by medroxyprogesterone. Such therapy does not slow the accelerated maturation of the skeleton and therefore will not avert ultimate stunting. Thyroid hormone administration in those with true sexual precocity in association with hypothyroidism will cancel or partially reverse the accelerated sexual development.

DISORDERS OF THE TESTES

Cryptorchidism. Terms such as undescended testes, cryptorchism, or cryptorchidism refer to testes that are incapable of descending spontaneously to the usual position in the scrotum. Such testes are located within the inguinal canal or in the abdominal cavity. The frequency of undescended testes at birth is as high as 10 percent, decreases to 1 percent at one year of age, and is below 1 percent among adults. The condition is bilateral in approximately one out of five persons with this problem. Rarely, it occurs in more than one member of a family. Undescended testes are to be differentiated from those that are temporarily retracted into the inguinal canal. At times what appears to be cryptorchidism really represents complete absence of the testes.

Frequency of cryptorchidism

Sperm production is decreased or absent in untreated cryptorchidism, but male hormone production is normal. A cryptic testis is more likely to be injured, and the blood supply is more likely to be cut off by twisting; also, cancer develops about 20 times more often in such an organ.

Gonadotropin, androgen, or surgical therapy of undescended testes is undertaken in the hope that the deleterious effects of the higher temperature of extrascrotal locations, injury, torsion, and cancer can be avoided. Human chorionic gonadotropin therapy evokes maturation of the external genitals, and in 20 to 70 percent of the cases of gonads located in the inguinal canal, the testes move down into the scrotum. Even when the testis reaches the scrotal position, its ability to produce spermatozoa tends to be low. Fertility may be higher, however, if such gonadotropin therapy is undertaken when the patient is five or six years of age. Male sex hormone therapy also produces a more pendulous adult scrotum, increases the size of the penis, and may induce the descent of testes. The testes, however, become or remain small, and fertility is low. Androgens are not used before the usual time of pubescence, or sexual maturation, because they accelerate skeletal growth and produce premature fusion of the epiphyses and stunting.

Male hypogonadism. Normal development and function of the male reproductive organs and sex-related or sex-influenced structures, such as the penis, prostate, larynx, and pubic, axillary, and facial hair, depends on release of pituitary gonadotropins at the appropriate time and in adequate amounts—of LH, which stimulates the Leydig, or male-sex-hormone-producing, cells of the testes, and of FSH, which stimulates the Sertoli, or sperm-producing, cells of these sex glands. Such release of FSH and LH marks the beginning of sexual maturation, or pubescence, and usually occurs between nine and 12 years of age. Earlier—*i.e.*, during prepubescence—the secretion of pituitary LH and FSH does not occur because the hypothalamus has not yet begun the production of the LH- and FSH-releasor hormones.

Types of hypogonadism

Defects in, or injury to, the hypothalamus, the pituitary, or the testes results in hypogonadism. Such defects can result from an absence of normal prenatal and postnatal development of these structures, including those instances associated with abnormalities of the sex chromosomes or from damage to the hypothalamus, pituitary, or testes prior to or after maturation.

Male hypogonadism can consist of deficient androgen production (Leydig cell hypofunction), deficient sperm formation (decreased Sertoli cell function), or both. Such hypogonadism can result from a shortage of pituitary gonadotropins (LH, FSH, or both) or can represent primary testicular failure. The persistent absence of either or both gonadotropins, with or without other evidences of pituitary insufficiency, identifies the hypothalamic—hypopituitary hypogonadotropic type of hypogonadism. In primary testicular failure, the target tissues of the gonadotropins in the testes—either the Leydig cells or the Sertoli cells, or both—are incapable of responding to LH, to FSH, or to both of these pituitary hormones. Ultimately, one or both gonadotropins rise above normal, depending on which target cells in the testes are defective. These are examples of hypergonadotropic hypogonadism.

The time of onset of the androgen deficiency and the presence or absence of associated pituitary hormone deficits determine the effects on body build. When a shortage of all the pituitary hormones, including FSH, LH, and growth hormone, occurs prior to or during puberty, the development of genitalia and secondary sex characteristics is retarded (hypogonadotropic hypogonadism), and dwarfism is present. If the same disorder occurs after maturity, previously developed primary and secondary sex features regress, but stature is normal.

If LH is lacking during the growth years with or without a shortage of FSH, the development of the genitalia and secondary sex characteristics is retarded and incomplete. When LH decreases or is lost after maturity, adult male sex features partially regress. If FSH supplies are normal, spermatogenesis can occur despite Leydig cell deficiency.

If only FSH is lacking, Leydig cell and somatic development are normal, but spermatogenesis does not occur, and the testes are small.

Primary testicular failure with lack of Leydig cell function prior to maturity also results in immaturity of genitalia and deficient secondary sex manifestations. If Leydig cell function becomes inadequate in adult life, sexual activity, the size of the testes and penis, and secondary sex characteristics decrease, but sperm formation may continue. If only spermatogenesis is absent because of primary testicular failure, the testes are small, but sexual function, the size of the penis, and secondary sex characteristics are not affected.

CHROMOSOMAL DISORDERS

Klinefelter's syndrome. Klinefelter's syndrome is one type of primary testicular failure usually associated with

visible abnormalities of the sex chromosomes. It is variably characterized by enlargement of the male breasts (gynecomastia), small testes with scarred sperm-producing tubules and reduced sperm formation, tall eunuchoid body build, and a tendency to intellectual retardation. The syndrome can occur without obvious gonadal and body abnormalities, and some individuals with Klinefelter's syndrome may be fertile.

Symptoms and signs of Klinefelter's syndrome

The majority of Klinefelter individuals have one extra female sex chromosome, resulting in an XXY pattern and a total of 47 chromosomes instead of 46. Other less frequent chromosomal patterns include XXXY, XXXXY, XXYY, XXXYY, mixtures (mosaics), and partial losses or deletions. About 40 percent of the diagnosed examples of Klinefelter's syndrome have a normal XY pattern. One variant of Klinefelter's syndrome, the XXXXY type, is characterized by fusion of the forearm bones and other skeletal anomalies, underdevelopment of the penis and scrotum, incomplete descent of the testes, and marked mental retardation.

Diabetes mellitus and goitre incidence are more common, and various cancers may be more prevalent, among Klinefelter's syndrome patients. Thyroidal trapping of radioactive iodine and the responses of the thyroid to injections of TSH may be low. Testosterone production tends to be below normal, with urinary 17-ketosteroids in the normal or low-normal range. Serum and urinary gonadotropins (FSH and LH) are usually, but not necessarily, increased.

Turner's syndrome. Gonadal dysgenesis (Turner's syndrome) is a disorder of development characterized in the extreme form by small "streak" gonads without secretory or germinal cells. Internal and external genitalia are female but undeveloped; body build is suppressed female in type, with absence of breasts and sex hair. Other abnormalities, such as stunted growth, web formation of the neck, shieldtype chest, coarctation of the aorta, increased carrying angle, short lateral metacarpals, kidney abnormalities, and other signs may be present. Chromosomes of body cells are normal, but sex chromosomes are abnormal in the majority of such individuals with XO, XX, and X ring patterns and mosaics; so-called super-female patterns with three or more X chromosomes may be present. In the remainder, the chromosomal pattern is normal female, and in these the sexual and body-build aberrations are less common. Though such persons usually are infertile, pregnancy, on rare occasions, may be possible.

Pure gonadal dysgenesis refers to Turner's type of streak gonads with a minimum of body abnormalities. Thus, the patient may have immature breasts, and height may be average or above average.

Mixed, or atypical, gonadal dysgenesis is characterized by an undifferentiated streak gonad on one side and an intra-abdominal testis on the other. This combination is related in part to true hermaphroditism and in part to testicular feminization. The clitoris may be enlarged. Chromosomal pattern may be XO/XY, XY, or one of a number of other combinations.

Hormone levels in gonadal dysgenesis

Growth hormone levels are normal in gonadal dysgenesis, though it has been suggested that they may be high and ineffective in stimulating growth. Thyroid hormone supplies are normal, but thyroidal trapping of iodine may be abnormal, the frequency of thyroiditis is increased, and myxedema can result. Cortisol supplies are normal, but there is evidence of decreased production of adrenal androgens after ACTH administration. Urinary 17-ketosteroids tend to be low-normal because the ovarian contribution is low or lacking. Urinary and serum FSH and LH measurements are generally, but not always, high. Estrogen and progesterone excretion is diminished. The prevalence of diabetes mellitus appears to be increased.

Turner's syndrome may occur with a male body type. In general, these persons are characterized by underdeveloped testes, decreased or absent sperm formation, stunted growth, webbing, skeletal abnormalities, and variably sparse body hair. Information on sex chromosomes is limited, but XO patterns have been found. (See also BIRTH DEFECTS AND CONGENITAL DISORDERS.)

INTERSEXES

In addition to the Klinefelter and the Turner types of defective testis and ovarian development usually associated with abnormalities of sex chromosomes and the female pseudohermaphroditism of the adrenogenital type already described, several other aberrations of gonadal and genital structures have been recognized. These include male pseudohermaphroditism, true hermaphroditism, ill-defined abnormalities of genitalia in association with a tumour of the gonad, and total absence of testicular or ovarian tissues.

Male pseudohermaphroditism. In male pseudohermaphroditism, the individual is a genetic and gonadal male, but the body build and external genitalia have female features. In its most marked form, this is classic testicular feminization, but other less severe types also occur. In testicular feminization, immature and infertile testes secrete normal androgens, but the tissues are unresponsive to the male sex hormone; body build is feminine with short vagina and breasts, but sex hair is absent. In the lesser forms of the disorder—the Lubs, the Gilbert–Dreyfus, and the Reifenstein types—body build is female in the first, and male body and genital configurations are present in the other two. Breasts develop and sex hair is present in all three of these subgroups.

Dysgenetic male pseudohermaphroditism is a nonhereditary subtype. Such persons have poorly differentiated but identifiable testicular tissue, internal ducts may be male or female, external genitals are poorly developed male, body build may be male or female, and chromosomal pattern is XY or XO/XY. Some of these individuals may be fertile.

Hermaphroditism. In true hermaphroditism, in about one-half of the individuals, separate collections of ovarian and testicular tissue are present, usually in the abdomen and scrotum, respectively. In the rest, an ovotestis is found, and, more often than not, such a combined organ is accompanied by another discrete gonad. The latter is usually an ovary. The ovarian tissue generally appears more normal than the testis, and ovulation may occur. A uterus is generally present, but the ducts usually correspond to the adjacent gonad. The external genitals are largely male, but hypospadias (*i.e.*, the urethra opening on the underside of the penis) is frequent. Breasts usually develop at puberty, and menstruation occurs in about one-half of these individuals. The chromosomal pattern of persons with true hermaphroditism is generally of the female type; male patterns and mosaic or other abnormalities, however, do occur.

Predominance of female organs in hermaphroditism

Gonadal neoplasm. It has been suggested that gonadal tumours such as the dysgerminoma (an ovarian or testicular tumour with undifferentiated germinal cells) also produce hormonal factors that affect normal female sexual development. Thus, precocious puberty has occurred in some instances of dysgerminoma, and increased levels of urinary gonadotropins have been reported. Masculinization has also been observed.

Absence of genital tissues. Genital structures, external and internal, may be entirely absent in persons with a female or male body type. Even in such instances, however, there may be some scattered cells from the primitive genital tissues that secrete sex hormones.

OTHER DISORDERS OF THE OVARY

Stein–Leventhal syndrome. The polycystic ovarian, or Stein–Leventhal, syndrome consists of cystic changes in the ovaries variably associated with absent, scant, or excessive menses, lack of ovulation, infertility, increased facial and body hair, and overweight. It has not been established that such polycystic changes represent a single entity, since they can be produced in animals by transplantation, irradiation, or subtotal removal of the ovaries and can occur spontaneously in humans. At least some instances, however, represent enzymatic disorders of steroid hormone production in the ovaries, resulting in the production of excess male hormones. In one of these, the enzymatic defect interferes with the production of estrogen by the ovaries, and the precursor steroids are converted to hormones with androgenic effects.

Signs and symptoms of polycystic ovary

The polycystic ovary is usually, but not always, enlarged, and the capsule is thickened. The ova do not mature, and neither ovulation nor corpus luteum formation occurs. The endometrium of the uterus and the vaginal cells fail to develop the normal post-ovulation progesterone effects (see also EMBRYOLOGY, HUMAN; MENSTRUATION; PREGNANCY). The pituitary fossa of such persons is not unusual. The serum calcium, phosphorus, and other solutes are within the normal range. Thyroid function is not disturbed. Occasional diabetic-like glucose tolerance curves are encountered. Serum LH is often intermittently increased, while FSH is normal or low.

Urinary 17-ketosteroids and 17-hydroxycorticosteroids are normal or slightly increased. Plasma cortisol and urinary cortisol derivatives are normal or, if altered, assume patterns seen in simple obesity. Urine pregnanediol, derived from progesterone produced by the corpus luteum, is low in those who are not ovulating.

The diagnosis of polycystic ovaries is certain only with laparotomy (exploratory surgery), but pelvic examination, culdoscopy (pelvic endoscopy), or gynecography (X-ray diagnosis) can also provide satisfactory evidence.

The excesses of ovarian androgenic steroids can be reduced by oral contraceptive steroids. Polycystic ovarian syndrome is also treated by cortisol-like steroids that reduce adrenal androgen and may restore menses and fertility. Wedge resection of a part of each ovary often corrects amenorrhea and infertility. The gonadotrophic inhibiting drug clomiphene or human menopausal gonadotropin (FSH) and human chorionic gonadotropin (HCG) may produce ovulation.

Hyperthecosis ovarii. Hyperthecosis ovarii, characterized by lutein-like cell proliferation deep within ovaries away from the sites of ovum maturation, is a disorder related to the polycystic ovarian syndrome. This change has been described chiefly in women in the second and third decades of life with or without diabetes mellitus, hypothyroidism, pelvic irritative disease, Brenner tumour (nodular ovarian tumour), cancer of the breast, or related disorders. Individuals with hyperthecosis ovarii have androgenic manifestations similar to those seen with polycystic ovaries.

TUMOURS

Origin of testicular tumours

Tumours of the testes. About 97 percent of the tumours of testes arise from the germinal epithelium. Apart from a variable tendency to increase gonadotropin secretions, patients with germinal cell tumours do not have any discernible endocrine changes. The remaining 3 percent of the tumours of the testes arise from the interstitium and secrete gonadal or adrenal steroids. Rarely, the testis may also be the site of other tumours, such as fibroma and sarcoma.

Of the germinal tumours of the testes—the seminoma, embryonal carcinoma, teratoma, teratocarcinoma, and choriocarcinoma—only the last may secrete large quantities of gonadotropins. Increases in urinary gonadotropins, however, are present in about one-third of the individuals with seminomas, embryonal carcinomas, and teratomas. It is likely that these tumours contain elements that elaborate gonadotropins, but other sources are not excluded. The gonadotropins have FSH properties in the case of seminomas and HCG effects in the case of carcinomas. The teratomas may also secrete estrogens and placental lactogen, and TSH has been found in choriocarcinomas.

Tumours originating from the interstitial cells of the testis usually produce androgens. The excesses of such steroids accelerate masculinization, decrease the size of the uninvolved testis, induce breast enlargement, and decrease spermatogenesis. Occasionally, such tumours produce excesses of estrogens. Rarely, adrenal rest (enclave) tumours develop in the testis, resulting in excesses of cortisol steroids and Cushing's syndrome.

Tumours of the ovary. About 10 percent of the tumours occurring in the ovary secrete male or female sex hormones. The feminizing tumours of the ovary exceed the masculinizing types in a ratio of about 4 to 1. The granulosa cell, the theca cell tumours, and occasionally others, produce feminization; the malignant arrhenoblastomas, the adrenal rest tumours, and most hilus cell (Leydig) tumours result in masculinization. Exceptions can be cited, however, in most categories. Some few miscellaneous tumours—such as the dysgerminoma (seminoma) associated with abnormalities of the genital and the thyroid-tissue-containing dermoid cyst or teratoma known as struma ovarii—also belong in the hormone-secreting category. At various times it has been suggested that others such as the Brenner tumour also secrete hormones.

The remaining 90 percent of ovarian tumours are of the types that do not produce hormones (the cystadenoma or adenocarcinoma category of the pseudomucinous and, especially, the serous types).

THE BREAST IN ENDOCRINE DISORDERS

Gynecomastia. In true gynecomastia—*i.e.*, enlargement of the breast in males—the ductules and surrounding tissues are increased in quantity. Pseudogynecomastia, on the other hand, merely represents an excess of fat in the breast area. True gynecomastia with and without hypogonadism usually occurs sporadically, but it has also been reported in father–son–cousin and other familial distributions. Pseudogynecomastia is common among overweight males.

True gynecomastia and pseudogynecomastia

The most frequent form of true gynecomastia, the subareolar node seen or felt in boys during puberty or adolescence, is usually a feature of normal development. It is present in minor degree at some time in all normal boys and need not be symmetrical. Such physiological gynecomastia appears to result from increases in androgens, estrogens, adrenal steroids, gonadotropins, or other hormones that normally occur during pubescence.

The most common endocrine disorder in older boys and adults with marked true gynecomastia is Klinefelter's syndrome, discussed previously. Increases in breast tissue have also been described in various other endocrine disorders, including pituitary tumours, acromegaly, hyperthyroidism, adrenal tumour, Cushing's syndrome, Addison's disease, tumours of the testes, cryptorchidism and other genital abnormalities, and diabetes mellitus. Also, androgen or estrogen therapy can produce true gynecomastia.

Gynecomastia that occurs in untreated cirrhosis or during the treatment of cirrhosis with a high-calorie–high-protein diet probably results from excesses of estrogens. Also, resumption of a normal caloric intake after prolonged starvation may be associated with enlargement of the male breasts and tenderness of the breasts and testes.

Enlargement of the breasts has been noted at birth, after surgical removal of the prostate, in ulcerative colitis, congestive heart failure, skin disorders, vitamin D poisoning, rheumatoid arthritis, cancer of the lung or kidney, Hodgkin's disease, leukemia, myotonia dystrophica, arthritis, paralyses, and during treatment with digitalis, amphetamine, and other drugs. Most of the above associations could be fortuitous, but a causal relationship was probably present in those patients with a history of estrogen, androgen, or other drug therapy.

Removal of the cause, such as estrogen excesses, is followed by some recession of the gynecomastia. In others, surgical excision may be dictated by symptoms, cosmetic reasons, adverse effects on the personality, fear of cancer, and other reasons.

Galactorrhea. Galactorrhea, or secretion of milk-like fluid from the breasts, can occur in either sex. Though rare, the possibility of galactorrhea as a result of manipulation or breast cancer must always be raised. In males, galactorrhea has been associated in all but a few instances with either an intracranial tumour (acromegaly, pineal tumour with sexual precocity, angiosarcoma of the pituitary) that presumably removes the prolactin inhibitor of the hypothalamus and permits prolactin secretion by the pituitary or with a cancer (of the testis, adrenal, or kidney) that presumably secretes a prolactin-like hormone or related materials or increases androgen or estrogen secretion. Galactorrhea in females may follow pregnancy or, in women who have not been pregnant,

may develop in association with brain lesions, enlargement of the pituitary gland, other endocrine disorders, or appear after surgery or drug therapy.

Galactorrhea in females

In females, persistent lactation without suckling, which follows upon a recent pregnancy, is called the Chiari–Frommel syndrome. Malnutrition, psychiatric disturbances, and amenorrhea can be present, and the uterus and ovaries may be small.

Galactorrhea in a female who has never been pregnant is termed the Ahumada–del Castillo or the Argonz–del Castillo syndrome. Such galactorrhea appears to result from excesses of secretion from the pituitary eosinophils. This implies that excessive secretion by the anterior pituitary eosinophilic cells can result in two syndromes, acromegaly or lactation, and that both may occur in the same individual. This possibility is supported by the demonstration that human growth hormone does possess prolactin activity and that injections of growth hormone increase galactorrhea. On the other hand, growth hormone levels may or may not be increased in the plasma or serum of individuals with galactorrhea.

When a pituitary tumour is found in a female with galactorrhea as the sole manifestation, an Albright syndrome is said to be present. In addition to, or perhaps as a subdivision of, the Albright syndrome, galactorrhea in women has been associated with acromegaly or with other brain tumours, including craniopharyngioma and basophil adenoma. Endocrinopathy other than acromegaly may also be found in females with galactorrhea. This may be hypopituitarism, Cushing's syndrome, Addison's disease, goitre, hyperthyroidism, myxedema, or hypoparathyroidism.

Galactorrhea in females has also been reported following encephalitis, pituitary stalk section, various surgical procedures, pneumoencephalography, and chlorpromazine, reserpine, birth-control pill, progesterone, or other drug therapy.

Therapy of galactorrhea in both sexes includes removal of the cause when it is known and administration of estrogen–progesterone combinations (see further REPRODUCTIVE SYSTEM DISEASES).

VI. The pancreas: diabetes mellitus

Levels of blood sugar are in great measure controlled by two hormones, insulin and glucagon, both produced by the pancreatic islet cells. An excess of insulin produces low blood-sugar levels, and excesses of glucagon raise them. Losses of insulin secretion or of its effect result in diabetes mellitus. Tumours of pancreatic islets of the insulin-secreting type (insulinoma) produce low blood-sugar levels. Those made up of glucagon-secreting cells result in high blood sugars and even diabetes.

Cells within the islet tissues of the pancreas elaborate a protein hormone, insulin, that lowers blood glucose levels and stimulates the formation of fat and protein. Diabetes mellitus is usually a genetic, and less frequently an acquired, disorder of the metabolism of carbohydrates, fats, and proteins resulting from a relative or an absolute shortage of insulin or of insulin action. It is most readily recognized by the presence of unduly high blood-glucose levels in the fasting state or following a glucose or food load. In uncontrolled diabetes, however, fat formation is also diminished with an increase in lipolysis; *i.e.*, the amount of fat mobilized from the tissues. Similarly, in severe untreated diabetes, protein formation is decreased, and negative balances of tissue proteins may ensue.

Prevalence of diabetes mellitus

As a result of community and other surveys, the prevalence of diabetes mellitus in North America is estimated at about 2 percent, but in the course of an individual's lifetime, the probability of developing diabetes is higher. Almost all children with diabetes, and most of those adults with the more severe insulin-dependent type of diabetes, have probably inherited the trait from both parents. Those who have the trait from only one parent are carriers and may or may not develop the disease. Acquired, or nongenetic, diabetes is much less frequent than the genetic type. It is most clearly identifiable when it follows upon removal or destruction of the pancreas or is caused by such disorders as Cushing's syndrome, acromegaly, pheochromocytoma, hyperthyroidism, or other disorders.

The diagnosis of diabetes mellitus is most often based on the finding of elevated blood-glucose or serum glucose levels obtained in the fasting state or during a glucose tolerance test. The glucose is administered by mouth or intravenously in a variety of dosages, and blood or serum samples are analyzed for glucose drawn during one of each of several time schedules. Interpretation of the results of an oral glucose tolerance test in diagnosing glucose intolerance or diabetes mellitus is simplified when the results are expressed as the Glucose Tolerance Sum for two or for three hours ($GTS_{0\text{-}2\ hr}$ and $GTS_{0\text{-}3\ hr}$).

The $GTS_{0\text{-}2\ hr}$ value is the sum of the 0-, ½-, 1-, and 2-hour glucose levels in venous blood when 1.75 grams of glucose are administered per kilogram of body weight. When $GTS_{0\text{-}2\ hr}$ is 500 or less, there is a 98 to 100 percent probability that the test is clearly normal by the standards of the World Health Organization, the British Diabetic Association, and the United States Public Health Service. On the other hand, when the $GTS_{0\text{-}2\ hr}$ is 801 or higher, the test virtually always fulfills each of the sets of criteria cited above for diabetes. Since values between 501 and 800 are variably classifiable as normal or abnormal by these same standards, this range represents the equivocal zone.

Tolerance tests with GTS values in the equivocal zone should be repeated at intervals of months or years.

CLASSIFICATION OF DIABETES MELLITUS

Diabetes mellitus occurs in man as a spectrum with seven stages based on the intensity of the carbohydrate and fat disturbances.

The seven stages of diabetes mellitus

Stage I is prediabetes—*i.e.*, the phase preceding the appearance of any carbohydrate disturbance. It is more likely to occur in individuals with the following individual or family histories: diabetes, obesity, abortions, stillbirths, newborn deaths, birth of large babies, or pregnancies with high blood sugars, excesses of amniotic fluid, and toxemia.

Stage II is stress diabetes. It is present during a period of stress and usually disappears after the stress is removed. Such stress may include infection, trauma, adrenal steroid excesses, or drug therapy.

Stage III is the most common undiagnosed form of glucose intolerance and is the earliest phase of what may turn into fully developed diabetes mellitus. It is characterized by normal fasting blood-glucose levels with unduly high blood-sugar levels after a meal or after glucose administration.

Stage IV is the most commonly recognized form of diabetes mellitus. The fasting blood glucose is elevated, and the after-meal and glucose tolerance test blood-sugar concentrations are also unduly increased. In Stages III and IV, there are no ketone bodies (products of fat metabolism) in the urine or blood plasma. This cardinal feature sharply delimits these two stages from Stages V, VI, and VII of diabetes, each of which is characterized by the presence of ketone bodies.

Stage V, or ketosis, is characterized by ketone bodies in the urine and high blood-sugar levels. There is, however, no accumulation of ketone bodies in the plasma. Respirations are normal.

Stage VI is diabetic ketoacidosis. Ketone bodies are present in the urine and are accompanied by ketone accumulation in the plasma and reduction of the serum carbon dioxide content. Slight to moderate decreases in serum pH (7.3 to 7.1) are present (pH is a measure of acidity and alkalinity, a reading of 7.0 being neutral, values above are alkaline, values below are acidic). Rapid respirations are common, and deep (Kussmaul type) overbreathing may develop.

Stage VII is diabetic acidosis coma with marked accumulation of ketone bodies in plasma and urine, decrease in serum carbon dioxide to less than ten milli-equivalents per litre, and reduction of serum pH to values as low as 6.8 or 6.9. Deep overbreathing is almost always present.

In the mildest type of glucose intolerance or early diabetes (Stage III), the fasting blood-sugar levels are nor-

mal, and marked rises in blood glucose appear only after a carbohydrate or food load. In other words, in the basal state the amounts of sugar released from glycogen stores or produced from protein can be metabolized without raising the blood sugar. In a more advanced phase (Stage IV), the residual ability to dispose of carbohydrate of endogenous origin is further limited, so that the blood sugar is high even in the fasting state. In Stages III and IV, however, there is still considerable residual ability to utilize glucose as a fuel. Indeed, by virtue of the law of mass action, the high blood-sugar level enhances the disposal of glucose. In these mild stages of diabetes, day-to-day survival is not in jeopardy.

Fat utilization in advanced stages of diabetes

In the more advanced stages of diabetes (Stages V, VI, and VII), the tissues cannot utilize glucose in amounts adequate to meet energy needs because insulin supplies or effects are insufficient. Hence, fatty acids become the fuel because they can be used when insulin action is absent or insufficient. Marked shifts to fat as a fuel create problems, however, in addition to those attributable to insufficient utilization of glucose. Fatty acids are mobilized from fat depots of the body in excess of the ability of the tissues to use them. Derivatives of these fatty acids (β-hydroxybutyric and acetoacetic acids) accumulate in body fluids with acetone, a derivative of acetoacetic acid, present as an easily identifiable indicator. This indicator is the indisputable signal of undue reliance on fat as fuel because of inability to utilize carbohydrate in adequate amounts. It means that the diabetes has reached the most advanced stages, and survival is threatened. In addition to the underutilization of glucose and overmobilization and underutilization of fat, diabetes in these advanced stages is characterized by disturbances of protein metabolism. Protein formation is decreased, protein catabolism (breakdown) is increased, and the resultant amino acid excesses are converted to sugar or ketones.

OCCURRENCE OF DIABETES

Diabetes in adults. Most instances of adult-onset diabetes occur in overweight persons and are relatively mild (Stage III and IV), with unduly high blood-sugar levels as the chief manifestation; ketone bodies are absent. The shortage of effective insulin is relative rather than absolute. Despite the high blood sugar, there is enough insulin action and sufficient residual ability to extract energy from carbohydrate; ketosis, therefore, does not occur. The complete absence of symptoms, or even signs in the earliest phase of diabetes, has resulted in such terms as latent or chemical diabetes. Diabetes of maturity onset, however, may also produce enough of an increase in blood glucose to increase urine volumes (polyuria), thirst (polydipsia), food intake (polyphagia), weight loss, and other symptoms. Most individuals with adult-onset diabetes are overfed, underactive, and overweight. Significant alterations of one, two, or all three of these variables can eradicate laboratory evidence of diabetes. Treatment begins with close scrutiny and adjustment of the diet in terms of calories and foodstuffs, administration of insulin as needed for maximal control of diabetes; use has been recommended of certain oral drugs, such as the sulfonylureas or phenformin, to facilitate glucose utilization in those in whom such medications are indicated.

Rarely, under the stress of illness, trauma, pregnancy, and drug or adrenal-steroid therapy, the ability to extract energy from carbohydrate decreases, and the tissues turn to fat as a fuel. Fatty acids are then overmobilized, and ketone bodies may appear. Some few individuals with maturity-onset diabetes are ketoacidosis prone and insulin dependent, even in the absence of stress or illness. Such persons are generally not overweight. They cannot be treated by caloric restriction and weight reduction; they must receive insulin.

Less usual forms of diabetes observed in the adult include the lipoatrophic type, in which body fat is decreased, serum cholesterol and triglycerides are high, cirrhosis is common, and insulin is mandatory. Mild and generally non-insulin dependent diabetes may develop with the adult type of premature aging—a condition referred to as Werner's syndrome.

Diabetes in children. In children, obesity is not a clue to diabetes, as it may be in adults. Diabetic children generally are not overweight, nor is there a history of overweight. Respiratory infections are common antecedents of symptoms and signs that lead to diagnosis of childhood diabetes. This sequence, of course, is of little practical value because of the frequency of such infections in this age group. As in adults, increased urine volumes and increased thirst are the two most common symptoms, but they occur more frequently in juvenile diabetes. Increased food intake, weight loss, and a tendency of the patient to tire easily are next in the order of frequency. Irritability, onset of acidosis or coma, vomiting, abdominal pain, and recurrence of bed-wetting are other indices that may be indicative of juvenile diabetes. The diabetes of childhood differs from that in adults in that it is more severe and almost always requires insulin in addition to diet therapy.

Examples of transient diabetes have been observed in infants. In some of these, respiratory or skin infections were present. The origins of such transient diabetes are obscure.

CAUSE AND TREATMENT OF DIABETES

Diet and insulin therapy. A consistent intake of calories, predictably distributed among carbohydrates, fats, and proteins and divided into the three main meals and between-meal and before-bedtime snacks, is the keystone of successful regulation of diabetes with diet alone, with insulin, or with other hypoglycemic agents.

Types of insulin

In North America and in many countries of western Europe, some or all of the following types of insulin are available for the treatment of diabetes: Protamine Zinc, which has low intensity but long action; NPH Ultra-Lente, Lente, Semi-Lente, and Globin, which exhibit intermediate intensity of action and duration; Regular or crystalline, which gives rapid action of short duration.

Diabetic ketosis, ketoacidosis, and acidosis coma must be managed with the last of these. Also, this is the insulin used in multiple daily injections for the treatment of "brittle" (unpredictable or labile) diabetes. Prophylaxis of ketosis, ketoacidosis, and coma in insulin dependency and in attempts at optimal treatment of all types of diabetes is effected with the intermediate types in a variety of programs: NPH, Lente, or Globin alone or with Regular; Lente and Semi-Lente or Ultra-Lente; Lente and Regular, and other combinations. Protamine Zinc Insulin (PZI) is still used by persons and physicians who found this form suitable before the other types became available. PZI, however, has a cumulative effect that, in the course of time, can produce dangerous hypoglycemia.

Special types of insulin may be employed to treat allergic reactions and undue resistance to insulin, *viz.*, pure pork instead of the usual beef–pork preparation, or dealanated pork insulin from which the terminal amino acid, alanine, has been removed, leaving a 50-amino acid moiety that is chemically indistinguishable from the same segment of human insulin.

The chief mechanism of sulfonylurea action is an increased secretion of endogenous insulin and a decrease in endogenous glucagon, the pancreatic hormone that raises blood-sugar levels. It can be used as the sole blood-sugar lowering agent in conjunction with a diabetic diet in non-insulin dependent diabetes. Phenformin, on the other hand, does not exert its effects by increasing insulin output but does enhance glucose utilization, provided that insulin supplies and insulin action (endogenous or exogenous) are adequate. It also controls the rate at which foodstuffs are absorbed from the gut. Hence, it is rational to employ a diabetic diet and to use phenformin as the sole blood-sugar lowering agent in non-insulin dependent diabetes, as an adjuvant in insulin therapy of non-insulin dependent diabetes, and as an aid in the regulation of diabetes dependent on the administration of exogenous insulin. Also, it is reasonable to use phenformin and a sulfonylurea drug in diabetes of Stage III or IV, which are non-insulin dependent.

Diabetic acidosis and coma. Inadequate diabetic regulation resulting from a relative or absolute shortage of

effective insulin is the ultimate cause of diabetic ketoacidosis or coma. Such a degree of inadequate regulation of diabetes may be a consequence of an insufficiency of insulin or its action in previously untreated diabetes, omission of the usual injection of insulin, or failure to increase the dosage when the requirements for insulin rise. Increases in the need for insulin occur during inactivity, major or minor infections, insulin shocking, insulin resistance, emotional trauma, pregnancy, surgical operations, thyroid crises, and other stresses. If the increased need for insulin is not met, the blood sugar rises, and then mild ketosis, ketoacidosis, and acidosis coma ensue.

Periods requiring increased insulin

A history of vomiting can be obtained in three-quarters or more of the children and adults suffering from diabetic ketoacidosis. Abdominal pain may be a result of, or occur with, the nausea and vomiting in 40 or more percent of these individuals and can be intense enough to mimic abdominal disease. Deep overbreathing (of the Kussmaul type) is one of the manifestations of diabetic ketoacidosis. It generally appears when the blood serum carbon dioxide is reduced to about ten milli-equivalents per litre. Shallow and rapid respirations, however, precede the deep overbreathing. Coma can then develop. Circulatory collapse may result as a consequence of dehydration and salt depletion. Weakness, paralyses, or disturbed sensations resulting from high or low serum potassium levels or other causes may characterize early acidosis or coma; these symptoms and signs can also develop during the early hours of treatment.

Several types of non-ketoacidotic coma may occur in diabetes mellitus. These include: (1) coma as a result of a cerebral hemorrhage or occlusion, drug excesses, kidney failure, or advanced liver disease; (2) coma caused by extremely low blood-sugar levels due to excess insulin or other anti-diabetic therapeutic measures; (3) lactic acidosis following tissue-oxygen shortages; (4) hyperosmolar coma as a consequence of high levels of glucose, of sodium, or both; and (5) cerebral edema with coma following treatment of ketoacidotic coma.

Long-term concomitants and complications of diabetes. Diabetes mellitus, usually of many years' duration, may be accompanied by thickening of the basement membrane of small blood vessels and by accelerated and exaggerated atherosclerosis of the larger vessels. Basement membrane changes in capillaries are responsible for the small blood vessel disorders in the kidneys, eyes, and nerves and are present in other tissues such as the conjunctiva, skin, and muscle. The atherosclerosis may result in such conditions as myocardial infarction, gangrene, or stroke. Diabetes also predisposes to infections, necrobiosis, atrophy of fat, contractures of the hands, cancer of the pancreas, and pregnancy complications.

Effects on blood vessels

The appearance and intensity of the small blood vessel basement changes are definitely related to the duration of the diabetes and less clearly to the adequacy of diabetic regulation. As far as lesions of the large blood vessels are concerned, atherosclerosis tends to appear earlier, is more severe, and produces myocardial infarction, stroke, gangrene, and other serious consequences more frequently. Two variables predispose to the increased atherosclerosis. One is genetic: high blood pressure and accelerated atherosclerosis develop more frequently in nondiabetic relatives of persons with diabetes than in the general population. The other variable is metabolic: unduly high serum fat or lipids—*i.e.*, triglycerides and cholesterol—levels occur in diabetes and predispose to atherosclerosis. Such lipid excesses are treated by regulation of diabetes, caloric restriction, diet manipulation, and administration of certain drugs that lower serum lipids.

Pancreatic islet cell tumours. Pancreatic islet cell tumours that secrete excesses of insulin (insulinomas) may be multiple and can become cancers. In persons with an islet cell tumour, unduly low blood-sugar levels develop spontaneously or may follow upon prolonged fasting or exercise. Stimuli such as tolbutamide, leucine, or glucagon are used to support a diagnosis of an islet cell tumour. Administration of each of these agents produces a rise in serum insulin and a fall in blood sugar in normal individuals and excessive responses in those with an insulinoma. Therapy consists of surgical removal of the tumour.

Various combinations of islet cell tumours with tumours of the pituitary, parathyroids, adrenal cortex, adrenal medulla, and thyroid have been recorded in sporadic or familial instances.

Glucagon in diabetes. Since glucagon raises blood-sugar levels by releasing liver glycogen, it is not surprising that pancreatic islet cell tumours made up of glucagon-producing cells can result in diabetes mellitus. Also, levels of glucagon in persons without such a tumour play a role in determining the concentrations of blood sugar. As already cited, the sulfonylurea drugs are used in the treatment of diabetes mellitus to reduce glucagon and to increase insulin levels in the serum.

VII. Other endocrine glands

THE PINEAL GLAND

In man, the pineal is a pear-shaped midline structure located at the back of the base of the brain. It becomes calcified by the sixth decade in about 70 percent of the population. In the past, a variety of roles has been tentatively assigned to the pineal, including the regulation of growth, the size of the endocrine organs, sexual maturation, blood-sugar levels, and skin pigmentation. Attempts have also been made to implicate it in psychoses and epilepsy.

Effects of pineal extracts

More recent studies indicate that a number of principles or effects can be elicited, some in animals and some in man, with preparations derived from the pineal, but their physiologic significance, if any, in man is not established. These include a melanocyte contracting principle (melatonin), an accelerator of adrenocortical aldosterone secretion (glomerulotropin), and an inhibitor of estrus in rats (anestrin) that may be the same as melatonin. Also, serotonin and metabolites such as 5-hydroxyindoleacetic acid (5-HIAA) and 5-methoxyindoleacetic acid, histamine, and 8-lysine vasopressin have been demonstrated in extracts of the pineal.

In the rat, light striking the retina sets up nervous impulses that reduce the melatonin in the pineal. The decrease in melatonin reduces its inhibiting effect on the rate of estrus cycle. Hence, this represents a transducer system whereby nervous impulses affect humoral or hormonal secretion akin to the supra-optic–hypophyseal system that controls vasopressin output and the hypothalamic releasor and inhibitor systems that act on the anterior pituitary.

Tumours of the pineal may be associated with accelerated and, less often, with retarded sexual maturation. True parenchymatous pinealomas are generally present in those with repressed sexual maturation. On the other hand, sexual precocity occurs in conjunction with nonparenchymatous tumours, such as gliomas and teratomas, that destroy the pineal. The sexual precocity occurs almost exclusively in males.

THE THYMUS

Studies in animals have established that the thymus, a collection of cells behind the breastbone, must be present in the first few days of life for the subsequent appearance of certain immune responses and antibodies. The thymus may be the source of lymphocytes that migrate to the lymph nodes, spleen, and other sites and participate in immunologic maturation. Simultaneously or alternatively, the thymus may elaborate a principle that stimulates lymphocyte formation in other body sites. Normally, the thymus decreases in size beyond the neonatal period but continues to play an immunogenic role. If the thymus is removed shortly after birth, the ability to develop normal lymphoid tissue, small lymphocytes, and plasma cells and to reject tissue transplants from donors of foreign strains or different species is reduced or lost.

The thymus as a source of lymphocytes

A number of auto-immune disorders present in animals have been related to a defective or absent thymus. These include auto-immune hemolytic anemia and systemic lupus erythematosus. In man, agammaglobulinemia and the increased frequency of certain types of leukemia, rheumatoid arthritis, and Hodgkin's disease may also be

related to defective immune responses in which the thymus plays or has played a role. Excesses of cortisol hormones, as in Cushing's syndrome, are associated with decreased immune responses and increased frequency and severity of infections. This is mediated, in part at least, by the lymphopenic action of cortisol excesses, an effect akin to the thymolytic effect of cortisol.

Several disorders in man have been associated with enlargement of the thymus, including myasthenia gravis, deficiency of gamma globulins with increase in infections, decreased red blood cell formation, increased destruction of red blood cells by hemolysis, and shortage of circulating white blood cells of the small lymphocyte type. An auto-immune component has been identified or postulated in each of these. Also, several endocrine disorders—including thyrotoxicosis, thyroiditis, Addison's disease, and hypoparathyroidism—have auto-immune components in which the thymus at one time or another has played, or still plays, a role. Thus, there is evidence that, in thyrotoxicosis and thyroiditis, thymic parenchyma may be enlarged. The exact mechanisms, however, have not been defined.

It is possible that some of the sudden deaths in infancy initially attributed to enlargement of the thymus may have represented adrenocortical insufficiency of the Addisonian crisis type, since in the absence of cortisol-type steroids, the thymus enlarges. Thus, removal of the pituitary in animals results in atrophy of the adrenal glands and increases the thymus and lymphoid tissues elsewhere in the body. Also, the enlarged thymus present in infants born with massive brain abnormalities is probably attributable to the associated adrenal atrophy.

In animals, extracts of the thymus may increase or decrease sugar metabolism, promote or retard normal growth, regulate fertility, and accelerate or halt the spread of cancer, but the factors and mechanisms involved require verification.

BIBLIOGRAPHY. T.S. DANOWSKI, *Outline of Endocrine Gland Syndromes*, 2nd ed. (1968), presents in summary and reference form the findings in the various endocrine disorders that occur spontaneously or are induced in man. The same author's *Diabetes Mellitus, with Emphasis on Children and Young Adults* (1957), contains detailed information on the features of the type of diabetes mellitus that usually occurs in the younger years. T.S. DANOWSKI et al., "Utility of Equivocal Glucose Tolerances," *Diabetes*, 19:524–526 (1970), is a discussion of the resolution of much of the uncertainty in reconciling the interpretation of glucose tolerance tests in normal and diabetic persons by use of the Glucose Tolerance Sum principle. R.C. KHURANA *et al.*, "Insulin and Glucose Patterns in Control Subjects and in Proved Insulinoma." *Amer. J. Med. Sci.*, 262:115–128 (1971), is an article that answers questions concerning the presence or absence of excess circulating insulin levels, by reference to control studies in healthy subjects.

(T.S.D.)

Endocrine Systems

Most animals have specialized organ systems, each of which is adapted for a particular function and usually situated in a particular part of the organism. The functions of organ systems such as the digestive system, reproductive system, and excretory system must be integrated; in addition, the composition of the fluid medium in which all tissues are bathed must be regulated with some degree of constancy, or the complex organisms that depend on them cannot survive.

Two systems, consisting of definable pathways that extend throughout the body of an animal, allow the integration of widely separated functions; they are the circulatory system and the nervous system. The nervous system, by means of nerve-cell pathways, integrates sense organs, which detect changes in the environment, with internal organs such as glands and muscles. The circulatory system, by means of blood-vessel pathways, conveys blood containing a variety of substances to all parts of the body.

The endocrine system is a group of glands the secretions of which, called hormones, integrate the activities of organ systems and help to maintain a constant internal environment. A hormone is secreted from the gland in which it is formed and travels in the blood to a specific tissue or organ, commonly called a target, where it regulates in time, amount, or quality the function of that organ or tissue. The activities of certain endocrine glands may be influenced either indirectly by the secretions of specialized regions of the nervous system called neurohemal organs or directly by nerves. Thus, there is a very close relationship between the endocrine system, which secretes hormones; the nervous system, which regulates endocrine gland activity; and the circulatory system, which conveys hormones to their targets.

Many examples of endocrine regulation have been established in vertebrate and invertebrate animals. During the digestive process, for example, when food enters the intestine, a hormone, secretin, is released from the lining layer (mucosa) of the intestine into the blood. When secretin reaches the pancreas in sufficient quantity, it evokes the secretion of pancreatic juice into the intestine to aid in digestion. The regulatory function of secretin is to coordinate the functions of the intestine and the pancreas during digestion of food. The secretin mechanism, initially described in 1902, was among the first endocrine phenomena to be recognized.

Various other kinds of blood-borne substances (for example, oxygen and minerals) can influence the function of particular organs, yet they are not hormones. Carbon dioxide, for example, which is produced in many parts of the body, may, after transport in the blood, affect certain functions. It is termed a parahormone since it lacks specificity; that is, it has no specific source and occurs generally.

Neurohormones and neurohemal organs

Neurohormones are substances manufactured not by glandular structures, but by nerve cells. The axons of neurosecretory nerve cells—that is, the long processes that usually direct nerve impulses away from the cell body—generally end in a group upon a set of specialized blood vessels. The unit so formed is known as a neurohemal organ. Neuroendocrine phenomena are important in that they provide a mechanism by which external changes, perceived by sense organs, can initiate responses in many organ systems and processes by affecting endocrine glands (see Figure 1). There are three ways in which this can occur:

1. Nerves may lead from sensory cells to neurosecretory cells that release a neurohormone into the blood. In vertebrates, this type of neurosecretory cell is located in a neurohemal organ called the pars nervosa, a region of the pituitary gland, or hypophysis.
2. Nerves may lead from sensory cells to neurosecretory cells that terminate in a neurohemal organ called the median eminence below the brain (hypothalamus). Neurohormones known as releasing hormones, released from the median eminence, are carried by the blood to the pars distalis region of the pituitary gland, where they bring about the release of hormones, which in turn affect a broad variety of processes.
3. Sensory nerves, via a chain of nonneurosecretory nerve cells, may directly lead to pituitary cells, as, for example, in the pars intermedia region of the pituitary gland (Figures 1, 3).

This article describes the endocrine systems of vertebrate and invertebrate animals. The endocrine system of man is dealt with in ENDOCRINE SYSTEM, HUMAN; the article HORMONE contains discussions of the individual hormones secreted by endocrine glands.

GENERAL FEATURES OF VERTEBRATE ENDOCRINE SYSTEMS

Relationships. *Of endocrine organs to each other.* The number of endocrine glands and the variety of their roles may, at the outset, make any discussion of endocrine function seem complex. Figure 3 shows in schematic fashion the functions and relationships of endocrine glands. At the upper left is the pituitary gland, the function of which is controlled by the brain. On the right side of the figure are the other major endocrine glands of vertebrates. Targets (*i.e.*, sites of action) of the pituitary gland hormones may be separated into two types: targets that are themselves endocrine glands, such as the thyroid,

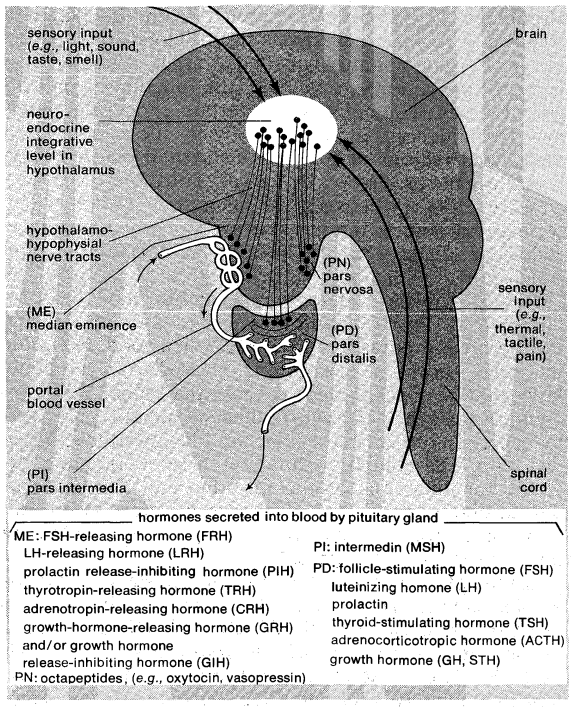

Figure 1: The mechanism by which environmental changes perceived by sense organs initiate responses through neuroendocrine phenomena.

the gonads (ovaries and testes), and the adrenal cortex; and targets that are not—*e.g.*, kidney, uterus, pigment cells, mammary gland, skeleton. Of the major endocrine glands shown in Figure 3, some are under pituitary control; others—for example, the parathyroids, the ultimobranchial gland, the pancreas, the adrenal medulla, and endocrine tissue of the digestive tract—are not. The pancreas, parathyroid glands, and ultimobranchial gland respond to changes in blood levels of particular substances; the adrenal medulla responds to nervous stimulation; and the endocrine tissue of the digestive tract responds to local stimuli not yet identified.

Endocrine glands thus regulate various processes by the hormones they secrete; their respective functions, in turn, are regulated by a nerve supply, by blood levels of metabolic compounds (metabolites), or by other hormones.

Of endocrine organ systems to the blood. The most common arrangement of endocrine gland cells is as branching cords of cells (Figure 2), an arrangement particularly conducive to the efficient release of hormones. Each cord is usually no more than two cells thick; and between the cords are blood-filled spaces, usually of the type known as sinusoids. Only the thyroid gland and neurosecretory systems have cellular arrangements other than this one. The thyroid is made up of follicles, or minute bags of cells (Figure 2), with walls one cell thick. Surrounding these follicles is a close network of blood capillaries. In neurosecretory systems, the secretory ends of nerve cells terminate on or very close to blood vessels (Figure 2), forming neurohemal organs. Neurohemal organs include the median eminence and the pars nervosa of the pituitary gland, the urophysis in fishes, and the sinus gland in crustaceans.

Functions. Endocrine functions are divisible into two phases: (1) function of the gland itself, which is to manufacture and release a hormone in response to a stimulus; (2) function or action of the hormone in regulating activities of particular targets. These functions are dealt with more fully in succeeding sections of this article and in the article HORMONE.

General properties of hormones. *Chemical nature.* Fatlike and protein-like hormones

Generally, vertebrate hormones are either substances called peptides, which consist of two or more nitrogen-containing compounds called amino acids, or they are steroids, which are complex fatlike substances. Although the chemical structures of steroid hormones are similar, slight structural variations determine whether the hormone acts as a corticoid—a name given to hormones formed in the outer region (cortex) of the adrenal gland—as a male hormone formed in the testis, or as a female hormone formed in the ovary. The active principle of the hormone of the thyroid gland is the amino acid thyroxine. The hormone adrenaline, synthesized in the inner region (medulla) of the adrenal gland, is a relatively simple molecule derived from the amino acid tyrosine. The neurohormones whose structures are known are relatively simple molecules; *e.g.*, thyrotropin-releasing hormone contains three amino acids, the hormones from the pars nervosa region of the pituitary gland contain eight or nine amino acids. The gastrointestinal hormones and the hormone intermedin (MSH), formed in the pars intermedia of the pituitary gland, consist of about 19 amino acids; the hormones from the pars distalis of the pituitary gland, the parathyroid gland, and the pancreas are protein in nature, containing larger numbers of amino acids.

The structures of two invertebrate hormones, both found in arthropods, have been completely established. Ecdysone, or molting hormone, is a steroid, and juvenile hormone is a member of a group of fatlike compounds called terpenoids.

Mechanisms of action. The functions of hormones are diverse: some cause target organs to synthesize various substances, including enzymes and other proteins, for activities such as secretion and growth; a few evoke movements such as muscular contraction or pigment redistribution; many regulate the metabolism of particular substances (*e.g.*, glucose, calcium, phosphate, oxygen) either in specific organs or generally throughout the organism; others influence behaviour by affecting the nervous system.

Hormonal function involves interaction with responding cells either at the cell surface or within the cell. In many instances, the hormone acts at the cell surface to cause the release, just inside the cell membrane, of the compound cyclic adenosine monophosphate (cyclic-AMP), which actually stimulates the characteristic hormonal actions. The cyclic-AMP system at the cell surface includes a receptor substance, probably a protein, that binds the hormone; cyclic-AMP, therefore, is formed only in response to a specific hormone.

Some hormones evoke a change—generally an increase—in the permeability of the membrane of the responsive

From A. Gorbman and H.A. Bern, *Textbook of Comparative Endocrinology* (© 1963); by John Wiley & Sons, Inc.

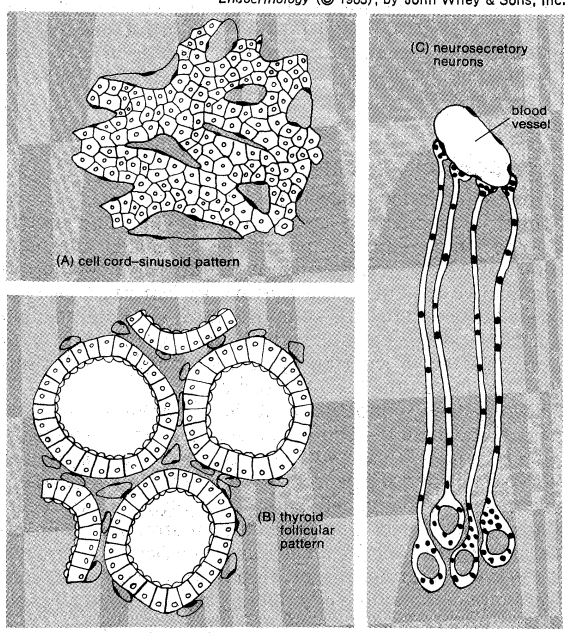

Figure 2: The three most common types of endocrine cell arrangements; each has a different relationship between secretory cell and blood channel into which its hormonal product is released.

cell; others stimulate the transport across the membrane of particular metabolites—*e.g.*, insulin accelerates the transport of glucose; vasopressin increases the transport of sodium and water in the kidney; aldosterone promotes the transport of potassium. In some instances, these actions are mediated through a second messenger, such as cyclic-AMP or through stimulating the synthesis of particular enzymes. Some hormones are known to evoke the synthesis of particular cell products such as structural proteins and enzymes by a mechanism that involves activation of the genetic material of the cell.

VERTEBRATE ENDOCRINE SYSTEMS

Neurosecretory systems. *The hypothalamus and the neurohypophysis (nervous pituitary).* In the lower part of the diencephalon of the brain (hypothalamus) are a number of assemblages, or nuclei, of nerve cell bodies where neurosecretory granules are produced. These granules appear to contain, in addition to the hormones, a protein that acts as a hormonal carrier by attaching to them. The granules can be seen under the light microscope after staining. Stainable neurosecretory material travels principally to the pars nervosa of the pituitary gland and is, therefore, primarily related to the hormones produced by the pars nervosa—vasopressin, oxytocin. Nonstainable neurosecretory material similarly travels from other nuclei of nerve cell bodies in the anterior and posterior hypothalamus to the median eminence. In lower vertebrates some of the neurosecretory material in the median eminence is stainable, even if it is not stainable in the nerve cell bodies from which it arises.

Releasing hormones of the median eminence

The median eminence neurosecretions are called releasing hormones. That at least one releasing hormone exists for each of the six hormones of the pars distalis has been established in the rat and rabbit. The releasing hormones are: thyrotropin-releasing hormone (TRH); adrenocorticotropin-releasing hormone (CRH); somatotropin- (growth hormone-) releasing hormone (GRH) and/or somatotropin release-inhibiting hormone (GIH); luteinizing hormone-releasing hormone (LHRH); follicle stimulating hormone-releasing hormone (FRH or FSHRH); and prolactin-release-inhibiting hormone (PIH). Possibly there may be no separate FRH. The substance that was purified as LHRH releases both follicle stimulating hormone (FSH) and luteinizing hormone (LH).

Five of these brain hormones stimulate the release of their respective hormones from the pars distalis of the pituitary gland; two (PIH and GIH) inhibit the release of hormones from the pars distalis. Destruction of the hypothalamic area where PIH arises increases the amount of prolactin secreted by the pituitary. These relationships have been established for a few mammals that have been investigated. Birds appear to have a prolactin-releasing hormone, and bony fishes appear to have a thyrotropin release-inhibiting hormone in place of, or in addition to, a thyrotropin-releasing hormone.

A special blood vessel supply, the hypophysial portal system, carries blood directly from the median eminence to the pars distalis (see Figures 1 and 3). This arrangement permits the releasing hormones to exert their typical action in the pars distalis before becoming diluted in the general circulation.

The pineal organ. The pineal organ, or body, is one of the most variable in structure of the endocrine glands. It develops from the roof of the diencephalon of the brain, whereas the hypothalamus develops from the lower part and floor of the diencephalon. The role of this organ is not yet fully understood. In some lower vertebrates (*e.g.*, lampreys, reptiles) the pineal has a well-developed eye-like structure. In others, some of the pineal cells, though not organized as an eye, have a photoreceptor type structure, and experiments show that the organ is in fact a light receptor. In lower vertebrates nerves connect the stalk, or base, of the pineal to other nervous centres. In birds and mammals this nervous connection is lacking, but the pineal is connected with the sympathetic part of the autonomic nervous system.

Two principal cell types in the pineal organ are the parenchymal and the glial. The parenchymal cells, which apparently are the endocrine units, contain granules thought to contain the hormone melatonin. Since the parenchymal cells develop from embryonic brain cells, they and their hormone are considered neurosecretory. The formation of melatonin, which is derived from the amino acid tryptophan, depends on an enzyme found only in the pineal organ.

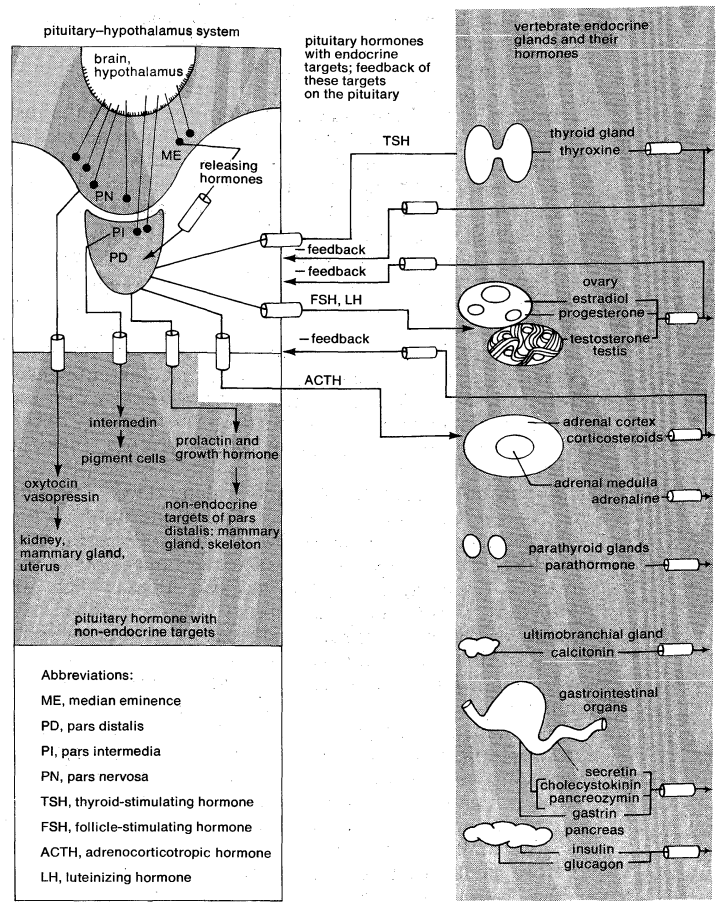

Figure 3: The functions and relationships of the components of the vertebrate endocrine system.

The adenohypophysis. The adenohypophysis develops as a finger of gland tissue that separates from the roof of the mouth cavity and becomes attached to the neurohypophysis and the hypothalamus. In most vertebrates it differentiates into three recognizable zones of tissue, the largest of which is the pars distalis; the next largest is the pars intermedia; and the smallest is the pars tuberalis. The last two may be absent in certain vertebrate groups. All three zones consist of cell cords, but only the pars distalis has an extremely rich blood sinusoid network, supplied by the portal blood vessels from the median eminence that carry the hormone releasing factors.

Hormones of the pars distalis

Six types of cells occur in the pars distalis, each identifiable with one of the six protein hormones found there: thyroid-stimulating hormone (TSH); adrenocorticotropic hormone (ACTH); follicle-stimulating hormone (FSH); luteinizing hormone (LH); growth or somatotropic hormone (GH or STH); and prolactin. Because the target of FSH and LH is the gonads, which are themselves endocrine glands, these hormones are called gonadotropins.

The pars intermedia usually has one type of secretory cell. It contains and apparently secretes the melanocyte-(pigment-cell) stimulating hormone (MSH), a peptide. There is some uncertainty concerning regulation of the release of MSH. Certain neurons from the hypothalamus, abundantly distributed throughout the pars intermedia, terminate directly upon the secretory cells. The compound norepinephrine appears to be liberated at the endings of most of these neurons (*i.e.*, they are adrenergic), but some are neurosecretory. The control of MSH secretion is of interest because the mechanism is the basis for the ability of lower vertebrates (fishes, amphibians, reptiles) to match the colour and sometimes even the pattern of their background.

The pars tuberalis has no known function or hormone. When present, it is generally near the median eminence. In reptiles and birds, in fact, the portal vessels from the median eminence pass through the pars tuberalis to the pars distalis, and the pars tuberalis, therefore, forms a bridge.

The thyroid gland. The thyroid gland develops in the embryo from tissue that grows out of the floor of the pharynx, becomes detached, and eventually completes its differentiation in the neck near the upper end of the trachea. In man, the thyroid has two lobes, which are joined by a bridge (isthmus) that crosses the trachea. An abnormality occurs in some individuals—a duct, or solid mass of tissue, is retained, joining the thyroid to its point of origin, which, in the adult human, is at the back of the tongue.

The shape of the thyroid gland is variable; however, its microscopic units always are follicles (Figure 2) with walls one cell thick. The centre of the follicle is a viscous fluid, which contains the stored hormone, thyroxine, attached to a protein (thyroglobulin). Thyroglobulin does not normally leave the follicle and must be dissociated before the thyroxine bound to it can be released.

The thyroid follicles are among a small number of animal tissues that can selectively take up iodine from the blood. The distinctive functions of thyroid tissue include the ability to accumulate iodine, to couple it with the amino acid tyrosine, and, in a few relatively simple steps, to synthesize thyroxine in the thyroglobulin form. Thyroid-stimulating hormone (TSH) stimulates several steps in this process: the movement of the iodine into the follicle and the manufacture of enzymes important in the iodination of tyrosine in the thyroidal protein and in the digestion of the thyroglobulin to free the hormone (see also the discussion in HORMONE).

Negative feedback

The thyroxine circulating in the blood has actions in many tissues; they are outlined in succeeding sections. An important self-regulatory action, however, is dealt with at this point, that of negative feedback—an important control mechanism in endocrine systems generally—on the hypothalamus and the pituitary (see Figures 3 and 4).

Figure 4 illustrates the negative feedback system of thyroxine and indicates those elements in the system that are stimulatory and those that are inhibitory. It can be seen that introducing thyroxine into the system augments the inhibition on the hypothalamus and pituitary by thyroid hormone already present. The rate of formation of TRH and TSH thus would decrease. This is the way by which extraneous thyroxine reduces the activity of the thyroid gland. Removal of the thyroid, on the other hand, leaves the hypothalamus-pituitary TSH system completely unopposed, causing the pituitary uselessly to secrete TSH. This also happens when the diet lacks iodine, and the thyroid makes insufficient thyroxine. The pituitary, unopposed by negative feedback of thyroxine, again secretes large amounts of TSH, which stimulates excessive enlargement of the thyroid and, although it is capable of responding, still lacks the iodine necessary to make the hormone. Such feedback (or more precisely, lack of feedback) results in enlargements of the thyroid, known as goitre, in man and other animals in geographical areas where dietary iodine is very low.

Ultimobranchial gland. The ultimobranchial gland is so-named because during embryonic development it separates from the most posterior of the branchial (pharyngeal) pouches. The hormone produced by this gland is calcitonin, which reduces the amount of calcium in the blood.

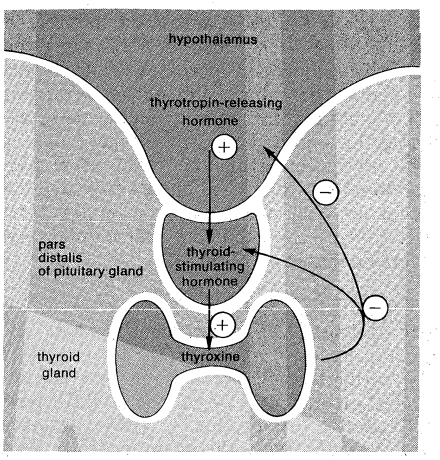

Figure 4: Hypothalamus–pituitary–thyroid self-regulatory system.

Features of ultimobranchial tissue

In most vertebrates, the embryonic ultimobranchial tissue migrates from its pharyngeal points of origin to the level of the heart. In fishes and amphibians, the tissue is sometimes in contact with the membranous sac (pericardium) surrounding the heart. In many vertebrates other than mammals, the ultimobranchial glands in the adult are of unequal size, and in many species only one gland persists. In mammals, the ultimobranchial tissue fuses during embryonic development with the thyroid and then differentiates as thyroid-like follicles, or as scattered interfollicular C cells within the adult thyroid gland. In mammals, the ultimobranchial thyroid follicles may resemble thyroid follicles, but they do not metabolize iodine.

Whether the ultimobranchial tissue is separate or intrathyroid, it appears to be responsive to blood levels of calcium: that is, high levels of blood calcium appear to activate ultimobranchial tissue and cause it to secrete calcitonin, a relatively small peptide hormone; low levels of blood calcium appear to inhibit calcitonin production.

Parathyroid glands. Like the ultimobranchial glands, the parathyroid glands are derivatives of the pharyngeal pouches of the vertebrate embryo. Because of their multiple origins from opposite sides of the pharynx, they may be quite widely separated in the neck region of the adult. They vary in number from one to two pairs; rarely are there three pairs. Only in the mammals are they commonly fused with the thyroid gland. This fusion is not as intimate as in the case of the mammalian ultimobranchial gland, however; in man and the rat, for example, the parathyroids are small round bodies just under the fibrous capsule that surrounds the thyroid gland.

The two kinds of mammalian parathyroid cells

Microscopically, the parathyroids are organized in the cell cord–sinusoid pattern (see Figure 2). In mammals, two kinds of cells are distinguishable, the chief cells and the oxyphil cells. The more numerous chief cells appear to manufacture the parathyroid hormone parathormone, a peptide. The function of the less numerous oxyphil cells in the mammalian parathyroids has not yet been established.

The microscopic structure of parathyroid cells under different conditions of blood calcium content suggest that parathyroid cells respond to differences in blood calcium level. They are activated to secrete parathormone when the blood calcium content is low and are quiescent when the content is high. The ultimobranchials and parathyroids together form a system sensitive to altered blood calcium levels, and they reciprocally regulate these levels.

Gastrointestinal endocrine system. Thyroxine-producing, calcitonin-producing, and parathormone-producing glands are derived from the developing wall of the upper digestive tract. A larger group of hormone-secreting glands is derived from the embryonic midgut, or abdom-

inal level of the digestive tract: gastrin is secreted by the stomach wall; insulin and glucagon are secreted by the pancreas, which in the embryo becomes separated from the intestine; secretin, cholecystokinin-pancreozymin (CCK-PZ), and possibly others are secreted by tissues that remain in the intestinal wall. Studies have indicated that cholecystokinin and pancreozymin are merely different phases of action of the same hormone. For convenience the two names, usually combined and hyphenated, are abbreviated CCK-PZ.

Several of the hormones of the midgut, all of which are relatively small peptides, resemble each other chemically. There are, for example, numerous duplications of sequences of the amino acids constituting the hormones. Secretin and glucagon especially resemble each other —14 of the 27 amino acids of secretin are found as duplicates in the glucagon molecule. Gastrin is of particular interest since four amino acids at one end of the molecule, which consists of 17 amino acids in chainlike arrangement, have all of the actions, though weaker, of the entire molecule. The augmenting action of the first 13 amino acids in the gastrin molecule can be simulated by attaching through chemical methods various other groups to the last four amino acids; for example, such a compound named pentagastrin has generally higher physiological activity than gastrin itself.

The amino acid sequence at one end of the intestinal hormone cholecystokinin-pancreozymin molecule (CCK-PZ) is the same as that of gastrin. Although CCK-PZ contains 33 amino acids, its chemical resemblance to gastrin not unexpectedly means that some of the actions of gastrin and CCK-PZ overlap; *e.g.*, CCK-PZ has 4 percent of the activity of gastrin on frog stomachs. The differences in action between CCK-PZ and gastrin apparently reside in the part of the molecule preceding the five identical terminal amino acids. Interestingly, the skins of certain hylid frogs contain a peptide called caerulein, consisting of ten amino acids; the last five are identical with those at one end of gastrin and CCK-PZ. In pharmacological tests, caerulein has some of the effects ascribable to gastrin and CCK-PZ.

Hormonal effects during digestion

When food enters the stomach, the distension of the organ stimulates nerves leading to gastrin-secreting cells scattered through the mucosa (inner lining layer). The gastrin then released by the stomach into the blood affects the stomach itself, principally stimulating the enzyme-forming cells to secrete pepsin, so-called parietal cells to secrete acid, and the stomach musculature to contract. Even before food enters the stomach, however, some secretion of gastrin and acid may be started by nervous stimuli originating in the brain. This is known as the cephalic phase of gastric stimulation. The increased quantity of acid in the stomach has a direct negative feedback action on the acid-secreting and gastrin-secreting cells, retarding their function after conditions favourable for gastric digestion have been achieved.

The effects of gastrin on liver, pancreatic, and intestinal function, though relatively weak, have meanwhile begun. When the acidified food enters the intestine from the stomach, two more hormones, secretin and CCK-PZ, are released into the blood by intestinal mucosal cells and activate the flow of pancreatic secretion. In addition, these two hormones affect the function of the liver, the gall bladder, and the intestine itself. Secretin also has an inhibiting effect on gastric acid secretion and on gastric muscular movements. CCK-PZ has a slight stimulatory action on gastric functions but reduces gastric acidity by competing with gastrin for sites of action on responsive cells in the stomach. Displacement of gastrin by CCK-PZ, a weaker stimulant, moderates the actions of gastrin on the stomach. The inhibiting effect of secretin and CCK-PZ on gastric acid secretion was once thought to be the action of an intestinal hormone called enterogastrone. The existence of enterogastrone as a separate chemical entity, however, is no longer considered valid.

The three principal hormones of the gastrointestinal wall, and possibly glucagon from the pancreas, have interlocking and interrelated actions, forming a system for endocrine regulation of the digestive process. It is thought that this interrelatedness derives from the evolutionary divergence of both the hormones and the glandular and muscular receptors. Comparison of gastrin molecules from six mammalian species shows that, of the total number (17) of amino acids, these vary by only one or two, which are never at the "active" end of the molecule. The variation is caused by single changes (mutations) in the genetic code. When similar comparisons are available for gastrins and other gastrointestinal hormones of lower vertebrates, an interesting evolutionary picture should appear.

The gastrointestinal endocrines were the first of the endocrine systems to be demonstrated experimentally, and although the chemical structure of the hormones has been established, the identity of the cells secreting these hormones has been elusive. Gastrin does not originate in a separate organ, but in isolated endocrine cells scattered through the mucosal layer of the gastric wall. It is thought that the cellular sources of the intestinal hormones may be a similar type of cell of the intestinal mucosa. The function of these cells is not yet fully understood, but they resemble, in relative position and structure, the gastrin-secreting cells.

Pancreatic endocrine tissue. In most vertebrates, the tissue that eventually becomes the insulin-glucagon secretory system originates in the embryo with the pancreas as single or multiple outpocketings of the upper part of the intestine. As the pancreas differentiates into secretory units, part of it remains connected with the pancreatic ducts and, in the adult, functions directly in the digestive process. A part of the developing pancreas, however, differentiates into islands of tissue isolated from the ducts; these islands are responsible for the endocrine function of the pancreas. In vertebrates with the pancreatic development described above, the endocrine cell units are called islets of Langerhans. In some vertebrates—bony fishes for example—the endocrine pancreatic tissue may become partly separated from the exocrine pancreas. In cartilaginous fishes, the endocrine tissue, which retains an anatomical relationship to the ducts, presumably does not secrete into them. In the most primitive vertebrates, the cyclostomes, the endocrine pancreatic tissue is in the intestinal wall near the point of attachment of the bile duct.

Role of alpha and beta cells in mammals

In all vertebrates, the endocrine pancreas is organized as cell cords separated by sinusoids. Two principal cell types are distinguishable, and as many as three more minor cell types may also occur. In mammals, the most numerous cell type, recognizable by its position and by details of its intracellular structure, is the beta cell, which has been identified by a variety of experimental procedures as the source of insulin. The alpha cell, which is usually found in greatest numbers near the edges of mammalian islets, is considered to be the source of glucagon. Functions of the other cell types are not clear, but one may produce gastrin; the human disease known as the Zollinger-Ellison syndrome, for example, is characterized by pancreatic islet cell tumours and high levels of gastrin in the blood.

The proportions of islet alpha and beta cells relative to each other vary widely and characteristically among vertebrate species. In birds and reptiles, alpha cells are more numerous; in amphibians, beta cells predominate.

If blood or saline fluids high in glucose are experimentally introduced into the pancreatic artery, insulin is immediately released. Similar introduction of fluids low in glucose stops insulin release and activates the release of glucagon. Such experimental results indicate that the alpha and beta cells are directly sensitive to differences in glucose concentration in the blood. As in the case of blood calcium regulation (see below *Parathyroid–ultimobranchial system*), the alpha and beta cells form part of a regulatory system for maintaining a relatively constant blood glucose level. This role is further described in the article HORMONE, as is the molecular variation among vertebrates of the insulin molecule.

Adrenal medulla. In the higher vertebrates—reptiles, birds, and mammals—the adrenal glands are generally rounded or angular organs composed of two basic kinds of tissue: one secreting steroid hormones, the other se-

creting adrenaline (epinephrine) and noradrenaline (norepinephrine). In mammals, the adrenaline and noradrenaline-secreting cells are in the core, or medulla, of the organ, and the steroid-secreting tissue forms the outer shell, or cortex (Figure 5). The cells of the medulla are sometimes referred to as chromaffin cells because they can be stained by chromate-containing tissue preservatives.

In lower vertebrates, chromaffin cells are found not only in association with those tissues equivalent to the adrenal cortex, called the interrenal tissue, but also on the kidney, where they are even more widely distributed, and along the roof of the body cavity, where they are associated with nerve ganglia of the sympathetic nervous system. The distribution of the chromaffin-adrenal medullary cells partly reflects their embryonic origin and their association with sympathetic ganglia—they originate from the neural crests of the embryonic neural tube, which also give rise to the sympathetic ganglia. The higher vertebrates show a more intimate association between adrenal cortical and medullary tissues than do the lower vertebrates. No distinct functional value has yet been recognized for this anatomical association (see Figure 5).

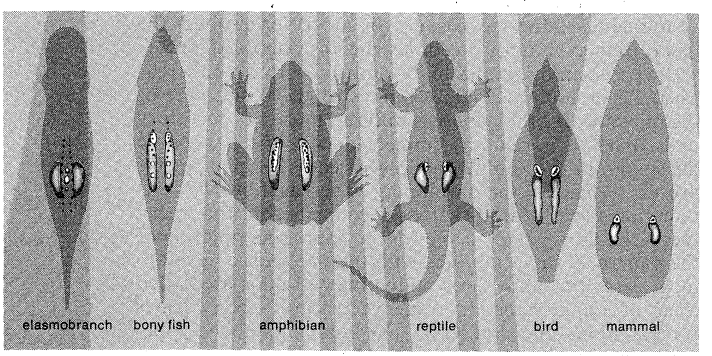

Figure 5: *Patterns of vertebrate adrenal glands.* White, interrenal or cortical tissue; black, chromaffin or medullary tissue; shaded area, kidney.

Regardless of the type of organization, the chromaffin cells secrete into the blood noradrenaline and the closely related adrenaline. Among the vertebrates, there is a wide variation in the proportions of these two hormones in the blood and in the adrenal medullary tissue. In the adrenal medulla of mammals, the cells are arranged in a branching cell cord-sinusoid pattern. Chromaffin cells, whether in a glandular mass, in a single group, or in small groups, are innervated by nerve cells from the central nervous system. They are thus endocrine glandular counterparts for the nerve cells that release noradrenaline as a chemical transmitter of impulses between cells.

Range of effects of adrenaline and noradrenaline

Adrenaline and noradrenaline have a wide variety of target organs, including the heart and blood vessels and most of the organs with smooth muscle in their walls (*e.g.*, the hollow viscera, the uterus); in addition, these hormones affect the metabolism of glucose and the dispersion of pigment in skin pigment cells. Because of their chemical similarity, the physiological actions of noradrenaline and adrenaline also are similar; however, their effects may vary considerably in degree, and in a few instances oppose each other. Furthermore, the precise actions of adrenaline and noradrenaline on a given organ or physiological process may differ in different animal groups.

One of the many as yet unexplained phenomena involving the function of adrenaline and noradrenaline is the extremely large concentrations of these hormones found in the heart muscle of hagfishes. The hagfish heart, however, is not innervated, nor does it appear to respond to additional quantities of adrenaline or noradrenaline.

Adrenal cortex. Adrenal cortical tissue and the gonads are the only steroid hormone-secreting endocrines in vertebrates. The embryonic origin of these glands is also similar—that is, they develop, as do the kidneys, from condensations of loosely organized cells called mesenchyme cells in the body wall above the abdominal cavity. In elasmobranch fishes, the condensed masses of mesenchyme cells commonly differentiate as median glands between the two kidneys (see Figure 5) and are known as interrenals. In bony fishes, the interrenal tissue is associated with the kidneys much further forward and may emerge from within the kidney, attached to the walls of veins carrying blood toward the heart. In addition, bony fishes have two or more so-called Stannius corpuscles attached to or embedded in the kidney. These develop from the mesonephric region of the embryonic kidney. Studies indicate that the Stannius corpuscles may secrete adrenal steroid hormones. In amphibians, interrenal or adrenocorticoid tissue, arranged either as a single mass or in segmented units, is embedded in or on the kidney and mixed with chromaffin cells. In reptiles, birds, and mammals, the adrenal mesenchymal masses generally form the pair of discrete glandular organs typically associated with chromaffin tissue at the upper ends of the kidneys.

The embryonic origins of these tissues explain the general anatomical association of the adrenocortical tissue, the kidney, and the gonadal tissue, even though details of the association are highly variable; for example, accessory adrenocortical cells commonly are found among the testicular ducts, which develop in the embryo from the early kidney.

The usual arrangement of adrenocortical tissue is as cords or columns. The adrenals of lower vertebrates appear to have fewer and smaller blood vessels among the cords. The mammalian adrenal cortex is regularly structured in a concentric pattern, the cell cords in the outermost zone (zona glomerulosa) being arranged in whorls, with the next zone (zona fasciculata) arranged in long parallel columns. There is some evidence that the zones secrete different steroids.

A small amount of steroid hormone is stored in the steroid-secreting cells as lipid (fat) droplets. Corticoadrenal cells, therefore, stain well with fat stains, unless adrenocortical hormone (ACTH) from pituitary is injected; ACTH stimulates release of the hormone stored in the cells.

Cortical adrenal gland cells and interrenal gland cells produce a variety of hormones related in structure; a relatively small number of them predominate, namely cortisol, corticosterone, and aldosterone. In certain fishes, a related steroid, 1-alpha hydroxycorticosterone, is produced in relatively high concentration. Corticosteroids belong to one of two general classes, depending on their principal or strongest action: mineralocorticoid and glucocorticoid. Mineralocorticoids (*e.g.*, aldosterone) affect the movement of water and salts through organs of exchange with the environment such as the kidneys (skin and gills in aquatic animals). Glucocorticoids (*e.g.*, cortisol, corticosterone) chiefly affect metabolic formation of carbohydrates, such as glucose from noncarbohydrate substances (gluconeogenesis); and the general activity of connective tissue cells, called fibroblasts; and of cells involved in the immunological response. Glucocorticoids may have some mineralocorticoid action and vice versa.

In mammals, the synthesis of glucocorticoids in the zona fasciculata of the adrenal cortex is regulated by ACTH. ACTH release is in turn controlled by the hypothalamus; the glucocorticoids thus are steroid hormones that participate chiefly in neuroendocrine reflexes and that serve as the chief negative feedback controls on ACTH secretion.

Aldosterone is formed mainly in the zona glomerulosa of the mammalian adrenal cortex. Its formation is controlled to a minor degree by ACTH, but it is influenced by the renin-angiotensin system, a combination of a kidney-produced enzyme and a peptide hormone that affects blood pressure, sodium concentration, and water movements, (see HORMONE for a more detailed description).

The stress response

Experiences harmful to an organism, such as pain, poisoning, general trauma, starvation, and disease, can excite nerves that lead eventually to a common terminus in the hypothalamus, where adrenocorticotropin-releasing hormone (CRH) is formed. Stimulation of CRH enhances ACTH stimulation of high levels of glucocorticoid secretion; the physiological consequences—the utilization of

proteins to form carbohydrate and an increase in the amount of sugar and protein in the blood—are prominent features of a phenomenon known as the stress response.

The stress response of interrenal and adrenal cortical tissues is an important adaptive system. The conversion of noncarbohydrates such as protein and fat to carbohydrates results in a source of energy for animals that are starving or in some other adverse condition. Destruction of lymphoid tissue and lymphocytes as a result of high levels of glucocorticoid secretion releases proteins, including antibodies, into the blood. The increased amounts of blood protein temporarily overcome large losses in blood volume resulting from hemorrhage. The increased antibody level helps the organism to resist infections. Because of a stress response, the Pacific salmon arrives at the end of his spawning migration with a tremendously enlarged interrenal, as well as high blood levels of glucocorticoids; both changes are adaptive, since, in moving upstream, the salmon does not stop to feed. The intensive gluconeogenesis during this time results in the depletion of tissue proteins; the glucose formed from the protein provides the energy for the muscular work involved in upstream migration.

Ovary and testis. The gonads (the ovary and the testis) are double glands in the sense that their external secretion, the sex cells (ova and spermatozoa), are released into ducts, and their internal secretions, the hormones, are released into the blood. Early in development a pair of urogenital structures develops from the body wall, above the body cavity near the adrenal cortex, and splits lengthwise into an embryonic urinary system and a genital ridge. The genital ridge contains elements capable of differentiating into either a testis or an ovary, depending on the genetic sex of the individual. In a few vertebrate species, the differentiated gonad contains, either simultaneously or successively, both male and female structures and hormones.

The ducts of the mesonephric kidney, which remains functional in lower vertebrates but usually degenerates in reptiles, birds, and mammals, are used to convey spermatozoa toward the external male organs. The female ducts and passages do not have such a close relationship to the urinary system except at the opening leading outside the body.

The endocrine elements in both the ovary and the testis, the interstitial tissues, are so-called because they are found between and among the germinal tissues, which are the seminiferous tubules in the testis and the ovarian follicles in the ovary. Cellular layers, called the theca, in the wall of the ovarian follicle also are endocrine. In many vertebrates, a structure, the corpus luteum, develops from the follicular wall after the ovum is released. The corpus luteum, composed of cords of large cells separated by sinusoids, is an endocrine gland and secretes the steroid hormone progesterone.

The typical hormone of the testicular interstitial cells is the steroid testosterone; in certain species and under particular circumstances, other androgens (male hormones) may be secreted. The typical female sex hormone, or estrogen, presumably secreted by the ovarian interstitial and thecal tissues, is estradiol.

Reproduction, one of the most highly adaptive functions possible in an organism, is geared to the presence or absence of a sexual partner, to temperature, to season of the year, and to various aspects of the life cycle of a particular animal species. Accordingly, the cycles of sex cell production and of sex hormone secretion are controlled by mechanisms involving the pituitary gland, environmental sensors, and neuroendocrine mechanisms (Figures 1 and 3). The functions of these interlocking endocrine controls, their feedback relations, and their cyclic activity are described in greater detail in HORMONE.

Role of the hypothalamus in reproductive regulation

The hypothalamus integrates the complex factors necessary for a successful reproductive system. It receives important neurosensory information—*e.g.*, season of the year, temperature, availability of a mate—is subject to feedback from the sex hormones, and exerts control over both the release of gonadotropic hormones from the anterior pituitary (adenohypophysis) and sexual behaviour. The integration of these many factors is complex and only imperfectly understood thus far. A beginning has been made, however, in understanding the difference in hypothalamic activities in male and female rats. The pituitaries of adult female rats, and many other female mammals, alternately release follicle-stimulating hormone (FSH) and luteinizing hormone (LH) to maintain cyclic ovarian function. The pituitary is stimulated by the hypothalamus to release the hormones. The noncyclic secretion of FSH and LH in the male is balanced by feedback action of testosterone from the testis. The explanation for the differentiation of variable sex hormone feedback function in the female hypothalamus and a static feedback equilibrium in males apparently lies in the sexual differentiation that occurs in the embryo and newborn. Sexual differentiation can be altered experimentally; for example, giving male hormone to a late embryo or a newborn female rat causes its hypothalamus to differentiate in the male (noncyclic) pattern. Adult female rats that have been altered this way are sterile; although they have normal ovaries, they do not have cyclic ovarian function because the hypothalamus has been "programmed" to stimulate a noncyclic supply of gonadotropins from the pituitary. Such females also have abnormal malelike sex behaviour.

INVERTEBRATE ENDOCRINE SYSTEMS

Excepting the arthropods, it can be said that invertebrate endocrine systems are virtually unknown. Much of the lack of information results from the difficulty of applying to small organisms the usual procedures and criteria for proving that a given mechanism is endocrine. The procedures involve: (1) surgical removal of the suspected gland and observation of consequences; (2) elimination of the consequences of removing the gland by reimplantation of glands or by injection of gland extracts; and (3) extraction, isolation, and chemical characterization of the responsible hormone from glands.

Methods used to determine endocrine function

In most invertebrate groups, even though it has not been possible to establish the existence of endocrine mechanisms by these methods, some evidence has been obtained for neurosecretion. Nerve cells with a presumed neurosecretory function and containing granules of the proper size and structure have been found in coelenterates, flatworms, roundworms, nemertean worms, annelid worms, mollusks, arthropods, and protochordates. In the majority of invertebrates, however, there is little evidence to indicate the nature of the function of these cells. In annelid worms it has been shown that regeneration of certain body parts and maturation of sex cells in the gonads may not occur when the brain is injured or removed; this has been taken as evidence for an endocrine relation of the brain to these processes. Even if such a relationship does exist, however, it remains to be proved that the nerve cells are involved.

In echinoderms such as starfishes, an egg-shedding hormone can be extracted from the radial nerves in the rays, or arms. The precise source of this substance, which may be considered more a pheromone—a chemical substance by which individuals of a species communicate—than a hormone, is not yet known. In a variety of mollusks, both the anatomy and the seasonal variations in staining of large neurosecretory cells have been established. A direct relation to internal functions, however, is not yet known, although the electrical activity of some of the cells has been studied. In the octopus, a discrete nonneurosecretory, but innervated structure, the optic gland, is believed to have a gonadotropic function; *i.e.*, it influences the gonads.

Endocrine and neuroendocrine functions in the arthropods have been better established than in any other invertebrate groups. Not only are anatomical features well defined but functions are also fairly well understood, and the chemical nature of some of the arthropod hormones is known.

Insects. Figure 6 summarizes the general structure of the central nervous system and known glands of an insect. Although individual differences exist in the disposition of the parts in different insects, all parts are usually

represented in all insects, at least in the immature (larval) forms.

Neurosecretory neurons

The brain, or cerebral ganglion, of insects contains groups of the cell bodies of neurosecretory neurons. Each group, referred to as a pars intercerebralis, sends secretion-laden axons toward organs called the corpus cardiacum and the corpus allatum on each side (see Figure 6). Nerves connect the brain and the corpora. In addition, discrete neurosecretory neurons occur in the chain of nervous ganglia behind the brain. Several kinds of neurosecretory cells occur in the brain and ganglia, possibly with different functions, since they stain differently. The two corpora cardiaca presumably release neurosecretory factors important in various insect functions. One of these neurosecretory hormones, known as prothoracotropic or ecdysiotropic hormone, stimulates the prothoracic gland, or ecdysial gland, in the larva to secrete an important hormone—ecdysone, or molting hormone. The prothoracic gland degenerates in the adult insect.

Some of the neurons between the corpora cardiaca and the brain traverse the latter and terminate in a glandular structure, the corpus allatum, on each side. The corpora allata secrete juvenile hormone, which, in the larva, has a role in development and the periodic shedding of skin (molting) and, in the adult, appears to be gonadotropic.

Analogies and similarities exist between the brain–thoracotropic–prothoracic gland system of insects and the brain–pituitary–pituitary target organ systems of vertebrates. The same can be said of the brain-corpus cardiacum-juvenile hormone-target organ system. As is explained below, similar brain–neurosecretion–primary target gland-secondary target organ systems occur in crustaceans. The adaptive value of these systems is the same in all animals in which they have been demonstrated. The systems provide a way for sense organ-detected changes in the environment to influence, or to trigger, an internal functional adjustment. It is dangerous, for example, for some animals to molt under conditions of dryness. In such cases low humidity or high humidity, as perceived through appropriate sense organs, inhibit or favour release of molting hormone through a nervous input at the neurosecretion level in the brain. In a similar manner, it is most favourable and efficient if certain gonadotropic functions occur only when a sexual partner ready for mating is present. Internal reproductive changes (*e.g.*, ripening of gametes, ovulation) often are triggered either by pheromonal signals from the opposite sex or by mechanical or tactile signals such as touching particular external structures—*e.g.*, vagina of the rabbit, genital structures in the roach. Sensory signals from a possible mate are integrated in the central nervous system and eventually result in release of a gonadotropin from the appropriate gland (pituitary or corpus allatum).

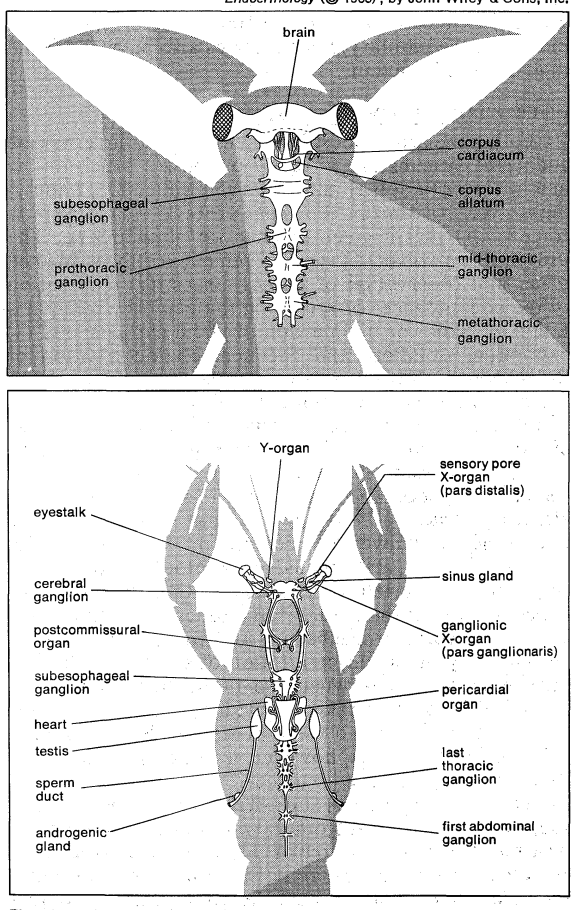

Figure 6: ***Invertebrate endocrine systems.***
(Top) Central nervous and endocrine structures of a silkworm moth; (bottom) endocrine system of a generalized male crustacean.

Crustaceans. In crustaceans, as in insects, the primary neurosecretory structure is the brain, or cerebral ganglion; other groups of neurosecretory cells are located in nervous ganglia apart from the brain (Figure 6). In addition, there is a separate group of neurosecretory cells known as the X-organ in the eyestalk. The neurosecretory cells terminate in several neurohemal organs in order to discharge their hormones into the blood; perhaps the best known neurohemal organ is the sinus gland in the eyestalk. The postcommissural organ serves a neurohemal function for nerve cells in nearby thoracic ganglia. Crustaceans have two known nonneurosecretory glands, the Y-organ and the androgenic glands (Figure 6); both types are under the control of blood-borne neurosecretory substances from cells in the central nervous system.

It has been established that the neurosecretory cells of the brain and the eyestalk are involved in the control of molting through inhibition of the Y-organ, in gonadal function through inhibition of the androgenic gland, in the metabolism of carbohydrate and probably other substances, in the dispersion of body pigment, and in the rhythmic movement of pigment in the retina of the eye.

There is strong evidence that the neurohormone released from the pericardial organs accelerates the action of the heart. A simultaneous loss, or discharge, of neurosecretory granules from the neurohemal organ and an increase in heart rate can be brought about by electrically stimulating the neurons leading to the pericardial organs.

The crustacean molting hormone, called crustecdysone, secreted by the Y-organ, is a steroid very similar chemically to ecdysone, the molting hormone of insects. Molting in insects is a phenomenon only of larvae, but it occurs throughout the life of crustaceans; both groups, however, have similar endocrine mechanisms.

The structure of the presumed hormone of the crustacean androgenic gland has not yet been fully characterized. But the androgenic gland and the corpus allatum of insects appear to have analogous gonadotropic functions. There are, however, greater dissimilarities in gonadotropic functions between crustaceans and insects than in molt-control systems between the two groups.

COMPARATIVE, ADAPTIVE, AND EVOLUTIONARY ASPECTS OF ENDOCRINE SYSTEMS

It is valuable to compare endocrine mechanisms among animal groups, to recognize consistent evolutionary trends, and to define the adaptive values or purposes of these trends.

The neurosecretory cell. Although it has been commonly said that neurosecretory cells illustrate the most widespread and common endocrine phenomenon, accumulating knowledge about neurosecretory cells has made clear the fact that comparisons among neuron-derived secretory cells cannot be made more readily than comparisons among secretory cells derived from other sources. Secretory nerve cells may exemplify the most plastic of all endocrine systems; that is, they are readily modified, or adapted, to serve a variety of particular functions. It may not be any more valid to compare two different kinds of neurosecretory cells—*e.g.*, in a fish and in an insect, in the hypothalamus and in the spinal cord,

in the cerebral ganglion and in an abdominal ganglion—than it is to compare two glandular endocrine secretory cells, one in the thyroid and one in the pancreas.

Properties of neurosecretory cells

It is useful nevertheless to summarize the properties of neurosecretory cells, in order to show the many ways by which they may differentiate and thus adapt to particular functions.

The neurosecretory cell (see Figure 7) has a neuron-like form; that is, the cell is composed of a cell body, projections called dendrites (D, in Figure 7), a long axon (A, in Figure 7), and synaptic contacts with other neurons at least at one end. Some neurosecretory cells do not have all of these structural features; others have additional ones. Evidence indicates that some hypothalamic neurosecretory cells may have special fibres, called recurrent collateral fibres (labelled possible RC in Figure 7), extending from a point on the axon near the end of the cell (neuron terminal) to the cell body (perikaryon, PK). Recurrent collateral fibres allow a variety of feedback relationships between the neuron terminal and the cell body. Some neurosecretory cells vary widely from Figure 7; for example, the axon in some cells—*e.g.*, molluscan brain, Speidel cells in the spinal cord of elasmobranch fishes—is extremely short, and the size of other cells may be large enough to require blood from small blood vessels (capillaries).

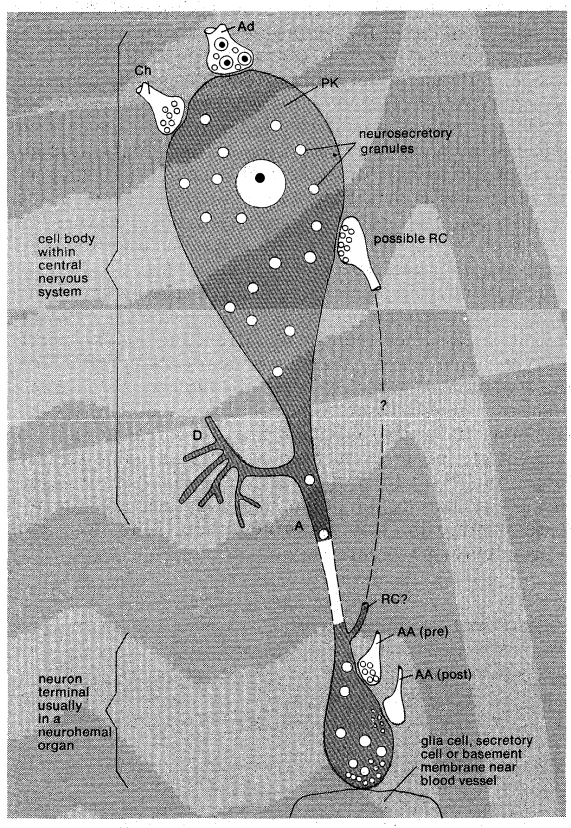

Figure 7: Generalized neurosecretory cell (see text).

One important structural variable of neurosecretory cells, and one that determines the precise character of their function, is the nature of the incoming (afferent) neurons that form contacts, called synapses, across which nerve impulses are transmitted to the cell body. Considerable progress has been made in the identification of afferent neurons for brain neurosecretory cells of the nudibranch mollusk *Aplysia*. Drugs that block certain classes of neuronal function and techniques used to study cellular components reveal that neurosecretory cell bodies differ in the relative numbers upon them of various kinds of nerve fibre endings, such as those that liberate the compound acetyl choline at the synapse (cholinergic, Ch in Figure 7) and those that liberate norepinephrine (adrenergic, Ad in Figure 7).

A second important variable of neurosecretory cell function is the point at which the cell ends. The most common termination is in a neurohemal organ; as has been mentioned, there are numerous types. Generally, neurohemal organs consist of secretory endings of one type of neurosecretory cell and the blood vessels upon which they lie. An exception is the vertebrate median eminence, which contains at least six types of neurosecretory endings; the number of types has not yet been resolved for the crustacean sinus gland. Some invertebrate neurosecretory cells and the elasmobranch Speidel cell may have no apparent neurohemal organs; the endings of these cells are dispersed in connective tissue that contains blood vessels. Some neurosecretory cells end in direct synaptic contact with glandular secretory cells, as for example, in the corpus allatum of insects, in the pars intermedia of most vertebrate pituitary glands, and in the pars distalis of the pituitary of fishes.

Another variable in neurosecretory cells is the type of connection of their neuron terminals. Formerly it was thought that the axons of neurosecretory cells do not synapse with other neurons at their neuron terminals; however, more recently inconspicuous axon endings have been found upon neurosecretory endings. These are either pre-synaptic (AA pre in Figure 7) or post-synaptic (AA post in Figure 7); in the first instance, the impulse is coming from the neurosecretory cell, in the second, it is going to the neurosecretory cell.

Still another important variable in neurosecretory cells is the chemical nature of the neurosecretory secretion. Chemical differences have been shown by staining techniques among almost contiguous neurosecretory cells in the brains of arthropods. Neurosecretions whose chemical nature has been established include several from the vertebrate pituitary gland—thyrotropin releasing hormone (TRH), luteinizing hormone-releasing hormone (LRH), growth hormone release-inhibiting hormone (GIH), oxytocin, and vasopressin—all of which are peptides. Based on relatively crude chemical evidence, some hormones (*e.g.*, ecdysiotropic hormone of insects) are believed to be small proteins. It is probably safe to conclude that no particular uniformity will be found in the chemical nature either of the neurosecretory hormones or of their intracellular protein carriers, called neurophysins.

Finally, it should be pointed out that the overt physiological roles of neurosecretions are extremely broad; *i.e.*, they exert direct effects on general metabolism, control the functions of important endocrine glands such as the pituitary gland and the Y-organ, and regulate the function of particular organ systems—the kidney in excretion, the uterus in reproduction—and adaptive pigmentary changes. The location of the neurosecretory cells in the central nervous system—that is, their contact with sensory systems on one hand and numerous effector systems on the other hand—is highly strategic. It is no wonder, then, that they have been subjected to many kinds of adaptive pressures, and, in response, have evolved in many directions, in the ways outlined above, to subserve a variety of vital functions.

Hypothalamus–pituitary control systems. In most vertebrate groups the structural features of the hypothalamus–pituitary system seem comparable; that is, there is a neurohemal organ, the median eminence, from which blood vessels carry neurosecretory hormones directly to sinusoids in the pars distalis region of the pituitary gland (see Figures 1, 3). This relationship, as has been pointed out, makes possible the regulation by the brain of hormonal secretions of the pituitary gland. Among the vertebrates, however, are several exceptions, undoubtedly of functional significance, to the arrangement of blood vessels between the brain and the pituitary gland. The evolutionary or adaptive functional significance of these anatomical variations has not yet been established.

The most primitive living vertebrates, the Agnatha, apparently have no blood vessel connection between the brain and the pituitary gland. One cyclostome group, the hagfishes, lives deep in the ocean under nearly constant physical conditions. Since no seasonal changes occur, it may be that there is no functional advantage in the regulation of pituitary gland functions to outside conditions

through hypothalamic neurosecretion; hagfishes, for example, breed continuously. Another group of Agnatha, the lampreys, however, breed and migrate seasonally, so that there must be some regulation of functions of the sex organs (among others) through neurosensory systems affected by environmental seasonal cycles. But lampreys have no hypothalamus-pituitary blood system, so that the mechanism by which seasonal changes affect seasonal reproductive behaviour is not known.

Because Agnatha lack a hypothalamus-pituitary blood vessel connection, even though such a system would be advantageous to the lampreys, it is possible that this relationship first evolved in the vertebrate line between the Agnatha and other vertebrates.

The regulation of the pars distalis region of the pituitary gland of cartilaginous fishes also is of interest. One part of the pars distalis, called the ventral lobe, secretes several hormones, including gonadotropins, but has no blood vessel connection to the median eminence; yet gonadotropic hormone secretion in elasmobranchs is regulated according to season or other external environmental events.

In birds and in elasmobranchs, the median eminence differentiates into at least two regions, a specialization that may permit the secretion of specific releasing hormones into specific portal blood vessels that go to a particular part of the pars distalis. Whether or not such a regional segregation of the hypothalamus-pituitary system exists has not yet been proved.

In bony fishes, the hypothalamus and pars distalis are intimately associated. In fact, many hypothalamic neurosecretory neurons cross the boundary between hypothalamus and pars distalis, and terminate on or very near the secretory gland cells. It would appear, then, that bony fishes have a system whereby the hypothalamus can directly regulate secretion by the pars distalis. The relative advantages or disadvantages of such direct control remain to be evaluated.

Parathyroid-ultimobranchial system. The study of the evolution of anatomical features of vertebrate endocrine systems, with the exception of the hypothalamus–pituitary system, usually involves subtle changes. The parathyroid–ultimobranchial system, however, involves relatively important evolutionary differences in structure among the various groups. The hormones and their functions—maintenance of a constant blood level of calcium—on the other hand, appear to be more constant, apparently an exception to the generalization that it is not the hormones that vary, but the uses to which they are put.

Variation in blood calcium regulating mechanisms

The parathyroid gland, for example, is the only vertebrate endocrine organ that is not present in all vertebrates. None of the fishes has a parathyroid. In addition, the hypercalcemic (blood-level increasing) hormone of higher vertebrates, parathormone, is relatively inactive in altering blood calcium levels in fishes. It is reasonable to assume that fishes must regulate blood calcium levels. Their diets vary in calcium content depending on the environment, and, unlike most vertebrates, the skeletal reservoir of calcium is relatively slight, and some bone (acellular bone) is not readily available for metabolic purposes. The ultimobranchial body of fishes, on the other hand, is an excellent source of the hypocalcemic (blood-level lowering) hormone, calcitonin. In fact, calcitonin from salmon and dogfishes is so readily available, and so potent in humans, that it is used in medicine.

Amphibians have parathyroids, but their structure is unlike that of higher vertebrates, consisting, in frogs and salamanders, of whorls of cells (see Figure 2). In reptiles, birds, and mammals, parathyroids are composed of the familiar cell cords and sinusoids. In amphibians and reptiles, who have a well-developed calcitonin-secreting ultimobranchial gland; the parathyroids commonly undergo degenerative changes in the winter and regenerative changes in the spring.

The mechanism of blood calcium regulation in mammals involves the interaction of both parathormone and calcitonin. The mechanisms of regulation in fishes, in which only calcitonin is available, or in amphibians and reptiles, which have a seasonally developed parathyroid gland, clearly indicate an evolution of endocrine structures regulating calcium metabolism in vertebrates.

The two glands that regulate the blood level of calcium through hormonal secretion are derived from the lateral pouches of the pharynx. The glands separate and remain separated in the heart and neck regions of most groups of higher vertebrates. In mammals, however, the structures that will form the ultimobranchial and parathyroid glands consistently migrate into and fuse with the thyroid gland, which has a different embryonic origin. Generally, when such a modification of embryonic development is consistently evolved in a given group of organisms, some functional advantage (not yet established in this case) exists for the evolutionary trend.

Thyroid glands and thyroid function. The vertebrate endocrine organs are present in some form, with the exception of the parathyroids, in the lowest vertebrates, but are lacking in the invertebrates. Thus, the evolutionary beginnings and ancestry of vertebrate endocrine organs have been lost in those extinct prevertebrate animals that have disappeared and whose fossil record is either absent or of no help in understanding endocrine evolution.

The thyroid gland and its function seems to be an exception, at least in part. The formation of the relatively simple hormone thyroxine involves the addition of iodine to proteins containing the amino acid tyrosine. Two iodotyrosines may, even in the test tube, couple to form thyroxine. Although iodotyrosines form easily, the coupling of iodotyrosines to form thyroxine is a much slower process. Naturally-occurring iodotyrosines have been found in numerous invertebrates. In fact, the first iodoproteins and iodotyrosines were obtained in the 19th century from corals before they were known to occur in the thyroid. Naturally-occurring nonthyroidal thyroxine has been reported much more rarely, but it has been found in some invertebrates, especially mollusks.

Thus, the thyroid hormone probably existed without any known function long before the gland itself was evolved. It must be assumed that the occurrence of iodotyrosines and thyroxine was a natural chemical accident, but that the evolution of the thyroid gland followed the development of a physiological role for thyroxine. The special functions of the thyroid gland are: (1) to extract and to concentrate iodine from the blood to add iodine rapidly to a protein; (2) to provide enzymes that favour rapid protein iodination, diiodotyrosine coupling, and the release of thyroxine from its protein; and (3) to store and release thyroxine as necessary.

Special functions of the thyroid

From A. Gorbman and H.A. Bern, *Textbook of Comparative Endocrinology* (© 1963); by John Wiley & Sons, Inc.

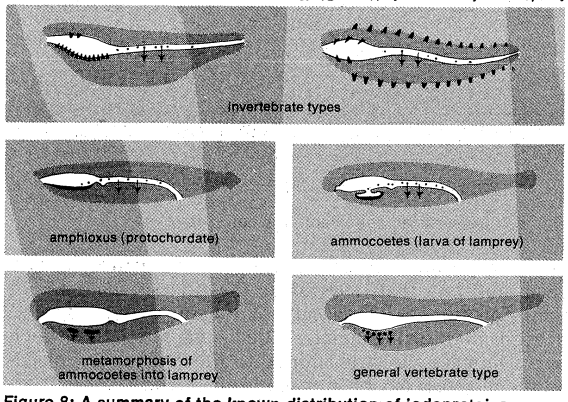

Figure 8: A summary of the known distribution of iodoproteins (shown as solid black) in the animal kingdom, suggesting a pattern of evolution of thyroid function.

Groups of cells in the floor of the pharynx of protochordates (*e.g.*, amphioxus, sea squirts) that concentrate iodine and convert it to thyroxine have been described. This is significant for two reasons: (1) the protochordates are the invertebrates most closely allied with the earliest vertebrates; and (2) the floor of the pharynx is the em-

bryonic source of thyroid tissue. In developing lampreys, an analogous region of the pharynx concentrates iodine; later, this same region develops into thyroid follicles. The fact that, in the larval lamprey, thyroid function—the formation of thyroxine—begins before the thyroid gland has developed from the pharynx may provide a link between the condition in protochordates and the fully evolved condition in the follicular thyroid of all other vertebrates (see Figure 8 for the presumed evolutionary progression of the thyroid).

Energy

The concept of energy is most useful in the understanding of the physical world, and, at the same time, the general rule or law developed for describing the role of energy is one of the most abstract ideas in the formulation of that understanding.

Energy is usually and most simply defined as the equivalent of or capacity for doing work. The word itself is derived from the Greek *energeia: en*, "in"; *ergon*, "work." Energy can either be associated with a material body, as in a coiled spring or a moving object, or it can be independent of matter, as light and other electromagnetic radiation traversing a vacuum. The energy in a system may be only partly available for use. The dimensions of energy are those of work, which, in classical mechanics, is defined formally as the product of mass (m) and the square of the ratio of length (l) to time (t): ml^2/t^2. This means that the greater the mass or the distance through which it is moved or the less the time taken to move the mass, the greater will be the work done, or, the greater the energy expended. More popularly, energy is expressed in such work units as foot-pounds, joules, ergs, British thermal units, kilowatt-hours, or tons of TNT-equivalent explosive energy.

GENERAL CONSIDERATIONS

The concept of energy conservation. A fundamental law that has been observed to hold for all natural phenomena requires the conservation of energy; *i.e.*, that the total energy does not change in all the many changes that occur in nature. The conservation of energy is not a description of any process going on in nature, but rather it is a statement that the quantity called energy remains constant regardless of when it is evaluated or what processes go on between successive evaluations.

Application of law of conservation of energy

The law of conservation of energy is applied not only to nature as a whole but to closed or isolated systems within nature as well. Thus, if the boundaries of a system can be defined in such a way that no energy is either added to or removed from the system, then energy must be conserved within that system regardless of the details of the processes going on inside the system boundaries. A corollary of this closed-system statement is that whenever the energy of a system as determined in two successive evaluations is not the same, the difference is a measure of the quantity of energy either added to or removed from the system in the time interval between the two evaluations.

Energy can exist in many forms within a system and may be converted from one form to another within the constraint of the conservation law. These different forms include gravitational, kinetic, heat, elastic, electrical, chemical, radiant, nuclear, and mass energy. It is the universal applicability of the concept of energy, as well as the completeness of the law of its conservation within different forms, that makes it so attractive and useful.

Development of the concept of energy. The term energy was not applied as a measure of the ability to do work until rather late in the development of mechanics. Indeed, the development of classical mechanics may be carried out without recourse to the concept of energy. The idea of energy, however, goes back at least to Galileo in the 17th century. He recognized that, when a weight is lifted with a pulley system, the force applied multiplied by the distance through which that force must be applied (or, by definition, the work) remains constant even though either factor may vary. The concept of *vis viva*, or living force, a quantity varying as the mass multiplied by the square of the velocity, was introduced in the 17th century. In the 19th century, the term energy was applied to the concept of the *vis viva*.

Newton's first law of motion recognizes force as being associated with the acceleration of a mass. It is almost inevitable that the integrated effect of the force acting on the mass would then be of interest. Of course, there are two kinds of integral of the effect of the force acting on the mass that can be defined. One is the integral of the force acting along the line of action of the force, or the spatial integral of the force; the other is the integral of the force over the time of its action on the mass, or the temporal integral.

Evaluation of the spatial integral leads to a quantity that is now taken to represent the change in kinetic energy of the mass resulting from the action of the force and is just one-half the *vis viva*. On the other hand, the temporal integration leads to the evaluation of the change in momentum of the mass resulting from the action of the force. For some time there was debate as to which integration led to the proper measure of force, the German philosopher-scientist Gottfried Wilhelm Leibniz arguing for the spatial integral as the only true measure, while earlier the French philosopher and mathematician René Descartes had defended the temporal integral. Eventually in the 18th century, the physicist Jean d'Alembert of France showed the legitimacy of both approaches to measuring the effect of a force acting on a mass and that the controversy was one of nomenclature only.

To recapitulate, force is associated with the acceleration of a mass; kinetic energy, or energy resulting from motion, is the result of the spatial integration of a force acting on a mass; momentum is the result of the temporal integration of the force acting on a mass; and energy is a measure of the capacity to do work. It might be added that power is defined as the time rate at which energy is transferred (to a mass as a force acts on it, or through

transmission lines from the electrical generator to the consumer).

Conservation of energy was independently recognized by many scientists in the first half of the 19th century. The conservation of energy as kinetic, potential, and elastic energy in a closed system under the assumption of no friction has proved to be a valid and useful tool. Further, upon closer inspection, the friction, which serves as the limitation on classical mechanics, is found to express itself in the generation of heat, whether at the contact surfaces of a block sliding on a plane or in the bulk of a fluid in which a paddle is turning or any of the other expressions of "friction." Heat was recognized as a form of energy by the English physicist James Prescott Joule, who also proved experimentally the fixed equivalence between mechanical and heat energy. As more detailed descriptions of the various processes in nature became necessary, the approach was to seek rational theories or models for the processes that allow a quantitative measure of the energy change in the process and then to include it and its attendant energy balance within the system of interest, subject to the overall need for the conservation of energy. This approach has worked for the chemical energy in the molecules of fuel and oxidizer liberated by their burning in an engine to produce heat energy that subsequently is converted to mechanical energy to run a machine; it has also worked for the conversion of nuclear mass into energy in the nuclear fusion and nuclear fission processes.

The role of friction

ENERGY CONSERVATION AND TRANSFORMATION

Understanding of details of the conservation of energy requires both the quantitative evaluation of energy in its various forms and understanding of the mechanisms by which the transition of energy from one form to another may occur.

In order to be quantitative in the discussion of any physical process, a consistent set of units is necessary. The modern practice is to use the so-called metre–kilogram–second (mks) set. Thus, distance is measured in metres, mass in kilograms, and time in seconds. Fundamental quantities are expressed in terms of these units, and then any derived quantities are assigned units consistent with the mks system. Thus the derived unit for force is obtained from the relation force F equals the product of mass m and acceleration a:

$$F = ma.$$

When the mass expressed in kilograms is multiplied by the acceleration in metres per second^2, the force has the unit newtons. Energy has the units of force times distance; that is, newton-metres. This unit is also called the joule, which is also equal to a watt-second. In the discussions that follow, the energy units will usually be given in joules. The units of other derivable quantities will be given when introduced.

An ideal system. A simple example of a system in which energy is being converted from one form to another is provided in the tossing of a ball with mass m into the air. When the ball is thrown vertically from the ground, its speed and thus its kinetic energy decreases steadily until it comes to rest momentarily at its highest point. It then reverses itself, and its speed and kinetic energy increase steadily as it returns to the ground. The kinetic energy E_k of the ball at the instant it left the ground (point 1) was half the product of the mass and the square of the velocity, or $\frac{1}{2}mv_1^2$, and decreased steadily to zero at the highest point (point 2). As the ball rose in the air, it gained gravitational potential energy E_p. Potential in this sense does not mean that the energy is not real but rather that it is stored in some latent form and can be drawn upon to do work. Gravitational potential energy is energy that is stored in a body by virtue of its position in the gravitational field. Gravitational potential energy of a mass m is observed to be given by the product of the mass, the height h attained relative to some reference height, and the acceleration g of a body resulting from the Earth's gravity pulling on it, or mgh. At the instant the ball left the ground at height h_1 its potential energy E_{p1} is mgh_1. At its highest point, its potential energy E_{p2} is mgh_2. Applying the law of conservation of energy and assuming no friction in the air, these add up to form the following equations:

Potential energy

$$E_{k1} + E_{p1} = E_{k2} + E_{p2}$$

or

$$\tfrac{1}{2}mv_1^2 + mgh_1 = 0 + mgh_2.$$

In this idealized example, the kinetic energy of the ball at ground level is converted into work in raising the ball to h_2 where its gravitational potential energy has been increased by $mg(h_2 - h_1)$. As the ball falls back to the ground level h_1, this gravitational potential energy is converted back into kinetic energy and its total energy at h_1 again is $\frac{1}{2}mv_1^2 + mgh_1$. In this chain of events, the kinetic energy of the ball is unchanged at h_1; thus the work done on the ball by the force of gravity acting on it in this cycle of events is zero. This system is said to be a conservative one.

If there were a change in kinetic energy at the end of the complete cycle, however, the work done by the forces acting on the ball would not be zero. Thus the force of air friction acting on the ball as it is rising and falling does negative work on the ball; *i.e.*, the ball does work on the air, thereby reducing its kinetic energy. In this case, the net work done by the force of gravity through the round trip is not zero. This system is said to be nonconservative.

Perpetual motion. At this point, it is useful to consider the possibility of constructing a perpetual-motion machine. It is necessary first to define the meaning of the term. A perpetual-motion machine is one that can go through a series of energy transfers and, on returning to its original energy condition, has had the effect of doing work on some external system while undergoing these energy transfers. The law of the conservation of energy directly implies that there is no perpetual motion since that law limits the energy in a system to a finite value, and, hence, if the original energy conditions are regained, no energy was available for a perpetual-motion machine to do external work. To the extent that external work was done, the system failed to regain its original energy condition. The difference in the initial and final energy states (*i.e.*, the change in energy content divided by the initial energy) is a measure of the efficiency of the system in going through the sequence of energy transfers that comprise the cycle.

Gravitational potential energy. *The bouncing ball.* When a ball is moved vertically upward, the kinetic energy removed from the ball is converted into gravitational potential energy by virtue of overcoming the force of gravity over the distance that the ball is being lifted. On its downward path the loss in gravitational potential energy results in an increase in the kinetic energy of the ball given by the magnitude of the gravitational force times the distance that the ball had fallen. In this case the potential energy is directly proportional to the vertical displacement of the object—*i.e.*, $E_p = mgh$. The magnitude of the force that must be overcome in lifting the body against gravity is mg, and it is in the direction opposite to the increase in gravitational potential energy. More generally, the mode of coupling between the loss or gain of kinetic energy and the attendant gain or loss of potential energy, whatever its form, is via the force acting on the object in question. In the one-dimensional case, the force F is equal to the derivative of the potential with respect to distance; *i.e.*, the rate of change (dE_p) of the potential with respect to a change in distance (dr), evaluated at a particular point, and the equation can be written as

Deriving the potential energy

$$F = -\frac{dE_p}{dr}.$$

In the general three-dimensional case, the relation between the potential and the force can be written using vector notation. A vector value is indicated by bold-faced symbol, and so the force is written $\mathbf{F}$. The gradient of the potential is written ∇E_p, and thus: $\mathbf{F} = -\nabla E_p$. But ∇E_p is the shorthand way of writing the sum of the compo-

nents; *i.e.*, the partial derivative of E_p with respect to x, $\frac{\partial E_p}{\partial x}$, the change in E_p along the x-coordinate and $\boldsymbol{i}$ the unit vector along the x-coordinate, and the other symbols that are similar, thus:

$$\nabla E_p = \boldsymbol{i}\frac{\partial E_p}{\partial x} + \boldsymbol{j}\frac{\partial E_p}{\partial y} + \boldsymbol{k}\frac{\partial E_p}{\partial z}.$$

The result is a vector quantity. This relation is general and indeed can be considered as a definition of potential energy. It is important to realize that the storage of potential energy is a result of the system and not of its individual components. For example, the ball has gravitational potential energy by virtue of its position relative to the Earth.

Attraction between two masses. Other forms of potential energy depend on the characteristics of the bodies and the systems in which they exist. Thus, as one considers the gravitational attraction between two masses, m and m', wherever large variations in their separation distance, r, can occur, the observed variation in their mutual attractive force is given by the product of the masses and a constant G divided by the distance squared:

$$F = \frac{Gmm'}{r^2}.$$

The potential energy, then, is

$$E_p = -\frac{Gmm'}{r}.$$

The constant of universal gravitation

G is called the constant of universal gravitation. When the force is expressed in newtons, the masses in kilograms, and the distance in metres, then $G = 6.673 \times 10^{-11}$ newton-metre^2 per kilogram^2. The units of E_p, the potential energy, are newton-metres, or joules. Writing the gravitational potential as mgh, as was done in the Earth–ball example, is valid only when there are small changes in height, h, relative to the separation between the two masses. Since the attraction of the Earth on masses external to it acts as if all the Earth's mass were concentrated at its centre, when only moderate changes in height relative to the Earth's radius occur near its surface, the acceleration, g, may be assumed to be almost constant. For example, in moving from the Earth's surface (which is about 4,000 miles [6,000 kilometres] from its centre) to 10 miles (16 kilometres) above the Earth's surface, the acceleration decreases from about 9.80 metres per sec^2 to 9.75 metres per sec^2.

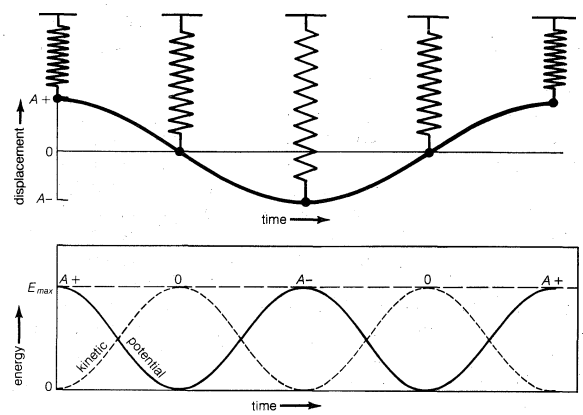
Energy of elastic spring. Energy may be stored in an elastic spring by either extending or compressing the spring. The force F, acting to restore the spring to its equilibrium position in an elastic spring, is proportional to the displacement from the equilibrium position and is opposite in direction to the displacement. When the displacement x is measured in metres, the restoring force F in newtons, and the spring constant k in newtons per metre, then the equation is simply $F = -kx$, and the elastic potential energy E_p, in joules, is given by

$$E_p = \tfrac{1}{2}kx^2.$$

The elastic potential energy is independent of the direction of displacement from equilibrium; *i.e.*, displacement that either stretches or compresses the spring will store energy.

Understanding the distribution of energy in its various forms in a physical problem can often be facilitated by constructing an appropriate graphical energy diagram. If a mass is suspended from a spring in a gravity-free space, displacement of the spring from its equilibrium position stores potential energy in the spring. When the spring is released, the restoring force accelerates the mass, giving it kinetic energy. At the moment it is released, the potential energy stored in the spring is at its maximum value, while the kinetic energy is zero. As the system moves toward the equilibrium position, the stored energy decreases while the force tending to restore the system to equilibrium imparts to the mass a kinetic energy until, at the equilibrium displacement, the potential energy is zero, but the kinetic energy has reached a value that is equal in magnitude to the potential energy at the point of maximum displacement. As the mass moves past the equilibrium position, the spring exerts a retarding force on it, which tends to slow the mass down and thus decrease its kinetic energy. Concurrently, the displacement of the spring from equilibrium again results in energy being stored in the spring. Thus, in an ideal system the total kinetic plus potential energy remains unchanged but is being transformed continually from one to the other. This transfer of energy from one form to another is shown graphically in the Figure. The total energy in the

Transfer of energy in a spring



(Top) Schematic representation of the sequence of positions taken by the moving end of an oscillating spring; at position 0 the potential energy is zero, and the kinetic energy is maximum. At A+ and A— the potential energy is maximum and the kinetic energy is zero. (Bottom) Graph of the energy changes from maximum potential energy to zero, with time.

oscillating system remains constant, but at specific times is completely in the form of kinetic energy, while at other times it is completely in the form of potential energy. In such oscillating systems the characteristic frequency of oscillation can be determined from the basic physical parameters for the spring–mass system. The frequency f is given by the product of $\frac{1}{2}\pi$ times the square root of the ratio of spring constant to mass:

$$f = \tfrac{1}{2}\pi\sqrt{k/m}.$$

Thus, the frequency of oscillation is independent of the energy stored in the system; since k is a constant, any increase in mass will reduce the frequency.

Energy of interaction between charged particles. In considering the interaction between charged particles in electrostatics, the force is given by Coulomb's law, which states that between two charges at rest there is a force that is directly proportional to the product of the charges and inversely proportional to the square of the distance between them. The force acts along the straight line between the two charges. Thus, if q_1 and q_2 are the respective charges measured in coulombs, r is the separation distance between them, F is the force in newtons, and $\frac{1}{4\pi\varepsilon_0}$ is the constant needed to make the two sides of the equation equal, then

Coulomb's law of electrostatics

$$F = \frac{1}{4\pi\varepsilon_0}\frac{q_1q_2}{r^2}.$$

The value of $\frac{1}{4\pi\varepsilon_0}$ is determined experimentally to be 9×10^9 newton-metre^2 per coulomb^2. If the charges are of the same sign, the force tends to push the charges apart; if they are of opposite sign, the force tends to pull them together. In applying Coulomb's law, it is useful to introduce the concept of an electrical field E, the force per unit charge acting on a charge at a point as a result of all the other charges. Thus, the electric field at point 1 due to the charge at point 2 would be, using the equation above:

$$E(1) = \frac{1}{4\pi\varepsilon_0}\frac{q_2}{r^2},$$

so that the force on a charge q_1 located at point 1 is (by

substituting for $\frac{q_2}{r^2}$) the product of charge and field:

$$F(1) = q_1 E(1).$$

The real advantage to the concept of the electric field is in investigations into the effect of a complicated array of charges. Evaluation of the energy in an electric field yields an energy density u_E at a point with a field of magnitude E in a vacuum, in a relationship of the same type as the first equations above ($E_p = \frac{1}{2}kx^2$):

$$u_E = \tfrac{1}{2}\varepsilon_0 E^2.$$

In this equation, if E has the units volts per metre (or joules per coulomb-metre), then ε_0 has the units coulomb^2 per newton-metre^2, and u_E has the units of joules per metre^3.

A particle with charge q moving through a magnetic field B will interact with the field in such a way that a force will be exerted on the particle. The magnitude of the force acting on the charged particle depends on its velocity v relative to the orientation of the magnetic field and on the size of the charge. The force is a maximum when the magnetic field vector $\boldsymbol{B}$ and the velocity vector $\boldsymbol{v}$ are mutually perpendicular and the force acts in a direction perpendicular to the plane defined by the direction of the $\boldsymbol{B}$ and $\boldsymbol{v}$ vectors. More specifically, the magnitude of the force in vector notation can be written as a product of these values:

$$\boldsymbol{F} = q\boldsymbol{v}\boldsymbol{B}.$$

Yukawa potential

The potential term thought to describe the nuclear force between two particles in the nucleus is called the Yukawa potential, after its discoverer, Hideki Yukawa, and has a form that makes the Yukawa potential decrease much more rapidly with distance than the potential does in the relation that holds for gravitational and electrostatic potential by an exponential factor, so that the potential and thus the force falls to zero very rapidly. Experimentally, nuclear forces do not extend beyond about 10^{-13} cm.

Energy of rotational system. Energy can also be stored in a rotational system. Examples of systems of this type include the solar system at one extreme and individual atoms at the other. In either case, an attracting force is balanced by the centrifugal force produced by the rotation of one body about the other. In the solar system, the attracting force is gravitational, while within an atom the attracting force is electrostatic. The kinetic energy of translation (movement) in the orbit and the consequent centrifugal force is necessary to prevent the attractive force from pulling the objects together. For the electron rotating around the nucleus other constraints are necessary; these will be discussed briefly later.

Potential energy can also be stored by the distortion of a stretched thin sheet or membrane from its equilibrium shape. Such a sheet could be the head of a drum or the film of a soap bubble.

Energy in electrical network. It is possible to store energy in an electrical network. For example, a system consisting of a capacitor (a device in which large charges can be accumulated at low voltage) and a pure inductance (see below) can sustain an oscillating electrical current indefinitely, assuming that the circuit's electrical resistance is zero. An inductor is a device for converting an electrical current into a magnetic field with the consequent storage of energy in that field. The energy u_B in joules stored in the magnetic field of an inductance of L henrys (unit of inductance) by passing a current of i amperes through it is given by the type of equation used several times above:

$$u_B = \tfrac{1}{2}L i^2.$$

A capacitor can similarly store energy in its electric field when a charge is placed in it. The energy u_E in joules stored in the electric field of a capacitor of C farads (unit of capacitance) by placing a charge of q coulombs in it is determined by the formula (of the type already used above):

$$u_E = \tfrac{1}{2}\frac{q^2}{C}.$$

Assuming a capacitor containing an initial charge is connected to an inductance, a current will be caused to flow through the inductance as the capacitor discharges. The discharge of the capacitor results in a decrease in the energy stored in its electric field, while the flow of the current through the inductance results in the building of a magnetic field. The total energy at any time is given by the instantaneous value of the energy in the electric field and the magnetic field. Assuming no resistance, the total energy in the system will remain constant while the energy stored in each component will oscillate at a frequency independent of the amount of energy stored.

ENERGY AND STATISTICAL AND QUANTUM MECHANICS

Statistical mechanics. Earlier, it was mentioned that the classical physics of particles interacting with each other could be derived in principle without resorting to the concept of energy. In practice, however, the number of variables necessary to describe the position and velocity of many particle systems presents a computing problem that rapidly gets out of hand. In fact, unique solutions are not possible even for three-body problems. In systems with many individual particles, useful generalizations about the properties of the system can be made by analyzing the energy distribution within the group of particles. This field is called statistical mechanics.

Stellar energies

In a star cluster, the potential energy depends upon the resultant sum of all the gravitational forces that act toward the centre of the cluster. As a star moves about within the cluster, its relative kinetic and potential energies will vary according to its distance from the cluster centre. The detailed path of the star can be extremely complicated, as it may pass in the vicinity of other individual stars and be deflected in its path by the gravitational attraction of the nearby star. After a cluster has existed for a very long time, enough gravitational interactions will have taken place so that the energy of the cluster is divided approximately equally among the individual stars. The energy will never be equal for all stars since the specific results of an individual encounter is to change the energy of the two interacting stars: presumably one leaves the encounter with more energy than the average and the other with less. On the average, however, each star should have its share of the total energy. Under these circumstances the cluster is said to be in a state of statistical equilibrium. It has been shown that under such conditions the total potential energy of the cluster is exactly twice as great as the combined kinetic energy of all the cluster stars. This relation is known as the virial theorem. Thus, by measuring the average speeds of the stars in the cluster, the total kinetic energy and hence the total potential energy can be estimated, and an estimate of the mass of the cluster can be derived. Consideration of the energy balance within the cluster allows an estimate of the total mass of the cluster.

Statistical mechanics considerably beyond the scope of this article is also applied to the problem of a large number of molecules of gas in a system in which the total energy remains fixed. Very briefly, the Maxwell–Boltzmann law of energy distribution states that the particles in the system tend to distribute themselves according to a factor in which the Boltzmann constant, k, corresponds to the energy required to raise the temperature of the molecules 1° K, and T is the absolute temperature. The distribution of energy among the particles (with a mass m) is such that the number of particles n having a speed between v and $(v + dv)$ is $n(v)$ and these values are related in a somewhat more complex equation:

The Maxwell-Boltzmann law of energy distribution

$$n(v) = \sqrt{\frac{m}{2\pi kT}}\, e^{-mv^2/2kT} dv.$$

(The value of Boltzmann's constant is 1.3806×10^{-23} joule per degree Kelvin.)

Concepts of quantum mechanics. Detailed descriptions of the energy associated with atomic phenomena necessitate the use of quantum mechanics. The essence of quantum mechanics lies in the realization that only certain specific values of the momentum of certain particles are possible and that these allowed values differ by h, Planck's constant (6.6262×10^{-34} joule-second). As a re-

sult, an electron rotating around the nucleus of an atom has fixed allowed values for its transitional kinetic energy and hence its total energy.

Transition of an electron from a high energy level to a lower one will make energy available to be radiated as a photon of electromagnetic radiation. The photon will have a characteristic frequency ν given by the ratio of E, the energy available from the transition, to Planck's constant: $\nu = E/h$. Indeed, all electromagnetic radiation consists of photons whose energy and frequency are related in this way. The photon also has a momentum given by the ratio of the energy to c, the speed of light: E/c. The value of the concept of the momentum of a photon is demonstrated in the consideration of the elastic collision between a photon and an electron, a phenomenon called Compton scattering. The problem is readily solved using classical methods of two-body collisions, assuming conservation of energy and momentum and assigning the photon the energy and momentum as indicated.

The use of quantum mechanics is necessary in dealing with atomic phenomena because the absolute amounts of energy involved are so small that the changes associated with going from one allowed quantum level to the next are significant. Energy quanta exist in all physical problems, but they are usually so small that they are indistinguishable from the energy continuum normally assumed. The nucleus–electron problem can be solved under the restrictions imposed by quantum mechanics using position and velocity models that are quite similar to the models used in ordinary mechanics to solve two-body problems. When one considers the large number of particles that can be in the interior of the nucleus itself, however, using statistical methods becomes desirable. Thus, the field of statistical quantum mechanics has become a powerful tool in this area.

The propagation of energy. The transfer of energy can be accomplished either by mechanical interaction between particles or by the radiation of energy in the form of an electromagnetic wave. When a mechanical collision occurs between particles, the computation of the energy transfer is straightforward, assuming the laws of conservation of energy and conservation of momentum.

The energy E associated with an electromagnetic wave has already been identified as being the product of its frequency, ν, and Planck's constant, h: $E = h\nu$. Closer examination of electromagnetic radiation reveals that, as the name suggests, electric and magnetic fields are associated with the propagation of the radiation. The mutually perpendicular fields are coupled in such a way that the energy of the wave oscillates between the two (considered as vector fields) in the plane perpendicular to the direction of propagation of the radiation. The total energy content of the wave is also given by a vector quantity called Poynting's vector. It is a measure of the rate at which the field energy moves through space. The electromagnetic wave also has a momentum density that is given by $1/c^2$ times the Poynting vector. The implications of this flow of energy and momentum are that, among other things, when radiation is absorbed or emitted, a transfer of energy and momentum occurs. Thus the direction of a beam of electromagnetic radiation in one direction with its momentum flow results in the imparting of an oppositely directed momentum to the light source.

Poynting's vector as a measure of wave energy

Equivalence of mass and energy. Expressing the kinetic energy of a moving mass as $\frac{1}{2}mv^2$ becomes invalid as the velocity gets very large and, in that instance, Einstein's theory of relativity must be used to calculate the effect upon energy of this large velocity. The kinetic energy, E_k, is expressed in terms of the product of the mass at low velocity, m_0, and the square of the speed of light, c, multiplied by a ratio relating the square of the velocity, v^2, to c^2:

$$E_k = m_0c^2\,[(1 - v^2/c^2)^{-\frac{1}{2}} - 1].$$

This equation reduces to $\frac{1}{2}m_0v^2$ for small v. If a variable relativistic mass, m, of the body is defined as being equal to the mass at low or no speed, m_0, multiplied by the ratio relating v^2 to c^2—*i.e.*, $m = m_0\,[1 - v^2/c^2]^{-\frac{1}{2}}$ (showing that as the velocity approaches the speed of light, the relativistic mass, m, approaches infinity)—and this is substituted in the equation, then the kinetic energy can also be written as

$$E_k = (m - m_0)\,c^2.$$

Rearranging this equation,

$$m = m_0 + E_k/c^2.$$

It is apparent from the equation that the relativistic mass of a body increases directly with its kinetic energy. Also, the equivalence of mass and energy is evident when it is expressed as energy = mass × (velocity of light)^2. This relationship is valid not only for kinetic but for all other forms of energy and thus it is possible to achieve a significant compression in the classical laws of physics. In classical physics the law of the conservation of mass and the law of conservation of energy were considered independent and equally vital fundamental statements. With relativity, the conservation of mass is a special case of a more general law of the conservation of energy. Direct experimental verification of this equivalence can be obtained from the study of nuclear reactions in which particles are added to existing nuclei with a consequent liberation of energy. Comparison of the mass of the ingredients going into the reaction with the mass of the products created in the reaction shows a mass discrepancy that agrees with the measured amount of energy liberated. Using these data, the equivalence of mass and energy can be directly tested. The equivalence also holds for chemical reactions in which the combining of ingredients results in either the liberation or the absorption of energy. For full details concerning nuclear energy, see NUCLEUS, ATOMIC; NUCLEAR FISSION; NUCLEAR FUSION.

Hamiltonian and Lagrangian formulations. In the sections above, the study of energy, generally started with a definition of the position and velocity of particles and then an understanding for their interaction developed. One of the products of this analysis is the identification of the quantity called energy and the discovery of the usefulness and the generality of the concept of energy. It is quite reasonable to question the possibility of beginning with the concept of energy and building a formalism that will allow the determination of a suitable set of coordinates for the particles in the system and the computation of their values. This approach has proven to be successful, and two quite complementary methods have evolved. One is the method of Lagrange, in which a quantity L, called the Lagrangian, is defined and which is equal to the difference between kinetic energy E_k and potential energy E_p:

Lagrange method

$$L = E_k - E_p.$$

In mechanical problems, the kinetic energy E_k is in the form of a quadratic in velocity, while the potential energy E_p is a function of position. Use of the Lagrangian method affords a technique for analyzing not only conservative systems but also nonconservative ones. The method results in an evaluation of the external forces imposed on a system along each of its coordinate axes. For a conservative system, this external force is zero by definition; for nonconservative ones, it is not. Solving the Lagrangian equations including the externally imposed forces allows the evaluation of nonconservative systems. Also, the method can be used to test a system to determine if it is indeed conservative or not. Of even greater value is the fact that the method is not restricted to mechanical systems. It can also be applied to systems in which the motions are not directly observable, including the phenomena in optics, acoustics, and electricity. The problem is to determine an appropriate set of coordinates such that they can be used to describe the potential energy, while a quadratic in their time derivative (*i.e.*, the "velocity") describes the kinetic energy.

Another approach is through use of the special function called the Hamiltonian. The Hamiltonian H is, in fact,

Hamiltonian method

$$H = E_k + E_p,$$

and thus has a numerical value equal to the total value of the energy of the system. The Hamiltonian and Lagrange

techniques each have greater value when applied to certain kinds of specific problems. A significant operational difference is that a solution of a given problem using the Lagrange method requires twice as many boundary conditions as the solution using the Hamiltonian.

SOME SPECULATIONS ON ENERGY

The concept of energy has demonstrated a remarkable survivability in the rapidly expanding understanding of the nature of things. To a large extent this survivability is no doubt a result of its adaptability to cover an increasingly complex set of phenomena that are revealed as ability to observe the physical world increases. Thus, in attempting to understand the structure of the nucleus within the context of the conservation of energy and with the hint afforded by the discovery of the positron, a complete set of antimatter particles was postulated and their existence verified experimentally. Indeed, it would appear that the concept of energy has value not only in explaining the readily observable physical world but, when data accumulate that cannot be explained with the incomplete facts, the use of the concept of the conservation of energy can be very helpful in indicating where to look for missing answers. On the other hand, the concept of the conservation of energy might suggest a "steady-state universe." It is difficult, however, to reconcile all of the observed data to a steady-state universe. Perhaps the data that have been collected have been obtained by observing quantities on only one-half of the universe.

BIBLIOGRAPHY. ROBERT B. LINDSAY and HENRY MARGENAU, *Foundations of Physics* (1936, reprinted 1963), carefully presented development of many of the concepts relative to energy, particularly useful since in many cases both the historical and the logical development of the ideas are presented; RICHARD P. FEYNMAN, ROBERT B. LEIGHTON, and MATTHEW SANDS, *The Feynman Lectures on Physics*, 3 vol. (1963–65), a detailed and careful treatment of all the concepts considered in this article, for the relatively informed reader; ROBERT RESNICK and DAVID HALLIDAY, *Physics for Students of Science and Engineering*, 2 vol. (1960), a widely adopted text used for teaching physics at the university level.

(R.L.Se.)

Energy Sources

Energy sources as a term covers all fuels, flowing water, sunlight, and the winds with which man, by the use of appropriate conversion devices, provides himself with necessary energy. This article is a survey of highlights in the discovery and exploration of primary, renewable, and expendable sources of energy, and of the conversion devices used to produce that energy. For information on specific engines and electric power see DIESEL ENGINE; GASOLINE ENGINE; TURBINE; ELECTRIC POWER.

HISTORY

Man first made use of energy from a source outside his own body when he discovered how to use fire, greatly enhancing his ability to survive.

Early sources of fuel

Wood was long the principal—in some regions the only—fuel. In addition to its use for heating and cooking, it became a source of charcoal for reducing ores to metals.

The first fossil fuels to be exploited were surface deposits of asphalt, peat, and coal; oil from surface seepage; and gas, venting from underground reservoirs. Asphalt is known to have been burned as early as 6000 BC in the Middle East, where huge surface deposits exist. The abundance of fossil fuels probably contributed to the development of burned brick, pottery, and other furnace products in this period. Asphalt played a notable role in the technological advances made under the Babylonian Empire, Mesopotamia (2500 to 538 BC), but its use diminished after 538 BC.

Natural gas escaping from underground reservoirs through vents sometimes became ignited and burned for years, even centuries. Even before 1000 BC natural gas was used in China for lighting, heating, and cooking. The Chinese, furthermore, are said to have drilled deep wells through hard formations to obtain natural gas, which they transported through bamboo pipelines.

Many parts of the world contain extensive coal deposits, but coal was difficult to mine with primitive tools and only the Chinese are known to have mined it to supplement natural gas and their dwindling supply of wood. Although coal was used to some extent in England in Roman times, finally becoming an article of commerce in the 13th century, fossil fuels were otherwise forgotten for nearly 2,000 years. Wood was the primary fuel for heating, cooking, and producing charcoal. With wood supplies dwindling rapidly, it was established in 1709 that coke from coal could be substituted for charcoal in the reduction of ores. The new coke industry, together with the production of coal gas for illumination, led to a rapid expansion of the coal-mining industry, soon to be accelerated even more by the introduction of steam engines.

Petroleum, known to the Babylonians though not extensively used, first came into prominence in the 17th century, when an oil well drilled in Modena, Italy, in 1640 provided fuel for street lighting. Commercial oil wells were developed in Romania in 1650. Oil had been discovered early in the history of the U.S., principally in New York and Kentucky, but the petroleum industry was not established in the U.S. until a major commercial oil well was brought into production in western Pennsylvania in 1859. Within ten years, kerosene for lamps was being shipped throughout the world from Pennsylvania. A generation later the automobile created a huge demand for gasoline. Since then the market for products made from this fossil fuel has grown rapidly and steadily.

The wind as an energy source for ship propulsion has been used by man for a very long time indeed. The earliest sailing ships, with both oars and sails, were replaced, as navigation techniques developed, by larger ships that depended on sails alone.

Windmills, probably invented in China, spread slowly into the Middle East. They were used in Persia (now Iran) before the 10th century and reached Europe, via the Arabs, by the 12th century. These early windmills were an important inanimate source of mechanical energy, especially for drainage and milling grain.

Waterwheels irrigated Babylonian fields 3000 years ago, and the Romans powered large flour mills and sawmills with them. In the Middle Ages this source of mechanical energy was much used in the Arab world and in Europe. Most early factories, depending upon water for power, were located beside dams. Although the amount of energy produced by waterwheels was small compared to modern power plants, water at one time provided most of the energy for industry. The waterwheel with its spillway was a part of many early American communities, and some rural areas still have mills operated by waterpower. The building of large hydraulic power plants followed the development of equipment for generating and transmitting electricity.

The development of steam power in the 18th century and its refinement and proliferation in the 19th began a revolution in energy exploitation that is still continuing. Its many facets can best be examined by starting with a definition of the related terms energy and power.

FORMS OF ENERGY

Energy is the *capacity* for doing work (this definition is generally accepted although thermal energy cannot be converted completely into work). Power is the *rate* of doing work and is thus the rate of energy flow.

Energy may be potential, kinetic, thermal, electrical, chemical, nuclear, or other forms. In addition, there are heat and work; *i.e.*, energy in the process of transfer from one body to another. After being transferred, energy is designated according to its nature. For example, heat transferred may become thermal energy, and work done may appear as mechanical energy.

Energy and motion

All forms of energy are associated with motion. For instance, a body has kinetic energy if it is in motion. A raised object, such as a trip-hammer, and a tensioned device, such as a spring or bow, though at rest have the potential for creating motion. They contain potential energy as a result of their position or configuration. Ther-

mal energy is a manifestation of motion of and within the molecules of a substance. For example, the temperature of a gas such as helium is related directly to the velocity of its molecules as they move in random motion. An electric current is the flow of electrons through a conductor. Chemical energy and nuclear energy are potential energies resulting from the configuration of atoms in a molecule or of subatomic particles in the nucleus of an atom.

Energy is measured by the work required to create the motion, the position, or the configuration. The minimum work required to raise a mass equals exactly the potential energy of the mass as a result of its being raised. Mechanical work is the product of force times the distance through which the force acts. Thus, one pound of force acting through one foot does one foot-pound of work. Or, to take an example from the new metric-based SI system, the work done by a force of one newton acting over a distance of one metre is one joule (or one watt-second).

A unit of thermal energy may be the foot-pound, although other units frequently are more convenient. The British thermal unit, BTU, is the quantity of heat required to raise the temperature of one pound of water one degree Fahrenheit near the point of maximum water density (39.1° F). In the SI (International System of Units) system, the preferred term for heat is the joule. One BTU is equal to 1,055 joules. An appropriate unit for expressing the quantities of energy in world fuel reserves is the *Q* unit, which is equal to 10^{18} BTU.

The nature of heat

The nature of energy and the relationship between thermal energy and mechanical energy were obscure and controversial for a long period of time. Greek philosophers believed that energy was a fluid permeating a substance. The nature of heat was clarified in 1798 by Sir Benjamin Thompson, count von Rumford. Engaged in superintending the boring of cannon in the military arsenal at Munich, he observed the amount of heat produced by the action of the boring bar upon the brass castings. Finally, James Prescott Joule showed conclusively in his experiments that the nature of heat and the nature of energy are the same, and that other forms of energy can be transformed into an equivalent amount of heat. In the best known of his experiments, Joule caused a paddle to rotate in a cylindrical vessel of water containing fixed paddles, acting as baffles, to prevent the water itself from rotating; the agitated water rose in temperature enough to be measured by a sensitive thermometer. Joule determined the mechanical equivalent of the energy required to raise the temperature of the water. Refinements in this measurement led to the value of 778 foot-pounds per BTU. This is the mechanical equivalent of heat.

Since power is the rate of doing work, such units as foot-pounds per second and BTU per hour are used. The horsepower unit was established by James Watt, who measured the maximum rate of work done by horses. He multiplied the result by a factor of 1.5 to rate his steam engines conservatively in terms of horsepower. One horsepower equals 550 foot-pounds per second.

Energy can be changed in form, but the total amount of energy in an isolated system cannot be changed. Thus, energy can neither be created nor destroyed. This statement summarizes many experimental observations of the conversion of energy, and this fact is useful in solving many problems involving energy. For example, the total energy contained in the fuel and air for an engine must equal the sum of the work done by the engine, the thermal energy from the engine, and the energy present in the combustion products.

Although the total amount of energy in an isolated system remains unchanged, there may be a great difference in the quality of different forms of energy. Many forms of energy, in theory, can be transformed completely into work or into other forms of energy. This is true for mechanical energy and electrical energy. The random motions of constituent parts of a material associated with thermal energy, however, represent energy that is not available completely for conversion into directed energy.

The Carnot cycle

In 1824 Sadi Carnot described a theoretical power cycle of maximum efficiency for converting thermal into mechanical energy. He demonstrated that this efficiency is determined by the magnitude of the temperatures at which heat energy is added and waste heat is given off during the cycle. A practical engine operating on the Carnot cycle has never been devised, but the Carnot cycle determines the maximum efficiency of thermal energy conversion into any form of directed energy.

According to the theory of relativity proposed by Albert Einstein in 1905, the apparent mass of a body increases in proportion to its kinetic energy. Mass and energy are thus said to be equivalent, and one can be converted into the other. This relationship between mass and kinetic energy may be shown to hold for all other forms of energy as well. The principle of conservation of mass proves to be merely a special case of the broader principle of conservation of energy. The equivalence of mass and energy has been confirmed by investigations of atomic nuclei whose energies affect mass in a measurable amount. In chemical reactions the change in mass with energy is not measurable. Even in nuclear fission the decrease is small for the large amount of energy released.

ENERGY CONVERSION

Energy can be changed from one form to another in many ways. Useful mechanical or electrical energy is produced by fuel-burning heat engines, by electric generators, batteries, photoelectric cells, and by many other devices, most of which have important applications.

The steam engine

Man's need for mechanical energy first became acute toward the end of the 17th century, when deposits of coal and metal ores near the surface were becoming exhausted, and the deep pits were flooded with groundwater. The problem of pumping water out of the useless mines attracted the attention of such men as Thomas Newcomen, who developed a steam pumping engine in England in 1705. By converting thermal energy into mechanical energy, this engine made available quantities of mechanical energy limited only by the capacity of the engines and the availability of fuels. The Newcomen engine converted less than 1 percent of thermal energy into work. But because it filled an important need, it continued to be used until it was replaced by Watt's engine, invented in 1763. Equipped with a separate condenser to lower the temperature of the exhaust steam, Watt's engine had an efficiency of more than 2 percent. By 1900 many improvements, including three separate expansion cycles and higher steam temperatures, had raised the efficiency of the steam engine to about 17 percent. This engine has been replaced by the more compact and efficient steam turbine. With improvements and the use of very high temperature steam, the efficiency of thermal energy conversion is approaching 40 percent.

The energy conversion processes of the steam power plant were described by William Rankine, a Scottish physicist whose "Rankine cycle" (1859) explained how a liquid in a boiler vaporized by the addition of heat converts part of this energy into mechanical energy when the vapour expands in an engine. As the exhaust vapour is condensed by a cooling medium such as water, heat is lost from the cycle. The condensed liquid is pumped back into the boiler. This concept of a power cycle is useful to engineers in developing equipment and designing power plants (see also STEAM POWER).

Poor materials and faulty methods of construction were the cause of many disastrous explosions in early steam boilers. The resultant casualties and property losses motivated the Reverend Robert Stirling to invent a power cycle that operated without a high-pressure boiler. In his engine, patented in 1816, air or some other gas, heated by external combustion through a heat exchanger, was displaced, compressed, and expanded by two pistons. At this time, when thermodynamics was still unknown as an engineering science, Stirling originated the idea of a regenerator to store thermal energy during part of the cycle and then return this energy to the working fluid; *i.e.*, regenerate. His engine in theory is equal in efficiency to

that of the Carnot engine. Although a successful engine was built for a factory in 1843, general use has been restricted by the engine's high cost. Nevertheless, until about 1920, small engines of this general type pumped water on farms and generated electricity for small communities, burning wood or coal in the firebox. The high efficiency and freedom from air-polluting emissions have created renewed interest in the Stirling engine.

The gas turbine. The operation of a gas turbine power plant, such as a turbojet engine, is described by the Brayton cycle, originally devised for reciprocating engines—engines in which combustion took place at constant pressure in the cylinder. The urgent need for improved aircraft propulsion during World War II led to the development of efficient, lightweight air compressors and gas turbines that made possible the turbojet engine operating on the Brayton cycle. Compressed air, heated by the combustion of petroleum, is used to turn a turbine to drive the compressor, while excess energy accelerates the exhaust gas to high velocity for producing thrust (see also JET ENGINE).

The Brayton cycle

The internal-combustion engine. Engines in which combustion takes place within the working cylinder originated early in the 19th century. Not until 1876, however, did Nikolaus August Otto of Germany demonstrate his practical gas engine. Its many applications, which included motor vehicles, led to the rapid development of the internal-combustion engine, and with that came a great demand for gasoline.

The internal-combustion engine patented by Rudolf Diesel in 1892 was developed to burn powdered coal, at that time an unwanted waste product of coal mining. In the diesel engine, air is compressed to a temperature high enough to ignite fuel injected into the cylinder. Changing the fuel to oil resulted in an engine suited to many industrial and marine applications, including the propulsion of submarines (see also DIESEL ENGINE).

Direct energy-conversion devices. Requirements for energy for space vehicles led to an exhaustive investigation, starting in 1955, of all possible energy sources (much of the literature on this subject has come from these programs). Direct energy-conversion devices are of interest for providing electrical energy in space vehicles because of their reliability and their lack of moving parts. Sometimes called static energy-conversion devices, they can be considered to use electrons as the working fluid in place of the vapour or gas in a dynamic heat engine.

In a thermoelectric generator, for example, electrons driven by thermal energy across a potential difference at the junction of two conductors made of dissimilar materials create an electric current. This effect was discovered in 1821 by Thomas Johann Seebeck of Germany when he observed that a compass needle near a circuit made of different conducting materials was deflected when one of the junctions was heated. He investigated many materials, including some now classified as semiconductors, that produce electrical energy with an efficiency of 3 percent. This efficiency was comparable to that of the steam engines of that time. Nevertheless, the usefulness of the discovery of the thermoelectric effect went unrecognized as a means for producing electricity because of Seebeck's interpretation of this as a magnetic effect caused by a difference in temperatures. Only recently have thermoelectric generators come into their own, producing electricity in special situations in which static thermal energy conversion devices with high reliability but a modest efficiency of some 5 percent are preferred (see also THERMOELECTRIC DEVICES).

Another static energy conversion device that has been investigated extensively for the space program is the thermionic generator. Electrons are driven in a vacuum by thermal energy from a high-temperature electrode, across a potential difference, to a cooler electrode. Thomas Alva Edison was the first to observe an electric current between an incandescent filament and a cold electrode in an evacuated tube, but not until 1958 did active development of thermionic generators begin. Although their performance has since been improved greatly, the lack of suitable materials for use at very high temperatures and problems in construction have limited their reliability. When these problems are solved, thermionic generators will be properly suited for use with nuclear reactors or radioisotope heat sources (see also THERMIONIC DEVICES).

Thermionic generators

Radiant energy also can drive electrons across a potential difference at a semiconductor junction in which the concentrations of impurities are different on the two sides of the junction. The silicon solar cell, announced in 1952, is a reliable power source with no moving parts and is particularly suited for power generation in space where the sun presents an inexhaustible source of energy. Efficiencies of the order of 14 percent have been achieved in converting solar energy directly into electrical energy. The cost of solar cells limits their commercial use.

Chemical energy can be converted directly into electrical energy by electrochemical reactions in a battery or fuel cell. The efficiency of the process is not limited by the maximum theoretical efficiency of energy conversion when chemical energy is converted to thermal energy for operation of a heat engine. Batteries and fuel cells with efficiencies of over 80 percent (at very low current) have been demonstrated, whereas the best efficiencies obtained in heat engines are about half this value.

In 1800 Alessandro Volta constructed an electrochemical cell for producing electricity from two metals in contact with a salt solution. A battery for producing higher potential, called Volta's pile, was made of alternate plates of silver and zinc separated by cloth or paper soaked in salt solution. Many types of batteries were developed during the 19th century, and this source of electricity made possible early electrochemical discoveries. The lead–acid secondary battery for storing electrical energy was developed by Gaston Planté of France in 1859. Among its many applications was the electric automobile.

In a fuel cell, another electrochemical producer of electricity, continuous operation is achieved by feeding fuel and oxidizer to the cell and removing the reaction products. Sir William Grove constructed such a cell in 1839, with hydrogen and oxygen reacting on platinum electrodes to produce electricity. One of the main objectives of electrochemical research was to find a process for the direct electrochemical oxidation of fuels, such as coal, to supply the growing requirements for electricity. When large generators driven by steam power plants and waterpower were developed to meet these requirements, interest in fuel cells dwindled. The need for silent portable electric generators for electronic equipment during World War II, and, more recently, for efficient energy conversion devices in the space program, has created renewed interest in fuel cell research. Interesting developments include the electrochemical oxidation of alcohols and hydrocarbon fuels to produce electricity and the hydrogen–oxygen fuel cell for manned space travel (see also BATTERIES AND FUEL CELLS).

The fuel cell

Many other devices produce electrical energy. Some of these produce a potential difference by heating or applying a mechanical force on certain crystals (piezoelectricity). The magnetohydrodynamic generator utilizes a conducting fluid flowing through a magnetic field to generate electricity. In reverse, electrical energy can accelerate a fluid to produce thrust in an electric rocket motor (see also MAGNETOHYDRODYNAMIC DEVICES).

The processes by which muscles convert chemical energy into mechanical energy are the subject of intensive research and are now partly understood. Blood carries food material and oxygen to the muscle where they react through the mediation of a system of proteinaceous substances called enzymes, producing heat as well as mechanical energy. A muscle at rest produces very little heat; but very soon after stimulation, resistance to stretch develops rapidly and heat production increases. Additional heat is produced as the muscle shortens. The amount is proportional to the distance of shortening and independent of load. A rapidly shortening muscle exerts less tension than when shortening slowly, and less thermal energy is released per unit distance. Perhaps some

day these remarkable processes can be applied to inanimate energy conversion (see also MUSCLE CONTRACTION).

ENERGY SOURCES AND THEIR DEPLETION

Primary energy sources. The primary sources of energy include nuclear fusion, nuclear fission, radioactivity, and the motion of the earth and the moon. All forms of energy can be traced to these origins.

Nuclear fusion. Energy is released in the sun by thermonuclear reactions that fuse hydrogen and other light elements into heavier elements, releasing very large amounts of energy. This is the source of the radiant energy that illuminates the earth and provides a practically inexhaustible supply of energy on earth and in space. Winds in the earth's atmosphere are created by the thermal effects of solar energy, and even the energy in flowing streams is produced indirectly from solar radiation.

Nuclear power generation

The time will undoubtedly come when, after other fuels are consumed, man will have to depend upon thermonuclear reactions for energy. While large amounts of energy will be produced from nuclear fission, the total will be insignificant compared with the potential of nuclear fusion. The attainment of practical power generation from controlled fusion is perhaps the most formidable technical challenge that man has faced. If the problem can be solved, deuterium (heavy hydrogen) is available from water in quantity sufficient to provide virtually unlimited energy (see also NUCLEAR FUSION).

Nuclear fission. Fissionable nuclear fuels are remarkable sources of energy. The energy released by the fissioning of one atom of uranium, for example, is several million times greater than that produced by the combustion of one molecule of gasoline. The knowledge of means for releasing atomic energy came about through a series of discoveries with the final development being motivated by the effort to create superior bombs for military use.

Radioactivity. The energy released in nuclear fission is in the form of radiations and kinetic energy of the fission products, which are released at high velocity. Most of these become thermal energy in the fuel elements as the fission products come to rest and as some of the radiations are absorbed. The thermal energy can be converted in part into mechanical energy, which can then be converted into electrical energy by a steam turbine driving a generator.

Only 0.72 percent of natural uranium is composed of the fissionable isotope, uranium-235. This can be separated from uranium-238 by diffusion processes to construct bombs and compact nuclear reactors. Since the energy from nuclear fuels would be quite limited if only the uranium-235 were utilized, reactors have been developed to produce fissionable plutonium-239 from uranium-238, in addition to producing thermal energy for the generation of electricity. Similarly, fissionable uranium-233 can be produced from nonfissionable thorium to increase greatly the energy available from nuclear fuels, which far exceeds the energy available from fossil fuels (see also NUCLEAR FISSION and NUCLEAR REACTOR).

Many radioactive isotopes, particularly of the heavy elements, are unstable, releasing energy as they decay. Not only do they occur naturally in thorium and uranium and in some other minerals but they can be created through fission and other nuclear processes. Thus, there are a large number of both natural and artificial radioisotopes whose properties vary in decay rate and energy production. Natural radioactive materials make up only a minute part of the earth, but they release sufficient energy to maintain the elevated temperature of the earth's interior. Radioactivity is therefore the origin of energy obtained from the earth in geothermal steam wells.

Radioisotopes can produce electrical energy in small amounts for special purposes. Demonstrated as early as 1913 was a type of nuclear battery for generating electricity directly from radiations released in radioactive decay. In 1953 a toy steam engine was operated with the radioisotope polonium-210 as its heat source to publicize power generation from nuclear energy. This led to the development of a radioisotope-heated thermoelectric generator demonstrated in 1954. Similar generators have been incorporated in space satellites to provide part of the power for operating the electronic equipment on board. Many other radioisotope power sources have since been developed, and some of these have been left to generate energy for experimental apparatus set up on the moon (see also RADIOISOTOPES, APPLICATIONS OF).

Recurring energy sources. Because some kinds of energy are continuously being created from primary sources, they are said to be recurring. These include solar energy, the energy in wind and flowing streams, geothermal energy, the energy in tides, fuel from trees and other plants, and a possible source of energy in thermal gradients in the ocean (oceanothermic energy). Although the total amount of energy in these recurring sources is large in relation to world energy needs, only a very small amount can be collected at reasonable cost. Thus, these sources provide only a small part of the world's total energy requirements.

Solar energy

Solar radiation outside the earth's atmosphere is 1.4 kilowatts per square metre. Expressed in terms of Q units ($Q = 10^{18}$ BTU) the amount of solar radiation striking the earth's atmosphere in one year is 5,000 Q. More than half of this reaches the surface of the earth, with 900 Q per year being absorbed over land and the remainder over water. The amount of solar energy absorbed each year by the process of photosynthesis in land vegetation has been estimated to be 0.15 Q. The energy in streams is about 0.17 Q per year, of which only about 2 percent is utilized by man. The energy in the winds is about 90 Q annually, but the amount that drives windmills is relatively insignificant.

Many attempts have been made to use solar energy to operate power plants, to cook, and to heat. Solar concentrators such as large parabolic mirrors, accurately oriented toward the sun, are necessary to produce the required high temperatures for generating power and cooking. Their cost makes power generation uneconomical if other energy sources are available. The practicability of heating homes with solar radiation depends upon their location and the cost of other fuels.

The wind contains tremendous amounts of energy, but it is intermittent and diffuse. Windmills usually are expensive relative to the energy delivered. Nevertheless, windmills are being reconsidered as energy sources, even in industrial nations, with a unit for generating 24,000 kilowatts of electric power being studied. Interest in energy from the winds will increase as fossil-fuel costs rise and as methods of energy transmission and storage are improved. This source of energy is predicted to provide at least a small percentage of the world's requirements.

The energy that could be recovered from undammed streams to generate power economically has been estimated at some 0.02 Q per year. Not included in this estimate is the energy in large rivers in remote areas of Asia or from the proposed closing of the Straits of Gibraltar. If the Straits are closed, evaporation would lower the Mediterranean Sea and power could be produced at the Straits and at river mouths. These sources of energy and many other proposed hydroelectric projects also will become more attractive as fossil-fuel reserves diminish. At present, hydroelectric power is estimated to provide 2 percent of the world's energy requirements.

Geothermal energy flows from the hot interior of the earth to the surface, where it is lost by radiation into space. Studies have been made of methods to extract energy directly from the earth through pipes buried at great depths, but the amount of energy obtained would be small because the earth is a poor thermal conductor. No economically feasible method seems possible, except in a few fortunate areas that have wells of natural steam or hot water. The most famous of these is at Larderello, Italy, where wells drilled as deep as 2,000 feet produce superheated steam at great pressure. The steam not only drives turbines to generate electricity but in addition contains chemical impurities that are recovered as valuable by-products. Another is near Reykjavík, Iceland, where the hot water from geothermal wells is piped to

heat buildings. A large natural vent of superheated steam in a remote region of New Zealand was once considered as a source of energy for the production of heavy water (deuterium oxide) for the atomic energy program. In California, however, geothermal steam was generating electricity in the 1960s and the facilities to take greater advantage of this energy from the earth were being expanded in the early 1970s.

Experiments by Georges Claude in 1929 demonstrated that energy can be obtained from the ocean in tropical regions where the difference in temperature between the warm water at the surface and cold water at great depths can operate a Rankine power cycle. The equipment for extracting oceanothermic energy is expensive and subject to storm damage, but there is a continuing interest in the process.

Tidal energy

There is a great amount of energy in the tides, but the ocean has been a difficult energy source to harness. This energy comes from the energy of rotation of the earth. As a result, the rate of rotation of the earth is slowing slightly. Spring tides sometimes rise as high as 52 feet in some parts of the world and many areas contain bays that favour the construction of dams to create storage basins, but the energy source is intermittent and varies with the seasons. At Rance, France, a successful tidal power project was developed in the 1960s. Several other sites, including the Bay of Fundy, in North America, have been studied. Many small waterwheels have been operated by tidewater. Even though only a small fraction of the energy in tides can be captured, this source of energy is expected to be put to greater use in the future.

Until about AD 1700, wood and farm wastes (stalks, cobs, and dried dung) provided most of the energy requirements of the world. In many countries where other fuels are not available, these sources still provide energy for heating and cooking. In forested areas wood is used extensively for fuel, supplying about 4 percent of the world's energy requirements. A secondary fuel, ethyl alcohol, is produced in quantity by fermentation of farm products. Tropical countries have expressed some interest in alcohol as a fuel for internal-combustion engines.

Energy storage. Most energy systems need a provision for storing energy to meet peak power requirements or emergencies or to drive systems that operate entirely on stored energy. Most machines have provisions for storing either potential or kinetic energy: a counterweight stores potential energy when it is lifted; springs of all types store energy; water pumped into an elevated reservoir stores energy; capacitors in circuits store small amounts of electricity; batteries store large amounts of energy and for long periods. Thermal energy can be stored by heating a material or by a phase change, such as evaporating water into steam. Fuels release stored chemical energy by combustion with natural oxygen in the atmosphere or with liquid oxygen. The performance of many products is limited by their energy storage capacity.

Expendable energy sources. The fossil fuels (coal, lignite, peat, petroleum, and natural gas) are natural resources that are being consumed at an appreciable rate. Although deposits continue to be discovered, the reserves of these fuels remaining in the earth are finite. The amounts that can be recovered economically are difficult to estimate, depending as they do upon the future value of the fuels and their mining cost. For example, coal occurs in seams of various thicknesses and at various depths. If coal seams no less than 24 inches thick are to be mined, much less coal is available than if recovery extends to seams as narrow as 14 inches. Estimating oil reserves presents similar difficulties. A 1953 estimate put minimum recoverable resources at 38 *Q* (32 *Q* of coal, 5 *Q* of oil and gas, and 1 *Q* of oil shales and tar), whereas other estimates put recoverable coal reserves at 200 *Q*. Nevertheless, the quantities of fossil fuels available in the earth's crust are not large compared to increasing rates of consumption. Although the amount of recoverable fuel will increase as more efficient mining methods are developed, certainly at some time in the future uranium and thorium will supply a major part of world energy requirements. Ultimately, if the technical problems of controlling nuclear fusion are solved, man will have an essentially unlimited source of energy.

(C.R.R.)

Engels, Friedrich

The German socialist philosopher Friedrich Engels was, with Karl Marx, one of the two founders of modern Communism. As the junior member of the "partnership" that worked out the theories of what has come to be known as Marxism or Marxist Communism, Engels played an indispensable role. Marx once noted, with pleasure, that their enemies used the singular verb when speaking of "Marx-Engels."

Born on November 28, 1820, in Barmen, an industrial city in the Prussian Rhine Province, now in West Germany, Engels grew up in the environment of a family marked by moderately liberal political views, a steadfast loyalty to Prussia, and a pronounced Protestant faith. His father was the owner of a textile factory in Barmen and also a partner in the Ermen & Engels cotton plant in Manchester, England. Even after Engels openly pursued the revolutionary goals that threatened the traditional values of the family, he usually could count on financial aid from home. The influence of his mother, to whom he was devoted, may have been a factor in preserving the tie between father and son.

Aside from such disciplinary actions as the father considered necessary in rearing a gifted but somewhat rebellious son, the only instance in which his father forced his will on Engels was in deciding upon a career for him. Engels did attend a *Gymnasium* (secondary school), but he dropped out a year before graduation, probably because his father felt that his plans for the future were too undefined. Engels showed some skill in writing poetry, but his father insisted that he go to work in the expanding business. Engels, accordingly, spent the next three years (1838–41) in Bremen acquiring practical business experience in the offices of an export firm.

In Bremen, Engels began to show the capacity for living the double life that characterized his middle years. During regular hours, he operated effectively as a busi-

Novosti Press Agency

Engels, print by H. Schey.

ness apprentice. An outgoing person, he joined a choral society, frequented the famed *Ratskeller*, became an expert swimmer, and practiced fencing and riding (he outrode most Englishmen in the fox hunts). Engels also cultivated his capacity for learning languages; he boasted to his sister that he knew 24. In private, however, he developed an interest in liberal and revolutionary works, notably the banned writings of "Young German" authors such as Ludwig Börne, Karl Gutzkow, and Heinrich Heine. But he soon rejected them as undisciplined and inconclusive in favour of the more systematic and all-embracing philosophy of Hegel as expounded by the "Young Hegelians," a group of leftist intellectuals, including the theologian and historian Bruno Bauer and the anarchist Max Stirner. They accepted the Hegelian dialectic, basically that rational progress and historical change result from the conflict of opposing views, ending in a new synthesis. The Young Hegelians were bent on accelerating the process by criticizing all that they considered irrational, outmoded, and repressive. As their first assault was directed against the foundations of Christianity, they helped convert an agnostic Engels into a militant atheist, a relatively easy task since by this time Engels' revolutionary convictions made him ready to strike out in almost any direction.

Hegel and the dialectic process

In Bremen Engels also demonstrated his talent for journalism by publishing articles under the pseudonym of Friedrich Oswald, perhaps to spare the feelings of his family. He possessed pungent critical abilities and a clear style, qualities that were utilized later by Marx in articulating their revolutionary goals.

After returning to Barmen in 1841, the question of a future career was shelved temporarily when Engels enlisted as a one-year volunteer in an artillery regiment in Berlin. No antimilitarist disposition prevented him from serving commendably as a recruit; in fact, military matters later became one of his specialties. In the future, friends would often address him as "the general." Military service allowed Engels time for more compelling interests in Berlin. Though he lacked the formal requirements, he attended lectures at the university. His Friedrich Oswald articles gained him entrée into the Young Hegelian circle of "The Free," formerly the "Doctors Club" frequented by Karl Marx. There he gained recognition as a formidable protagonist in the philosophical battles, mainly directed against religion.

After his discharge in 1842, Engels met Moses Hess, the man who converted him to communism. Hess, the son of wealthy Jewish parents and a promoter of radical causes and publications, demonstrated to Engels that the logical consequence of the Hegelian philosophy and dialectic was communism. Hess also stressed the role that England, with its advanced industry, burgeoning proletariat, and portents of class conflict, was destined to play in future upheavals. Engels eagerly seized the opportunity to go to England, ostensibly to continue his business training in the family firm in Manchester.

Conversion to communism

In England (1842–44), Engels again functioned successfully in business. After hours, however, he pursued his real interests: writing articles on communism for continental and English journals, reading books and parliamentary reports on economic and political conditions in England, mingling with workers, meeting radical leaders, and gathering materials for a projected history of England that would stress the rise of industry and the wretched position of the workers.

In Manchester, Engels established an enduring attachment to Mary Burns, an uneducated Irish working girl, and though he rejected the institution of marriage, they lived together as man and wife. In fact, the one serious strain in the Marx-Engels friendship occurred when Mary died in 1863 and Engels thought that Marx responded a little too casually to the news of her death. In the future, however, Marx made a point of being more considerate, and, when Engels later lived with Mary's sister Lizzy, on similar terms, Marx always carefully closed his letters with greetings to "Mrs. Lizzy" or "Mrs. Burns." Engels finally married Lizzy, but only as a deathbed concession to her.

In 1844 Engels contributed two articles to the *Deutsche-französische Jahrbücher* ("German-French Yearbooks"), which were edited by Marx in Paris. In them Engels put forth an early version of the principles of scientific socialism. He revealed what he regarded as the contradictions in liberal economic doctrine and set out to prove that the existing system based on private property was leading to a world made up of "millionaires and paupers." The revolution that would follow would lead to the elimination of private property and to a "reconciliation of humanity with nature and itself." On his way to Barmen, Engels went to Paris for a ten-day visit with Marx, whom he had earlier met in Cologne. This visit resulted in a permanent partnership to promote the socialist movement.

The partnership with Marx

Back in Barmen, Engels published *Die Lage der arbeitenden Klasse in England* (1845; *The Condition of the Working Class in England in 1844*, 1887), a classic in a field that later became Marx's specialty. Their first major joint work was *Die deutsche Ideologie* (1845; *The German Ideology*, 1938), which, however, was not published until more than 80 years later. It was a highly polemical critique that denounced and ridiculed certain of their earlier Young Hegelian associates and then proceeded to attack various German socialists who rejected the need for revolution. Marx's and Engels' own constructive ideas were inserted here and there, always in a fragmentary manner and only as corrective responses to the views they were condemning.

Upon rejoining Marx in Brussels in 1845, Engels endorsed his newly formulated economic, or materialistic, interpretation of history, which assumed an eventual communist triumph. That summer he escorted Marx on a tour of England. Thereafter he spent much time in Paris, where his social engagements did not interfere significantly with his major purpose, that of attempting to convert various émigré German worker groups—among them a socialist secret society, the League of the Just—as well as leading French socialists to his and Marx's views. When the league held its first congress in London in June 1847, Engels helped bring about its transformation into the Communist League.

Marx and he together persuaded a second Communist Congress in London to adopt their views. The two men were authorized to draft a statement of Communist principles and policies, which appeared in 1848 as the *Manifest der kommunistischen Partei* (commonly known as *Communist Manifesto*). It included much of the preliminary definition of views prepared earlier by Engels in the *Grundsätze des Kommunismus* (1847; *Principles of Communism*, 1925) but was primarily the work of Marx.

Communist Manifesto

The Revolution of 1848, which was precipitated by the attempt of the German states to throw off an authoritarian, almost feudal, political system and replace it with a constitutional, representative form of government, was a momentous event in the lives of Marx and Engels. It was their only opportunity to participate directly in a revolution and to demonstrate their flexibility as revolutionary tacticians with the aim of turning the revolution into a Communist victory. Their major tools were the *Neue Rheinische Zeitung, Organ der Demokratie*, which Marx edited in Cologne with the able assistance of Engels. Such a party organ, then appearing in a democratic guise, was of prime importance for their purposes; with it they could furnish daily guidelines and incitement in the face of shifting events, together with a sustained criticism of governments, parties, policies, and politicians.

After the failure of the revolution, Engels and Marx were reunited in London, where they reorganized the Communist League and drafted tactical directives for the Communists in the belief that another revolution would soon take place. But how to replace his depleted income soon became Engels' main problem. To support both himself and Marx, he accepted a subordinate position in the offices of Ermen & Engels in Manchester, eventually becoming a full-fledged partner in the concern. He again functioned successfully as a businessman, never allowing his Communist principles and criticism of capitalist ways to interfere with the profitable operations of his firm. Hence he was able to send money to Marx

constantly, often in the form of £5 notes, but later in far higher figures. When Engels sold his partnership in the business in 1869, he received enough for it to live comfortably until his death in 1895 and to provide Marx with an annual grant of £350, with the promise of more to cover all contingencies.

Engels, who was forced to live in Manchester, corresponded constantly with Marx in London and frequently wrote newspaper articles for him; he wrote the articles that appeared in the *New York Tribune* (1851–52) under Marx's name and that were later published under Engels' name as *Revolution and Counter-Revolution in Germany in 1848*. In the informal division of labour that the two protagonists of communism had established, Engels was the specialist in nationality questions, military matters, to some extent in international affairs, and in the sciences. Marx also turned to him repeatedly for clarification of economic questions, notably for information on business practices and industrial operations.

Marx's *Kapital*, his most important work, bears in part a made-in-Manchester stamp. Marx similarly called on Engels' writing facility to help "popularize" their joint views. While Marx was the brilliant theoretician of the pair, it was Engels, as the apt salesman of Marxism directing attention to *Das Kapital* through his reviews of the book, who implanted the thought that it was their "bible." Engels almost alone wrote *Herrn Eugen Dührings Umwälzung der Wissenschaft* (1878; *Herr Eugen Dühring's Revolution in Science* [*Anti-Dühring*], 1934), the book that probably did most to promote Marxian thought. It destroyed the influence of Karl Eugen Dühring, a Berlin professor who threatened to supplant Marx's position among German Social Democrats.

After Marx's death (1883), Engels served as the foremost authority on Marx and Marxism. Aside from occasional writings on a variety of subjects and introductions to new editions of Marx's works, Engels completed volumes 2 and 3 of *Das Kapital* (1885 and 1894; *Capital*, 1907 and 1908) on the basis of Marx's uncompleted manuscripts and rough notes. All the while he corresponded extensively with German Social Democrats and followers everywhere, so as to perpetuate the image of Marx and to foster some degree of conformity among the "faithful." His work was interrupted when he was stricken with cancer; he died in London on August 5, 1895.

Assessment

During his lifetime, Engels experienced, in a milder form, the same attacks and veneration that fell upon Marx. An urbane individual with the demeanour of an English gentleman, Engels customarily was a gay and witty associate with a great zest for living. He had a code of honour that responded quickly to an insult, even to the point of violence. As hatchetman of the "partnership," he could be most offensive and ruthless, so much so that in 1848 various friends attempted unsuccessfully to persuade Marx to disavow him.

Except for the Communist countries, where Engels has received due recognition, posterity has generally lumped him together with Marx without adequately clarifying Engels' significant role. The attention Engels does receive is likely to be in the form of a close scrutiny of his works to discover what differences existed between him and Marx. As a result, some scholars have concluded that Engels' writings and influence are responsible for certain deviations from, or distortions of, "true Marxism" as they see it. Yet scholars in general acknowledge that Marx himself apparently was unaware of any essential divergence of ideas and opinions. The Marx-Engels correspondence, which reveals a close cooperation in formulating Marxist policies, bears out that view.

MAJOR WORKS

Die Lage der arbeitenden Klasse in England (1845; trans. as *The Condition of the Working Class in England in 1844*, with an appendix and preface by Engels, 1887); (with Karl Marx) *Manifest der kommunistischen Partei* (1848; "The Communist Manifesto," trans. in *The Red Republican*, 1850); "Der deutsche Bauernkrieg," in *Neue Rheinische Zeitung Politisch-ökonomische Revue* (1850, republished by Engels as a book in 1870; *The Peasant War in Germany*, 1926); *Herrn Eugen Dührings Umwälzung der Wissenschaft* (1877–78; *Herr Eugen Dühring's Revolution in Science* [*Anti-Dühring*], 1934); *Die Entwicklung des Sozialismus von der Utopie zur Wissenschaft* (1882), three chapters from *Anti-Dühring* with an appendix on "The Mark," trans. by E. Aveling as *Socialism, Utopian and Scientific* (1892); *Der Ursprung der Familie, des Privateigenthums und des Staats* (1884; *The Origin of the Family, Private Property and the State*, 1902); *Zur Wohnunsfrage*, six articles in the *Volksstaat* (1872, reprinted as a pamphlet in 1887; *The Housing Question*, 1935); *Ludwig Feuerbach und der Ausgang der klassischen deutschen Philosophie* (1888; *Ludwig Feuerbach and the Outcome of Classical German Philosophy*, 1934); *Revolution and Counter-Revolution in Germany in 1848*, ed. by Eleanor Marx Aveling (1896), 20 articles from the *New York Tribune*, 1851–52, written by Engels, revised and signed by Marx (U.S. edition, *Germany: Revolution and Counter Revolution*, 1933).

Engineering

Engineering is the professional art of applying science to the optimum conversion of the resources of nature to benefit man. The words engine and ingenious are derived from the same Latin root, *ingenerare*, meaning "to create." The early English verb *engine* meant "to contrive." Thus the engines of war were devices such as catapults, floating bridges, and assault towers; their designer was the "engine-er," or military engineer. His counterpart was the civil engineer, who applied the same knowledge and skills to devising structures, streets, water supplies, sewage systems, and other projects of benefit to civilians.

Associated with engineering is a great body of special knowledge; preparation for professional practice involves extensive training in the application of that knowledge. Standards of engineering practice are maintained through the efforts of professional societies, usually organized on a national or regional basis, with each member acknowledging a responsibility to the public over and above responsibilities to his employer or to other members of his society.

Engineering is an art requiring the judgment necessary to adapt knowledge to practical purposes, the imagination to conceive original solutions to problems, and the ability to predict performance and cost of new devices or processes.

The function of the scientist is to know, while that of the engineer is to do. The scientist adds to the store of verified, systematized knowledge of the physical world; the engineer brings this knowledge to bear on practical problems. Engineering is based principally on physics, chemistry, and mathematics and their extensions into materials science, solid and fluid mechanics, thermodynamics, transfer and rate processes, and systems analysis.

Unlike the scientist, the engineer is not free to select the problem that interests him; he must solve problems as they arise; his solution must satisfy conflicting requirements. Usually efficiency costs money; safety adds to complexity; improved performance increases weight. The engineering solution is the optimum solution, the end result that, taking many factors into account, is most desirable. It may be the cheapest for a specified level of performance, the most reliable within a given weight limit, the simplest that will satisfy certain safety requirements, or the most efficient for a given cost. In many engineering problems, the social costs are significant.

Resources employed by engineers

Engineers employ two types of natural resources—materials and energy. Materials are useful because of their properties: their strength, ease of fabrication, lightness, or durability; their ability to insulate or conduct; their chemical, electrical, or acoustical properties. Important sources of energy include fossil fuels (coal, petroleum,

gas), wind, sunlight, falling water, and nuclear fission. Since most resources are limited, the engineer must concern himself with the continual development of new resources as well as the efficient utilization of existing ones.

The results of engineering activities contribute to the welfare of man by furnishing food, shelter, and comfort; by making work, transportation, and communication easier and safer; and by prolonging life and making it pleasant and satisfying.

HISTORY OF THE ENGINEERING PROFESSION

The first engineer known by name and achievement is Imhotep, builder of the famous stepped pyramid at Ṣaqqārah, near Memphis, probably *c.* 2550 BC. Imhotep's successors—Egyptian, Persian, Greek, and Roman—carried civil engineering to remarkable heights on the basis of empirical methods aided by arithmetic, geometry, and a smattering of physical science. The Pharos (lighthouse) of Alexandria, Solomon's Temple in Jerusalem, the Colosseum in Rome, the Persian and Roman road systems, the Pont du Gard aqueduct in France, and many other large structures, some of which endure to this day, testify to their skill, imagination, and daring. Of many treatises written by them, one in particular survives to provide a picture of engineering education and practice in classical times: Vitruvius' *De architectura*, published in Rome in the first century after Christ, a ten-volume work covering building materials, construction methods, hydraulics, measurement, and town planning.

Medieval European engineers, like the engineers of the classic world, combined military and civil skills and in the realm of construction carried technique, in the form of the Gothic arch and flying buttress, to a height unknown to the Romans. The sketchbook of Villard de Honnecourt, one of the best known of the Gothic engineers, who lived during the first half of the 13th century, reveals the wide knowledge of the professional engineer in mathematics, geometry, natural and physical science, and draftsmanship.

In the Far East, in India, China, Japan and other regions, engineering had a separate but very similar development, with more and more sophisticated techniques of construction, hydraulics, and metallurgy helping to create advanced civilizations such as the Mongol Empire, whose large, beautiful cities impressed Marco Polo in the 13th century.

Civil engineering

The term civil engineer first came into general use in the 18th century, which also saw the first engineering school founded (1747). This was the École Nationale des Ponts et Chaussées, or National School of Bridges and Highways, which grew out of the Corps des Ponts et Chaussées, or National Road and Highway Commission, of France. Its graduates were imbued with the new taste for the rationalization of knowledge, a spirit that led to research and formulation of theories on such subjects as fluid pressure. John Smeaton (1724–1792), the British designer of Eddystone Lighthouse and other notable structures, was apparently the first to call himself a civil engineer and thereby sever his profession from that of the military engineer. Thomas Telford (1757–1834), Scottish builder of the Menai Straits Bridge, accepted the presidency of the Institution of Civil Engineers, obtaining a royal charter in 1828 that made it the world's first engineering society.

Civil engineers of the 19th-century world built structures of all kinds, designed water-supply and sanitation systems, laid out railroad and highway networks, and planned cities. England and Scotland were the birthplace of the second branch of the modern profession, mechanical engineering (*q.v.*), as a derivation of the inventions of the Scottish engineer James Watt and the textile machinists of the Industrial Revolution. The development of the British machine-tool industry gave tremendous impetus to the study of mechanical engineering both in Britain and abroad.

The slow growth of knowledge of electricity, from Alessandro Volta's original electric cell of 1800 through the experiments of Michael Faraday and others, culminating in the Gramme dynamo and electric motor in 1872 (named after the Belgian Z.T. Gramme), created a branch of the profession of enormous influence: electrical and electronics engineering (*q.v.*). The electronics aspect came into prominence through the researches of such scientists as James Clerk Maxwell of Britain and Heinrich Hertz of Germany in the latter 19th century, the development of the vacuum tube by Lee De Forest of the U.S. in the early 20th century, and the invention of the transistor in the mid-20th century. In the early 1970s, electrical and electronics engineers outnumbered all others in the world.

Chemical engineering

Another major branch of the profession, chemical engineering, grew out of the 19th-century proliferation of industrial processes involving chemical reactions in metallurgy, food, textiles, and many other areas. By 1880 the use of chemicals in manufacturing had created a new industry whose function was the mass production of chemicals. The design and operation of the plants of this industry became a function of the new chemical engineer.

Aerospace engineering, an offshoot of mechanical engineering and the development of powered flight and rocketry, and computer engineering, which traces its origins to the 19th-century inventions of Charles Babbage of Great Britain and J.M. Jacquard of France, are among the most important frontier areas of the engineering profession in the 20th century, with many spectacular achievements already recorded and an incalculable promise for the future.

ENGINEERING FUNCTIONS

The branches indicate what the engineer works with; the functions describe what he does. In order of decreasing emphasis on science, the major functions of all engineering branches are the following:

Research. The research engineer seeks new principles and processes by employing mathematical and scientific concepts, experimental techniques, and inductive reasoning.

Development. The development engineer applies the results of research to useful purposes. Ingenious and creative application of new knowledge may result in a working model of a new electrical circuit, a chemical process, or an industrial machine.

Design. In designing a structure or a product, the engineer selects methods, specifies materials, and determines shapes to satisfy technical requirements and to meet performance specifications.

Construction. The construction engineer is responsible for preparing the site, determining procedures that will economically and safely yield the desired quality, directing the placement of materials, and organizing the personnel and equipment.

Production. Plant layout and equipment selection, with consideration of human and economic factors, is the responsibility of the production engineer. He chooses processes and tools, integrates the flow of materials and components, and provides for testing and inspection.

Operation. The operating engineer controls machines, plants, and organizations providing power, transportation, and communication. He determines procedures and supervises personnel to obtain reliable and economic operation of complex equipment.

Management and other functions. In some countries and industries, engineers analyze customers' requirements, recommend units to satisfy needs economically, and resolve related problems. In some industries, too, engineers decide how assets are to be used.

ENGINEERING EDUCATION

The future engineer must study sciences and their application, resources and their conversion, and man and his needs. The first stage of professional preparation is usually a college degree, but as in other modern professions where rapid change is the rule, learning must be continuous.

Undergraduate curriculum. The integrated undergraduate engineering program, developed primarily in Europe and the U.S. over the past century, provides the basic education for entrance into the profession. It provides

Development of skills

opportunities for students to master important concepts; to become adept in powerful techniques; to develop creative approaches to problem solving; and to become skillful in oral, written, graphic, and mathematical communication. By integrating the study of humanities, social sciences, mathematics, physical sciences, and technology and by providing experience in analysis, synthesis, and experimentation, the undergraduate engineering program offers a modern liberal education.

The typical curriculum leading to the bachelor's degree is defined by a series of courses. General education is provided by a pattern of courses selected from the humanities and social sciences. Basic science education includes mathematics, physics, computer programming, and often statistics, chemistry, and biology. Engineering sciences include materials, mechanics, thermodynamics, transfer and rate processes, electrical science, and information processing.

The combination of general education with basic and engineering science may provide the common preparations for all engineering students at a given school. Specialization to meet the needs and interests of individuals is offered through majors or options—combinations of courses to provide depth in a specific branch or function.

Graduate study. More and more engineers in the U.S., U.S.S.R., and other countries hold advanced degrees. In engineering, graduate study is characterized by highly sophisticated concepts, more advanced mathematics, greater depth in special topics, more opportunity for individual work, and less dependence on formal courses.

Modern trends. Early engineers were trained by apprenticeship to a skilled practitioner. As the body of knowledge gained by observation, testing, and research increased, organized programs of study were initiated in established schools. Following World War II, new trends became apparent, the result of the rapidly growing body of theoretical knowledge. Greater emphasis was placed on mathematics, physical science, and the engineering sciences. The current trend is toward more basic and less applied courses, greater use of computers and probability theory, and, at least in some countries, additional humanities and social sciences.

ENGINEERING AS A PROFESSION

The organization of the engineering profession in most countries reflects the pattern of branching development that resulted in diverse technical societies. This fragmentation is evidenced by the fact that no national or international organization represents all the members of the profession.

Technical societies. The first engineering society, the British Institution of Civil Engineers, reflected the new importance of the civil engineer in the early 19th century. As new fields opened up and new discoveries created the need for specialists, organizations were formed to facilitate the sharing of ideas. In the developed countries, there are hundreds of technical societies devoted to serving such special interests. Nearly every one publishes a journal containing accounts of the work of its members and conducts meetings to keep members informed of new developments. In addition, the major technical societies

Professional status of the engineer

are concerned with the professional status of the engineer and his education, often defining the first and assisting in formulating the second. One international engineering society is the Institute of Electrical and Electronics Engineers (IEEE), New York. Its 160,000 members belong to geographical units in the U.S., Canada, Europe, the Near East, North Africa, and Latin America.

Registration. In some countries, society membership includes the license to practice in that branch. In others registration by a government body ensures that those "professing" a knowledge of science and skill in the art of engineering are competent to practice. The requirements usually include being of good moral character; having practiced in a responsible capacity for a stipulated period; and passing an examination of qualifications to plan, design, or supervise the construction of engineering projects.

Recognition of the increasing role of engineering in government decision making led to the creation (1964) of the National Academy of Engineering (NAE), Washington, D.C., a private organization chartered by Congress. A major objective of the NAE is to identify the changing needs of society, assess the technical resources available, and sponsor programs to meet these needs.

ENGINEERING RESPONSIBILITIES

One activity common to all engineering work is problem solution. The problem may involve quantitative or qualitative factors; it may be physical or economic; it may require abstract mathematics or common sense. Of great importance is the process of creative synthesis or design, putting ideas together to create a new and optimum solution of the problem. Since the engineer functions at the sociotechnological "interface" (with science and technology on one side and individuals and communities on the other), he bears a unique responsibility to decide on priorities, establish performance criteria, select materials and processes, and specify evaluation procedures.

Problem solution. Although engineering problems vary greatly in scope and complexity, the same general approach is applicable. First comes an analysis of the overall situation and a preliminary decision on a plan of attack. In line with this plan, the usually broad and vague problem is reduced to a more categorical question that can be clearly stated. The stated question is then answered by deductive reasoning from known principles or by creative synthesis, as in a new design. The answer or design is always checked for accuracy and adequacy. Finally, the results for the simplified problem as stated are interpreted in terms of the original problem and reported in an appropriate form.

In his search for solutions to problems, especially new problems, the engineer is in conflict with a rather intractable environment and often in competition with predecessors who tried and failed and with contemporary rivals who are trying to solve the same problem. His success depends on his ability to create a new idea, a new device, a new process, or a new material.

Decision making. The engineer not only makes technological advances available to man but also may be charged with the responsibility to see that such advances do indeed enhance the welfare of man. By virtue of his knowledge, his skill, and his unique role in society, the engineer must concern himself with the results of technological progress such as its effect on the physical environment and its social and economic impact. The successful engineer of the future will be prepared for decision making on complex problems in broad areas. He will be skilled in the use of sophisticated tools and creative in the development of new techniques. He will have the vision to conceive vast projects, the talent to analyze them as integrated man–machine–environment systems, and the ability to predict their technical performance and their human impact.

Social implications

BIBLIOGRAPHY. Works on the history of the engineering profession, with discussions of the evolution of its functions, include: A.P.M. FLEMING and H.J.S. BROCKLEHURST, *A History of Engineering* (1925); R.S. KIRBY *et al.*, *Engineering in History* (1956); J.K. FINCH, *The Story of Engineering* (1960); B.V. BOWDEN (ed.), *Faster than Thought: A Symposium on Digital Computing Machines* (1953); and S. THOMAS, *Computers: Their History, Present Applications, and Future* (1965). Contemporary descriptions may be found in R.J. SMITH, *Engineering as a Career*, 3rd ed. (1969); and T.J. HOOVER and J.C.L. FISH, *The Engineering Profession*, 2nd ed. (1950).

(R.J.Sm.)

Engineering, Military

Military engineering is the oldest of the engineering skills, and military engineers were the first scientific soldiers, out of whose experience the profession of civil engineering came into being. Since then, the arts of military and of civil engineering have developed side by side.

Today the wartime function of military engineers is to apply at all stages engineering knowledge and resources to the furtherance of their commander's plan. Their role can conveniently be divided into three main tasks: (1)

combat engineering, or tactical engineer support on the battlefield; (2) strategic support by the execution of works services required in the communications zones, such as the construction of airfields, depots, the improvement of ports and road and rail communications, and the storage and distribution of fuels; and (3) ancillary support such as the provision and distribution of maps and the disposal of unexploded bombs and warheads.

The military engineers also carry out in peacetime a wide variety of civil works programs. Some are employed on vast projects dealing with coastal engineering and flood control, improving navigational capabilities of major rivers, development of hydroelectric power, water supply, provision of recreational amenities, and pollution control. Military engineers are also employed in providing aid to the civil community, particularly in disaster relief following earthquakes, hurricanes, and severe flooding.

The earliest military engineers. Evidence of the work of the earliest military engineers can be found in many parts of the world; for example, in Europe the hill forts constructed by the men of the late Iron Age, in the Middle East the massive fortresses incorporating the remarkably sophisticated military ideas of the Medes and Persians, and in Africa the high dressed-stone wall fortifications protecting the holy city of Zimbabwe in Rhodesia, built by the military engineers of a lost civilization. The greatest ancient defensive work ever built by human hands is probably the Great Wall of China, started in the 3rd century BC to defend the 1,000-mile frontier of the Celestial Empire from its barbarian neighbours. Another epic feat of ancient military engineering is known only through the written record of Herodotus, the Greek historian of the Persian wars of the 5th century BC. According to Herodotus, the Persian king Xerxes ordered his engineers to construct a pontoon bridge across the Hellespont (modern Dardanelles), which was accomplished by a mile-long chain of boats, 676 in all, arranged in two parallel rows.

Protection of garrison towns

The Romans. Examples of Roman military engineering works can still be seen throughout Europe and the Near East. Their *castra*, or military garrison towns, were protected by ramparts and ditches and interconnected by straight military roads along which their legions could speedily march to wherever they were needed. Like the Chinese, the Roman military engineers also built walls to protect the limits of their empire, though not of the same size and extent. A famous example is Hadrian's Wall in Britain, 73 miles (117 kilometres) long, from the Solway Firth to the North Sea just north of Newcastle-upon-Tyne, which protected the northern frontier of Roman Britain from the turbulent Picts and Scots. Throughout the long Punic Wars (264–146 BC), when Rome and Carthage struggled for supremacy at sea, harbours and defended naval bases were built, along with a system of watchtowers and forts, to guard against sea raiders. Roman military engineers thus became skilled in the construction of seaward defenses, harbours, and lighthouses and other navigational aids, tasks that remained the military engineer's province for many centuries. Roman engineers also developed a battering ram, slung from a beam mounted on a wheeled platform and provided with overhead cover, to be used against the wall or gate of an enemy fort. They also developed such engines as the giant catapult and the ballista, a large crossbow whose bowstring was drawn back by a windlass. These devices were used to hurl heavy rocks, showers of stones, or firebrands at defended places or at troops in the open. Still another impressive area of achievement by Roman military engineers was bridging; Caesar gives a detailed account of how his soldiers constructed a wooden lashed-trestle bridge over the Rhine, a feat that would tax the ingenuity of a modern military engineer.

The Middle Ages. The arts of fortifying and of attacking fortified places reached new heights in the centuries following the fall of the Roman Empire, partly as a result of the growth of cities in the later Middle Ages. Medieval engineers, both Arab and European, became proficient at mining operations, by which tunnels were driven under walls of castles or cities and their timbering set fire, causing the masonry overhead to collapse.

Prefabricated forts in 1066

William the Conqueror brought a novel wooden fort, or donjon, from Normandy to England in prefabricated sections to erect on the Hastings beachhead in 1066. As he advanced through the country William built a great number of such temporary forts. The method used was to raise a high mound of earth, called a motte, the top of which was flattened and surrounded by a wooden palisade. Within this palisade a tall wooden tower, or donjon, was built. Timber was used because it lent itself to rapid construction and was readily available locally. Furthermore, the unconsolidated made-up earth of the motte would not have supported the weight of a stone tower. Around the motte an outer defense was provided, called the bailey, consisting of a ditch the soil from which was thrown inward to form a bank that was surmounted by a wooden palisade. These temporary forts were abandoned as castles of permanent construction were built to replace them; the motte and bailey design was retained, however. The donjon, later known as the keep, was often a great tower made of flint, bound together by cement, with walls 20 feet (six metres) thick at the base. The outer defenses of the bailey were equally massive. These castles were an emblem of conquest and became the most effective instruments for enforcing law and order and the most important military and administrative centres in the land. A system of military roads, following the Roman pattern, interconnected them.

Early in the 12th century the crusaders, having captured Jerusalem and retaken the Holy Places, were faced with the problem of defending their conquests with minimum garrisons. Their solution was to build great fortresses, the most impregnable of their day, in strategic locations chosen mostly by French military engineers. As the increasing power of the Muslims gradually forced the knights out of the Holy Land, they withdrew first to Cyprus, then to Rhodes, and finally to Malta. Employing Italian and Spanish engineers, they constructed a series of fortifications on Malta and defenses covering dockyard creeks essential for the maintenance of their ships. In 1565 Süleiman the Magnificent sent a vast naval and military force against Malta. The Turkish forces landed and overran some of the outer defenses of the island, but the remaining works withstood all attacks, and Süleiman's expedition ignominiously withdrew.

The age of firearms. The Renaissance produced a succession of outstanding military engineers and men of remarkable genius, the most famous being Leonardo da Vinci. The age also witnessed rapid development of the cannon and all forms of firearms, a development that brought about a reappraisal of the design of fortifications and the techniques of siege warfare. Leonardo brought his fertile and inventive brain to bear on all facets of military engineering. He carefully analyzed the elementary military engineering tasks of using pick and shovel and basket and barrow for removing excavated soil. He developed the art of casting cannons and was expert in the use of gunpowder, both as a propellant and as a demolition explosive. He designed cranes, earth-moving equipment, and other devices of military value. Leonardo also invented types of assault boats and bridges and several siege devices. A gifted hydraulic engineer, he was a forerunner of the British military engineers who later built vast irrigation projects in India and the 20th-century U.S. Army Corps of Engineers, which is responsible for flood control and works connected with the rivers, harbours, and other waterways of the United States.

The frequent campaigns fought in the Low Countries during the 17th century largely involved besieging and defending the great barrier fortresses guarding the frontier between France and the Netherlands. The twin techniques of fortification and siege warfare were exclusively a matter for the military engineer. By midcentury these techniques reached such a state of perfection that they did not change until the latter half of the 19th century, when breach-loading artillery and the high explosive shell called for drastic alterations in the design and construction of defenses.

The outstanding military engineer of this era was Sébastien Le Prestre de Vauban of France (1633–1707). Although he is credited with having said "You do not fortify by systems but by good sense and experience," the design of his fortresses was often rigidly stylized and elaborate. The lines, or traces, of his fortifications, moreover, designed so that direct or flanking fire from both gun and musket could be brought to bear on all approaches, were slavishly copied by succeeding generations of military engineers. Indeed, Vauban's bastion trace became the accepted trace for the fire trench of World War I (see FORTIFICATIONS).

So lasting was Vauban's influence that the French school of military engineering was held to be the leading authority on the profession for many generations, and when the Army Corps of Engineers was constituted in 1779 during the U.S. War of Independence, George Washington turned to France to provide him with military engineer officers.

French Revolutionary and Napoleonic Wars, 1793–1815. In these wars, armies grew to unprecedented sizes. Fighting spread from Portugal to Moscow and further afield to the Americas, Egypt, South Africa, and India. In the many campaigns, siege operations were carried out by the traditional Vauban methods. When the French threatened England, vulnerable points on the southern coast of England were defended by hastily erected Martello towers, built on the Norman motte and bailey principle. The outer walls, however, consisted of masonry bastions and the thick-walled stone tower was armed with cannon. The Martello tower construction was later used for coast defense in both Canada and the U.S.

The Martello tower

An entirely new system of field defenses was adopted during the construction of the Lines of Torres Vedras by the Duke of Wellington during the Peninsular War in Portugal. Artillery fire could be brought down from a series of mutually supporting redoubts of low silhouette sited in great depth on dominant features and covering all approaches. Fields of fire for the guns were cleared of all obstructions, and streams were dammed to produce inundations to channel enemy lines of approach. Each redoubt was defended by a small close-support garrison of Portuguese militia. Wellington's field army was left available for manoeuvre and counterattack. Though Wellington had less than half as many men as the French, the latter could not risk assaulting these defenses and had to withdraw.

19th-century military engineering. The long period of peace that followed the Napoleonic Wars witnessed another great step forward in the fields of science and engineering and a rapid opening of new territories. The military engineers were quick to study how these technological advances could be put to a military use. In the new territories, they often found themselves the only professional engineers in the land and took personal responsibility for their exploration, mapping, defense, and development.

The U.S. Army Corps of Engineers led the way in exploring much of the American West, breaking trail for the immigrants who followed. They explored, surveyed, and mapped the land, built forts and roads, and later assisted in building the transcontinental railways. They also improved harbours and inland waterways and constructed dams and levees. They were responsible for maintaining coastal defenses. Similarly in Canada, India, Australia, New Zealand and other countries of the British Empire, the surveys and many of the public buildings and utilities, roads, bridges, railways, telegraphic communication systems, irrigation projects, harbours, and maritime defenses were the work of the British military engineers.

British and French military engineers first used the electric telegraph in the Crimean War (1853–56). Forward headquarters were connected by land line to their respective commanders in chief, who in turn were connected by means of a 340-mile (550-kilometre) submarine cable, laid by the Royal Engineers, to an existing transcontinental line to their governments in London and Paris. A new era in the control of war had dawned; among other political effects, the public at home received prompt news reports from correspondents at the front.

Submarine mining and searchlights. During the U.S. Civil War (1861–65), some 40 ships were sunk or disabled by mines or torpedoes; and interest in this form of warfare was intensified. Engineer submarine mining units were formed to lay electrically controlled mines in time of war to protect naval bases and important commercial ports. The Brennan torpedo, an underwater wire-controlled guided missile with a range of 1,000 yards (900 metres), was also developed. Submarine mining later became a naval responsibility, and the military engineers then developed defense electric lights to illuminate targets by night for coastal batteries. Subsequently they developed anti-aircraft searchlights and sound locators for air defense. Though infrared light and radar made searchlights obsolete in their traditional role, they are still used for battlefield illumination by military engineers.

The Brennan torpedo

For many hundred years military engineers used gunpowder and firing accessories obtained from the artillery when they had to carry out demolitions. In the 1860s, however, guncotton with detonating fuse was introduced as a demolition explosive. World War I produced trinitrotoluene (TNT), which was used to fill high-explosive shells and, later, shaped demolition charges that produced a molten jet of metal to penetrate the target. The search for new high explosives during the interwar years produced cyclonite (RDX), which probably represents the limit of what is chemically practicable for a service explosive. In 1942 plastic explosive (PE) was introduced. It made explosives quicker and easier to place and was more resistant to weather and battle hazards. Ammonal, common in World War I, was retained in World War II for mined charges. Pellets of RDX–wax–aluminum and ammonium nitrate and fuel oil slurries have since been used in mined charges with success (see EXPLOSIVES).

Early military aviation. Early in the 1860s French, British, and U.S. military engineers adapted balloons for a variety of military purposes, mostly intelligence. Subsequently, man-carrying kites were employed for artillery spotting when the wind was too strong for captive balloons. Later, powered airships and airplanes were brought into service. Aerial navigational aids, ground-to-air wireless communication, and aerial photography followed. The pioneering days of military flying were over, and shortly before World War I military engineers of most armies handed over their responsibility for aeronautics to other organizations.

Transportation and movement control. Since the introduction of railways, military engineers have been responsible in theatres of war for the construction and maintenance of the permanent way and bridges of railway systems, the control of the rail movement of troops and military matériel, and the repair of locomotives and rolling stock. They have operated armoured trains and have been responsible for the rail mounting of superheavy guns. Military-operated railways played a constantly growing role in wars of the 19th and 20th centuries as logistical requirements grew.

Road mechanical transport and power tools. To increase mobility and work capacity, steam traction engines, capable of towing a train of trailers, were introduced into the service by military engineers in the 1860s. These were the forerunners of military road mechanical transport. Employed as static machines these traction engines could, by means of certain attachments, be used as cranes or as prime movers to operate a variety of power tools. From this beginning the vehicle-mounted air compressor and its associated pneumatic tools later developed. Many of these pneumatic devices in their turn were replaced by electric power tools driven by lightweight generators. Thus over the years the source of power has become smaller, while the output from individual tools for use in the field has simultaneously increased.

Developments during World War I. Protracted trench warfare in World War I called upon all of the traditional siegecraft skills of the military engineers. Mining

and countermining were carried out on a scale never before attempted. The greatest achievement was the firing in June 1917 by British sappers of over 1,000,000 pounds (450,000 kilograms) of explosive, placed in 16 chambers 100 feet (30 metres) deep, which completely obliterated Messines Ridge in Belgium and inflicted 20,000 German casualties.

Trench tramways and light railways were built for the maintenance of forward troops. Large camouflage projects were carried out to screen gun positions, storage dumps, and troop movements from enemy observation. Forestry and quarrying units were raised and production workshops established, for provision of trench-fortification matériel and pit props and to meet the requirements of the vast construction projects carried out in rear areas.

The scope of military signalling increased enormously and reached such a size and complexity that, when World War I ended, military telecommunication engineers became a separate corps in all armies. New techniques were developed for fixing enemy gun positions. Map making by use of aerial photographs (photogrammetry) developed. Field printing presses were set up to provide vast quantities of maps of the fighting areas, and a grid system was introduced for maps covering the whole theatre of operations (for a full discussion, see MAPS AND MAPPING). German, British, and French military engineers also introduced means of using toxic gas and flame throwers, and tanks as weapons of war were developed by the British and French.

Photogrammetry in map making

In the Middle East, British and Indian engineers carried out several major river-crossing operations in Mesopotamia (Iraq) and operated craft on the Tigris and Euphrates rivers, which were used as the main supply routes for the campaign. In the Sinai Peninsula of Egypt and in Palestine the provision of water for the horse cavalry divisions was a major engineering task. The Royal Engineers piped Nile water from Egypt across the Sinai Desert to Jerusalem.

Interwar years. Defense was the major concern of most European governments during the interwar years. French military engineers designed and constructed the Maginot Line, a most sophisticated and assumed impregnable defensive system protecting France's common frontier with Germany and Luxembourg. The Germans constructed their Siegfried Line covering the same frontiers, and the Czechs built a defensive system to protect their northern frontier. The Russians constructed a looser system covering their long western frontier. For the air defense of Great Britain anti-aircraft batteries and searchlight positions were built to defend towns and service installations, and for passive air defense deep, gasproof air raid shelters were constructed in large numbers, and attempts were made to camouflage vulnerable points from aerial observation.

Developments during World War II. Military engineers of World War II faced and mastered problems on a scale and often of a character previously not experienced. Because of the importance of air power, airfields and airstrips had to be built, usually in great haste, frequently under fire. Amphibious operations, involving the landing of troops on a hostile shore, created a host of engineering problems, from underwater demolition of obstacles to rapid construction of open-beach dock facilities, such as the prefabricated mulberry harbour to maintain the Normandy landings in 1944. To meet the logistical needs of huge armies operating in remote regions, enormous base facilities were constructed.

The air battle. The construction and maintenance of forward airfields was a major problem for the engineers of all armies, especially the British and U.S. Allied airfields could never have been built without large quantities of earthmoving machinery mostly of American origin. For the construction of forward airfields it was often necessary to airlift light items of plant and later to lift sections of heavier items that could be reassembled on the ground. Great advances were made in the science of soil stabilization, and a variety of rapid airfield surfacing materials were developed, the American pierced steel plank being the most successful. For combined operations in the Pacific, floating airfields, consisting of prefabricated sections bolted together, were developed. Methods of piping aviation and other fuel from seagoing tankers, and its storage ashore in tank farms, were brought to a high state of perfection. After the Allied landing in Normandy in 1944, a pipeline was laid on the bed of the English Channel to supply fuel to the Allied forces in northwestern Europe.

Development of floating airfields

Armoured warfare. The most common devices used by World War II military engineers to stop enemy armour were the antitank ditch and the antitank mine. The ditch was only effective in locations where it could not be bypassed and where it could be kept under constant observation and fire. The antitank mine was first widely used during the fighting in the Western Desert of Egypt, where the minefield was the most easily provided obstacle to the movement of armoured forces. Special mine-warfare drills, techniques, and equipment were developed by the British and German military engineers for minelaying, mine location, and breaching minefields. As an adjunct to the antitank mine, antilifting devices, antipersonnel mines, and booby traps were introduced.

Bridging. Most armies at the outbreak of World War II possessed bridging equipment that would carry a tank weighing up to 30 tons. By 1940, however, tanks of 40-ton weight were being built, and it was known that this would soon not be the upper limit. To carry these increased weights, the Bailey Bridge was developed by the Royal Engineers in Britain. Its pin-connected rectangular truss panels made it easy to mass-produce. It also provided great flexibility on span and load capabilities. It could be used as a fixed span bridge or, with pontoons, as a raft or floating bridge. It was simple to construct quickly by day or at night. The equipment was produced in large quantities in Great Britain, the United States, and in Italy and was a vital factor in preserving the mobility of Allied armies in all theatres of operations, thus making a substantial contribution to ultimate victory. On the eastern front Soviet engineers developed a type of bridge with a deck just below the surface of the water, making it difficult to spot from the air.

Military roads. One of the most extraordinary feats of military engineering during World War II was the building in 1944 by Allied forces of a supply road from Ledo, India, to the Burma road at a point where the road was still in Chinese hands. This Stilwell, or Ledo road, as it was called, opened in January 1945, was 478 miles (770 kilometres) long, twisting through mountains, swamps, and jungles.

American amphibious operations were the main feature of the war in the Pacific. Amphibious operations in the European theatre culminated in the Normandy landings, the greatest combined operation in military history.

Although the engineering tasks varied in size in these operations, they were basically similar. They included the removal of beach obstacles and the neutralization of beach mines, the construction of beach roadways, the clearance of beach exits and the liquidation of fixed defenses, the construction of roads and administrative areas on the beachhead, and the construction of forward landing grounds and air-dropping zones. Special equipment, including armoured engineer equipment that had to be capable of wading ashore from landing craft, was developed for these tasks.

Great advances were made in air survey due largely to the use of American equipment and calculating machines to speed up survey computations. Methods of map and air chart reproduction also became more sophisticated, and the requirement for military maps for all theatres of operations reached astronomical proportions. All of the camouflage techniques developed during World War I were employed, and, in addition, inflatable dummy tanks, vehicles, and landing craft were produced, mostly in the U.S., and used extensively in deception plans.

Despite the many novel tasks imposed by World War II, traditional engineering jobs played a substantial role. Armies on the defensive constructed fortifications and carried out defensive demolitions on a scale never before seen. Outstanding were the German fortifications along

the Atlantic coast ("Fortress Europe") as well as the Siegfried Line in Germany. Concrete pillboxes played a major role, in addition to a variety of obstacles, many underwater; mines, both land and underwater, were laid by the millions. These vast works were constructed by the German Todt organization, which also specialized in demolition as German armies slowly retreated through the Soviet Union, Italy, and France.

The Manhattan Project. But the largest task carried out by World War II engineers, and indeed by any military engineering establishment in history, was undoubtedly the Manhattan Project, which produced the atomic bombs dropped on Hiroshima and Nagasaki. Civilian scientists as well as engineers were recruited in large numbers for this mammoth project. Its success made it a model for later large-scale engineering efforts involving many scientists and engineers from different disciplines. In a sense, it brought military engineering full circle; whereas early military engineers were the first all-round scientific soldiers, the modern military engineering project must enlist a team bringing together experts in all branches of engineering and scientific knowledge.

Engineers since World War II. In the late 1950s the U.S. Corps of Engineers constructed a network of radar warning systems across Canada and a series of Nike batteries to defend vulnerable points against the possibility of an attack across the polar ice cap by jet aircraft carrying nuclear bombs. In the 1960s they constructed a series of intercontinental ballistic missile bases. Introduction of these intercontinental missiles caused military surveyors to take a closer interest in the shape and size of the world. They developed ways of linking missile bases with far distant targets using geodetic satellites. Modern weapon systems, using advanced tracking, navigation, and locating devices, require mapping information direct from a computer.

Construction of air bases

The military confrontation of the Cold War and the conflicts in Korea and Vietnam resulted in construction of strategically placed air bases in Europe, the countries bordering the Arctic, Africa, and the Far East. In the varying emergencies military engineers performed not only their traditional combat and support roles but also, in addition, often carried out important peaceful works, such as dams and power stations to assist underdeveloped countries.

In the foreseeable future military engineers will probably continue to carry out their present civil-engineering tasks, such as river control. Their skills will be required in disaster areas stricken by earthquake, flood, or hurricane. In confrontations and insurgencies the military engineers will continue to combine traditional combat engineering with civil tasks. They will, of course, be equipped and trained for war in which nuclear weapons may be used. They will also undoubtedly play a part in the exploitation of the seabed and the continued exploration of the moon and deep space.

Education. Military engineering is not itself a discipline but rather the application of civil and other engineering disciplines to military problems. The military engineer must strive in his profession as a soldier and study the engineering lessons of past campaigns; and he must also keep abreast of developments in the engineering disciplines in civil life and, where possible, apply them to military purposes. The British Royal Military Academy was founded in 1741 at Woolwich to train cadets destined for commissions in the engineers and artillery, but it was not until 1812 that a school was set up at Chatham for the instruction of junior officers and soldiers of the engineers in fieldworks and siegecraft. It is now the Royal School of Military Engineering (RSME) and instructs in all branches of military and civil engineering undertaken by the Royal Engineers. The first school founded specifically to train military engineers was established at Mézières in France in 1748. In 1795 it moved to Metz where it was renamed the École Polytechnique. After World War II, the École l'Application du Génie was established at Angers and in 1946 the École Supérieure Technique du Génie was opened for the higher education of engineer officers. Claude Crozet, a graduate of the École Polytechnique, joined the staff of the United States Military Academy at West Point in 1817, becoming the first professor of civil engineering in the United States. Engineering continued to be stressed at West Point, and for many years every commandant was an engineer. Schools of military engineering, organized on the lines of the British RSME, exist in Canada, Australia, India, and Pakistan.

England

England is the predominant part of the United Kingdom, yet constitutionally it does not exist. It is not mentioned in the title of its sovereign. Elizabeth II is queen of "the United Kingdom of Great Britain and Northern Ireland and Her other Realms and Territories." Scotland and Wales have their own departments of state and Cabinet ministers, while Northern Ireland has its own Parliament and government for domestic affairs. But England has no such special rights, not even a separate set of official statistics, which are conventionally compiled either for the United Kingdom, in which the administration embraces the whole country—as in overseas trade, taxation, and defense—or for England and Wales, as in the administration of the law, education, and various social services (where Scotland exercises an independent authority). It is rare for institutions to operate for England alone. A notable exception is the Church of England, the Anglican Communion having separate churches in Wales and Scotland. Otherwise, England retains its separate identity only in such activities as sport. Cricket is strictly a matter for England and English counties (apart from the Glamorgan County Cricket Club in Cardiff, South Glamorgan, Wales), and England fields its own teams in rugby and soccer football. But in its institutions, England gives the appearance of having been swallowed up in the larger mass of the United Kingdom since the Act of Union of 1707. It sometimes seems that Scotland and Wales have been more successful in retaining or securing their own special institutions. Thus, the British Broadcasting Corporation (BBC) has set up national broadcasting councils for Scotland and Wales but none for England, and there are other such examples of apparently preferential treatment.

England's dominance in the United Kingdom, nevertheless, is unquestionable. Occupying a little more than half of the landmass, England has more than four-fifths of the population, estimated in 1974 to be 46,436,000 out of a total of 55,968,000, for the U.K. as a whole. The bulk of the most fertile lowlands are in England, and it enjoys a more agreeable climate, warmer and drier than the rest of the kingdom. Six of the U.K.'s seven major metropolitan areas, or conurbations, are in England, which also has a higher proportion of wealth and natural resources than the rest of the U.K. Population and wealth increase

with proximity to London, the national capital. London, in turn, with its ring of densely populated home counties in an area up to 50 or 60 miles in radius, dominates England, as England dominates Great Britain (England, Scotland, and Wales). There are good historical grounds for this being so. London was the biggest town in Roman Britain and has been the capital of a unified England since the Norman Conquest of 1066. Roman control of England fanned out with a network of roads based on London—a radial pattern that persists today. The Romans extended their rule approximately to the Welsh and Scottish borders of today, driving the Brythons back into the far southwest and the mountains of Wales and holding off the Scottish clans in the north. The frontiers of Roman rule in Britain were close to those of England today. In the subsequent 1,500 years, England has retained its frontiers short of most of upland Britain. The hill and mountain people of Wales and Scotland retain their sense of identity, and the English theirs, though they share a common language (although Welsh is still the common tongue in many rural areas of the principality) and a single sovereignty.

Extent of Roman rule

The "Englishness" of England is a quality hard to define, yet there is no doubt that it exists. Most institutions are British, but poets have very rarely saluted Britain (Britannia who rules the waves in the patriotic song with words by a Scottish poet being the exception). But poets by the score have celebrated England and the English, from William Langland in the medieval English of the 14th century onward. Shakespeare is self-consciously English and for England. The art historian Nikolaus Pevsner has written of "The Englishness of English Art." Yet this is not an insular character. It has been continually enriched from abroad. The English of Anglo-Saxon England were able to absorb the Danish and Norse invaders and their Norman French conquerors. And when the English went on to conquer first the remainder of the British Isles and then a worldwide empire, they did so without the dilution or dispersal of their essential character. The dominant role of the English is recognized implicitly in the numerous histories of Britain and the British Empire that are inaccurately called "A History of England." A remarkable capacity to absorb and transmute alien elements can be seen in English literature, which in the 20th century has been able to take into the mainstream of its tradition poets as Irish as W.B. Yeats, as Welsh as Dylan Thomas, or as securely in the classic line as the U.S. expatriate T.S. Eliot. (For related information, see UNITED KINGDOM; LONDON; MANCHESTER; LIVERPOOL; BIRMINGHAM; THAMES RIVER; ENGLISH CHANNEL; NORTH SEA; BRITAIN AND IRELAND, HISTORY OF.)

THE LAND AND ITS DIVERSITY

Extent and boundaries. One fundamental English characteristic is diversity within a small compass. England occupies about one-thousandth of the world's land area but contains about one-eightieth of the world's population and is, therefore, one of the most densely populated countries in the world. Even the farthest points of England are no more than a day's journey from London. Some approximate road distances from London are: to Dover, for the Channel crossing to France, 72 miles; to Southampton, the port for Atlantic routes, 77 miles; to Land's End, the farthest southwesterly point, 289 miles; to the southwestern port of Bristol, 116 miles; to the northwestern port of Liverpool, 197 miles; to the Scottish border at Carlisle, 300 miles; and to Berwick-upon-Tweed, 337 miles. No place in England is more than 75 miles from the sea.

Geological history. Within this small area, the diversity of England is based on a geological structure of remarkable complexity, spanning 600,000,000 years. Almost every phase of geological history is illustrated in the intricate patterns of the geological map of England, from the oldest igneous rocks, to be found at the western extremities in Cornwall and Cumberland, to the most recent alluvial soils of reclaimed fenland in East Anglia. Between lie bands of sandstones and limestones of different geological periods, witness to primeval times when large parts of central and southern England were submerged below warm seas. In the period of Alpine mountain building, these sedimentary rocks were lifted and folded, so that they now run from southwest to northeast, to yield chains of low hills rising to about 800 feet and fanning out from the Channel coast into the North and South Downs, the Wiltshire and Berkshire downs, and the Cotswolds and the Chilterns, extending through Lincolnshire and Yorkshire to the sea. In more recent geological times these hills were rounded into characteristic plateaus with west-facing escarpments by the great glaciers of three successive Ice Ages, the glaciers extending as far south as the northern outskirts of London. When the ice melted, the landscape was further altered by deep deposits of sand, gravel, and glacial mud.

Hills and downs

Subsequently, the processes of erosion by rain and river and the tides and subsidence in parts of the east of England have further shaped the hills and the coastline. A more substantial chain of hills, the Pennines, with moorland tops rising to between 2,000 and 3,000 feet, split the north of England into northwest and northeast. These hills of limestone, grit stone, and carboniferous strata are associated with major coalfields, some outcropping to the surface, others deeply buried. This geological history underlies the characteristic variety of the English landscape, for in journeys of only a few miles it is possible to pass through a succession of different soil structures: from chalk down to alluvial river valley, from limestone to sandstone and acid heath, from clay to sand, and so on, each type of soil bearing its own special class of vegetation. The geological complexity of England is strikingly illustrated in the cliff structure of its shoreline. Along the south coast from the ancient granite cliffs of Land's End in the extreme southwest are found a succession of sandstones of different colours and of limestones of different ages, culminating in the white chalk from the Isle of Wight to Dover.

These main groups are cut into by coves, bays, and beaches of particular local identity. A constantly changing panorama of cliffs, bays, and river estuaries distinguishes the whole of the English coastline, which, with its many indentations, is some 2,000 miles long.

Man's influence on the landscape. Though the significance of the ever-changing geological structure can hardly be exaggerated, the landscape as it is seen today has been significantly changed by man. Only the remotest moorland and mountain tops have been untouched; even the bleak Pennine moors of the north are crisscrossed by dry stone walls, and their vegetation modified by the cropping of mountain sheep. There is virtually no genuine wilderness left in England. The face of the country has been constantly worked over for centuries, acre by acre, and the marks of its exploitation and use dominate the contemporary landscape. The oldest traces are the antiquarian survivals, such as the Bronze Age forts studding the chalk downs of the southwest, the little rectangular Celtic fields of Cornwall, and the corrugations left by the strip farming of medieval open fields.

Towns and villages

More significant is the structure of town and village, which was established in Roman-British and Anglo-Saxon times and which has persisted as the basic pattern. The English live in scattered groups of high-density occupation, whether in village, or town, or, in modern times, in cities. The effect is to make England even in the 20th century look still a rural country, though 90 percent of its people are urban dwellers and less than 3 percent are engaged in agriculture. Despite a large amount of badly managed urban sprawl, as cities spilled out into conurbations, England, as seen from the air or from any number of hilltop viewpoints, is notable for extensive tracts of farming countryside that lie between its towns, its smaller villages often engulfed in the vegetation of trees, copses, hedgerows and fields: in a phrase of the poet Gerard Manley Hopkins, "the sweet especial rural scene," which occupies so large a place in English literature and English art.

The quality of the English scene is deeply rooted in its geology. Local building materials account for the traditional look of the Cotswold village, built of silvery lime-

stone with stone roofs. The colour of the stone also often identifies the locality. A honey-coloured stone (which weathers badly) was much used in Oxford, and a rusty ironstone is typical in North Oxfordshire and Northamptonshire, along the line of an ironstone belt. The Pennine gritstone adds a special severity to the moorland villages of the north. Timber frame and thatch are the building materials of the river valleys, and excellent clay provides the warm red brick of southern England. In recent years the easy transport of cheap but alien materials is to be blamed for many jarring intrusions into the harmonious towns and villages originally built mainly of local materials.

The visual impact of a mostly green and pleasant land can, however, be seriously misleading. England is primarily an industrial country, built up in the second half of the 18th century, during the first few generations of the Industrial Revolution, by ruthless exploitation of the coalfields and equally ruthless exploitation of cheap labour, especially in the cotton-textile areas of Lancashire, in the woollen-textiles areas of Yorkshire, and in the engineering centres of the Midlands and the Northeast. England has large tracts of dismally ugly derelict areas, scarred by the spoil heaps of the coal mines, by quarries and clay pits, by abandoned industrial plants, and run-down slums. About 100,000 acres have been officially listed as derelict, and the figure is probably an underestimate.

Climate. The diversity of the English landscape is accentuated by its weather. In a temperate maritime zone, it does not run to extremes but is certainly one of the most erratic climates in the world. The averages are moderate enough, ranging in the Thames Valley from 39° to 40° F (about 4° C) for the coldest month and 62° to 64° F (17°–18° C) for the warmest; but the extremes recorded in England go below 0° F (−18° C) and above 90° F (32° C). The Roman historian Tacitus recorded that the climate was "objectionable, with frequent rains and mists, but no extreme cold." Yet the winter of 1962–63 saw most of England heavily snowbound for nearly ten weeks, and snow cover may be expected in the higher parts of England on about 50 days a year. Though it is thought of as a wet country, lowland England has less than 40 inches (1,000 millimetres) of rainfall annually, and it frequently suffers from drought, the rising demand on water supplies becoming an increasing cause of official concern. In parts of Southeast England, the annual rainfall averages as little as 20 inches. Charles II expressed a judicious view when he said that the English climate was the best in the world—"a man can enjoy outdoor exercise in all but five days of the year." But no one would dispute that it is unpredictable: hence Dr. Samuel Johnson's observation that "when two Englishmen meet their first talk is of the weather." This changeability of the weather, not only season by season but day by day and even hour by hour, has had a profound effect on English art and literature.

Rainfall

The English painters John Constable and J.M.W. Turner were precursors of Impressionism in their exploration of the constantly changing light of English skies, and Constable painted cloudscape for its own sake. English poets down the centuries can be found constantly referring to the weather, from William Langland in the 14th century opening his poem *Piers Plowman* with the line, "In a somer seson whan soft was the sonne," to Shakespeare in the 16th century commenting on "the uncertain glory of an April day," and W.H. Auden in the 20th century with his "traffic of magnificent cloud."

Plant and animal life. England shares with the rest of Britain a below-average range of vegetation and living creatures, partly because the island was separated from the mainland of Europe soon after much of it had been swept bare by the last Ice Age (about 10,000 years ago) and partly because the land has been so industriously worked by its dense population. Predatory wild animals, such as the wolf, disappeared centuries ago. More recently birds of prey have suffered at the hands of farmers protecting their stock and their game birds. Under new protective laws, including a law restricting the collecting of birds' eggs, some of the less common birds have been re-establishing themselves. The bird life of England is unusually varied mainly because the country lies along the line of bird migrations and provides winter feeding grounds for some species and summer breeding habitats for others. Some birds have found town gardens, in which they are likely to be fed, a favourable environment, and in London about 100 different species are recorded annually. London has also been found a favourable habitat by foxes, which in small numbers have colonized woods and heaths within a few miles of the city centre. Though the species of plants may not be so great in number as those of the European mainland, they span a wide range and include some rarities. Certain Mediterranean species are to be found in the sheltered and almost subtropical valleys of the Southwest, while vestiges of the Ice Age tundra survive in parts of the moorland of the Northeast. England has been noted for a profusion of summer wildflowers in its fields, lanes, and hedgerows. In some parts these have been severely reduced by the use of herbicides on farms and roadside verges. Cultivated gardens account for much of the varied vegetation of the country, being enriched by the importation of many species of trees, shrubs, and flowering plants from all over the world.

Conservation efforts. The landscape for which England is famed has been seriously threatened by rising population, increasing urbanization, and increased wealth that has led to greater personal mobility. More and more townspeople seek recreation in the countryside and, by sheer numbers, are destroying what they look for. This dilemma has come to be known as the "leisure explosion." Not only England is affected, of course, but it was in England that these pressures first led to active intervention, to start with by individual action and later by action by public authorities, to set up a system of institutions and law to preserve the heritage of the past. One of the earliest of such initiatives was the establishment of the National Trust, a private organization dedicated to the permanent preservation of beautiful countryside and fine buildings. With a membership of over 250,000, the National Trust has become the largest single private landowner in the country with holdings covering more than 600 square miles. Its properties, which include some notable beauty spots, are visited by 2,000,000 to 3,000,000 people annually, and it has launched a special campaign to save 900 miles of coastline from the threat of damaging development. Although the National Trust extends to Wales and Northern Ireland, there is a separate National Trust for Scotland. In a similar spirit, the Civic Trust was established in 1957 with the object of preserving and enhancing the best "townscape." Many hundreds of local societies dedicated to the protection of the urban environment have been set up, and there are many other voluntary organizations working to protect and improve the English scene, among them the Council for the Protection of Rural England; the Commons, Open Spaces and Footpaths Preservation Society; and the Historic Churches Preservation Trust. Here the law has been extended and strengthened. The Town and Country Planning Acts of 1947 and 1968 require local government planning authorities to prepare development plans and to control development. Buildings of architectural and historic interest are listed and may not be demolished or altered without authority. The Civic Amenities Act of 1967 provided for areas of distinguished urban architecture to be designated "conservation areas." Local authorities may issue tree preservation orders to prevent indiscriminate felling. "Green belts" of countryside protected from building development have been mapped out in the plans for London and other conurbations. The quality of town life has been improved by smoke control and checks on river pollution, so effectively that the recorded sunshine in London and other major urban centres has been greatly increased and the "pea soup" fogs that occurred in London in the early 1950s have become memories of the past. Fish are returning to reaches of rivers such as the Thames, the Tyne, and the Tees from which they had been driven by industrial pollution.

The "leisure explosion"

Among a number of governmental institutions concerned with the environment is the Countryside Commission, which exists to promote recreation in the countryside, to protect designated areas of outstanding natural beauty, and to manage the national parks, seven of which are in England. It also manages long-distance footpaths, among them the Pennine Way, which runs for 250 miles over the summits of the moorland spine of northern England; some 80 miles of the South Downs Way; and a North Downs equivalent that runs, in part, along the route that Chaucer and his pilgrims took to Canterbury. Government recognition of the importance of these policies was indicated by the appointment of a cabinet minister responsible for the environment by the Labour government of 1969 and the founding of a Department of the Environment headed by a cabinet minister by the Conservative government in 1970. A Royal Commission was set up in 1969 to keep a continuous watch on pollution of the environment. While these measures applied to Great Britain as a whole, they were of particular relevance to England with its high-density urban development.

THE PEOPLE AND THEIR LANGUAGE

By ethnic origin the English are a mongrel breed. Their language is polyglot, drawn from a variety of sources, and its vocabulary has been augmented by importations from all over the world. The English language does not serve to identify the English, for it is the main language of Wales, Scotland, Ireland, many Commonwealth countries, and of the United States. The primary source of the language, however, is the main ethnic stem of the English. The Anglo-Saxons who invaded and colonized England in the 5th and 6th centuries have a record of continuous occupation since. It was their language that has prevailed and provides about half the words in modern English vocabulary.

Roman and Anglo-Saxon occupation

In the millennia following the last Ice Age, the British Isles were peopled by migrant tribes from the continent of Europe and, later, by traders from the countries of the Mediterranean area. In the time of the Roman occupation, England was inhabited by Celtic Brythons, but the Celts withdrew before the Teutonic Angles, Saxons, and Jutes (from northwest Germany) into the mountain areas of the west and north. The Anglo-Saxons neither preserved nor absorbed the Roman-British culture they found in the 5th century. There are remarkably few traces of Celtic or Roman Latin in the early English of the Anglo-Saxons, though some words survive in place-names, such as the Latin *castra* for camp providing the suffix "cester" and *combe* and *tor*, Celtic words for "valley" and "hill." Old Norse, the language of the Danes and Norsemen, has left more extensive traces, partly because it was a language with closer affinities to Anglo-Saxon and because the Danish occupation of large tracts of eastern and northern England was for a time quite deeply rooted, as some place-names show.

The history of the centuries before the Norman Conquest is poorly documented, but what stands out is the tenacity of the Anglo-Saxons in surviving a succession of invasions. They united most of what is now England at different times in the 9th, 10th, and 11th centuries, only to be overthrown by the Normans in 1066. For two centuries French became the language of the court and the ruling nobility; yet English prevailed and, by the middle of the 13th century, had re-established itself as the predominant tongue, to become an official language again in 1362. The characteristic English way of life prevailed too. From what evidence comes down from the Dark Ages, it seems that the Anglo-Saxons were stolid, industrious, and persistent colonizers, clearing the forests and opening up new land for farming. They were neither migrants nor mere piratical marauders but settlers.

Both before and after the Norman Conquest, the English showed a notable capacity for absorbing and transmuting outside influences. Church Latin and Norman French were incorporated into the language during the Middle Ages. It was then enriched by the Latin and Greek of the educated scholars of the Renaissance. The seafarers, explorers, and empire builders of the modern history have imported words from all corners of the globe, most copiously from Europe but also from Asia. These foreign words have been so completely absorbed into the language that they pass unselfconsciously as English. The English, it might be said, are great anglicizers.

The English have also absorbed and anglicized people of alien race, from Scandinavian pillagers and Norman conquerors to Latin churchmen. In the royal line, a Welsh dynasty of monarchs, the Tudors, was succeeded by the Scottish Stuarts, to be followed by the Dutch William of Orange and the German Hanoverians. For the Scots, the Welsh, and the Irish, English became their main language, and many moved into England to seek their fortunes and to settle down as English by adoption. England provided a haven for refugees from the time of the Huguenots in the 17th century to the totalitarian persecutions of the 20th century. Jews, too, have settled in England in large numbers. In recent decades there has been large-scale immigration of non-white peoples from India and Pakistan, Africa, and the Caribbean, posing seemingly more difficult problems of assimilation, and restrictive immigration regulations have been successively imposed that are out of key with the open-door policy that had been accepted as an English tradition for many generations. To be counted English, it has never been necessary to be of purebred English stock, and indeed, there can be few English who are.

Immigration of non-white peoples

THE REGIONS OF ENGLAND

Traditional regions. Though a small and homogeneous country bound together by law, administration, and a comprehensive transport system, distinctive regional differences persist in England. These arise from geography and history. It was natural for different groups of the population to establish themselves in recognizable physical areas. In the north, for example, the east and west are separated by the Pennines, which rise to more than 2,000 feet, and the estuaries of the Humber, the Thames, and the Severn form natural barriers. The regions that have been defined for administrative purposes have some arbitrary boundaries but nevertheless reflect true regional feeling. There are eight of them: the Southwest, the Southeast, the West Midlands, the East Midlands, East Anglia, the Northwest, Yorkshire and Humberside, and Northern England.

The Southwest. The Southwest contains the last stronghold of Celtic Britain, Cornwall, where a Celtic language was spoken until the 18th century and where the countryside is dotted with some 300 Celtic stone crosses. There is even a small nationalist movement, *Mebyon Kernow* (Sons of Cornwall), seeking to revive the old language. Though it has, as yet, no political significance, it reflects the disenchantment of a declining area, with the exhaustion of mineral deposits toward the end of the 19th century. The neighbouring county of Devon also shares this economic decline. On the other hand, these southwestern counties have a large share of the rapidly expanding tourist industry, with a splendid coastline and the Dartmoor and Exmoor national parks. Farther east and closer to the economic magnet of the London area, the counties of Dorset, Hampshire, Wiltshire, and Gloucestershire have a greater variety of new industry.

The Southeast. The Southeast, centred upon London, is of a size and wealth to match many nation states, with more than 17,000,000 people, 7,400,000 of them in Greater London. This is the dominant area of England and the most rapidly growing one despite planning controls directed toward restricting its growth. London itself is a victim of urban sprawl that has been checked too late. It is the administrative headquarters not only of government but of many of Britain's industrial and commercial undertakings. The area as a whole has an extensive range of manufacturing industry, though not in great concentrations apart from east London and the Thames Estuary. There is an above-average concentration of science-based industry and research around London. An effectively enforced green-belt policy has slowed

The expansion of London

down the expansion of London, and the region as a whole still has one-third of its area devoted to farming or horticulture. London is the focus of the nation's transport system, with the mainline railway network based on the London termini, two international airports, at Heathrow and Gatwick, and a third proposed at Foulness at the mouth of the Thames. The Port of London is the largest and commercially most important in Britain. Eight new towns have been established in the Southeast, and five existing towns have been expanded to take the overflow of London population, the scarcity of housing in inner London being particularly acute. With its theatres, concert halls, museums, and art galleries, London is emphatically the cultural capital of the country. Whether the people of the Southeast feel a regional identity is questionable. The Sussex Downs and the Bedfordshire plain or Oxford and Canterbury have nothing much in common apart from being within the magnetic pull of London. Loyalties are more specifically to towns, such as Oxford, Cambridge, or Brighton, and within London there is a sense of belonging more to localities—such as Chelsea or Hampstead, which acquire something of the character of urban villages—than to the metropolis as a whole.

The West Midlands. Regional characteristics are stronger outside the Southeast. The West Midlands, centred upon Birmingham, includes the Black Country (an urban agglomeration whose name accurately reflects the coating of grime and soot afflicting the buildings of the region), with some 1,500 different industrial trades, mainly in the metal industries. The major industry is automobile manufacture, with a wide range of component suppliers. With a long history going back to the beginnings of the Industrial Revolution, the West Midland towns are ugly but prosperous, with some of the highest wages in the country. It is an area in which there is a remarkable specialization place by place: locks and keys in Willenhall; needles and hooks in Redditch; the bulk of the country's pottery and china in five towns grouped around Stoke-upon-Trent; chocolate at Bournville; and carpets at Kidderminster. The region is not exclusively industrial, however, with the Shakespeare country around Stratford-on-Avon, the fruit-growing orchards of the Vale of Evesham, and hill country on the Welsh border.

The East Midlands. The East Midlands are less coherent as a region, taking in the manufacturing towns of Northampton (footwear); Leicester (hosiery and knitwear); Nottingham (hosiery, lace, bicycles, pharmaceuticals, tobacco); and Derby (engineering, aero-engines). The region also includes some of the most productive coalfields, ironstone mining, and much of England's best farmland in broad swathes between the industrial towns.

East Anglia. This region retains an air of remoteness that belongs to its history. With the North Sea on its northern and eastern flanks, it was at one time almost cut off by fenland to the west (now drained) and forest (long ago cleared) to the south. In medieval times it was one of the richest of the wool regions and, in some parts, was depopulated to make way for sheep. The traces of deserted villages can still be seen. Now it is the centre of some of the most industrialized farming in England. Vast fields are put down to cereals and sugar beet, and there are five times the national percentage of people employed in farming. It is the most thinly populated of the English regions but is beginning to be industrialized, with North Sea gas being brought ashore on the Norfolk coast.

Industrialized agriculture

The Northwest. The qualities of the regions become more distinctive the farther they are from London. The Northwest is in essence Lancashire, with the conurbations of Manchester and Liverpool, traditionally wet and murky, home of the declining cotton-textiles industry—rapidly being replaced by diversified engineering—but still much ravaged by the Industrial Revolution. It is a region that expresses itself in an accent of its own, with strongly flavoured variety-hall humour (of which George Formby and Gracie Fields were classic examples). It gave birth to British "pop" with the Beatles and other groups in Liverpool and still celebrates an earthy community life in wakes weeks (the factory holidays) and trips to Blackpool, the epitome of the north country seaside. It is a region still painfully breaking into the new territories of modern industry, its old cotton towns symbolically overshadowed by the grim gritstone Pennine escarpments, which have been stripped of their trees by the pollution of generations of industrial smoke.

Yorkshire and Humberside. A similar character belongs to industrial Yorkshire, on the east side of the Pennines watershed, where the valley mills are engaged in the manufacture of woollen textiles and clothing. Here too there is a strong accent to the regional style of speech and a rugged independence of character expressed in a tough style of humour. The conurbations of Leeds and Bradford take in the woollen and commercial centres. Farther south, steel is concentrated at Sheffield, world-famous for its cutlery. West Yorkshire based its prosperity on coal, but, like other parts of the country, it has been diversifying into other industries, notably chemicals and engineering. Here, too, industrialism has left ugly scars. But Yorkshire is not only industry. There are extensive areas of farming, the deep-sea-fishing industry operating from Hull, and tourist country along a fine coast and in the beautiful valleys of the Yorkshire Dales, with an exceptional repertoire of church architecture and country mansions.

Northern England. The official northern region extends to the Scottish border, taking in both North Yorkshire and the Lake District, and is therefore more than usually anomalous. The Lake District is a highly distinctive region of igneous mountains, the highest in England, rising to just over 3,000 feet, and so shut off that it retains a strong sense of local identity quite unlike the Northeast, which, from the river Tees to the Scottish border, is by cultural climate a region of its own. Here there are more concentrations of declining 19th-century industry, notably in the Durham coalfields and some of the Tyneside shipyards. It is at the same time a region in which modernization is going on rapidly, particularly in the complex of chemical industries on Teesside, one of the largest concentrations of chemical industries in Europe. The local flavour of life can be found in the folk songs of Tyneside and the coal-mining villages and in the dialect known as Geordie. The smallest of the designated conurbations, of some 800,000 population, is centred at Newcastle upon Tyne. The region also contains some of the most deserted land in England, in the Cheviot Hills along the Scottish border.

The Lake District

Regional disparities. The regional differences of England invite comparisons that re-emphasize the predominance of the south and particularly of the London area. The regions of the North and the Southwest may be more distinctive in character, but they are significantly poorer in wealth and social resources. The Southeast and the West Midland regions, on the other hand, are above the national average for incomes and the proportion of high-income earners. The worst parts of the North have a much higher mortality rate than the best parts of the Southeast, and this can be explained both by the bad housing, the higher level of unemployment, and the worse poverty of the North. There is a greater concentration of social services in the Southeast, especially in the London area: a wider choice of schools, hospitals, doctors, dentists, and medical specialists. The best professional and managerial jobs are to be found in London and the Southeast; there are more school pupils staying on after the minimum school-leaving age, more university students, and more universities. The attractions of this area and also of the southern parts of the Midlands are much greater for the setting up of new industries than places in the North that have a greater need of them. Hence the drift away from declining areas far from London into the already overcrowded Southeast has continued regardless of planning controls and incentives to industrialists to go to designated development areas in less favoured parts of the country.

ADMINISTRATION AND SOCIAL CONDITIONS

Government and politics. It is hard to identify a specifically English role in contemporary government and

politics, for these operate on a nationwide British basis. Historically, the English may be credited with the evolution of Parliament, which, in its medieval form, was related to the Anglo-Saxon practice of regular gatherings of notables, and the glory of the 1688 Revolution, which affirmed the rule of law, parliamentary control of taxation and of the army, freedom of speech, and religious toleration. Freedom of speech and opinion with proper opportunities for reasonable debate form part of the continuing English tradition, but the development of party and parliamentary government in its modern forms took place after the Act of Union of 1707, since when, in politics, the history of England has been the history of Britain. There have been prime ministers as robustly English as Robert Walpole, William Pitt, or Winston Churchill, but they are in a line that includes the Jew Benjamin Disraeli, the Welshman David Lloyd George, and the Scots Harold Macmillan and Alec Douglas-Home.

Local government

In government the English legacy remains conspicuous in local affairs, which are still largely administered on a county base that can be traced back to the Anglo-Saxon shires. The separation of county and town in local government was the principle underlying the late Victorian reorganization of local government, but the reforms of the 1970s, while retaining an exclusively urban base for local government in the conurbations, reunite county and town elsewhere with a minimum of disturbance to county boundaries that in many places date back 900 years.

The law. The English have given the world, notably North America and much of the Commonwealth, the system of English law that has acquired a status and universality to match Roman law. This, too, had its origins in Anglo-Saxon times, and two of its hallmarks are its preference for customary law (the common law) rather than statute law and its system of application by locally appointed part-time magistrates or justices of the peace, locally chosen juries, and by the travelling judges going from one county town to another on circuit. Under the Normans, the Anglo-Saxon system was retained but formalized; for example, by the recording of case law to provide uniform precedents. This began toward the end of the 13th century. In modern times there has been a greater reliance upon the statute law contained in about 3,000 acts of Parliament, but there are over 300,000 recorded cases to turn to for precedent. Other aspects of the English law are the fundamental assumption that an accused person is deemed innocent until proved guilty and the independence of the judiciary from intervention by crown or government in the judicial process.

Religion. Increasingly, England is a secular country. Though more than one-half the population are baptized in an Anglican church and for form-filling purposes would say they belonged to the Church of England, fewer than one in ten of the baptized are communicant churchgoers. The Church of England still has 18,000 churches, but it has been in financial difficulties, and it has closed down underused churches and sold off redundant sites. The nonconformist Free Churches have nominally fewer members, but there is probably greater dedication among them, as with the Roman Catholic Church, with about 4,000,000 adherents in England. Apart perhaps from some isolated centres of Irish settlement in the Northwest, there is complete religious tolerance in England and no overt prejudice against Catholics; it is quite usual for 30 or 40 members of Parliament to be Catholic, with a few of them government ministers. The decline in churchgoing has been thought to be an indicator of decline in religious belief, but opinion polls substantiate the view that belief in God and the central tenets of Christianity survives the flagging fortunes of the churches.

CULTURAL LIFE

England's contribution to the culture of the United Kingdom and of the world is too vast for anything but a random sampling. There is the complicating factor that in the contemporary cultural scene, England is not always distinguishable from Wales and Scotland or even Northern Ireland. Furthermore, what may count as mainly English achievements have often been shared with people from other countries.

Science. In the sciences, for example, the splitting of the atom was first accomplished in the Cavendish Laboratory in Cambridge by Ernest Rutherford, a New Zealander. The deoxyribonucleic acid (DNA) molecule was unravelled in Cambridge by two English geneticists, Francis Crick and Maurice Wilkins, and an American, James Watson. Radar detection of aircraft was perfected at a research station in Suffolk by a team headed by a Scot, Robert Watson-Watt. Penicillin was discovered in a London hospital by Alexander Fleming, a Scot, and developed as a medical drug by Howard Florey, an Australian, in Oxford. In the sciences the English are sometimes said to be better at fundamental theory than at its application. Certainly Isaac Newton on gravitation and Charles Darwin on evolution have changed the history of scientific thought. But William Harvey on the circulation of the blood and Joseph Lister on antiseptic surgery were working as practical surgeons. The innovating engineers of the early Industrial Revolution were highly practical men. The choice of the Greenwich meridian as the base line for measuring longitude reflects the practicality of English astronomers, navigators, and geographers. The practical application of highly sophisticated new techniques to fundamental research is seen in the radio telescopes at Jodrell Bank and at Cambridge. In the design of nuclear power plants, research institutions in England have been abreast or ahead of the rest of the world. England has also been ahead with the design of advanced aircraft. One of the first jet engines was designed by Frank Whittle and flown in England in 1941, and the Anglo-French supersonic airliner Concorde is built in England at Bristol and powered by Rolls-Royce engines made in Derby.

Eminent Englishmen in science

Architecture. England, however, is still most famous for its architecture and its literature, both reflecting the regional diversity of the country. Architecture has been much influenced from abroad, but foreign styles take on an English aspect. So the Gothic architecture of France was transformed into a characteristically English style by the delicate use of stone to provide a framework for walls that were almost all glass, culminating in triumphs of the perpendicular style, such as King's College Chapel at Cambridge. European Renaissance influences can be seen in the buildings of Christopher Wren, yet his many London churches seem essentially English. The magnificent country houses of the 18th century are likewise not mere importations of a foreign fashion but fit their own landscape; and many such landscapes were designed by the great English garden and park designers, William Kent, Lancelot ("Capability") Brown, and Humphry Repton. Small-scale domestic architecture is often just as commendable for its fitness to its situation, and an intimate, friendly urbanity is to be found in the best of England's town centres and villages, this being partly the result of using local materials, whether stone, brick, tile, or thatch. The bulk of the building of the last 100 years excites much less enthusiasm. Many industrial slums have been condemned for demolition, but much contemporary building that is adequate for habitation or work is drearily uninspired. The reconstruction of the war-damaged city areas of England provided opportunities for notable new architecture, and some original design and construction was undertaken; for example, the Barbican scheme in a large bombed area north of St. Paul's, London, and the group of concert halls with an art gallery and the new National Theatre on the south bank of the Thames. Outside London, notable projects include the Coventry precinct and cathedral by Sir Basil Spence; a batch of new universities founded during the 1960s, among them those near Brighton, Canterbury, Colchester, Norwich, and York; and a number of local-authority housing developments, including new towns.

Modern building trends

Literature. In literature, regional influences have often strongly affected English writers—such as Wordsworth in the Lake District, the Brontë sisters on the Yorkshire moors, Thomas Hardy in Dorset, D.H. Lawrence in the Midlands coalfields, and Charles Dickens in London. It

is a characteristic that persists, in J.B. Priestley, a Yorkshireman, in Evelyn Waugh, a west-country squire, and John Betjeman, a Londoner, whose poetry is a record of his passion for English towns and landscape.

Visual arts. Regional attachments are also to be found in the visual arts. The sculptors Henry Moore and Barbara Hepworth both come from Yorkshire, and something of the quality of moorland stone can be seen in their work. Hepworth's later work has echoes of the granite coastline of Cornwall, where she settled, and Cornwall has become the chosen working place of a number of English artists. Even in music the landscape intrudes, as in Benjamin Britten's opera *Peter Grimes*, based as it is on a story of the fishing village in Suffolk where Britten lives.

Institutionally, the arts in Britain have grown in both scope and vigour since World War II. Publishers break records for the numbers of books produced; the sale of paperbacks has spread from established bookshops to newsagents and tobacconists. London theatres (about 30 in the West End) play to full houses, and many new repertory theatres have been established in the provinces. Music flourishes as never before in England, and visiting conductors have said that they find the English concert audience one of the most appreciative in the world. Long-playing records are sold by the tens of millions annually. Attendance at art galleries and museums doubled in the 1960s, but it was feared that the introduction of admission charges might reduce attendance. Subsidies to support the arts and literature in Britain are administered by the Arts Council, a considerable proportion of them being devoted to maintaining and extending the arts in regional centres outside London. Arts Council subsidies have also been used to develop the international fame of companies such as the Royal Opera and the Royal Ballet (both of Covent Garden) and of leading London orchestras, which make regular foreign tours.

The Arts Council

Leisure. Though England has a lively intellectual and artistic life, its characteristic pursuits are of a more popular kind. The exploitation of leisure is increasingly the concern of commerce: holiday camps, foreign holiday package tours, gambling of many kinds from bingo to horse-race betting and football (soccer) pools, and the transformation of the traditional English pub by trendy interior decoration and the introduction of new kinds of beer allegedly more palatable to women. The English weekend, accorded to most of the population, is the occasion for trips into the countryside and for outdoor activities ranging from fishing to mountaineering. England gave to the world the sports of cricket, association football, and rugby football, but team and spectator sports tend to be giving way to more individualistic activities. In spite of persistent commercial tempting to do something else, the English remain a stay-at-home people. The Englishman's home is still his castle, and gardening the most frequent pastime, except for watching television, which absorbs nearly a quarter of the average person's leisure time. The English prefer living in houses to apartments, and about three out of four have gardens. They keep pets, they "do-it-yourself" in house maintenance and many other odd jobs, and their desire for privacy still mystifies foreign onlookers.

THE OUTLOOK

Will the Englishness of England survive? Its essential qualities are small scale and local, even insular and parochial, whether one is considering the landscape or the people, in town or country. The prevailing trends are almost all inimical, blatantly so when supergrid electric power lines dwarf the village scene or when the street corner village-in-the-city community is obliterated by an urban motorway or displaced by the supermarket. The life of provincial capitals is diminished when the fast new intercity rail services link them to London by a journey of two hours or so. England is most truly England when separate places retain their distinctive individuality, whether in the style of a town centre or in the speech and the occupations of the people. Currently a powerful and perhaps irresistible process of standardization averages out and levels down the differences between places. A standard housing estate in Southampton may be indistinguishable from its counterpart in Carlisle at the other end of the country. "Subtopia" is the word that has been coined for this spread of a faceless urban uniformity. A different kind of facelessness is spreading over the countryside as industrialized farming imposes its standardized requirements on the land, grubbing out hedgerows and hedgerow trees to create a prairie of 100-acre fields geared to the tempo of the tractor. Thousands of miles of hedgerow have been disappearing each year as England establishes itself as the country with more farm tractors to the acre than anywhere else in the world. The personality of regions and of individual towns is diluted by the move away from specialization in one industry. Often the declining industries—such as textiles, steel, shipbuilding, and coal—have been the foundation for a strong regional character. Diversification into other industries paradoxically has a sameness rather than variety about it, for much the same mix of new light industries settles into new trading estates wherever they may be. Ideas, manners, topics of conversation, styles of clothing, ways of speech, and tastes in food and drink increasingly tend to be standardized throughout the country by the pervasive influence of mass-circulation newspapers, network television and radio, and the chain stores that dominate every town centre. England is served by and serves the mass market. Physical mobility (from place to place) and social mobility (from one economic class to another) tend toward rootlessness. The English now more commonly move away from their birthplace than stay there, the population drift being away from established city and town centres toward suburbs. The 1971 census showed that all the conurbations except West Yorkshire had lost population since 1951. More than 600,000 moved out of London in the decade 1961 to 1971, and of the 35 next largest towns 22 had a declining population.

"Subtopia"

There are, however, vigorous counter-responses to these tendencies. Planning authorities, egged on by civic societies, attempt to remedy the visual clutter of subtopia, and the renewal of city centres is high in planning priorities. Conservationists are active in campaigning to protect the countryside, while the English as a whole have been growing more actively critical and concerned about their environment. The right to have a bigger say by public participation in local planning has been recognized in the 1968 Town and Country Planning Act.

In temperament the English have often been thought by outside observers to be reserved, conventional, deferential, snobbish; and (as the French Duc de Sully observed in the 17th century) to take their pleasures sadly. Much of that has changed since 1945. The English led the way in fashion with bright colours, miniskirts, and gay, casual dress for men. The English turned rock music into pop and spiced it with not-so-quiet social revolution. Social restlessness in England in some of its more conspicuous forms—student protest, the underground press, and women's liberation—seemed sometimes to be borrowing second-hand from abroad. England, like other countries, was not immune to global "trendiness." More important, in a society that had been noted for its elaborately stratified class structure, the revolt against deference saw the end of conventional class snobbery, though it was fast replaced by a snobbery of success. Outbreaks of teenage violence suggested that England might be becoming not only brassy and brazen but "bloodyminded" too. Yet foreign observers continued to repeat the well-established compliments to the English for their politeness, reasonableness, good nature, and the relaxed tolerance of their democracy.

BIBLIOGRAPHY. Many of the most useful sources deal with the United Kingdom rather than with England exclusively. An official handbook, *Britain* (HMSO, annual), surveys contemporary British life and institutions, and includes an extensive up-to-date bibliography. Other important official sources are the *Census 1971* reports and *Social Trends*, a statistical analysis periodically brought up to date.

Among recent histories are the *Oxford History of England*, 15 vol. (1936–65), whose last volume, A.J.P. TAYLOR, *English History, 1914–45*, has a discursive bibliography; and *The*

Pelican History of England, 8 vol. (1955–65), whose last volume, DAVID THOMSON, *England in the Twentieth Century, 1914–63*, also has a helpful bibliography. For social history, G.M. TREVELYAN, *English Social History: A Survey of Six Centuries, Chaucer to Queen Victoria* (1946), is classic but somewhat conventional; the interconnections of social and cultural history are examined by RAYMOND WILLIAMS, *Culture and Society, 1780–1950* (1958) and *The Long Revolution* (1961). RICHARD HOGGART, *The Uses of Literacy* (1957), deals with the impact of mass media on working class culture; the structure and role of newspapers is examined by COLIN SEYMOUR-URE in *The Press, Politics, and the Public* (1968). Regional differences are surveyed in B.E. COATES and E.M. RAWSTRON, *Regional Variations in Britain* (1971), and D. ELLISTON ALLEN, *British Tastes* (1968). Some other studies of 20th-century English life and attitudes are GEORGE ORWELL, *The English People* (1947); ROBERT GRAVES and ALAN HODGE, *The Long Weekend: A Social History of Great Britain, 1918–1939* (1963); MALCOLM MUGGERIDGE, *The Thirties*, new ed. (1967); R. LEWIS and A. MAUDE, *The English Middle Classes* (1949); GEOFFREY GORER, *Exploring English Character* (1955) and *Sex and Marriage in England Today* (1971); and E.J.B. ROSE, *Colour and Citizenship: A Report on British Race Relations* (1969).

England's place in contemporary British politics can be judged from D.E. BUTLER, with various associates, in *The British General Election* (separate volumes on the elections of 1950, 1951, 1955, 1959, 1964, 1966, and 1970); D.E. BUTLER and D. STOKES, *Political Change in Britain* (1969); D.E. BUTLER and J. FREEMAN, *British Political Facts 1900–1967* (1968); and D.E. BUTLER, *The Electoral System in Britain* (1953). *The Royal Commission Report on Reform of English Local Government* (1969) is the most valuable and thorough recent study even though its proposals were not adopted.

For geology, geography, and natural history, the "New Naturalist Series" provides authoritative studies for the general reader, among them DUDLEY STAMP, *British Structure and Scenery*, 2nd ed. (1947); GORDON MANLEY, *Climate and the British Scene* (1952); and J.A. STEERS, *The Sea Coast* (1953). Another work by J.A. STEERS, *The English Coast and the Coast of Wales* (1966), is a paperback associated with a campaign to preserve the coastline. A brief introduction to wildlife, with useful book lists, is R.S.R. FITTER, *Wildlife in Britain* (1963). For conservation of the landscape and of the human environment, recent history is summarized in DUDLEY STAMP, *The Land of Britain: Its Use and Misuse*, 3rd ed. (1962), and *Nature Conservation in Britain* (1969). W.G. HOSKINS, *The Making of the English Landscape* (1955), is based on original field research; COLIN BUCHANAN, *Traffic in Towns* (1964), is a seminal official study; NAN FAIRBROTHER, *New Lives, New Landscapes: Planning for the 21st Century* (1970), deals with agriculture in an urban society; ROBERT ARVILL, *Man and Environment* (1967); and JOHN BARR, *Derelict Britain* (1969), study the impact of industrialism. There are useful book lists in H.E. BRACEY, *People and the Countryside* (1970); and VICTOR BONHAM-CARTER, *The Survival of the English Countryside* (1971). Recent trends in urban development are examined in R.H. BEST and J.T. COPPOCK, *The Changing Use of Land in Britain* (1962); FREDERICK GIBBERD, *Town Design* (1967); F. OSBORN and A. WHITTICK, *The New Towns* (1969); J.B. CULLINGWORTH, *Housing and Local Government* (1966); and D.V. DONNISON, *The Government of Housing* (1967). England's historic architecture is cataloged with lively commentary in NIKOLAUS PEVSNER, *The Buildings of England*, 37 vol. (1951–70), county by county; and its local characteristics are the theme of A. CLIFTON-TAYLOR, *The Pattern of English Building* (1962). W. GAUNT, *A Concise History of English Painting* (1964), is a reliable guide; NIKOLAUS PEVSNER, *The Englishness of English Art* (1956), expands a series of broadcasts. A. SAMPSON, *Anatomy of Britain* (1971), is a breezy, informative work on the world of public institutions, politics, and business.

(W.H.Th.)

English Channel

A narrow, wedge-shaped sea separating Great Britain and France and tapering eastward to its junction with the North Sea at the Strait of Dover (French Pas de Calais), the English Channel (French La Manche), with a size of 34,700 square miles (89,900 square kilometres), is the smallest of the shallow seas covering the fringing continental shelf of Europe. From its mouth in the North Atlantic Ocean—an arbitrary limit marked by a line between the Scilly Isles and the Isle of Ushant—its width gradually narrows from 112 miles to a minimum of 21 miles, while its average depth decreases from 400 to 150 feet. Although the English Channel is a feature of notable scientific interest, especially in regard to tidal movements, its strategic location lent it immense significance, over the centuries, as both a route and a barrier during the peopling of Britain and the emergence of the nation states of modern Europe. By the 1970s, as the United Kingdom appeared to turn politically toward Europe, the long-discussed project for a Channel tunnel at the sea's eastern end—potentially one of the greatest engineering projects in the world—moved closer to realization.

Strategic importance

The current English name (in general use since the early 18th century) probably derives from the designation "canal" in late 16th-century Dutch sea atlases, although earlier names had included Oceanus Britannicus and the British See; the French have regularly used La Manche (a reference to the sleevelike coastal outline) since the early 17th century. Scholars adduced reasons for the Channel's existence as early as the 17th century, but detailed scientific study awaited the first official hydrographic surveys (French coast: 1829; English coast: 1847), and the geological map of the seabed based on borings made in 1866 was the world's first of its kind. Further studies were associated with early plans for a Channel tunnel, and modern surveys, using sophisticated techniques, have made the Channel seabed one of the most intensively studied sea floors in the world since the end of World War II.

Geological evolution. The contemporary Channel is probably the result of a complex structural downfolding dating from the mid-Tertiary (about 25,000,000 years ago), although signs of a downwarp tendency occur as early as 270,000,000 years ago. The direct ancestor of the Channel may well have been a sea occupying the downfold 1,000,000 or 2,000,000 years ago, with a sea level 600–700 feet above the present level. The withdrawal of water by the Ice Age glaciers produced, about 25,000 years ago, a sea level at least 300 feet lower than the present. Later, the melting of the ice raised the sea level to its present mark, and the ecologically important land bridge across the Dover Strait was finally submerged about 8,000 years ago.

Submarine topography and deposits. The sea floor dips fairly steeply near the coasts but is generally flat and remarkably shallow (especially in relation to nearby land elevations), with its greatest depth of 565 feet in the Hurd Deep, one of a group of anomalous deep, enclosed, troughs in the bed of the western Channel. It has been shaped by the effect upon its rock strata (with their varying degrees of hardness) of such forces as: weathering and erosion (when much of the area was dry land); sea-level changes; and contemporary erosion and deposition by marine currents.

The floor of the western Channel (200 to 400 feet deep) is relatively flat and featureless, reflecting fairly uniform rock types, mostly limestone. Harder igneous rocks cause shoals to emerge (as in the case of the Scilly Isles and Channel Islands), and submerged cliffs and narrow depressions provide some additional variety.

In the central Channel (150 to 200 feet deep) depths are fairly uniform over chalk outcrops, but alternations of clays and limestones give rise to an undulating terrain, with deeps reaching almost twice the average. A continuation of the Seine Valley system north of the Cotentin Peninsula complicates the relief forms. Farther east again, the sea floor is smoother and the geology simpler. Depths range from six to 160 feet, with such elongated banks as the Varne and the Ridge greatly constricting shipping lanes.

Because the Channel, unlike the Irish or North seas, lay south of the scouring action of Ice Age glaciers, superficial deposits are either very thin (three feet or less) or entirely absent. They represent a complex reworking of deposits of various ages, and their distribution reflects tidal currents: where these are strong, the seabed is bare except for pebbles; decreasing velocities give rise to sand and gravel ribbons and waves (the latter up to 40 feet thick) and to thick beds of fine-grained deposits in sheltered areas, notably Golfe de Saint-Malo.

Hydrography. Tides are generally strong, especially in the Dover Strait, and may be visualized as an oscillation

The "double-tide" phenomenon

(modified by Earth rotation and configuration) about a north–south line through the centre of the Channel—*i.e.*, with a rise to the west accompanying a fall to the east. The central portion experiences daily double tides (helpful to shipping movements at Southampton which has a double, or prolonged, high tide), and the Golfe de Saint-Malo experiences, at 28 feet or more, the greatest tidal range.

Surface temperatures range from 45° F (7° C) in February to 61° F (16° C) in September, although shallow coastal waters are warmer in summer. There is little temperature change with depth in the well-mixed eastern waters, but bottom-water temperatures fall to 41° F (5° C) in the west. Surface salinities decline eastward from just under the Atlantic level of 35.6 parts per thousand; coastal readings are further reduced by the influx of river water, especially from the larger French landmass. There is an overall water flow through the Channel to the North Sea, a complete replacement taking about 500 days.

Historical associations. From earliest times, depending on historical factors, the Channel served as a route for, and a barrier to, invaders of Britain from the continent. Early Stone Age man crossed the Strait of Dover; later invaders crossed the western end of the Channel, trading the copper, tin, and lead they found in England's Devon and Cornwall, and successive Bronze and Iron Age invaders followed the same route. Caesar's invasion of 55 BC again favoured the Dover route in the east, while William the Conqueror's famous invasion in 1066 crossed from Normandy to Hastings. With the later loss of Normandy to the British, the Channel again became a defensive line: it was the scene of major military actions from the sea battle of 1588, pitting the English against the Spanish Armada, to the Dunkirk evacuation in 1940 and the launching of the Normandy beachhead in 1944.

Resources and economic activity. Located at the junction of the Atlantic Ocean and the North Sea, the respective waters of which are rich in warm- and cold-water plankton, the Channel is favoured from the latter with cod, herring, and whiting and from the former with hake, pilchard, and mullet. The traditional fishing industry has declined in the present century with the development of deep-sea fishing, the exhaustion of resources, and the advent of pollution problems; but coastal fishing remains important in Bretagne (Brittany), and skin diving has stimulated shell fishing in Cornwall.

A good climate, sandy beaches, and an attractive coast have encouraged the growth of a major tourist industry on both sides of the Channel, starting with the fashionable resorts of the late 18th century. Portsmouth and Plymouth are now declining naval ports, with very minor commercial functions. Cherbourg is probably not changing much in character, but Southampton and Le Havre are losing passengers while gaining tremendous container and oil-refining capacity and also experiencing a general commercial growth. England and France both use Channel waters for cooling nuclear-powered generating stations, while the tidal-power generating station on the River Rance (in Bretagne), utilizing a tidal range of over 37 feet, is a unique feature. Another unique feature is the Channel tunnel project, conceived in 1802, initiated, and then halted, in the late 19th century and revived in 1957. By the 1970s the idea of a tunnel under the Strait of Dover seemed to be coming closer to realization: if finally implemented, it would have immense economic effects on the entire region bordering the Channel.

BIBLIOGRAPHY. The most concise and up-to-date accounts of the English Channel from the point of view of navigation, the ports, and natural conditions are contained in *The Channel Pilot* (1971) and *The Dover Strait Pilot* (1971), published by the Hydrographic Office of the British Navy. A useful summary of physical conditions, together with bibliography, may be found in R.W. FAIRBRIDGE (ed.), *Encyclopedia of Oceanography* (1966); and the wider geological setting is outlined in D.T. DONAVAN (ed.), *Geology of Shelf Seas* (1968). An important early account of geology and structure is W.B.R. KING, "The Geological History of the English Channel," *Q. Jl. Geol. Soc. Lond.*, 110:77–101 (1954); and morphology is discussed by A.H.W. ROBINSON in "The Floor of the British Seas," *Scott. Geog. Mag.*, 68:64–79 (1952). The most up-to-date review of Channel structure, geological outcrops, and superficial deposits, with comprehensive bibliographies, is found in F.M. DELANY (ed.), *The Geology of the East Atlantic Continental Margin*, 4 pt. (1971). Tidal information will be found in the British Admiralty Tide Tables and Pocket Tidal Atlases. A helpful summary is found in J.A. WILLIAMSON, *The English Channel: A History* (1959). The definitive publication on the Channel tunnel is *Proposals for a Fixed Channel Link* (HMSO Cmd. 2137; 1963); and a recent assessment is DONALD HUNT, "Channel Tunnel Enters Final Phase," *New Scient.*, 49:238–239 (1971). An excellent account of British ports and trade is JAMES BIRD, *The Major Seaports of the United Kingdom* (1963).

(C.E.E.)

English Language

English is widely spoken in all six continents and has had a strong effect in many regions in which it is not the principal language spoken. The portmanteau words Franglais, Russlish, and Japlish, for example, have been invented by resentful purists to describe the numerous expressions, in vogue among the young, resulting from the infiltration of English into French, Russian, and Japanese, respectively.

The widely diffused English-speaking community is fairly stable in the British Isles, North America, and Australasia. In Africa, the Indian subcontinent, and Southeast Asia its future remains uncertain and unpredictable. People who speak English fall into three groups: those who have inherited it as their native language; those who have acquired it as a second language within a society that is largely bilingual; and those who are driven by necessity to use it for some practical purpose—administrative, professional, or educational. One person in seven of the world's entire population now belongs to one of these three groups.

The future of English

ORIGINS AND BASIC CHARACTERISTICS

Parent tongue

English belongs to the Indo-European family of languages and is therefore related to most other languages spoken in Europe and western Asia from Iceland to India. The parent tongue, called Proto-Indo-European, was spoken about 5,000 years ago by nomads believed to have roamed the southeast European plains. Germanic, one of the language groups descended from this ancestral speech, is usually divided by scholars into three regional groups: East (Burgundian, Vandal, and Gothic, all extinct), North (Icelandic, Faeroese, Norwegian, Swedish, Danish), and West (German, Netherlandic [Dutch and Flemish], Frisian, English). Though closely related to English, German remains far more conservative than English in its retention of a fairly elaborate system of inflections. Frisian, spoken by the inhabitants of the New Dutch province of Friesland and the islands off the west coast of Schleswig, is the language most nearly related to Modern English. Icelandic, which has changed little over the last thousand years, is the living language most nearly resembling Old English in grammatical structure.

Modern English is analytic (*i.e.*, relatively uninflected),

whereas Proto-Indo-European, the ancestral tongue of most of the modern European languages (*e.g.*, German, French, Russian, Greek), was synthetic, or inflected. During the course of thousands of years, English words have been slowly simplified from the inflected variable forms found in Sanskrit, Greek, Latin, Russian, and German, toward invariable forms, as in Chinese and Vietnamese. The German and Chinese words for "man" are exemplary. German has five forms: *Mann, Mannes, Manne, Männer, Männern.* Chinese has one form: *ven.* English stands in between, with four forms: man, man's, men, men's. In English only nouns, pronouns, and verbs are inflected. Adjectives have no inflections aside from the determiners "this, these" and "that, those." (The endings *-er, -est,* denoting degrees of comparison, are better regarded as noninflectional suffixes.) English is the only European language to employ uninflected adjectives; *e.g.*, "the tall man," "the tall woman," compared to Spanish *el hombre alto* and *la mujer alta.* As for verbs, if the Modern English word ride is compared with the corresponding words in Old English and Modern German, it will be found that English now has only five forms (ride, rides, rode, riding, ridden), whereas Old English *ridan* had 13, and Modern German *reiten* has 16 forms.

In addition to this simplicity of inflections, English has two other basic characteristics: flexibility of function and openness of vocabulary.

Loss of inflection

Flexibility of function has grown over the last five centuries as a consequence of the loss of inflections. Words formerly distinguished as nouns or verbs by differences in their forms are now often used as both nouns and verbs. One can speak, for example, of "planning a table" or "tabling a plan," "booking a place" or "placing a book," "lifting a thumb" or "thumbing a lift." In the other Indo-European languages, apart from rare exceptions in Scandinavian, nouns and verbs are never identical because of the necessity of separate noun and verb endings. In English, forms for traditional pronouns, adjectives, and adverbs can also function as nouns; adjectives and adverbs as verbs; and nouns, pronouns, and adverbs as adjectives. One speaks in English of the Frankfurt Book Fair, but in German one must add the suffix *-er* to the place-name and put attributive and noun together as a compound, Frankfurter Buchmesse. In French one has no choice but to construct a phrase involving the use of two prepositions: Foire du Livre de Francfort. In English it is now possible to employ a plural noun as adjunct (modifier), as in "wages board" and "sports editor"; or even a conjunctional group, as in "prices and incomes policy" and "parks and gardens committee."

Openness of vocabulary implies both free admission of words from other languages and the ready creation of compounds and derivatives. English adopts (without change) or adapts (with slight change) any word really needed to name some new object or to denote some new process. Like French, Spanish, and Russian, English frequently forms scientific terms from Classical Greek word elements.

English possesses a system of orthography that does not always accurately reflect the pronunciation of words; this is discussed below in the section *Orthography.*

CHARACTERISTICS OF MODERN ENGLISH

Phonology. British Received Pronunciation (RP), by definition, the usual speech of educated people living in London and southeastern England, is one of the many forms of standard speech. Other pronunciations, although not standard, are entirely acceptable in their own right on conversational levels.

The chief differences between British Received Pronunciation, as defined above, and a variety of American English, such as Inland Northern (the speech form of western New England and its derivatives, often popularly referred to as General American), are in the pronunciation of certain individual vowels and diphthongs. Inland Northern American vowels sometimes have semiconsonantal final glides (*i.e.*, sounds resembling initial *w*, for example, or initial *y*). Aside from the final glides, this American dialect shows four divergences from British English: (1) the words cod, box, dock, hot, and not are pronounced with a short (or half-long) low front sound as in British "bard" shortened (the terms front, back, low, and high refer to the position of the tongue); (2) words such as bud, but, cut, and rung are pronounced with a central vowel as in the unstressed final syllable of "sofa"; (3) before the fricative sounds *s, f,* and *θ* (the last of these is the *th* sound in "thin") the long low back vowel *a,* as in British "bath," is pronounced as a short front vowel *a,* as in British "bad"; (4) high back vowels following the alveolar sounds *t* and *d* and the nasal sound *n* in words such as tulips, dew, and news are pronounced without a glide as in British English; indeed, the words sound like the British "two lips," "do," and "nooze" in "snooze." (In several American dialects, however, these glides do occur.)

The consonants

The 24 consonant sounds comprise six stops (plosives): *p, b, t, d, k, g;* the fricatives *f, v, θ* (as in "thin"), *ð* (as in "then"), *s, z,* ʃ (as in "ship"), ʒ (as in "pleasure"), and *h;* two affricatives: *t*ʃ (as in "church") and *d*ʒ (as the *j* in "jam"); the nasals *m, n,* ŋ (the sound that occurs at the end of words such as "young"); the lateral *l;* the vibrant or retroflex *r;* and the semivowels *j* (often spelled *y*) and *w*. These remain fairly stable, but Inland Northern American differs from British English in two respects: (1) *r* following vowels is preserved in words such as "door," "flower," and "harmony," whereas it is lost in British; (2) *t* between vowels is voiced, so that "metal" and "matter" sound very much like British "medal" and "madder," although the pronunciation of this *t* is softer and less aspirated, or breathy, than the *d* of British English.

Like Russian, English is a strongly stressed language. Four degrees of stress may be differentiated: primary, secondary, tertiary, and weak, which may be indicated, respectively, by acute (ˊ), circumflex (ˆ), and grave (ˋ) accent marks and by the breve (˘). Thus, "Têll mè thĕ trúth" (the whole truth, and nothing but the truth) may be contrasted with "Têll mé thĕ trûth" (whatever you may tell other people); "blâck bîrd" (any bird black in colour) may be contrasted with "blâckbìrd" (that particular bird *Turdus merula*). The verbs "permít" and "recórd" (henceforth only primary stresses are marked) may be contrasted with their corresponding nouns "pérmit" and "récord." A feeling for antepenultimate (third syllable from the end) primary stress, revealed in such five-syllable words as equanímity, longitúdinal, notoríety, opportúnity, parsimónious, pertinácity, and vegetárian, causes stress to shift when extra syllables are added, as in "histórícal," a derivative of "hístory" and "theatricálity," a derivative of "theátrical." Vowel qualities are also changed here and in such word groups as période, periódical, periodícity; phótograph, photógraphy, photográphical. French stress may be sustained in many borrowed words; *e.g.*, bizárre, critíque, duréss, hotél, prestíge, and techníque.

Pitch, or musical tone, determined by the rate of vibration of the vocal cords, may be level, falling, rising, or falling–rising. In counting "one," "two," "three," "four," one naturally gives level pitch to each of these cardinal numerals. But if a person says "I want two, not one," he naturally gives "two" falling pitch and "one" falling–rising. In the question "One?" rising pitch is used. Word tone is called pitch, and sentence tone is referred to as intonation. The end-of-sentence cadence is important for meaning, and it therefore varies least. Three main end-of-sentence intonations can be distinguished: falling, rising, and falling–rising. Falling intonation is used in completed statements, direct commands, and sometimes in general questions unanswerable by "yes" or "no"; *e.g.*, "I have nothing to add." "Keep to the right." "Who told you that?" Rising intonation is frequently used in open-ended statements made with some reservation, in polite requests, and in particular questions answerable by "yes" or "no": "I have nothing more to say at the moment." "Let me know how you get on." "Are you sure?" The third type of end-of-sentence intonation, first falling and then rising pitch, is used in

sentences that imply concessions or contrasts: "Some people do like them" (but others do not). "Don't say I didn't warn you" (because that is just what I'm now doing). Intonation is on the whole less singsong in American than in British English, and there is a narrower range of pitch. American speech may seem more monotonous but at the same time may sometimes be clearer and more readily intelligible. Everywhere English is spoken, regional dialects display distinctive patterns of intonation.

Intonation in American and British English

Morphology. *Inflection.* Modern English nouns, pronouns, and verbs are inflected. Adjectives, adverbs, prepositions, conjunctions, and interjections are invariable.

Most English nouns have plural inflection in (*-e*)*s*, but this form shows variations in pronunciation in the words cats (with a final *s* sound), dogs (with a final *z* sound), and horses (with a final *iz* sound), as also in the 3rd person singular present-tense forms of verbs: cuts (*s*), jogs (*z*), and forces (*iz*). Seven nouns have mutated (umlauted) plurals: man, men; woman, women; tooth, teeth; foot, feet; goose, geese; mouse, mice; louse, lice. Three have plurals in *-en*: ox, oxen; child, children; brother, brethren. Some remain unchanged; *e.g.*, deer, sheep, moose, grouse. Five of the seven personal pronouns have distinctive forms for subject and object.

The forms of verbs are not complex. Only the substantive verb ("to be") has eight forms: be, am, is, are, was, were, being, been. Strong verbs have five forms: ride, rides, rode, riding, ridden. Regular or weak verbs customarily have four: walk, walks, walked, walking. Some that end in a *t* or *d* have three forms only: cut, cuts, cutting. Of these three-form verbs, 16 are in frequent use.

In addition to the above inflections, English employs two other main morphological (structural) processes—affixation and composition—and two subsidiary ones—back-formation and blend.

Types of affixes

Affixation. Affixes, word elements attached to words, may either precede, as prefixes (do, undo; way, subway), or follow, as suffixes (do, doer; way, wayward). They may be native (*over*do, waywardness), Greek (*hyper*bole, the*sis*), or Latin (*super*sede, ped*iment*). Modern technologists greatly favour the neo-Hellenic prefixes *macro-* "long, large," *micro-* "small," *para-* "alongside," *poly-* "many," and the Latin *mini-*, with its antonym *maxi-*. Greek and Latin affixes have become so fully acclimatized that they can occur together in one and the same word, as, indeed, in "ac-climat-ize-d," just used, consisting of a Latin prefix plus a Greek stem plus a Greek suffix plus an English inflection. Suffixes are bound more closely than prefixes to the stems or root elements of words. Consider, for instance, the wide variety of agent suffixes in the nouns act*or*, artis*an*, dot*ard*, engin*eer*, financ*ier*, hire*ling*, magistr*ate*, merch*ant*, scient*ist*, secret*ary*, song*ster*, stud*ent*, and work*er*. Suffixes may come to be attached to stems quite fortuitously, but, once attached, they are likely to be permanent. At the same time, one suffix can perform many functions. The suffix *-er* denotes the doer of the action in the words worker, driver, and hunter; the instrument in chopper, harvester, and roller; and the dweller in Icelander, Londoner, and Trobriander. It refers to things or actions associated with the basic concept in the words breather, "pause to take breath"; diner, "dining car on a train"; and fiver, "five-pound note." In the terms disclaimer, misnomer, and rejoinder (all from French) the suffix denotes one single instance of the action expressed by the verb. Usage may prove capricious. Whereas a writer is a person, a typewriter is a machine. For some time a computer was both, but now, with the invention and extensive use of electronic apparatus, the word is no longer used of persons.

Composition. Composition, or compounding, is concerned with free forms. The primary compounds "already," "cloverleaf," and "gentleman" show the collocation of two free forms. They differ from word groups or phrases in phonology, stress, or juncture or by a combination of two or more of these. Thus, "already" differs from "all ready" in stress and juncture, "cloverleaf" from "clover leaf" in stress, and "gentleman" from "gentle man" in phonology, stress, and juncture. In describing the structure of compound words it is necessary to take into account the relation of components to each other and the relation of the whole compound to its components. These relations diverge widely in, for example, the words cloverleaf, icebreaker, breakwater, blackbird, peace-loving, and paperback. In "cloverleaf" the first component noun is attributive and modifies the second, as also in the terms aircraft, beehive, landmark, lifeline, network, and vineyard. "Icebreaker," however, is a compound made up of noun object plus agent noun, itself consisting of verb plus agent suffix, as also in the words bridgebuilder, landowner, metalworker, minelayer, and timekeeper. The next type consists of verb plus object. It is rare in English, Dutch, and German but frequent in French, Spanish, and Italian. The English "pastime" may be compared, for example, with French *passe-temps*, the Spanish *pasatiempo*, and the Italian *passatempo*. From French comes "passport," meaning "pass (*i.e.*, enter) harbour." From Italian comes "portfolio," meaning "carry leaf." Other words of this type are daredevil, scapegrace, and scarecrow. As for the "blackbird" type, consisting of attributive adjective plus noun, it occurs frequently, as in the terms bluebell, grandson, shorthand, and wildfire. The next type, composed of object noun and a present participle, as in the terms fact-finding, heart-rending (German *herzzerreissend*), life-giving (German *lebenspendend*), painstaking, and time-consuming, occurs rarely. The last type is seen in barefoot, bluebeard, hunchback, leatherneck, redbreast, and scatterbrain.

Back-formations and blends. Back-formations and blends are becoming increasingly popular. Back-formation is the reverse of affixation, being the analogical creation of a new word from an existing word falsely assumed to be its derivative. For example, the verb "to edit" has been formed from the noun "editor" on the reverse analogy of the noun "actor" from "to act," and similarly the verbs automate, bulldoze, commute, escalate, liaise, loaf, sightsee, and televise are backformed from the nouns automation, bulldozer, commuter, escalation, liaison, loafer, sightseer, and television. From the single noun "procession" are backformed two verbs with different stresses and meanings: procéss, "to walk in procession," and prócess, "to subject food (and other material) to a special operation."

Two types of blends

Blends fall into two groups: (1) coalescences, such as "bash" from "bang" and "smash"; and (2) telescoped forms, called portmanteau words, such as "motorcade" from "motor cavalcade." In the first group are the words clash, from clack and crash, and geep, offspring of goat and sheep. To the second group belong dormobiles, or dormitory automobiles, and slurbs, or slum suburbs. A travel monologue becomes a travelogue and a telegram sent by cable a cablegram. Aviation electronics becomes avionics; biology electronics, bionics; and nuclear electronics, nucleonics. In cablese a question mark is a quark; in computerese a binary unit is a bit. In astrophysics a quasistellar source of radio energy becomes a quasar, and a pulsating star becomes a pulsar.

Simple shortenings, such as "ad" for "advertisement," have risen in status. They are listed in dictionaries side by side with their full forms. Among such fashionable abbreviations are exam, gym, lab, lib, op, spec, sub, tech, veg, and vet. Compound shortenings, after the pattern of Russian *agitprop* for *agitatsiya propaganda*, are also becoming fashionable. Initial syllables are joined as in the words Fortran, for formula (computer) translation; mascon, for massive (lunar) concentration; and Tacomsat, for Tactical Communications Satellite.

Syntax. Sentences can be classified as (1) simple, containing one clause and predication: "John knows this country"; (2) multiple or compound, containing two or more coordinate clauses: "John has been here before, and he knows this country"; and (3) complex, containing one or more main clauses and one or more subordinate clauses: "John, who has been here before, knows this country" or "Because he has been here before, John knows this country." Simple, declarative, affirmative sentences have two main patterns with five subsidiary patterns within each. Verb and complement together

form the predicate. "Complement" is here used to cover both the complement and the object of traditional grammarians (see Table 1).

Table 1: Simple Sentences—First Pattern

subject	verb	complement
1. John	knows	this country
2. Science	is	organized knowledge
3. Elizabeth	becomes	queen
4. The captain	falls	sick
5. Nothing	passes	unobserved

In (1) the complement is the direct object of a transitive verb; in (2) it is a predicative nominal group forming the second component of an equation linked to the first part by the meaningless copula is; in (3) it is a predicative noun linked with the subject by the meaningful copula becomes; in (4) it is a predicative adjective; and in (5) it is a predicative past participle.

Table 2: Simple Sentences—Second Pattern

subject	verb	inner complement	outer complement
6. John	gives	Mary	a ring
7. The sailors	make	John	captain
8. You	have kept	your record	clean
9. The driver	finds	the road	flooded
10. We	want	you	to know

In Table 2 each sentence contains four components: subject, verb, and two complements, first and second, or inner and outer. In (6) inner and outer complements consist of indirect object (without preposition) followed by direct object; in (7) these complements are direct object and appositive noun; in (8) direct object and predicative adjective; in (9) direct object and predicative past participle; in (10) direct object and predicative infinitive.

One can seldom change the word order in these 10 sentences without doing something else—adding or subtracting a word, changing the meaning. There is no better way of appreciating the importance of word position than by scrutinizing the 10 frames illustrated. If, for instance, in (6) one reverses inner and outer complements, one adds "to" and says, "John gives a ring to Mary"; one does not say "John gives a ring Mary." Some verbs, such as "explain" and "say," never omit the preposition "to" before the indirect object: "John's father explained the details to his son." "He said many things to him." If, in (10), the inner and outer complements are reversed (*e.g.*, "We want to know you"), the meaning is changed as well as the structure.

Positions of adjectives

Apart from these fundamental rules of word order, the principles governing the positions of adjectives, adverbs, and prepositions call for brief comment. For attributive adjectives the rule is simple: single words regularly precede the noun, and word groups follow—*e.g.*, "an unforgettable experience" but "an experience never to be forgotten." There is a growing tendency, however, to abandon this principle, to switch groups to front position, and to say "a never to be forgotten experience." In the ordering of multiple epithets, on the other hand, some new principles are seen to be slowly emerging. Attributes denoting permanent qualities stand nearest their head nouns: "long, white beard," "six-lane elevated freeway." The order in multiple attribution tends to be as follows: determiner; quantifier; adjective of quality; adjective of size, shape, or texture; adjective of colour or material; noun adjunct (if any); head noun. Examples include: "that one solid, round, oak dining table," "these many fine, large, black race horses," "those countless memorable, long, bright summer evenings."

Adverbs are more mobile than adjectives. Nevertheless, some tentative principles seem to be at work. Adverbs of frequency tend to come immediately after the substantive verb ("You are often late"), before other verbs ("You never know"), and between auxiliaries and full verbs ("You can never tell"). In this last instance, however, American differs from British usage. Most Americans would place the adverb before the auxiliary and say "You never can tell." (In the title of his play of that name, first performed in 1899, George Bernard Shaw avowedly followed American usage.) Adverbs of time usually occur at the beginning or end of a sentence, seldom in the middle. Particular expressions normally precede more general ones: "Neil Armstrong set foot on the Moon at 4 o'clock in the morning on July 21, 1969." An adverb of place or direction follows a verb with which it is semantically bound: "We arrived home after dark." Other adverbs normally take end positions in the order of manner, place, and time: "Senator Smith summed it all up most adroitly [manner] in Congress [place] last night [time]."

In spite of its etymology (Latin *prae-positio* "before placing"), a preposition may sometimes follow the noun it governs, as in "all the world over," "the clock round," and "the whole place through." "This seems a good place to live in" seems more natural to most speakers than "This seems a good place in which to live." "Have you anything to open this can with?" is now more common than "Have you anything with which to open this can?"

The above are principles rather than rules, and in the end it must be agreed that English syntax lacks regimentation. Its structural laxity makes English an easy language to speak badly. It also makes English prone to ambiguity. "When walking snipe always approach up wind," a shooting manual directs. The writer intends the reader to understand, "When you are walking to flush snipe always approach them up against the wind." "John kept the car in the garage" can mean either (1) "John retained that car you see in the garage, and sold his other one" or (2) "John housed the car in the garage, and not elsewhere." "Flying planes can be dangerous" is ambiguous because it may mean either (1) "Planes that fly can be dangerous" or (2) "It is dangerous to fly planes."

Two ways in which "John gives Mary a ring" can be stated in the passive are: (1) "A ring is given to Mary by John" and (2) "Mary is given a ring by John." Concerning this same action, four types of question can be formulated: (1) "Who gives Mary a ring?" The information sought is the identity of the giver. (2) "Does John give Mary a ring?" The question may be answered by "yes" or "no." (3) "John gives Mary a ring, doesn't he?" Confirmation is sought of the questioner's belief that John does in fact give Mary a ring. (4) "John gives Mary a ring?" This form, differing from the declarative statement only by the question mark in writing, or by rising intonation in speech, calls, like sentences (2) and (3), for a "yes" or "no" answer but suggests doubt on the part of the questioner that the action is taking place.

Origins of English words

Vocabulary. The vocabulary of Modern English is approximately half Germanic (Old English and Scandinavian) and half Italic or Romance (French and Latin), with copious and increasing importations from Greek in science and technology and with considerable borrowings from Dutch, Low German, Italian, Spanish, German, Arabic, and many other languages. Names of basic concepts and things come from Old English or Anglo-Saxon: heaven and earth, love and hate, life and death, beginning and end, day and night, month and year, heat and cold, way and path, meadow and stream. Cardinal numerals come from Old English, as do all the ordinal numerals except "second" (Old English *other*, which still retains its older meaning in "every other day"). "Second" comes from Latin *secundus* "following," through French *second*, related to Latin *sequi* "to follow," as in English "sequence." From Old English come all the personal pronouns (except "they," "their," and "them," which are from Scandinavian), the auxiliary verbs (except the marginal "used," which is from French), most simple prepositions, and all conjunctions.

Numerous nouns would be identical whether they came from Old English or Scandinavian: father, mother, brother (but not sister); man, wife; ground, land, tree, grass; summer, winter; cliff, dale. Many verbs would also be identical, especially monosyllabic verbs—bring, come,

get, hear, meet, see, set, sit, spin, stand, think. The same is true of the adjectives full and wise; the colour names gray, green, and white; the disjunctive possessives mine and thine (but not ours and yours); the terms north and west (but not south and east); and the prepositions over and under. Just a few English and Scandinavian doublets coexist in current speech: no and nay, yea and ay, from and fro, rear (*i.e.*, to bring up) and raise, shirt and skirt (both related to the adjective short), less and loose. From Scandinavian, "law" was borrowed early, whence "by-law," meaning "village law," and "outlaw," meaning "man outside the law." "Husband" (*hus-bondi*) meant "householder," whether single or married, whereas "fellow" (*fe-lagi*) meant one who "lays fee" or shares property with another, and so "partner, shareholder." From Scandinavian come the common nouns axle (tree), band, birth, bloom, crook, dirt, egg, gait, gap, girth, knife, loan, race, rift, root, score, seat, skill, sky, snare, thrift, and window; the adjectives awkward, flat, happy, ill, loose, rotten, rugged, sly, tight, ugly, weak, and wrong; and many verbs, including call, cast, clasp, clip, crave, die, droop, drown, flit, gape, gasp, glitter, lift, rake, rid, scare, scowl, skulk, snub, sprint, thrive, thrust, and want.

Borrowing from French

The debt of the English language to France is large. The terms president, representative, legislature, congress, constitution, and parliament are all French. So, too, are duke, marquis, viscount, and baron; but king, queen, lord, lady, earl, and knight are English. City, village, court, palace, manor, mansion, residence, and domicile are French; but town, borough, hall, house, bower, room, and home are English. Comparison between English and French synonyms shows that the former are more human and concrete, the latter more intellectual and abstract; *e.g.*, the terms freedom and liberty, friendship and amity, hatred and enmity, love and affection, likelihood and probability, truth and veracity, lying and mendacity. The superiority of French cooking is duly recognized by the adoption of such culinary terms as boil, broil, fry, grill, roast, souse, and toast. "Breakfast" is English, but "dinner" and "supper" are French. "Hunt" is English, but "chase," "quarry," "scent," and "track" are French. Craftsmen bear names of English origin: baker, builder, fisher (man), hedger, miller, shepherd, shoemaker, wainwright, and weaver, or webber. Names of skilled artisans, however, are French: carpenter, draper, haberdasher, joiner, mason, painter, plumber, and tailor. Many terms relating to dress and fashion, cuisine and viniculture, politics and diplomacy, drama and literature, art and ballet come from France.

In the spheres of science and technology many terms come from Classical Greek through French or directly from Greek. Pioneers in research and development now regard Greek as a kind of inexhaustible quarry from which they can draw linguistic material at will. By prefixing the Greek adverb *tēle* "far away, distant" to the existing compound photography, "light writing," they create the precise term "telephotography" to denote the photographing of distant objects by means of a special lens. By inserting the prefix *micro-* "small" into this same compound, they make the new term "photomicrography," denoting the electronic photographing of bacteria and viruses. Such neo-Hellenic derivatives would probably have been unintelligible to Plato and Aristotle.

Greek borrowings

Many Greek compounds and derivatives have Latin equivalents with slight or considerable differentiations in meaning (see Table 3).

At first sight it might appear that some of these equivalents, such as "metamorphosis" and "transformation," are sufficiently synonymous to make one or the other redundant. In fact, however, "metamorphosis" is more technical and therefore more restricted than "transformation." In mythology it signifies a magical shape changing; in nature it denotes a postembryonic development such as that of a tadpole into a frog, a cocoon into a silkworm, or a chrysalis into a butterfly. Transformation, on the other hand, means any kind of change from one state to another.

Ever since the 12th century, when merchants from the Netherlands made homes in East Anglia, Dutch words have infiltrated into Midland speech. For centuries a form of Low German was used by seafaring men in North Sea ports. Old nautical terms still in use include buoy, deck, dock, freebooter, hoist, leak, pump, skipper, and yacht. The Dutch in New Amsterdam (later New York) and adjacent settlements gave the words boss, cookie, dope, snoop, and waffle to American speech. The Dutch in Cape Province gave the terms apartheid, commandeer, commando, spoor, and trek to South African speech.

Table 3: Equivalent Compounds and Derivatives*

from the Greek	from the Latin
Nouns	
dys-troph-y	mal-nutr-it-ion
hypo-sta-sis	sub-stan-ce
hypo-the-sis	sup-pos-it-ion
meta-morph-o-sis	trans-form-at-ion

syn-chron-ic	con-temp-or-ary

*The italicized suffixes *-al*, *-escent*, and *-ous*, attached to some of the Greek adjectives, are of Latin origin.

German contributions

The contribution of High German has been on a different level. In the 18th and 19th centuries it lay in technicalities of geology and mineralogy and in abstractions relating to literature, philosophy, and psychology. In the 20th century this contribution has sometimes been indirect. "Unclear" and "meaningful" echoed German *unklar* and *bedeutungsvoll*, or *sinnvoll*. "Ring road" (a British term applied to roads encircling cities or parts of cities) translated *Ringstrasse;* "round trip," *Rundfahrt;* and "the turn of the century," *die Jahrhundertwende.* The terms "classless society," "inferiority complex," and "wishful thinking" echoed *die klassenlöse Gesellschaft, der Minderwertigkeitskomplex*, and *das Wunschdenken.*

Along with the rest of the Western world, English has accepted Italian as the language of music. The names of voices, parts, performers, instruments, forms of composition, and technical directions are all Italian. Many of the latter—allegro, andante, cantabile, crescendo, diminuendo, legato, maestoso, obbligato, pizzicato, staccato, and vibrato—are also used metaphorically. In architecture, the terms belvedere, corridor, cupola, grotto, pedestal, pergola, piazza, pilaster, and rotunda are accepted; in literature, burlesque, canto, extravaganza, stanza, and many more are used.

From Spanish, English has acquired the words armada, cannibal, cigar, galleon, guerrilla, matador, mosquito, quadroon, tornado, and vanilla, some of these loanwords going back to the 16th century, when sea dogs encountered hidalgos on the high seas. Many names of animals and plants have entered English from indigenous languages through Spanish: "potato" through Spanish *patata* from Taino *batata*, and "tomato" through Spanish *tomate* from Nahuatl *tomatl*. Other words have entered from Latin America by way of Texas, New Mexico, Arizona, and California; *e.g.*, such words as canyon, cigar, estancia, lasso, mustang, pueblo, and rodeo. Some have gathered new connotations: bonanza, originally de-

noting "goodness," came through miners' slang to mean "spectacular windfall, prosperity"; mañana, "tomorrow," acquired an undertone of mysterious unpredictability.

From Arabic through European Spanish, through French from Spanish, through Latin, or occasionally through Greek, English has obtained the terms alchemy, alcohol, alembic, algebra, alkali, almanac, arsenal, assassin, attar, azimuth, cipher, elixir, mosque, nadir, naphtha, sugar, syrup, zenith, and zero. From Egyptian Arabic, English has recently borrowed the term loofah (also spelled luffa). From Hebrew, directly or by way of Vulgate Latin, come the terms amen, cherub, hallelujah, manna, messiah, pharisee, rabbi, sabbath, and seraph; jubilee, leviathan, and shibboleth; and, more recently, kosher, and kibbutz.

English has freely adopted and adapted words from many other languages, acquiring them sometimes directly and sometimes by devious routes. Each word has its own history. The following lists indicate the origins of a number of English words: Welsh—flannel, coracle, cromlech, eisteddfod; Cornish—gull, brill, dolmen; Gaelic and Irish—shamrock, brogue, leprechaun, ogham, Tory, galore, blarney, hooligan, clan, claymore, bog, plaid, slogan, sporran, cairn, whisky, pibroch; Breton—menhir, penguin; Norwegian—ski, ombudsman; Finnish—sauna; Russian—kvass, ruble, tsar, verst, mammoth, ukase, astrakhan, vodka, samovar, tundra (from Lapp), troika, pogrom, duma, soviet, bolshevik, intelligentsia (from Latin through Polish), borscht, balalaika, sputnik, soyuz, salyut, lunokhod; Polish—mazurka; Czech—robot; Hungarian—goulash, paprika; Portuguese—marmalade, flamingo, molasses, veranda, port (wine), dodo; Basque—bizarre; Turkish—janissary, turban, coffee, kiosk, caviar, pasha, odalisque, fez, bosh; Hindi—nabob, guru, sahib, maharajah, mahatma, pundit, punch (drink), juggernaut, cushy, jungle, thug, cheetah, shampoo, chit, dungaree, pucka, gymkhana, mantra, loot, pajamas, dinghy, polo; Persian—paradise, divan, purdah, lilac, bazaar, shah, caravan, chess, salamander, taffeta, shawl, khaki; Tamil—pariah, curry, catamaran, mulligatawny; Chinese—tea (Amoy), sampan; Japanese—shogun, kimono, mikado, tycoon, hara-kiri, gobang, judo, jujitsu, bushido, samurai, banzai, tsunami, satsuma, No (the dance drama), karate, Kabuki; Malay—ketchup, sago, bamboo, junk, amuck, orangutan, compound (fenced area), raffia; Polynesian—taboo, tattoo; Hawaiian—ukulele; African languages—chimpanzee, goober, mumbo jumbo, voodoo; Eskimo—kayak, igloo, anorak, mukluk; Algonkian—totem; Nahuatl—mescal; languages of the Caribbean—hammock, hurricane, tobacco, maize, iguana; Aboriginal Australian—kangaroo, corroboree, wallaby, wombat, boomerang, paramatta, budgerigar.

The alphabet

Orthography. The Latin alphabet originally had 20 letters, the present English alphabet minus *J*, *K*, *V*, *W*, *Y*, and *Z*. The Romans themselves added *K* for use in abbreviations and *Y* and *Z* in words transcribed from Greek. After its adoption by the English, this 23-letter alphabet developed *W* as a ligatured doubling of *U* and later *J* and *V* as consonantal variants of *I* and *U*. The resultant alphabet of 26 letters has both uppercase, or capital, and lowercase, or small, letters.

English spelling is based for the most part on that of the 15th century, but pronunciation has changed considerably since then, especially that of long vowels and diphthongs. The extensive change in the pronunciation of vowels, known as the Great Vowel Shift, affected all of Geoffrey Chaucer's seven long vowels, and for centuries spelling remained untidy. If the meaning of the message was clear, the spelling of individual words seemed unimportant. In the 17th century during the English Civil War, compositors adopted fixed spellings for practical reasons, and in the order-loving 18th century uniformity became more and more fashionable. Since Samuel Johnson's *Dictionary of the English Language* (1755), orthography has remained fairly stable. Numerous tacit changes, such as "music" for "musick" (*c.* 1880) and "fantasy" for "phantasy" (*c.* 1920), have been accepted, but spelling has nevertheless continued to be in part unphonetic. Attempts have been made at reform. Indeed, every century has had its reformers since the 13th, when an Augustinian canon named Orm devised his own method of differentiating short vowels from long by doubling the succeeding consonants or, when this was not feasible, by marking short vowels with a superimposed breve mark (◡). William Caxton, who set up his wooden printing press at Westminster in 1476, was much concerned with spelling problems throughout his working life. Noah Webster produced his *Spelling Book*, in 1783, as a precursor to the first edition (1828) of his *American Dictionary of the English Language*. The 20th century has produced many zealous reformers. Three systems, supplementary to traditional spelling, are actually in use for different purposes: (1) the Initial Teaching (Augmented Roman) Alphabet (ITA) of 44 letters used by educationists in the teaching of children under seven; (2) the Shaw alphabet of 48 letters, designed in implementation of the will of George Bernard Shaw; and (3) the International Phonetic Alphabet (IPA), constructed on the basis of one symbol for one individual sound and used by many trained linguists. Countless other systems have been worked out from time to time, of which R.E. Zachrisson's "Anglic" (1930) and Axel Wijk's *Regularized English* (1959) may be the best.

Obstacles to spelling reform

Meanwhile, the great publishing houses continue unperturbed because drastic reform remains impracticable, undesirable, and unlikely. This is because there is no longer one criterion of correct pronunciation but several standards throughout the world; regional standards are themselves not static, but changing with each new generation; and, if spelling were changed drastically, all the books in English in the world's public and private libraries would become inaccessible to readers without special study.

HISTORICAL BACKGROUND

Among highlights in the history of the English language, the following stand out most clearly: the settlement in Britain of Jutes, Saxons, and Angles in the 5th and 6th centuries; the arrival of St. Augustine in 597 and the subsequent conversion of England to Latin Christianity; the Viking invasions of the 9th century; the Norman Conquest of 1066; the Statute of Pleading in 1362 (this required that court proceedings be conducted in English); the setting up of Caxton's printing press at Westminster in 1476; the full flowering of the Renaissance in the 16th century; the publishing of the King James Bible in 1611; the completion of Johnson's *Dictionary* of 1755; and the expansion to North America and South Africa in the 17th century and to India, Australia, and New Zealand in the 18th.

Old English. The Jutes, Angles, and Saxons lived in Jutland, Schleswig, and Holstein, respectively, before settling in Britain. According to the Venerable Bede, the first historian of the English people, the first Jutes, Hengist and Horsa, landed at Ebbsfleet in the Isle of Thanet in 449; and the Jutes later settled in Kent, southern Hampshire, and the Isle of Wight. The Saxons occupied the rest of England south of the Thames, as well as modern Middlesex and Essex. The Angles eventually took the remainder of England as far north as the Firth of Forth, including the future Edinburgh and the Scottish Lowlands. In both Latin and Common Germanic the Angles' name was Angli, later mutated in Old English to Engle (nominative) and Engla (genitive). "Engla land" designated the home of all three tribes collectively, and both King Alfred (known as Alfred the Great) and Abbot Aelfric, author and grammarian, subsequently referred to their speech as Englisc. Nevertheless, all the evidence indicates that Jutes, Angles, and Saxons retained their distinctive dialects.

Four Old English dialects

The River Humber was an important boundary, and the Anglian-speaking region developed two speech groups: to the north of the river, Northumbrian, and, to the south, Southumbrian, or Mercian. There were thus four dialects: Northumbrian, Mercian, West Saxon, and Kentish (see Figure 1). In the 8th century, Northumbrian led in literature and culture, but that leadership was destroyed by the Viking invaders, who sacked Lindisfarne,

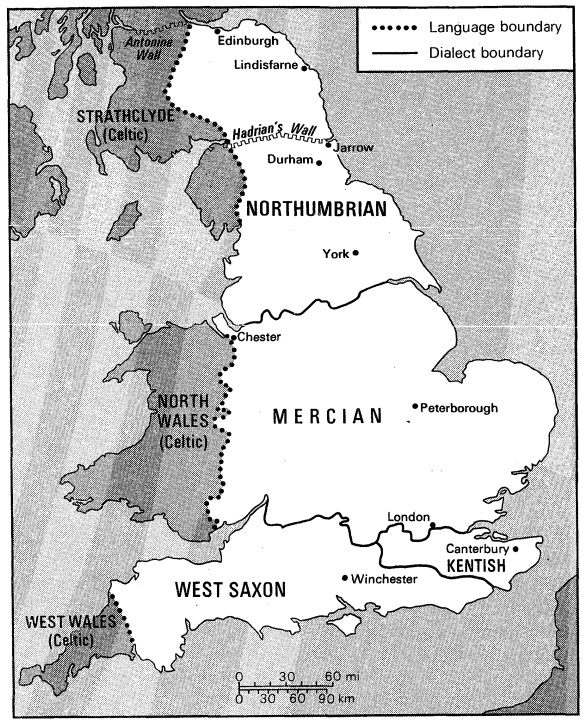

Figure 1: Old English dialects.

an island near the Northumbrian mainland, in 793. They landed in strength in 865. The first raiders were Danes, but they were later joined by Norwegians from Ireland and the Western Isles who settled in modern Cumberland, Westmorland, northwest Yorkshire, Lancashire, north Cheshire, and the Isle of Man. In the 9th century, as a result of the Norwegian invasions, cultural leadership passed from Northumbria to Wessex. During King Alfred's reign, in the last three decades of the 9th century, Winchester became the chief centre of learning. There the Parker Chronicle (a manuscript of the Anglo-Saxon Chronicle) was written; there the Latin works of the priest and historian Paulus Orosius, St. Augustine, St. Gregory, and the Venerable Bede were translated; and there the native poetry of Northumbria and Mercia was transcribed into the West Saxon dialect. This resulted in West Saxon's becoming "standard Old English"; and later, when Aelfric (*c.* 955–*c.* 1010) wrote his lucid and mature prose at Winchester, Cerne Abbas, and Eynsham, the hegemony of Wessex was strengthened.

In standard Old English, adjectives were inflected as well as nouns, pronouns, and verbs. Nouns were inflected for four cases (nominative, genitive, dative, and accusative) in singular and plural. Five nouns of first kinship—*faeder*, *mōdor*, *brōthor*, *sweostor*, and *dohtor* ("father," "mother," "brother," "sister," and "daughter," respectively)—had their own set of inflections. There were 25 nouns such as *mon*, *men* ("man," "men") with mutated, or umlauted, stems. Adjectives had strong and weak declensions, the strong showing a mixture of noun and pronoun endings and the weak following the pattern of weak nouns. Personal, possessive, demonstrative, interrogative, indefinite, and relative pronouns had full inflections. The pronouns of the 1st and 2nd persons still had distinctive dual forms:

iċ	"I"	*wit*	"we two"	*wē*	"we"
thū (*þū*)	"thou"	*ġit*	"you two"	*ġē*	"you"

There were two demonstratives: *sē*, *sēo*, *thaet*, meaning "that," and *thes*, *thēos*, *this*, meaning "this," but no articles, the definite article being expressed by use of the demonstrative for "that" or not expressed at all. Thus, "the good man" was *sē gōda mon* or plain *gōd mon*. The function of the indefinite article was performed by the numeral *ān* "one" in *ān mon* "a man," by the adjective–pronoun *sum* in *sum mon* "a (certain) man," or not expressed, as in *thū eart gōd mon* "you are a good man."

Verbs had two tenses only (present–future and past), three moods (indicative, subjunctive, and imperative), two numbers (singular and plural), and three persons (1st, 2nd, and 3rd). There were two classes of verb stems. (A verb stem is that part of a verb to which inflectional changes—changes indicating tense, mood, number, etc.—are added.) One type of verb stem, called vocalic because an internal vowel shows variations, is exemplified by the verb for "sing": *singan*, *singth*, *sang*, *sungon*, *gesungen*. The word for "deem" is an example of the other, called consonantal: *dēman*, *dēmth*, *dēmde*, *dēmdon*, *gedēmed*. Such verbs are called strong and weak, respectively. Inflection of verbs

All new verbs, whether derived from existing verbs or from nouns, belonged to the consonantal type. Some verbs of great frequency (antecedents of the modern words "be," "shall," "will," "do," "go," "can," "may," and so on) had their own peculiar patterns of inflections.

Grammatical gender persisted throughout the Old English period. Just as Germans now say *der Fuss*, *die Hand*, and *das Auge* (masculine, feminine, and neuter terms for "the foot," "the hand," and "the eye"), so, for these same structures, Aelfric said *sē fōt*, *sēo hond*, and *thaet ēaġe*, also masculine, feminine, and neuter. The three words for "woman," *wīfmon*, *cwene*, and *wīf*, were masculine, feminine, and neuter, respectively. *Hors* "horse," *sċēap* "sheep," and *maeġden* "maiden" were all neuter. *Eorthe* "earth" was feminine, but *lond* "land" was neuter. *Sunne* "sun" was feminine, but *mōna* "moon" was masculine. This simplification of grammatical gender resulted from the fact that the gender of Old English substantives was not always indicated by the ending but rather by the terminations of the adjectives and demonstrative pronouns used with the substantives. When these endings were lost, all outward marks of gender disappeared with them. Thus, the weakening of inflections and loss of gender occurred together. In the North, where inflections weakened earlier, the marks of gender likewise disappeared first. They survived in the South as late as the 14th century.

Because of the greater use of inflections in Old English, word order was freer than today. The sequence of subject, verb, and complement was normal, but when there were outer and inner complements the second was put in the dative case after *tō*: *Sē biscop hālgode Ēadrēd tō cyninge* "The bishop consecrated Edred king." After an introductory adverb or adverbial phrase the verb generally took second place as in modern German: *Nū bydde iċ ān thing* "Now I ask [literally, "ask I"] one thing"; *Thȳ ilcan gēare gesette Aelfrēd cyning Lundenburg* "In that same year Alfred the king occupied London." Impersonal verbs had no subject expressed. Infinitives constructed with auxiliary verbs were placed at the ends of clauses or sentences: *Hīe ne dorston forth bī thǣre ēa siglan* "They dared not sail beyond that river" (*siglan* is the infinitive); *Iċ wolde thās lytlan bōc āwendan* "I wanted to translate this little book" (*āwendan* is the infinitive). The verb usually came last in a dependent clause—*e.g.*, *āwrītan wile* in *gif hwā thās bōc āwrītan wile* (*gerihte hē hīe be thǣre bysene*) "If anyone wants to copy this book (let him correct his copy by the original)." Prepositions (or postpositions) frequently followed their objects. Negation was often repeated for emphasis.

Middle English. One result of the Norman Conquest of 1066 was to place all four Old English dialects more or less on a level. West Saxon lost its supremacy and the centre of culture and learning gradually shifted from Winchester to London. The old Northumbrian dialect became divided into Scottish and Northern, although little is known of either of these divisions before the end of the 13th century (Figure 2). The old Mercian dialect was split into East and West Midland. West Saxon became slightly diminished in area and was more appropriately named the South Western dialect. The Kentish dialect was considerably extended and was called South Eastern accordingly. All five Middle English dialects (Northern, West Midland, East Midland, South Western, and South Eastern) went their own ways and developed their own characteristics. The so-called Katherine Group of writ-

ings (1180–1210), associated with Hereford, a town not far from the Welsh border, adhered most closely to native traditions, and there is something to be said for regarding this West Midland dialect, least disturbed by French and Scandinavian intrusions, as a kind of Standard English in the High Middle Ages.

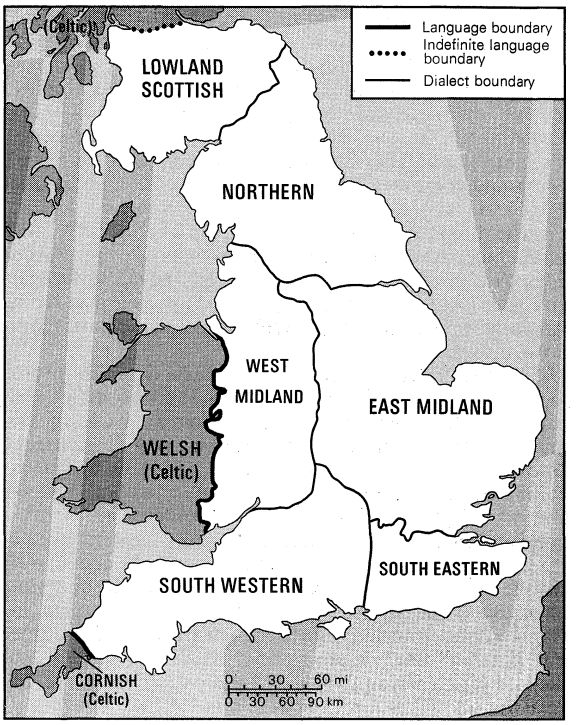

Figure 2: Middle English dialects.

Another outcome of the Norman Conquest was to change the writing of English from the clear and easily readable insular hand of Irish origin to the delicate Carolingian script then in use on the Continent. With the change in appearance came a change in spelling. Norman scribes wrote Old English *y* as *u*, *ȳ* as *ui*, *ū* as *ou* (*ow* when final). Thus, *mycel* ("much") appeared as *muchel*, *fȳr* ("fire") as *fuir*, *hūs* ("house") as *hous*, and *hū* ("how") as *how*. For the sake of clarity (*i.e.*, legibility) *u* was often written *o* before and after *m*, *n*, *u*, *v*, and *w*; and *i* was sometimes written *y* before and after *m* and *n*. So *sunu* ("son") appeared as *sone* and *him* ("him") as *hym*. Old English *cw* was changed to *qu*; *hw* to *wh*, *qu*, or *quh*; *ċ* to *ch* or *tch*; *sċ* to *sh*; *-ċġ-* to *-gg-*; and *-ht* to *ght*. So Old English *cwēn* appeared as *queen*; *hwaet* as *what*, *quat*, or *quhat*; *dīċ* as *ditch*; *sċip* as *ship*; *secge* as *segge*; and *miht* as *might*.

Norman changes in spelling

For the first century after the Conquest, most loanwords came from Normandy and Picardy, but with the extension south to the Pyrenees of the Angevin empire of Henry II (reigned 1154–89), other dialects, especially Central French, or Francien, contributed to the speech of the aristocracy. As a result, Modern English acquired the forms canal, catch, leal, real, reward, wage, warden, and warrant from Norman French side by side with the corresponding forms channel, chase, loyal, royal, regard, gage, guardian, and guarantee, from Francien. King John lost Normandy in 1204. With the increasing power of the Capetian kings of Paris, Francien gradually predominated. Meanwhile, Latin stood intact as the language of learning. For three centuries, therefore, the literature of England was trilingual. *Ancrene Riwle*, for instance, a guide or rule (*riwle*) of rare quality for recluses or anchorites (*ancren*), was disseminated in all three languages.

The sounds of the native speech changed slowly. Even in late Old English short vowels had been lengthened before *ld*, *rd*, *mb*, and *nd*, and long vowels had been shortened before all other consonant groups and before double consonants. In early Middle English short vowels of whatever origin were lengthened in the open stressed syllables of disyllabic words. An open syllable is one ending in a vowel. Both syllables in Old English *nama* "name," *mete* "meat, food," *nosu* "nose," *wicu* "week," and *duru* "door" were short, and the first syllables, being stressed, were lengthened to *nāme*, *mēte*, *nōse*, *wēke*, and *dōre* in the 13th and 14th centuries. A similar change occurred in 4th-century Latin, in 13th-century German, and at different times in other languages. The popular notion has arisen that final mute *-e* in English makes a preceding vowel long; in fact, it is the lengthening of the vowel that has caused *e* to be lost in pronunciation. On the other hand, Old English long vowels were shortened in the first syllables of trisyllabic words, even when those syllables were open; *e.g.*, *hāligdaeg* "holy day," *ārende* "message, errand," *crīstendōm* "Christianity," and *sūtherne* "southern," became *hŏliday* (Northern *hăliday*), *ĕrrende*, *chrĭstendom*, and *sŭtherne*. This principle still operates in current English. Compare, for example, trisyllabic derivatives such as the words chastity, criminal, fabulous, gradual, gravity, linear, national, ominous, sanity, and tabulate with the simple nouns and adjectives chaste, crime, fable, grade, grave, line, nation, omen, sane, and table.

There were significant variations in verb inflections in the Northern, Midland, and Southern dialects as shown in Table 4. The Northern infinitive was already one syllable (*sing* rather than the Old English *singan*), whereas the past participle *-en* inflection of Old English was strictly kept. These apparently contradictory features can be attributed entirely to Scandinavian, in which the final *-n* of the infinitive was lost early in *singa*, and the final *-n* of the past participle was doubled in *sunginn*. The Northern unmutated present participle in *-and* was also of Scandinavian origin. Old English mutated *-ende* (German *-end*) in the present participle had already become *-inde* in late West Saxon (Southern in the accompanying table), and it was this Southern *-inde* that blended with the *-ing* suffix (German *-ung*) of nouns of action that had already become near-gerunds in such compound nouns as *athswering* "oath swearing" and *writingfether* "writing feather, pen." This blending of present participle and gerund was further helped by the fact that Anglo-Norman and French *-ant* was itself a coalescence of Latin present participles in *-antem*, *-entem*, and Latin gerunds in *-andum*, *-endum*. The Northern 2nd person singular *singis* was inherited unchanged from Common Germanic. The final *t* sound in Midland *-est* and Southern *-st* was excrescent, comparable with the final *t* in modern "amidst" and "amongst" from older *amiddes* and *amonges*. The Northern 3rd person singular *singis* had a quite different origin. Like the *singis* of the plural, it resulted almost casually from an inadvertent retraction of the tongue in enunciation from an interdental *-th* sound to postdental *-s*. Today the form "singeth" survives as a poetic archaism. Shakespeare used both *-eth* and *-s* endings ("It [mercy] blesseth him that gives and him that takes," *The Merchant of Venice*). The Midland present plural inflection *-en* was taken from the subjunctive. The past participle prefix *y-* developed from the Old English perfective prefix *ge-*.

Table 4: Variations in Verb Inflections

	Northern	Midland	Southern
Infinitive	sing	singe(n)	singen
Present participle	singand	singende	singinde
Present singular			
1st person	singe	singe	singe
2nd person	singis	singes(t)	singst
3rd person	singis	singeth-es	singeth
Present plural	singis	singen	singeth
Past participle	sungen	(y)sunge(n)	ysunge

Chaucer's language

Chaucer, who was born and died in London, spoke a dialect that was basically East Midland. Compared with his contemporaries, he was remarkably modern in his use of language. He was in his early 20s when the Statute of Pleading (1362) was passed, by the terms of which all

court proceedings were henceforth to be conducted in English, though "enrolled in Latin." Chaucer himself used four languages; he read Latin (Classical and Medieval) and spoke French and Italian on his travels. For his own literary work he deliberately chose English.

Transition from Middle English to Early Modern English. The death of Chaucer at the close of the century (1400) marked the beginning of the period of transition from Middle English to the Early Modern English stage. The Early Modern English period is regarded by many scholars as beginning in about 1500 and terminating with the return of the monarchy (John Dryden's *Astraea Redux*) in 1660. The 15th century witnessed three outstanding developments: the rise of London English, the invention of printing, and the spread of the new learning.

The speech of London

Although the population of London in 1400 was only about 40,000, it was by far the largest city in England. York came second, followed by Bristol, Coventry, Plymouth, and Norwich. The Midlands and East Anglia, the most densely peopled parts of England, supplied London with streams of young immigrants. The speech of the capital was mixed, and it was changing. The seven long vowels of Chaucer's speech had already begun to shift. Incipient diphthongization of high front /i:/ (the *ee* sound in "meet") and high back /u:/ (as in "fool") led to instability in the other five long vowels. (Symbols within slash marks are taken from the International Phonetic Alphabet.) This remarkable event, known as the Great English Vowel Shift, changed the whole vowel system of London English. As /i:/ and /u:/ became diphthongized to /ai/ (as in "bide") and /au/ (as in "house") respectively, so the next highest vowels, /e:/ (this sound can be heard in the first part of the diphthong in "name") and /o:/ (a sound that can be heard in the first part of the diphthong in "home"), moved up to take their places, and so on. The whole process is summarized in Table 5.

Table 5: Vowel Shifts in London English

Chaucer's spelling	Chaucer's pronunciation*	Shakespeare's pronunciation	present pronunciation*	present spelling
lyf	li:f	leif	laif	life
deed	de:d	di:d	di:d	deed
deel	de:l	de:l	di:l	deal
name	na:mə	nɛ:m	neim	name
hoom	hɔ:m	ho:m	houm	home
mone	mo:n	mu:n	mu:n	moon
hous	hu:s	hous	haus	house

*Expressed in the International Phonetic Alphabet.

Every one of the sounds appearing in this table can still be heard somewhere in living English dialects.

When Caxton started printing at Westminster in the late summer of 1476, he was painfully aware of the uncertain state of the English language. In his prologues and epilogues to his translations he made some revealing observations on the problems that he had encountered as translator and editor. At this time, sentence structures were being gradually modified, but many remained untidy. For the first time, nonprofessional scribes, including women, were writing at length.

The revival of classical learning was one aspect of that Renaissance, or spiritual rebirth, that arose in Italy and spread to France and England. It evoked a new interest in Greek on the part of learned men such as William Grocyn and Thomas Linacre, Sir Thomas More and Desiderius Erasmus. John Colet, dean of St. Paul's in the first quarter of the 16th century, startled his congregation by expounding the Pauline Epistles of the New Testament as living letters. The deans who had preceded him had known no Greek, because they had found in Latin all that they required. Only a few medieval churchmen, such as Robert Grosseteste, bishop of Lincoln, and the Franciscan Roger Bacon could read Greek with ease. The names of the seven liberal arts of the medieval curricula (the trivium and the quadrivium), it is true, were all Greek—grammar, logic, and rhetoric; arithmetic, geometry, astronomy, and music—but they had come into English by way of French.

Renaissance scholars adopted a liberal attitude to language. They borrowed Latin words through French, or Latin words direct; Greek words through Latin, or Greek words direct. Latin was no longer limited to Church Latin: it embraced all Classical Latin. For a time the whole Latin lexicon became potentially English. Some words, such as consolation and infidel, could have come from either French or Latin. Others, such as the terms abacus, arbitrator, explicit, finis, gratis, imprimis, item, memento, memorandum, neuter, simile, and videlicet, were taken straight from Latin. Words that had already entered the language through French were now borrowed again, so that doublets arose: benison and benediction; blame and blaspheme; chance and cadence; count and compute; dainty and dignity; frail and fragile; poor and pauper; purvey and provide; ray and radius; sever and separate; strait and strict; sure and secure. The Latin adjectives for "kingly" and "lawful" have even given rise to triplets; in the forms real, royal, and regal and leal, loyal, and legal, they were imported first from Anglo-Norman, then from Old French, and last from Latin direct.

After the dawn of the 16th century, English prose moved swiftly toward modernity. In 1525 Lord Berners completed his translation of Jean Froissart's *Chronicle*, and William Tyndale translated the New Testament. One-third of the King James Bible (1611), it has been computed, is worded exactly as Tyndale left it; and between 1525 and 1611 lay the Tudor Golden Age, with its culmination in Shakespeare. Too many writers, to be sure, used "inkhorn terms," newly-coined, ephemeral words, and too many vacillated between Latin and English. Sir Thomas More actually wrote his *Utopia* in Latin. It was translated into French during his lifetime but not into English until 1551, some years after his death. Francis Bacon published *De dignitate et augmentis scientiarum* (*On the Dignity and Advancement of Learning*, an expansion of his earlier *Advancement of Learning*) in Latin in 1623. William Harvey announced his epoch-making discovery of the circulation of the blood in his Latin *De Motu Cordis et Sanguinis in Animalibus* (1628; *On the Motion of the Heart and Blood in Animals*). John Milton composed polemical treatises in the language of Cicero. As Oliver Cromwell's secretary, he corresponded in Latin with foreign states. His younger contemporary Sir Isaac Newton lived long enough to bridge the gap. He wrote his *Principia* (1687) in Latin but his *Opticks* (1704) in English.

Plans to regulate English

Restoration period. With the restoration of the monarchy in 1660, men again looked to France. John Dryden admired the Académie Française and greatly deplored that the English had "not so much as a tolerable dictionary, or a grammar; so that our language is in a manner barbarous" as compared with elegant French. After the passionate controversies of the Civil War, this was an age of cool scientific nationalism. In 1662 the Royal Society of London for the Promotion of Natural Knowledge received its charter. Its first members, much concerned with language, appointed a committee of 22 "to improve the English tongue particularly for philosophic purposes." It included Dryden, the diarist John Evelyn, Bishop Thomas Sprat, and the poet Edmund Waller. Sprat pleaded for "a close, naked, natural way of speaking; positive expressions; clear senses, a native easiness; bringing all things as near the mathematical plainness" as possible. The committee, however, achieved no tangible result, and failed in its attempt to found an authoritative arbiter over the English tongue. A second attempt was made in 1712, when Jonathan Swift addressed an open letter to Robert Harley, earl of Oxford, then Lord Treasurer, making "A Proposal for Correcting, Improving, and Ascertaining [fixing] the English Tongue." This letter received some popular support, but its aims were frustrated by a turn in political fortunes. Queen Anne died in 1714. The Earl of Oxford and his fellow Tories, including Swift, lost power. No organized attempt to found a language academy on French lines has ever been made since.

With Dryden and Swift the English language reached

its full maturity. Their failure to found an academy was partly counterbalanced by Samuel Johnson in his *Dictionary* (published in 1755) and by Robert Lowth in his *Grammar* (published in 1761).

Johnson's *Dictionary*

Age of Johnson. In the making of his *Dictionary*, Johnson took the best conversation of contemporary London and the normal usage of reputable writers after Sir Philip Sidney (1554–86) as his criteria. He exemplified the meanings of words by illustrative quotations. Johnson admitted that "he had flattered himself for a while" with "the prospect of fixing our language" but that thereby "he had indulged expectation which neither reason nor experience could justify." The two-folio work of 1755 was followed in 1756 by a shortened, one-volume version that was widely used far into the 20th century. Revised and enlarged editions of the unabbreviated version were made by Archdeacon Henry John Todd in 1818 and by Robert Gordon Latham in 1866. See also the articles JOHNSON, SAMUEL and DICTIONARY.

It was unfortunate that Joseph Priestley, Robert Lowth, James Buchanan, and other 18th-century grammarians (Priestley was perhaps better known as a scientist and theologian) took a narrower view than Johnson on linguistic growth and development. They spent too much time condemning such current "improprieties" as "I had rather not," "you better go," "between you and I," "it is me," who is this for?", "between four walls," "a third alternative," "the largest of the two," "more perfect," and "quite unique." Without explanatory comment they banned "you was" outright, although it was in widespread use among educated people (on that ground it was later defended by Noah Webster). "You was" had, in fact, taken the place of both "thou wast" and "thou wert" as a useful singular equivalent of the accepted plural "you were."

As the century wore on, grammarians became more numerous and aggressive. They set themselves up as arbiters of correct usage. They compiled manuals that were not only descriptive (stating what people do say) and prescriptive (stating what they should say) but also proscriptive (stating what they should not say). They regarded Latin as a language superior to English and claimed that Latin embodied universally valid canons of logic. This view was well maintained by Lindley Murray, a native of Pennsylvania who settled in England in the very year (1784) of Johnson's death. Murray's *English Grammar* appeared in 1795, became immensely popular, and went into numerous editions. It was followed by an *English Reader* (1799) and an *English Spelling Book* (1804), long-favourite textbooks in both Old and New England.

19th and 20th centuries. In 1857 Richard Chenevix Trench, dean of St. Paul's, lectured to the Philological Society on the theme, "On some Deficiencies in our English Dictionaries." His proposals for a new dictionary were implemented in 1859, when Samuel Taylor Coleridge's grandnephew, Herbert Coleridge, set to work as first editor. He was succeeded by a lawyer named Frederick James Furnivall, who in 1864 founded the Early English Text Society with a view to making all the earlier literature available to historical lexicographers in competent editions. Furnivall was subsequently succeeded as editor by James A.H. Murray, who published the first fascicle of *A New English Dictionary on Historical Principles* in 1884. Later Murray was joined successively by three editors: Henry Bradley, William Alexander Craigie, and Charles Talbut Onions. Aside from its *Supplements*, the dictionary itself fills 12 volumes, has over 15,000 pages, and contains 414,825 words, illustrated by 1,827,306 citations. It is a dictionary of the British Commonwealth and the United States, a fact symbolized by the presentation of first copies in the spring of 1928 to King George V and Pres. Calvin Coolidge. It exhibits the histories and meanings of all words known to have been in use since 1150. From 1150 to 1500 all five Middle English dialects, as has been seen, were of equal status. They are therefore all included. After 1500, however, dialectal expressions are not admitted, nor are scientific and technical terms not in general use. Otherwise, the written vocabulary is comprehensive. A revised edition of this dictionary, known as *The Oxford English Dictionary*, was published in 1933.

Proposals for a new dictionary

VARIETIES OF ENGLISH

British English. The abbreviation RP (Received Pronunciation) denotes the speech of educated people living in London and the southeast of England and of other people elsewhere who speak in this way. If the qualifier educated be assumed, RP is then a regional (geographical) dialect, as contrasted with London Cockney, which is a class (social) dialect. RP is not intrinsically superior to other varieties of English; it is itself only one particular regional dialect that has, through the accidents of history, achieved more extensive use than others. Although acquiring its unique status without the aid of any established authority, it may have been fostered by the public schools (Winchester, Eton, Harrow, Rugby, and so on) and the ancient universities (Oxford and Cambridge). Other varieties of English are well preserved in spite of the levelling influences of film, television, and radio. In the Northern dialect RP /ɑ:/ (the first vowel sound in "father") is still pronounced /æ/ (a sound like the *a* in "fat") in words such as laugh, fast, and path; this pronunciation has been carried across the Atlantic into American English.

Features of the Northern dialect

In the words run, rung, and tongue, the received-standard pronunciation of the vowel is /ʌ/, like the *u* in "but"; in the Northern dialect it is /u/, like the *oo* in "book." In the words bind, find, and grind, the received standard pronunciation of the vowel sound is /ai/, like that in "bide"; in Northern, it is /i/, like the sound in "feet." The vowel sound in the words go, home, and know in the Northern dialect is /ɔ:/, approximately the sound in "law" in some American English dialects. In parts of Northumberland, RP "it" is still pronounced "hit," as in Old English. In various Northern dialects the definite article "the" is heard as *t*, *th*, or *d*. In those dialects in which it becomes both *t* and *th*, *t* is used before consonants and *th* before vowels. Thus, one hears "t'book" but "th'apple." When, however, the definite article is reduced to *t* and the following word begins with *t* or *d*, as in "t'tail" or "t'dog," it is replaced by a slight pause as in the RP articulation of the first *t* in "hat trick." The RP /tʃ/, the sound of the *ch* in "church," becomes *k*, as in "thack," ("thatch, roof") and "kirk" ("church"). In many Northern dialects strong verbs retain the old past-tense singular forms band, brak, fand, spak for RP forms bound, broke, found, and spoke. Strong verbs also retain the past participle inflection *-en* as in "comen," "shutten," "sitten," and "getten" or "gotten" for RP "come," "shut," "sat," and "got."

In some Midland dialects the diphthongs in "throat" and "stone" have been kept apart, whereas in RP they have fallen together. In Cheshire, Derby, Stafford, and Warwick, RP "singing" is pronounced with a *g* sounded after the velar nasal sound (as in RP "finger"). In Norfolk one hears "skellington" and "solintary" for "skeleton" and "solitary," showing an intrusive *n* just as does "messenger" in RP from French *messager*, "passenger" from French *passager*, and "nightingale" from Old English *nihtegala*. Other East Anglian words show consonantal metathesis (switch position), as in "singify," and substitution of one liquid or nasal for another, as in "chimbly" for "chimney," and "synnable" for "syllable." "Hantle" for "handful" shows syncope (disappearance) of an unstressed vowel, partial assimilation of *d* to *t* before voiceless *f*, and subsequent loss of *f* in a triple consonant group.

In South Western dialects, initial *f* and *s* are often voiced, becoming *v* and *z*. Two words with initial *v* have found their way into RP: "vat" from "fat" and "vixen" from "fixen" (female fox). Another South Western feature is the development of a *d* between *l* or *n* and *r*, as in "parlder" for "parlour" and "carnder" for "corner." The bilabial semivowel *w* has developed before *o* in "wold" for "old," and in "wom" for "home," illustrating a similar development in RP by which Old English *ān* has become "one," and Old English *hāl* has come to be

South Western dialects

spelled "whole," as compared with Northern *hale*. In South Western dialects "yat" comes from the old singular *geat*, whereas RP "gate" comes from the plural *gatu*. Likewise, "clee" comes from the old nominative *clea*, whereas RP "claw" comes from the oblique cases. The verbs keel and kemb have developed regularly from Old English *cēlan* "to make cool" and *kemban* "to use a comb," whereas the corresponding RP verbs cool and comb come from the adjective and the noun, respectively.

In Wales, people often speak a clear and measured form of English with a musical intonation inherited from ancestral Celtic. They tend to aspirate both plosives (stops) and fricative consonants very forcibly; thus, "true" is pronounced with an audible puff of breath after the initial *t*.

Lowland Scottish was once a part of Northern English, but two dialects began to diverge in the 14th century. Today Lowland Scots trill their *r*'s, shorten vowels, and simplify diphthongs. A few Scottish words, such as bairn, brae, canny, dour, and pauky, have made their way into RP. Lowland Scottish is not to be confused with Scottish Gaelic, a Celtic language still spoken by about 50,000 people (all bilingual) in the Highlands and the Western Isles. Thanks to Robert Burns and Sir Walter Scott, many Scottish Gaelic words have been preserved in English literature.

Irish pronunciation

Northern Ireland has dialects related in part to Lowland Scottish and in part to the southern Irish dialect of English. Irish pronunciation is conservative and is clearer and more easily intelligible than many other dialects. Its literature has reached worldwide audiences, whether written by Englishmen born in Ireland, such as Jonathan Swift, Laurence Sterne, Oliver Goldsmith, Sir Richard Steele, Edmund Burke, Oscar Wilde, and George Bernard Shaw, or by authentic Irishmen, such as James Joyce, William Butler Yeats, and John Millington Synge. The influence of Irish Gaelic on the speech of Dublin is most evident in the syntax of drama and in the survival of such picturesque expressions as "We are after finishing," "It's sorry you will be," and "James do be cutting corn every day."

American and Canadian English. The dialect regions of the United States are most clearly marked along the Atlantic littoral, where the earlier settlements were made. Three dialects can be defined: Northern, Midland, and Southern. Each has its subdialects.

The Northern dialect is spoken in New England. Its six chief subdialects comprise northeastern New England (Maine, New Hampshire, and eastern Vermont), southeastern New England (eastern Massachusetts, eastern Connecticut, and Rhode Island), southwestern New England (western Massachusetts and western Connecticut), the inland north (western Vermont and upstate New York), the Hudson Valley, and metropolitan New York (Figure 3).

The Midland dialect is spoken in the coastal region from Point Pleasant, in New Jersey, to Dover, in Delaware. Its seven major subdialects comprise the Delaware Valley, the Susquehanna Valley, the Upper Ohio Valley, northern West Virginia, the Upper Potomac and Shenandoah, southern West Virginia and eastern Kentucky, western Carolina, and eastern Tennessee.

The Southern dialect area covers the coastal region from Delaware to South Carolina. Its five chief subdialects comprise the Delmarva Peninsula, the Virginia Piedmont, northeastern North Carolina (Albemarle Sound and Neuse Valley), Cape Fear and Pee Dee valleys, and the South Carolina Low Country, around Charleston.

These boundaries, based on those of the *Linguistic Atlas of the United States and Canada*, are highly tentative. To some extent these regions preserve the traditional speech of southeastern and southern England, where most of the early colonists were born. The first settlers who came to Virginia (1607) and Massachusetts (1620) soon learned to adapt old words to new uses, but they were content to borrow names from the local Indian languages for unknown trees, such as hickory and persimmon, and for unfamiliar animals, such as raccoons and

Atlantic Seaboard dialect areas after Hans Kurath, *A Word Geography of the Eastern United States*; copyright © 1949, University of Michigan Press, Ann Arbor

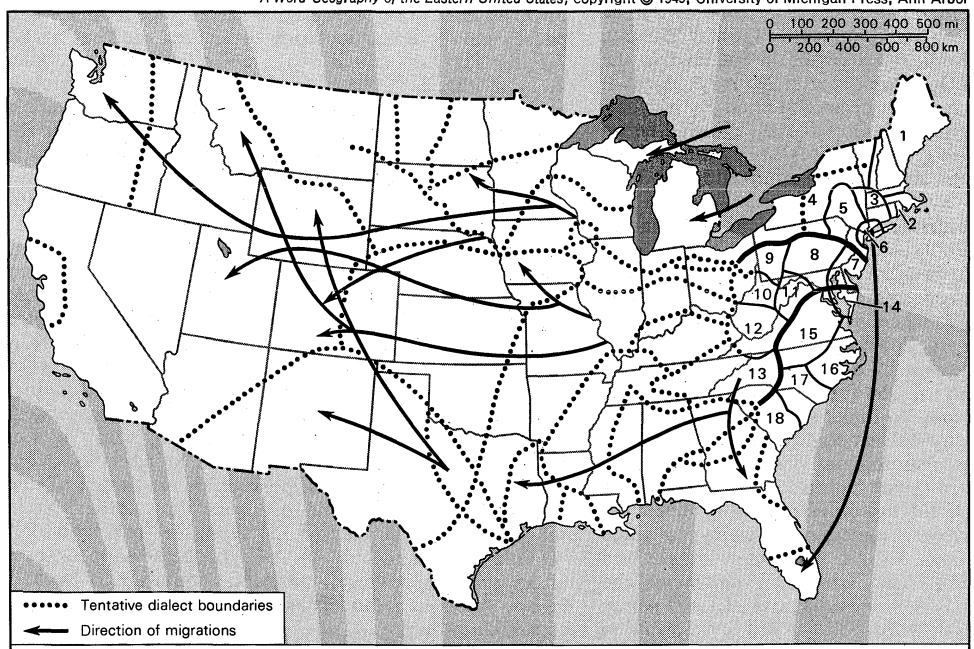

Figure 3: Dialect areas of English in the United States.

woodchucks. Later they took words from foreign settlers: "chowder" and "prairie" from the French, "scow" and "sleigh" from the Dutch. They made new compounds, such as "backwoods" and "bullfrog," and gave new meanings to such words as "lumber" (which in British English denotes disused furniture, or junk) and "corn" (which in British English signifies any grain, especially wheat).

Before the Declaration of Independence (1776), two-thirds of the immigrants had come from England, but after that date they arrived in large numbers from Ireland. The potato famine of 1845 drove 1,500,000 Irishmen to seek homes in the New World, and the European revolutions of 1848 drove as many Germans to settle in Pennsylvania and the Middle West. After the close of the American Civil War, millions of Scandinavians, Slavs, and Italians crossed the ocean and eventually settled mostly in the North Central and Upper Midwest states. In some areas of South Carolina and Georgia the American Negroes who had been imported to work the rice and cotton plantations developed a contact language called Gullah, or Geechee, that made use of many structural and lexical features of their native languages. This remarkable variety of English is comparable to such "contact languages" as Sranan (Taki-Taki) and Melanesian Pidgin. The speech of the Atlantic Seaboard shows far greater differences in pronunciation, grammar, and vocabulary than that of any area in the North Central States, the Upper Midwest, the Rocky Mountains, or the Pacific Coast. Today, urbanization, quick transport, and television have tended to level out some dialectal differences in the United States.

The Gullah dialect

The boundary with Canada nowhere corresponds to any boundary between dialects, and the influence of United States English is strong, being felt least in the Maritime Provinces and Newfoundland. Nevertheless, in spite of the effect of this proximity to the United States, British influences are still potent in some of the larger cities; Scottish influences are well sustained in Ontario. Canada remains bilingual. One-third of its people, living mostly in the province of Quebec, have French as their home language. Those provinces in which French is spoken as a mother tongue by 10 percent or more of the population are described as "federal bilingual districts" in the Official Languages Bill of 1968.

Australian and New Zealand English. Unlike Canada, Australia has no European language other than English within its borders. There are still many Aboriginal languages, though they are spoken by only a few hundred speakers each and their continued existence is threatened. Over 90 percent of the population is British. By the mid-20th century, with rapid decline of its Aboriginal tongues, English was without rivals in Australia.

During colonial times the new settlers had to find names for a fauna and flora (*e.g.*, banksia, iron bark, whee whee) different from anything previously known to them: trees that shed bark instead of leaves and cherries with external stones. The words brush, bush, creek, paddock, and scrub acquired wider senses, whereas the terms brook, dale, field, forest, and meadow were seldom used. A creek leading out of a river and entering it again downstream was called an anastomizing branch (a term from anatomy), or an anabranch, whereas a creek coming to a dead end was called by its native name, a billabong. The giant kingfisher with its raucous bray was long referred to as a laughing jackass, later as a bushman's clock, but now it is a kookaburra. Cattle so intractable that only roping could control them were said to be ropable, a term now used as a synonym for "angry" or "extremely annoyed."

A deadbeat was a penniless "sundowner" at the very end of his tether, and a no-hoper was an incompetent fellow, hopeless and helpless. An offsider (strictly, the offside driver of a bullock team) was any assistant or partner. A rouseabout was first an odd-job man on a sheep station and then any kind of handyman. He was, in fact, the "down-under" counterpart of the wharf labourer, or roustabout, on the Mississippi River. Both words originated in Cornwall, and many other terms, now exclusively Australian, came ultimately from British dialects. "Dinkum," for instance, meaning "true, authentic, genuine," echoed the "fair dinkum," or fair deal, of Lincolnshire dialect. "Fossicking" about for surface gold, and then rummaging about in general, perpetuated the term fossick ("to elicit information, ferret out the facts") from the Cornish dialect of English. To "barrack," or jeer noisily, recalled Irish "barrack" ("to brag, boast"), whereas "skerrick" in the phrase "not a skerrick left" was obviously identical with the "skerrick" meaning "small fragment, particle," still heard in English dialects from Westmorland to Hampshire.

"Rouseabout" and "roustabout"

Some Australian English terms came from Aboriginal speech: the words boomerang, corroboree (warlike dance and then any large and noisy gathering), dingo (reddish-brown half-domesticated dog), galah (cockatoo), gunyah (bush hut), kangaroo, karri (dark-red eucalyptus tree), nonda (rosaceous tree yielding edible fruit), pokutukawa (evergreen bearing brilliant blossom), wallaby (small marsupial), and wallaroo (large rock kangaroo). Australian English has slower rhythms and flatter intonations than RP. Although there is remarkably little regional variation throughout the entire continent, there is significant social variation. The neutral vowel /ə/ (as the *a* in "sofa") is frequently used, as in London Cockney: "arches" and "archers" are both pronounced [ɑ:tʃəz], and the pronunciations of RP "day" and "go" are, respectively, [dəi] and [gəu].

Although New Zealand lies over 1,000 miles away, much of the English spoken there is similar to that of Australia. The blanket term Austral English is sometimes used to cover the language of the whole of Australasia, or Southern Asia, but this term is far from popular with New Zealanders because it makes no reference to New Zealand and gives all the prominence, so they feel, to Australia. Between North and South Islands there are observable differences. For one thing, Maori, which is still a living language (related to Tahitian, Hawaiian, and the other Austronesian [Malayo-Polynesian] languages), has a greater number of speakers and more influence in North Island.

The English of India–Pakistan. In 1950 India became a federal republic within the Commonwealth of Nations, and Hindi was declared the first national language. English, it was stated, would "continue to be used for all official purposes until 1965." In 1967, however, by the terms of the English Language Amendment Bill, English was proclaimed "an alternative official or associate language with Hindi until such time as all non-Hindi states had agreed to its being dropped." English is therefore acknowledged to be indispensable. It is the only practicable means of day-to-day communication between the central government at New Delhi and states with non-Hindi speaking populations, especially with the Deccan, or "South," where millions speak Dravidian (non-Indo-European) languages—Telugu, Tamil, Kannada, and Malayalam. English is widely used in business, and, although its use as a medium in higher education is decreasing, it remains the principal language of scientific research.

English an alternative official language

In 1956 Pakistan became an autonomous republic comprising two states, East and West. Bengali and Urdu were made the national languages of East and West Pakistan, respectively, but English was adopted as a third official language and functioned as the medium of interstate communication. (In 1971 East Pakistan broke away from its western partner and became the independent state of Bangladesh.)

African English. Africa is the most multilingual area in the world, if people are measured against languages. Upon a large number of indigenous languages rests a slowly changing superstructure of world languages (Arabic, English, French, and Portuguese). The problems of language are everywhere linked with political, social, economic, and educational factors.

The Republic of South Africa, the oldest British settlement in the continent, resembles Canada in having two recognized European languages within its borders: English and Afrikaans, or Cape Dutch. Both British and

Dutch traders followed in the wake of 15th-century Portuguese explorers and have lived in widely varying war-and-peace relationships ever since. Although the Union of South Africa, comprising Cape Province, Transvaal, Natal, and Orange Free State, was for over a half century (1910–61) a member of the British Empire and Commonwealth, its four prime ministers (Botha, Smuts, Hertzog, and Malan) were all Dutchmen. In 1970 Afrikaners outnumbered Britishers by 3 to 2. The Afrikaans language began to diverge seriously from European Dutch in the late 18th century and has gradually come to be recognized as a separate language. Although the English spoken in South Africa differs in some respects from standard British English, its speakers do not regard the language as a separate one. They have naturally come to use many Afrikanerisms, such as *kloof*, *kopje*, *krans*, *veld*, and *vlei*, to denote features of the landscape and occasionally employ Bantu names to designate local animals and plants. The words trek and commando, notorious in South African history, have acquired almost worldwide currency.

Afrikanerisms in South African English

Elsewhere in Africa, English helps to answer the needs of wider communication. It functions as the official language of administration in the Bantu states of Botswana, Lesotho, and Swaziland and in Rhodesia, Zambia, Malawi, Burundi, Rwanda, Uganda, and Kenya. The University of East Africa, inaugurated in 1963, has three interstate constituent colleges in which the language of instruction is English, at Kampala (Makerere), Uganda; at Nairobi, Kenya; and at Dar es Salaam, Tanzania.

The West African states of Gambia, Sierra Leone, Ghana, and Nigeria, independent members of the Commonwealth, have English as their official language. They are all multilingual. The official language of Liberia is also English, although its tribal communities constitute four different linguistic groups. Its leading citizens regard themselves as Americo-Liberians, being descendants of those freed Negroes whose first contingents arrived in West Africa in 1822. South of the Sahara Desert, indigenous languages are extending their domains and are competing healthily and vigorously with French and English.

THE FUTURE OF ENGLISH

Geographically, English is the most widespread language on Earth, and it is second only to Mandarin Chinese in the number of people who speak it. The ITU (the International Telecommunication Union) has four official languages: English, French, Spanish, and Russian. The influence of these languages upon one another will inevitably increase.

It is reasonable to ask if changes in English can be predicted. There will doubtless be modifications in pronunciation, especially in that of long vowels and diphthongs. In weakly stressed syllables there is already a discernible tendency, operating effectively through radio and television, to restore the full qualities of vowels in these syllables. This tendency may bring British English more into line with American English and may bring them both a little nearer to Spanish and Italian. Further, it may help to narrow the gap between pronunciation and spelling. Other factors will also contribute toward the narrowing of this gap: advanced technological education, computer programming, machine translation, and expanding mass media. Spelling reformers will arise from time to time to liven up proceedings, but, all in all, traditional orthography may well hold its own against all comers, perhaps with some regularization. Printing houses, wielding concentrated power through their style directives, will surely find it in their best interests to agree on uniformity of spelling. Encyclopaedic dictionaries—computerized, universal, and subject to continuous revision—may not go on indefinitely recording such variant spellings as "connection" and "connexion," "judgment" and "judgement," "labor" and "labour," "medieval" and "mediaeval," "plow" and "plough," "realise" and "realize," "thru" and "through."

Factors leading toward conformity

Since Tudor days, aside from the verb endings *-est* and *-eth*, inflections have remained stable because they represent the essential minimum. The abandonment of the forms thou and thee may encourage the spread of yous and youse in many areas, but it is not necessarily certain that these forms will win general acceptance. The need for a distinctive plural can be supplied in other ways (*e.g.*, the forms "you all, you fellows, you people"). The distinctions between the words "I" and "me," "he" and "him," "she" and "her," "we" and "us," "they" and "them" seem to many authors to be too important to be set aside, in spite of a growing tendency to use objective forms as emphatic subjective pronouns and to say, for instance, "them and us" instead of "they and we" in contrasting social classes. Otherwise, these distinctive forms may remain stable; they are all monosyllabic, they are in daily use, and they can bear the main stress. They will therefore resist levelling processes.

Considerable changes will continue to be made in the forms and functions of auxiliary verbs, catenative (linking) verbs, phrasal verbs, and verb phrases. Indeed, the constituents of verbs and verb groups are being more subtly modified than those of any other word class. By means of auxiliaries and participles, a highly intricate system of aspects, tenses, and modalities is gradually evolving.

In syntax the movement toward a stricter word order seems to many to be certain to continue. The extension of multiple attributives in nominal groups has probably reached its maximum. It cannot extend further without incurring the risk of ambiguity.

In vocabulary there will be further increases, if the present trends continue. Unabbreviated general dictionaries already contain 500,000 entries; even larger dictionaries, with 750,000 entries, will be required soon. Coiners of words will probably not confine themselves to Greek and Latin in creating new terms, but they will exercise their inventive powers in developing an international technical vocabulary that is increasingly shared by Russian, French, and Spanish and that is slowly emerging as the universal scientific language of tomorrow.

BIBLIOGRAPHY

Dictionaries: The Oxford English Dictionary, 13 vol. (1933), is the reissue of *The New English Dictionary on Historical Principles* (1884–1928). Derivative dictionaries include *The Shorter Oxford English Dictionary on Historical Principles*, 2nd ed., 2 vol. (1939); *The Concise Oxford Dictionary of Current English*, 5th ed. (1964); *The Pocket Oxford Dictionary of Current English* (1969); *The Little Oxford Dictionary of Current English*, 4th ed. (1969); *Oxford Illustrated Dictionary* (1962); and *The Advanced Learner's Dictionary of Current English*, 2nd ed. (1963). Other one-volume dictionaries include *Chambers' Twentieth Century* (1972); *The Universal Dictionary of the English Language*, rev. by E.H. PARTRIDGE (1952); *Longmans English Larousse* (1968); and P. HANKS, *Encyclopedic World Dictionary* (1971).

The leading American dictionary is *Webster's Third New International Dictionary of the English Language* (1961), actually 8th in the series since the first appeared in 1828. *Webster's New Collegiate Dictionary* (1973) is an abbreviated version. Other comprehensive dictionaries are *The New Century Dictionary of the English Language*, 2 vol. (1959) and *Funk and Wagnalls New Standard Dictionary of the English Language* (1963). Two comprehensive dictionaries are outstanding: *The Random House Dictionary of the English Language* (1966); and *The American Heritage Dictionary of the English Language* (1969).

Up-to-date and reliable etymological dictionaries include ERNEST WEEKLEY, *An Etymological Dictionary of Modern English*, 2 vol. (1921, reprinted 1967); E.H. PARTRIDGE, *Origins*, 5th rev. ed. (1971); and ERNEST KLEIN, *A Comprehensive Etymological Dictionary of the English Language*, 2 vol. (1966–67). *The Oxford Dictionary of English Etymology* (1966) will long remain the most authenic work in this field.

The two great historical dictionaries of American English are: *A Dictionary of American English on Historical Principles*, ed. by SIR WILLIAM A. CRAIGIE and JAMES R. HULBERT, 4 vol. (1936–44); and *A Dictionary of Americanisms on Historical Principles*, ed. by MITFORD M. MATHEWS, 2 vol. (1951).

Modern usage: H.W. FOWLER'S somewhat eccentric *A Dictionary of Modern English Usage* (1926) was thoroughly updated by SIR ERNEST GOWERS (1965). It has its transatlantic counterpart in the following two works: BERGEN and CORNELIA EVANS, *A Dictionary of Contemporary American Usage*

(1957); and MARGARET NICHOLSON, *A Dictionary of American-English Usage* (1957).

Grammar and structure of English: HAROLD WHITEHALL, *Structural Essentials of English* (1956); A.A. HILL, *Introduction to Linguistic Structures: From Sound to Sentence in English* (1958); J.H. SLEDD, *A Short Introduction to English Grammar* (1959); R.B. LONG, *The Sentence and Its Parts* (1961); PAUL ROBERTS, *English Sentences* (1962); MARTIN JOOS, *The English Verb* (1964); H.A. GLEASON, *Linguistics and English Grammar* (1965); N.C. STAGEBERG, *An Introductory English Grammar* (1965); A.E. DARBYSHIRE, *A Description of English* (1967); R. QUIRK *et al.*, *A Grammar of Contemporary English* (1972); B.M.H. STRANG, *Modern English Structure*, 2nd ed. rev. (1968).

Phonetics of English: Handbooks include HANS KURATH and R.I. MCDAVID, *The Pronunciation of English in the Atlantic States* (1961); and A.C. GIMSON, *An Introduction to the Pronunciation of English* (1963).

Histories: The fullest account of the "external history" of the language is given by A.C. BAUGH in *A History of the English Language*, 2nd ed. (1963). FERDINAND MOSSE, *Esquisse d'une histoire de la langue anglaise* (1947), is a masterpiece—brief, lucid, and profound. KARL BRUNNER, *Die englische Sprache: Ihre geschichtliche Entwicklung*, 2nd ed., 2 vol. (1960–62), is indispensable to advanced students.

Two brief surveys written early in the century are recognized classics and remain stimulating: HENRY BRADLEY, *The Making of English* (1904, rev. by SIMEON POTTER, 1968); and J.O.H. JESPERSON, *Growth and Structure of the English Language* (1905, reprinted 1971). Other fairly substantial histories include STUART ROBERTSON and F.G. CASSIDY, *The Development of Modern English*, 2nd ed. (1955); G.L. BROOK, *A History of the English Language* (1958); M.M. BRYANT, *Modern English and Its Heritage*, 2nd ed. (1962); M.W. BLOOMFIELD and L.D. NEWMARK, *A Linguistic Introduction to the History of English* (1963); W.N. FRANCIS, *The English Language, an Introduction* (1965); THOMAS PYLES, *The Origins and Development of the English Language* (1964); SIMEON POTTER, *Our Language*, rev. ed. (1968); J.W. CLARK, *Early English: A Study of Old and Middle English* (1967); A.C. PARTRIDGE, *Tudor to Augustan English* (1969); J.A. SHEARD, *The Words We Use*, rev. ed. (1970); and B.M.H. STRANG, *A History of English* (1971). F.T. VISSER, *An Historical Syntax of the English Language*, 3 vol. (1963–73), provides copious illustrations and bibliographies.

Special studies: GEORGE W. TURNER, *The English Language in Australia and New Zealand* (1966); SIMEON POTTER, *Changing English* (1969); JOHN W. SPENCER (ed.), *The English Language in West Africa* (1971); MITFORD M. MATHEWS (ed.), *The Beginnings of American English* (1931); THOMAS PYLES, *Words and Ways of American English* (1952); ALBERT H. MARCKWARDT, *American English* (1958).

Bibliographies: ARTHUR G. KENNEDY, *A Bibliography of Writings on the English Language from the Beginning of Printing to the End of 1922* (1927); HAROLD B. ALLEN, *Linguistics and English Linguistics* (1966). New books are recorded in the *Annual Bibliography of English Language and Literature* (annual), edited for the Modern Humanities Research Association, and in *The Year's Work in English Studies* (annual), edited for the English Association. Books, theses, and current studies are announced in *Research in Progress in the Modern Languages and Literatures* (7/year), a supplement to Publications of the Modern Language Association of America (PMLA).

(S.P.)

Enlightenment

The Enlightenment was a movement of thought and belief concerned with the interrelated concepts of God, reason, nature, and man that claimed wide assent among European intellectuals in the 17th and 18th centuries. Although diverse in emphases and interests, the Enlightenment attacked the established ways of European life and, in its conviction that right reason could discover useful knowledge, aspired to the conquest of man's happiness through freedom.

ANTECEDENTS OF THE ENLIGHTENMENT

Ancestral roots. The roots of the Enlightenment reach back to the days when Greek philosophers discovered a regularity in nature and concluded that its governing principle was reasoning mind and when, under the promptings of Socrates, they turned to consider man and ascribed a high value to his intellectual powers. Individual philosophers and their schools raised Greece to a brilliant eminence, but its glory faded and Rome emerged as the heir. The Romans saved much, adapted much, and made contributions of their own; but the Greco-Roman culture finally lost its vitality. Unheralded, there came in a tide of Eastern religions preaching doctrines of personal salvation. Christianity won the competition for converts, and before the end of the 4th century it became the exclusive religion of the empire. Christianity sprang from an environment totally alien to that of the Greeks and Romans, and its purposes were so contrary to theirs that many fervent Christians wanted to repudiate pagan writings altogether. But the overwhelming majority of the converts were Greeks and Romans, for whom a radical break with their past was unthinkable; pagan literature was the only available source for philosophical justifications and for educational materials. And so Christianity had to make a cultural accommodation, but it tried to suppress the most immoral aspects of paganism and to bend the rest to the special purposes of the faith. The greatest achievement was that in the 13th century when Thomas Aquinas took up newly found manuscripts of Aristotle and made them into the very fundament of Christian philosophy.

Again, intellectual history moved from triumphs to reverses. More scholastic disputation badly injured Thomas' dominion; the papacy was moved to Avignon in 1309 (the discreditable "Babylonian Captivity"), and, worse still, expanding secular concerns in the 14th century shook the old order, nowhere more disruptingly than in Italy. Symptomatic of this change of atmosphere was Petrarch's newborn zest for classical letters and the response to it on the part of countless enthusiasts who roamed far and wide in search of forgotten manuscripts. Several revivals of classical letters during the Middle Ages had rescued many works from destruction, but the old religious purposes were not that of Petrarch and his friends, who wanted the ancient authors stripped of the distortions wrought upon them through the centuries of Christian editing and interpretation. These new men, the Humanists, sought to recapture the spirit of Greece and Rome, which had been expressed with such wisdom and beauty; and they produced a magnificent body of criticism and letters, historiography and science that made a glorious epoch in European history.

Petrarch's role in the revival of classical learning

But after about a century, intellectual life in Italy suffered ruinously from political turmoil, and Humanism went over the Alps to find congenial homes in Germany and elsewhere in western Europe. There the central purpose of Humanism was to serve religion, and this was especially true for Erasmus, who wanted to perfect a philosophy of Christ. Erasmus saw many things to reform, but when, in 1517, Martin Luther raised the standard of revolt, Erasmus drew back in horror.

The turbulent Luther unleashed more furies than he could have anticipated. A century later the old ecumenical church of the West was broken. The Protestants were appealing to the authority of the Scriptures, and the Catholics were invoking the authority of the organic church; and the Council of Trent (1545–63) closed the door on useful dialogue between them. Meanwhile, the course of the Reformation had thrown up problems of its own, and debates over would-be solutions had scattered cross-purposes and confusion. By the 17th century Europe was without a community of thought. The Renaissance had spread the diverse stream of Greek philosophizing, and Platonism, Stoicism, and Epicureanism competed for a hearing. Catholics and Protestants discharged their guns across an unbridgeable chasm; newer political questions raised up a veritable Pandora's box of conflicting opinions.

The decision of the Renaissance had been to keep the synthesis between classical letters and the Christian faith, but more recent developments had injured that hope. Inescapably, the need for an intelligible and accepted medium of communication sent men back to classical points of view, points of view not necessarily in conflict with Christian judgment but at the same time independent of it. One notable appeal to the minds of all Europeans was couched in terms of revived Stoicism. It was made by

Grotius' appeal to natural law

Hugo Grotius, a noble and scholarly Dutch jurist. In his *De Jure Belli ac Pacis* (1625) he invoked natural law as the rule governing international relations. For 2,000 years no one had denied the existence of natural law, but there was a fresh significance in the emphasis Grotius placed on its primacy and on its independence of Christian theology. This law, said the devoutly Christian Grotius, was so immutable that God himself could not change it.

The scientific revolution. Another development was working out a new frame of reference—the beginning of modern science, a discipline that soon lost patience with religious quibbling and, no less, with the absurdities of Greek and Roman science.

Bacon and Descartes. The great prophet of this newest learning, the man who stirred the imagination of the next generations by painting the enrichment of human life through new discoveries, was Francis Bacon. Suspicious of the mathematics that had been making great technical strides, he proposed an all-comprehending method of induction. In contrast, Descartes drove from his mind everything except simple ideas, whose truth was undeniable, and he proceeded by rigorous deduction to work out his whole philosophic system. Despite the gulf between these two methods, Bacon and Descartes were allied in basic purpose and in influence. Both were at war with what they considered a harmful past; both dreamed of improvement in man's lot as the duty of science; both separated science from theology. Both, too, saw the need for practical experiment, and neither had a useful notion of how to go about it.

Galileo. The honour of fundamental pioneering belongs to Galileo Galilei, a man of genius, piety, and truculence. Taking up the old figure of speech that God had given man two books, Holy Writ and nature, he insisted emphatically that the language of the book of nature was mathematics. For his purposes, Galileo limited his world of nature to properties capable of mathematical analysis, such as extension and motion, and therefore capable of being described in terms of precise natural laws. His method of research he elegantly demonstrated in working out the law of falling bodies by mathematical analysis of hypotheses and checking by experiment.

Such achievements should have been renown enough for any man, but Galileo had yet another triumph. As a starting point for it he had the astronomical work of Copernicus, Tycho Brahe, and Kepler. Their studies had done mortal damage to the Ptolemaic notion of a universe rotating around the Earth, but these great explorers had left behind them not only a storm of emotional resistance but also a number of crucial unanswered questions. Report had come to Galileo of a new invention called a telescope, and he made one for himself. In a few nights of peering into the heavens he saw a system of structure and motion that proved the Copernican heliocentric explanation to all but the most hidebound defenders of the old order. With the discredit of the Ptolemaic astronomy, the whole of Aristotelian natural philosophy became untenable, and Galileo in 1632 recklessly set down his views in *Dialogo sopra i due massimi sistemi del mondo, tolemaico e copernicano.* He dedicated his book to the Pope, but that act of courtesy availed him little. He was called before the Inquisition to hear a verdict already prepared; but the broader significance of the trial was that Galileo's new scientific way of thinking had gone so far from inherited modes that no reasoned interchange was possible, and the church based its condemnation on fear.

Newton. Another difficult problem remained: the need to construct a general system of mechanics that could account for the motions of the stars in terms of observed behaviour of matter on Earth. A number of scientists worked at it, but it fell to Isaac Newton to win the honour of success. In 1687 the Royal Society, under the authorization of its secretary Samuel Pepys, published Newton's *Philosophiae Naturalis Principia Mathematica.* In this work, with prodigious mathematical reasoning, Newton presented the law of universal gravitation.

Newton modestly confessed that he did not know what gravitation was, and when his calculations indicated some irregularities that seemed to require the direct intervention of God to set them right, he was honest enough to say so. The German scientist and philosopher Gottfried Wilhelm Leibniz, who had quarrelled with him over priority in the invention of the calculus, attacked Newton harshly for picturing God as a clumsy watchmaker, but few had patience with such small matters. Newton had explained the universe; he had vindicated the rationality of nature; and he was, said the zealous Voltaire, the greatest man who had ever lived. Behind this enthusiasm for Newton and for natural philosophy there lay a serious question. The mounting tide of discoveries in physics pressed toward the autonomy and the moral neutrality of science, but the spirit of the time could not allow this kind of isolation for so wonderful an instrument of knowledge. The by-product of science had been the destruction of wide domains of medieval error; perhaps its methods, its experimental reasoning, could be used for all of man's problems. Indeed, Newton himself had suggested the possibility.

The effect of Newton's discovery of the law of gravitation

THE AGE OF THE ENLIGHTENMENT

Enlightened religion. The Christian faith showed a powerful tenacity when confronted by this avalanche of new facts and new conclusions, but it could not fail to be acutely sensitive to the changing intellectual fashions. By the early 18th century, radical ideas hitherto submerged came into the open and precipitated a debate fraught with great consequences. Hitherto, the rationalists had had no base for comparison except their knowledge of the ancient world. Latterly, they had become acquainted (in considerable measure through Jesuit missionaries) with pious Egyptians and Siamese and with Chinese, who, they said, had no real religion at all but were still men of exemplary virtue. More recently still, another stock character came upon the European stage: the noble savage, truly a child of innocence who worshipped his god in simple faith and obeyed the precepts of Mother Nature. And, finally, this growing breed of scientists was steadily grinding out disturbing implications. Good Christians though most of them were, they showed that Christianity's views of nature could not stand up under the tests of experimental reason.

The rise of Deism. Such considerations led dissatisfied men to assume that, beneath the world's religious diversities, there was a common body of beliefs, a religion planted by nature in all men everywhere. In 1624, while Grotius was preparing his case for natural law in international relations, Lord Herbert of Cherbury published his *De Veritate*, a definition of natural religion. He said that certain beliefs are so manifest that all men of reason accept them: the existence of one God who dispenses rewards and punishments, and the obligation resting on man to worship him in repentant piety and virtue. These articles sufficed for a religious life in the present world and for salvation in the hereafter. Deism, as this doctrine came to be called, did not always radiate Herbert's lofty Stoic tone, but his statement was so representative that it persisted until Thomas Paine, in his *Age of Reason* (1794–96), wrote the swan song of the movement.

The Deists' views

The Deists maintained the old synthesis between God, reason, and nature, but, reasoning from a mathematically ordered nature to its architect, they allowed the architect only the qualities manifest in his handiwork. Grand metaphysical systems fell under the ban as mere extravagant nonsense; philosophizing, said the dominant voice, should follow the method of the natural sciences. Such convictions led inescapably to relentless warfare on those beliefs that were unique to Christianity. The Holy Writ of the Christians suffered denunciation as groundless historical confusion; but the Old Testament came in for special attention—it was scornfully dismissed as a repository of the crimes and obscenities in which God connived with the so-called chosen people. With equal vigour the Deists ridiculed biblical prophecy out of court; the notion that God would make revelations in such a book, or in later manifestations, was utterly offensive to the rational mind. Miracles, therefore, were unthinkable. It would do

violence to reason to suppose that God would, or could, set aside the laws that gave expression to his own eternal being.

Deism was never an organized movement. Its first home was among English intellectuals. Around 1700 a series of books appeared that hit ruthlessly at what they held to be the misconceptions and offenses of orthodox Christianity and argued for a depersonalized God, whom anyone could discern for himself. Some of the authors offended good taste and the law by their blasphemies; some wrote with calculated prudence. But during a half century the central core of their argument remained essentially unchanged: Christianity was an indefensible burden on the back of natural religion. But then English Deism went quietly into decline, in part because public disputation was reduced to tedious repetition and in part because the Anglican Church was too preoccupied with political advantages and social dominance to wish to disturb its fat slumber by theological contentiousness. England in 1688–89, with its Glorious Revolution, had settled its wracking political issue, and it was time to relax. The clergy preached cooly on the prudential morality of the Christian life, while Joseph Addison taught his readers the affable urbanity appropriate to a civilized society in an age of reason. Deism moved its headquarters to the Continent.

France had its own native roots of Deism, which grew vigorously on the disillusionments and discontents of the reign of Louis XIV. Voltaire was already committed to an anti-Christian Rationalism before he sought a haven in England in 1726. On his return after two years of exile he wrote a sparkling report, *Lettres philosophiques*, which reaffirmed his commitment to the Deist view of religion. Through his remaining years, his faith remained inflexible. Pressed by more radical opinions, he held steadfastly, in the end somewhat frenziedly, to the God whose evidence he saw in nature and whose existence he deemed necessary to preserve the social order. His one change of emphasis was in the growing vehemence of his anti-clericalism. In the 1760s he completed his *Dictionnaire philosophique*, a witty but earnest compendium of malice toward Christianity, and at the same time, poltroon though he frequently was, he entered the public lists to bring justice to several persons he considered to be victims of ecclesiastical murder. By then he had adopted in rage the motto *Écrasez l'infâme!:* "Every sensible man, every honourable man, must hold the Christain sect in horror."

No one was more temperamentally removed from Voltaire than Jean-Jacques Rousseau, but when he included a profession of Deist faith in his novel *Émile*, Voltaire sent him an enthusiastic compliment. Rousseau's profession was a manifesto for reason as the only reliable test for religious truth and equally an attack on all doctrines and clerical institutions that stood between autonomous man and God. Rousseau characteristically made a place for heightened emotion in such passages as the invitation to go to the sublime book of nature and learn there to worship the Creator; but the overtone of anti-intellectualism did not obscure the rational doctrine of Deism.

The spread of Deism

Throughout France opposition to the church spread, drawing strength from the debilities of the *ancien régime*, and the Deist faith went on to the culturally less well prepared soil of Germany and to the British colonies in America. The movement kept up its momentum far into the second half of the 18th century, but it then paid the price of its lack of organization and the weakness of its emotional impact on uncritical minds. Without a sacred text, without a compelling leader, Deism was always a matter of individual judgment and thereby vulnerable to centrifugal forces.

The Christian response

Naturally, when established societies felt the shock of Deist subversion, they resorted to the time-honoured methods of defense. First came Christianity's dogmatic assertion of truth from pulpit and press (*e.g.*, in 1770 French publishers brought out 90 books in support of the Catholic faith). Behind such gentle measures, however, there were, in considerable diversity, grimmer ways of suppressing dissent. Grimmest was the vengeance of the Inquisition, but hardly less so was the possibility of civil judgments, including the death penalty. And then came the *Index Librorum Prohibitorum* (*Index of Forbidden Books*), ecclesiastical and state censorship and licenses to print, and book burnings. Much skilled and harsh determination went into devising means to stifle corrupting thought. Many individuals suffered many punishments, but heresy was a hydra-headed monster, thriving on persecution and on the stupidities of its enemies.

In Vienna in 1772 the political authorities suddenly realized that they had to put their own *Catalogue of Forbidden Books* in that self-same *Catalogue*, because the impure of heart were finding it a useful guide to spirited reading. Administrative inefficiency and, notably in France, competing authorities helped to dent the cutting edge of tyranny, but the greatest aid for those dealing in illicit materials was their own ingenuity in adapting the arts of the smuggler and the forger into their affairs. Books sold under the table, books without authors, books with false places of publications—all were commodities that did well. In these deceptions Voltaire was by no means alone, but he was a superior master. His brilliant style was more clearly his own than was an acknowledged signature, but in edition after edition he denied writing the *Dictionnaire philosophique*, and no policeman challenged his audacity.

Such cat-and-mouse antics were not the whole story of this confrontation. The real trouble was more subtle. Christianity was rooted in both reason and revelation, and, according to the Fathers and the doctors of the church, these sources were not in conflict; revelation simply had the higher truths. Now came Deism, professing to have the full credentials of reason and demanding that the Christians show how they could, in reason, defend revelation. Again the first battleground was England. Increasingly, supporters of the Christian faith found themselves driven to admit the validity of natural religion and then to search out reasonable grounds for adding revelation. John Tillotson, future archbishop of Canterbury, spoke for many when he stated that Christianity was needed to complete the findings of natural religion: its service was to test the reasoning process and to give a supplementary motive for a moral life. Tillotson conceded much, but his contemporary and fellow Christian John Locke went even further when he accepted reason as the judge of things above reason. Bishop Butler's *Analogy of Religion Natural and Revealed* (1736) offered a fresh line of Christian defense. It became a famous book, but, despite the kindly Bishop's Christian dedication, it did not demolish many Deists. In the pinch, he did not venture into dogmatic assertions based on the usual Christian sources; he took his stand on probability, and he reminded his readers that there were things in natural religion and in nature just as difficult to believe as was orthodox Christian doctrine: after all, Newton could not explain gravitation. Comparable gestures toward a friendly view of the rational standard appeared in Holland, in Germany with a group of prominent Lutheran pastors, and in France, where the Jesuits had a high skill in reasoned debate until their expulsion in 1762. The consequence was that, on the Continent as in England, the theological content of practical, daily religion declined significantly. The popular preachers discoursed in muted tones of reasonableness on the beauties of Christian virtue.

While Deists and Christians were exchanging blows, they tended to agree that God in his benevolence had designed the Earth for man's happiness; "the best of all possible worlds," Leibniz said. Another said that the sun rises and shines for men, and still others pointed to the evidence of the Creator's forethought—the density of water to facilitate navigation; the shape of the melon to make it easy to cut. Even Voltaire, having no conception of change in the universe, surveyed the mountains and saw in them the wisdom and the benevolence of God.

Atheism. Both Deists and Christians heard with anxiety that their happy assumptions were threatened by the upsurge of atheism. Materialism was an ancient philoso-

The rise of Materialism

phy. Epicurus had propounded it, and his Roman disciple Lucretius had put it into his poem *De rerum natura*, which, still later, had excited the Renaissance enthusiasts for classical letters. Throughout the whole of its history, Epicureanism had been a scandal for the mass of literate people, but a notable moment came in 1563, when a French Humanist published a new edition of Lucretius and urged his readers to forget the absurd ideas and concentrate on the poetry. The plea helped a bit, but a far more significant work of salvage was done in the 17th century by Pierre Gassendi, a Catholic priest of blameless repute. Boldly, Gassendi said that Epicurus had not been an advocate of vice but had cultivated the virtues of honesty and inner peace. His Materialism, Gassendi went on, was erroneous; but he shrewdly suggested that it could be made palatable by postulating Divine Providence behind Epicurus' atoms and voids. Descartes would not admit a void in his universe, but he made a contribution, however unwillingly, by his dualism of spirit and matter, which made all animals, including physical man, into purely mechanical structures. With the growth of science, the 18th century took kindly to Gassendi's revival of atomistic philosophy and to the Cartesian mechanistic view of nature. In England David Hartley rewrote Lockean psychology and explained mental life in terms of physical vibrations building complex patterns by the equally mechanical processes of association. In France another physician, La Mettrie, brazenly spelled out the title of his book, *L'Homme-machine* (1747), and stated that man, like everything else, was reducible to matter in motion. "We are no more committing a crime," he wrote, "when we obey our primitive instincts than the Nile is committing a crime with its floods, or the sea with its ravages." Voltaire would not entertain what was to him an offensive notion, but the Encyclopaedist Denis Diderot was tempted and succumbed. The most powerful atheist influence was that of Baron d'Holbach, a wealthy German who had settled in Paris to wage war against God. He commissioned the publication of a whole library of books in addition to those he wrote himself; his only criterion was that a book should serve the cause. In his eyes, religion was the main source of degradation. Rumours circulated about his dinner parties, and ordinary folk felt uneasy when they passed his house, but d'Holbach went further in his anger against Christianity than many men were willing to go.

Skepticism. One further, and more powerful, threat to both Deism and Christianity was skepticism, also a philosophic doctrine that had ancient roots. Because of the lasting popularity of Montaigne's essays of the 16th century, one must see in the meditations of this gentle devotee of ancient letters a fresh source for modern doubt. As he mused on human folly and fanaticism, he repeatedly threw in his personal conclusion, "What do I know?" It was a diffident question, but over several generations it prodded many minds.

The influence of Pierre Bayle

A century later, subdued reflection gave way to a noisy uproar. The cause was Pierre Bayle, whose course from Protestantism to Catholicism and back to Protestantism sent him into a life of exile and of hostility to all religions. His instrument of vengeance was his *Dictionnaire historique et critique*, the first edition of which appeared in 1697. In form it was a collection of biographical sketches with comments, but the individuals chosen and the amount of space given to each reflected Bayle's deadly purpose—to demolish the vices of religion. With learning and wit and with a titillating spice of salaciousness, Bayle drove his sword at every exposed surface of the erstwhile eternal verities. Perhaps nowhere did he hit harder than at the Old Testament when he asked how it was that, when Holy Writ chronicles the morally offensive record of King David, it goes on to call him a man after God's heart.

Bayle's *Dictionnaire* had an extraordinary success. It was soon expanded in new editions, translated into English and German, and boiled down into abridgments and digests. The rollcall of those who read it was a veritable *Who's Who* of the 18th century. Frederick II of Prussia commissioned two abridgments; Benjamin Franklin and Thomas Jefferson recommended it to their friends; Voltaire drew inspiration from it for his own *Dictionnaire philosophique;* Diderot wrote a lyrical article on Bayle for the *Encyclopédie* and was enraged when the rascally publisher suppressed the main substance. No one, however, was more persuaded than the Scottish former Presbyterian David Hume.

At 28 Hume published the first two volumes of *A Treatise of Human Nature*. The subtitle showed the cast of a mind that never changed: *an Attempt to introduce the experimental Method of Reasoning into moral subjects*. From this first, and unsuccessful, book to his posthumous *Dialogues concerning Natural Religion* (1779), Hume, with amiable reasonableness, dissected all certainty from human affairs. Down went the concept of cause and effect, an idea seemingly essential to all rational thinking; down went the celebrated powers of human reason. But the realm of belief suffered most notoriously in this raging storm of doubt. The miracles of so-called revealed religion he subjected to the test of experience, and they dissolved beyond rescue except for the most willful believers. Even natural religion could not stand up to the test of fact; there was no universal consensus supporting it. According to Hume, primitive men, in their fear, invented gods, many gods, to gain protection, and it was only a long time later that monotheism emerged from ignoble calculations. The great trouble, said Hume, was that men assumed that the Supreme Being gave his qualities to them as an endowment of the creation, whereas in reality men ascribed to God their own values. Here, then, was a repugnant philosophy; nothing was left but mere uncertainty and probability at best. The only saving grace, Hume puckishly admitted, was that one could not be a skeptic all the time.

Christian defenses. In the eyes of orthodox believers in Christ, the new trends were all manifestations of a perverse spirit that incited defiance as well as consternation. From Christians little moved to dispute came an assertion that their religion did not need to submit to these debasing tests of rationality. The mystics and others of unassailable conviction went their own ways, indifferent to foolish clamours. Still, it was not always easy. Blaise Pascal, mathematical genius and convert to the rigorous faith of the Jansenists of France, had felt agonizingly the tension between the old ways and the new. He had been convinced that human reason could not explain the ultimate philosophic questions, and he sought for moral certainty in Christian revelation. The universe was vast and men were insignificant, but they had souls and they were dependent on God. In his fear of the vastness of space, Pascal committed himself to a supreme act of faith: "The heart has its reasons which reason does not know." As a student of the law of probability derived from the gambling table, Pascal took refuge in his wager on the existence of God: "if I lost I would have lost little; if I had won I would have gained eternal life."

Chief of those who a century after Pascal would not accept the threatened demolition of the Christian faith was John Wesley, an Oxford student of the classics, early given to piety and a second-time convert through the Moravian Brethren (a German pietist sect). It was no novelty when Wesley said that reason could not produce the love of God, but it was strangely exhilarating when he told his spiritually hungry followers, "A true and living faith in Christ is inseparable from a sense of pardon from all past and freedom from all present sins." For 50 years Wesley preached his simple message of the love of God manifested in Christ, and the humble folk found consolation as Wesley travelled up and down England preaching an average of 1,000 sermons a year.

And so before the end of the 18th century something less than success had crowned the efforts of those earnest men who used emancipated reason and the methods of science to explain God and the ancient mysteries of the universe. The old faith had been buffeted, but Wesley was only the first announcement of a religious trend toward the unleashed emotional flights of the Romantics.

The investigation of man. Meanwhile, the attempt to examine the nature of man in the light of new thought

raised difficult problems. The old and continuing Christian view had a harsh consistency: man carried in him the stamp of Adam's sin until the hour of redemption through Christ's atonement arrived. The Renaissance concept of the dignity of man was an implied criticism of the old belief. But now, in the heady days of rationalistic deductions, it seemed axiomatic that God had implanted his reason and his goodness in man. In this view there was no place for original sin; were it otherwise, the creation would have been monstrously unjust, and that was unthinkable. But the difficulty about this happy analysis was to find men who were convincing demonstrations of the thesis.

The notion of the goodness of man

Locke's epistemology. Because a priori reasoning about man was not very profitable, it was in order to utilize Newton's new scientific method to study human nature. The pioneer was John Locke, and his vehicle was *An Essay Concerning Human Understanding* (1690). Locke's purpose was to determine the scope and limitation of human knowledge through an investigation of the workings of the mind. In the end he set a low limit to knowledge, but what made him the great teacher of the 18th century was his description of the mental process: all knowledge arises from experience, from sensations sorted and combined by reflection. There are no innate ideas; every child is born with a mind like a blank sheet of paper on which the impingement of the external world inscribes the data of life's accumulation of learning. Bishop Berkeley attacked Locke for assuming a world of substance as the source of sensations when that world was beyond the reach of knowledge; but aside from Berkeley's criticism, the psychology of the next century was essentially a gloss on Locke.

The Lockean investigation had demolished not only innate ideas but also innate depravity. Environment made the man, and the most obvious corollary was that the way to improve man was to improve the environment. It was a lesson that gave new dimension to human possibilities and therefore a strong impetus to the zeal for humanitarian reform.

Ethical questions. Locke was primarily concerned with epistemology and gave little attention to the nonmental aspects of man. The language of the day spoke of the passions—the emotions—and their role became increasingly important as the study of human behaviour continued. The rationalist deduction held to man's inherent goodness by virtue of his reason: to know what was right was to do what was right. This statement hardly fitted the observable facts, and a qualification was added: when reason was not obscured, it would tell man what was right and he would act accordingly. But, again, this revision was short of full accuracy: it was established fact that a man who clearly knows the truth may not serve it. It was therefore in order to investigate more carefully the inner sources of moral action. Even exalted rationalists had to admit the existence of ethical promptings in the nonintellectual side of human nature (*i.e.*, in the passions), and two generations and more sought a precise explanation. Early in the 18th century, the 3rd Earl of Shaftesbury found it in an instinctive love for the good because of its inherent worth, its beauty, and its reflection of nature. Bishop Butler pointed to the conscience, the voice of God speaking to the human soul. Even David Hume turned from his skepticism long enough to ascribe to man an innate sentiment for humanity, and his friend Adam Smith, the calculating economist, gained his first celebrity in 1759 from a book that asserted that sympathy was a guiding emotion in human conduct. Across the channel, Voltaire, that alleged prince of cynics, found in man a natural benevolence never seen in the beasts, and the radical Morelly wrote in his *Code de la nature* (1775), "In the natural order the idea of active or passive benevolence precedes every other idea, even that of Divinity."

Running through these comforting reassurances was perforce a question of the relation between this ethical faculty, rooted in the emotional impulses, and reason. Shaftesbury was persuaded that rationality and moral emotion could never be at odds because both were the gifts of nature. Butler contended that conscience had its own power of reasoning. In the second half of the century the common voice began to falter. Adam Smith could not say that sympathy and reason would invariably counsel the same moral decision, and Hume, returned to his most destructive vein, wrote in his *Treatise*, "We speak not strictly and philosophically when we talk of the combat of passion and of reason. Reason is, and ought only to be, the slave of the passions, and can never pretend to any other office than to serve and obey them." Many of Rousseau's passages implied, however unphilosophically from Hume's point of view, an open conflict between reason and the passions. Under the inspiration of Rousseau's idealized man of virtue, novelists were soon playing variations on the theme that goodness was merely a matter of opening the heart's emotional spigots.

Conflict between reason and the passions

Meanwhile, the discussion of ethics had addressed itself to an even more important theme. Christianity had always made its basic appeal to man's desire for the happiness of heaven and his fear of the torments of hell. It was easy to generalize this human predilection and say simply that the dynamic force in life was the desire to secure pleasure and to avoid pain. Christian John Locke agreed: "Pleasure and pain and that which causes them, good and evil, are the hinges on which our passions turn." With a boldness that threatened to become unseemly, numerous writers, notably the exuberant Diderot, sang praises of the passions and in so doing obliquely discounted reason.

It was necessary to think of the ethical implications. Few were ready to make the pursuit of pleasure a moral code in itself. The extravagant determinists could argue that man's decisions and acts were simply the consequences of matter in motion and that there could thus be no question of morality in human life; but most reflections on ethics, despite Hume, assigned to reason some kind of brake on personal misbehaviour. Others contended that the experience of living with people taught men the need they had of each other and the ensuing necessity for reciprocal obligations. In addition, as a justification to some and a reassurance to others, there circulated an assumption of a mysterious harmony between self-interest and the common good. Montesquieu wrote, "Everyone pursues the common good under the impression that he is following his own private advantage." The impudent Bernard de Mandeville expressed the same conviction in his *Fable of the Bees* and summarized the whole matter in his pithy aphorism: "Private vices, Publick benefits." Alexander Pope was more eloquent: "Thus God and Nature link'd the gen'ral frame/ And bade Self-love and Social be the same."

The brave Newtonians had confidently set out to create a science of morals, but they had only created confusion. Another question arose: if there was this anxiety about the capacity of the individual to find within himself a reassuring incentive to ethical conduct, was it possible to find a source external to the individual? For believing Christians the answer was simple: God through the Holy Scriptures and his providential governance of the world has given his commands, and it was man's duty to obey them. It was a far more difficult task for the would-be scientific thinkers, who had broken relations with the Christian God. Thomas Hobbes in the mid-17th century had left a suggestion. In a bit of hypothetical history he told of people who in the state of nature were, each and every one, under the sovereignty of pleasure and pain. The consequence was war of all against all, and life was "solitary, poor, nasty, brutish, and short." To escape from this deadly plight, these people set up a state and consigned to it an all-comprehensive power to rule. The compact created obligation. Hobbes's successors faced the same problem. To restrain moral anarchy it was imperative to design a code based on the welfare of the community. The expression "the greatest happiness for the greatest number" had first appeared in the 1730s, and Claude-Adrien Helvétius made an ominous suggestion. In his book *De l'esprit* (1758), burned by the parlement of Paris and anathematized in Rome, Helvétius explained how to take this self-centred creature man and make out

of him a social being: "It is solely through good laws that one can form virtuous men. Thus the whole art of the legislator consists of forcing men, by the sentiment of self-love, to be always just to one another." Out of such materials Jeremy Bentham drew his blueprint for a laissez-faire democracy.

ASPECTS OF ENLIGHTENMENT THOUGHT

Humanitarianism. It was perhaps less important that these 18th-century thinkers could not fashion an agreed science of morals than that so many people were deeply concerned. The Deist search for natural religion had led to wide-ranging investigations of peoples all over the Earth, with investigations centred not on manifest differences in colour and customs but on what people had in common. And they found much. "It is universally acknowledged," Hume wrote in 1748, "that there is a great uniformity among the acts of men, in all nations and ages, and that human nature remains still the same in its principles and operations. History informs us of nothing new or strange in this particular. Its chief use is only to discover the constant and universal principles of human nature." The sum totality of all men made up humanity, and humanity, by some subtlety, inspired loyalty and compassion. Under this influence, vaunted reason was turning itself unobtrusively into reasonableness. When the concept of natural law was applied to social problems it underwent a significant modification. It no longer stated what was, but what ought to be; and since in so many respects the human condition fell far short of the ought, the Enlightenment became critical, reformist, and eventually revolutionary.

Universal principles of human nature

Locke's demonstration that environment made men provided the dynamic inspiration for a vast attack on prevailing abuses. In the presence of disinterested compassion, those laboured analyses of man chained forever to his pleasures and pains seemed sterile and irrelevant. The long, ceaseless campaigns waged by the intellectuals for freedom of religion and speech might appear to a cynic to be breast-beating exercises to secure their own privileges and rights, but certainly the cynic's yardstick could not measure a countless list of self-jeopardizing acts by men working to increase individual freedom for the simple reason that individual freedom was good. Out of that same simple reasoning came an attack on the inhumanity of Europe's brutal administration of brutal law.

One blind spot, as later generations would call it, was the Enlightenment's little thought for the misfortunes of the lesser rungs of the European social ladder. The poor Europe had had with it always. Sympathy leaped more readily over the horizon to embrace people of dark hue whose status touched the European conscience. Atheist and Christian equally agreed that slavery was morally wrong, and they made common cause against it.

The religious radicals and their Christian enemies also shared an insistent sense of all men linked together in universal brotherhood. Standing in the way of the ideal were many grim realities, but the most baffling was the sovereign state, which demanded the obedience and, far too often, the blood of its people. Despite early warnings of a ferment of nationalism, men of many divergent persuasions toward other issues sounded their defiant calls to world citizenship. Invoking the spirit of Grotius, the Swiss lawyer Vattel pleaded for a society of states living together in peace under the morally binding prescriptions of natural law. Other men who loved peace recalled a proposal attributed to Henry IV of France to establish a formal international confederation that would make war in Europe impossible; the Abbé de Saint-Pierre revived this project in 1713 and worked at his cause for 30 years without gaining many converts. Rousseau published a rather lukewarm restatement, and there the peace campaign rested until 1795, when Immanuel Kant spoke the final word for the Enlightenment in "Zum ewigen Frieden." But Kant's eloquence was to no purpose, for at the time Europe was already two years into a war that would not end until 1815.

Social thinking. The application of the Enlightenment's rationalistic and scientific tools to social fields led to no settled agreement, either as to method or to conclusions.

Political thought. The Reformation had thrown up doctrines ranging from primitive communism to the divine right of kings. Bishop Bossuet restated with the best French eloquence of the 17th century the special relation between God and Louis XIV, but the ancient principle of the natural law went on talking about the state of nature, the social contract, and natural rights. The weight of these theories were, by their very nature, on the side of radicalism. Yet a curious thing happened—the first notable statement of political philosophy in the new age of mathematical rationalism was a secularized theory of absolutism. The author was Thomas Hobbes, who became a rigorous reasoner when, in middle age, he chanced upon Euclid's *Elements*. Hobbes started with natural law but, as indicated above, he admitted no "ought to be." The law imposed a sleepless search for pleasure and the passionate desire to escape pain. The people caught in the desperate consequences of this rule of life made a social compact whereby all resigned their individual powers into the hands of a sovereign outside the compact, whose authority for all practical purposes was unlimited. Hobbes had many acute insights into human affairs, but Charles II, whom he was trying to support in the distress of his exile in France, was so scandalized that Hobbes had to flee the royal presence and take refuge with Oliver Cromwell.

The social compact

Half a century later John Locke accepted Hobbes's strong sense of individualism and his conception of the state as a mere mechanical convenience rather than a divine institution, but in all other respects his arguments went back to pre-Hobbesian terms. The state of nature, said Locke in the second of his *Two Treatises of Government*, was a social regime of men of good will; in it, natural law had endowed men with rights, principal among which were life, liberty, and property. Certain confusions arose when every man defined for himself and tried to protect his own rights, and it was minor difficulties and not desperation that inspired the formation of a political community specifically and exclusively for the protection of individual rights. Government was derived from the consent of the people, and it functioned by majority rule. Locke's purpose had been to compose a challenge to Charles II's brother, who was heir apparent; but the *Treatises* were not published until 1690, and by that time the Glorious Revolution had closed a troubled period and Locke's revolutionary tract was appropriated as a defense of the Revolution. Thereafter, England settled down for a long time to enterprises requiring no new political philosophizing.

While England was relaxing into complacency, most of the Continent still remained too bound to a lethargic inheritance to think of formal political theory. A few Germans, a few men of the Low Countries, an occasional Italian rose sufficiently above their bleak routines to more systematic thought, but it is best, for summary purposes, to concentrate on the affairs of France. Long before the death of Louis XIV, times were out of joint and remained so, with few respites, to the end of the monarchy. There were paralyzing difficulties, however, in finding the causes of the disturbed temper of the 18th century and proposing suitable remedies. The French monarchy had done too well in that it had stifled all prospects of generally popular institutions and had made public discussion a hazardous occupation. The monarchy had done badly in that it had not rooted out the mentality and the vested interests and important agencies of feudalism. The monarchy had also done badly in that its close ties with the Catholic Church made every grievance against the church either obliquely or overtly a grievance against the royal structure of power. The consequences were disastrous for judicious thinking about politics.

All his life Voltaire unremittingly poured his energy into supporting the powers of the crown against the parlements, the medieval law courts that had become citadels of aristocratic resistance. Montesquieu wanted a greater role in government for the nobility of which he was a member; for that reason he held the British House of

Lords in high esteem. Diderot, not by instinct a political animal, never understood the contest between king and nobles and always blew hot or cold as immediate circumstances prompted him. And yet for him, as for Voltaire, realism bade him acknowledge that all kings of France, even Louis XIV, had faults; but he never revealed doubts about the monarchy. He had courted Louis XV for preferments and had got them, and he took pride in the fact that Frederick II of Prussia had courted him. A new trend stretching across Europe from Spain to Russia gave plausibility to the thought that man's best hope for reforms lay in the vigorous sovereign. In the most unexpected capitals, rulers were reorganizing their governments, removing tax and other burdens on trade, and restraining the brutalities of the law. No enlightened Philosophe in France could complain until he realized that these so-called enlightened despots had another, and a repugnant, face turned toward war and conquest.

What was left for France to talk about, and to write about on condition of prudence, were the abuses of political power along with those of ecclesiastical power. Despite this dejecting atmosphere, in 1762 a new kind of political book appeared in Paris. It was called *Du contrat social* and its author was the difficult, emotionally unstable Jean-Jacques Rousseau, who had first won fame by a perfervid attack on the evil consequences of civilization. Rousseau proposed a society able to cultivate the individual's moral stature without injury to his freedom. It was a fresh effort at that knottiest problem of political philosophy. For a solution he returned to the old, and now somewhat derided, idea of a social contract. According to Rousseau, each individual ceded his rights and powers to a general will of which he was part—that is, an equal participant in the political life. As he stated the terms, they logically ruled out a distinction between rights and powers reserved to the individual and the authority and functions assigned to the community, that issue which was of paramount importance to Locke. By Rousseau's reckoning, the individual was as free after the contract as he had been in the state of nature; he had merely substituted for natural freedom a civic freedom by which he was elevated into a moral being. Some later readers have found in *Du contrat social* dangerous undertones of totalitarianism because of the equivocal place of the individual in relation to the general will, because of the axiom that the general will was right, and because of a prescription of a civic religion with penalties for defiance. Other latter-day students have rejected the imputation. It may be permissible to conclude that Rousseau, in writing ostensibly a book on political theory, did not really have his mind on politics. In one respect, nonetheless, he gained in clarity over John Locke. The *Two Treatises of Government* had referred to the powers of an undefined majority; *Du contrat social* wound up in an emotionally suffused claim for political democracy.

Rousseau's *Du contrat social*

Both men had their triumphs. In America Thomas Jefferson incorporated strict Lockean doctrine in the Declaration of Independence. When shortly thereafter the French revolutionaries wrote their own declaration, they made a place for Rousseau's general will and sovereignty of the nation. On both sides of the Atlantic, however, there was fumbling over the fundamental question of popular government: who was to have the right to vote.

The mainstream of Enlightened thought had no quarrel with Locke's assertion that property was a natural right. Yet Rousseau, in agreement with Hume, was uneasy. Although he did not write down specific remedies, he was persuaded that political democracy could not work without a relative economic equality. In the seething atmosphere of the second half of the 18th century, a little band of dissenters took their criticisms far beyond Rousseau's doubts. In 1755 the obscure Morelly, in *Le Code de la nature*, attacked property as the mother of all crimes tormenting the world, and he made a proposal that was to have a long history: let every man contribute to the commonweal according to his abilities and receive according to his needs. Two decades later the Abbé de Mably, starting with equality as the law of nature, contended along with Morelly—and, for that matter, with the early Rousseau—that the introduction of property had destroyed the golden age of man. Soon, François-Noël Babeuf, civil servant turned radical journalist, tried to organize a revolution within a revolution to secure the true equality ordained by nature. In England William Godwin, taking his stand on the immutable laws of the universe, rigorously pushed reason into condemning not only property but even the state and marriage. Such scandalous utterances, however, were only tiny specks in the sky. As the old century was dying, property seemed to be resting on a firm ground of support.

The law. For the Enlightenment, the law under which men actually lived required urgent consideration. There could hardly have been a greater contrast between the law of the courts and that which reason allegedly perceived in nature. Once Grotius had given his definition, the law of all lands was summoned to the supreme tribunal of reason. Man-made law, said the indictment, was valid only insofar as it conformed with nature's law. Even the famous jurist William Blackstone, steeped in the English common law, accepted the argument. On the Continent, where there was little ground for contentment, the spirit of legal thought was uncompromising; the law, said the zealots, was not made by edicts and legislative enactments but was discovered by right reason. The instrument of reform was a rigorous code, a summation of legal wisdom that could be administered with mechanical precision. The outcome was partial victory in the Prussian and Austrian codes and in the Code Napoléon.

Economic theory. Another aspect of human affairs that the Enlightenment sought to judge was the economic. The practical background was a long history of extensive state intervention in economic pursuits—mercantilism—and a recent history of middle class dissatisfactions. In France the wars of Louis XIV had wrought great misery, and even before the King's death, critics had dared to propose reforms. Among the first to apply rationalist criteria was the Sieur de Boisguillebert, in whose judgment state interference did violence to the law of nature, which prescribed a harmony of interests; right reasoning under the stimulus of free competition was the proper guide to economic behaviour. A half century later Louis XV's physician, François Quesnay, founded the physiocratic school on essentially the same assumptions. The physiocrats' economic man was motivated by self-interest but lived under nature's dictate of harmony; it followed, therefore, that unfettered private activity was the certain means to the commonweal.

The question of state interference

Adam Smith's *Inquiry into the nature and causes of the Wealth of Nations* (1776), a declaration of economic independence, criticized the physiocrats' emphasis on the unique importance of land but otherwise revealed Smith's kinship. Smith began with the butcher and the baker intent on their own good and went on to demonstrate the merit of "the system of natural liberty." Sharing the British dislike of extremes, he was not dogmatic; but behind his array of observations and utilitarian arguments there lurked the old rational conviction about "the great Director of Nature" leading men "by an invisible hand" to serve a wider cause than their immediate own. Smith had no illusions about the way men conducted their business affairs, and he wanted the state to protect the weak against the strong. Nonetheless, his bias was for the free individual determining his own destiny. Smith spoke at the right moment and became a revered teacher of the following generations.

The meaning of history. The Enlightenment's thought about history began with a dilemma. The basic rationalist values were timeless, and the practical purpose of examining the world's past experience was to strip away the accidents of time and place and lay bare Hume's "constant and universal principles of human nature." Another service from studying history was required: when real men were so far removed from the man of reason and nature, it was the task of the historians to explain the causes of the gap. To their labours most of the students of the past brought a point of view that suggested the answers in advance. As a result, numerous historical

works glossed the theme of the evil consequences of religious and political benightedness. The histories of such as Voltaire, Guillaume Raynal, Hume, and Edward Gibbon, who recorded the triumph of barbarism and religion, were heavy guns in the arsenal of the Enlightenment. They were not, however, simply camouflaged propaganda. The Reformation had inspired solid historical scholarship, even if its purpose had been partisan, and the grave scholars of the 17th century had built on it to amass documentary materials and to broaden the skills of criticism. The luminous names of the 18th century had a surer grasp, and their masterpieces—for such many were—made Europe conscious of the pleasure and the importance of reading history.

This quietly intruding sense of historical change prompted reflection, not only on the relation of the Enlightenment to the past but also on what mankind could expect in the future. Earlier speculations were not useful guides for the latter. The ancient world had generally thought in terms of cycles in which there was a deterioration of ages from gold to iron. The Christians accepted from their predecessors the idea of cosmic cataclysm, but they would admit just one, which would come at God's own appointed time; in the meanwhile, the only significance of human history was the drama of salvation for individual souls. The Renaissance tended to return to the idea of the cycle, but it was that of youth, maturity, and decay of states after the manner of Aristotle's history of the Greek polis rather than the total upheaval of the cosmos assumed by the ancient world. The happy rebirth in 15th-century Italy was, then, merely the beginning of a new cycle. Still in the 18th century, when Montesquieu reflected on the causes of the greatness and decadence of the Romans, his interpretation continued the Renaissance approach to history.

The harbinger of a new way of thinking was Francis Bacon, the aforementioned prophet of science. The Greeks and Romans, he contended, belonged to the youth of the world, and his own generation was the heir of all accumulated knowledge. It was a mistake to be chained to the hopelessness of the notion of the cycle; by the proper method of inquiry, man could move on to great benefits through the conquest of nature. It was significant that whereas Thomas More had constructed his *Utopia* in a remote setting, Bacon put his *New Atlantis* in the future.

The idea of progress

Bacon had been thinking in terms of useful knowledge, and he found the Greeks and Romans the children and not the adults of time. Such talk was offensive to the literate community that had been raised on classical literature. For such people a comparison between the two ages had to be a comparison of their literatures, and for those spiritually suckled on Homer and Virgil there was no comparison. By the late 17th century, brazen writers began to defend the literature of their own time, and for a whole century cultural Europe resounded with the cut and thrust of the warfare between the "ancients" and the "moderns." The battles raged on the subjective field of taste, and a clear-cut victory was manifestly out of the question. Long before the end of this contest Bernard Fontenelle, permanent secretary of the Académie des Sciences, had shifted the ground from letters to scientific achievement, and few could deny him his claim for progress up to his day. But more significantly, Fontenelle was primarily concerned with the future, and for its course he detected a law of progress that would guide man's destiny to still better things.

As social dissatisfaction, and hopes, mounted late in the 18th century, the idea of scientific and intellectual progress quietly slipped into a belief in the general progress of mankind, moral no less than material. Hard-headed realists like Voltaire were too oppressed with the continuing perversities of the world to fall into an easy optimism; knowledge could be used for bad purposes as well as for good, and future improvements were dependent on the role of sound reason. Such a qualification, however, had little restraining value for those whose vision of the future had become assured. Young Anne-Robert-Jacques Turgot, the future minister of Louis XVI, surveyed all human history and found it a record of the progress of the race toward perfection; even in ages of apparent barbarism, men and society had moved, however slowly, in the right direction and in the future would continue to do so under a law of acceleration. Turgot's friend the Marquis de Condorcet converted these calm anticipations into fervent prophecy. Hiding in 1793 from the revolution that he had joyfully served, Condorcet hastily composed his *Esquisse d'un tableau historique des progrès de l'esprit humain*. He saw mankind facing its tenth and culminating epoch—a new day in which the steady march toward perfectibility could not be stopped. The time would come, said this man under sentence of death, when the sun would shine only on free men who knew no master but their reason.

The end of the Enlightenment. A chronology of the disintegration of the Enlightenment is impossible. For all of its belief in eternals, it was from the beginning a flow of ideas in which emphases shifted and trains of thought broke under the impact of new evidence and new insights. Newton's physics and Locke's epistemology were absorbed into the uneasy synthesis, but eventually they bore a heavy responsibility for the decay. Natural law as perceived by right reason was, for many of the latter-day lovers of science, sinking into a bloodless cliché, while the pleasure–pain doctrine built up its empire of utilitarianism. At the high noon of religious rationalism, John Wesley cried defiance with his emotional Methodism. Nature, once considered a synonym of reason and visible proof of the existence of God and his benevolence, broke up into something to be studied with scientific objectivity and something to be enjoyed in romantic indulgence. Not by any means the least blow to the Enlightenment's timeless verities was the revolutionary growth of historical mindedness, of the turn toward rethinking all mortal affairs as well as scientific questions in terms of ceaseless change. In the dying days of the Enlightenment the Western mind was setting out on the road that led to Edmund Burke and Hegel and to Darwin and Marx.

Later times have ridiculed a naïve epoch, but the Enlightenment's moral and intellectual significance is high because it tried to rethink in new idioms the oldest values and beliefs in the history of Western civilization.

Entoprocta

The Entoprocta, a small phylum of aquatic invertebrates, are found attached to some object (*i.e.*, are sedentary). Some entoprocts live as individuals; others form colonies. Most are marine: *Pedicellina*, for example, forms clumps on seaweeds or bryozoans (small marine invertebrates) that are found near low tidemark.

General features

Entoproct individuals are called zooids; a *Pedicellina* colony, for example, consists of a series of distinct zooids, which originate from a creeping, branching stolon (or stemlike attachment structure) and attain a height of about two millimetres, occasionally four or five millimetres. Although they are small, zooids may be so numerous that the substance supporting them has a fuzzy appearance. The body of a zooid consists of a stalk bearing a tentacle-crowned head, called the calyx. The calyx is soft; the stalk may be soft or hard. Each *Pedicellina* zooid, for example, consists of a globular calyx that is linked to the stolon by a flexible supporting stalk, which can move from its base in a jerky, sweeping manner. The outer surface of the calyx bears a circle of tentacles; most of the interior of the calyx contains the alimentary canal, which is U shaped and has both mouth and anus encircled by tentacles. The anus is raised on a papilla, leaving a space (or atrium) between the rectum and the mouth. Related to *Pedicellina* is *Barentsia*, which has a jointed stalk of rigid segments, and the freshwater *Urnatella*, which has a nodular stalk.

Less familiar genera, although they are represented by many more species, are *Loxosoma* and *Loxosomella;* individuals are not joined by stolons but often occur in dense aggregations known as loxosome populations. The individuals are very small (often only 0.5 millimetre high) and are of biological interest because they live in intimate associations with other animals (*e.g.*, polychaetes, sipunculids, sponges, and bryozoans). Loxosomes apparently are energy commensals; they obtain food from the respiratory or feeding currents of the host animal.

Structure of entoprocts.
(A) *Loxosoma singulare* zooid with two buds. (B) *Urnatella gracilis* colony consisting of a flexible stalk with urnlike segments. (C) *Pedicellina cernua* calyx (top view).

Budding and reproduction

Natural History. Entoprocts reproduce asexually and sexually. Asexual reproduction, called budding or blastogenesis, gives rise to both the pedicellinid colony and the loxosome population. In pedicellinids the stolons are blastogenic; the colony grows by the linear extension and the branching of stolons, which produce at their tips a succession of buds that differentiate into zooids.

In the loxosomes, which lack stolons, the calyx is blastogenic and commonly produces two series of buds. The daughter zooids break free and may either swim away, stalk foremost (resembling miniature torpedoes), or use a "foot" on the end of the stalk to move over the host's surface. In *Loxosomella* the foot contains a cement gland. In *Loxosoma*, however, the stalk has a sucking disc at the end, and a zooid of this genus retains the ability to move throughout its life, using foot and tentacles alternately as points of attachment to a surface.

Entoprocts can disperse themselves over large regions by sexually produced larvae. Zooids may be of one sex or hermaphroditic, having both male and female sexual organs in one animal, in which case the testes mature first. In both types, ducts from the paired gonads unite and open into the atrium (*i.e.*, the space between rectum and mouth), and fertilization is internal. Several young embryos attach themselves to a part of the atrial wall in front of the rectum that supplies nutriment for the embryos, which develop and eventually are released as larvae. In *Urnatella* one larva develops inside an ovary.

The entoproct larva resembles an annelid larva; in the entoproct larva, however, the girdle of locomotory cilia (*i.e.*, hairlike processes) is not located in an equatorial position but is found near the basal pole. The *Pedicellina* larva, which has a structural resemblance to an inverted and nontentaculate adult calyx, attaches base downwards (with mouth and anus toward the surface). In the metamorphosis (change) of a larva into a zooid, the gut is reoriented so that mouth and anus are in the adult positions. Although loxosome larvae may metamorphose, daughter zooids usually are budded off (*i.e.*, set free) directly from the larvae. Daughter zooids also may form internally, the larva rupturing to release the zooid.

Entoprocts with stolons can regenerate (*i.e.*, replace) lost parts of their bodies. Lost calyces, for example, are replaced quickly. *Barentsia* and *Urnatella* colonies survive the winter as dormant buds or stolon sections which germinate into new colonies in the spring.

Feeding and digestion

Form and function. All entoprocts feed on organic particles that are filtered from the surrounding water. Ciliated tentacles on the outer margin of the calyx spread widely. Long lateral cilia drive water inward between the tentacles. The inner surface of each tentacle bears a tract of short frontal cilia. The tract descends into a ciliated groove, which passes the tentacle bases and extends to the mouth. Food particles, thrown by the long lateral cilia onto the short frontal cilia are trapped in mucus, carried down the tentacles, around the ciliated groove, and into the mouth. Unsuitable particles are removed by the water flow. If disturbed, the tentacles can be folded inward so that they lie within a muscular membrane that unites their bases.

The body wall consists of an outer, cuticle-covered epidermis (or skin), below which (particularly in the stalk) is a layer of muscle fibres. The primitive body cavity is filled with connective tissue and fluid. In colonial entoprocts, muscle cells at the junction of the calyx and the stalk contract rhythmically every few seconds and may serve as pumps to assist the movement of nutrients from the calyces toward the growing tips of the stolons.

In marine entoprocts two flame-cell nephridia (*i.e.*, excretory tubules) share an opening into the atrium. The freshwater genus, *Urnatella*, has many nephridia, which have an osmoregulatory (*i.e.*, water-removing) function.

From a double ganglion above the stomach, nerves radiate to the tentacles and to some parts of the viscera.

Distinguishing characteristics

Evolution and classification. Entoprocts are characterized by stalked, pseudocoelomate zooids that contain a U-shaped gut (*i.e.*, both mouth and anus open within a circle of 6 to 36 ciliated tentacles). The larva and the pattern of its early development indicate that the entoprocts may be linked remotely with the Annelida and their related phyla. There is no evidence of a close link with any phylum.

First described in 1774, entoprocts were classified with the Bryozoa, in which filter-feeding, tentaculated zooids also are present. The similarities between the two groups, however, are superficial. Methods of food capture, for example, differ fundamentally; in addition, bryozoan zooids are coelomate, and the anus opens outside the tentacles. The name Entoprocta was introduced in 1869, and the group was first recognized as a phylum in 1888. Alternative names (Calyssozoa and Kamptozoa) were proposed in 1921 and 1929.

The phylum is small and has no known fossil members. The subdivision into three families does not accord fully with the considerable differences between colonial and

noncolonial forms. It might be more accurate if two orders were recognized; the first order would include the families Pedicellinidae (about 30 species classified into 6 genera according to stalk structure) and Urnatellidae (2 species), and the second order would contain only the Loxosomatidae (about 100 species).

Enzyme

Enzymes comprise an important group of proteins that make possible the chemical reactions that constitute metabolism. They are efficient and specific—that is, they accelerate the rate of one kind of chemical reaction of one type of compound, and they do so far more efficiently than man-made catalysts. They act as biological catalysts, or accelerators, of the thousands of successive complex biochemical reactions that take place in all living things. Enzymes are controlled by activators and inhibitors that initiate or block reactions. All cells contain enzymes, which usually vary in number and composition, depending on the cell type; an average mammalian cell, for example, is about one one-billionth (10^{-9}) the size of a drop of water and contains about 3,000 enzymes.

GENERAL FEATURES

Historical background. Although little was known about the chemical nature of enzymes until the 20th century, enzymatic reactions have been used by man since prehistoric times. Among man's earliest discoveries was that the juice of grapes ferments and turns into wine, a process attributed by the Greeks to the god Bacchus. Not until the 19th century was it understood that the conversion of grape sugar to alcohol is a process catalyzed by enzymes found in yeast. Another enzymatic action was discovered by chance when primitive herdsmen filled canteens consisting of the stomachs of slaughtered animals with milk instead of water and found that the milk soon formed clumps of cheese. The reason for the transformation, the action on milk of an enzyme (rennin) released from the lining of animal stomachs, was not known until centuries later. Rennin from calves' stomachs is still widely used in the production of cheese. Throughout history, accidental discoveries of enzymatic reactions have enabled man to carry out other processes; *e.g.*, the leavening of bread, the brewing of beer, the formation of vinegar, and the tenderizing of meat.

The existence of enzymes was established in the middle of the 19th century by scientists studying the process of fermentation. Their role as catalysts of all living things followed rapidly. Developments before 1850 included (in 1833) the separation from malt of the enzyme amylase, which converts starch into sugar, and (in 1836) the isolation from the stomach wall of animals of a component of gastric juice that could partially digest food in a test tube, the enzyme pepsin.

Enzymes were known for many years as ferments, from the Latin word for yeast. In 1878 the name enzyme, from the Greek words meaning "in yeast," was introduced and has since been universally used.

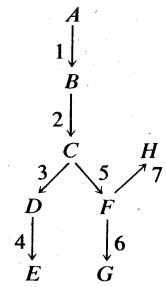
Importance. *In biology.* Almost all of the numerous and complex biochemical reactions that take place in animals, plants, and micro-organisms are regulated by enzymes.

The role of enzymes in metabolism

Some enzymes help to break down large nutrient molecules, such as proteins, fats, and carbohydrates, into smaller molecules. This process occurs during the digestion of foodstuffs in the stomach and intestines of animals. Other enzymes guide the small molecules through the intestinal wall into the bloodstream. Still other enzymes promote the formation of large, complex molecules from the small, simple ones to produce cellular constituents. Enzymes are also responsible for other functions; *e.g.*, the storage and release of energy, the course of reproduction, the processes of respiration, vision, etc. They are indispensable to life.

Each enzyme is able to promote only one type of chemical reaction. The compounds on which it acts are called substrates. Enzymes operate in tightly organized metabolic systems called pathways. A seemingly simple biological phenomenon—the contraction of a muscle, for example, or the transmission of a nerve impulse—actually involves a number of chemical steps in which one or more chemical compounds (substrates) are converted to substances called products; the product of one step in a metabolic pathway serves as the substrate for the succeeding step.

The role of enzymes in metabolic pathways can be illustrated diagrammatically. The chemical compound represented by *A* (see diagram) is converted to product *E* in a series of enzyme-catalyzed steps, in which intermediate compounds represented by *B*, *C*, and *D* are formed in succession. They act as substrates for enzymes represented by 2, 3, and 4. Compound *A* may also be converted by another series of steps, some of which are the same as those in the pathway for the formation of *E*, to products represented by *G* and *H*.



The letters represent chemical compounds; numbers represent enzymes that catalyze individual reactions. The relative heights represent the thermodynamic energy of the compounds; *e.g.*, compound *A* is more energy-rich than *B*, *B* more energy-rich than *C*. Compounds *A*, *B*, etc., change very slowly in the absence of a catalyst but do so rapidly in the presence of catalysts 1, 2, 3, etc.

The regulatory role of enzymes in metabolic pathways can be clarified by using a simple analogy: that between the compounds, represented by letters in the diagram, and a series of connected water reservoirs on a slope. Similarly, the enzymes represented by the numbers are analogous to the valves of the reservoir system. The valves control the flow of water in the reservoir; that is, if only valves 1, 2, 3, and 4 are open, the water in *A* flows only to *E*, but, if valves 1, 2, 5, and 6 are open, the water in *A* flows to *G*. In a similar manner, if enzymes 1, 2, 3, and 4 in the metabolic pathway are active, product *E* is formed, and, if enzymes 1, 2, 5, and 6 are active, product *G* is formed. The activity or lack of activity of the enzymes in the pathway therefore determines the fate of compound *A; i.e.*, it either remains unchanged or is converted to one or more products. In addition, if products are formed, the activity of enzymes 3 and 4 relative to that of enzymes 5 and 6 determines the quantity of product *E* formed compared with product *G*.

Both the flow of water and the activity of enzymes obey the laws of thermodynamics; hence, water in reservoir *F* cannot flow freely to *H* by opening valve 7, because water cannot flow uphill. If, however, valves 1, 2, 5, and 7 are open, water flows from *F* to *H*, because the energy conserved during the downhill flow of water through valves 1, 2, and 5 is sufficient to allow it to force the water up through valve 7. In a similar way, enzymes in the metabolic pathway cannot convert compound *F* directly to *H* unless energy is available; enzymes are able to utilize energy from energy-conserving reactions in order to catalyze reactions that require energy. During the enzyme-catalyzed oxidation of carbohydrates to carbon dioxide and water, energy is conserved in the form of an energy-rich compound, adenosine triphosphate (ATP). The energy in ATP is utilized during an energy-consuming process such as the enzyme-catalyzed contraction of muscle.

Because the needs of cells and organisms vary, not only the activity but also the synthesis of enzymes must be regulated; *e.g.*, the enzymes responsible for muscular activity in a leg muscle must be activated and inhibited at appropriate times. Some cells do not need certain enzymes; a liver cell, for example, does not need a muscle enzyme. A bacterium does not need enzymes to metabolize substances that are not present in its growth medium. Some enzymes, therefore, are not formed in certain cells, others are synthesized only when required, and still others are found in all cells (see also GENE). The formation and activity of enzymes are regulated not only by genetic mechanisms but also by organic secretions (hormones) from endocrine glands and by nerve impulses. Small molecules also play an important role (see below *Enzyme flexibility and allosteric control*).

The significance of enzymes in disease

If an enzyme is defective in some respect, disease may occur. The enzymes represented by the numbers 1 to 4 in the diagram must function during the conversion of the starting substance *A* to the product *E*. If one step is blocked because an enzyme is unable to function, product *E* may not be formed; if *E* is necessary for some vital function, disease results. Many inherited diseases of man result from a deficiency of one enzyme. Some of these are listed in Table 1. The disease called albinism, for example, results from an inherited lack of ability to synthesize the enzyme tyrosinase, which catalyzes one step in the pathway by which the pigment for hair and eye colour is formed (see also METABOLISM, DISEASES OF; BIRTH DEFECTS AND CONGENITAL DISORDERS).

Table 1: Enzymes Identified with Hereditary Diseases

disease name	defective enzyme
Albinism	tyrosinase
Phenylketonuria	phenylalanine hydroxylase
Fructosuria	fructokinase
Methemoglobinemia	methemoglobin reductase
Galactosemia	galactose-1-phosphate uridyl transferase

In medicine. Enzymes play an increasingly important role in medicine. The enzyme thrombin is used to promote the healing of wounds. Other enzymes are used to diagnose certain kinds of disease, to cause the remission of some forms of leukemia—a disease of the blood-forming organs—and to counteract unfavourable reactions in people who are allergic to penicillin. The enzyme lysozyme, which destroys cell walls, is used to kill bacteria. Research concerning medical applications of enzymes may lead to their use as preventives of tooth decay and as anticoagulants in the treatment of thrombosis, a disease characterized by the formation of a clot, or plug, in a blood vessel. Enzymes may eventually be used to control enzyme deficiencies and abnormalities resulting from diseases.

In industry. The most efficient catalysts known to man, enzymes are used in industrial processes involving the preparation of certain chemical compounds and the tanning of leather; they are valuable in analytical procedures involving the detection of very small quantities of specific substances. Enzymes are necessary in such food-related industries as cheese making, the brewing of beer, the aging of wine, and the baking of bread. Enzymes also may be used to clean clothes. For industrial use of enzymes see BAKING AND BAKERY PRODUCTS; BREWING; and WINE MAKING.

GENERAL PROPERTIES

Classification and nomenclature. The first enzyme name, proposed in 1833, was diastase. Sixty-five years later, it was suggested that all enzymes be named by adding "-ase" to a root indicative of the nature of the substrate of the enzyme. Although enzymes are no longer named in such a simple manner, with the exception of a few—*e.g.*, pepsin, trypsin, chymotrypsin, papain—most enzyme names do end in "-ase."

Any systematic classification of enzymes should be based on a common property or quality that varies sufficiently to be useful as a distinguishing feature. In this regard, three properties of enzymes could serve as a basis for enzyme classification—the exact chemical nature of the enzyme, the chemical nature of the substrate, and the nature of the reaction catalyzed. Adequate information about the detailed chemical structures of more than a few enzymes does not yet exist. In addition, although, as indicated above, early attempts at enzyme classification were based on the nature of broad groups of substrates (*e.g.*, enzymes called carbohydrases act on carbohydrates), close functional similarities among enzymes in different groups were often obscured. By general agreement, then, enzymes now are classified according to their substrates and the nature of the reaction they catalyze.

Systematic and trivial names

In an attempt to devise a rational system of enzyme nomenclature, two names are given to an enzyme. One, known as the systematic name, is based on logical principles but is often long and awkward; the other, "trivial" name is short and generally used but not usually exact or systematic (see Table 2). In the scheme of systematic nomenclature, six main groups of enzymatic reactions are recognized; each catalyzes one reaction type and is subdivided on the basis of detailed definitions of the reaction catalyzed and of the substrate involved in the reaction. Enzymes that catalyze reactions in which hydrogen is transferred belong to the group known as oxidoreductases; those that catalyze the introduction of the elements of water at a specific site in a molecule are called hydrolases. The other four groups of reactions are the transferases—which catalyze reactions in which substances other than hydrogen are transferred—the lyases, the isomerases, and the ligases. Oxidoreductases and transferases account for about 50 percent of the approximately 1,000 enzymes recognized thus far. Table 2 lists a few enzymes, their trivial names, their systematic names, and their biological roles.

Chemical nature. Little was known about the chemical nature of enzymes until the beginning of the 20th century, although scientists were almost convinced that they were proteins. In 1926, the enzyme urease was the first to be crystallized and clearly identified as a protein. Within the next few years, the digestive enzymes pepsin, trypsin, and chymotrypsin were shown to be proteins. Since that time, hundreds of enzymes, all of them proteins, have been prepared and characterized by chemical methods. Much of the knowledge of protein chemistry has, in fact, resulted from studies involving enzymes and from attempts to understand their nature and mode of action.

Although some enzymes consist of a single chain of the amino acids (*i.e.*, simple organic molecules containing nitrogen), most enzymes are composed of more than one chain. Each chain is called a subunit. Many enzymes have two, four, or six subunits, and some consist of as many as 12 to 60 subunits. In many cases, the subunits have identical structures; in others, however, several different types of subunit chains are involved. (See PROTEIN for a detailed discussion of the chemical nature of proteins.)

Much of the dry weight of plants and animals is attributable to proteins; with the exception of proteins that act as structural elements, most of the proteins in physiologically active tissues such as kidney and liver are enzymes. Regardless of the exact amount of enzymatic protein in an organism, it is clear that hundreds of different enzymes must be present in each tissue to account for the myriad reactions comprising metabolism.

Cofactors. Although some enzymes consist only of protein, many are complex proteins; *i.e.*, they have a protein component and a so-called cofactor. A complete enzyme is called a holoenzyme; if the cofactor is removed, the protein, no longer enzymatically active, is called the apoenzyme. A cofactor may be a metal—such as iron, copper, or magnesium—a moderately sized organic molecule called a prosthetic group, or a special type of substrate molecule known as a coenzyme. The cofactor may aid in the catalytic function of an enzyme, as do metals and prosthetic groups, or take part in the enzymatic reaction, as do coenzymes.

Coenzymes

A coenzyme serves as a type of substrate in certain enzymatic reactions and thus reacts in the exact propor-

Table 2: Classification of Some Enzymes

systematic name*		trivial name	reaction catalyzed	biological role
code number†	name‡			
1.1.1.1	alcohol: NAD oxidoreductase	alcohol dehydrogenase	alcohol + NAD → acetaldehyde NADH	alcoholic fermentation
1.1.1.27	L-lactate: NAD oxidoreductase	lactic dehydrogenase	lactate + NAD → pyruvate + NADH	carbohydrate metabolism
2.7.1.40	ATP: pyruvate phospho transferase	pyruvate kinase	pyruvic acid + ATP → phosphoenol-pyruvic acid + ADP	carbohydrate metabolism
3.1.1.7	acetylcholine: acetyl hydrolase	acetylcholinesterase	acetylcholine + H_2O → acetate + choline	nerve-impulse conduction
3.4.4.13	peptide peptido hydrolase	thrombin	peptide bond + $H_2O \rightarrow -\overset{O}{\overset{\|}{C}}-OH + H_3{}^+N-$	blood-clotting mechanism

*Based on recommendations (1964) of the International Union of Biochemistry. †The numbering system is as follows: the first number places the enzyme in one of six general groups—1, oxidoreductases; 2, transferases; 3, hydrolases; 4, lyases; 5, isomerases and 6, ligases. The second number places the enzyme in a subclass based on substrate type or reaction type; *e.g.*, the enzyme may act on molecules with —CHOH groups. The third number places the enzyme in a subsubclass, which specifies the reaction type more fully; *e.g.*, NAD coenzyme required. The fourth number is the serial number of the enzyme in its subsubclass. ‡NAD and NADH represent the oxidized and reduced forms of nicotinamide adenine dinucleotide (NAD), respectively; ATP and ADP represent adenosine triphosphate and adenosine diphosphate, respectively.

tions (*i.e.*, stoichiometrically) required for reaction, rather than in catalytic quantities. A coenzyme may, for example, assume the role of a hydrogen acceptor, as does nicotinamide adenine dinucleotide (NAD), which accepts hydrogen from the substrate, or a chemical-group donor, as does adenosine triphosphate (ATP), which donates phosphoric acid to the substrate. After ATP has donated a phosphoric acid molecule to the substrate, the phosphoric acid can be reacquired in a second stoichiometric reaction catalyzed by a second enzyme. The catalytic nature of a coenzyme is apparent only when it couples the activities of two enzymes in this way. Coenzymes thus are the links, or shuttles, in metabolic pathways that enable substances—*e.g.*, hydrogen, phosphoric acid—to be exchanged.

An interesting aspect of coenzymes is that many of them are closely related to vitamins, which are necessary for the proper functioning of life processes. Many vitamins are essential for the synthesis of coenzymes; since coenzymes play a vital role in metabolism, it is not difficult to understand why certain vitamins are essential. Table 3 lists some coenzymes, the type of enzymes with which they react, and the vitamins required for their synthesis in mammals (see also VITAMIN; NUCLEOTIDES).

Table 3: The Relationship Between Coenzymes and Vitamins

name of coenzyme	some enzymes with which it reacts	vitamin needed for synthesis
Adenosine triphosphate	kinases, muscle enzymes	none
Nicotinamide adenine dinucleotide	dehydrogenases	nicotinic acid
Pyridoxal phosphate	transaminases	pyridoxine
Biotin	carboxylases	biotin
Coenzyme A	acyl transferases	pantothenic acid

THE NATURE OF ENZYME-CATALYZED REACTIONS

The nature of catalysis. In a chemical reaction—for example, one in which substance *A* is converted into product *B*—a point of equilibrium eventually is reached at which no further chemical change occurs; *i.e.*, the rate of conversion of *A* to *B* equals the rate of conversion of *B* to *A*. The so-called thermodynamic-equilibrium constant expresses this chemical equilibrium. A catalyst may be defined as a substance that accelerates a chemical reaction but is not consumed in the process. The amount of catalyst has no relationship to the quantity of substance altered; very small amounts of enzymes are very efficient catalysts. Because the presence of an enzyme accelerates the rate of conversion of a compound to a product, it accelerates the approach to equilibrium; it does not, however, influence the equilibrium point attained.

The molecules in the watery medium of the cell are in constant thermal motion but, because they are more or less stable compounds, they would react only occasionally to form products in the absence of enzymes. There exists an energy barrier to the reaction of a molecule. The energy required to overcome the barrier to reaction is called the energy of activation. A reaction proceeds to equilibrium only if the molecules have sufficient energy of activation to form an activated complex, from which products can be derived. Enzymes greatly increase the chances for reactions by their ability to make large numbers of specific molecules more reactive (*i.e.*, unstable) by forming intermediate compounds with them. The unstable intermediates quickly break down to form stable products, and the enzymes, unchanged by the reaction, are able to catalyze the formation of additional products.

The role of the active site. That the compound on which an enzyme acts (substrate) must combine in some way with it before catalysis can proceed is an old idea, now supported by much experimental evidence. The combination of substrate molecules with enzymes involves collisions between the two. Enzymes are large molecules, the molecular weights of which (based on the weight of a hydrogen atom as 1) range from several thousand to several million. The substrates on which enzymes act usually have molecular weights of several hundred. Because of the difference in size between the two, only a fraction of the enzyme is in contact with the substrate; the region of contact is called the active site. Usually, each subunit of an enzyme has one active site capable of binding substrate.

The characteristics of an enzyme derive from the sequence of amino acids, which determine the shape of the enzyme (*i.e.*, the structure of the active site) and hence the specificity of the enzyme.

Figure 1A shows the way in which the substrate fits into the active site of an enzyme. A small portion of the structure of the enzyme is represented by the various dark lines and symbols. The triangles labeled *A* and *B* represent the amino acids at the active site that actually catalyze the reaction in which the bond (indicated by the indentation) in the substrate molecule is broken as a product forms. The circles in the enzyme structure represent amino acids that function in attracting certain regions of the substrate, so that it is held in the proper position to allow the reaction at the active site to proceed.

Forces attracting enzyme and substrate

The forces that attract the substrate to the surface of an enzyme may be of a physical or a chemical nature. Electrostatic bonds may occur between oppositely charged groups—the circles containing plus and minus signs on the enzyme are attracted to their opposites in the substrate molecule. Such electrostatic bonds can occur with groups that are completely positively or negatively charged (*i.e.*, ionic groups) or with groups that are partially charged (*i.e.*, dipoles). The attractive forces between substrate and enzyme may also involve so-called hydrophobic bonds, in which the oily, or hydrocarbon, portions of the enzyme (represented by H-labeled circles) and the

substrate are forced together in the same way as oil droplets tend to coalesce in water.

Modifications in the structure of the amino acids at or near the active site usually affect the enzyme's activity, because these amino acids are intimately involved in the fit and attraction of the substrate to the enzyme surface. The characteristics of the amino acids near the active site determine whether or not a substrate molecule will fit into the site. A molecule that is too bulky in the wrong places, as indicated by the arrow in Figure 1B, cannot fit into the active site and thus cannot react with the enzyme. In a similar manner, a molecule lacking essential attractive forces (indicated by the arrow in 1C) or the appropriately charged regions (indicated by the arrow in 1D) might not be bound to the enzyme. On the other hand, a molecule with a bulky group (1E) at a position such that it does not interfere with the binding of the molecule to the enzyme or with the function of the active site is able to serve as a substrate for the enzyme. The idea of a fit between substrate and enzyme, called the "key–lock" hypothesis, was proposed by a German chemist, Emil Fischer, in 1899 and explains one of the most important features of enzymes, their specificity. In most of the enzymes studied thus far, a cleft, or indentation, into which the substrate fits (see 1A), is found at the active site.

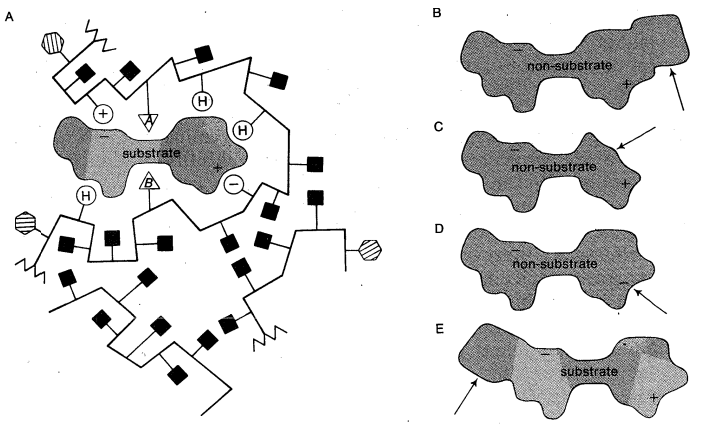


Figure 1: The role of active site in lock and key fit of a substrate—the key—to an enzyme—the lock (see text).

The specificity of enzymes. *Substrate specificity.* Since the substrate must fit into the active site of the enzyme before catalysis can occur, only properly designed molecules can serve as substrates for a specific enzyme; in many cases, an enzyme will react with only one naturally occurring molecule. Two oxidoreductase enzymes from Table 2 will serve to illustrate the principle of enzyme specificity. One (alcohol dehydrogenase) acts on alcohol, the other (lactic dehydrogenase) on lactic acid; the activities of the two, even though both are oxidoreductase enzymes, are not interchangeable—*i.e.*, alcohol dehydrogenase will not catalyze a reaction involving lactic acid or vice versa, because the structure of each substrate differs sufficiently to prevent its fitting into the active site of the alternative enzyme. Enzyme specificity is essential because it keeps separate the many pathways, involving hundreds of enzymes, that function during metabolism.

Figure 1 illustrates enzyme specificity. As mentioned above, the molecules in B, C, and D cannot serve as substrates for the enzyme because they are either too large (B), too small (C), or too repulsive because of charge (D) to bind to the enzyme's active site. Molecules the structural differences of which do not affect the active site (see arrow, Figure 1E), are able to react with the enzyme and are substrates.

Not all enzymes are as highly specific as the example in Figure 1; digestive enzymes such as pepsin and chymotrypsin, for example, are able to act on almost any protein, as they must if they are to act upon the varied types of proteins consumed as food. On the other hand, thrombin, which reacts only with the protein fibrinogen, is part of a very delicate blood-clotting mechanism and thus must act only on one compound in order to maintain the proper functioning of the system.

When enzymes were first studied, it was thought that most of them were "absolutely specific"—*i.e.*, that they would react with only one compound. In most cases, however, a molecule other than the natural substrate can be synthesized in the laboratory; it is enough like the natural substrate to react with the enzyme. Use of these synthetic substrates has been valuable in understanding enzymatic action. It must be remembered, however, that, in the living cell, many enzymes are absolutely specific for the compounds found there.

Reaction specificity. All enzymes isolated thus far are specific for the type of chemical reaction they catalyze—*i.e.*, oxidoreductases do not catalyze hydrolase reactions, and hydrolases do not catalyze reactions involving oxidation and reduction. An enzyme therefore catalyzes a specific chemical reaction but may be able to do so on several similar compounds.

The mechanism of enzymatic action. An enzyme attracts substrates to its active site, catalyzes the chemical reaction by which products are formed, and then allows the products to dissociate—*i.e.*, separate from the enzyme surface. This sequence is shown in Figure 2. The combination formed by an enzyme and its substrates is called the enzyme–substrate complex. When two substrates and one enzyme are involved, the complex is called a ternary complex; one substrate and one enzyme are called a binary complex. The substrates are attracted to the active site by electrostatic and hydrophobic forces, which are called noncovalent bonds because they are physical attractions and not chemical bonds (see above *The role of the active site*).

The enzyme–substrate complex

In Figure 2, two substrates (S_1 and S_2) bind to the active site of the enzyme during step (1) and react to form products (P_1 and P_2) during step (2). The products dissociate from the enzyme surface in step (3), releasing the enzyme. The enzyme, unchanged by the reaction, is able to react with additional substrate molecules in this manner many times per second to form products. The step in which the actual chemical transformation occurs—step (2) of Figure 2—is of great interest, and, although much is known about it, it is not yet fully understood. In general there are two types of enzymatic mechanisms, one in which a so-called covalent intermediate forms (see below) and one in which none forms (Figure 2B). Figure 2A and B show in detail the catalytic events that occur during an enzyme-catalyzed reaction.

Figure 2A shows the mechanism by which a covalent intermediate—*i.e.*, an intermediate with a chemical bond between substrate and enzyme—forms. One substrate, $B - X$ (in 2A), reacts with the group N on the enzyme surface to form an enzyme-B intermediate compound. The intermediate compound then reacts with the second substrate, Y, to form the products $B - Y$ and X.

Many enzymes catalyze reactions by this type of mechanism. Acetylcholinesterase (Table 2 and Figure 2A) is used as a specific example in the sequence described below. The two substrates (S_1 and S_2) for acetylcholin-

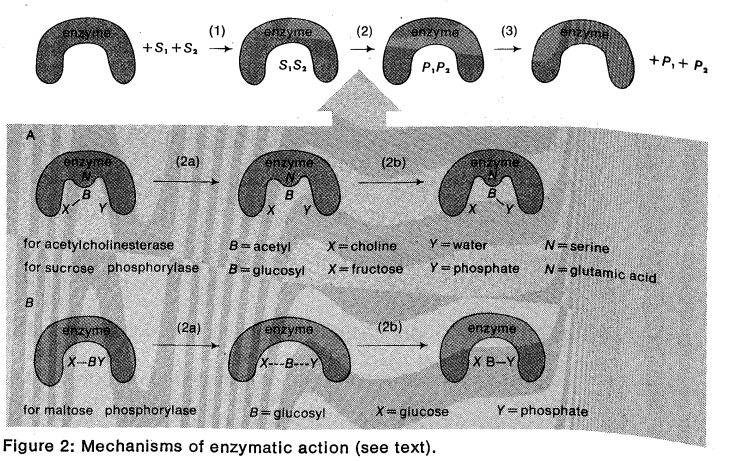

Figure 2: Mechanisms of enzymatic action (see text).

esterase are acetylcholine (the $B - X$ of Figure 2A) and water (the Y of Figure 2A). After acetylcholine ($B - X$) binds to the enzyme surface, a chemical bond forms between the acetyl moiety (B) of acetylcholine and the group N (part of the amino acid serine) on the enzyme surface. The result of the formation of this bond, called an acyl–serine bond, is one product, choline (X), and the enzyme-B intermediate compound (an acetyl–enzyme complex). The water molecule (Y) then reacts with the acyl–serine bond to form the second product, acetic acid ($B - Y$), which dissociates from the enzyme. Acetylcholinesterase is regenerated and is again able to react with another molecule of acetylcholine. This kind of reaction, involving the formation of an intermediate compound on the enzyme surface, is generally called a double displacement reaction.

Sucrose phosphorylase (see Figure 2A) acts in a similar way. The substrate for sucrose phosphorylase is sucrose, or glucosyl-fructose ($B - X$), and the group N on the enzyme surface is a chemical group called a carboxyl group (COOH). The enzyme-B intermediate, a glucosyl–carboxyl compound, reacts with phosphate (Y) to form glucosyl-phosphate ($B - Y$). The other product (X) is fructose.

In double displacement reactions, the covalent intermediate between enzyme and substrate apparently influences the reaction to proceed more rapidly. Because the enzyme is unaltered at the end of the reaction, it functions as a true catalyst, even though it is temporarily altered during the enzymatic process.

Although many enzymes form a covalent intermediate, the mechanism is not essential for catalysis; some reactions proceed as illustrated in Figure 2B. One substrate (Y) reacts directly with the second substrate ($X - B$), in a so-called single displacement reaction. The B moiety, which is transformed in the chemical reaction, is involved in only one reaction and does not form a bond with a group on the enzyme surface. In Figure 2B, the enzyme maltose phosphorylase directly affects the bonds of the substrates ($B - X$ and Y), which, in this case, are maltose (glucosylglucose) and phosphate, to form the products, glucose (X) and glucosylphosphate ($B - Y$).

Covalent intermediates between part of a substrate and an enzyme occur in many enzymatic reactions, and various amino acids—serine, cysteine, lysine, and glutamic acid—are involved.

The rate of enzymatic reactions. *The Michaelis–Menten hypothesis.* If the velocity of an enzymatic reaction is represented graphically as a function of the substrate concentration (S), the curve obtained in most cases is a hyperbola (see Figure 3). The mathematical expression of this curve, shown in the equation below, was developed in 1913 by two German biochemists, L. Michaelis and M.L. Menten. In the equation, V_M is the maximal velocity of the reaction, and K_M is called the Michaelis constant,

The Michaelis constant, K_M

$$\text{velocity} = \frac{V_M(S)}{K_M + (S)}.$$

The shape of the curve is a logical consequence of the active-site concept; *i.e.*, the curve flattens at the maximum velocity (V_M), which occurs when all the active sites of the enzyme are filled with substrate. The fact that the velocity approaches a maximum at high substrate concentrations provides support for the assumption that an intermediate enzyme–substrate complex forms. At the point of half the maximum velocity ($\frac{V_M}{2}$ in Figure 3), the substrate concentration in moles per litre (M) is equal to the Michaelis constant, which is a rough measure of the affinity of the substrate molecule for the surface of the enzyme. K_M values usually vary from about 10^{-8} to 10^{-2} M, and V_M usually varies from 10^5 to 10^9 molecules of product formed per molecule of enzyme per second. The value for V_M is referred to as the turnover number when expressed as moles of product formed per mole of enzyme per minute. The binding of molecules that inhibit or activate the protein surface usually results in similar types of curves.

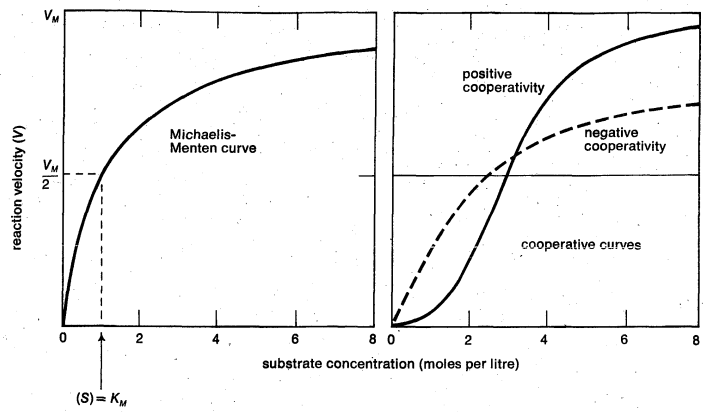

Figure 3: Curves representing enzyme action (see text).

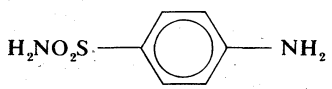
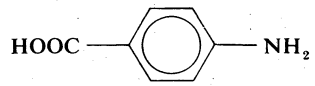
The efficiency of enzymes. Enzymes are more efficient than man-made catalysts operating under the same conditions. Because many enzymes with different specificities occur in a cell, adequate space exists only for a few enzyme molecules catalyzing one specific reaction. Each enzyme, therefore, must be very efficient. One molecule of the enzyme catalase, for example, can produce 10^{12} molecules of oxygen per second. The catalytic groups at the active site of an enzyme act 10^6 to 10^9 times more effectively than do analogous groups in a nonenzymatic reaction.

The reason for the great efficiency of enzymes is not completely understood. It results in part from the precise positioning of the substrates and the catalytic groups at the active site, which serves to increase the probability of collision between the reacting atoms. In addition, the environment at the active site may be favourable for reaction—that is, acidic and basic groups may act together more effectively there, or some strain may be induced in the substrate molecules so that their bonds are broken more easily, or the orientation of the reacting substrates may be optimal at the enzyme surface. The theories that have been formulated to account for the high catalytic efficiency of enzymes, although reasonable, still remain to be proved.

Inhibition of enzymes. Some molecules very similar to the substrate for an enzyme may be bound to the active site but be unable to react. Such molecules cover the active site and thus prevent the binding of the actual substrate to the site. This inhibition of enzyme action is of a competitive nature, because the inhibitor molecule actually competes with the substrate for the active site. The inhibitor sulfanilamide (see below), for example, is similar enough to a substrate (*p*-aminobenzoic acid) of an enzyme involved in the metabolism of folic acid that it binds to the enzyme but cannot react. It covers the active site and prevents the binding of *p*-aminobenzoic acid. This enzyme is essential in certain disease-causing bacteria but is not essential to man; large amounts of sulfanilamide therefore kill the micro-organism but do not harm man. Inhibitors such as sulfanilamide are called anti-metabolites. Sulfanilamide and similar compounds that kill a pathogen without harming its host are now widely used in chemotherapy.



sulfanilamide
(inhibitor)



p-aminobenzoic acid
(substrate)

Some inhibitors prevent, or block, enzymatic action by reacting with groups at the active site. The nerve gas di-

isopropyl fluorophosphate, for example, reacts with the serine at the active site of acetylcholinesterase to form a covalent bond. The nerve-gas molecule involved in bond formation prevents the active site from binding the substrate, acetylcholine, thereby blocking catalysis and nerve action. Iodoacetic acid similarly blocks a key enzyme in muscle action by forming a bulky group on the amino acid cysteine, which is found at the enzyme's active site. This process is called irreversible inhibition.

Some inhibitors modify amino acids other than those at the active site, resulting in loss of enzymatic activity. The inhibitor causes changes in the shape of the active site. Some amino acids other than those at the active site, however, can be modified without affecting the structure of the active site; in these cases, enzymatic action is not affected.

Such chemical changes parallel natural mutations. Inherited diseases frequently result from a change in an amino acid at the active site of an enzyme, thus making the enzyme defective. In some cases, an amino acid change alters the shape of the active site to the extent that it can no longer react; such diseases are usually fatal. In others, however, a partially defective enzyme is formed, and an individual may be very sick but able to live.

Effects of temperature and pH. Enzymes function most efficiently within a physiological temperature range. Since enzymes are protein molecules, they can be destroyed by high temperatures. An example of such destruction, called protein denaturation, is the curdling of milk when it is boiled. Increasing temperature has two effects on an enzyme. First, the velocity of the reaction increases somewhat, because the rate of chemical reactions tends to increase with temperature; second, the enzyme is increasingly denatured. Increasing temperature thus increases the metabolic rate only within a limited range. If the temperature becomes too high, enzyme denaturation destroys life. Low temperatures also change the shapes of enzymes. With enzymes that are cold-sensitive, the change causes loss of activity. Both excessive cold and heat are therefore damaging to enzymes.

Denaturation of enzymes

The degree of acidity or basicity of a solution, which is expressed as pH, also affects enzymes. As the acidity of a solution changes—*i.e.*, the pH is altered—a point of optimum acidity occurs, at which the enzyme acts most efficiently. Although this pH optimum varies with temperature and is influenced by other constituents of the solution containing the enzyme, it is a characteristic property of enzymes. Because enzymes are sensitive to changes in acidity, most living systems are highly buffered; *i.e.*, they have mechanisms that enable them to maintain a constant acidity. This acidity level, or pH, is about 7 in most organisms. Some bacteria function under moderately acidic or basic conditions; and the digestive enzyme pepsin acts in the acid milieu of the stomach. There is no known organism that can survive in either a very acidic or a very basic environment (see also HOMEOSTASIS).

ENZYME FLEXIBILITY AND ALLOSTERIC CONTROL

The induced-fit theory. The key–lock hypothesis (see above *The nature of enzyme-catalyzed reactions*) does not fully account for enzymatic action; *i.e.*, certain properties of enzymes cannot be accounted for by the simple relationship between enzyme and substrate proposed by the key–lock hypothesis. A theory called the induced-fit theory retains the key–lock idea of a fit of the substrate at the active site but postulates in addition that the substrate must do more than simply fit into the already preformed shape of an active site. Rather, the theory states, the binding of the substrate to the enzyme must cause a change in the shape of the enzyme that results in the proper alignment of the catalytic groups on its surface. This concept has been likened to the fit of a hand in a glove, the hand (substrate) inducing a change in the shape of the glove (enzyme). Although some enzymes appear to function according to the older key–lock hypothesis, most apparently function according to the induced-fit theory.

During step 1 in Figure 4, which illustrates the induced-fit theory, the substrate approaches the enzyme surface and induces a change in its shape that results in the correct alignment of the catalytic groups (indicated by triangles *A* and *B*). In the case of the digestive enzyme carboxypeptidase, the binding of the substrate causes a tyrosine molecule at the active site to move by as much as 15 angstroms (one angstrom equals 10^{-8} centimetres). Circles *C* and *D* in the figure represent substrate-binding groups on the enzyme that are essential for catalytic activity. During step 2 the catalytic groups at the active site react with the substrate to form products. The products separate from the enzyme surface during step 3, and the enzyme is able to repeat the sequence.

Nonsubstrate molecules that are too bulky (Figure 4D) or too small (Figure 4E) alter the shape of the enzyme so that a misalignment of catalytic groups *A* and *B* occurs; such molecules are not able to react even if they are attracted to the active site.

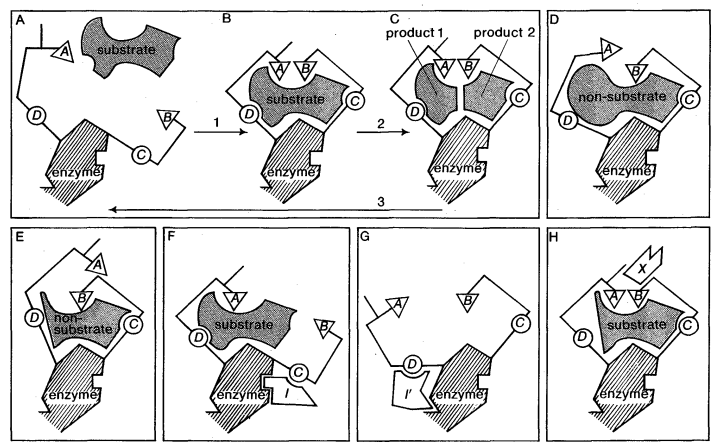


Figure 4: Induced-fit binding of a substrate to an enzyme surface and allosteric effects (see text).

The induced-fit theory explains a number of anomalous properties of enzymes; for example, "noncompetitive inhibition" (Figure 4F), in which a compound inhibits the reaction of an enzyme but does not prevent the binding of the substrate. In this case, the inhibitor compound *I* attracts the binding group *C* so that the catalytic group *B* is too far away from the substrate to react. The site at which the inhibitor binds to the enzyme is not the active site and is called an allosteric site. The inhibitor changes the shape of the active site to prevent catalysis without preventing binding of the substrate.

Figure 4G shows the effect of an inhibitor (*I*), which distorts the active site by affecting the essential binding group *D;* as a result, the enzyme can no longer attract the substrate. In Figure 4H, a so-called activator molecule, *X*, affects the active site so that a nonsubstrate molecule is properly aligned and hence can react with the enzyme; *X* is called an allosteric activator of the reaction. Such activators can affect both binding and catalytic groups at the active site.

Enzyme flexibility is extremely important because it provides a mechanism for regulating enzymatic activity. As shown in Figure 4F and G, the orientation at the active site can be disrupted by the binding of an inhibitor at a site other than the active site. Moreover, the enzyme can be activated by molecules that induce a proper alignment of the active site for a substrate that alone cannot induce this alignment (Figure 4H).

The importance of enzyme flexibility

As mentioned above, the sites that bind inhibitors and activators are called allosteric sites to distinguish them from active sites. Allosteric sites are in fact regulatory sites able to activate or inhibit enzymatic activity by influencing the shape of the enzyme. When the activator or inhibitor dissociates from the enzyme, it returns to its normal shape. Thus, the flexibility of the protein structure allows the operation of a simple, reversible control system similar to a thermostat.

Types of allosteric control. *Feedback inhibition and allosteric activation.* Allosteric control can operate in

many ways; two examples serve to illustrate some general effects. A pathway consisting of ten enzymes is involved in the synthesis of the amino acid histidine. When a cell contains enough histidine, synthesis stops—an appropriate economy move by the cell. Synthesis is stopped by the inhibition of the first enzyme in the pathway by the product, histidine; the mechanism is similar to that of Figure 4G. The inhibition of an enzyme by a product is called feedback inhibition; *i.e.*, a product many steps removed from an initial enzyme blocks its action. Feedback inhibition occurs in many pathways in all living things.

Allosteric control can also be achieved by activators. The hormone adrenaline (epinephrine) acts in this way. When energy is needed, adrenaline is released and activates, by allosteric activation, the enzyme adenyl cyclase. This enzyme catalyzes a reaction in which the compound cyclic adenosine monophosphate (cyclic AMP) is formed from ATP. Cyclic AMP in turn acts as an allosteric activator of enzymes that speed the metabolism of carbohydrate to produce energy. This type of allosteric regulation also is widespread in biological systems.

Thus, a combination of allosteric activation and inhibition allows the production of energy or materials when they are needed and shuts off production when the supply is adequate.

Induction and repression. Allosteric control is a rapid method of regulating products continuously needed by living things. Yet some cells have no need for certain enzymes, and it would be wasteful for the cell to synthesize them. In this case, certain molecules, called repressors, prevent the synthesis of unneeded enzymes. The repressors are proteins that bind to deoxyribonucleic acid (DNA) and prevent the first step in the process resulting in protein synthesis. If certain metabolites are added to cells that need an enzyme, enzyme synthesis occurs—*i.e.*, it is induced. Addition of galactose to a growth medium containing *Escherichia coli* bacteria, for example, induces the synthesis of the enzyme beta galactosidase. The bacteria thus can synthesize this galactose-metabolizing enzyme when it is needed and prevent its synthesis when it is not. The way in which the synthesis of enzymes is induced or repressed in mammalian systems is less well understood but is believed to be similar.

Different types of cells in complex organisms have different enzymes, even though they have the same DNA content. The enzymes actually synthesized are the ones needed in a specific cell and vary not only for different types of cells—*e.g.*, nerve, muscle, eye, and skin cells—but also for different species.

Cooperativity in allosteric enzymes. In an enzyme consisting of several subunits, or chains, alteration in the shape of one chain as a result of the influence either of a substrate molecule or of allosteric inhibitors or activators may change the shape of a neighbouring chain. As a result, the binding of a second molecule of substrate occurs in a different way from the binding of the first, and the third is different from the second. This phenomenon, called cooperativity, is characteristic of allosteric enzymes.

Cooperativity (see Figure 3) is reflected by a sigmoid curve, as compared to the hyperbolic curve of Michaelis–Menten. An enzyme of several subunits that exhibits cooperativity is far more sensitive to control mechanisms than is an enzyme of one subunit and hence one active site.

The first example of cooperativity was observed in hemoglobin, which is not an enzyme but behaves like one in many ways. The absorption of oxygen in the lungs and its deposition in the tissues is far more efficient because the subunits of hemoglobin show positive cooperativity, so-called because the first molecule of substrate makes it easier for the next to bind.

Negative cooperativity (also illustrated in Figure 3), in which the binding of one molecule makes it less easy for the next to bind, also occurs in living things. Negative cooperativity makes an enzyme less sensitive to fluctuations in concentrations of metabolites and may be important for enzymes that must be present in the cell at relatively constant levels of activity.

Some enzymes are closely associated aggregates of several enzyme units; the pyruvate dehydrogenase system, for example, contains five different enzymes, has a total molecular weight of 4,000,000, and consists of four different types of chains. Apparently, the enzymes in cells may be organized by forming complex units, by being absorbed on a cell wall, or by being isolated by membranes in special compartments. Since a pathway involves the stepwise modification of chemical compounds, aggregations of the enzymes in a given pathway facilitate their function in a manner similar to an industrial assembly line (see also METABOLISM).

(D.E.K.)

Epaminondas

A Greek statesman and general who was largely responsible for breaking the military dominance of the Spartans, Epaminondas, by his innovations in the conventional scheme of Greek tactics, opened the way for Alexander the Great's military victories and, by his creation of new political centres in the Peloponnese, permanently altered the balance of power in Greece. His remarkable personality was well on the way to making his native city, Thebes, the leading city of 4th-century Hellas, when his death in battle cut short his progress.

Epaminondas was born in Thebes of an aristocratic family in the last years of the 5th century BC (about 410 BC). His father, though poor, provided his son with a good education. Particularly attracted to philosophy, the boy became a devoted pupil of Lysis of Tarentum, a Pythagorean, who had settled in Thebes. Epaminondas did not at first take any part in political life but served on military expeditions. There is a legend that he saved the life of his colleague Pelopidas in battle in 385.

In 382 the Spartans took advantage of an expedition to northern Greece to conspire with a few Thebans and seize power by a sudden coup. For three and a half years the government was in the hands of this small dictatorship, backed by a Spartan garrison in the Cadmeia (the citadel of Thebes). Many of the previous leaders, including Pelopidas, were driven into exile. Epaminondas remained in private life, but when Pelopidas, returning secretly from Athens, successfully overthrew the dictatorship in 379 and frightened the Spartan garrison into surrender, Epaminondas is said to have been one of those who led the popular uprising in Thebes. No individual part is attributed to him for the next eight years, during which Thebes, in alliance with Athens, successfully fought off Sparta and re-established its traditional leadership in a federation of the cities of Boeotia. In 371 the general war was ended at a peace conference, but Sparta and Athens combined to refuse recognition to the Theban federation by insisting that each city of Boeotia should be a separate party to the treaty, while Thebes claimed that its federation should be treated as a single unit. Epaminondas, who was boeotarch (one of the five magistrates of the federation), maintained this position, even when it led to the exclusion of Thebes from the peace treaty. The Spartans had an army stationed on Thebes's western frontier, waiting to follow up their diplomatic success by a crushing military attack. But in the Battle of Leuctra (371) Epaminondas was ready with a tactical innovation. Instead of the usual advances of heavily armed infantry drawn up in an equal number of ranks over the whole front, he massed his troops on the left wing to the unprecedented depth of 50 ranks against

Epaminondas' first victory

an overall Spartan depth of 12. The Spartans, who according to Greek convention had their best troops on the right wing, were overwhelmed by the force of the Theban advance. The novelty consisted in striking the enemy first at their strongest, instead of their weakest, point, with such crushing force that the attack was irresistible. The defeat of the Spartans inflicted such heavy losses on the very limited numbers of the Spartan soldiers that it seriously threatened the possibility of raising another Spartan army. The Boeotian federation had been saved, and after more than a year the Theban army, once more led by Epaminondas, proceeded to press home its victory. In the winter (a most unusual season for Greek warfare) of 370–369 they invaded the Peloponnese and penetrated the valley of the Eurotas (modern Evrótas). For the first time for at least two centuries an enemy army was in sight of Sparta. The subject population of Helots revolted, and Epaminondas re-created the state of Messenia, which had been enslaved by the Spartans for 300 years. He also encouraged the Arcadians, who had broken from Sparta's league, to found Megalopolis (Big City) as a federal capital. These new political creations served to keep Sparta in check so that it was never again a serious military power outside the Peloponnese. Epaminondas' brilliant success was met with jealousy and political opposition at home. He had stayed abroad over his year of office and was impeached on his return but acquitted. In 369–368 he led a second successful invasion of the Peloponnese, gaining further allies for Boeotia. In 367 he also served as a common soldier in an army sent to rescue his friend Pelopidas, who was a prisoner of Alexander, tyrant of Pherae (Thessaly). The expedition got into difficulties from which it was only rescued when Epaminondas was appointed general. This resulted in his re-election as boeotarch. He then returned to Thessaly and secured the release of Pelopidas. In 366 he invaded the Peloponnese for a third time, with a view to strengthening the Theban position there. He obtained assurances of fidelity from several states and, perhaps because of these assurances, decided not to overthrow the oligarchical governments that had been established by the Spartans. This was not accepted by the Theban government, which was in favour of overthrowing the oligarchs and establishing new democracies.

Third Peloponnesian expedition

Athens had supported Sparta and was at war with Thebes. In 364–363 Epaminondas made a bold attempt to challenge Athens' naval empire. With a new Boeotian fleet, he sailed to Byzantium, with the result that a number of cities in the Athenian Empire rebelled against their now-threatened masters. But the next year the outbreak of civil war in the Arcadian league brought Epaminondas once more to the head of a large allied army in the Peloponnese. He was met by Sparta, Athens, and their allies in the Battle of Mantineia (362). Epaminondas repeated on a large scale the tactics of Leuctra and was once more victorious but died of a wound on the field of battle. With his death all constructive initiative appeared to vanish from Theban policy.

BIBLIOGRAPHY. Of ancient sources, NEPOS, *Epaminondas* is vague and moralizing. PLUTARCH'S *Life of Epaminondas* is lost but can be indirectly approached through his *Life of Pelopidas* and PAUSANIAS. There is no important single work on the subject by a modern scholar, so it is best studied in the standard general histories. See especially M. CARY in the *Cambridge Ancient History*, vol. 6, ch. 4 (1927); and N.G.L. HAMMOND, *A History of Greece to 322 BC*, 2nd ed., ch. 2–3 and appendix 7 (1967), in which special attention is given to the chronological problems.

(H.W.P.)

Ephemeroptera

The order Ephemeroptera comprises the group of insects known as mayflies. Other common names for the winged stages are shadfly, sandfly, dayfly, fishfly, and drake. The aquatic immature stage, called a nymph or naiad, is widely distributed in freshwater; a few species can tolerate the brackish water of marine estuaries.

The winged stages attract attention through mass emergences when they may make roads slippery, clog gutters, and taint the air with an odour of decay. Mayfly nymphs are important in the energy transfer cycle that occurs in freshwaters (winged stages cannot feed). Some species are carnivorous, but the majority of nymphs feed on diatoms, algae, higher plants, and organic detritus; nymphs are devoured in turn by many carnivorous animals, especially fishes.

General features. *Appearance.* Winged mayflies have large compound eyes; short, bristlelike antennae; and functionless mouthparts and digestive tracts. Their membranous wings (usually with many veins) include a front pair and a hind pair, which is much smaller than the front pair or absent; in repose, the wings are held together upright over the body like those of a butterfly. The adult mayfly has two or three threadlike tails, usually as long as, or longer than, the body.

Nymphal characters

Nymphal characters include a single claw terminating each of the six legs. The surface of the thoracic region of the body is strongly rounded outward and bears the developing wings in external pads on the upper surface; the abdominal region usually is long and slender. Gills are attached to the outer edge of the upper surface of some of the ten segments into which the body is divided. The body of the nymph terminates in three, less often two, slender tails. Adult mayflies of North American species range in body length, exclusive of tails, from 2.5 millimetres, (0.1 inch) for *Caenis* to 32 millimetres (more than an inch) for *Hexagenia*.

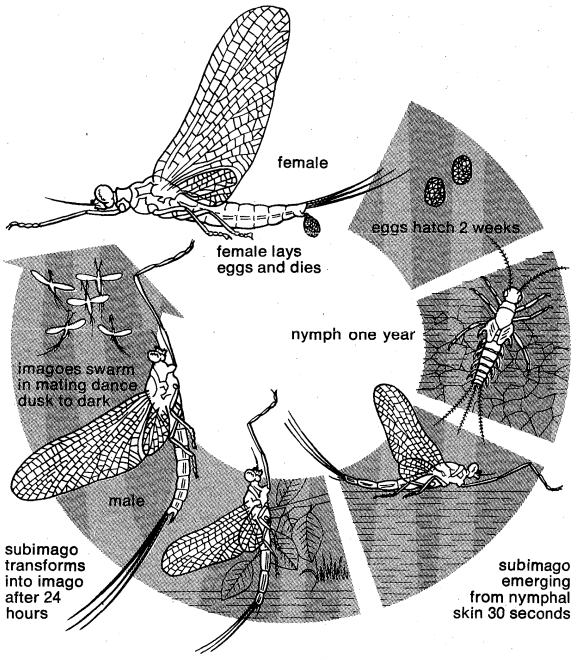
Distribution and abundance. Worldwide, about 2,000 species of mayflies have been described, nearly 600 of them from North America north of Mexico. The order, represented in all continents except Antarctica, occurs sparingly in many islands far distant from major landmasses; *e.g.*, only two species are known from Fiji. In areas of high biological productivity (*e.g.*, gravel-bottomed, hard-water, temperate-zone streams), as many as 1,400 nymphs have been found in one square foot of surface, and one gravel riffle (a shallow area extending across a stream bed) has yielded 33 species.

Natural history. *Life cycle.* The life cycle of mayflies consists of four stages: egg, nymph, subimago, and imago. Eggs, which vary widely in size and surface detail, may be oblong, oval, or rounded. Depending on the species, a female may produce fewer than 50 or more than 10,000 eggs. Eggs are laid in water and either settle to the bottom or adhere to some submerged object; they often hatch in about two weeks but may undergo a period of varying duration in which no growth occurs. This cessation of growth, known as diapause, is an adaptation that enables the insects to avoid conditions hostile to developing nymphs or to emerging winged stages.

Nymphal life may be as short as two weeks or as long as two years; an annual cycle is most common. As many as 50 molts (periodic shedding of skin) may occur, depending on the species and the environment. When growth is complete, the nymphal skin splits down the back and a winged form, called the subimago, or dun, emerges. The subimago flies from the surface of the water to some sheltered resting place nearby; after an interval lasting a few minutes to several days, but usually overnight, the skin is shed for the last time, and the imago, spinner, or adult stage emerges. Mayflies are the only insects that molt after developing functional wings. The subimago resembles the imago in overall appearance, although it is softer and duller in colour than the adult. The wings of the subimago, generally rather opaque, are tinted with gray, blue, yellow, or olive; heavy pigmentation along the veins may give the wings of the subimago a mottled appearance that rarely persists in the imago. Legs and tails of the subimago are shorter than are those of the imago. It is often incorrectly assumed that the two stages are different species.

Subimago and imago stages

Mating and egg deposition. Mating takes place soon after the final molt. In most species death ensues shortly after mating and oviposition (egg deposition). Winged existence may last only a few hours; *Hexagenia* males, however, may live long enough to engage in mating flights on two successive days, and female imagos that retain their eggs may live long enough to mate on either



Life cycle of the mayfly.

of two successive days. Groups of male imagoes perform a mating flight, or dance, over water as dusk approaches, flying into any breeze or air current. Individuals may fly up and forward, then float downward and repeat the performance. Females soon join the swarm, rising and falling as the dance continues. The male approaches the female from below and behind and grasps her thorax with his elongated front legs; mating is completed on the wing. After her release by the male, the female deposits her eggs and dies. A few species are ovoviviparous—*i.e.*, eggs hatch within the body of the female.

Methods of oviposition vary. Some species drop the rounded egg mass from a height of several feet in a manoeuvre suggestive of dive-bombing; in others, the female flies low over the water's surface, striking it at intervals with the tip of her abdomen and washing off a few eggs each time she strikes the water. Still other females extrude the eggs from two oviducts as two long packets, which usually adhere to each other; they may be dropped from a foot or more above the water, but more often, the female falls to the surface with wings extended and squeezes out the eggs as she dies. In a fourth type of oviposition, the female alights on some object protruding from the water and crawls under the surface, depositing the eggs while submerged. Females, unless they drop the eggs from a height of several feet, are vulnerable to feeding fishes. Mayflies sometimes mistake blacktopped roads for streams, forming swarms over them, and drop eggs on road surfaces.

Ecology. Mayfly nymphs are preyed upon by carnivorous invertebrates and fishes. Winged stages are devoured in flight by birds, bats, and predatory insects, including dragonflies, robber flies, and hornets. When at rest, mayflies may be preyed upon by spiders, beetles, birds, and certain mammals, especially flying squirrels in North America. During their transformation to the adult stage and especially during oviposition by females, mayflies are vulnerable to predation by fishes; artificial lures used by fishermen are patterned after them.

Form and function. Adaptations of form and function presumably determine distribution. The legs and jaws of some nymphs are modified for burrowing in silt or sand; other species are flattened, so that they can enter narrow crevices or cling to bottom materials in swift currents; long, slender legs and body adapt others for clambering on submerged vegetation. Strong swimmers are long and slender and occupy a variety of habitats. Gills may be platelike, feathery, or filamentous; often they are modified for specialized functions.

Paleontology and classification. Recognizable mayflies occur in the fossil record of the Upper Carboniferous Period (about 325,000,000 to 280,000,000 years ago), and they appear to have been abundant during the Permian. Represented largely by wing impressions, the fossil record is so incomplete that most systems of classification and interpretations of relationships are based on characteristics of recent forms, chiefly their morphology.

Distinguishing taxonomic features. Characteristics of the male genitalia are the most reliable means for identification of adult species. Many other features, including patterns of veins in the wings, affect generic and other higher categories of classification.

Annotated classification. The classification below is modified from that of George Edmunds, Jr. (1962).

ORDER EPHEMEROPTERA (mayflies)

Soft-bodied insects; life cycle consisting of 4 stages—egg, nymph, subimago, imago; wings membranous, at rest held vertically upward; hind wings reduced; mouthparts and digestive system of adults nonfunctional; only insect to molt after developing functional wings; antennae bristlelike; 5 superfamilies—Heptagenioidea (families Siphlonuridae, Baetidae, Metretopodidae, Oligoneuriidae, Heptageniidae, and Ametropodidae); Leptophlebioidea (families Leptophlebiidae, Ephemerellidae, Tricorythidae); Ephemeroidea (families Behningiidae, Potamanthidae, Euthyplociidae, Polymitarcidae, Ephemeridae, Palingeniidae); Caenoidea (families Neoephemeridae, Caenidae); Prosopistomatoidea (families Baetiscidae, Prosopistomatidae); about 2,000 species on all continents except Antarctica.

Critical appraisal. In addition to the scheme above, another classification increases the number of families to 25. Before the taxonomy is established with certainty, more attention must be given to nymphal characters, not only their morphology but also their physiology and behaviour. Many species remain undescribed.

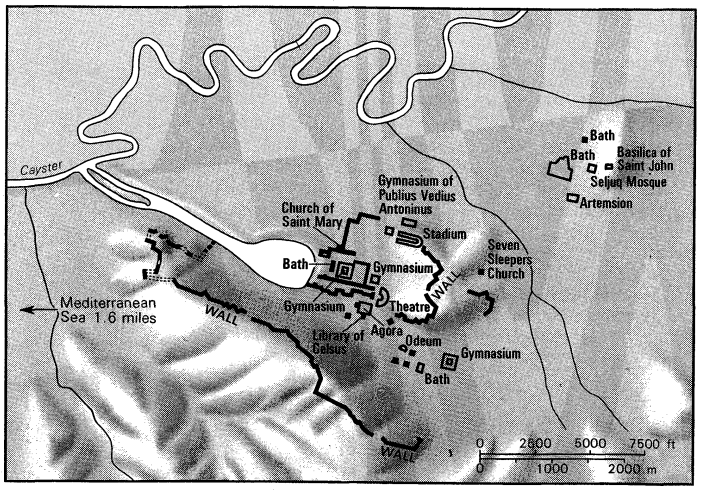
Ephesus

Ephesus was an ancient Ionian Greek city, the ruins of which lie near the modern village of Seljuq in the Izmir *il* (province) of Turkey. In Roman times it was situated on the northern slopes of the hills Coressus and Pion and south of the Cayster (Küçükmenderes) River, the silt from which has formed a fertile plain but has caused the coastline to move ever farther west. The Temple of Artemis, or Diana, to which Ephesus owed much of its fame and which seems to mark the site of the classical Greek city, was probably on the seaboard when it was founded (about 600 BC), one mile east by northeast of Pion (modern Panayir Dağ). In Roman times a sea channel was maintained with difficulty to a harbour well west of Pion. In late Byzantine times this channel in turn became useless, and the coast by the mid-20th century was three miles farther west. Ephesus commanded the west end of one great trade route into Asia, that along the Cayster valley, and had easy access to the other two, along the Hermus (Gediz) and the Maeander (Büyükmenderes) Rivers.

History. Ephesus enters history in the mid-7th century BC, when it was attacked by the Cimmerians. Unlike its neighbour, Magnesia, it survived the attacks. For part of the early 6th century the city was under tyrants. Though allied by marriage to the kings of Lydia, its people could not hold back the Lydian Croesus, who asserted a general suzerainty over the city. He did, however, present many



Principal sites of Hellenistic and Byzantine Ephesus.
Adapted from J. Keil, *Ephesos* (1964); Austrian Archeological Institute, Vienna

columns and some golden cows for a new and splendid rebuilding of the Artemiseum (Temple of Artemis). At this time, according to Strabo, the Ephesians began to live in the plain; and to this period, too, should be allotted the redrafting of the laws, said to have been the work of an Athenian, Aristarchus. Ephesus soon submitted to Cyrus of Persia. Early in the Ionian revolt (499–493 BC) against the Persians, Ephesus served as a base for an Ionian attack on Sardis; but it is not mentioned again until 494, when the Ephesians massacred the Chiot survivors of the battle of Lade. The massacre may have occurred because Ephesus was a commercial rival of the chief rebels, Chios and Miletus. Ephesus maintained friendly relations with Persia for about 50 years: in 478 Xerxes, returning from his failure in Greece, honoured Artemis of Ephesus, although he sacked other Ionian shrines, and left his children for safety in Ephesus; and Themistocles landed there in the 460s on his flight to Persia. But after 454 Ephesus appears as a regular tributary of Athens. Great Ephesians up to this time had been Callinus, the earliest Greek elegist (mid-7th century BC), the satirist Hipponax, and the famous philosopher Heracleitus, one of the Basilids.

The Greco-Persian wars

Ephesus shared in a general revolt of 412 BC against Athens, siding with Sparta in the Second Peloponnesian war, and remained an effective ally of Sparta down to the end of the war. Threatened by Persia after 403, Ephesus served in 396 as the headquarters of King Agesilaus of Sparta. In 394 the Ephesians deserted to Conon's anti-Spartan maritime league, but by 387 the city was again in Spartan hands and was handed by Antalcidas to Persia. There followed the pro-Persian tyranny of Syrphax and his family, who were stoned to death in 333 on Alexander the Great's taking the city. After 50 years of fluctuating fortune, Ephesus was conquered by the Macedonian general Lysimachus, and resettled around Coressus and Pion (286–281 BC). Lysimachus introduced colonists from Lebedus and Colophon and renamed the city after his wife, Arsinoo—a name soon dropped. This was the beginning of Ephesus' Hellenistic prosperity. It became conspicuous for the abundance of its coinage.

After the defeat of Antiochus the Great, king of Syria, by the Romans in 189 BC, Ephesus was handed over by the conquerors to the king of Pergamum. Attalus III of Pergamum bequeathed Ephesus with the rest of his possessions to the Roman people (133 BC). Thenceforth, Ephesus remained subject to Rome, except for a brief time beginning in 88 BC, when, at the instigation of Mithradates the Great of Pontus, the cities of Asia Minor revolted and killed their Roman residents. The Ephesians even killed those Romans who had fled for refuge to the Artemiseum; notwithstanding which they returned in 86 BC to their former masters. Their claim, preserved on an extant inscription, that in admitting Mithradates they had merely yielded to superior force was rudely brushed aside by Sulla, who inflicted a very heavy fine. Although it twice chose the losing side in the Roman civil wars and although it was stoutly opposed by Pergamum and Smyrna, Ephesus became under Augustus the first city of the Roman province of Asia. The geographer Strabo wrote of its importance as a commercial centre in the 1st century BC. The triumphal arch of 3 BC and the aqueduct of AD 4–14 initiated that long series of public buildings, ornamental and useful, that make Ephesus the most impressive example in Greek lands of a city of imperial times.

Meanwhile the Christian Church began to win converts. A famous protest in the theatre against the teachings of St. Paul, described in Acts 19, is dated about AD 57. According to local belief Ephesus was the last home of the Virgin, who was lodged near the city by St. John and died there. The tradition that St. Luke also died there seems to be less strongly supported. Ephesus was one of the seven churches of Asia to which the Revelation to John or Revelation was addressed.

The Goths destroyed both city and temple in AD 262, and neither ever recovered its former splendour. The emperor Constantine, however, erected a new public bath, and Arcadius rebuilt at a higher level the street from the theatre to the harbour, named after him, the Arkadiane. A general council of the church, held at Ephesus in AD 431 in the great double church of St. Mary, condemned Nestorius and justified the cult of the Virgin as Theotokos, "mother of God." A few years later according to legend, the Seven Sleepers of Ephesus (a group of 3rd-century Christian martyrs) were miraculously raised from the dead. They too became the object of a famous cult. The emperor Justinian built the magnificent basilica of St. John in the 6th century. By the early Middle Ages, the city was no longer useful as a port, and fell into decline; late Byzantine Ephesus, conquered by the Seljuqs in 1090, was merely a small town. After brief splendour in the 14th century, even this was deserted, and the true site of the Artemiseum remained unsuspected until 1869.

The Council of Ephesus

Excavations and extant remains. J.T. Wood, working at Ephesus for the British Museum between 1863 and 1874, excavated the odeum and theatre. In May 1869 he struck a corner of the Artemiseum. His excavation exposed to view not only the scanty remains of the latest edifice (built after 350 BC) but the platform below it of an earlier temple of identical size and plan subsequently found to be that of the 6th century BC, to which Croesus contributed. The sculptured fragments of both temples

were sent to the British Museum. In 1904 D.G. Hogarth, heading another mission from the museum, examined the earlier platform and found beneath its centre the remains of three yet older structures. In its earliest known phase the temple was apparently a small platform of green schist, containing a sealed deposit of primitive coins and other objects. These date from *c.* 600 BC.

It is impossible to assign the various architects named by ancient authors to the respective phases of the temple. At best, Chersiphron and Metagenes can be tentatively assigned to the Temple of Croesus, Chirocrates or Dinocrates to that of the 4th century. There had perhaps been some repairs toward 400 BC, associated with the architects Paeonius and Demetrius and with the prize-winning dedicatory hymn of the famous musician Timotheus. The Artemiseum passed rapidly through three phases before *c.* 550 BC. The temple of Croesus (the fourth phase) was remarkable for its great size (it was more than 300 feet long and 150 feet wide), for the carved figures round the lower drums of its columns (*columnae caelatae*), and for the smaller but elaborate figured friezes along its roof gutter (*sima*). Croesus' temple seems to have been burned down in 356 BC. The new temple built shortly afterward copied the old in its *columnae caelatae*, one of which was by Scopas; but the new *sima*, instead of small, crowded figures, had a more conventional, if vigorous, *rinceau* ornament. The cella contained, among other great works, the Amazons of Polyclitus, Phidias, and Cresilas.

Other ruins

Lysimachean Ephesus has been continuously excavated since 1894 by the Austrian Archaeological institute, but so solid and extensive is the Roman town that by the early 1960s the Austrians had rarely penetrated to Hellenistic levels.

On the hill of Ayasoluk (Hagios Theologos) is Justinian's church of St. John the Theologian, built around a shrine variously associated in the early Middle Ages with the death or bodily assumption of St. John. The church, uncovered since 1922, is a noble structure but badly restored. On the hill there is also a beautiful Seljuq mosque dedicated in 1375.

The public buildings of the city are arranged in a rectangular street pattern going back to Hellenistic days. They include the theatre, capable of seating nearly 25,000 spectators and completed in its present form under Trajan; the agora (market place), surrounded by stoas (sheltered promenades) dating from the time of Severus; the library of Celsus, also Trajanic and well known because of its façade; and an immense array of baths and gymnasiums.

All these buildings are to the west of Pion. On its north side is the stadium, and north of this the gymnasium of Publius Vedius Antoninus, relatively small but very complete and with a notable chapel for the cult of Antoninus Pius. South of Pion were the odeum—another gift of Vedius—a roofed semicircular theatre to hold 1,400 persons; also a series of fountains and aqueducts, notably the aqueduct of Gaius Sextilius Pollio, which crossed the valley from Coressus. The unmortared city wall along the crest of Coressus appears to be that of Lysimachus.

Of the early Byzantine city, besides the stretch of curtain wall on Panajir Dağ, there remain the ruined church of the Seven Sleepers to its east and the long double basilica of the Virgin, the scene of the council, to its west. This basilica was rebuilt several times; it was largely around this building, between the great gymnasiums and the stadium of the classical city, that the early Byzantine Ephesians gathered.

BIBLIOGRAPHY. G.E. BEAN, *Aegean Turkey: An Archaeological Guide* (1966), contains useful material on topography and history. KARL GSCHWIND, *Der ephesische Johannes und die Artemis Ephesia* (1965); and FRANZ MILTNER, *Ephesos, Stadt der Artemis und des Johannes* (1958), treat both St. John's city and Artemis. See also B.F. DEUTSCH, *Our Lady of Ephesus* (1965); and JOSEPH KEIL, *Ephesos: Ein Führer durch die Ruinenstätte und ihre Geschichte*, 5th ed. rev. (1964), a guide to the old city. Artemis is treated more specifically by B.L. TRELL in *The Temple of Artemis at Ephesus* (1945); and by HELLA KRAUSE-ZIMMER in *Artemis Ephesia* (1964), supplemented by HERMAN THIERSCH, *Artemis Ephesia: Eine archäologische Untersuchung* (1935); EMANUEL LOEWY, *Zur Chronologie der frühgriechischen Kunst: Die Artemistempel von Ephesos* (1932); W.R. WOOD, *Modern Discoveries on the Site of Ancient Ephesus* (1890).

Epic

An ambiguous term, "epic" is used most often to designate a long narrative poem recounting heroic deeds, though it has also been loosely used to describe novels, such as Tolstoy's *War and Peace*, and motion pictures, such as Eisenstein's *Ivan the Terrible*. In literary usage, the term encompasses both oral and written compositions. The prime examples of the oral epic are Homer's *Iliad* and *Odyssey*. Outstanding examples of the written epic include Virgil's *Aeneid* and Lucan's *Pharsalia* in Latin; *Chanson de Roland* in medieval French; Ariosto's *Orlando Furioso* and Tasso's *Gerusalemme liberata* in Italian; *Poema* (or *Cantar*) *de mio Cid* in Spanish; and Milton's *Paradise Lost* and Spenser's *Faerie Queene* in English. There are also seriocomic epics, such as the *Morgante* of a 15th-century Italian poet, Pulci, and the pseudo-Homeric *Battle of the Frogs and Mice*. Another distinct group is made up of the so-called beast epics—narrative poems written in Latin in the Middle Ages and dealing with the struggle between a cunning fox and a cruel and stupid wolf. Underlying all of the written forms is some trace of an oral character, partly because of the monumental persuasiveness of Homer's example but more largely because the epic was, in fact, born of an oral tradition. It is on the oral tradition of the epic form that this article will focus. The article SAGA deals with a related form. Discussions of the role of the epic in the development of the various literatures of the world may be found in such articles as LITERATURE, WESTERN; and LITERATURE, EAST ASIAN; and in articles on the arts of various peoples, such as AFRICAN PEOPLES, ARTS OF; and SOUTH ASIAN PEOPLES, ARTS OF.

GENERAL CHARACTERISTICS OF THE EPIC

An epic may deal with such various subjects as myths, heroic legends, histories, edifying religious tales, animal stories, or philosophical or moral theories. Epic poetry has been used by peoples all over the world and in different ages to transmit their traditions from one generation to another, without the aid of writing. These traditions frequently consist of legendary narratives about the glorious deeds of their national heroes. Thus scholars have often identified "epic" with a certain kind of heroic oral poetry, which comes into existence in so-called heroic ages. Such ages have been experienced by many nations, usually at a stage of development in which they have had to struggle for a national identity. This effort, combined with such other conditions as an adequate material culture and a sufficiently productive economy, tend to produce a society dominated by a powerful and warlike nobility, constantly occupied with martial activities, whose individual members seek, above all, everlasting fame for themselves and for their lineages.

The epic as a genre of heroic ages

Uses of the epic. The main function of poetry in heroic-age society, appears to be to stir the spirit of the warriors to heroic actions by praising their exploits and those of their illustrious ancestors, by assuring a long and glorious recollection of their fame, and by supplying them with models of ideal heroic behaviour. One of the favorite pastimes of the nobility in heroic ages in different times and places has been to gather in banquet halls to hear heroic songs, in praise of famous deeds, sung by professional singers as well as by the warriors

themselves. Heroic songs also were often sung before a battle, and such recitations had tremendous effect on the morale of the combatants. Among the Negro tribe of the Fulbe in The Sudan, for instance, whose epic poetry has been recorded, a nobleman customarily set out in quest of adventures accompanied by a singer (*mabo*), who also served as his shield bearer. The singer was thus the witness of the heroic deeds of his lord, which he celebrated in an epic poem called *baudi*.

The aristocratic warriors of the heroic ages were, thus, members of an illustrious family, a link in a long chain of glorious heroes. And the chain could snap if the warrior failed to preserve the honour of the family, whereas, by earning fame through his own heroism, he could give it new lustre. Epic traditions were to a large extent the traditions of the aristocratic families: the Old French word *geste*, used for a form of epic that flourished in the Middle Ages, means not only a story of famous deeds, but also a genealogy.

The passing of a heroic age does not necessarily mean the end of its heroic oral poetry. An oral-epic tradition usually continues for as long as the nation remains largely illiterate. Usually it is after the heroic age has passed that the narratives about its legendary heroes are fully elaborated. Even when the nobility that originally created the heroic epic perishes or loses interest, the old songs can persist as entertainments among the people. Court singers, then, are replaced by popular singers, who recite at public gatherings. This popular tradition, however, must be distinguished from a tradition that still forms an integral part of the culture of a nobility. For when a heroic epic loses its contact with the banquet halls of the princes and noblemen, it cannot preserve for long its power of renewal. Soon it enters what has been called the reproductive stage in the life cycle of an oral tradition, in which the bards become noncreative reproducers of songs learned from older singers. Popular oral singers, like the *guslari* of Yugoslavia, no doubt vary their songs to a certain extent each time they recite them, but they do so mainly by transposing language and minor episodes from one acquired song to another. Such variations must not be confounded with the real enrichment of the tradition by succeeding generations of genuine oral poets of the creative stage. The spread of literacy, which has a disastrous effect on the oral singer, brings about a quick corruption of the tradition. At this degenerate stage, the oral epic soon dies out if it is not written down or recorded.

The popular tradition of the epic

The ancient Greek epic exemplifies the cycle of an oral tradition. Originating in the late Mycenaean period, the Greek epic outlasted the downfall of the typically heroic age culture (*c.* 1100 BC), and maintained itself through the "Dark Age" to reach a climax in the Homeric poems by the close of the Geometric Period (900–750 BC). After Homer, the activity of the *aoidoi*, who sang their own epic songs at the courts of the nobility, slowly declined. During the first half of the 7th century, the *aoidoi* produced such new poems as those of Hesiod and some of the earlier poems of what was to become known as the Epic Cycle. Between 625 and 575 BC, the *aoidoi* gave way to oral reciters of a new type called rhapsodes or "stitchers of songs," who declaimed for large audiences the already famous works of Homer, while holding in their hand, a staff (*rhabdos*), which they used to give emphasis to their words. It seems probable that these rhapsodes, who played a crucial role in the transmission of the Homeric epic, were using some sort of written aids to memory before Homeric recitations were adopted in 6th-century Athens as part of the Panathenaic festivals held each year in honour of the goddess Athena.

Verbal formulas. To compose and to memorize long narrative poems like the *Iliad* and the *Odyssey*, oral poets used a highly elaborate technical language with a large store of traditional verbal formulas, which could describe recurring ideas and situations in ways that suited the requirements of metre. So long as an oral epic tradition remains in its creative period, its language will be continually refined by each generation of poets in opposite directions, called scope and economy. Scope is the addition of new phrases to express a larger number of recurrent concepts in varying metrical values fitting the possible positions in a verse. Economy is the elimination of redundancies that arise as gifted poets invent new set phrases that duplicate, both in a general sense and in metrical value, the formulas already existing in the traditional stock.

Nowhere has this refinement proceeded any nearer to perfection than in the language of the Homeric epic. As has been shown by statistical analysis, it exhibits a remarkable efficiency, both in the rareness of unnecessarily duplicative variants and in the coverage of each common concept by the metrical alternatives useful in the composition of the six-foot metric line the Greeks used for epic poetry.

Thus, for example, if the idea of a ship has to be expressed at the end of a line of verse, the ship may be described as "well-trimmed" (*nēos eisēs*), "curved" (*nēos amphielissa*), or "dark-prowed" (*nēos kyanoprōiros*), depending entirely on the number of feet that remain to be filled by the phrase in the hexameter; if the phrase has to cover the two final feet of the verse and the words have to be put in the dative case, the formula "of a well-trimmed ship" will be replaced by "to a black ship" (*nēi melainē*). The sole occurrence of "Zeus who gathers lightning" (*steropēgereta Zeus*), which is an exact metrical equivalent of the more common "Zeus who delights in thunder" (*Zeus terpikeraunos*), constitutes one of the very few actual duplications of such formulas found in Homer.

Finally, some of the typical scenes in the heroic life, such as the preparation of a meal or sacrifice, or the launching or beaching of a ship, contain set descriptions comprising several lines that are used by rote each time the events are narrated.

This highly formalized language was elaborated by generations of oral poets to minimize the conscious effort needed to compose new poems and memorize existing ones. Because of it, an exceptionally gifted *aoidos*, working just prior to the corruption of the genre, could orally create long and finely structured poems like the *Iliad* and the *Odyssey* and those poems could then be transmitted accurately by the following generations of rhapsodes until complete, written texts were produced.

BASES OF THE EPIC

Oral heroic poetry, at its origin, usually deals with outstanding deeds of kings and warriors who lived in the heroic age of the nation. Since the primary function of this poetry is to educate rather than to record, however, the personages are necessarily transformed into ideal heroes and their acts into ideal heroic deeds that conform to mythological or ideological patterns. Some of these patterns are archetypes found all over the world, while others are peculiar to a specific nation or culture. Thus, in many epic traditions, heroes are born as a result of an illegitimate union of a maiden mother with a divine or supernatural being; they are exposed at birth, fed by an animal, and brought up by humble foster parents in a rustic milieu; they grow up with marvellous speed, fight a dragon—in their first combat—to rescue a maiden whom they marry, and die young in circumstances as fabulous as those that surrounded their birth.

Heroic patterns and deeds

In the traditions of Indo-European peoples a hero is often a twin, who acquires soon after his supernatural birth an invulnerability that has one defect, generally of his heel or of some other part of his foot, which ultimately causes his death. He is educated by a blacksmith, disguises himself as a woman at some time in his youth, and conquers a three-headed dragon, or some other kind of triple opponent, in his first battle. He then begets, by a foreign or supernatural woman, a child who, reared by his mother in her country, becomes a warrior as brave as his father. When this child meets his unknown father, the latter fails to recognize him, so that the father kills his own child after a long and fierce single combat. The hero, himself, usually dies after committing the third of three sins.

In Japan, to take another example, renowned members

of the warrior aristocracy of the past, who have acquired the status of popular heroes, are in many cases supplied in their legend with four exceptionally brave and faithful retainers called their *shitennō* or guardians of the four cardinal points; these form the closest entourage of their lord—who is usually depicted as excelling in command but not in physical strength—and defend him from dangers. The retainers reflect a mythological model, taken from Buddhism, of four *deva* kings, who guard the teaching of the Buddha against the attack of the devils.

A striking pattern for a number of epic traditions has been found in a so-called "tripartite ideology" or "trifunctional system" of the Indo-Europeans. The concept was based on the discovery of the remarkable philosophy of a prehistoric nation that survived as a system of thought in the historic Indo-European civilizations and even in the subconsciousness of the modern speakers of Indo-European tongues.

This philosophy sees in the universe three basic principles that are realized by three categories of people: priests, warriors, and producers of riches. In conformity with this philosophy, most Indo-European epics have as their central themes interaction among these three principles or functions which are: (1) religion and kingship; (2) physical strength; (3) fecundity, health, riches, beauty, and so forth. In the long Indian epic the *Mahābhārata*, for example, the central figures, the Pāṇḍava brothers, together with their father Paṇḍu, their two uncles Dhṛtarāṣṭra and Vidura, and their common wife, Draupadī, correspond to traditional deities presiding over the three functions of the Indo-European ideology.

Central themes of Indo-European epics

During the first part of their earthly career, the Pāṇḍava suffer constantly from the persistent enmity and jealousy of their cousins, Duryodhana and his 99 brothers, who, in reality, are incarnations of the demons Kālī and the Paulastya. The demons at first succeeded in snatching the Kingdom from the Pāṇḍava and in exiling them. The conflict ends in a devastating war, in which all the renowned heroes of the time take part. The Pāṇḍava survive the massacre, and establish on earth a peaceful and prosperous reign, in which Dhṛtarāṣṭra and Vidura also participate.

This whole story, it has been shown, is a transposition to the heroic level of an Indo-European myth about the incessant struggle between the gods and the demons since the beginning of the world. Eventually, it results in a bloody eschatological battle, in which the gods and the devils exterminate each other. The destruction of the former world order, however, prepares for a new and better world, exempt from evil influences, over which reign a few divine survivors of the catastrophe.

EARLY PATTERNS OF DEVELOPMENT

Development in the ancient Middle East. The earliest-known epic poetry is that of the Sumerians. Its origin has been traced to a preliterate Heroic Age, not later than 3000 BC, when the Sumerians had to fight, under the direction of a warlike aristocracy, for possession of this fertile Mesopotamian land. Among the extant literature of this highly gifted people are fragments of narrative poems recounting the heroic deeds of their early kings: Enmerkar, Lugalbanda, and Gilgamesh. By far the most important in the development of Mesopotamian literature are the five poems of the Gilgamesh cycle. This epic tells the odyssey of a king, Gilgamesh, part human and part divine, who seeks immortality. A god who dislikes his rule, fashions a wild man, Enkidu, to challenge him. Enkidu first lives among wild animals, then goes to the capital and engages in a trial of strength with Gilgamesh, who emerges victorious. The two, now friends, set out on various adventures, in one of which they kill a wild bull that the goddess of love had sent to destroy Gilgamesh because he spurned her marriage proposal. Enkidu dreams the gods have decided he must die for the death of the bull, and, upon awakening, he does fall ill and die. Gilgamesh searches for a survivor of the Babylonian flood to learn how to escape death. The survivor shows him where to find a plant that renews youth, but after Gilgamesh gets the plant it is snatched away by a serpent. Gilgamesh returns, saddened, to his capital.

The legend of Gilgamesh

The legend of Gilgamesh was taken over by the Babylonians, who developed it into a long and beautiful poem, one of the masterpieces of mankind.

Another Babylonian epic, composed around 2000 BC, is called in Akkadian *Enuma elish*, after its opening words, meaning "When on high." Its subject is not heroic but mythological. It recounts events from the beginning of the world to the establishment of the power of Marduk, the great god of Babylon. The outline of a Babylonian poem narrating the adventure of a hero named Adapa ("Man") can be reconstructed from four fragmentary accounts. It shares with the *Epic of Gilgamesh* the theme of man's loss of an opportunity for immortality.

Among clay tablets of the 14th century BC, covered with inscriptions in an old Phoenician cuneiform alphabet, from Ras Shamra (the site of ancient Ugarit), in northern Syria, there are important fragments of three narrative poems. One of these is mythological and recounts the career of the god Baal, which seems to coincide with the yearly cycle of vegetation on earth. As was usual with the death of gods in the ancient Mediterranean world, Baal's end brings about a drought that ceases only with his resurrection. Another fragment, about a hero named Aqhat, is perhaps a transposition of this myth of Baal to the human level. Just as the death of Baal is avenged on his slayer by Baal's sister Anath, so is the murder of Aqhat, which also causes a drought, revenged by his sister Paghat. Since the end of the poem is missing, however, it is not known whether Paghat, like Anath, succeeded in bringing her brother back to life.

The third fragment, the Ugaritic epic of Keret, has been interpreted as a Phoenician version of the Indo-European theme of the siege of an enemy city for the recovery of an abducted woman. This theme is also the subject of the Greek legend of the Trojan War and of the Indian epic *Rāmāyaṇa*. The fragmentary text does not reveal, however, whether the expedition of Keret, like that of the Achaean army against Troy, was meant to regain the hero's wife or to acquire for him a new bride.

The Greek epic. In its originative stage, especially, the Greek epic may have been strongly influenced by these Oriental traditions. The Greek world in the late Bronze Age was related to the Near East by so many close ties that it formed an integral part of the Levant. At Ugarit a large quarter of the city was occupied by Greek merchants, whose presence is also attested, among other places, at the gate of Mesopotamia, at Alalakh, in what is now Turkey. Thus, it is no surprise that, for example, the Greek myth about the succession of the divine kingship told in the *Theogony* of Hesiod and elsewhere is paralleled in a Hittite version of a Hurrian myth. In it, Anu, Kumarbi, and the storm god respectively, parallel Uranus, Cronos, and Zeus in the *Theogony*. The Hittites had continuous diplomatic relations with the Achaeans of Greece, whose princes went to the royal court at Hattusas to perfect their skill with the chariot. The Greeks, therefore, had ample opportunity to become familiar with Hittite myths.

Eastern influences on the Greek epic

The *Epic of Gilgamesh* was then well-known in the Levant, as is indicated by discoveries of copies of it throughout this wide area. Many parallels with the *Epic of Gilgamesh* have been pointed out in the *Odyssey*; the encounters of Odysseus with Circe and Calypso on their mythical isles, for instance, closely resemble the visit by Gilgamesh to a divine woman named Siduri, who keeps an inn in a marvellous garden of the sun god near the shores of ocean. Like the two Greek goddesses, Siduri tries to dissuade Gilgamesh from the pursuit of his journey by representing the pleasures of life, but the firm resolution of the hero obliges her finally to help him cross the waters of death. In the *Iliad*, Patroclus, who dies as a substitute for his king and dearest friend, Achilles, and then gives Achilles a description of the miserable condition of man after his death, bears striking similarities to the friend of Gilgamesh, Enkidu.

If these are indeed borrowings, it is all the more re-

markable that they are used in Homer to express a view of life and a heroic temper radically different from those of the Sumerian epic of Mesopotamia. Gilgamesh persists in his quest of immortality even when Siduri shows him the vanity of such an ambition, but Odysseus shuns a goddess's offer of everlasting life, preferring to bear his human condition to the end. The loss of a beloved friend does not make Achilles seek desperately to escape from death; instead he rushes into combat to revenge Patroclus, although he knows that he is condemning himself to an early death, and that the existence of a king in Hades will be incomparably less enviable than that of a slave on earth. The Mesopotamian mind never tires of expressing man's deep regret at not being immortal through stories about ancient heroes who, despite their superhuman strength and wisdom, and their intimacy with gods, failed to escape from death. A decisively different idea, however, is fundamental to the Greek heroic view of life. It has been demonstrated that the Greek view is derived from an Indo-European notion of justice —that each being has a fate (*moira*) assigned to him and marked clearly by boundaries that should never be crossed. Man's energy and courage should, accordingly, be spent not in exceeding the proper limits of his human condition but in bearing it with style, pride, and dignity, gaining as much fame as he can within the boundaries of his *moira*. If he is induced by Folly (Ate, personified as a goddess of mischief) to commit an excess (*hybris*) with regard to his *moira*, he will be punished without fail by the divine vengeance personified as Nemesis.

The Greek heroic view of life

At the beginning of the *Iliad*, a plague decimates the Achaean army because its commander in chief, Agamemnon, refuses to return a captive, Chryseis, to her father, a priest of Apollo who offers a generous ransom. By unjustly insulting Achilles, Agamemnon commits another excess that causes the defeat of his army. Achilles, in the meantime, lets Ate take possession of his mind and refuses, to the point of excess, to resume his fight. He thus brings about a great misfortune, the loss of his dearest companion, Patroclus. Patroclus, however, also contributes to his own death by his *hybris* in pushing his triumph too far, ignoring Achilles' order to come back as soon as he has repulsed the enemy far from the Greek ships. The death of Hector also results from his *hybris* in rejecting the counsel of Polydamas and maintaining his army on the plain after the return of Achilles to combat. After so many disasters caused by the mischievous action of Ate among men, the last book of the *Iliad* presents a noble picture of Priam and Achilles, who submit piously to the orders of Zeus, enduring with admirable courage and moderation their respective fates.

On the other hand, at the beginning of the *Odyssey*, Zeus evokes the ruin that Aegisthus will have to suffer for having acted "beyond his due share" by marrying Clytemnestra and murdering Agamemnon. This sets an antithesis to the story of the wise Odysseus, who, to accomplish his destiny as a mortal hero, never changes his purpose trying always to make the best of his countless misfortunes. He earns by this the favour of Athena and succeeds eventually in regaining Ithaca and punishing the wooers of Penelope for their *hybris* during his long absence. Present scholarship inclines to the view that such admirably well-structured poems as the *Iliad* and the *Odyssey* could have been created only by a single highly gifted poet whose name was Homer. This position contrasts with the extreme skepticism that marked all phases of Homeric criticism during the previous century. Yet the personality of Homer remains unknown and nothing certain is known about his life.

Hesiod's contribution

In comparison, information derived from his own works is fairly plentiful about the other great epic poet of Greece, Hesiod. He produced them presumably around 700 BC, while tilling a farm in Askra, a small village of Boeotia. The social and geographical background of his poems, called didactic because of their occasionally moral and instructive tone, differs from the aristocratic society of Ionian Asia Minor that Homer addressed. Despite their different style, subjects, and view of life, however, Hesiod's *Theogony* and the *Works and Days* illustrate the same basic conception of justice as the Homeric epic. The *Theogony* describes a long sequence of primordial events that resulted in the present world order, in which man's inescapable lot is assigned to him by Zeus. The *Works and Days* explains, through a series of three myths, why the lot of man is to work hard to produce riches. Man has to shut his ears to the goddess who causes wars and lawsuits, listening only to the goddess who urges him to toil more laboriously than his neighbour to become richer. Pain and suffering have become unavoidable since Pandora opened the fatal jar containing all the ills of mankind at Prometheus' house in conformity with the will of Zeus. Moreover, the age of the race of iron has arrived when the fate of human beings is not to pass their lives in perpetual banquets or warfare, as did the preceding races, but to suffer constantly the fatigue and misery of labour. As long as the goddesses Aidos (a personification of the sense of shame) and Nemesis (a personification of divine retribution) stay with mankind, however, helping people observe their *moira* without committing excesses, man can still gain riches, merits, and glory by the sweat of his brow. Only if he knows how to avoid all faults in doing his daily work will he not offend Justice (Dike), the sensitive virgin daughter of Zeus. This is why it is so vitally important for a farmer to know all the rules listed in the rest of the poem about seemingly trivial details of his work.

LATER VARIATIONS

The Latin epic. Latin epic poetry was initiated in the 3rd century BC by Livius Andronicus, who translated the *Odyssey* into the traditional metre of Saturnian verse. It was not until the 1st century BC, however, that Rome possessed a truly national epic in the unfinished *Aeneid* of Virgil (70–19 BC), who used Homer as his model. The story of Aeneas' journey, recounted in the first six books, is patterned after the *Odyssey*, with many imitative passages and even direct translations, while the description of the war in the last six books abounds with incidents modelled after those from the *Iliad*. More basically, however, Virgil made use of another model, Rome's own national legend about the war fought under Romulus against the Sabines. This legend preserves, in a historical disguise, an original Indo-European myth about a primitive conflict between the gods of sovereignty and war and the gods of fecundity, ending with the unification of the two divine races. In the development of this theme by Virgil, Aeneas and the Etruscans can be seen as representing the gods of sovereignty and war, and the Latins representing the gods of fecundity. Aeneas, who has brought the Trojan gods to Rome, is forced to fight with the help of the Etruscans against the Latins. It is the destiny of Aeneas to rule, and it is the fate of the Latins to share their land and women with the invaders and to accept Aeneas as their king. This resembles the unification of the warring races that climaxes the Indo-European myth.

The power exercised by the Indo-European ideological pattern on the Roman mind even under the empire is seen in the *Pharsalia* of Lucan (AD 39–65). In this historical epic, Cato, Caesar, and Pompey are depicted respectively as moral, warlike, and popular in a way that gives the story a clear trifunctional structure.

The persistence of the Indo-European pattern

Germanic epics. A typical Heroic Age occurred during the wanderings of the Germanic tribes from the 3rd to the 6th centuries AD. Out of this, too, came a rich oral tradition, from which developed in the Middle Ages many epic poems. One of the greatest of these is the Old English *Beowulf*, written down in the 8th century. Archetypal Indo-European themes also reappear in these epics. For example, the theme of the fatal fight between father and son is recounted in the German *Hildebrandslied*, of which a 67-line fragment is extant. Again, an heroic version of the Indo-European myth about the rescue of the Sun Maiden from her captivity by the Divine Twins, which also provided the basic plot of the Greek Trojan cycle and the Indian *Rāmāyaṇa*, is found in the German *Gudrun* (*c.* 1230).

Chansons de geste. The French chansons de geste are epic poems whose action takes place during the reign of

Charlemagne and his immediate successors. The *Chanson de Roland*, probably written down about the end of the 11th century, is by far the most refined of the group. The story of the poem had developed from a historical event, the annihilation of the rear guard of Charlemagne's army at Roncesvalles in the Pyrenees in 778 by Basque mountaineers. The Basques, however, are transformed in the epic to the Saracens, who to a later generation typified France's enemies in Spain. The other chansons de geste, none of which is comparable to *Roland* as a literary work, have been classified into three main cycles. The Cycle of William of Orange forms a biography of William (probably a historical Count William of Toulouse, who had, like the hero of the epic, a wife called Guibourg and a nephew, Vivien, and who became a monk in 806). Guibourg, the most faithful of wives, and the noble Vivien take prominent roles in the epic. The so-called Cycle of the Revolted Knights groups those poems that tell of revolts of feudal subjects against the emperor (Charlemagne or, more usually, his son, Louis). The Cycle of the King consists of the songs in which Charlemagne himself is a principal figure.

Arthurian Romance. The Arthurian Romance seems to have developed first in the British Isles, before being brought to the Continent by Bretons, who migrated to Brittany in the 6th and 7th centuries. The core of the legend about Arthur and his knights derives from lost Celtic mythology. Many of the incidents in the former parallel the deeds of such legendary Irish characters as Cú Chulainn, an Ulster warrior said to have been fathered by the god Lug, and Finn, hero of the Fenian cycle about a band of warriors defending Ireland, both of whom are gods transformed into human heroes. The earliest extant works on Arthurian themes are four poems of Chrétien de Troyes, written in French between 1155 and 1185: *Erec*, *Yvain*, *Le Chevalier de la Charette* (left unfinished by Chrétien and completed by Godefroy de Lagny), and an unfinished *Perceval*. In German, after 1188, Hartmann von Aue (who also wrote two legendary poems not belonging to the Arthurian cycle, *Gregorius* and *Poor Henry*) modelled his *Erec* and *Iwein* on those of Chrétien. The story of Perceval was given a full account by Wolfram von Eschenbach (*c.* 1170–1220) in his *Parzival* and in the unfinished *Titurel*. Another incomplete work of Wolfram, *Willehalm*, deals with the legend of William of Orange. *Tristan* of Gottfried von Strassburg is based directly on the older French version of Thomas of Britain (*c.* 1170–80). The romance proper, however, although it has similarities to the epic, differs in its lack of high purpose: fictions are told for their entertainment value rather than as models for national heroism. Developed in France in the Middle Ages, the romance is usually an adventure story with a strong love interest, intimately associated with the "courtly love" tradition of that time.

Distinctions between the epic and the romance

The epic in Japan. In Japan, there were in ancient times families of reciters (*katari-be*) whose duty was to hand down myths and legends by word of mouth and to narrate them during official ceremonies and banquets. After the introduction of Chinese letters, however, from the 4th century AD onward, these traditional tales were put in writing and the *katari-be* professional gradually died out. By the end of the 7th century, each clan of the ruling aristocracy seems to have possessed a written document that recounted the mythology and lengendary history of Japan in a form biassed in favour of the clan concerned. These family documents were collected at the command of the emperor Temmu (672–686) and were used as basic materials for the compilation of the first national chronicles of Japan, the *Koji-ki* (712) and the *Nihon shoki* (720). The myths and legends, contained in the earlier parts of these two books, derive, therefore, from the oral tradition of *katari-be*. Although no document preserves those narrations in their primitive form, it is generally assumed that they were originally in the form of poems. Many scholars believe that they were genuine epic poems produced during a period of incessant warfare around the 4th century. At that time mounted aristocratic warriors of the future imperial family struggled to extend its power over the larger part of Japan. Exploits of warriors, such as the emperor Jimmu or Prince Yamato-Takeru, in the earliest extant texts—the *Koji-ki* and *Nihon shoki* of the 8th century—probably derive from a heroic epic about the wars of conquest of the first emperors, whose legendary feats were transformed into those of a few idealized heroic figures.

The middle of the Heian period (794–1185) saw the emergence of a new class of warrior known as samurai. They attached a greater importance to fame than to life. The battles they fought became the subject of epic narratives that were recited by itinerant blind priests to the accompaniment of a lute-like instrument called a *biwa*.

Tales of the samurai

In the early part of the 13th century, tales about the wars of the preceding century, fought between the two strongest families of samurai, the Genji or Minamoto and the Heike or Taira, were compiled in three significant war chronicles. The *Hōgen monogatari* and the *Heiji monogatari* deal with two small wars, the Hōgen (1156) and Heiji (1159), in which the Genji and Heike warriors fought for opposing court factions. The structure of the two works is roughly the same. Each celebrates the extraordinary prowess of a young Genji warrior, Minamoto Tametomo in the *Hōgen monogatari* and Minamoto Yoshihira in the *Heiji monogatari;* each hero fights to the finish in exemplary manner not so much to win, for from the beginning each foresees the defeat of his own side, as for the sake of fame; and the consummate courage of the two heroes forms a striking contrast to the cowardice of court aristocrats. The bitterly fought Gempei War (1180–85), in which survivors of the Genji family challenged and defeated the Heike, is recounted in detail in the *Heike monogatari*, the greatest epic of Japanese literature. The sudden decline and ultimate extinction of the proud Heike, whose members had held the highest offices of the imperial court, illustrates the Buddhist philosophy of the transitory nature of all things; it invites the readers to seek deliverance from the world of sufferings through a faith that will take them to a land of eternal felicity at the moment of their death. The work is filled with tales of heroic actions of brave warriors. The most conspicuous is Minamoto Yoshitsune, one of the chief commanders of the Genji army: the legend of this man of military genius continued to develop in later literature, so that he has become the most popular hero of Japanese legend.

The later written epic. The vitality of the written epic is manifested by such masterworks as the Italian *La Divina commedia* of Dante (1265–1321) and the great Portuguese patriotic poem *Os Lusíadas* of Luiz de Camões (1524–1580), which celebrates the voyage of Vasco da Gama to India. In more recent times, novels and long narrative poems written by such major authors as Scott, Byron, Tennyson, William Morris, and Melville, were patterned, to some extent, on the epic. Their fidelity to the genre, however, is found primarily in their large scope and their roots in a national soil; their distance from the traditional oral epic tends to be considerable.

Among the epics written in modern times, the Finnish *Kalevala* (first ed. 1835; enlarged ed. 1849) occupies a very special position. This is because its author, the Finnish poet-scholar Elias Lönnrot (1802–84), who composed this masterpiece by combining short popular songs (*runot*) collected by himself among the Finns, had absorbed his material so well, and identified himself so completely with the *runo* singers. He thus came close to showing what the oral epic, which he could study only at its degenerative stage, might have been at its creative stage, on the lips of an exceptionally gifted singer.

BIBLIOGRAPHY. H.M. CHADWICK, *The Heroic Age* (1912), and H.M. and N.K. CHADWICK, *The Growth of Literature*, vol. 1, *The Ancient Literatures of Europe* (1932), are two classic works on European heroic poetries that are still valuable. A more comprehensive and up-to-date general survey is given in C.M. BOWRA, *Heroic Poetry* (1952); and J. DE VRIES, *Heroic Song and Heroic Legend* (Eng. trans. 1963). A.B. LORD, *The Singer of Tales* (1960), was written by an authority on the Yugoslav oral epic of the *guslari*. G.S. KIRK, *The Songs of Homer* (1962), also contains a brief and clear account of the Heroic Age and oral poetry. On Homer, see

also W. SCHADEWALDT, *Von Homers Welt und Werk*, 4th ed. (1965); and C.M. BOWRA, *Homer and His Forerunners* (1955). F.R. SCHRODER, *Germanische Heldendichtung* (1935), is a basic reference book for the study of the Germanic epic. J.B. PRITCHARD, *The Ancient Near East* (1958), gives summaries and translations of Akkadian and Ugaritic epics. A theory of the epics of the Indo-Europeans is presented by G. DUMEZIL in *Mythe et épopée*, vol. 1 (1968). For the use of mythical themes in the epics of the Indo-Europeans, see also D. WARD, *The Divine Twins: An Indo-European Myth in Germanic Tradition* (1968); and R. CARPENTER, *Folk Tale, Fiction and Saga in the Homeric Epics* (1946).

(A.Y.)

Epicureanism

In a strict sense, Epicureanism is the philosophy taught by Epicurus (341–270 BC); in a broad sense, it is a system of ethics embracing every conception or form of life that can be traced to the principles of his philosophy. In ancient polemics, as often since, the term was employed with an even more generic (and clearly erroneous) meaning as the equivalent of hedonism, the doctrine that pleasure or happiness is the chief good. In popular parlance, Epicureanism thus means devotion to pleasure, comfort, and high living, with a certain nicety of style.

NATURE OF EPICUREANISM

Atomism; pleasure; friendship

Several fundamental concepts characterize the philosophy of Epicurus. In physics, these are Atomism, a mechanical conception of causality, limited, however, by the idea of a spontaneous motion, or "swerve," of the atoms, which interrupts the necessary effect of a cause; the infinity of the universe and the equilibrium of all forces that circularly enclose its phenomena; the existence of gods conceived as beatified and immortal natures completely extraneous to happenings in the world. In ethics, the basic concepts are the identification of good with pleasure and of the supreme good and ultimate end with the absence of pain from the body and the soul—a limit beyond which pleasure does not grow but changes; the reduction of every human relation to the principle of utility, which finds its highest expression in friendship, in which it is at the same time surmounted; and, in accordance with this end, the limitation of all desire and the practice of the virtues, from which pleasure is inseparable, and a withdrawn and quiet life.

In principle, Epicurus' ethic of pleasure is the exact opposite of the Stoic's ethic of duty. The consequences, however, are the same: in the end, the Epicurean is forced to live with the same temperance and justice as the Stoic. Of utmost importance, however, is one point of divergence: the walls of the Stoic's city are those of the world, and its law is that of reason; the limits of the Epicurean's city are those of a garden, and the law is that of friendship. Though this garden can also reach the boundaries of earth, its centre is always a man.

HISTORY OF EPICUREANISM

Epicurus' predecessors were, in physics, Leucippus and Democritus and in ethics, Antiphon Sophista, Aristippus of Cyrene, and Eudoxus of Cnidus, a geometer and astronomer. Epicurus differed from all of these in his systematic spirit and in the unity that he tried to give to every part of philosophy. In this respect, he was greatly influenced by the philosophy and teachings of Aristotle—taking over the essentials of his doctrines and pursuing the problems that he posed.

Epicurus' own life and teachings. In 306 BC, Epicurus established his school at Athens in his garden, from which it came to be known as The Garden.

His works. In accordance with the goal that he assigned to philosophy, Epicurus' teaching had a dogmatic character, in substance if not in form. He called his treatises *dialogismoi*, or "conversations." Since the utility of the doctrines lay in their application, he summarized them in *stoicheia*, or "elementary propositions," to be memorized. In this respect, Epicurus was the inventor of the catechetical method. The number of works produced by Epicurus and his disciples reveals an impressive theoretical activity. But no less important was the practical action in living by the virtues taught by him and in honouring the obligations of reciprocal help in the name of friendship. In these endeavours, continuous assistance was rendered by Epicurus himself, who, even when old and ill, was occupied in writing letters of admonishment, guidance, and comfort—everywhere announcing his gospel of peace and, under the name of pleasure, inviting to love (see EPICURUS).

Doctrine of Epicurus. Philosophy was, for Epicurus, the art of living, and it aimed to assure happiness and to supply means to achieve it. As for science, he was concerned only with the practical end in view. If possible, he would have done without it. "If we were not troubled by our suspicions of the phenomena of the sky and about death," he wrote, "and also by our failure to grasp the limits of pain and desires, we should have no need of natural science." But this science requires a principle that guarantees its possibilities and its certainty and a method of constructing it. This principle and this method are the object of the "Canon," which Epicurus substituted for Logic. Since he made the "Canon" an integral introduction to the "Physics," however, his philosophy falls into two parts, the "Physics" and the "Ethics."

His "Canon"

The name canon, which means "rule," is derived from a special work entitled "On the Criterion, or Canon." It held that all sensations and representations are true and serve as criteria. The same holds for pleasure and pain, the basic feelings to which all others can be traced. Also true, and included among the criteria, are what may be called concepts (*prolēpsis*), which consist of "a recollection of what has often been presented from without. . . ." Man, therefore, must always cling to that "which was originally thought" in relation to every single "term" and which constitutes its background. Since the truth attested by each of the criteria is reflected in the *phainomena*, man must cling to these, employing them as "signs," and must "conjecture" whatever "does not appear." With the use of signs and conjecture, however, the level of judgment is reached, and thought is well advanced into that sphere in which error is possible, a state that begins as soon as single terms are tied into a proposition. Error, which consists of what "our judgment adds" to the evidence, can be of two types, one relative to what is not an object of experience, the other relative to what is such an object but for which the evidence is dubious. Each type has its own method of proof. Following the principles and methods of the "Canon," Epicurus arrived at an Atomism that, like that of the ancient naturalist Democritus, taught that the atoms, the void space in which they move, and the worlds are all infinite. But in contrast to Democritus, who had followed the deductive route of the intellect, considering the knowledge of the senses to be spurious, Epicurus, following an inductive route, assigned truth to sensation and reduced the intellect to it. On the basis of the totality of problems as Aristotle posed them in his "Physics," Epicurus modified entirely the mechanical theory of causes and of motion found in Democritus and added the concept of a natural necessity, which he called nature, and that of free causality, which alone could explain the freedom of motion of man and animals. For this purpose he distinguished three forms of motion in the atoms: a natural one of falling in a straight line, owing to their weight; a forced one due to impacts; and a free motion of declination, or swerving from a straight line. Secondly, he made finite the number of forms of the atoms in order to limit the number of sensible qualities, since each form begets a distinctive quality, and he taught a mathematical as well as a physical Atomism. Lest an infinity of sensible qualities be generated, however, by an infinity of aggregations (if not of atomic kinds), Epicurus developed, from just this concept of infinity, the law of universal equilibrium of all the forces, or "isonomy." Upon it, enclosing the events in a circle, he founded a theory of cyclic returns.

Natural necessity and free causality

As part of his "Physics," Epicurus' psychology held that the soul must be a body. It is made of very thin atoms of four different species—motile, quiescent, igneous, and ethereal—the last, thinnest and the most mobile of all, serving to explain sensitivity and thought. Thus consti-

tuted, the soul is, from another perspective, bipartite: in part distributed throughout the entire body and in part collected in the chest. The first part is the locus of sensations and of the physical affects of pain and pleasure; the second (entirely dissociated from the first) is the *psychē* par excellence—the seat of thought, emotions, and will. Thought is due not to the transmission of sense motion but to the perception of images constituted by films that continuously issue from all bodies and, retaining their form, arrive at the *psychē* through the pores. The full autonomy and freedom of the *psychē* is assured, as, with an act of apprehension, it seizes at every moment the images it needs, meanwhile remaining master of its own feelings.

The object of ethics is to determine the end and the means necessary to reach it. Taking his cue from experience, Epicurus looked to the animal kingdom for his answer. He concluded from this cue that the chief end is pleasure. He distinguished two kinds—a "kinetic" pleasure of sense and a "static" pleasure, consisting in the absence of pain—and taught that the pleasure of sense is good, though it is not good merely as motion but rather as a motion favourable to the nature of the receiving sense organ. In essence, pleasure is the equilibrium of the being with itself, existing wherever there is no pain.

The two kinds of pleasure

Epicurus concluded that "freedom from pain in the body and from trouble in the mind" is the ultimate aim of a happy life. The damages and the advantages following the realization of any desire must be measured in a calculus in which even pain must be faced with courage if the consequent pleasure will be of longer duration.

Having thus given order to his life, however, the wise man must also provide himself with security. This he achieves in two ways—by reducing his needs to a minimum and withdrawing, far from human competition and from the noise of the world, to "live hidden"; and by adding the private compact of friendship to the public compact from which laws arise. To be sure, friendship stems from utility; but, once born, it is desirable in itself. Epicurus then added that "for love of friendship one has even to put in jeopardy love itself"; for every existence, being alone, needs the other. "To eat and drink without a friend," he wrote, "is to devour like the lion and the wolf." Thus, the utility sublimates itself and changes into love. But as every love is intrepid, the wise man, "if his friend is put to torture, suffers as if he himself were there" and, if necessary, "will die for his friend." Thus, into the bloody world of his time, Epicurus could launch the cry: "Friendship runs dancing through the world bringing to us all the summons to wake and sing its praises."

If man's unhappiness stemmed only from his own vain desires and from worldly dangers, this wisdom, founded upon prudence alone, would suffice. But besides these sources of unhappiness there are two great fears, fear of death and fear of the gods. If science, however, is effective in revealing the bounds of desire and (as already seen) in quelling the fear of the gods, it can also allay the fear of death. Regarding the soul as a body within another body, science envisions it as dissolving when the body dissolves. Death, then, "is nothing to us, so long as we exist, death is not with us; but when death comes, then we do not exist." But death is feared not only for what may be awaiting man in the beyond but also for itself. "I am not afraid of being dead," said the comic Epicharmus of Cos: "I just do not want to die." The very idea of not existing instills a fear that Epicurus considered to be the cause of all the passions that pain the soul and disorder men's lives. Against it Epicurus argued that if pleasure is perfect within each instant and "infinite time contains no greater pleasure than limited time, if one measures by reason the limits of pleasure," then all desire of immortality is vain. Thus, Epicurus' most distinguished pupil, Metrodorus of Lampsacus, could exclaim, "*bebiōtai*" ("I have lived"), and this would be quite enough. He who has conquered the fear of death can also despise pain, which "if it is long lasting is light, and if it is intense is short" and brings death nearer. The wise man has only to replace the image of pain present in the flesh with that of blessings enjoyed, and he can be happy even "inside the bull of Phalaris." The most beautiful example was set by Epicurus at the moment of his death:

The two great fears

> A happy day is this on which I write to you. . . . The pains which I feel . . . could not be greater. But all of this is opposed by the happiness which the soul experiences, remembering our conversations of a bygone time.

The ultimate concentration of all his wisdom is the *Tetrapharmacon*, preserved by Philodemus: "The gods are not to be feared. Death is not a thing that one must fear. Good is easy to obtain. Evil is easy to tolerate."

The Epicurean school. Epicurus' successor in the direction of the Garden was Hermarchus of Mitylene, and he was succeeded in turn by Polystratus, who was the last survivor to have heard Epicurus. Superior to both, however, were Metrodorus and Colotes, against whom a small work by Plutarch was directed. Among the Epicureans of the 2nd century BC, mention must be made of Demetrius of Lacon, of whose works some fragments remain, and Apollodorus, who wrote more than 400 books. Much was also written by his disciple Zeno of Sidon, who was heard by Cicero in 79 BC in Athens. After Zeno, there were Phaedrus, also a teacher of Cicero, who was in Rome in 90 BC, and Patro, the head of the school until 51 BC. Already famous as an epigram writer was Philodemus of Gadara (born 110 BC). In the papyri of Herculaneum, comprising the effects of Philodemus' library, there are sizable remains of almost all of his numerous works. Epicureanism had already been introduced in Rome, in the 2nd century BC. The first person to spread its doctrines in Latin prose was a certain Amafinius. At the time of Cicero, Epicureanism was in fact the philosophy in vogue; and the number of Romans subscribing to it was, according to Cicero, very large. Among the greatest was Titus Lucretius Carus (*c.* 95–55 BC), who, in the poem *De rerum natura* ("On the Nature of Things"), left an almost complete and amazingly precise exposition of Epicurus' "Physics." The extent to which Epicurus was still popular in the 1st century after Christ is demonstrated by Seneca, who cited and defended him. To the 2nd century AD belongs Diogenes of Oenoanda, who carved Epicurus' works on a portico wall. In the same century should perhaps be mentioned Diogenianus, fragments of whose polemic against the Stoic Chrysippus are found in the church historian Eusebius. Also Epicurean, between the 4th and 5th centuries, was the epigrammatist Palladas.

Lucretius' *De rerum natura*

On account of its dogmatic character and its practical end, the philosophy of Epicurus was not subject to development, except in the polemic and in its application to themes that Epicurus either had treated briefly or had never dealt with at all. To be aware of this, it is sufficient to run through what remains of the representatives of his school and particularly of the works of Philodemus of Gadara. Epicurus' philosophy remained essentially unchanged. Once truth has been found, it requires no more discussion, particularly when it completely satisfies the end toward which man's nature tends. The main thing is to see this end; all of the rest comes by itself, and there is no longer anything to do but follow Epicurus, "liberator" and "saviour," and to memorize his "oracular words."

Epicureanism and egoism in modern philosophy. In the Middle Ages Epicurus was known through Cicero and the polemics of the fathers. To be an Epicurean at the time of Dante meant to be one who denied Providence and the immortality of the soul. In the 15th century, the notable humanist Lorenzo Valla—following brief hints by Petrarch—wrote, in the dialogue *De voluptate* (1431; "On Pleasure"), the first modern defense of the ethics of Epicurus, maintaining that the true good is pleasure and not virtue but concluding that the supreme pleasure is that which awaits man in heaven, which even the Bible calls *paradisum voluptatis.* In the 16th century, in terms of attitude and direction of thought, the first two great Epicureans were Michel de Montaigne in France and Francesco Guicciardini in Italy. Epicurean in everything, as man and as poet, was the early 16th-century classicist Ludovico Ariosto. But not until the 17th-century Provençal abbot Pierre Gassendi was the system

of Epicurus to rise again in its entirety—this time, however, by approaching truth through faith. Gassendi in 1649 wrote a commentary on a book by the 3rd-century (AD) biographer Diogenes Laërtius. This comment, called the *Syntagma philosophiae Epicuri* ("Treatise on Epicurean Philosophy"), was issued posthumously at The Hague ten years later. At the same time, in England, Thomas Hobbes, a friend of Gassendi, took up again the theory of pleasure and interpreted it in a dynamic sense, which was therefore closer to the doctrine of the ancient Cyrenaics. Starting from the premise that, in the natural state, "man is a wolf to man," he concluded that peace, without which there is no happiness, cannot be guaranteed by anything but force, and that this force must be relinquished, by common agreement, to the power of only one.

Gassendi's revived Epicureanism

During the 17th and 18th centuries, the European nation in which Epicureanism was most active was France, where its representatives were called libertines, among them moralists such as François, duc de La Rochefoucauld, and Charles de Saint-Évremonde; scientists such as Julien de La Mettrie, who believed that man could be explained as a machine, Claude-Adrien Helvetius, who reduced the ethic of the useful to a form of experimental science but who put public above private well-being, and Paul Henri Dietrich, baron d'Holbach, who gave particular importance to the physics of the atoms. The purely sensistic conception of knowledge had its most thoroughgoing theoretician in Étienne de Condillac. In England, Adam Smith, developing the ethical concepts of Hume (founded on sympathy), surmounted the egoism that is the basis of every act by using the principle of the impartial observer invoked to sympathize with one or another of the antagonists. After him, the jurist Jeremy Bentham, eliminating sympathy, reduced ethics to the pure calculus of the useful, which—in an entirely Epicurean formula—he defined as a "moral arithmetic." In the Epicurean stream lay also the Utilitarianism (*q.v.*) of the 19th century, of which the greatest representative was John Stuart Mill.

Pleasure as a lifestyle

Epicureanism in contemporary philosophy. In contemporary times, the interpretation of pleasure as a psychic principle of action was inititated by Gustov Fechner, the founder of psychophysics, and developed toward the end of the century by Freud on the psychoanalytic level of the unconscious.

Epicureanism and egocentric hedonism have few faithful representatives among 20th-century philosophers, though the viewpoint remains as a residue in some strains of popular thinking.

CRITICISM AND EVALUATION

In the first half of the 17th century, at a time when Pierre Gassendi was reviving atomistic Epicureanism, René Descartes, often called the founder of modern philosophy, offered arguments that tended to undercut Atomism. Reality is a plenum, he held, a complete fullness; there can be no such thing as a vacuous region, or the void of Atomism. Since matter is nothing but spatial extension, its only true properties are geometrical and dynamic. Because extension is everywhere, motion occurs not as a passage through emptiness, as Epicurus supposed, but as vortices, or "whirlpools," in which every motion sets up a broad area of movement extending indefinitely around itself—a view that has tended to be confirmed in contemporary gravitational and field theory.

Close to the heart of Epicureanism is the principle, which occurred also in Democritus, that denies that something can come from or be rooted in nothing. In a poem composed by an ancient monist, Parmenides of Elea (born *c.* 515 BC), this principle had been expressed in the two formulas: "Being cannot be Non-Being," and "Non-Being must be Non-Being." Though Epicurus had faithfully adhered to this principle almost throughout his system, he has been criticized for abandoning it at one point—in the swerves that he attributed to occasional atoms that take them aside from their normal paths. Epicurus abandoned the principle at this point in order to avoid espousing a physics that was inconsistent with the autonomy that he observed in the physical behaviour of men and animals. But to his Stoic critics, the swerves of the atoms were a scandal, since they implied that an event can occur without a cause. It has seldom been noted, however, that the swerve is merely a special case—a transposition into atomistic terms—of Aristotle's theory of accidents (*i.e.*, of properties that are not essential to the substances in which they occur), inasmuch as an accident, too, as Aristotle himself had stated (*Met.* I 3), is without a cause. Moreover, a similar view has been seriously advanced in modern times under the name of tychism by Charles Sanders Peirce, a philosopher of science.

To the Stoic charge that Epicurus lacked a doctrine of Providence (since he viewed the gods as being lazy), Epicurus answered that "mythical gods are preferable to the fate" posited by the Stoics. It has been suggested that he might equally well have added that the "immobile Prime Mover" of Aristotle's theology was hardly less lazy than Epicurus' gods. Epicurus' way of phrasing this issue, however, must not obscure the fact that the problem of Providence and its secularization has been a crucial one in the philosophy of history ever since ancient times.

Critique of egoistic hedonism

The effort of Epicurus to reduce the good to pleasure reflects the only criterion to which he would entrust himself, the "evidence of those passions immediately present," which give man the word of Nature. In the argument of psychological hedonism, here implied, the Epicurean holds that men as a matter of fact do take satisfaction in pleasure and decry pain, and he argues then to an egoistic ethical hedonism that identifies the (objective) good with pleasure. Most moralists, however, have felt that a thoroughgoing psychological hedonism cannot be defended; that desire is often, as a matter of fact, directed toward an object with no thought at all about the pleasure that it will bring; that a mother's impulse to save her young from danger is more fundamental than any pleasure involved (which usually comes only afterward); that the tendency of a child to imitate his parents can be, in fact, quite painful; and that, as a 19th-century Utilitarian, Henry Sidgwick, has argued, in what he called the "hedonistic paradox," one of the most ineffective ways to achieve pleasure is to deliberately seek it out.

Some scholars have even argued that an Epicurean egoistic hedonism, however foresighted it may be, must logically be self-defeating. If the view is universalized, the egoist must advocate the maximization of his enemy's pleasure as well as of his own, which can lead to actions painful to himself. In consequence, the entire branch of ethics that covers the advising or judging of other agents is banned from consideration, and it may be questioned whether such a view can comprise an ethic at all.

On the other hand, it has been argued that man is subject to antinomies, or contradictions, that no system can escape; there are dimensions in his nature that transcend the rational level. Thus, whatever its rational credentials may be, Epicureanism, as an attitude toward life that was theorized in its purest form by Epicurus, nonetheless remains one of the important forms that human behaviour has often assumed; and, at its best, it has achieved a type of asceticism that, even in retirement and solitude, does not negate company but welcomes it, finding the purest joys of life in the unique richness of human encounters.

BIBLIOGRAPHY

Editions of Epicurus and Lucretius (original languages): The first complete collection of the extant works and fragments of Epicurus is H. USENER (ed.), *Epicurea* (1887, reprinted 1966). A smaller selection, with Eng. trans. and commentary, is CYRIL BAILEY (ed.), *Epicurus: The Extant Remains* (1926), a very useful book that includes the "Vatican Fragments." All of the ethical fragments (and several other items) are published in CARLO DIANO (ed.), *Epicuri Ethica* (1946), with extensive Latin comments. CARLO DIANO (ed. and trans.), *Lettere di Epicuro e dei suoi* (1946), containing 14 letters of Epicurus and his friends taken from Pap. Herc. 1418. G. ARRIGHETTI (ed.), *Epicuro, Opere* (2nd ed., 1967), contains all of the works and fragments (including the *Peri Physeos*), with notes and an *index verborum;* to be used with caution. Lucretius can be read in the three volumes prepared, with introduction, translations, and comments, by CYRIL BAILEY, *Lucreti, De Rerum Natura* (1947).

English translations of Epicurus and Lucretius: WHITNEY J. OATES (ed.), *The Stoic and Epicurean Philosophers* (1940), contains translations by CYRIL BAILEY and by H.A.J. MUNRO. See also *The Philosophy of Epicurus: Letters, Doctrines, and Parallel Passages from Lucretius*, trans. by GEORGE K. STRODACH (1963); DIOGENES LAERTIUS, *Lives of Eminent Philosophers*, bk. 10 on Epicurus, trans. by R.D. HICKS (1925); and LUCRETIUS, *On the Nature of the Universe*, trans. by R.E. LATHAM (1964).

Fundamental studies: Valuable for its breadth and richness of detail, CYRIL BAILEY, *The Greek Atomists and Epicurus* (1928; new ed., 1964), is a fundamental work. For Epicurus' psychology and his relation to Aristotle, see CARLO DIANO, "La psicologia d'Epicuro e la teoria delle passioni," in *Giornale critico della filosofia italiana* (1939–42). A book that stresses Epicurus' anti-Platonism is N.W. DEWITT, *Epicurus and His Philosophy* (1954). Also important for its perceptive study of Epicurus' religiosity and ethics is A.J. FESTUGIERE, *Épicure et ses dieux* (1946; Eng. trans., *Epicurus and His Gods*, 1956). See also the article "Epikur," by W. SCHMID in the *Reallexikon für Antike und Christentum*, 5:681–819 (1961); L.L. WHYTE, *Essay on Atomism: From Democritus to 1960* (1961); and BENJAMIN FARRINGTON, *The Faith of Epicurus* (1967). G.D. HADZSITS, *Lucretius and His Influence* (1935), traces the influence of Epicurean ideas, especially since Roman times, in a broad perspective. For further bibliography, see PHILLIP DE LACY, "Some Recent Publications on Epicurus and Epicureanism (1937–1954)," in *Classical Weekly*, 48:169–177 (1955).

Epicurus

The Greek philosopher Epicurus, creator of an ethical philosophy of simple pleasure, friendship, and retirement, founded schools of philosophy that survived directly from the 4th century BC until the 4th century AD. The principal sources for the life of Epicurus are a section of the works of Diogenes Laërtius, fragments from Philodemus, and six other notices. For a detailed account of his philosophy, see EPICUREANISM.

Epicurus, bronze bust from a Greek original, c. 280–270 BC. In the Museo Archeologico Nazionale, Naples.

Early life and training. Epicurus was born in 341 BC on the island of Samos of Athenian parents who had gone there as military settlers. His father, a schoolteacher, was named Neocles, his mother Chairestrate; both were of the same village, the deme Gargettos. According to his own report, Epicurus began his study of philosophy at the age of 14. One account has him turning to philosophy when his schoolmaster could not explain the concept of chaos in Hesiod, an early Greek philosophical poet. His first master is said to have been the Platonist Pamphilus of Samos. Much more significant, however, is the report that Epicurus was for three years (327–324) a student in the Ionian city of Teos, where his teacher was Nausiphanes, a disciple of the naturalistic philosopher Democritus. It may have been from this source that Epicurus' atomistic theory came, which he used not as a means of studying physics but as the basis for a philosophical system that ultimately sought ethical ends.

Youthful interest in philosophy

At the age of 18, Epicurus went to Athens to perform the two years of military training required for Athenian citizenship. While there he may have heard Xenocrates, second in succession after Plato as head of his Academy, and Aristotle, who was then in Athens. One year later Epicurus rejoined his parents at Colophon, where they had gone as exiles when, at the close of the Lamian War, Athens lost Samos to the Macedonians. For the next 10 years, there is virtually no record. It seems probable that Epicurus travelled and studied, and it is reasonable to suppose that this was the period during which he developed his philosophical outlook and confirmed it in exchanges with the Platonists and Aristotelians. A letter written by him from Teos, addressed to his mother, was preserved by Diogenes of Oenoanda. At the age of 32, Epicurus began to teach, first at Mytilene and subsequently at Lampsacus, a period that lasted from 311/310 to 307/306.

In various places Epicurus met the disciples who were destined to follow him to Athens and to become of great significance as vehicles through whom the Epicurean school would achieve its mature development: at Mytilene, he met his first disciple, Hermarchus, who eventually succeeded him as head of the Athenian school; and at Lampsacus, he met Metrodorus and Polyaenus, whose death preceded the master's and whose sons Epicurus provided for in his will; Metrodorus' brother, Timocrates; Leonteus and his wife, Themista, who had been a hetaera (an independent courtesan); Colotes, whom Epicurus flattered with the pet name Colotarion; and Idomeneus and his wife, Batis, sister of Metrodorus.

Thus, apart from his two years in Athens, Epicurus spent the first 35 years of his life in Asia. This need not mean, however, that he developed an aversion to the literary circles in Athens. Instead, his Asiatic ties, which he continued to cultivate intensely all his life (including two or three actual journeys to Asia Minor) seem to have been reflected mainly in his choice of words and style and, more significantly, in the ecumenical scope of his philosophy.

Retirement in The Garden

The schools at Athens and elsewhere. When Epicurus and his followers came to Athens in 306, he bought a house and, in the garden, established a school, which came to be known as Ho Kepos (The Garden). At this time in Athens, cultural life was dominated by the Academy of Plato and the Lyceum of Aristotle, both of which had passed into the hands of successors. These schools attracted both the best theoretical students and those concerned with the application of philosophy to politics and public life. Therefore, any school that hoped to endure through this period had to enter into direct rivalry with the Academy and the Lyceum by establishing itself—as did the Stoa a few years later—in the city of Athens.

What Epicurus brought to Athens was more a way of life than a school or a community. Unlike both of the famous schools, it admitted women, and even one of Epicurus' slaves, named Mouse. It taught the avoidance of political activity and of public life, although, when one follower from a school outside Athens rose to political power and then fell, he was succoured by the school. Quite different from the usual connotations borne by the term epicurean today, life in the house and garden was simple. Water was the usual drink, although a half-pint daily ration of wine was allowed, and barley bread was eaten. During a famine Epicurus saved his students by doling out a few numbered beans daily. There was no communal property, as was the case in Pythagorean schools. Whereas the relationships of the members of the school were not platonic, in either the contemporary or any later sense, there are only the attacks of Stoic opponents to support any idea of sexual irregularity. Epi-

curus wrote clearly but in no highly organized way. There was much correspondence with students in Athens and at other schools, some letters being concerned with doctrinal matters but many seeming to be merely social and friendly.

On the day in his 72nd year (270 BC) that Epicurus died painfully of prostatitis, he dictated an affectionate and touching letter to Idomeneus—probably intended, in fact, for all of his friends in Lampsacus—which displayed the spirit in which he had remained true to his philosophy of repose and serenity even in the throes of pain. Epicurus' will left the house, garden, and some funds to trustees of the school. Remaining funds were left to honour Epicurus' deceased family and to celebrate his birthday annually and his memory monthly. His slaves were freed, and provision was made that the daughter of Metrodorus should be wed to someone in the Athenian school, with the approval of Hermarchus.

Writings. Diogenes Laërtius described Epicurus as a most prolific writer and preserved three of his letters and the *Kyriai doxai* ("Principal Doctrines"). The three letters are (1) *To Herodotus*, dealing with physics; (2) *To Pythocles* (probably a disciple's abridgement), on meteorology; and (3) *To Menoeceus*, on ethics and theology. The *Kyriai* consists of 40 short aphoristic statements. Another major source is the papyri from the Casa dei Papiri discovered at Herculaneum (1752–54), which include not only parts of his great work *Peri physeōs* ("On Nature"), originally in 37 books, but also numerous fragments of correspondence with his friends.

Assessment. Many of Epicurus' methods made him comparable to a religious figure. The breadth of his appeal in Rome during the 1st century BC is indicated by the fact that the poet-philosopher Lucretius based his work on Epicurus (Lucretius in fact held Epicurus in reverential awe); by the references to his thought by the statesman-moralist Cicero; and by the detailing by the biographer Plutarch of how Cassius soothed the mind of Brutus with his Epicurean ideas. Epicurus' atomistic theory was revived in the 17th century by Pierre Gassendi, a French philosopher-scientist.

BIBLIOGRAPHY. For sources of additional information on the life and philosophy of Epicurus, see the bibliography to the article EPICUREANISM.

Epigraphy

Epigraphy (from the classical Greek *epigraphein*, "to write upon, incise," and *epigraphē*, "inscription") denotes a branch of scholarship devoted to the study of written matter recorded on hard or durable material. Because such media were exclusive or predominant in many of mankind's earliest civilizations, epigraphy is a prime tool in recovering much of the firsthand record of antiquity. It is thus an essential adjunct of the study of ancient man; it secures and delivers the primary data on which historical and philological disciplines alike depend for their understanding of the recorded past. In a narrower sense, epigraphy is the study of such documents as remain of the written self-expression of early cultures and as communication media in their own right, attesting to the development of visible sign systems and the art of writing as such. Finally, in later periods including our own, where perishable writing media predominate, epigraphy affords insights into the styles and purposes of monumental or otherwise exceptional techniques of written recording.

Uses of epigraphy

MATERIALS AND TECHNIQUES

The delimitation of epigraphy vis-à-vis contiguous and related areas of antiquarian scholarship meets with some ambiguity. In a wide sense, epigraphy concerns itself with the total firsthand transmission of the written remains of ancient civilizations (as opposed to *post-factum* copying) and the nature of the material (*e.g.*, stone, marble, metal, clay, terra-cotta, pottery, wood, wax tablets, papyrus, parchment) and the technique of recording (cutting, carving, engraving, casting, embossing, scratching, painting, drawing, etc.) have mere secondary relevance. Under this maximum definition certain subdisciplines may be included under the overall canopy of epigraphy: notably numismatics, which concerns itself with legends on coins and medals, and papyrology, the study of a special type of perishable record that is normally preserved only in the dry climate of Egypt and in adjacent desert regions. In the case of Egypt, papyrology tends to impinge upon wood and clay media as well, thus leaving mainly stone and metal objects as the concern of epigraphy proper.

In general, however, unless so subdivided, epigraphy encompasses inscriptions at large, be they on primary writing surfaces or on such assorted objects as vases, potsherds, gems, seals, stamps, weights, rings, lamps, and mirrors. A further related discipline is paleography, which concerns itself with the study of scribal hands and styles of writing and has significance for the dating of epigraphic as well as other written documents.

The nature of the materials and techniques used for inscriptions is closely tied to the external purpose of the record itself. Thus, inscriptions may be divided into monumental, archival, and incidental. Monumental inscriptions were intended for enduring display and were therefore, as a rule, executed in lasting material, such as stone or metal. Maximal exposure to mortal eyes need not have been the prime purpose of their originators—*e.g.*, the tomb chambers of Egyptian pharaohs, intended to be sealed forever, had their inner surfaces covered with monumental hieroglyphs; the great Bīsitūn inscription of King Darius I of Persia is on a high rock surface and legible only after precarious rock-climbing or from airborne conveyances. Under this classification may be included also micromonumental inscriptions found on such objects as coins, seals, and rings, meant to endure in their own right.

Monumental, archival, and incidental inscriptions

Archival inscriptions were essentially a feature of those early societies that kept records and that used such materials as have been preserved thanks to their intrinsic, accidental, or incidental durability. Many ancient Near Eastern cultures employed clay tablets for writing, which they fired to insure their soundness. Minoan and Mycenaean archivists in ancient Crete and Greece used perishable temporary clay records that were preserved by unintentional baking in the conflagrations that destroyed their storerooms. Papyrus records from Egypt have survived as a result of climatological chance—mainly low humidity. The official purposes of public display and of archival preservation were sometimes complementary, and therefore coincidental or overlapping matter has been preserved. In some cultures the techniques employed in monumental and archival writing tended to differ (notably in Egypt, where increasingly cursive hieratic or demotic script contrasted sharply with monumental hieroglyphic), and occasionally the language itself would be different (for example, in the Hittite Empire, where the clay tablets in cuneiform employed mainly straight Hittite or Akkadian, whereas the monumental "hieroglyphic" rock inscriptions and seals used a distinct language).

Incidental inscriptions may be defined as those not seriously meant for preservation. They include, for example, wall scrawlings of the graffiti type and casual records that were kept on cheap writing matter such as potsherds (*ostraka*) and scraps of papyrus. Many a city dump of ancient Egypt has yielded a rich harvest for the study of daily life.

INSCRIPTIONS AS HISTORICAL SOURCE MATERIAL

In studying the political, administrative, legislative, and dynastic records of extinct civilizations, the modern historian must bring to bear all the evidence at his disposal; and such evidence may vary sharply from one locality and period to another. Historiography in the modern sense—the analytical ordering and interpretation of past institutions and events—is an invention of ancient Greece, and even there it only gradually eschewed the fabulous. In many early societies (*e.g.*, Mesopotamia, Egypt), chronographic records were either annalistic or legendary in kind and sometimes apologistic or propa-

Evidence of extinct civilizations

gandistic in purport; and in others (*e.g.*, India) a cyclical world view prevailed and a lack of feeling for linear time depth precluded an ordered appreciation of the past, leaving only legendry—in such cases only synchronisms with time-anchored events elsewhere allow a precise dating.

Thus, the amount of predigested ancient information bearing on antecedent events may vary from sophisticated literary to scrupulous epigraphic, or may be wholly lacking or largely valueless. In the latter instances the historian is almost exclusively dependent for native information on primary documents, and such documents are in most cases inscriptional.

Ancient Mesopotamia. Surviving epigraphic matter from the 3rd and early 2nd millennia BC includes both historical and quasi-historical material. The Sumerian king list is a compilation of names, places, and wholly fabulous dates and exploits, apparently edited to show and promote time-hallowed oneness of kingship in the face of the splintered city-states of the period. The Sargon Chronicle is a piece of literary legendry concentrating on spectacular figures and feats of the past, whereas contemporary royal inscriptions, notably by Sargon I of Akkad and Gudea of Lagash, are historical documents in the proper sense.

Both kinds of texts are preserved also from the Babylonian and Assyrian periods, from the reign of Hammurabi (1792–1750 BC) to the 6th century BC. There are lists of date formulas and year names from Hammurabi's reign and from that of his son Samsuiluna; lists of Assyrian eponymous year names, based on those of dignitaries; the Babylonian king lists, running from Hammurabi through the Kassite era and the Assyrian domination of Babylon to the last flicker of Babylonian self-assertion in the early 6th century BC; the Assyrian king list from Khorsabad, which made good use of earlier compilations; and notably the so-called Synchronistic Chronicle, which juxtaposed the kings of Assyria and Babylonia in the same millennial sequence. Historical documents comprise, above all, the stately sequence of annals by the kings of Assyria, recorded on stone slabs, stelae, foundation markers of buildings, bronze gates, statues, and obelisks and in clay archives (prisms, cylinders, tablets). Starting in the Old Assyrian period, they were especially extensive in the reigns of Tiglath-pileser I (1115–1077 BC), Ashurnasirpal II (883–859 BC), Shalmaneser III (858–824 BC), Adad-nirari III (810–783 BC), Tiglath-pileser III (744–727 BC), Shalmaneser V (726–722 BC), Sargon II (721–705 BC), Sennacherib (704–681 BC), Esarhaddon (*c.* 680–669 BC), and Ashurbanipal (668–627 BC).

For all their swaggering bombast and flaunting of deliberate cruelty, the annals provide prime historical source material. The detail of the Assyrian conquest of Syria, Palestine, parts of Asia Minor, Cyprus, Arabia, and Egypt would be spotty indeed without recourse to these annals, for they show the centre of political power, unlike such provincial records as those from contemporary Egypt or the Old Testament.

Legal compilations and law codes

Legal compilations and law codes also have pride of place in the epigraphic record of ancient Mesopotamia. These form a unique succession, starting in the 3rd millennium BC with that of King Ur-Nammu of the Sumerian 3rd dynasty of Ur (*c.* 2100 BC), continuing with those of the Sumero-Akkadian king Lipit-Ishtar (in Sumerian) and King Bilalama of Eshnunna (in Akkadian, during the interval of the 3rd dynasty of Ur) and the rise of the Amorite dynasty of Hammurabi (*c.* 2000 BC), culminating in the great diorite stela of Hammurabi (*c.* 1750 BC), showing retardation and recrudescence in the Middle Assyrian laws that are found on clay tablets at Ashur (at the time of Tiglath-pileser I), and petering out in the fragmentary Neo-Babylonian laws dating from the 7th century BC.

The stela of Hammurabi must have been originally set up in some Babylonian population centre for the literate to read and know their rights. Some Elamite invader must have carried it off to Susa (perhaps *c.* 1200 BC), where it was found in 1901 and removed to the Louvre in Paris. The bulk of the stela contains the text of the code, partly erased on the obverse but restorable in some measure from clay-tablet versions of the same laws. The top depicts the king in a worshipful pose, receiving the laws from the sun god, Shamash. In reality Hammurabi —the sixth of 11 kings of the Old Babylonian or Amorite dynasty—was a practical codifier rather than a revelatory mediator of law. His code was an effort to fuse into a workable whole the ancient inheritance of Sumerian-based jurisprudence and the Semitic talion law (punishment according to the "eye-for-an-eye and tooth-for-a-tooth" principle) of the Akkadian superstratum. The result is not a model of economy or arrangement or logical organization, but the code of Hammurabi constitutes nevertheless the first great legal monument in the history of mankind. The later Assyrian laws show traces of further removal from the cradle of Sumerian civilization since they are both harsher and noticeably more primitive.

Ancient Egypt. Egypt attracted the special curiosity of the Greeks, and Herodotus (5th century BC) devoted an entire book to on-the-spot observations and fanciful tales about the land of the Nile. The lost *Aigyptiaka* (or *Aegyptiaca*) of Manetho (3rd century BC) contained the roster of 30 dynasties, which still underlies the chronology of ancient Egypt. Such classical writers as Strabo, Plutarch, and Pliny the Elder all dealt with various aspects of Egyptian antiquities.

Yet the fund of knowledge would be woefully skeletal and inaccurate without the explicit testimony of contemporary records from Egypt itself. The decipherment of the Egyptian writings gave the impetus to Egyptian epigraphy. The progress of excavations multiplied the corpora of texts, especially adding the papyrological dimension. In addition, cuneiform Akkadian on clay tablets was the international diplomatic medium of writing during the most brilliant phases of Egyptian history and is hence an integral part of the Egyptian epigraphic record.

Decipherment of Egyptian writings

The historically significant Egyptian epigraphic texts, apart from their external peculiarities, have likewise special traits relating to genres. There is little attempt at historiography and great fluctuation in bulk in the course of dynastic vicissitudes. They are mainly annalistic and thus firsthand accounts of pharaonic or other high-level deeds; but the peculiar features of stylization, stereotyping, and usurpation must frequently give the careful historian pause and sometimes debase the face value of the record. Written monuments became somewhat numerous during the 4th dynasty (*c.* 2613–2494 BC), that of the pyramid builders Khufu, Khafre, and Menkaure. Notable are the fragmentary annals of Snefru, which already alluded to dealings with Asia, the chronic goal of Egyptian territorial ambitions. Historic records persisted under the following two dynasties, with particular articulateness in the reign of Pepi I, third king of the 6th dynasty (*c.* 2345–*c.* 2181 BC), then subsided until a modest re-emergence in the (Theban) Middle Kingdom of the 12th dynasty (1991–1786 BC). Another silence shrouded the period of the Hyksos kings (*c.* 1720–1570 BC), broken only subsequently by such retrospective revulsion at the memory of barbarian domination as that in Queen Hatshepsut's temple inscription (*c.* 1475 BC) at Istabl Antar in Middle Egypt. The golden age of historical recording began in the 15th century BC with the central rulers of the 18th dynasty, notably Thutmose III and Amenhotep II and III. Thutmose's annals on the walls of the temple of Karnak describe 20 years of ceaseless military activity in Asia, some 16 campaigns in all, and are supplemented by stelae from Armant in Upper Egypt and Gebel Barkal near the Fourth Cataract, as well as by lists of conquered lands at Karnak. Similar material continued in the reigns of Amenhotep II and III, in the latter's case importantly supplemented by the cuneiform correspondence with foreign powers (Mitanni, Arzawa, etc.), which was subsequently stockpiled and archived by Ikhnaton in his transitory new capital, where it lay buried to await the modern excavators of Tell el-Amarna. Ikhnaton's religious preoccupations (he changed the offi-

Golden age of Egyptian historical recording

cial religion to the worship of the sun god Aton), and political apathy led to the loss of many of Egypt's Asian possessions. Records of Ikhnaton's short-lived son-in-law, Tutankhamen, at Thebes (*c.* 1350 BC), make recantation and restoration for the heresy. Tutankhamen's successor, the warlord-pharaoh Horemheb, left boastful accounts of foreign conquest that sound suspiciously grandiose in relation to plausible reality.

In the 19th dynasty (1320–1200 BC) Seti I went to war against the Syrians, Hittites, and Libyans, letting the world know about it on the walls of Karnak. But in this respect he was no match for his long-lived son, Ramses II, who usurped the monuments of others and covered unprecedented amounts of wall space with his own real or inflated exploits. (The Battle of Kadesh against the Hittites in 1299 BC, which ended in a stalemate, was given lavish coverage as a triumph on temple walls at Karnak, Abydos, and Abu Simbel.) In the 20th dynasty (1200–1085 BC) occurred incursions of the "sea peoples," and the records of Ramses III detailed both the crisis and the increasing accumulation of wealth and power in the religious establishment. Subsequently, Egyptian history receded from the world scene, with "Libyan" and "Ethiopic" dynasties and a brief Saite renaissance of the 26th dynasty (664–525 BC), already under the Assyrian and Babylonian shadow, soon to be replaced by the Persian. The firsthand political records declined accordingly, although they remain of significance for local history down to the Ptolemaic era, a dynasty that ruled Egypt beginning in 305 BC, founded by Ptolemy I Soter, a general under Alexander the Great.

No law codes have been found in Egypt, presumably because codification was not practiced. There are, however, royal administrative and legal decrees granting privileges and immunities and also records of legal proceedings, especially of the Theban tomb-robbery trials during the 20th dynasty.

Other ancient Near Eastern regions. Regions adjacent to the power centres of Mesopotamia, Egypt, and Iran were frequently mere political and administrative adjuncts, often obscure vassaldoms or adversaries without notable or attested written traditions. The Mitanni kingdom in northern Mesopotamia had some ephemeral big-power dealings with Egypt in the days of Amenhotep III, but its capital city is still lost in the sands, and thus its presently known epigraphic tradition is merely part of the correspondence in the Tell el-Amarna archives. The records of the Elamite kingdom with its capital at Susa were mostly ancillary to Mesopotamia in the 2nd millennium BC, and to Iran later on. The region of Syria and what later came to be called Palestine was in the 2nd millennium the object of an extended tug-of-war between Egypt and the Hittite kingdom.

The Hittite Empire. The Hittites were, in fact, the third great international power in the Near East during part of the 2nd millennium BC, and the epigraphic yield of their royal archives at Boğazköy in central Asia Minor matches or even surpasses in richness that of Mesopotamia and Egypt for the few centuries in question. The cuneiform records of the Hittites contain a tradition of unique royal political self-expression. These documents begin with the oldest known Hittite text, the inscription of the early ruler Anittas, detailing dynastic struggles of an obscure and possibly apocryphal past. From the founder of the Old Kingdom, the firmly historical Hattusilis I (Labarnas II), came an annalistic autobiography (excavated in 1957) and a "farewell address," or political testament, in Hittite as well as Akkadian versions. Subsequent events, including the capture of Babylon by Hattusilis' son, Mursilis I (*c.* 1590 BC), and the succeeding era of regicidal upheavals, are known from an edict of King Telipinus, who detailed them as he set about regulating the rights of royal succession. The subsequent founder of the Hittite Empire, Suppiluliumas I (*c.* 1350 BC), and his son Mursilis II left annals detailing their military and political deeds. Mursilis was a particularly prolific annalist and edited his father's annals as well. The great encounter with Ramses II at Kadesh in 1299 BC occurred in the reign of Mursilis' son, Muwatallis, and left an echo in the autobiography of his brother and successor, Hattusilis III. Hattusilis' autobiography is a tract of self-justification for a breach of the edict of Telipinus in deposing his nephew and predecessor Urhi-Teshub (Mursilis III).

The earliest Hittite texts

Other Hittite documents inveigh against treasonable behaviour ("Indictment of Madduwattas") or contain detailed instructions for military, civil, and court officialdom. Hittite queens had prerogatives of independent high-level initiative, and examples of their correspondence with foreign potentates supplement the archives of their husbands. The most remarkable external political documents are numerous state treaties, sometimes between equals but more often covenants specifying protectorate or vassaldom status for subordinate states on the fringes of the kingdom. Equally notable is the Hittite Law Code, relatively enlightened and mild in the face of its contemporary counterparts in Mesopotamia. Altogether, the inscriptional documents are practically the exclusive source material for knowledge of the Hittites; not even the existence or location of their empire was surmised prior to the discovery of their archives.

Syria-Palestine. After the collapse of the Hittite Empire (*c.* 1190 BC), significant records from Asia Minor ceased for many centuries, whereas local history in the Syro-Palestinian area was recorded in the inscriptions of petty dynasts increasingly under the shadow of Assyrian domination. The break with the past is evident in the writing systems (Hittite Hieroglyphs or West Semitic alphabet rather than cuneiform) and in the languages (Indo-European Anatolian, Canaanite, Aramaic). Into this category fall the stela of King Mesha of Moab (*c.* 830 BC) now in the Louvre, the Phoenician-language hieroglyphic inscription of Azitawadda of Adana (late 8th century BC), and those of the kings of Ya'diya-Sam'al. Contemporary cuneiform documents from the Urartu kingdom around Lake Van in eastern Anatolia are historically and culturally an offshoot of the history of 8th-century Assyria.

Ancient Iran. Epigraphically recorded history in ancient Persia began dramatically with the rise of the Achaemenid dynasty in the 6th century BC. Cyrus II the Great's conquest of Media, Lydia, and Babylonia, Cambyses' occupation of Egypt, and the incursions into Greece of the succeeding side branch of the family, beginning with Darius I, created in short order a world power destined for centre stage on the international scene for the following two centuries. The international character of the empire is reflected in the frequently trilingual royal inscriptions—with Akkadian and Elamite versions in traditional syllabic cuneiform, and the Old Persian text in its own simplified quasi-alphabetic system of wedge-shaped writing. The Achaemenids' time span ranges from Darius' great-grandfather, Ariaramnes, to their less glorious progeny, who were ultimately extinguished by Alexander the Great. The empire was centred in Persia; but a granite stela of Darius, found near the Suez Canal, recorded in Old Persian, Elamite, Akkadian, and hieroglyphic Egyptian the opening of a canal from the Red Sea to the Nile. The epigraphic material included rock surfaces, building walls, columns, doorways, cornices, statues, and doorknobs; bricks, plaques, plates, and tablets of clay, stone, gold, and silver; vases, weights, and seals. Almost all the longer texts were by Darius and Xerxes I; an important one of Xerxes was found on a stone tablet at Persepolis in 1967. The great Bīsitūn rock inscription of Darius runs to several hundred long lines in Old Persian alone, besides the Elamite and Akkadian versions. It is accompanied by 11 minor inscriptions, serving as keys to the sculpted scene of the panel, which shows Darius triumphant over the usurping impostor Gaumata and nine other rebels. The text is a self-statement of how Darius gained and consolidated his rule. It apparently had currency in the realm, apart from being tucked away on a sheer cliff wall, for a partial duplicate of the Akkadian version has been found on a dolerite (basalt) block from Babylon, and papyrus fragments from Elephantine have yielded scraps of an Aramaic edition. One peculiar documentary value of the text is

Rise of the Achaemenid dynasty

that the same period in Persian history is extensively covered in the Greek literary tradition by Herodotus, Ctesias, and others, and scholars can thus juxtapose Darius' own accounts with those of almost contemporary foreign historians. As an example, Darius stressed his role as saviour of the fatherland from the clutches of an upstart who pretended to be Smerdis, the brother of Darius' predecessor Cambyses. The latter had murdered Smerdis and was carrying on various outrages in Egypt when word came of the impostor's takeover back home. Darius stated that thereupon Cambyses "died his own death," meaning that it was a fatal matter without human interference, and that thus Darius' hands were clean in taking action against the impostor. According to Herodotus, Cambyses' legendary death involved a freak occurrence as he prepared to leave for home—an accidentally self-inflicted wound leading to gangrene. Both the meaning and intent of Darius' description are thus confirmed.

Juxtaposition of Darius' texts with Herodotus' historical writings

From later Arsacid (Parthian) and Sāsānid periods of Iranian history, there are likewise royal inscriptions that shed light on their respective eras down to the Islāmic conquest in the 8th century AD, and new specimens are still being discovered.

Ancient India. India's past became anchored in historical time and separable from legend only with the establishment of firm synchronisms with outside data. One such link is the Seleucid embassy of Megasthenes to the Maurya king Candragupta (Greek Sandrokottos) at Pāṭaliputra (Greek Palimbothra) in Magadha (modern day Bihar). The Maurya dynasty was continued in the early 3rd century BC by Candragupta's son Bindusāra (Amitrochates in the Greek sources) and had extended its power over much of the subcontinent. But then the Greek sources fall silent, and Indic literary tradition supplies only the usual web of timeless legendry. At this point, however, epigraphy makes a unique contribution in the form of the first authentic and datable historical documents from India, the edicts of Bindusāra's son and successor Aśoka. As a matter of epigraphic fact, Aśoka ruled all of northern India and a large portion of the south, from Taxila and beyond to Mysore and Kaliṅga (coast of Orissa and Andhra Pradesh). His 14 rock edicts and seven pillar edicts in numerous versions and copies, plus separate minor texts, are scattered over this expanse —in the Prākrit language of his time and in the Brāhmī script, except for some northwestern examples of the Aramaic-inspired Kharoṣṭhī writing. Even a Greek-Aramaic bilingual version was found in 1958 near Kandahār in Afghanistan. Aśoka's edicts are proclamations and ordinances in a Buddhistic spirit, designed to impart good order, morality, and moderation by the Emperor's personal enjoining and example. Particularly notable is the 13th rock edict, which bares the ruler's pangs of conscience over the conquest of Kaliṅga eight years after his coronation, his continuing sorrow over the cruelties committed, and his pledge to substitute the victory of Buddhist religious law (*dhamma*) for all earthly conquest.

Aśoka's edicts would rate a mere historiographic footnote for their inconsequential transitoriness, were it not that in the same breath Aśoka supplied the very synchronisms that are the main key to ancient Indian chronology. Among his western neighbours he mentioned Aṃtiyoge (Antiochus II Theos of Syria), Tulamaye (Ptolemy II Philadelphus of Egypt), Aṇtekine (Antigonus II Gonatas of Macedonia), Maka (Magas of Cyrene), and Alikasudaro (Alexander of Epirus or Alexander of Corinth). The dates of these contemporaries circumscribe the time of Aśoka's reign; combined with the earlier Greek synchronisms, they afford a firm foundation for the correlation of Indic and Mediterranean events. The edicts of Aśoka are thus a prime example of the value of inscriptions for historiographic dating and constitute a fixed record unparallelled in ancient Indian tradition. Later periods of Indian history, such as those of the Indo-Scythian and Gupta rulers, are also represented in epigraphic documents of some historical value.

The main key to Indian chronology

Ancient China. In China also, inscriptions are a means of separating chronological fact from historiographic legend. Nonepigraphic book composition on wood or bamboo strips had an early history in China, beginning in the later 2nd millennium BC; its scope was such that the Ch'in emperor Shih Huang Ti went down in history as a book burner in 213 BC. The San Tai, or three periods of early Chinese history (Hsia, *c.* 2205–1766 BC; Shang, *c.* 1766–1122 BC; Chou and Ch'in, *c.* 1122–206 BC), were long considered by Western scholars purely legendary down to the early Chou period, and the literary documents (such as the *Shu Ching* or "Classic of History") were dismissed as compilations consisting mostly of successive overlays of little historical value. But the historicity of written records from the later Shang era (*c.* 1400–1122 BC) is now apparent from the mass of inscribed archeological material found especially in northern Honan Province. These include, in particular, the so-called oracle bones (mostly tortoise shells and scapulae of animals), bearing incised records of royal divination. At the site of the Shang capital, Yin, were discovered inscribed vessels of bronze, bone, pottery, jade, and stone, probably ceremonial in nature and related to official ritual uses such as ancestor worship. The script is a mixture of pictograms, word signs, and phonograms. From the ensuing Chou era, bronze inscriptions of official provenance have likewise been found, especially records of royal largesse. Inscriptions from later periods form a steady but subsidiary source of information beside the larger, nonepigraphic written record.

Ancient Greece. The historically significant epigraphic record of classical Greece differs in many ways from most of those discussed above. Much of it is parallelled by a mature and independent tradition of professional literary historiography. Except for the preclassical Helladic (Mycenaean) period of the 2nd millennium BC (see below), there was no archival tradition, although the bulk of "monumental" records sometimes approximates the same purpose of massive preservation. There was no all-important power centre and no dominant rulership before Hellenistic and Roman times: thus the geographical scattering of records was extreme, although naturally with some focuses of emphasis such as Athens. Above all, there was continuity from the inception of literacy, with gradual but steady increase in bulk.

The special circumstances of the Greek epigraphic record

Epigraphically transmitted historiography in Greece is extremely scarce because the probing of past events has passed beyond the stage of dynastically centred and sheltered annalism; an example is the "Marmor Parium" (from the island of Paros and now at Oxford), which contains a chronographic rundown of traditional dates and events of Greek history. Rather than monolithic records of autocracy, there is history in the making by a plethora of tyrannical, oligarchic, or democratic microentities. Treaties of alliance and various other agreements between the multiple city-states—recorded on metal or stone and publicly displayed, or consecrated at such pan-Hellenic sanctuaries as Delphi or Olympia—form an important part of the epigraphic yield. Joint-citizenship covenants, decrees concerning the return of exiles, monetary agreements on coinage and debts, and tribute lists are typical examples. They are supplemented by the records of arbitration of interstate disputes, most often boundary matters, by third-party commissions. Thus, when around 240 BC a territorial disagreement arose between Epidaurus and Corinth, the Achaean League appointed a group of 151 Megarians as mediators, and their report survives. Further extensions of such "international" documentation are the *proxenia* decrees, which amount to letters of patent and resolutions of appreciation issued by one state to a citizen of another for service as *proxenos*, a kind of honorary consul looking after the interests of the other state's citizens. The extensive colonization efforts by the Greeks around the Mediterranean produced a further kind of political document—regulations governing conditions for emigration and return, citizenship rights of the colonists, and relations between the colony and the mother community. Not all historically meaningful international records are of the monumental type. Greek mercenaries of Pharaoh Psamtik II (ruled 594–589 BC) left their scrawlings on the legs of a colossal statue at Abu Simbel on the upper

Nile, proving by their names and dialect that they came from Rhodes and Ionia and were far abroad on foreign adventure.

Internal documents of the various Greek states include numerous records of decrees and ordinances, both administrative and legislative. Stereotyped Athenian ones are complemented by variant forms in other localities; most contain a preamble setting forth the date and the officialdom in charge, the circumstances occasioning the action, the decision itself, means and sanctions for its enforcement, and sometimes instructions for providing and affixing the very physical record that has been preserved. Sometimes they amount to formal laws, such as those directed against extravagances in funeral practices.

Financial data of the states were minutely and permanently inscribed on stone, and the accounts thus displayed recorded in detail the receipts, expenditures, and balances of public funds. Very specific reports cover projects of public construction, including both technical and budgetal details, allowing sometimes the integral modern reconstruction of the buildings from the reports alone. The records of the Erechtheum and the Parthenon at Athens are well preserved, as are inventories of military expenditures, especially those of the Athenian navy. Knowledge of the ephebic system at Athens, a paramilitary youth organization, is in the main based on epigraphic material.

The laws of Gortyn

The only law code in the Greek epigraphic tradition is the laws of Gortyn in central Crete, inscribed on the slabs of a circular wall which, if completely preserved, would have been nearly 100 feet (30 metres) in diameter. The 12 columns of text, each on four layers of stone and some five feet (1.5 metres) high, are about 30 feet (nine metres) in sideways length and contain more than 600 lines of text, being the longest Greek epigraphic monument; parts of some columns of further text survive, the so-called Second Code. The probable date of this inscription is the first half of the 5th century BC. The code deals with such matters as disputed ownership of slaves, rape and adultery, rights of a wife upon divorce or death of husband, disposition of children born after divorce, inheritance, sale and mortgaging of property, ransom, children of mixed marriages, and adoption. While self-contained, it evidently does not represent the entirety of laws; curiously, it stresses those areas of civil law (inheritance, adoption) that are notably lacking in the Hittite Law Code. The uniqueness of this code in the Greek world points up the relative isolation and marginality of the Cretan tradition, with tendencies to codification more reminiscent of Anatolia and the Near East generally.

Ancient Rome. While partly overlapping Greek inscriptions in time and type, those of Rome nevertheless present distinct peculiarities. There is a high measure of standardization in kind and style, despite lingering local traditions in more remote areas. Extensive and excessive use was made of initials and abbreviations, to the point of serious impediments to comprehension; lists of such abbreviations are standard adjuncts to modern handbooks on Latin epigraphy. Stone and bronze were standard material, but there was more use made of bricks, tiles, and terra-cotta, and practices of stamping and signing such matter are of help in identification and dating.

Literary and epigraphic records of early republican Rome are scant and fragmentary. Latin was at the time still largely confined to Rome proper, with Oscan, Etruscan, and colonial Greek spoken and written in much of Italy. With the arrival of extended political power there was little early literacy to fall back on, and historiographic attempts at retrospection ended in epicized myth and legendry (*e.g.*, in Livy). The Greeks on the southern coastal fringe had little truck with the hinterlands of early times. The Etruscan impact on Rome is evident, but shortcomings in discovering epigraphic records of Etruscan city sites (as opposed to necropolises) and in understanding the Etruscan language, limit the historical data derivable from Etruscology. The potential for such illumination is seen from the discovery of gold tablets at Pyrgi in 1964 that contain a dedication in Etruscan and Phoenician by the Etruscan king of Caere, Thefarie Velianas, to the syncretized goddess Uni (Juno) Astarte. Datable to around 500 BC, the text shows Etruscans ruling in the outskirts of Rome, with enough Phoenician or Punic (Carthaginian) maritime presence to warrant symbiotic and syncretistic bilingualism. The vital historical import of such attestations, pieced together with later Greek and Roman historiographic data, is patently manifest.

Texts from republican Rome

No historically important epigraphic Latin text from republican Rome antedates the 2nd century BC. The marble Columna Rostrata—found in Rome in 1565 and now at the Palazzo dei Conservatori on the Capitoline Hill—records a naval victory of Duilius (consul in 260 BC) over the Carthaginians; but the inscription, replete with fake archaism, dates from a restoration effort in early imperial days. The *fasti consulares* and similar lists afford a summary sequence of consulates, magistratures, and triumphs. The one truly significant epigraphic historical text is the "Res gestae divi Augusti," an autobiographical record of Augustus' rule, which was exhibited in many places but is best known as the Monumentum Ancyranum, from the bilingual (Latin and Greek) version carved on the walls of the Temple of Rome and Augustus at Ankara (Turkey).

By the time the epigraphic record became abundant, Rome's domination was secure and the political documentation was one of imperial outflow and of local sycophancy. Treaties of republican Rome with foreign powers survive merely in the works of literary historians. Among "internal" documents from republican days are several epigraphic texts of significance: the Senatusconsultum de Bacchanalibus, on a bronze tablet found in 1640 in Bruttium (the "toe" of Italy) and now in Vienna, is a consular edict on Senate authority, regulating Dionysiac outbursts in Italy in 186 BC; pieces of the laws Lex Acilia Repetundarum (123 BC) and Lex Agraria (111 BC) were found in the 16th century on opposite sides of what was once a large bronze tablet; the local laws of the town of Bantia (on the borderlands of Lucania and Apulia in southern Italy) are inscribed on a fragmentary bronze tablet found in 1790 (now in Naples), with a Latin-language text on one side and the longest known Oscan inscription on the other, both datable to the late 2nd century BC; parts of the Lex Cornelia de Viginti Quaestoribus (81 BC) are preserved on a large bronze tablet found at Rome; Julius Caesar's Lex Julia Municipalis of 45 BC was found near Heraclea in Lucania. On the whole, however, the transmission of Roman law, from the earliest fragments to the mature codifications, is nonepigraphic. In later times the flood of administrative decrees increases with the growth of centralized autocracy. Typically Roman epigraphic material of imperial date comprises further building inscriptions, military records, and honorific texts.

The oldest Turkic monuments

The Turkic peoples. The oldest monuments of Turkic languages—inscribed on stones, and datable to the early 8th century AD—were discovered in the late 19th century in southern Siberia around the Yenisey River and in northern Mongolia near the capital of Urga (modern Ulaanbaatar). Deciphered in 1893 by the Danish scholar Vilhelm Thomsen, they provide valuable insights into the history of Central Asia around the 7th century AD. These records of the Turk dynasty (Chinese T'u-chüeh) comprise especially texts found at Kosho-Tsaidam on the Orhon (Orkhon) Gol (river), including also Chinese text. These texts throw light on the nomadic culture of the tribal empire controlled by the Turk dynasty, including shamanism, calendar, customs, and social structure, with strong Chinese influence detectable in the latter. After the decline of the Turk people (*c.* 745), their successors, the Uighurs, perpetuated for a time the same kind of monumental dynastic epigraphy, the writing system of which is an offshoot of the Aramaic alphabet, presumably mediated by the Iranian-speaking Sogdians of Central Asia. Gradually, however, new scripts took over (especially the so-called Uighur alphabet, of Syriac origin, which was further transmitted to the Mongols and the Manchus) and inscriptional monuments gave way to manuscript records

such as those found in Chinese Turkistan (Turfan) in the late 19th century (along with texts in Sanskrit, Sogdian, Tocharian, and other Indo-European idioms), attesting to a coexistence of Buddhist, Manichaean, and Nestorian Christian religious communities. The later Turkish peoples, including the Anatolian Seljuqs and Ottomans, had an Islāmic book-tradition, to which the inscriptional record is merely incidental.

Northern Europe. The advent of writing was slow north of the Alps; it came either from direct expansionary exportation by Greek coastal colonies and the Roman Empire, as in Gaul and the Iberian Peninsula, or indirect inspiration from the same quarter, as in writing in the Irish and British ogham alphabet and the Germanic runes.

Celtic inscriptions. Celt-Iberian inscriptions from Spain and Celtic ones from Gaul and Ireland are scarce, mostly brief, and notably devoid of usable historical information, apart from their mere monumental existence and linguistic and onomastic (of or pertaining to names) content. Occasional items such as the fragmentary Gaulish Calendar of Coligny afford insights into local cultural practices, apart from an overwhelming trend to romanization.

Runes. The runic alphabet—a Germanic alphabet, originally of 24 letters, also called futhark—and its offshoots (the Scandinavian, especially Danish, 16-letter variety from the 9th century AD; and Anglo-Saxon versions, from the 3rd to the 10th centuries AD, also called futhorc) are probably of "North Etruscan" or "Sub-Alpine" Italic inspiration, datable to around 200 BC. The "North Italic" letters of the Germanic text *harixasti teiva*, "to the god Harigast," on a helmet from Negau (southern Austria) are probably from that time of transmission. Runic inscriptions from the era of migrations, ranging from eastern France through Germany up to Denmark and eastward via Poland to Romania, are supplemented by the later, richer yield from England and Scandinavia. Native Anglo-Saxon runic epigraphy, mostly in Northumbria, Mercia, and Kent, petered out around the 10th century, whereas the Scandinavian tradition (including its enclaves on British soil) endured for several more centuries. Sweden has some 3,000 runic monuments; Norway and Denmark, perhaps 400 each; while Iceland has remarkably few, apparently in inverse proportion to the literary flowering in that colonial outpost. The Vikings left their runic calling cards in far-flung places, including those in the Greek port of Piraeus, on the Black Sea coast, in Varangian Russia, in Scotland, Ireland, and the Isle of Man, and the Orkneys, Hebrides, and Shetland islands; Greenland has its share, but alleged specimens from North America, notably the Kensington stone from Minnesota, telling of the westward trek of an exploration party from Vinland, are invariably crude latter-day forgeries.

Runic monuments

The purposes of runic inscriptions were usually either dedicatory or commemorative, sometimes magic, and frequently sepulchral. The longest, that from Rök in Sweden (725 runes), seems to contain a catalog of epic deeds, possibly those of the Ostrogoth king Theoderic. The prime historical value of runic epigraphs is usually what and where they are, rather than what they depict or record.

INSCRIPTIONS AS SOCIAL AND CULTURAL RECORDS

In the preceding section, inscriptions were evaluated as sources for the presence and migrations of peoples, the existence and chronology of political states, their dynastic histories, foreign relations, internal governance, legal institutions, and official acts. In this section, epigraphy is surveyed for information about how past civilizations lived; their religious beliefs and practices; their business, financial, legal, and social relations; and what shape their aspirations assumed in terms of verbal creativity. The subdivision of civilizations surveyed differs somewhat arbitrarily from the earlier section by the omission of certain areas and the inclusion of Crete and Mycenaean Greece. In fact, Indic and Chinese epigraphic matter discussed above could just as well have fitted the "religious" slot, but its royal character and chronological importance for official history dictated otherwise. Conversely, the Cretan and Mycenaean tablets are purely economic inventories, but they might possibly have been included with history above for the very important historical fact that they prove the ruling presence of Greeks at Knossos during the 2nd millennium BC. The varying degree of importance of epigraphic material in various cultures persists: in Mesopotamia and the ancient Near East its dominance was nearly total; in Egypt it combined with the papyrological dimension; in Crete it was merely a flash in a prehistoric darkness; while in ancient Greece and Rome, it was a supplementary concomitant of the non-epigraphic literary tradition.

Ancient Mesopotamia. Ample specimens of Akkadian-language clay-tablet epistolography have been found at several sites, notably Tell el-Amarna in Egypt and Tell al-Ḥarīrī on the middle Euphrates (the ancient Mari of *c.* 1700 BC). The Amarna letters, about 400 of them, were composed in corrupt Akkadian by Canaanite scribes in Syria and Palestine and were largely official in character. The Mari letters, some 5,000 in number, are more illustrative of normal day-to-day written communication in a Mesopotamian milieu proper.

The Amarna and Mari letters

Legal inscriptions. Another aspect of everyday life in ancient Mesopotamia is amply illustrated by thousands of clay tablets of a practical legal nature, as distinct from the formal laws. These archivally preserved records from various periods use Sumerian, Old Akkadian, Babylonian, and Assyrian alike. They detail law suits, court decisions, marriage contracts, divorce proceedings and settlements, sale adoptions (fictitious acts circumventing prohibitions against land sales outside the family), loan agreements, tax receipts, and much else. Commercial inventories, such as those of the Old Assyrian merchant colony at *Karum Kanes* in central Asia Minor (20th century BC), complete the picture.

Cultic and literary texts. Due to the religious sanction of law, legal records were often stockpiled in temple archives. These latter are also the source of more directly cultic texts, such as descriptions of rituals, which come under such headings as "Temple Program for the New Year's Festivals at Babylon," "Ritual to be Followed by the Kalū (priest) when Covering the Temple Kettle-Drum," "Ritual for the Repair of a Temple," and "Program of the Pageant of the Statue of the God Anu at Uruk." Prayers, lamentations, and hymns in both Sumerian and Akkadian are extant, addressed to deities such as the goddess Ishtar, the moon god Sin, the sun god Shamash, the great triad Anu, Enlil, and Ea, and the Babylonian patron god Marduk. The Sumerian "Lament for the Destruction of Ur" bemoans the city's fall to Elamites and Subarians. Often the king himself is the spokesman in the text. Wisdom literature, such as proverbs and fables (*e.g.*, "Dispute between the Date Palm and the Tamarisk"), poetic meditations, oracles, divination records, omens, and prophecies are further examples of Mesopotamian genres that only epigraphy has preserved.

Sumerian and Akkadian narrative literature is likewise of wholly inscriptional transmission. It contains man's earliest preserved literary creations in the Sumerian sequence, especially the texts from tablets found at Nippur. These include the "Paradise myth" of the god Enki and the goddess Ninhursag in the pure, clean, and bright land of Dilmun; the story of Dumuzi and Enkimdu (the petulant shepherd god versus the peace-loving farmer god, inversely reminiscent of the Cain–Abel antagonism in Genesis but not culminating in murder); "The Deluge" with its Noah-hero Ziusudra; "Inanna's Descent to the Nether World," which prefigures the later Akkadian "Ishtar's Descent"; and the lays of Gilgamesh, which show the Sumerian traditions that were later partly organized and transformed into the Akkadian epic. The latter include "Gilgamesh and Agga of Kish," a story of confrontation between early Sumerian city-states; "Gilgamesh and the Land of the Living"; and "The Death of Gilgamesh," with its haunting parallelistic refrain "he lies, he rises not." The Akkadian *Epic of Gil-*

The Gilgamesh epic

gamesh is divided into 12 tablets, the longest of which is more than 300 lines; this "Flood Tablet" (the 11th) is virtually intact and comes, like almost all Assyrian-language Gilgamesh texts, from the library of Ashurbanipal at Nineveh (7th century BC). From the 2nd millennium there are fragments of a Hittite version from Boğazköy, as well as minor traces of a Hurrian translation. Old Babylonian correspondences to tablets 1–3 and 10 are found on a tablet from Sippar (*c.* 1800 BC). The 12th tablet is a literal translation from Sumerian, whereas the rest amounts to a self-contained Akkadian epic original, based on Sumerian motifs but with a thrust of its own. The most complete reconstruction involves a combination of Assyrian, Old Babylonian, and Hittite versions.

The other famous Mesopotamian epic, *Enuma elish*, "When on high," details the story of cosmic creation and of how Marduk became the great god of Babylon; it had more immediate cultic attachments because its recitation formed part of the New Year festival.

Further Akkadian literary creation is attested in the epic of Atrahasis, a tale of mankind's punishment through pestilence and flood, preserved in fragmentary Old Babylonian and Assyrian versions. The story of Adapa, found in parts in the Tell el-Amarna archives and the library of Ashurbanipal, is similar to Gilgamesh's quest for immortality. The myth of Zu deals with the theft of the tables of fate and the usurpation of almightiness by the bird god Zu. The legend of Etana, a namesake of the shepherd-king who ascended to heaven in the mythical postdiluvian Sumerian dynasty of Kish, recounts in its Old Babylonian and Assyrian recensions the heavenly flight of Etana on the wings of an eagle in order to acquire the magic birth plant that would cure his childlessness. Death-oriented themes appear in the tale of Ishtar's descent, in the story of Nergal and Ereshkigal, and in various netherworld texts associated with the Tammuz myth and liturgy.

The accidental preservation of Egyptian texts

Ancient Egypt. The multitude of incidental day-to-day written matter on potsherds and papyrus, preserved by climatological quirks in Egypt, affords insights into the normal living patterns of ordinary people during the pharaonic, the Hellenistic (Ptolemaic), and the Roman periods. More formal records of similar provenance may be described as legal in the widest sense, comprising such objects as land deeds, cadastral inventories (tax surveys), wills, adoption decrees, and trial transcripts. Thus many technicalities of landholding in the Nile Delta during certain ancient periods survive, unwarranted by any normal expectancies of epigraphic preservation elsewhere; only the happenstance of the Creto-Mycenaean records (see below *Crete and Mycenaean Greece*) has accidentally transmitted something analogous.

Ritualistic texts. Ritualistic texts are equally abundant, in both monumental and papyrological transmission. Notable among offertory liturgy was the mortuary service to the dead, acted out as a kind of ritual make-believe in which the offering was referred to as the eye of Horus (the sacrificer) being given up on behalf of his father, Osiris (the departed). Ritual drama in general is amply attested in Egyptian religious practice; day-to-day ceremonial in the cult of gods or god-kings (pharaohs) was recorded in the minutest detail. Magic texts include incantations and charms against such dangerous creatures as snakes, scorpions, crocodiles, and lions. Even the buried dead were deemed in need of such protection, and hence the preserved samples are largely of mortuary provenance. An important category of epigraphs is constituted by curses, imprecations, and threats of divine vengeance against enemies, evildoers, and tomb violators in particular. Dream interpretation and oracular inquiry are represented on both monuments and papyri.

Moral and didactic writings. Of a more secular nature and on the verge of true literature are moral and didactic writings, particularly during the early Middle Kingdom (began *c.* 2133 BC), when a profound social and spiritual crisis seems to have gripped Egypt. Of such kind are "The Admonitions of Ipuwer" (a denunciation of current sin and evil in Hebrew "prophetic" manner), the "Colloquy of a Prospective Suicide with His Own Soul," an especially copious compendium of conventional wisdom, frequently formulated as instructions from a royal or noble father to his son. Some parts offer remarkable parallels to the Hebrew book of Proverbs.

Mythical tales. On the same borderline to real literature stand mythical tales, including in particular the myths of creation by the god Atum of Heliopolis and the Memphite patron deity Ptah, whose eminence is reminiscent of the cultic fortunes of Marduk. The Memphite cosmogony, of 1st dynasty provenance, is an abstract one, with Ptah's creation conceived with his "heart" (mind) and "tongue" (word) rather than the usual physical detail. Other mythic tales concern the perils from the netherworld demon Apepi faced by the sun god Re during his nightly journey in his solar boat; the rivalries between Horus and Seth for the succession of Osiris (a patent allegory of the tensions between Lower and Upper Egypt); mortuary texts particularly concerned with the Osiris myth and the prospect of judgment (*e.g.*, the "Protestations of Innocence"), attested both monumentally and on papyri (the Book of the Dead); and pieces designed to bolster the supremacy of specific sites and deities, particularly Amon-Re at Thebes.

Poetry and prose. Out of the latter tendency emerged hymnic poetry during the 18th and 19th dynasties, triggered by an imperial trend toward unicentrism in government and universal syncretism in religion. The great hymns to Amon-Re were matched during Ikhnaton's "Amarna revolution" by his great Aton-hymn, uncannily reminiscent of the 104th Psalm of the Old Testament. Victory hymns and prayers are further examples of poetic genre, as are purely secular pieces, including several collections of love songs from *c.* 1300–1100 BC, songs of farmworkers and herdsmen, and feast songs for entertainment.

In nonreligious literary prose there is preserved the story of Si-nuhe, an account of the life of a Middle Kingdom official, his prosperous peregrination in Asia but continued yearning for the homeland, relieved at last by a chance to join the pharaonic court. Papyri and ostraca tell this story in a long succession of attestations through most of the 2nd millennium BC. Of later date (*c.* 1100 BC) is the "picaresque" narrative of the hieratic-script "Moscow papyrus," detailing the ill-financed mission of a certain Wen-Amon from Karnak to Byblos to buy timber for a ceremonial barge of Amon.

The Boğazköy archives

The Hittite Empire. The Boğazköy archives are the unique central storehouse of Hittite records for the duration of that empire (only minor additions have been found elsewhere, such as letters at Tell el-Amarna and Alalakh). The past of other cultures was known from external and nonepigraphic sources before the explorational and excavational discoveries of inscriptions; with the Hittites, however, the record is in one place and *in toto*.

Much may be learned of everyday life and social relations from legal texts, including the laws themselves. Such matters as family relations, property rights, land tenure, and commodity prices are dealt with in great and sometimes pedantic or amusing detail. More can be learned from gift deeds of land, cadastral lists, and trial records, the latter containing largely depositions of respondents and witnesses in civil suits. Unique in their kind are treatises on the training of racehorses. Astrological omen texts, divination records (hepatoscopy, auspicy, lottery oracles), and dream interpretations abound, largely patterned on Mesopotamian models; rituals of all kinds take up a disproportionate amount of space. Temple foundations and procedures, festival ceremonies, epidemics, impotence, family quarrels, countermagic, royal welfare, birth, insomnia, and the manipulation of deities are among the topics of Hittite ritual; in a class by itself is a funeral ritual for royalty, reminiscent of Homeric practices. Not only the Hittite language but Hattic, Hurrian, Luwian, and Palaic are used in rituals. Another large category is made up of hymns and prayers, most notably those of King Mursilis II, in particular his "plague prayers," in which he confesses sins and begs the storm god for mercy. Other notable examples are the prayer of Muwatallis to the sun god, the vows of Queen

Puduhepa to the sun goddess, and the prayer of Kantuzilis with its intimations of mortality. Native Anatolian mythical texts, such as those of the slaying of the dragon Illuyankas and of the disappearance of the god Telipinus, were part of ritual recitation. Other mythical matter points up the crossroads character of Hittite civilization, being made up of Akkadian, Hurrian, and Canaanite themes. Most of the Hittite epigraphic corpus has some connection with religion.

Other countries of the ancient Near East. Away from the big power centres some quite important sites remain to be identified, such as the Mitannian capital of Wassukkani. Others (*e.g.*, the fortress-town of Carchemish on the upper Euphrates, for some time a Hittite dependency) have yielded notable data, especially royal inscriptions in Hittite Hieroglyphs. In particular the French excavations at Ras Shamra on the Syrian coast since 1929 have uncovered the inscriptional and other remains of the small but strategic city-state of Ugarit, which flourished in the 15th–13th centuries BC. Its own vowelless cuneiform alphabet, a radical departure from the Mesopotamian syllabary prototype, denotes an archaic Semitic dialect closely akin to Canaanite. The written documentation of this crossroads community, in a variety of scripts and languages, provides information on the history of the area where Hittite and Egyptian power politics collided. But its most significant epigraphic products have been poetic epics of mythical and heroic scope, which go far to elucidate religious traditions otherwise known mainly from Old Testament bias. The great cycle of Baal and Anath brings to life the pantheon to which belonged also El, Asherah (the Astarte of the Phoenicians), Kothar ("Deft," the craftsman god), and Yamm (the sea god). The tale of Aqhat is also on the borderline of myth, while that of King Keret (or Kret) takes place in a saga world somewhat reminiscent of the Greek Homeric tradition.

The city-state of Ugarit

Scattered dedicatory inscriptions and papyrus texts shed some light on the lives and practices of the Aramaean-speaking populations during the 1st millennium BC. From Palestine there are the Hebrew ostraca of Samaria, datable to the reign of Jeroboam II of Israel (8th century BC), which record names, families, and administrative and religious practices. Of equal significance are the ostraca of Lachish in southern Palestine, which probably immediately preceded the Chaldean onslaught of 589 BC. Phoenician texts are scattered around the Mediterranean, and bear witness to an extensive and protracted maritime supremacy.

The Old Persian Achaemenid inscriptions (see above *Ancient Iran*) are of some value in assessing the state religion of the time, which seems to have been a rather anemic form of official Zoroastrianism. Later monuments from the wider Iranian area help map its complicated religious history, such as the great inscription of the Kuṣāṇa king Kaniṣka, found at Surkh-Kotal in Afghanistan in 1957 and attesting to the Iranian language and Mithraic cults of ancient Bactria in the 2nd century AD. The Sāsānian religious tradition of the 3rd–7th centuries, with its rigidified formal Zoroastrianism, is mainly of nonepigraphic attestation.

Crete and Mycenaean Greece. The decipherment of the latest and most copiously attested of the Minoan linear scripts, the so-called Linear B, by British cryptologist Michael Ventris in 1953, is a major example of the dramatic impact epigraphic discovery can have on the most varied antiquarian disciplines. It supplied incontrovertible proof that the Mycenaeans on the Greek mainland during the 2nd millennium BC were Greek in language and likewise that Knossos in Crete was a Greek-speaking stronghold at the time of its final destruction (*c.* 1400 BC). The records from Knossos, Pylos in Messenia, and Mycenae in the Argolid are exclusively perishable inventories on clay tablets, kept in royal palaces or emporia and apparently meant to be discarded or reused annually; thus they record data from the very last year of any given establishment, just before its final destruction in the fire that also accidentally ensured their preservation by baking the clay.

The Linear B script

The contents are brief, concise, practical, and quantifying in character. Nevertheless, they reveal an important amount of detail about a civilization that is otherwise accessible only via the testimony of archaeology, iconography, and the poetic memory of early classical Greece across several "dark" centuries. Apart from the philologically invaluable recording of preclassical linguistic forms and proper names, there is the cryptologic evidence of the syllabic writing system, which may yet help bring about a cogent decipherment and linguistic identification of the earlier forms of Cretan writing.

Something of bureaucratic accounting methods can be learned from the system of the tablets. Contents yield lists of personnel; of livestock and agricultural produce; of textiles, vessels, and furniture; of metals and military matériel (swords, corselets, chariots, etc.); as well as records of landholding and of temporal and cultic tribute. The cadastral inventories are significant for the light they shed on the system of land distribution as compared with classical Greece and especially with contemporary practices in adjacent culture areas, such as those recorded in the Hittite Law Code. The religious tributes are revelatory in proving what bold scholarship had merely surmised—that the bulk of the classical Greek deities existed in name and kind already in Mycenaean days. Something of the social order and the system of government can also be incidentally learned.

Classical Greece. Inscriptions in their variety and profusion are an important means of gauging everyday life in classical Greece, especially such more formal aspects as were deserving of recording. This qualification, however, does not prevent some obscene pederastic rock-carvings on the island of Thera from being the earliest epigraphic texts from the classical period (*c.* 8th century BC), in a form of the alphabet still strongly marked by its Phoenician source.

Earliest classical epigraphic texts

Business, financial, and legal texts. In a formal vein there is ample documentation of a business, financial, and legal type, such as regulations for building projects, contracts for medical services (*e.g.*, the Cypriot bronze tablet of Idalium, in a peculiar syllabaric script reminiscent of the Cretan and Cypro-Minoan types, used to write both Greek and the uninterpreted Eteocypriot language), collection agreements for defaulted notes, manumission decrees, records of bank deposits (frequently in a temple), and reports of land commissions (especially the Heraclean Tables from southern Italy).

Religious texts. Even in these formal documents it is impossible to keep out reference to religious establishments. Religion was, in fact, big business in classical Greece, and overlap in the records is frequent. Temples were often of the order of corporations, with extensive holdings of real estate and banking operations. The epigraphs of their transactions are coupled with minute records of dedicatory offerings, priest lists, administrative regulations, and ritualistic and liturgical instructions. So much of social life was centred around institutionalized religion that most of its documentation may be included under the latter heading. Dedicatory texts in the widest sense are common, often in verse, such as that by Nikandre of Naxos on a 7th-century-BC statue of Artemis at Delos, a kind of propitiatory offering to the maiden goddess on the occasion of marriage. Similar hexametric or elegiac texts are found as epitaphs, especially for those who perished in war or at sea.

Death-related inscriptions. Tomb inscriptions generally are the most numerous of all but tend to be laconic in style and lacking even in purely statistical data. Those from ancillary areas of the Greek-speaking world, such as the non-Greek ones from Lycia, Lydia, and Phrygia in Asia Minor, are sometimes more revealing to the extent that they are interpreted. Thus the Lycian stela of Xanthus, a tomb monument from the 5th century BC, runs to many hundreds of words, including a dozen lines of Greek. The peculiar Lycian system of matrilinear descent is clearly evident in the texts. The Lydian ones include a marble stela from the necropolis of Sardis with a Lydian-Aramaic bilingual epitaph that typically calls down the curse of Artemis of Ephesus on potential viola-

Tomb monuments

tors. Such imprecations are also standard in Phrygian sepulchral epigraphs. Some kinds of death-related inscriptions were intentionally buried, such as the curses that consigned the object to the infernal avengers. Another type is seen in the Orphic tablets—texts on thin gold found interred with the remains of devotees of the Orphic salvation religion near Sybaris in southern Italy, near Rome, and at Eleutherna in Crete. They are apparently meant as instructions to the deceased—exhortations to the soul on its progress in the beyond, enjoining the shunning of the spring of Lethe ("Oblivion") and the drinking from that of Mnemosyne ("Memory"), thus securing the end of transmigration of the soul and the attainment of perpetual higher consciousness.

Epigraphy and Greek literature. The Orphic texts provide the popular parallel to the Platonic myth of Er in the 10th book of *The Republic*, where Plato somewhat recast Lethe and Mnemosyne into Ameles ("Unmindfulness") and Anamnesis ("Recollection"). Thus, epigraphy not merely supplements the literary record of Greek civilization but also complements it in important aspects. If papyrology is included, important additions to the preserved portion of classical Greek literature have come from Egypt, especially in the papyri from Oxyrhynchus; these include such otherwise lost treatises as Aristotle's *Constitution of Athens* and entire dramatic works (*e.g.*, the *Dyscolus* of Menander).

Ancient Rome. The frequency of Roman inscriptions increased dramatically in direct proportion to the rise of Roman power; but that same rise brought centralization, stereotyping, and a certain sterility of the more formal parts of the epigraphic record. Much of the bulk is official, unidirectional, and from the top outward. The Greek-speaking parts of the empire continued in many of their ancient ways, and other annexed regions (such as Spain or Gaul) developed their own locally coloured practices. The spread of a variety of exotic religious cults all over the empire, among them Mithraism and Christianity, added a kind of epigraphic underground initially devoid of official sanction and largely unmatched by alternative avenues of preserved written transmission. Popular epigraphy, including such matter as graffiti at Pompeii and other Vulgar Latin inscriptions, provides further counterpoise to the official stereotypes.

From early republican days the Roman written record is very spotty. The earliest text of any length, the Forum inscription from the early 5th century BC, seems to refer to an augural rite (referred to by Cicero and Festus as the *juge auspicium*) which enjoins the immediate unyoking of beasts of burden that produce excrement. A 4th-century vase (the "Quirinal vase") is apparently a wedding present with an inscribed guarantee by the bride's guardian to use his good offices to further marital concord. Later texts of religious import include the "Song of the Arval Brethren" on a marble tablet found in the Vatican in 1778 (a chant largely reduced to gibberish by age-old ritualistic repetition), records of various other cultic "colleges" (*augures; fetiales,* or priestly diplomatic representatives; *salii,* or priests of Mars and Quirinus et al.), and outside of the Latin-speech area especially the seven Umbrian-language bronze tables found at Iguvium (modern Gubbio) in 1444, recording in more than 4,000 words the ritualistic details of a brotherhood (the Fratres Atiedii) that flourished in republican days. Official religion is further seen in many dedications, such as one found on Caelian Hill in Rome in the 18th century, which records the offering of a temple and statue to Hercules by Lucius Mummius in 146 BC in fulfillment of a vow he had made during his conquest of Greece and sack of Corinth. "Unofficial" cults, especially those of Mithra and Jupiter Dolichenus, can be traced and mapped throughout the empire chiefly with the help of dedicatory epigraphs. Sepulchral inscriptions are recorded in overwhelming numbers, not only in Latin but notably also in Etruscan; among the latter is the mummy wrap, a lengthy funeral liturgy inscribed on an apparently Etruscan mummy entombed in Egypt (now in Zagreb). The earliest notable Roman examples are the epitaphs in Saturnian verse on the sarcophagi of the Scipios from the 3rd century BC.

There are many texts of deep sentiment and poetic feeling. Yet the bulk itself is the main source of information because it affords what may be called demographic statistics, including population distribution, occupations, public health, and longevity. The frequent inclusion of the *cursus honorum*, or career summary of the departed, has similar informational value. Tombs were usually placed under the divine tutelage of the powers of the beyond. Imprecations against violation were common, as were buried curse tablets in Latin and in Oscan (the *defixiones*). Many of the unofficial inscriptions exhibit substandard degrees of literacy and colloquial features, being thus an important adjunct to the study of the totality of classical Latin and its subsequent developments.

THE USE OF INSCRIPTIONS

The dating of historical events. Inscriptions are important specimens for chronology because they are often physical objects contemporary in execution with their contents. The dating of the inscription itself frequently yields a trustworthy chronology of its message: a victory stela records something freshly deserving of celebration; an epitaph implies a recent death. Exceptions do exist, which record more or less remote events at a conscious historical remove; archival specimens, for example, and secondhand copies generally lack the contemporaneity of other inscriptions. On the whole, however, external dating is crucial and may be achieved in several ways. Excavated monuments can be chronologized by their archeological context, including stratigraphic analysis and radiocarbon dating of any adjacent remains of organic matter. The shape of the monument may permit stylistic and iconographic determination. The type and variety of script used, and especially the style of writing, often allow paleographic dating. Thus, the relative age of Hittite texts can be determined by spotting the typical "Old Hittite ductus" of the more ancient period, and the various "scribal hands" of the Linear B tablets have been differentiated with extreme subtlety. Sometimes a radical reform, such as the official adoption by Athens of the Ionic alphabet in 403 BC (replacing the local Attic variety), provides a chronological watershed. Internal evidence of the inscription may yield its own kind of dating, either by synchronism with otherwise known facts or events or in true calendaric fashion. The year is frequently indicated by a king's reign or the tenure of a magistrate. Such stable counting of time as, for example, from Rome's legendary founding in 753 BC, or from creation (5509 BC, according to Christian dating) is rare in inscriptions; it became more of a historian's device during the classical and postclassical periods. In smaller communities, however, especially in Asia Minor, analogous local departures were used (legendary or historical foundation dates or other epoch-making events), with confusing results for latter-day chronologists.

Contemporaneity of epigraphy

The use of inscriptions for the dating of historical events is most pervasive when the historical tradition itself is "timeless," as in ancient India; the entire Indian chronology comes to be anchored around the Aśokan inscriptions. Inscriptions also permit a check on the veracity of ancient historians such as Herodotus (dubbed both "father of history" and "father of lies"), as in the case of the Bīsitūn inscription of Darius. Equally dramatically, the Linear B tablets prove at one stroke that the Greeks were ensconced at Knossos in the 2nd millennium BC and that the bulk of the "Olympian" religion was already theirs at the time. Most significant of all, nothing would be known of the great Hittite Empire during the 2nd millennium BC, were it not for the discovery of its inscriptional archives.

The decipherment of ancient languages. Inscriptions as written records are usable only in proportion to their intelligibility. Important epigraphic corpora remain virtually undeciphered; *e.g.*, the "Indus script" from Mohenjo-daro and Harappā (3rd millennium BC), the Carian texts from Asia Minor and by Carian mercenaries in Egypt (1st millennium BC), and the pictographic Mayan "hieroglyphs" from Central America (*c.* AD 500–1500). Sometimes the writing system is intelligible, as in the

Undeciphered epigraphic corpora

case of Etruscan, but understanding remains deficient because the language is otherwise unknown and bilingual keys are lacking or inadequate. Chances for success are best if there are sufficiently extensive bilingual or multilingual copies, of which at least one language is previously understood. Such presence made possible the decipherment of ancient Egyptian (the Rosetta Stone of 196 BC, with hieroglyphic, demotic, and Greek versions). Once the affinity of an underlying language to known idioms is established (*e.g.*, Old Egyptian to Coptic, Old Persian to Avestan and Sanskrit, Akkadian to Hebrew), interpretation can proceed apace. The recovery of Hittite was not a true decipherment because the script was a relatively common variety of syllabic cuneiform. The interpretation was helped by the nature of the writing on the one hand (including intelligible ideograms, while an alphabet yields no such clues), and by the presence of Akkadian-Hittite bilinguals on the other; the soon-recognized Indo-European affinities of the Hittite language afforded further help. The Hittite Hieroglyphs were partly deciphered by painstaking internal analysis based on the correct assumption of an underlying dialect akin to Hittite; a bilingual with Phoenician text brought much welcome confirmation. The decipherment of Linear B was a sheer triumph of methodical cryptology, again based on the correct hunch that the hidden language was Greek.

In sum, the decipherment of ancient scripts and the recovery of lost languages are practically identical with the interpretation of previously unintelligible ancient inscriptions, because texts involved are almost exclusively epigraphic. Even when the language is otherwise preserved (as with classical Greek and Latin), inscriptions yield essential additional data for its history, dialects, and social diversification.

THE HISTORY OF EPIGRAPHY

Greek and Latin inscriptions. Inscriptions have commonly elicited the curiosity of posterity, and such ancient Greek historians as Thucydides and Polybius already made scholarly use of them. Sporadic systematic interest in Greek and Latin inscriptions is attested in later ages; *e.g.*, Cola di Rienzo in the 14th century made a collection, and Cyriacus of Ancona (Ciriaco de' Pizzicolli) in the 15th century was a renowned recorder of ancient written monuments on his mercantile travels to Greece, Anatolia, and Egypt. Cyriacus' material formed the nucleus of various compilations in the succeeding centuries, normally on a geographic basis. A rival typological method of publication was launched by Martin Smetius in Leiden in the late 16th century and was followed in the early 17th by a monumental collection of Janus Gruter and Joseph Justus Scaliger. After copious additions of material during the 18th and early 19th centuries, the *Corpus Inscriptionum Graecarum* was launched by August Böckh in 1815 under the aegis of the Berlin Academy and was completed in four volumes (1828–59). The material had by then again outrun the publication, and it was resolved in 1868 to re-edit completely all Attic inscriptions. After the completion of the new three-volume *Corpus Inscriptionum Atticarum*, U. von Wilamowitz-Moellendorff took charge in 1902 and settled upon a new corpus called *Inscriptiones Graecae*, which encompassed all Greek inscriptions from European Greece (including Magna Graecia in Italy) and Cyprus. Those of Anatolia were left to the *Tituli Asiae Minoris* of the Vienna Academy, which began with the Lycian-language inscriptions from Lycia in 1901 and continued with the Greek and Latin ones from Lycia in 1920–44. The rest of Greek Anatolia was combed somewhat by the multivolume American series, *Monumenta Asiae Minoris Antiqua* (since 1928). *Inscriptiones Graecae*, framed in 14 volumes, has turned partly into a kind of overall umbrella for diverse coverage; volumes 6, 8, 10, much of 11, parts of 12, and 13 were never completed, being pre-empted by such other large publications as *Inschriften von Olympia*, *Fouilles de Delphes*, V. Latyshev's *Inscriptiones Antiquae Orae Septentrionalis Ponti Euxini Graecae et Latinae* and G. Mikhaylov's *Inscriptiones Graecae in Bulgaria Repertae*, *Inscriptions de Délos*, and M. Guarducci's *Inscriptiones Creticae*. The continuous influx of new material is inventoried and presented in such annual outlets as *Supplementum Epigraphicum Graecum* (since 1923) and "Bulletin épigraphique" in the *Revue des études grecques*. Large recent undertakings either supplement or complement the *Inscriptiones Graecae*, such as *The Athenian Tribute Lists* (from the American excavations in the Agora) and *Inscriptions grecques et latines de la Syrie* (six volumes, 1929–67). There are, in addition, numerous more localized or specialized collections.

Epigraphic collections

The *Corpus Inscriptionum Latinarum*, founded by Th. Mommsen in Berlin in 1862, comprises 16 volumes fortified with copious supplements; it covers the classical Latin world and is notable for its homogeneity and systematization. Current finds and studies are presented in *L'année épigraphique* (since 1888). Etruscan inscriptions are less perfectly published in the antiquated *Corpus Inscriptionum Etruscarum;* many important later finds are included in transcription in M. Pallottino's *Testimonia Linguae Etruscae* and in M. Fowler and R.G. Wolfe, *Materials for the Study of the Etruscan Language* (1955; a computerized corpus). Of further relevance to the Roman world are collections of the type of E. Diehl, *Inscriptiones Latinae Christianae Veteres;* M.J. Vermaseren, *Corpus Inscriptionum et Monumentorum Religionis Mithriacae;* and *Inscriptiones Italiae.*

Other inscriptions. R.A.S. Macalister's *Corpus Inscriptionum Insularum Celticarum* (1945–49) gathers the oghamic and other early texts from Ireland and elsewhere. The runic inscriptions are inventoried in a variety of compilations. The *Corpus Inscriptionum Semiticarum*, in Paris (since 1881), covers in separate volumes Phoenician, Aramaic, and other speech areas. Urartean texts were collected by C.F. Lehmann-Haupt in *Corpus Inscriptionum Chaldicarum* (1928–35); the earlier found Hieroglyphic Hittite texts, by L. Messerschmidt in the antiquated *Corpus Inscriptionum Hettiticarum*. The *Corpus Inscriptionum Iranicarum*, intended to gather the epigraphs of Persia proper (Achaemenid, Seleucid, Parthian, Sāsānid) and of eastern Iran and Central Asia, began in London in 1955. The *Corpus Inscriptionum Indicarum* has published four volumes since the 1870s, comprising the Aśoka, Indo-Scythian, Gupta, and Kalacuri-Cedi periods, supplemented by the series *Epigraphia Indica* and *South Inaian Inscriptions.*

No equally closed corpora exist for cuneiform and Egyptian documents. The Hittite texts come closest to such organization, issued mainly in two great ongoing series, *Keilschrifttexte aus Boghazköi* (German Oriental Society) and *Keilschrifturkunden aus Boghazköi* (Berlin Academy). But mostly the publication is haphazard—as part of excavation records (*Keilschrifttexte aus Assur*), depending on storage sites (*Cuneiform Texts* in the British Museum), or on the basis of genres (F. Thureau-Dangin, *Rituels accadiens*). The same pattern holds true of the Egyptian records.

Much epigraphic material is published in excavation reports and in many archeological and antiquarian periodicals; *e.g.*, *Hesperia*, *Journal of Hellenic Studies*, *Bulletin de correspondance hellénique*, *Archeologia classica*, *Studi Etruschi*, and *Syria*. Specifically epigraphic serial publications include *Epigraphica* (Milan, since 1939), *Kadmos* (Berlin, since 1962), *Zeitschrift für Papyrologie und Epigraphik* (Bonn, since 1967), and *Chiron* (Munich, since 1971).

BIBLIOGRAPHY. J.B. PRITCHARD (ed.), *Ancient Near Eastern Texts Relating to the Old Testament*, 3rd ed. (1969), gives translations of inscriptional material, especially from Egypt, Mesopotamia, Palestine, and Asia Minor. J. FRIEDRICH, *Entzifferung verschollener Schriften und Sprachen* (1954; Eng. trans., *Extinct Languages*, 1957), deals especially with the decipherment of inscriptions, while his *Kleinasiatische Sprachdenkmäler* (1932), transliterates a variety of epichoric texts from Asia Minor. R.G. KENT, *Old Persian*, 2nd ed. rev. (1953), is a comprehensive work including grammar, texts, and lexicon. W. HINZ, *Altiranische Funde und Forschungen* (1969), includes a number of important recent inscriptional finds from ancient Iran. J. BLOCH, *Les Inscriptions d'Aśoka* (1950), gives texts and translations of all Aśokan epigraphs; whereas

R.B. PANDEY, *Historical and Literary Inscriptions* (1962), provides a transliterated selection of later Indic epigraphy as well. L. DEROY, *Initiation à l'épigraphie mycénienne* (1962), provides a comprehensive survey of the study of Mycenaean tablets. E.S. ROBERTS, *An Introduction to Greek Epigraphy*, 2 vol. (1887–1905), remains the classic compendium of its kind; while more recent, shorter surveys of its subject are found in G. KLAFFENBACH, *Griechische Epigraphik* (1957); and A.G. WOODHEAD, *The Study of Greek Inscriptions* (1959). A more elaborate recent treatment is that of M. GUARDUCCI, *Epigrafia greca*, 2 vol. (1967–69). The Cretan laws have been sumptuously edited and commented in R.F. WILLETTS, "The Law Code of Gortyn," *Kadmos*, suppl. 1 (1967). The old standard works on Latin inscriptions, J.E. SANDYS, *Latin Epigraphy*, 2nd ed. rev. (1927); and R.L.V. CAGNAT, *Cours d'épigraphie latine*, 3rd ed. (1898), are updated only in such summary surveys as R. BLOCH, *L'épigraphie latine*, 3rd ed. (1964). The elaborate edition of the principal Umbrian inscription by J.W. POULTNEY, *The Bronze Tables of Iguvium* (1959), gives text, translation, grammar, extensive commentary, and facsimiles of the tables themselves. R.W.V. ELLIOTT, *Runes; An Introduction* (1959), is especially thorough on the side of British runes; while W. KRAUSE, *Runen* (1970), is a compact but comprehensive survey of the entire field of runology.

(J.Pl.)

Epistemology

Epistemology (Greek *epistēmē*, "knowledge") is here understood as the study of the nature and validity of knowledge. Typically, epistemologists examine the degrees of certainty and probability and the differences between knowing (with certainty) and believing (without being certain). Their concern is primarily with human knowledge. It is true that, on observing the behaviour of animals, birds, and insects, they note certain points of comparison with human behaviour that may be held to illuminate and justify the view that animals can be said to know; and they may conceive of divine knowledge, too, as comparable to human knowledge but greatly transcending it—as perfect omniscience free from all the imperfections of human knowledge. But both inquiries depend upon a prior acquaintance with human knowledge.

It is not the intention of this article to present a chronological study of theory of knowledge throughout the ages. Though, in the course of the argument, the main teachings of the leaders in this field will be discussed, they will not be presented chronologically; the interest lies in concept and theory rather than in history.

Nor is it the purpose of the article to consider what is usually termed the philosophy of science (though this is what "epistemology" sometimes connotes in Continental philosophy). In all inquiries, including the sciences, there are common epistemological problems; but there are also specific problems pertaining to each of the different sciences, for instance, problems about methodology. These are not the concern of this article but are the task of the specialists in each particular field—in biology, physics, geology, and so on—or of the philosopher of science, whose prerogative it is to provide a catalog of methodologies and to discuss the specific problems of the sciences (see SCIENCE, PHILOSOPHY OF). The present article deals, instead, with what in Europe is sometimes called gnosiology.

The following subsection of the article will be followed by a subsection on the relations between epistemology and certain other disciplines, such as psychology and logic. In the first main section a brief sketch will be given of the points at issue in *contemporary* epistemological theories. The argument will be confined to theories; that is to say, individual authors will not be discussed. It will present the state of play in this field of inquiry at the present moment. In the suceeding sections, the main topics of epistemological theory set forward by past and present philosophers will be dealt with. In the sixth section some concluding reflections will be given.

The main topics are thus outlined as follows:

I. Function, scope, and relations of epistemology
  Epistemology as a discipline
  Relation of epistemology to other disciplines
    Relation to metaphysics
    Relation to psychology
    Relation to philosophy of mind
    Relation to logic
    Relation to other studies
II. Diversities of contemporary epistemological theory
  Sense perception
    Sense-datum theory
    Phenomenalism
    Perceptual assurance of physical objects
  Levels of assurance
    Quest for certainty
    Belief
  Mental activity
    Thinking and language
    Inference
    Reason and the a priori
III. Rationalist orientation
  Rationalism prior to Kant
    Classical Rationalism
    Rationalist elements in Scholasticism
    17th-century Rationalism
  Critical Rationalism of Kant
  Post-Kantian Rationalism
    Rationalism of absolute Idealism
    Realist Rationalism
  Attempts to transcend reason
IV. Empiricist orientation
  Ancient Greek and medieval Empiricism
    Classical philosophers
    Medieval philosophers
  Modern and recent Empiricism
    Early forerunners
    Classical British Empiricists
    Assessments and recent expressions of Empiricism
V. Conceptual thinking
  Concepts
  Language
  Universals
VI. Concluding reflections
  Conflict of Empiricism with Rationalism
  Blend of Empiricism with Rationalism

I. Function, scope, and relations of epistemology

EPISTEMOLOGY AS A DISCIPLINE

The need for knowledge about knowledge

If "the proper study of mankind is man," then epistemology or theory of knowledge is a worthy part of that study, for it deals with an aspect of human life that is of fundamental importance. To act wisely in the world, it is necessary to know that world and understand it; this is not to say, however, that, if a man knows, he will inevitably use the knowledge wisely. It is true that the past several centuries have witnessed rapid advances in knowledge that have made possible higher standards of life; but it is equally true that this very knowledge has frequently been misused, increasing man's misery. Moreover, the new knowledge has sometimes provoked a sense of insecurity, even a certain loss of morale. The universe has been shown to be incomparably vaster and man's role in it less significant than had been assumed. Advances in astronomy, nuclear physics, chemistry, and biology have in many respects been disturbing. Yet, paradoxically, men are proud of these achievements. If the world seems now less cozy than it used to be, if its very vastness is forbidding, it is man himself who has discovered the truth about the world—if it is the truth. Indeed, man is also uneasy about his liability to error. Men assert confidently what they take to be the truth, only to find later that their assertions frequently have been false—hence man's great need not only to know the world around him but also to know himself better and, in particular, the need to understand the character and reliability of his own cognitive powers. The epistemologist seeks to provide an urgently needed knowledge about knowledge.

RELATION OF EPISTEMOLOGY TO OTHER DISCIPLINES

The disciplines most closely related to epistemology are metaphysics, psychology, philosophy of mind, and logic.

Relation to metaphysics. Traditionally, metaphysics (the study of the nature of Being) was held to have three parts—ontology, cosmology, and epistemology—and was ranked as the highest of the university secular studies. Today, because of the influence of Positivist and Empiricist teachings, the tendency is to deny it any place whatsoever in the curriculum, on the grounds that what it at-

tempts to study transcends human comprehension and is not susceptible of philosophical analysis. But epistemology, though it is a part of metaphysics, has not suffered the same fate. Recently there have been signs of a possible partial restoration of metaphysics, and because the studies are concerned with the problem of the general structure of the world, the findings of metaphysicians may become a matter of interest to epistemologists.

The present tendency to reject metaphysics

Relation to psychology. Fifty years ago, psychology and epistemology were closely related branches of philosophy, and, in fact, insofar as philosophy was concerned with the *genesis* of knowledge, there was no distinction between them. The part concerned with the *validation* of knowledge was linked with logic; but logic was not as sharply separated from psychology as it is today. A century ago the Empiricist John Stuart Mill spoke of logic as "not a science distinct from . . . psychology. . . . Its theoretic grounds are wholly borrowed from psychology." In the early years of the 20th century, however, psychology broke away from philosophy, rejected its methods, and became an empirical discipline. Epistemologists, on the other hand, continued to use, with greater precision, the methods of analysis. They subjected their key concepts—know, believe, see, infer, and true—to close analysis, with useful results. The trend of psychology and epistemology away from each other ignores the fact that there are points at which they could still help each other: the epistemologist's analysis of concepts could help psychologists in the study of cognition. Conversely, the epistemologist would benefit from examining the work of psychologists on such things as the beginnings of knowledge of number, of movement, and of reality in young children, and it would be advantageous if various epistemological theories of sense perception were to show an awareness of, for example, psychological studies of perceptual systems and the role of accumulated past experience in conditioning present perception.

Psychology's break with philosophy

Relation to philosophy of mind. Philosophy of mind is a comparatively new discipline whose boundaries at present are loosely drawn. In the widest interpretation it would presumably include epistemology as one branch of its total subject matter, for an inquiry into the whole of mental life would cover the study of the theoretical or cognitive aspect of mind. In fact, philosophy of mind tends to leave the study of the nature and validity of knowledge to the epistemologist and concentrates on other issues: first, on the nature of mind and its relation to body; second, on the distinction between the self and other selves; and third, on the description of the various aspects of the mind's life. In his study of the cognitive aspect the philosopher of mind leans on the work of the epistemologist and finds it necessary to familiarize himself with the findings of epistemology and psychology. But the philosopher of mind is necessarily concerned with practice as well as with theory—*i.e.*, with willing and acting—and he is concerned too with man's emotional life. The epistemologist, in turn, finds it clearly of importance for him to come to terms with some of the problems considered by the philosopher of mind. Thus, his theory of knowledge is likely to be influenced by the attitude that he adopts toward the mind–body problem; he is concerned with the central notion of a knowing self; and he finds that the descriptions provided by philosophy of mind of mental states, mental acts, and mental dispositions are of considerable value.

Relation to logic. It is sometimes said that epistemology is an admixture of many disciplines, of, for instance, metaphysics, psychology, and (since its method is analytic) logic. The fact is that the aims of epistemology are very different from those of logic. The concern of logic is with the formal structure of valid reasoning; it sets down the principles of valid inference. Epistemology, on the other hand, deals with the nature of cognition of all kinds: with man's awareness of the world in sense perception, his insights into possible hypotheses, his guesses—which are in no sense the concern of logicians. Though epistemology makes use of logical teaching on inference and particularly on deduction, it is also true that there is a difference between the epistemologist's attitude and that of the logician: the logician seeks the form of deduction in general and formulates it: *p* implies *q; p*, therefore, *q*. The epistemologist accepts his formulation but then asks what addition is necessary to describe the inference in full. If, for instance, there is present an intuition that *p implies q*, this is a point that is irrelevant to the logician but of great concern to the epistemologist. Epistemology cannot be identified with logic even in respect to that part of it that is most analytical in character but logical techniques can be applied to the problems of epistemology (see LOGIC, APPLIED: *Epistemic logic*).

Difference in aims and scope

Relation to other studies. Three other studies are related to epistemology, though not as closely as those already considered: (1) *Morals:* it is sometimes argued that a person ought to accept certain beliefs, even when he is not completely convinced of their truth, because of the good consequences of the acceptance, and it can also be argued that a moral issue is present in any act of knowing, that knowledge is an ethical concept, that knowledge that a certain proposition is true involves the duty to accept or believe the proposition. (2) *Sociology:* the problem of the influence of society and its prevailing culture upon the beliefs of an individual or of the way social relationships affect the power of a man to see the truth for himself occurs not only at the level of ordinary life; when scientists work in teams, for example, the question arises whether pressure is exerted to bring an individual scientist into line with the rest of the team in his acceptance or rejection of scientific theories (are there, for example, group ideologies in science as there are in politics?). Sociologists often provide epistemologists with interesting information on such topics as whether philosophical theories are communal or individual. (3) *Philosophy of religion:* Interrelationships here have to do with such questions as whether all human knowledge is illumination; whether there is special revelation; whether men literally "see all things in God"; whether it is essential that any knowledge that men may gain of God is God's self-revelation to them; and how revelation fits into the rest of man's knowledge (see RELIGION, PHILOSOPHY OF: *Basic themes and problems in the philosophy of religion: The problem of God, the Absolute, or the supreme value: The knowledge of God*).

Morals, sociology, philosophy of religion

II. Diversities of contemporary epistemological theory

It is impossible to provide a single definition to cover all of the many uses of the words know, knowing, and knowledge. The use that most concerns the epistemologist is knowing that something is the case. Such knowing may be certain knowledge or it may be only probable knowledge. Knowing that something is the case is propositional knowledge: it is knowing that a proposition or statement is true or probable. Such knowledge presupposes that language exists. But "knowing that" is only one kind of knowing; and no epistemologist would say that knowing is knowing only insofar as something is expressed in a verbal statement—it is not mere assertion. Further, even though a man asserts that he knows something, it need not always follow that he does know it, for he may be stating something he really knows to be untrue, or he may be in error. There has been considerable contemporary concern about the so-called performative uses of "I know that . . ."; thus a man may use sentences beginning with this utterance to express, for instance, conviction or to emphasize a point ("I *know* that he will come") or to express agreement, or even to plead with someone ("I know that you will help"). It is thus wrong to identify knowing with saying that one knows.

The meanings of knowing

Epistemologists draw a distinction between "knowing that" and "knowing how." (One could similarly distinguish between "knowing that" and "knowing why," "knowing where," "knowing who," and so on.) "Knowing how" is not a knowing that something is the case. "I know how to speak German" points to a skill or capacity. "Knowing *how*" may also include some "knowing *that*" —knowing, for instance, that, in German, the verb tends to come at the end of a sentence. Of the two, "knowing that" is of greater interest to the epistemolo-

gist because the statement, if significant, has truth value. Among true–false statements, however, there is a further distinction in the ways in which a statement may be true. "Lead is heavy," for example, differs from "If something has a given quality, then it either has that quality, or it does not have it": the first is a factual statement made on the basis of sensory experience; the second is a logical truth and not a matter of experience. The first is contingent—lead might not have been heavy but in fact it is; the second is necessary. Acceptance of the finality of this distinction makes it possible to distinguish, in turn, between two kinds of knowings—one factual (of the external world and of the world of mind or spirit), the second logical. Finally, there is a distinction between immediate (direct) and mediate (indirect) knowledge. One form of the distinction comes down from the ancients, that between uninferred and inferred knowledge; a more modern form is that between knowledge by acquaintance and knowledge by description; a third is the distinction between knowing a sense-datum or sensum or phenomenon directly and knowing the thing itself, the reality behind it, indirectly.

Factual and logical; immediate and mediate

SENSE PERCEPTION

Sense-datum theory. The study of sense perception begins with consideration of a person's factual knowledge of the world and is concerned not merely with that world but with man's consciousness of it as well. The world is conceived of as a world of material objects that exist in space and time and continue in being over a period of time. Such objects are solid and are able to affect other objects and to be affected by them. Among the objects that they affect is man's body; and he, through his sense organs in particular, registers those affections. The outcome, it is claimed, is that he becomes aware of the physical world. Physiologists and psychologists describe these sensory processes without pretending to a full knowledge of them.

Anomalies of perception

The above account, however, needs considerably more detailed analysis, and with analysis comes dissension. In the first place, it is naïve to suppose that a table before a man directly affects his eyes and so enables him to see it; it is rather the light rays deflected from the table that affect his eyes. If this fact be admitted, it may still be argued that the presence of the table is nevertheless the differentiating factor causing him to see a brown, rectangular patch when he now looks in its direction. But to say this may also be naïve, for in another light its colour may appear yellow and from another angle its shape may appear rhomboid. It may be said that these are abnormalities and that the man knows how to allow for them. But the contention involves the assumption that the "normal" colour is the real colour. Such an assumption requires justification.

Reflection on these contradictions led to the so-called sense-datum theory. According to this theory, the yellow object must be included among the objects seen, so must the florin-sized moon that is seen. Furthermore, if a man sees a mirage, he sees it, and it, too, is a visible object. Objects immediately seen or felt are said to be sense-data that exist, though they are to be distinguished from "real" objects in the physical world. The moon that a man sees is different (*e.g.*, in size) from the "real" moon; yet, it is supposed to be related to it; the problem is to define how the two are related, to determine whether a person can gain any knowledge about the "real" moon by considering the characteristics of the visible moon.

Sense-data, sensa, or sensibilia exist, in this theory, as particular objects, and in this sense the dualism of sensum and real object is complete. Sense-data, some say, can even exist unsensed. They are "there." On the whole, however, theorists tend to be neutral on the nature of their existence; sense-data are fleeting private objects rather than public ones, and, since they are linked with specific physical objects, they may in some way represent them. But this part of the doctrine is invariably vague, and it does not necessarily follow that the sense-data must be products of the affection of sense organs and brain by external physical things; it is at least conceivable that they are brought about by man's own action or, again, by God's action. Therefore, the fact that a person experiences sense-data does not permit him to assert that physical objects exist.

Problem of the existence of material objects

This conclusion, however, is unwelcome to sense-data theorists, some of whom have tried to counter it by arguing for a causal theory of perception on the following lines: because sense-data exist and have come into being, it is natural to infer that they must have been caused, but the most plausible answer as to how they are caused is that they are the product of the action of physical objects upon sense organs. Yet, the causal argument, which may be strong in other contexts, is weak in this context. For in the dualist sense-datum theory (1) the person does not know directly that physical objects exist, and (2) he does know that sense-data could conceivably have been wrought by other means. It is consequently difficult in this theory to justify belief in physical objects and doubly difficult to characterize the physical objects linked with specific sense-data.

Three lines of action in response to this predicament appear possible. First, the epistemologist can attempt a thorough re-examination of the ways in which men come to know the existence of physical objects. Second, he can deny the independent existence of physical objects and attempt to develop a fresh Idealist, or mind-centred, theory of sense perception. Third, he can adopt a phenomenalist theory—an alternative that was in fact attempted by the Empiricists David Hume and John Stuart Mill and elaborated in the mid-20th century.

Phenomenalism. The phenomenalist begins by asserting that any attempt to infer the existence of physical objects upon experiencing sense-data is wholly unnecessary. Both (1) the naïve theory that a person sees at least the surface of physical objects directly and (2) the causal argument have been discredited. He is sure only of the phenomena—of what appears. But this is quite enough, the phenomenalist suggests, to enable a person to *talk* significantly of physical objects; and, if so, nothing more is needed. He can certainly talk sensibly of this table without first showing that physical objects exist independently of himself. For here is a brown, rectangular phenomenon in front of him: if he puts his hand on it, it feels smooth; if he presses upon it, he feels a resistance; if he tries to lift it, it feels heavy. He experiences, too, the phenomena of space and of time; for he has to move forward in space to experience the tactual, and he has an experience of earlier and later. When he says "There is a table here," all he means is: "If I look in the right direction, if there is sufficient light, etc., I shall see a brown, rectangular figure"; "If I stretch out my hand, I shall feel a smooth surface"; and so on. In other words, without any loss of meaning, he can always reduce a physical-object sentence into sentences about sense-data.

Criticisms and rejoinders of phenomenalism

Though phenomenalism still has its defenders, it has met with considerable criticism. (1) It is argued that in stating the theory the phenomenalist already presupposes the existence of physical objects. In saying "If I put out my hand, I feel a smooth surface," he presupposes his own existence as a physical body. If the phenomenalist replies that he sees his hand as he sees the table, phenomenally, it may be countered that, when he says that he puts out his hand, this *I* is, at least, a physical object bringing about a certain change in a situation and that such causal changes cannot be accounted for in pure phenomenalist terms. The phenomenalist, however, might argue, in turn, that the account of causation that is presently orthodox is itself one that is framed in terms of a constant and regular conjunction of phenomenally observed sequences. The question then remains whether the orthodox account is true. (2) The series of phenomenalist statements into which the phenomenalist reduces a physical-object statement is an infinite one because there are, for instance, an infinite number of locations from which an object may appear. The phenomenalist reduction must, therefore, consist of more statements than any human being could ever complete. The phenomenalist might reply that sufficient phenomena might be observed to make an approximate reduction possible and so to

enable him to speak significantly of the physical object. But the question would still remain as to the point at which it could be said that he has observed sufficient of these related phenomena to justify speaking of one and the same physical object. (3) The physical-object statement, "There is a table here," is a categorical statement (of sheer fact); but the phenomenalist statements into which it is reduced are hypothetical: "If I look in this direction, I shall see a brown, rectangular patch." No categorical statement, however, can be reduced without loss of meaning into hypothetical statements. The physical-object statement categorically asserts the existence of a physical object. The phenomenalist might reply that the sentence "I now see a brown patch" is a categorical statement that is nonetheless phenomenalist. Yet, if this be granted, the sentence is still not a physical-object sentence, for, even if (improbably) it were held to be an affirmation of the existence of the *I* perceiving, it would still not necessarily be the categorical affirmation of a physical object. Clearly, not one of the phenomenalist's reductive statements is a categorical physical-object statement; thus the reduction must always be inadequate.

It has sometimes been maintained that the only difference between phenomenalist and realist is one of language, that, although the realist chooses to speak in the physical-object language and the phenomenalist in sense-data language, both are speaking of the same thing. Yet, it would appear that, if the criticism just considered is sound, then what is asserted categorically in the physical-object statement, viz., the existence of the physical object, quite apart from any linguistic considerations, can never be asserted in phenomenalist statements.

The need for a radical change of theory

Perceptual assurance of physical objects. The problems of sense perception were studied closely and energetically by epistemologists (by the British philosophers C.D. Broad and H.H. Price, in particular) in the decades between the world wars. Their approach was from the Empiricist angle, and, in spite of protests from Realists, the sense-datum theory tended to dominate the scene until adherents of the theory found it difficult to silence the critics who held that the theory ruled out complete assurance that physical objects exist. Discussion of sense perception thus reached an impasse and in the postwar period little advance has been possible; hence, philosophers have tended to turn to other problems. The one development has been that of phenomenalism, but, as has been seen, it too has failed to silence the critics.

It seemed necessary, therefore, to make a radical change in the approach to these problems. The Idealist solution, that only mind-dependent objects exist, appears to many philosophers to conflict with man's assurance of the existence of independent physical objects, the very same assurance that beclouds the sense-datum theory and phenomenalism. Some epistemologists are therefore tentatively approaching the problem from the study of this assurance itself. The acquisition of sense-data, they argue, is not the beginning out of which comes assurance of the existence of physical bodies; on the contrary, it presupposes that assurance. Sense experience offers further knowledge of that of which the existence is already known. The mistake that Empiricists have made is to identify sense perception with the acquisition of sensa, such as yellow, square, or heavy, and then to explain knowledge of the physical by compounding and relating such data. This is to enter into the perceptual experience when it is at an advanced stage, but to assume that this is its beginning, and to solidify by abstraction the elements that one then finds. For a human being to survive as an organism he has to interact with objects around him, and from the first, therefore, it has been a condition of his life that he should be aware of the world of objects around him. He possesses a nervous system that makes interaction possible and enables him to seek actively for information. Sensations are accompaniments of the operations of such nervous systems; they are wrongly conceived as objects in themselves. Some have felt that a false emphasis on sensations has blinded the philosopher to the real situation and has caused a crop of problems that have confused him.

A new Empiricism may thus be in the making that finds confirmation and backing in new teachings in psychology and physiology. In this view, no veil hangs between man and the world, or certainly none formed from sense-data. This is an Empiricism without skepticism. Nonetheless, certain difficulties remain, the chief among them being perhaps the part that seeing colours and hearing sounds play in clarifying the qualities pertaining to objects in the world. Is, for example, an object lying before the observer really brown and rectangular; are there some qualities that belong to things essentially, whereas others are only contingent; and can such problems ever be solved by philosophical reflection upon sense experience?

The newer non-skeptical Empiricism

LEVELS OF ASSURANCE

Quest for certainty. Of central importance to epistemology is the alleged assurance of the existence of a physical world. How this assurance is to be graded is a critical problem; a person may be certain of the existence of an external world containing physical objects but not be certain that the world is exactly as it appears in sense perception. On the contrary, such a person may think it necessary to carry out further tests and may check to determine, if he can, the qualities and relations of objects. In certain circumstances, he may even be doubtful about the very existence of an object that appears to be present; he may suspect an optical illusion or even a hallucination. But he is still certain that the external world and physical objects within it exist. He would claim certainty, too, for much else—for instance, that he himself exists and that other persons exist, that two and two are four, and that, if a thing has a particular quality, it cannot at the same time not have it. These a person takes to be certainties. Nonetheless, people frequently fail to achieve such certainty, and there are philosophers who hold that men never attain complete certainty. Complete certainty must then be further considered. The traditional Rationalist asserts that man gains complete certainty in the exercise of the faculty of reason; reason can provide him with absolute truth, at least in those areas in which it is free to function. It does not and cannot mislead, as the senses do; it in no way rests on sense perception. It is positive and contains no hypothetical element; it is not itself inferential, though it provides the principles basic to inference. It is intuitive and direct, providing indubitable and infallible knowledge—*i.e.*, knowledge of what is necessary.

Rationalist approach to certainty

There are philosophers who continue to defend a Rationalism of this full-blooded kind, though many, if not most, philosophers are hesitant about its claims and would reply that, admittedly, men are completely certain of many things, that such knowledge is contrasted with belief, which may carry a high degree of assurance but is never completely certain, but that, though a person may be certain of something and not merely opine it, it is still possible that he may be in error. If this is so, then he does not know infallibly by reason, and being sure is not enough. It has been asserted that there are three necessary conditions of knowledge: (1) a man, say Arthur, is sure that a certain proposition *p* (*e.g.*, "London is in England") is true; (2) he is able to justify his assurance by producing adequate evidence for *p;* and (3) *p* is, in fact, true. Yet the cogency of the theory thus formulated has been questioned. It is not clear what justifying a man's assurance (2) signifies. Apparently it means causing others, say William and Henry and Mary, to be sure by producing evidence for them to consider. This only means, however, that others are now sure, too. But if one doubts Arthur's assurance he may also doubt that of William, Henry, and Mary. So again, though it is obvious that, if Arthur really knows that something is true, it is true, Arthur may nonetheless think that he knows something even though it is false. Moreover, William, Henry, and Mary may all think they know it too, and yet it may be false. This means that conditions (2) and (3), though genuine conditions of knowledge along with (1), cannot possibly be used as tests whether Arthur is knowing. So there is no adequate test whether Arthur is knowing, and yet it is admitted that men can be sure and at the same time be in error. Such a conclusion points to skepticism about the Ration-

alist's ideal. One should be content with belief, the skeptics argue, and not claim certainty. With the necessary modifications, many philosophers could adapt the formulation used in the case of knowing something and apply it to believing it instead. They could then hold, as many philosophers do, that belief occurs only if (1) someone believes that something is the case; (2) what is believed to be the case is evident for the person believing it; (3) what is believed to be the case is true.

Infallible versus certain knowledge

The question then arises, however, whether the rejection of the possibility of completely certain knowledge is justified. The distinction between infallible knowledge and fallible certain knowledge is of vital importance in this context. To say that men are never certain is to go against the facts. The fact is that men are daily quite certain of where they live, the size of their paycheck, that they are now tired, and so on; what does lie beyond them is infallible knowledge of absolute truth. But to deny the possibility of infallible knowledge is not to deny that of certain knowledge. It would appear, therefore, that the schools that speak today of certainty being beyond the reach of men and of all alleged knowledge being only belief are in error and that their error rests on their failure to distinguish between complete certainty, of which man *is* capable, and knowledge of absolute truth, beyond every possibility of error, of which, apparently, he is not capable.

Belief. In some of its uses, the word belief has an emotive overtone, as when a man speaks of belief in God, signifying thereby an element of trust in and esteem for the object. But most often the word is used without evaluative overtones. To believe is to accept something as being the case; it is a species of knowing that is not certain but probable. There are degrees of probable knowledge, ascending from the lowest probability to the highest. Further, belief may be either dispositional or occurrent—dispositional, as when a man is called kind although not now performing a kind act, and occurrent, as when he is said to be angry only while actually in that state of mind. A person gets used to certain recurrences and comes to believe dispositionally that they will go on recurring—that his food will nourish him, that clouds presage rain, and that fire causes heat. Some epistemologists argue that all believing is dispositional. And, for those who also deny the possibility of certain knowledge, it would seem that all cognition is dispositional. But this would seem to be an extreme view. Although much believing is properly dispositional, not all of it need be. If, for instance, an attorney in examining a case looks at all the evidence, weighs the possibilities carefully, and finally concludes that Smith is in all likelihood guilty, he cannot be said to have acquired this belief dispositionally; for in his case there is an act of judging, and the belief is thus an occurrent.

Sources and adequacy of evidence

The sources of the evidence on which a man may base belief require consideration. The first of these is, clearly, sense perception, the actual seeing, touching, and hearing; the second is the memory of such experiences; and the third is inference from the information gained initially by the senses. In addition, an observer may be conscious of his own feelings of pleasure, pain, joy, sorrow, grief, envy, love, and hatred. From these sources a body of information may be acquired to which a person can turn when seeking evidence and by which he is so disposed that certain statements are acceptable while others arouse suspicion. Another important source of evidence is "hearsay knowledge," all that a person has been or is being told by others. His information would be very slight indeed if it were confined to what he has gained independently of others; for the greater part of it comes from communication with others—through talking, writing, reading, picturing, and so on.

The next question debated is one as to the adequacy of evidence for or against a belief. Evidence is usually taken to be adequate (1) when it enables a man to settle the point at issue, to make up his mind, and (2) when it provides him with the truth. It has been suggested that there is no real difference here, for only a knowledge of the truth could settle the issue. But men often have to make up their minds on mere probabilities. Moreover, if knowledge is always fallible, then to say that the evidence is adequate would inevitably be to speak relatively; it would be adequate for the person now seeking to determine its adequacy. He would want to re-examine the evidence and to check the sensory experiences, the memory, and the inferring. He would reflectively study the dispositions and tendencies, both those that seem almost mechanical—for instance, beliefs that (to quote David Hume) are "lively ideas associated with present impressions"—and those that are the outcome of wide attentive experience of recurring phenomena stored over many years. He would ask whether too much was being taken for granted in such dispositional beliefs and whether they could always be trusted. In the same way, he would check the hearsay knowledge; the time and circumstances in which the informants reported and the reliability of the informants are important. Having carried out this re-examination of the evidence, he would seek for fresh evidence. The total result of his labours might then be that he would still find the evidence inadequate or adequate enough to base a probable belief upon it or entirely satisfactory. In such circumstances the test of adequacy would be subjective throughout; on the other hand, it would now be a test satisfying a reasonable man. Whether this would give it objectivity depends presumably on the account one gives of the reasonable. At this stage it would be wrong to assume that the adequacy is ever other than subjective.

There is also the further debatable point whether a belief for which the evidence has been shown to be adequate, a justified belief, is identical with knowledge in the strict sense. It can now be seen that the evidence is adequate only in a relative and not an absolute sense; nonetheless, it justifies belief in the opinion of reasonable men. A person might be convinced and certain, so that justified belief would here be one with knowledge in the strict sense and not be mere opinion. On the other hand, such knowledge would not be infallible and would not be knowledge of absolute truth. Clearly, three states are to be distinguished: (1) probable knowledge; (2) certain knowledge, which is not knowledge of absolute truth; and (3) infallible knowledge of absolute truth. Adequate evidence gives man (2), and, in this sense, fully justified belief is certain knowledge; but it is not knowledge of absolute truth.

Meaning of probable

The meaning of the term probable requires brief consideration. The probable is sometimes defined as what is believed—*i.e.*, it is subjectively determined. Efforts may be expended to make it less subjective by bringing forward supporting objective statements; but the probable, in this sense of the word, is never wholly objective. In other senses, however, the probable is objective throughout. When the mathematician speaks of what is probable—for instance, the probability of an event recurring in a sequence of events—he seeks objective certainty, and his probability is the ratio of the number of favourable cases to the total number (both favourable and unfavourable) of equally possible cases and can be worked out mathematically. In another sense, the mathematically determined probability of an event can turn out to be improbable; if the occurrence has, for example, only a 4 percent probability, one should speak of the occurrence as being improbable. Finally, it is reasonable to ask whether, if it is said that a statement is probable, this means that the speaker is certain that it is probable or merely thinks it is probable that it is probable.

MENTAL ACTIVITY

Thinking and language. What distinguishes contemporary epistemology from earlier studies in the field is its profound interest in linguistic problems. On the one hand, the demand for precision in the use of language has been greatly stressed. Some writers have spoken of the need for a special, technically exact, philosophic language; others have held that the whole task of philosophy is to make completely plain what is being said at any moment. Doubts have been expressed about the possibility of a specialist philosophic language, and attempts to handle philosophic problems in the language of formal logic so

far have not always been successful. It has further been doubted whether analysis, in the sense of analyzing precisely what is being said, is the whole of philosophy. Probably no one would deny, however, that as high a degree of linguistic precision as is possible is a requirement in all philosophic discussion and that the epistemologist, for instance, has been helped by closer analyses of such words as know, believe, and see.

His interest in linguistic problems has been heightened, too, by his realization of the part that language plays in human thinking. It has even been argued that there can be no thinking without the use of language. It would seem difficult to deny, however, that men who are capable of thinking verbally need not always do so: intelligent thinking in a football player on the field is not necessarily verbal thinking. Nonetheless, it remains true that human thinking is, for the most part, verbal. The question that then arises—and it is central to epistemology—is that of the influence of language on thinking. At issue is not so much the different influences that different natural languages—English, Chinese, Iroquoian—have on the thought of the respective peoples but the differences in thought that the use of language in general makes possible. Of great importance is the fact that it makes possible statements (in which a quality of a subject is predicated or a member is placed in a class or a class in another class) or compound statements (involving conjunction, disjunction, or implication). Though one sometimes speaks of animals as "deducing" something, yet logical deduction, which adds power to thought, appears to be possible only when a person has learned to speak in statements and to think verbally.

Nature of the concept and of the universal

Difficult problems that arise in discussing thinking are those of the nature of the concept and of the universal (or general term—see below *V. Conceptual thinking: Concepts* and *Universals*). There is fairly general agreement that a concept is not, as traditionally assumed, an inner accusative (or object)—although some contemporary accounts of "intentions" as objects of thought seem to come close to saying this. In general, however, the teaching that the concept is any kind of an object is rejected; philosophers prefer to speak, instead, of having concepts, and the fact that a person has a concept is revealed by what he says and does. In this view, the concept is a mental capacity and is thus dispositional; *i.e.*, present even while not overtly expressed. The concept of liberty that a person has, for instance, will be clear from what he says. But even this interpretation of what a concept is can hardly be adequate. The concept of liberty for the English speaker is rather the accretion of both linguistic and nonlinguistic dispositions around the word liberty, and to understand it fully would be to make plain the character of these accretions.

The problem of universals is more metaphysical because it involves consideration of what it is that lies behind the successful use of general words like man or whiteness (as opposed to "Adolf Hitler" or "this sheet"). Nominalists reply that nothing is behind it but man's powers of grouping, classifying, and naming; conceptualists claim that man's ability to use general words successfully involves dispositional beliefs about what is and what occurs, as well as linguistic dispositions; realists stress the importance of recognizing recurrences in nature. (For a discussion of these rival schools, see below *V. Conceptual thinking: Universals.*) The final theory of universals must assure man freedom to frame universals as principles of thought, but also, since thought must be applicable to the real world, knowledge of universals must in some cases rest upon a recognition of recurrences in nature.

Problem of induction

Inference. Textbooks group induction with deduction as species of logical inference. Induction, sometimes described as a passage from the observation of particular cases to general statements, is claimed to be the method of many of the natural sciences, normally providing probable conclusions only. Further, it is the method in daily life of finding rough generalizations or working hypotheses. But induction is somewhat hesitatingly grouped with deduction as a method of logical demonstration, for philosophers have been hard pressed to establish the validity of inductive procedures. On the face of it, induction is a passage from some cases to all, from all the observed cases (all observed swans are white) to all cases (all swans are white); and this is an extrapolation that cannot be logically justified. It is generally claimed, however, that the element of induction in inductive reasoning may be bolstered by items of deduction and also by analogical reasonings. Attempts have been made to use statistical methods, based on the mathematical theory of probability, to strengthen the induction. Again, it has been suggested that induction should not be thought of solely as a passage from particular observations to a generalization, that this step should rather be followed by a secondary induction, viz., the testing of such a generalization by its coherence, or lack of coherence, with the system of generalizations already established in the relevant field of inquiry.

But these proposals have not satisfied the critics, some of whom insist roundly that induction is a nonlogical type of demonstration. Indeed, it has been argued that the passage from observations to generalization is no demonstration whatsoever, certainly not one susceptible of logical analysis; "induction" in this view becomes simply an inspired guess, a hunch. Once a generalization or hypothesis is made, it can then be tested logically (*e.g.*, the discovery of one negative instance will refute it). Others reject this view and argue that the thinker, in proceeding inductively, does not merely leap at a generalization but also makes a rational estimate of the probability of the generalization, and in so doing, he proceeds logically.

Deduction from premises

Of all mediate knowledge the surest is established by deduction, a passage from premises known to be true to conclusions following validly from these premises (see SYLLOGISTIC). The epistemologist, however, is concerned with the nature of inference, seen at its best in deduction. Inference has been conceived as a technique of sentence transformation providing an efficient means of advancing in thought. On a different view, inference begins with a thought content that develops of itself in thought. For both of these views, inference is in a certain sense passive. On a third view, however, inference is an activity, viz., perceiving or intuiting an implication. The premises necessarily imply the conclusion; no one can choose what he is about to intuit, but the intuiting itself is free and the mind active.

Further, there are problems about acquiring premises. It is essential that the reasoner should have established their truth, for a valid inference from true premises can never yield a false conclusion. But these truths, as has been seen, may be either truths of fact or truths of reason. Whether this difference can be ignored or necessitates two theories of inference depends upon a person's view of reason.

Reason and the a priori. Finally, consideration must be given to contemporary Rationalism. Its expression differs in detail from the older traditional doctrine, but what is essential to it today, as in the past, is the assertion that account must be taken of man's faculty of reason as a source of information that cannot be derived from any other source. Reason, operating in its purity, provides knowledge of foundational concepts, such as being, unity, substance, and cause, and of principles, such as noncontradiction (that a statement and its negation cannot both be true), which are conditions necessary for the possibility of knowledge. It provides, that is to say, the pure a priori features of human knowledge, as contrasted with the a posteriori features derived from experience. Traditionally, thus pure a priori knowledge is infallible.

The Rationalist today can adduce considerable evidence in favour of his thesis, an instance being the manner in which man's thinking is dominated by such principles as that of noncontradiction. He does not claim that all knowledge is acquired by reason (he claims less in this respect than did the traditional school); but he insists on a certain minimum of a priori without which human knowledge, he holds, cannot be understood. Nonetheless, the Rationalist thesis confronts acute problems, one of which is whether there are truths that only reason, a special exclusive faculty, can know. Analytic truths are

Analytic, categorial, and transcendent truths

said to be of this nature; so, too, are categorial truths about the structure of the world, and, in addition, there are transcendent truths. In respect to the first, the so-called analytic truths, it must be admitted that a statement can be true solely in virtue of the meaning of its terms (*e.g.*, "A bachelor is unmarried"). Once the terms are understood, the truth of the statement must be granted. Here, it is said, is a truth apprehended by reason. Yet the question can be asked whether it is in fact essential to suppose a special faculty to be at work here. These statements are analytic; they are necessary and, in that sense, a priori. Yet it may be asked whether this discerning or intellectual perceiving—that, since the terms mean what they do mean, the statement must be accepted as true—is really a special faculty operative only in this very limited field or whether it may not be the discerning that provides assurance throughout man's cognitive experiences.

As for the body of basic categorical knowledge that Rationalists believe conditions the development of further knowledge, considerable doubt is expressed today about their description of such knowledge—*e.g.*, of substance and of cause. The fact is that the bases of man's conceptual systems can and do change, that the principles usually held to be basic to thought in general, such as those of noncontradiction, identity (that everything is what it is), and excluded middle (that no third statement can be admitted between two contradictories), are still being reformulated and amended by logicians. It is not clear how this rethinking could happen, if reason once and for all had planted these absolute truths upon man's mind. Finally, it is argued that knowledge of the transcendent, the nonempirical, which, too, is taken to be a priori, may well have been derived from the experienced, even though it itself is never directly experienced. Thus, Rationalism has had to face considerable criticism. Some of the criticisms have pointed toward the view that human knowledge rests throughout on convention, but conventionalism itself has come up against assurances that man has in his experience about things and occurrences that are independent of him; and such knowledge can in no way be regarded as conventional.

Though it is inevitable that many matters that are relevant to contemporary epistemology have been omitted from this brief sketch, some of the gaps will be filled in later. The purpose of the foregoing outline has merely been to provide an insight into the main confrontations.

III. Rationalist orientation

In the next three sections the main doctrines of epistemology are set out primarily on a notional rather than a chronological basis. Epistemological theories can be divided roughly according to whether, in the gaining of knowledge, they stress the role of (1) reason, (2) sense experience, or (3) concept and language.

RATIONALISM PRIOR TO KANT

Pre-Socratic Rationalism

Classical Rationalism. Though ancient Greek Rationalism had its first explicit expression in Plato's doctrine of Forms or Ideas, there had been earlier suggestions of Rationalism. The Greek philosophers had consciously set before themselves the task of understanding the world, primarily the physical world, and this they interpreted to mean understanding the laws that hold within that world and its permanent structure and order. This was to assume, however, that it was an ordered and rational world—an assumption that is seen clearly in many of the extant fragments from early Greek writers. Thus, the philosopher and mathematician Pythagoras of Samos (flourished late 6th century BC) thought that "all things are numbers"; and the monist Parmenides, a generation after him is held by many scholars to have been a Rationalist. Certainly, a little later Anaxagoras argued in Athens that *nous* (reason or intellect) was the original cause of movement in the universe. He described *nous* as "the thinnest of all things," as infinite, completely pure and unmixed, and as absolute in power and in knowledge of all things. Both Plato in the *Phaedo* and Aristotle in the *Metaphysics* expressed disappointment that Anaxagoras made so little use of the notion of *nous* in his cosmology.

Theory of Forms in Plato. In his theory of Forms or Ideas, Plato, no doubt influenced by Socrates, put forward the first fully explicit Rationalist epistemology. Possibly the most striking description of Form and of the knowledge of it is found in the *Symposium*, in which it is said that a man who has observed many beautiful objects and reflected about them may, of a sudden, glimpse supreme Beauty, "eternal, unproduced, indestructible"—not beauty relative to a time, a place, a thing, or a person but absolute Beauty. "All other things are beautiful through a participation of it." Along with the Form of Beauty go the Forms of the Good and of the Just discussed in *The Republic*. Other forms mentioned by Plato are those of unity, plurality, equality, likeness, unlikeness, motion, and rest. Later, he adds the Forms of things, for instance, of man and all living creatures, of fire and water, possibly even of hair, clay, and dirt.

Nonsensory origin of the Forms of Plato

The Forms are not known by the senses, and he explains in the *Phaedo* how the senses may show things to be more or less equal, though equality itself ("the just equal") is not seen or felt but is known independently of sense. Forms, Plato holds, may be recalled from knowledge that the soul possessed prior to its union with its present body or may be directly apprehended. In either case the knowledge emanates from a divine element in the soul that knows the transcendent Form and eternal object and thereby reveals its own eternity. The same account of Forms is found in *The Republic*, in which a contrast is made between opinion and knowledge. Opinion, resting on sense experience, informs a person of the phenomenal, but knowledge reveals the unchanging real; the former is fallible but the latter infallible.

Thus, the outcome of Plato's discussion of knowledge was, first, a conviction that, whereas sensory experience is superficial and deceptive, the soul nevertheless is able to know—and to know infallibly—the immutable, the essential, the Forms that exist separated from the phenomenal. Secondly, a universal science that is eternally true is possible.

In turning to Plato's later dialogues, it is surprising that so little attention is paid in them to the Forms. The most important epistemological study among them, the *Theatetus* (to be considered later in *IV. Empiricist orientation: Classical philosophers*), is an examination of sensory knowledge and of belief that manages to carry this out without once referring explicitly to the Forms. The *Philebus* and *Timaeus* have only certain comparatively brief references to them. The *Sophist* also fails to provide a full discussion of Forms; and what is most interesting is that, in it, Plato argues that "change, life, soul, and understanding" are real along with the Forms. The one dialogue of this latter period that deals at length with the Forms is the *Parmenides*, in which the ancient monist Parmenides takes the young Socrates to task and is critical of his theory of Forms. The purpose of the dialogue is puzzling; though it is sometimes thought that Plato here repudiates his earlier doctrine of Forms, this is not the generally accepted view. Instead, the dialogue may well express some of Plato's doubts about the adequacy of his earlier views on a crucial point—the relationship between the Forms and the particulars that participate in the Forms. Possibly it may express, too, his doubts about the ontological status of the Forms and of the relations that the Forms have to one another.

What is important is Plato's statement of Rationalism. The senses do not reveal the true structure of the world, he holds, but reason reveals it; consequently rational knowledge must be clearly distinguished from sensory awareness. These are quite distinct faculties and their objects are probably distinct as well. Knowledge of the objects that reason reveals is presupposed in all other knowledge. The theory of Forms thus aimed at providing a Rationalist foundation for any subsequent epistemology. Further, it provided ontology (the study of Being) with the permanent and immutable (in contrast to the mere flux of the followers of the Pre-Socratic philosopher Heracleitus) and morality with absolute standards (in contrast to the subjectivity of the Sophists, private teachers of success).

Categories, nature, and reason in Aristotle. Aristotle qualified Plato's Rationalism but did not reject it. He was critical of the Platonic view that knowledge is a universal system deducible from a principle, such as that of the Form of the Good. However excellent such a deductive universal science may appear in theory, Aristotle saw that in practice it transcends human capabilities; when human knowledge is considered as it is, it is clearly not Plato's universal science, and his epistemology is erroneous because the theory of Forms on which it rests is erroneous. In his *Ethics* and *Metaphysics,* Aristotle attacked the concept of a Form. Plato, he held, thinks of it as a separate existence, an individual. But, if the Form man is an individual existent, it presumably has something in common with Socrates; but this common element points to a further Form, the third man, and this begins an infinite regress (a fourth man, a fifth man, . . .).

Criticism of Plato's transcendent Forms

Aristotle held, instead, that the things of the world are individual existences having qualities. Though each individual is a substance separate from every other, individuals may have qualities in common. Yet, if two substances have a common quality, this in no way justifies the assertion that a Form of that quality exists. In Aristotle's opinion this theory is false and misleading, for the quality—admittedly common and admittedly as real as the things sharing it (though not particular, as they are) —exists as a quality of both and possibly of many other things. It does not exist as a self-subsistent entity, and there is no Good in the Platonic sense, though many things are good.

Nor, finally, did Plato succeed in making clear the relations between the Forms. Aristotle rejected the view that there is a genus, such as Being or Good, which contains all other Forms as species within it or which has as species substance, quality, quantity, and relation. Aristotle held that the latter are what he called categories and listed. What exists may be a substance, a quality, or a quantity, and what has being may exist in any of these senses. But there is, for Aristotle, nothing that exists that is all of these things, that is to say, Being; a category is not a species of the genus Being.

In these respects, then, Aristotle rejected certain aspects of Plato's Rationalism, but he nonetheless retained Rationalism itself and reaffirmed it, holding that the world is rationally ordered (though there is a place for chance in it). God is its unmoved mover. Because God, however, is wholly self-contemplative, it is nature rather than God that controls the growth of the world, a nature that "does nothing in vain" but always works for an end.

There are difficulties in this account of the function of nature. It is not clear, for example, that nature proceeds rationally; Aristotle thought that conscious reason is not found at any level of life lower than man. In the *Ethics* a high value is set on reason, and its use in contemplation is said to be man's deepest happiness. It is "the best thing in us, for even if it be small in bulk, in power and worth it surpasses everything." Aristotle followed Plato in ascribing the adjective divine to reason. His fullest account of it is in *De anima* (*On the Soul*), in which his psychology is set forth. A man's soul, he wrote, is to his body as axeness is to axe; it is that which realizes the body's potentiality. Like other living things, men learn how to find nourishment; they reproduce themselves; they see, imagine, desire, and seek. But man, too, can reflect and think, can affirm that a predicate pertains to a subject or deduce one statement from another. Human beings thus possess intelligence and the power of reason (*nous*). Insofar as it concerns itself with material provided by sensory experience and imagination, he held, reason itself partakes of the passivity of these faculties.

Reason as divine: "the best thing in us"

Man's rationality, however, reflects also the presence of active, as opposed to passive, reason. Active reason does not proceed mediately, through judgment and deduction, which are fallible; it is direct knowledge. Being wholly free from the affection of the material and in no way dispositional, active reason owes nothing to the development into which it momentarily enters and which it illuminates; it remains, instead, what it is essentially, immortal and eternal. It would appear from this (the passage is difficult to interpret) that Aristotle—in spite of his emphatic rejection of the theory that knowledge of transcendent Forms is essential for the attainment of truth—nonetheless concluded that man gains the final truth only when an element enters into the knowing process that has not appeared previously in that process; that which is no development of it but something itself wholly transcendent, eternal, and infallible. This is active reason. By it man knows such basic principles as that of noncontradiction.

Later Greek and Roman Rationalism. There are Rationalist elements in extant fragments from the Stoics, Epicureans, and Skeptics, the most notable writers of which were Zeno of Citium, Epicurus, Chrysippus, Poseidonius, Carneades, and Aenesidemus. All of these (with the possible exception of Poseidonius) were Materialists; yet the Stoics, in particular, freely introduced Rationalist elements (which could not always be made consistent with their Materialism) into their philosophies. Even the Skeptics, paradoxically, employed rational arguments against Rationalism.

Finally, reference must also be made to Plotinus, the foremost Neoplatonist philosopher, who was a Rationalist in the respect that he paid to *nous.* In Plotinus' view, *nous* is the wisdom in the universe and the first emanation of the One, which is supreme. Through *nous* the world is illumined throughout all stages of its hierarchy. These stages consist in the One, *nous,* soul, soul-in-body, matter. Man, who is soul-in-body, can strive by rational means to understand what is above him; he may grasp the rationality of the world. Yet he cannot take the final step by reason alone; God is the One; God is not an object standing over against a knower, and men cannot be such knowers. The final step is not reasoning to God nor even intuiting him; it is union with him. Plotinus' philosophy thus ends in a mysticism that rests on Platonic Rationalism.

Plotinus' *nous*

Rationalist elements in Scholasticism. The Scholastics, as the philosophers of medieval Christendom were called, are characterized by their outstanding confidence in reasoning and are sometimes criticized for having overemphasized the importance of sheer deductive argument and of subtle analysis in philosophy. Yet their confidence in reasoning and argument does not of itself prove them to have been Rationalists, except in a superficial sense. As has been seen, Plato was a Rationalist not in stressing the importance of deductive argument but in his doctrine of eternal Forms apprehended by the infallible grasp of *nous* (rational intuition); and Aristotle, who rejected the Forms as separate, eternal entities, nevertheless accepted and retained the notion of a supreme intuitive faculty essential to knowledge.

In the centuries that followed, there was considerable discussion of the celebrated account of active and passive *nous* in Aristotle's *De anima;* in the teaching (in the 11th and 12th centuries) of the great Arab-language philosophers Avicenna and Averroës, for instance, some part of the separatedness of the Platonic Forms was brushed off onto Aristotle's *nous.* As stated above, Plotinus thought of *nous* as separate and, while not deifying it, made it the first emanation from the One. The Arabs, too—and, after them, Siger of Brabant, of the secular faculty at Paris—tended to speak of *intellectus* not as a faculty in the human mind but as a separate entity, in which men participate, so that it is one in all men. In the ensuing (13th) century, however, St. Thomas Aquinas rejected this doctrine forcibly. To accept it, he argued, is to make impossible a coherent account of the intellectual lives of men in view of the intellectual differences between them; it is to deny man's individuality and so his moral responsibility; and it is to impugn his status as "master of his own operations." Though Aquinas rejected this influential doctrine, he in no way rejected Aristotle's Rationalism in so far as this (along with Plato's) consists in regarding the intellect as the supreme faculty in knowing.

The works of Aquinas best reveal the character of Scholastic Rationalism. The soul, he held, is "the first principle of life in those things which live" and shows itself in two aspects, viz., knowledge and movement. In man's case the

Thomas Aquinas' view of the soul

soul organizes the life of the body, and soul-in-body possesses not only sensitive and nutritive powers but also intellectual powers. Intellect, being one of the soul's powers, is not the essence of the individual human soul, but neither is it the same in all men. The intellectual principle is multiplied according to the number of bodies. Man is the lowest of intellectual beings, as contrasted with angels and God, and his intellect is described as "potentiality with regard to things intelligible." But it is not mere potentiality, for Aquinas accepted Aristotle's view that the human soul has, too, its active *nous:* human intellect is able to participate in the superior intellect of God and so man is illumined and things are made intelligible. Intellect, wherever it is found, is concerned with the universal and general. In perfect intelligences, these universals and the relations between them are all grasped directly, but man "advances from one thing understood to another" through discursive reasoning. Nonetheless, both the intuition and the reasoning are intellectual, though reasoning has a certain measure of imperfection as compared with intuiting. Men, however, are not wholly deprived of intuitive knowledge since they can begin with principles, such as that the whole is greater than the part, which come to man *naturaliter*—*i.e.*, "everyone knows them."

Not that these principles are known innately; but, since man is intelligent, they are from the first present "in potential." Man needs the occasion to activate what is there. His mind "is at first like a clean tablet on which nothing is written": but then he experiences the sensible; and, in consequence, what is all along present potentially in his intelligent life is now actualized, and he gains understanding. "With us to understand is to be passive." Bodily sensations provide the occasion, and the person, who is soul as well as body—*i.e.*, intellectual as well as sensitive—is illumined. Aquinas did not adopt the Platonic view that sensation and intellect are alien to one another in man's case. On the contrary, it is through sensory experience that the human intellect comes to understand, and it is to the soul's advantage that it is united with the body. Man's knowledge begins with sense experience, and it can do so because the sensory phantasma (or presentations of the mind) can be illuminated by active intellect, which then by its power abstracts intelligible species or concepts from them. The senses determine the particular, but intellect then receives the universal. Having received it, however, the human intellect—because of its lowly grade—is not powerful enough to gain immediate and full understanding, but it gains enough to proceed mediately by discursive reasoning.

So Aquinas demonstrates the necessity of sensory experience as providing particular sense images and of intellect as illuminating the sensory so as to abstract the universal. Just as in Aristotle, there are thus two aspects to human intellect: (1) the actualizing of the potential, which is the work of intellect as active, and (2) the passive reception of understanding, passive intellect. Aquinas made sure, however, that his own theory of knowledge, in spite of its recognition of the necessity of sensory experience, is no sensualism but is Rationalist in its recognition that knowledge is possible only on the possession of rational powers. Of all the Scholastics, Aquinas was thus the most like Aristotle in his epistemology, and he shared in his Rationalism.

The work of Duns Scotus and William of Ockham

The fortunes of Rationalism in Scholastic thought after the death of Aquinas can be traced in the philosophies of two scholars. At the turn of the 14th century, Duns Scotus, the great British Scholastic, sought to make clearer the character of a truly rational knowledge and maintained that arguments from effects to causes (*e.g.*, from the existence of the world to the existence of God) never provide conclusive proof. Man knows of God's existence through revelation; he can have no a priori proof—the only kind that, in Scotus' view, would be a true rational demonstration. William of Ockham, trained as an Oxford Franciscan, developed the same theme in the mid-14th century. Like Scotus he had no doubts about revelation and the faith, but he carried skepticism about Aristotle's and Aquinas' Rationalism well beyond Scotus. He asked whether the intelligible species are anything other than the philosopher's own mental creations. He even suggested that *intellectus,* whether active or passive, might be nothing more than an abstraction thought to be a real entity. Entities, said Ockham, should not be unnecessarily multiplied.

17th-century Rationalism. Descartes, Spinoza, and Leibniz—sometimes known as "the continental Rationalists"—mark the climax of precritical Rationalism.

Cartesian Rationalism. René Descartes is held to have been the father of modern Rationalism. His Rationalism lies in two features of his teaching, presented in his *Discours de la méthode* (1637; *Discourse on Method,* 1950): first, in what he says about method and, second, in his account of clear and distinct knowledge. Having expressed dissatisfaction with his education, he decided to subject everything that he had hitherto accepted as true to a methodical doubt in order to build a surer science of God, man, and nature. His main interest in the *Discourse,* it is clear, was in the latter, the science of nature. (His particular purpose was "to deduce rules in medicine of greater certainty than those at present in use.") Descartes, himself an expert mathematician, attributed the success of mathematicians in his day to the method that they employed. Mathematicians begin with the simplest truths, the foundational axioms, and pass step-by-step to knowledge of the more complex. He proposed to use "all that is best both in geometrical analysis and in algebra" to solve the problems of natural science. Each of these problems was to be divided into the simplest possible parts; and, beginning with these simples, by chains of easy reasonings, satisfactory conclusions could be reached. This meant, he admitted, assuming a specific order to exist in the natural world, although one cannot be sure that it does exist there. The aim is to project mathematical order into the physical world so as to enable the inquirer to understand it rationally. In every case the investigator should also check each link in the chain by careful enumerations and reviews. This procedure is rational in a specific way, for Descartes sought not merely any order, as all Rationalists do, but an order that is strictly mathematical.

Descartes' reliance on the mathematical method

Of fundamental importance to his whole epistemology is another rule:

> To accept nothing as true which I do not know to be such clearly (*évidemment*) that is, carefully to avoid precipitancy and prejudice and to comprise nothing more in my judgments than what presents itself so clearly and so distinctly to my mind, that I have no ground whatsoever for holding it in doubt.

What is clear is "present and manifest to an attentive mind," and what is distinct is "precise and different from all other objects." The mind grasps the clear and distinct as infallibly true, so that an intuition of this order is the irrefutable answer to Skepticism. Descartes held that "*intuitus*" is

Descartes' notion of clear and distinct knowledge

> not the fluctuating testimony of the sense, nor the misleading judgment of a wrongly combining imagination, but the pure intellectual cognising (*conceptum*) of which an unclouded and attentive mind is capable; a cognising so ready and so distinct that we are wholly freed from doubt about that which we thus intellectually apprehend.

He who seeks for truth must not hope to find it in sense perception—he must "detach his mind" from the senses—nor again in blundering imagination but in a pure intellectual apprehension of infallible truth resistant to doubt. Here, then, at the opening of modern philosophy, is a definitive assertion of man's power to know indubitably by pure intellect, entirely by the light of reason.

Later, Descartes would seem to qualify the absoluteness and finality of *intuitus,* for he appeared to appeal to God's veracity as the final guarantee of the truth of what is known clearly and distinctly. Inasmuch as his argument—both to his own existence from his consciousness that he thinks (*Cogito, ergo sum*) and subsequently to God's existence—rests on intuition, it has been held that he is here involved in a vicious circle. His defenders, however, have held that no such circle is involved, that Descartes was pointing to the source of all man's powers in

God and at the same time to his own failures, particularly his failures of memory. The failure, in some views, applies to the occasions on which he fails to intuit clearly and distinctly; for, whenever he does so intuit, in spite of his general fallibility, he attains infallible knowledge. There is, further, a relation between *intuitus* and deduction Descartes speaks of both as part of the intellectual faculty of knowledge, which knows and never fails to know. Yet, Descartes has to admit that deducton is not as certain as intuition, for it is not simple. Intuition, is simple as sheer apprehension and also in its object. It can only apprehend "the simple nature," for the latter alone is clear and distinct. Deduction, on the other hand, is complex. Yet, it too, being intellectual, can give man the truth, as long as he does not *will* to err.

But the problem, then, is how to relate deduction to the intuitive apprehension of simple truth—which is what, in Descartes's view, knowledge essentially is. Deduction is mediate knowledge of the complex and can be knowing in the strict sense, Descartes argues, because each implication in the deduction is intuited; the implication itself must be "a simple nature." Yet, it cannot be the sheer simple of Descartes's sheer intuition. It must be simple in the sense of a "simple relation." But this raises two questions: (1) whether this relation is simple in the sense required and (2) whether, if deduction is intellectual, in this narrow sense, the Cartesian deduction would not have to be confined to the reasoning of pure mathematics and whether, in particular, inferences about the natural world—which are neither simple nor clear and distinct—could ever be *deductio*. This is to ask, in other words, whether deductive knowledge is always knowledge of the logically possible rather than of what actually is. It would appear that there remain difficulties in the account of deduction that Descartes provided.

Subsequent continental Rationalism. If this were a history of Rationalism, it would be necessary to add here extensive accounts of the 17th-century philosophies of Benedict de Spinoza and Gottfried Leibniz.

Spinoza's use of the mathematical approach

Spinoza, like Descartes, emphasized the importance of proceeding in a strictly orderly manner. The order to be followed is that of mathematics, as reflected in the title of his famous work *Ethica in Ordine Geometrico Demonstrata* (completed 1675).

All true knowledge thus shares the necessity of mathematics; each step and every new conclusion must be demonstrated with logical necessity. But this is to assume a metaphysic: the world known must be a system that is rational and necessary, and, if it is such a system, it must be one. Spinoza thus speaks of it as God, or Substance. Men know it under two aspects—thought and extension—that are not to be regarded, however, as different entities (as in Descartes's account of mind and body) but as two attributes of the one entity. A change in the body is a change in the mind; if the body is affected by another body, there is a parallel change in the mind, and this is the explanation of sense perception. The mind has an "idea." If it happens to a person's mind as the result of a body affecting his body, the idea is not an adequate thought of his body or of the other body; it is confused. But people do have adequate ideas—*i.e.*, ideas such that, if one thinks any one of them, he will see that it has all of the intrinsic marks of a true idea. This is the stage of *ratio* as contrasted with sense perception. The object is known as self-evident, clear and distinct (as Descartes said), but as something, too, that cannot be methodically doubted. "Whoever has a true idea, at the same time knows that he has a true idea, nor can he doubt the truth of the matter." Or, "for the certainty of truth no other sign is necessary than to have a true idea." True ideas, too, are the same for all men; a common body of science that all men accept can be worked out. But Spinoza, having reached this point, does not find it complete as an account of human knowledge, for he thinks that beyond *ratio* is an intuitive knowledge of God, of the one Substance. It is in this intuition that man finds pure intellect, and out of this insight comes an "intellectual love of God" that is eternal.

Like Descartes and Spinoza, Leibniz wished to see the method of the mathematician applied to philosophical problems. For this purpose he demanded a new symbolic logic that would ease the burden of philosophical speculation and at the same time ensure accuracy. Given such a logic, philosophers could settle their differences with the ease of an accountant, merely by calculating. Leibniz realized that such a calculus would only be possible if the world were one system, but this did not mean that it would have to be one Substance as Spinoza thought. The world, Leibniz held, is a composite of a vast number of simples; each simple, or "monad," is a substance having its own qualities. Every monad is different from every other monad; it "has no windows by which anything may enter or go out." Any knowledge that it has, consequently, is innate and comes from within. It is the subject of its own predicates and is constantly changing; for it expresses (without observing) the changes of all other things, and this is its "perception." Though this is a kind of knowledge, it is confused and indistinct.

Leibniz' symbolic logic

There are, however, monads—and men are monads of this kind—that know eternal and necessary truths (their opposites being impossible). They have this knowledge because they are reflective and contemplate themselves. They are thus led to such truths as the principle of noncontradiction. Here, the knowledge is clear, distinct, adequate, and intuited and is the highest that a man can attain. But Leibniz saw that man is also aware of contingent happenings, or truths of fact, about which he makes statements that are true without being necessary. They do not occur without a reason, however, for there is a sufficient reason for them in God's will, insofar as God desires to bring about the best of an infinity of possible universes. Necessary truths, on the other hand, are not dependent on God's will but depend solely on his understanding. Because God chose this universe as the best, the whole of it is in harmony with itself. Insofar as man is rational and apprehends the necessary and eternal, he is a being capable of understanding some part of the universe and so of entering into a relationship with God.

CRITICAL RATIONALISM OF KANT

In the 18th century, Immanuel Kant, the founder of critical philosophy, was a Rationalist but a Rationalist with a difference. He had been trained in the school of Leibniz and his systematizer, Christian Wolff, and accepted their philosophic standpoint until middle life, when he became critical of what he termed their "dogmatic Rationalism." The *Kritik der reinen Vernunft* (1781; *Critique of Pure Reason*, 1929), Kant's chief work, was a sustained and penetrating examination of the claims that Rationalists had made for human reason with the rejection of many of them. Nonetheless, Kant remained a Rationalist.

Kant's criticism of dogmatic Rationalism

Kant rejected the view of Descartes, Spinoza, and Leibniz that the philosopher should adopt the methods of mathematics. To suppose that the problems of philosophy can be dealt with by these methods is, he thought, to deceive oneself; for, whereas the mathematician constructs his own concepts, defines for himself what a triangle is, sets down axioms, and draws chains of inferences with exactness, the philosopher deals with concepts of metaphysics, such as space, time, substance, and causality, or of morals or aesthetics and does not construct his concepts but has to wait on experience and then seek concepts that appear to explain it. Inevitably, therefore, the method of philosophy is different from that of mathematics. In the second place, Kant takes the doctrine of representative perception seriously. Sensory experience provides a phenomenal knowledge of things. Consequently, no universal statement about what is experienced is immediately applicable to the real world; it is "a representation of a representation." In the third place, in such a situation, any talk of calculating the universe seems naïve. Kant denies that rational analysis, of itself, can provide new knowledge of what exists, and it is idle to expect analytical demonstrations to establish the nature of what lies beyond immediate experience. They cannot, for instance, prove or disprove the being of God. Kant expressly criticized Leibniz for "intellectualizing appearances." Leibniz, he said, had spoken of sensations as con-

fused, feeble intellections not yet clarified into adequate ideas and had failed to realize that sensibility and understanding are "two sources of representations which, while quite different, can supply objectively valid judgments of things only *in conjunction* with each other."

Kant's total rejection of dogmatic Rationalism is the explanation of the curious arrangement of his *Critique*. At the outset he had divided the work into what he intended to be two main parts, viz., (1) the transcendental doctrine of elements and (2) the transcendental doctrine of method. In the actual composition, however, the latter turned out to be little more than an appendix dealing with the uses of reason and reporting certain positive uses of it on the practical side. In respect to the theoretical side, however, Kant was content to repeat the warning given in the transcendental dialectic that, whereas pure reason is adequate in mathematics, it cannot provide, independently of experience, knowledge of the real world.

Yet, in spite of what has just been said, Kant remained a Rationalist. More often than not his thought was conditioned by his Rationalist training, and his language was the language of the Leibniz–Wolff school. This complicates his argument, especially at those points at which he was moving away from this school. Certainly, this continued use of the language and procedures of the "dogmatists" would not of itself make Kant a Rationalist; but his comment on Leibniz, referred to above, is more revealing in the contrast it makes between Leibniz and John Locke, a British Empiricist. Leibniz had intellectualized sensibility just as Kant thought that Locke had sensualized intellectual concepts. Leibniz and the dogmatic Rationalists were wrong, Kant believed, in supposing that knowledge is gained by intellect or reason only and that sensation is a low, passive form of intellect, unclear and confused; they did not understand that human knowledge must involve the operation of two distinct faculties, sensibility and intellect. Nevertheless, as against what he took to be Locke's standpoint, Kant fully endorsed the Rationalist criticism. If no account of human knowledge that ignores empirical elements is adequate, equally no account of knowledge in purely empirical terms is adequate; for a rational element is present in all knowledge.

It would appear that, although experience is admittedly a source of information, elements that are not empirically given are already present in the simplest experiences, that a man's more elementary experiences of himself and of things around him, for instance, involve space and time; but space and time are not given. So, too, in the case of the more precise knowledge of the natural sciences, features are present that, in Kant's view, cannot be derived from sensibility; insofar as knowledge is scientific, its statements are true necessarily, and, being necessary, they are also universal and eternal. Kant assumed, without ever proving it, that space and time are not given empirically, and he further assumed that experience can never provide the universal and necessary. These are basic assumptions of Cartesian Rationalism, and Kant accepted them without question. It then follows that there are elements in all knowledge that are not empirical. Kant's main purpose in the *Critique* was to reveal these elements, and, insofar as this is the case, the *Critique* is predominantly a Rationalist statement, even if it rejects some part of the earlier Rationalism.

The synthetic a priori and the categories

Kant agreed that a priori elements enter into all human knowledge. But, whereas dogmatic Rationalism held that all a priori knowledge is analytic, Kant held that the most important part of it is synthetic—*i.e.*, it provides genuine additional knowledge. Kant did not deny the possibility of an a priori knowledge that is purely analytic in the Leibnizian sense, but he regarded a man's knowledge of himself and of the natural world as synthetic rather than analytic and yet as involving features not given in experience—that is, as a priori. Whatever is given in sensation becomes part of a system of unified experience; the occurrence of the system presupposes a "unity of apperception" transcending sense. Such apperception should not be regarded as the work of memory alone, and it is no mere disposition; it involves the judgment-making and statement-making function—that is, the logical function. It is a system thought of, for instance, in terms of substance, a thing that is, or in terms of quantity, quality, or relation.

> All the manifold, therefore, so far as it is given in a single empirical intuition is *determined* in respect of one of the logical foundations of judgment and is thereby brought into one consciousness. Now the *categories* are just these functions of judgment, in so far as they are employed in determination of the manifold of a given intuition. Consequently, the manifold in a given intuition is necessarily subject to the categories.

Kant's account of the categories is worked out at great length in the transcendental deduction of the categories. Deducing in this context means justifying, and what he seeks to justify is that the process of knowing, bringing the given manifold into one consciousness, is regulated by pure concepts of the understanding, not given in experience. Sometimes the suggestion is made that these categories are innate, sometimes that men possess them although they are never conscious of acquiring them; but always it is insisted that they are not derived from the senses. They are the contribution of intellect or reason or understanding to the totality that is human knowledge. The number of the categories is fixed, and Kant gives a list of them and in complicated arguments attempts to prove the necessity of each category.

Transcendental Idealism

Kant's stress on knowledge as a coherent system pertaining to one consciousness leads to Idealism; the absolute Idealism that developed out of this aspect of his philosophy will be considered below. But, when Kant himself referred to Idealism in the *Critique of Pure Reason*, he was speaking of something else, viz., of the ontology of immediate objects of perception.

In two important passages, one in the first edition only and the other in the second only, he reflected on the difficulties arising from the accounts given of sense perception by Descartes and the British Empiricists. Sense perception is of appearances only, which, it is supposed, are representations of physical objects; the physical objects represented are not directly seen. But whether or not they exist is a question, it may be argued, that cannot be answered. One is tempted to hold that nothing can be said about the existence or nonexistence of such objects. This is one form of Idealism, however, that Kant rejected. Nonetheless, he did not reject Idealism. He proposed, rather, to give significance to talk about a physical object by thinking of it not as a "thing-in-itself" beyond the veil of sense but as phenomenal. It is what appears, appearing always in accordance with empirical laws and with the principles of space and time. These are not laws and principles of things-in-themselves but of the empirically known, of "the actual." Such an Idealism, which Kant termed transcendental, he thought was consistent with his view that space and time and the categories are a priori, for the transcendentals can apply to the actual physical world only if that world is phenomenal. They could not apply to things-in-themselves.

Subsequent reflection on this problem, however, led him to introduce a new theory in the second edition of the *Critique*. It is not only true that man does experience physical objects (though again not as things-in-themselves) in sense perception, but it is also true that such an experience is necessary if he is ever to be conscious of his own existence. For this is a consciousness of a being in time and presupposes whatever is necessary for experience of such a being. What is presupposed is perception of something permanent, and he found such an experience in his perception of a physical object or thing outside himself. Thus, he cannot know that he exists if he does not also already know that physical things having a measure of permanence exist.

POST-KANTIAN RATIONALISM

Rationalism of absolute Idealism. Absolute Idealism was first set forth explicitly and fully by Hegel, whose first published work, entitled *Differenz des Fichte'schen und Schelling'schen Systems der Philosophie* (1801), reveals the sources of his Idealism. Johann Fichte, an ethi-

cal Idealist, had developed Kant's notion of the ego, the conscious, free, creative moral agent, and applied it beyond the realm of morality to metaphysics and epistemology. The universe itself is to be explained in terms of absolute creative ego, and consciousness is to be understood in the same terms. Knowing is creating rather than discovering. Friedrich von Schelling, an aesthetic Idealist, on the other hand, had concentrated on the unity and systematic identity of consciousness that he thought was implicit in Kant's doctrines, particularly the doctrine of the unity of apperception. Schelling argued that it involves an identity of being, so that subject and object, the knower and nature, that which is other than him, are all one. Hegel built his system on these foundations.

The system of G.W.F. Hegel

To Hegel, the fundamental reality is not matter but mind, of which matter is one manifestation. Absolute mind is immanent, dynamic, and developing, the development being orderly and tending to ever-increasing complexity. The order is dialectical. The three-fold dialectical argument begins with a thesis, opposite which stands an antithesis; and out of both emerges a synthesis. It is not merely a method of argument or thought but is itself the method of the development of the universe—and this fact, indeed, explains its great usefulness in thought. Thus, the *Encyklopädie* (1817), the fullest statement of Hegel's philosophy, is set out in three parts: (1) the science of the idea in and for itself—*i.e.*, logic; (2) the science of the idea in its otherness—*i.e.*, the philosophy of nature; and (3) the science of the idea returning to itself out of its otherness—the philosophy of mind.

Hegel's is a logic very different from that of the textbooks of his day. The latter dealt with fixed, stereotyped, and rigid methods of reasoning, so abstract as to be in the extreme case almost irrelevant to being. A new logic, he claimed, is needed, not of reasoning but of reason. "The battle of reason is the struggle to break up the rigidity to which the understanding has reduced everything." Hence, much of the "Logic" of the *Encyklopädie* (its first part) is a discussion of epistemological problems, leading up to a final part that is a study of the idea itself—as it is rational but also as it has values, is free, and is the good. The second part, the "Philosophy of Nature," proceeds by the same sort of dialectic through the study of narrow mechanics and physics to organic nature; and the third part, the "Philosophy of the Spirit," begins with subjective mind, the sensitive nutritive organic consciousness operating in the world of nature, and proceeds through the objective mind of the person in society to absolute mind revealed in the deepest consciousness of the world in art, religion, and philosophy. These are themes that Hegel also elaborated in his other works, for instance, in the *Phänomenologie des Geistes* (1807; *Phenomenology of Mind*, 1910). It is seen that, in a negative sense, Hegel was opposing the formalism of the past while setting out positively a theory of development and evolution, both metaphysical and epistemological, which deeply influenced the thought of the 19th century. His faith, in the last resort, is a faith in reason; his evolutionary theory in no way rests on change. Reality works out its own development rationally. The foundation of his philosophy (and that of his followers) rested on his celebrated statement, "What is rational is real, and what is real is rational."

Absolute Idealism was a powerful force in the German universities in the mid-19th century, although (apart from Hegel) the movement yielded no outstanding thinkers; possibly the most important was Ludwig Feuerbach, a humanizer of theology, who gave a strongly naturalistic turn to the Hegelian teaching and provided some of the foundations of the Marxist philosophy. Outside Germany, absolute Idealism flourished at the turn of the 20th century in Britain in the writings of F.H. Bradley and others, in America in those of Josiah Royce, and, somewhat later, in Italy in Benedetto Croce.

The system of F.H. Bradley

Bradley did not regard his philosophy as Hegelian; he was critical of Hegel and was doubtful, indeed skeptical, about many points in his philosophy. Nevertheless, the influence of Hegel is apparent everywhere in his writings. Metaphysics, logic, psychology, and epistemology are, in his view, all one inquiry. Human knowledge is what it is because the universe, of which the thinking man is a part, is what it is—that is to say, a rational system, coherent and self-fulfilling. Accordingly, the criterion of successful thought is its systematic coherence; thinking is of relations, all of which are internal to the system. Advance in knowledge thus lies in the widening of systematic thought rather than in the discovery of isolated facts. At the same time, Bradley gave only qualified assent to the theory that knowing is creating; he thought it "a partial truth." Indeed, the statement that "man *makes* truth" is so erroneous, he thought, as to be misleading. What must be said, however, is that man's knowledge is participation in the Absolute's knowledge of itself. "The Reality," he explained, "was known always, and now [in me] its knowledge occurs. My contribution leaves it unincreased, and yet is indispensably requisite." That there is this human contribution to the totality of truth can, however, only be maintained if it be granted that there are degrees of truth, for no human knowledge can be complete and absolute in itself. Further, it is in terms of this incompleteness of knowledge (rather than of total ignorance) that human error is to be explained.

Realist Rationalism. Though Rationalism was supposed by many to have reached its definitive expression in absolute Idealism, there were certain Rationalist epistemologies that were not Idealist. Thus, contemporaneous with Bradley at Oxford, John Cook Wilson put forward a theory of knowledge that rested on a very close analysis of such concepts as knowledge, apprehension, judgment, statement, belief, thought, definition, inference, induction, and deduction. The members of the Cook Wilson school were critical both of Hegel and of Kant, finding their main inspiration in Plato and Aristotle, especially in the Platonic distinction between knowing and opining. Knowledge and belief differ in kind and not in degree, as the Idealists had taught. Both Cook Wilson and his follower H.A. Prichard insisted that knowledge is *sui generis*. A person knows that he knows, and he knows too that the experience of believing is a different experience. When he does know, he cannot then be in error. Thus, the epistemology of this school rests finally on the assertion of infallible knowing and is comparable in this respect to the epistemologies of Plato, of Aristotle, and indeed of Descartes, insofar as Descartes rested infallibility on the nature of the knowing itself rather than on the fact that God is not a deceiver. This Oxford school was in this respect essentially Rationalist but not Idealist.

Cook Wilson and the Oxford school

It can be said, too, of the most successful and most influential critic of British Idealism, G.E. Moore, that, though his "Refutation of Idealism" (1903) was the main factor in the decline of that school, the common-sense intuitionism of his writings ranks him still among the Rationalists. Indeed, a long list of post-Hegelian philosophers who rejected absolute Idealism and yet were Rationalists could be drawn up. Only two further instances are cited here. Prior to World War II, Edmund Husserl, the founder of Phenomenology, propounded a philosophy very different from both absolute Idealism and the Realisms of his day. The very strong Rationalistic basis of his theory is sometimes neglected, though he insisted upon it throughout. Knowledge in the strict sense is infallible certainty; it is insight into the self-evident, self-evidence being the mark of all sound knowledge. Logical law, which is so known, is in no sense an empirically based probability. Again, in the later writings of the U.S. philosopher Brand Blanshard (born 1892), while his earlier Idealism is abated, his Rationalist philosophy is still emphatically and powerfully maintained.

ATTEMPTS TO TRANSCEND REASON

In concluding this section, reference must be made to claims that man can transcend reason to achieve a higher knowledge. Plato's account of knowledge of Being and Kant's of the thing-in-itself are sometimes interpreted in this way, though safer examples are to be found in the epistemologies of Plotinus and Spinoza. In the 3rd century AD, Plotinus, the foremost philosopher of Neoplatonism, spoke of (1) an irrational soul, that which senses and imagines without ever using the faculty of reasoning.

Plotinus' views of the soul

But he also held that man, through intellectual self-discipline, may become (2) a rational soul and have true understanding of himself and of the world. Moreover, above the rational is (3) a soul in which *nous* provides immediate insight. This is human reason at its best. There is still a higher knowledge than *nous*, however—if indeed it can be called knowledge—viz., the soul's knowledge of God. How can man experience God? He does not see him, for God is no object standing over against the knower. Plotinus was led to use the metaphor of contact. Man touches God, and the touch becomes union. Toward the close of the sixth book of the *Enneads*, Plotinus described the ecstasy of this knowledge that transcends reason. It is not to be interpreted, however, as a rejection of reason; it is the outcome of disciplined thought and intellectual struggle leading to intuitive knowledge.

Plotinus' account of man's knowledge of God found a modern counterpart in Spinoza's *Ethicsa*. For Spinoza, however, God is not "beyond being" but is Being. To know anything as it is, not in isolation but as it relates to and depends upon other things, is already to begin to know the infinite. It is to understand and have rational knowledge of the Substance that is. Yet, insofar as this is knowledge of the general and universal features of Substance, it cannot be the highest knowledge, for the highest must be an intuitive and nonabstract knowledge of Substance or God; and this involves feeling as well as reason. It is an "intellectual love of God." *Ratio* thus passes into a higher stage of knowledge that Spinoza named *"scientia intuitiva."*

Irrationalism

In such epistemologies as these, Rationalism is accepted and an effort made to complement it. But there are other epistemologies that are critical of it: human reason, it is held, works through abstraction and generalization and misses what is individual and concrete; its scope is thus limited, and it is blind to important epistemological features. For man does know what is individual and concretely real. This is a point emphasized at the turn of the 20th century by the French intuitionist Henri Bergson, who was not antirational but rejected the view that true and reliable knowledge is to be found only by closing the mind to all possible procedures other than the rational. The truth is that discursive intellectual understanding needs to be supplemented by what Bergson called intuition. For example, clock time, which human intelligence has brought into being, needs to be understood in terms of the underlying intuition of real time. Again, rational argument pointing to determination in human life is to be tested by the intuition of free will. Furthermore, the prophetic intuition that God is love is of greater significance in religion than any logical demonstrations about God's nature. Human intelligence needs the supplementation and possibly the correction provided by intuition.

On the other hand, a note of impatience with Rationalism, if not of bitterness toward it, was present in an earlier writer, the Danish Christian Søren Kierkegaard, who flourished in the mid-19th century and who in his *Either/Or* (1843) and his *Philosophical Fragments* (1844) argued that the life of reason dehumanizes man; the intellectual fails to commit himself, so that, in a sense, he himself never exists; a man has to choose, to take sides, in order to be, and the intellectual tends to stay on the fence. In the second place, the intellectual assumes that nothing can be true that is contrary to reason and so rules out the "absolute paradox" of religion, particularly of the Christian religion. This same charge had been made earlier (in the 17th century) by Blaise Pascal, a scientist and religious philosopher, and indeed by all who accept the view that knowledge rests not on reason but on a fundamental act of faith.

Opposition to the domination of human life by intellectual disciplines has come, too, from those who see danger in the influence of modern science. The Neo-Kantians Wilhelm Windelband and Heinrich Rickert in Germany, for instance, opposed the doctrine that the naturalism and positivism of the sciences provided a true view of human life and sought to set out a new life philosophy.

As a final point it is notable that much so-called anti-Rationalist criticism is directed rather against the "understanding" than the "reason" in Kant's sense of these two terms. And, as has been seen, Kant himself, and other Rationalists, were only too well aware of the defects of the understanding.

IV. Empiricist orientation

ANCIENT GREEK AND MEDIEVAL EMPIRICISM

Classical philosophers. Empiricist elements are discernible in the Pre-Socratics and in Plato and Aristotle.

Pre-Socratics. The early philosophers of Greece were curious about the nature of the external world; in particular, they sought to solve the problem whether the apparently different objects in it are ultimately composed of one material—for instance, of water, air, or fire. Their concern was with what exists and not with the knowledge of it or with the mind that knew. They took it for granted that their method was to be observation plus speculation on what was observed. They are sometimes said to have been Empiricists. But, if they were, they were not consciously so, and it is questionable whether the description is appropriate, particularly to the Pythagoreans and the Eleatics. Nevertheless, such accounts as remain of, for instance, the philosophy of Leucippus, whom Aristotle said was the first to put forward the atomic theory, suggest that his opposition to Parmenides' monist theory of being rested on empirical grounds. The evidence of the senses does not support Parmenides' theory, and by this criticism Leucippus adjudged it false and put forward in its stead a pluralistic atomic theory, asserting the existence of a void between the particles of reality. Sometime later, Leucippus' atomic theory was defended by Democritus, perhaps the greatest of the physical philosophers. By then, however, Protagoras, Socrates, and others were grappling with epistemological problems.

Democritus himself is reported as affirming that sensation is due to the passage of atoms from outside objects through the sense organs into the soul, which, like all else, is material and consists of atoms. Though images are left in the soul, they are inevitably distorted in the process—and so is the "knowledge" thus gained. The ancient Skeptic Sextus Empiricus reported him as saying: "Sweet and bitter, hot and cold, and colour exist by convention only; in reality atoms and the void exist." This would seem to mean that any knowledge based on the senses is likely to be unreliable because of the condition of the human body and of those things that impinge and press upon it. Yet, Democritus, apparently, wished to affirm that the atoms and the void are fully known. (Aristotle's criticism of this claim was that no successful account of the knowledge of objects can rest on a purely Materialist philosophy.) Though an evaluation of the exact teaching of Democritus is impossible in view of the fewness of the extant fragments, it is interesting to find doubts being expressed from the first about the cogency of "information" gained through "distorting" sensory media.

Theaetetus of Plato. In dealing with sense perception, the most significant work in classical literature is undoubtedly Plato's *Theaetetus*, and it is a mark of his genius that almost at the beginning of the discussion of this problem he should have produced so penetrating a study. The *Theaetetus* is divided into three parts: the first (151d–187a), the part to be considered here, examines the theory that sense perception is knowing, the second that true judgment is knowing, and the third that true judgment, with the reason (*logos*) for affirming it, is knowing. Each of these three theories is rejected. The mathematician Theaetetus, a leading personage of the dialogue, defends the view that sense perception (*aisthēsis*) is knowledge. By sense perception he means the perception of objects, particularly their visual perception. Things are as they appear to the observer. This thesis is put forward as the position of Protagoras, the Sophist, and Theaetetus and Socrates sympathize with it. If a man now sees a patch of yellow in front of him, it is beyond all doubt and infallible that there is a patch of yellow before him. But the question remains whether this is infallible knowledge. If the object of true knowledge has any

Whether sense perception is knowledge

permanence and is one and the same for all, then seeing the yellow patch is not an instance of true knowledge. A wind feels warm to one person but cold to another, and it may be possible to argue that sense perception, while in a sense infallible, is yet always relative. Heracleitus had held that whatever is known is in a process of flux and is never permanent. Just now, and for a particular observer now, the wind is warm. The wind and he himself who now feels the wind to be warm are both changing ceaselessly, but for the moment it must be granted that for him the wind is warm. Such sense perception could then be said to be infallible knowledge of the truth.

It has to be asked whether this account of knowledge can stand examination, whether any and every man is to be the measure of truth, and indeed whether living things other than man might also serve. The theory would seem to hold that, since pigs and baboons presumably have sense perceptions, a pig can be the measure of truth. Again, a distinction is made between wise and foolish men on the ground that the former are more likely to know the truth and less likely to lapse into falsehood, but this distinction would be meaningless if what every man experiences, however foolish the man, is invariably the truth. This would appear to assume that the statements of the inexpert are as true as those of the expert, that, if doctor and patient disagree about the latter's illness, both know the truth equally well. Even though it be granted that in sense perception each and every individual is in a sense infallible, it is still reasonable to ask if it can be supposed that this is true outside sense perception. Surely the infallibility of sensation is no infallible knowledge of the truth. Truth is permanent: once true always true. But, if all things are changing, then what men wish to know would be constantly changing: nothing would stay from one moment to the next to be known. Furthermore, the observer who knew a moment ago will be changing. If this is indeed a world of constant flux and nothing more is to be said, it is a fair question whether there can be any place within it for permanent truth.

Sensation, truth, and change

Plato sums up. It is said that perception is knowledge in the strict sense, infallible knowledge. A man sees the colour that he sees, and no error can enter. Yet, it is a question whether this is what is meant by knowledge. Seeing a shade of colour is a very different thing from knowing something about a physical object. The former is the product of one sense only—vision. The latter involves more than all of the special senses can give. It involves a knowledge of the being of objects, that they exist; of the difference between them; of likeness or unlikeness. Such knowledge is given not through the operation of one special sense but through the power of the mind itself, which reveals a truth that holds for the future as well as for the present, since it is permanent. Strictly speaking, seeing a shade of colour, smelling a smell, or hearing a sound, in spite of their infallibility, are not genuine instances of knowing. In Plato's view, to find true knowledge a man must apprehend the Forms.

Importance of sense perception in Aristotle. Aristotle shared Plato's Rationalism even though he rejected his theory of Forms; on the other hand, he did not share Plato's general mistrust of sense perception. Some of Aristotle's most original contributions to learning were made in the field of biology, the outcome of his own close observation of nature and of the seriousness with which he took the information that the senses provide. Moreover, his father was a physician of Ionian stock, and the Ionians prided themselves on the accuracy of their observations. Sense perception, Aristotle thought, provides the starting point of learning. To survive, all living things must have first, powers of nutrition, but, in addition, they must have, those of sensation so as to be aware of objects and, in particular, to be able to distinguish between them. Living things need sensory powers in order to select what is nutritious, but these powers, too, provide experience, which—in the human case—can be stored up, compared with other experiences, reflected upon, and used to understand the world. "Without sense-perception there can be no learning and no understanding," for there would be nothing to reason about in respect to nature. Aristotle conceived of sensation as one faculty that specifies itself in the various ways of the five senses. In addition, however, the sensory faculty perceives "common" sensibles (common to two or more of the senses)—*e.g.*, being one or many, being of a certain shape, being in movement or at rest. These are known in sense perception but not through any one, and only one, specific sense. Further, a person may see a colour and at the same time incidentally perceive a concomitant, "as when a certain white object is perceived as the son of Diares." Today such a perception is frequently contrasted with the bare sensation of the white patch and said to involve recognition. Aristotle clearly counted both the perception and recognition of the physical object as a part of the knowledge that the senses provide.

Biological approach to sense perception

Nevertheless, he recognized, too, that sense perception is inadequate. He emphasized that sense perception is knowledge of the particular—the particular taste or colour and also the particular thing or person or the particular event. It is knowledge of the here and now, though it is true that a person's remembering the same particulars occurring over and over again may lead to an expectation and a generalization—for instance, that, given a certain occurrence, then a certain other occurrence will always follow. Aristotle was aware of the part induction can play in yielding general knowledge, but such knowledge is not completely certain; it is not necessary and universal knowledge. Human beings are capable of a necessary and universal knowledge that is true not for this moment but eternally. Though sense perception never provides such knowledge, reason does—not only in providing mankind with the ways of procedure, particularly the syllogism, which makes demonstrated, necessary, and universal conclusions possible, but also by providing the fundamental laws upon which the demonstrations rest. Aristotle agrees with Plato that the highest field of human knowledge is one into which sense perception does not enter; the most to be expected of sense perception is that it leads to generalizations that can be argued about rationally. But Aristotle would add that any conclusions produced by such arguments, insofar as they apply to the natural world, can and should always be tested by appealing to sensory experience. In *De generatione animalium* he remarked, for instance, that, though theories about the generation of bees are many,

> the facts have not yet been sufficiently grasped; if ever they are, then the credit must be given rather to observation than to theories, and to theories only if what they affirm agrees with the observed facts.

Aristotle was as clear as any Empiricist that the conclusions of reasoning, if they are about the world, are to be verified or falsified by the evidence of the senses.

Post-Aristotelian Empiricism. A word may be added about the two principal post-Aristotelian schools, those of the Stoics and Epicureans, particularly in view of 17th-century assumptions that these schools founded a thoroughgoing Empiricism. Not all of the extant fragments confirm this view, particularly in the case of the Epicureans. It is noteworthy that, in one account of Epicurus' views on the infallibility of sense perception, he is said to have held that what is seen in hallucinations and in dreams is true. This would seem to suggest that, by the infallibility of the senses, he meant no more than Socrates did in the *Theaetetus*—that is, that, if one sees a blue patch, one is undeniably seeing a blue patch—even if it be seen in a hallucination. But this is very different from claiming that sense perception gives infallible knowledge of the world. Cicero complained, possibly unfairly, that Epicurus failed to give due attention to deductive and intuitive rational knowledge and suggested that this made it easier for him to magnify sense perception.

The Stoics and Epicureans

Whatever be said of Epicurus, however, the ancient fragments make it clear that the Stoics were confirmed Empiricists. They held that the senses provide the soul with the first material for thought, the sensible "presentations"; up to this point, the soul is like a sheet of white paper with nothing written upon it. But this, in the Stoic view, is not the only source of presentations and is not reliable. In sensation the soul gives its assent. For the soul,

though analogous to white paper in taking the sensory impressions, is yet not actively passive. On the contrary, it receives the sensory presentations, deliberates upon them, presents conceptual material of its own, and after deliberation recognizes and firmly grasps the truth. Sensation of itself cannot provide such knowledge. It is notable that, in developing an epistemology, the Stoics and Epicureans were further hindered by the necessity of explaining human knowledge in terms of a narrow atomistic Materialism.

Medieval philosophers. Up to the time of Albertus Magnus, in the 13th century, the task of philosophy was primarily to justify the Christian faith by rational argument. This curtailed the growth of natural science. Albertus, a scientist as well as a theologian, was the first influential thinker to insist that, whereas the authority in disputes on the faith was the theologian, he was not necessarily the authority in more mundane inquiries. If the question was one of medicine, one should turn to Hippocrates and to Galen; if of physics, to Aristotle. Information in physics, Albertus held, comes first from the senses, and the development of the natural sciences comes best through disciplined observation.

This lesson was not forgotten by his most distinguished pupil, St. Thomas Aquinas. In the natural sciences, Aquinas acknowledged the authority of Aristotle, and his thought followed closely that of Aristotle both in the latter's account of sense perception and of its role in knowledge. But he did not follow Aristotle blindly. Thus, in his commentary on Aristotle's *De anima*, he sometimes openly disagreed—for instance, in the examination of Aristotle's doctrine of incidental sense objects. He did not disapprove, however, of the Empiricist strain in Aristotle's approach to nature or of the view that human knowledge in this field begins with and rests upon sense experience.

Yet, oddly enough, real advances in the natural sciences came not from the Dominican Aristotelians of the Albertus–Aquinas school but from their critics, the Oxford Franciscan Platonists, of whom the most important figure was Roger Bacon, a 13th-century friar, who owed much to his teacher, the influential Robert Grosseteste. The explanation of the success of the Franciscans is simple but also profound: they were mathematicians; they believed that the development of the natural sciences could take place only by applying mathematics to the findings of sensory observation. Experimental science was in part disciplined observation but also in part applied mathematics. Bacon's own experiments were of no great importance, but he had the genius to see the right way to proceed.

The movement in the 14th century to liberate the natural sciences from dominance by theology was furthered by skepticism about the adequacy of reason in metaphysics. The view that the universal (or general) concept known by the intellect was the true object of knowledge was now questioned; the true object is the real, and the real is the particular and individual. Concrete "thisness," as Duns Scotus termed it, is not to be ignored. William of Ockham regarded knowledge of the individual existent through sensory intuition as the foundation of knowledge. He did not deny the need for abstraction in order to help judgment, but it is erroneous, in Ockham's view, to suppose that abstracted objects or conceptions contemplated by the mind exist outside the mind; universals belong to the mind's abstraction and conception, not to the real world. It followed from this that a strictly Rationalist theology, concerned with the concept of a divine being, could not positively assert the existence of the divine being, because the concept is a creation of the human mind. Man has, says Ockham, no intuition of God (as one can now intuit this white patch before him). The being of God is revealed; it is not known either by intuition or again by abstract thought; it is a matter of faith. On the other hand, the being of a particular natural object is known intuitively in sense perception, and this fact completely justifies the Empiricist approach to the natural sciences, as contrasted with that of the Rationalist. Such was the solution of the problem of man's knowledge of God and of nature that finally emerged from the medieval schools, and it was a solution that eased the way of the Empiricist.

MODERN AND RECENT EMPIRICISM

Central to the modern discussion of Empiricism are the contributions of John Locke, George Berkeley, and David Hume. But three other slightly earlier figures cannot be ignored, viz., Francis Bacon, Pierre Gassendi, and René Descartes.

Francis Bacon's attempt to provide a method for science

Early forerunners. Francis Bacon, at the turn of the 17th century, expressed optimism about modern science in his *Advancement of Learning* (1605), in which he stressed the need for more experimental work and less speculation. In the *Novum Organum* (1620) he attempted to set forth the complete method for the new science. The proper approach to nature, Bacon held, is Empiricist rather than Rationalist. This means that the procedure is inductive, passing from the observation of particulars to generalizations, and not deductive. But Bacon is critical of those Empiricists who think their task completed when they have jumped from observations to any sort of theory. It must be "a gradual and unbroken ascent" ultimately to the most general axioms by "dwelling duly and orderly" on the observed phenomena. True advance demands patience and the greatest of care in view of "the dullness, incompetency and deceptions of the senses." Bacon had some important insights. In discussing negative and affirmative instances, for example, he held that "in the establishment of any true axiom, the negative instance is the more forcible of the two." Yet, his occasional insights do not add up to a complete theory. What can be claimed for him is that he taught Empiricists to question their assumptions and their procedures while continuing to reject the mere speculation, divorced of reference to experience, of the Rationalists.

The work of Pierre Gassendi

A contemporary of Descartes and a reviver of Epicureanism, Pierre Gassendi was influential in his day in France and was not without influence elsewhere, particularly in England. His scientific contribution was limited, largely because of his lack of mathematical understanding. He was, indeed, suspicious of demands for complete mathematical certainty in the natural sciences, for the observations of nature and of life provide a foundation for probability only. "I live," he said, "from day to day, accepting nothing which goes beyond the limits of probability." His fame rested rather on his influential advocacy of a new metaphysic based on the Epicurean physics of atoms moving within a void. He advocated, too, the moral teaching of Epicurus and his epistemology. Gassendi was charged in his day with being, in his theory of knowledge, a sensationalist (who reduced experience to sensations). It is true that he believed that there is "nothing in the intellect" not derived from the senses and that he asserted, with Epicurus, that the senses never err (the Theaetetan infallibility of bare sensation). But this does not make Gassendi a sensationalist, for he also admitted readily that the senses are frequently deceptive and are then to be corrected by reason, "which is superior to sense."

In his lifetime Gassendi, though much the lesser man, was regarded as Descartes's rival. And, indeed, the standpoints of the two philosophers were very different. Descartes sought certainty in metaphysics, in physics, in psychology, and in morals and believed that man has the powers to establish it if he chooses, whereas Gassendi thought that probability based finally on sense experiences is sufficient for human needs.

Descartes, in his *Principia Philosophiae* (1644), gave an account of the nature of sensation, showing how neural movements affect the brain and, through it, the mind. The information thus provided is of great utility in a practical sense, but none of it is wholly reliable. It tends to be deceptive and creates deep prejudices that are inimical to a true knowledge of the world. Descartes emphatically rejected the Empiricist view that there is nothing in the intellect that was not first in the senses; it contradicts his own Rationalist account of knowledge. The most that sensation can do is to provide material for

thought; it can suggest, for instance, the notion of extension, which the intellect can then handle geometrically. It suggests too the existence of an external world of physical objects. Sometimes an object taken to be external is not in fact external, as in the case of illusions; but Descartes argued that doubts about the existence of an external world on this ground can be dissipated by noting that the perception of it is provided by a veracious Creator who has also provided man with a means of testing the validity of the perception—by the criterion of clear and distinct ideas. Thus, sensation is useful and, in a limited way, illuminating; but for full illumination one must turn to reason and intellect—for instance, to the mathematical analysis of the external world. Given this illumination, observation and experiment can be exceedingly valuable, but without it they do not provide an adequate basis for human knowledge.

Classical British Empiricists. The classical sources for the study of Empiricism are the writings of three British philosophers—John Locke, George Berkeley, and David Hume.

Influence of Gassendi: the "clean slate"

John Locke's new way of ideas. John Locke was said by Leibniz to have been "established in the system of Gassendi" and was viewed on the Continent in the early 18th century as the champion of the Gassendists. He was not so regarded at home, however, for the influence of other (English) movements upon him was too obvious. Leibniz clearly had in mind the conflict between Gassendi and Descartes and held that, in this conflict, Locke was on Gassendi's side. This judgment, however, needs qualification, for, though Locke was suspicious of Cartesian speculation and theories, yet his was not a simple choice between Gassendi and Descartes. Locke had cooperated with leading English scientists, such as Robert Boyle, a pioneering physicist and chemist, and Thomas Sydenham, an eminent physician, and had studied the work of Isaac Newton. Locke had learned from these scientists that the new science was not merely the product of a better empirical observation of nature; it rested, too, on a successful application of mathematical techniques. This latter element had not been emphasized in the teaching of Gassendi.

If this qualification be made, it is then safe to acknowledge Locke's debt to Gassendi. In the *Essay* he set out to consider "the original, certainty, and extent of human knowledge, together with the grounds and degrees of belief, opinion, and assent." In Locke's treatment of the origin of knowledge Gassendi's influence is very obvious. At the beginning, Locke affirmed, the mind is as "white paper, void of all characters." It lacks innate ideas, though it does possess innate powers. It is "a clean slate." Ideas come to be written upon it through sensation of the external world and reflection (introspection) of the internal world; "these two are the fountains of knowledge, from whence all the ideas we have, or can naturally have, do spring." Locke showed in Book I of the *Essay* how, as against the Cartesians, there are not innate ideas in the mind, and his main purpose in Book II was to establish that all of man's ideas originate in sensation or reflection. This does not mean that all ideas, say of the external world, are themselves sensed, for, from what is sensed, other ideas may be derived. It means instead that, if a man lacked all five senses, if he had no sensory experiences, he would have no knowledge of the external world; for such knowledge, sense perception is essential. And this is Empiricism.

Locke's view of the representational function of perception

Locke acknowledged that there are difficulties in the theory. The senses, he explained, "convey into the mind several distinct perceptions of things; and the mind is thus stocked with ideas." How is this statement to be interpreted? Is "having an idea" itself a knowing? When Locke spoke in Book IV of knowing with certainty, knowing in the strict sense, this is not to be identified with the having of ideas in sense perception but with intuiting that ideas are, or are not, related in certain ways. Nevertheless, he did find it necessary to admit a "sensitive" knowledge that is more than merely probable. A person may imagine, for instance, a cat with webbed feet, but he would not then claim that it existed; if he saw such a creature, however, he would make this claim. A man cannot deny that the sun that he now sees exists. Sense perception is a knowledge of existents, and Locke never thought otherwise; yet, this is difficult to accord with what he said about the representative function of sensory ideas.

The senses, he explains, "convey into the mind several distinct perceptions of things." There are three elements that should be distinguished: (1) the mind, (2) the physical thing, (3) the idea or perception. The mind in Locke's day was generally held to be a substance that has real existence and that is distinct from a physical substance; on the whole, Locke accepted this view, though he was not prepared to rule out the possibility that God may have "super-added" to man's material body "the faculty of thinking." This would necessitate that there exist two substances in the world, material and immaterial, but not that man is a dualism of two substances. The second element is the physical thing known—for instance, the table. It is necessary to distinguish, however, between the mediately and the immediately known; what is known in sense perception (the table) is known mediately. For what one is aware of immediately is the third element, the idea or perception—*e.g.*, the brown colour of the table or its smoothness. A complex of simple ideas represents the table, and it is through being immediately aware of this complex that one becomes mediately aware of the table. The purpose of this doctrine is to explain how, in seeing a table, one may sometimes see its colour to be brown and sometimes some other colour. Things are not always what they appear to be, but men, nonetheless, know them through their appearances. Locke did think that in the case of certain qualities, which he called primary—*e.g.*, solidity, being extended, or being in motion or at rest—the observer could be sure that the ideas resemble the real qualities; but this is not so in the case of ideas of secondary qualities—*e.g.*, colours, tastes, and smells. Yet, he did not doubt that men do know physical things through sense perception.

Berkeleian Idealism. There are acute difficulties in Locke's account of sense perception as was made clear by contemporary critics, one of whom, Bishop George Berkeley, an immaterialist of the early 18th century, accepted the view that knowledge of the world originates in the having of ideas in sense experience. But he did not accept Locke's next step—*i.e.*, that these ideas represent qualities or things in the external world; on the contrary, he regarded representationalism as a millstone around Locke's neck. An idea may possibly represent another idea: *a* could be like *b* (in which *a* and *b* are ideas), but *a* can never be like a material thing and cannot represent it.

Immaterialism

Berkeley rejected the widespread assumption that a material world exists beyond the veil of ideas, but, even were it true, Berkeley would still hold that having ideas would throw no light on its nature. Further, Locke's distinction between ideas of primary and ideas of secondary qualities does not help him, for the very same arguments that show that ideas of secondary qualities cannot be representations of the qualities of material things show, too, that ideas of the primary qualities cannot be such representations. Yet, for the Empiricist the origin of knowledge lies in the gaining of ideas; and it would appear to follow that the knower cannot really know his world, because, apparently, the only means of doing so is through the discredited representations. Berkeley's answer is that ideas do not represent a material world and that this answer need not disturb the would-be knower dependent upon ideas; for there *is* no material world. One reason among several that Berkeley had for adopting an immaterialist philosophy—and an important one for him—is that it finally solves the difficulties of the representationalist theory.

If, however, a person does adopt immaterialism, there is a problem of what is to be said in a positive way about ideas, since the theory that they are representations is rejected. Berkeley's solution lies in the adoption of Idealism, the theory that what exists and what is real is solely mind having ideas. Ideas exist as being perceived by a mind, their *esse* ("to be") is *percipi* ("to be perceived"). Berkeley

Idealism: "To be is to be perceived"

himself acknowledged that this system of Idealism might be criticized on the ground of its subjectivity. If a person claims that what is is what he perceives, then what is would be subject to his whim at any moment, and there would be no objectivity and no order in the world. But this, Berkeley replied, is to fail to grasp the nature of the process of having ideas. When a man opens his eyes in broad daylight, he is constrained to see what he does see. What he sees is not determined by him. In imaging or daydreaming, he is free to conjure up what idea he chooses, but, when he sees something, then what he sees is in no way dependent on his will. Nonetheless, the idea seen is dependent on mind, though clearly not on his mind; thus, when he sees it, it must be given to him by some universal mind able to produce all these ideas. They are certainly not of the viewer's willing; they are lively and distinct and come in such an order and with such a coherence that one soon gets used to their regularity. The rules followed are, in fact, the laws of nature, which are thus revealed to man not by reasoning nor by intuitively grasping an objective necessity but by experience. Knowing the world of nature is a process of becoming familiar with the established ways "wherein the mind we depend on excites in us the ideas of sense." In this way, one knows objective law, and Berkeleian Idealism is not to be equated with subjectivism.

Impressions in Hume. Whereas reflections on the difficulties in Locke's Empiricism helped to lead Berkeley to Idealism, they led the Scottish philosopher David Hume, of the ensuing generation, to Skepticism—though in both cases other factors were also at work. Berkeley had argued that, beginning with Lockean Empiricism, a coherent system of philosophy could be maintained but only if it were an Idealist system. Hume, however, could not accept the view that the physical object could be identified with an idea. He was also more conscious than Berkeley of the deep skepticism present in Locke's own philosophy. The 18th century was Rationalist; but paradoxically, it acknowledged Locke, the Empiricist, as the source of its Rationalism. Locke's appeal to the life of reason, as contrasted with that of emotion and passion, had been very effective. Furthermore, there were, in fact, Rationalist elements at the heart of his epistemology, since he thought man capable of absolutely certain knowledge by rational intuition and by it alone. Nonetheless, man's link with the existing physical world, he held, is through ideas, and the correctness of their representation is suspect, at least in the case of ideas of secondary qualities. As a consequence, Locke explicitly affirmed that man's knowledge of the physical world does not extend to that certainty that would permit it to be called scientific. Observing the phenomena gives useful hints and clues; but "certainty and demonstration," he held, "are things we must not, in these matters, pretend to." This is the skepticism present in Locke, a skepticism regarding the possibility of exact and certain knowledge of the natural world; and it is the skepticism that Hume developed.

Skepticism

Hume himself acknowledged that certainty is possible in a very limited field, viz., when the ideas are clear and necessary and the relations between them can be grasped by reason. Such is the case, for instance, in arithmetic and algebra. Others had argued that the causal principle that whatever begins to exist must have a cause of existence is also known rationally and that knowledge of it provides a base for the objective, necessary science of nature. Hume, in a brilliant argument, claimed to refute this view on Empiricist grounds.

To understand the refutation, however, a student first needs to understand Hume's earlier account of ideas. Knowledge begins with "impressions"—this is Hume's term—and impressions come with "a force and liveliness" that make them unique. "Ideas" are in turn "faint images of these" impressions. This blue colour is a sensed impression; the perceiver can later recall the colour, and then it is an idea. An impression and the corresponding idea can be simple or complex, and, in the case of a simple impression, say the taste of a pineapple, the corresponding idea exactly resembles the impression. If someone thus speaks of a simple idea, it is perfectly justifiable to ask him what simple impression it exactly resembles. If he cannot answer, his idea lacks clarity. In the same way, it is reasonable to ask to what simple impression the idea of a causal relation corresponds. In view of Hume's phenomenalism, one answer is impossible for him: he cannot speak of an impression of a physical thing exerting power and so causing change. Certain impressions may suggest the presence of a continuing existent, but such an existent is never experienced. This is not to say that it does not exist but that man cannot know it, for he is confined to the phenomenal. For him it is the perceptions that are real, and, since "nothing is ever present to the mind but perceptions," a knowledge of what exists beyond these is impossible. It is true that men talk of a physical object; but what they have in mind then is "a bundle of perceptions," though this bundle may recur so constantly in their experience that they tend to think of it as a continuing identity. This is a part of their experience; yet, it does not establish the existence of a continuing physical object in the world. Thus, it makes no sense to say that a person has an impression of one real thing acting on or affecting another.

Impressions and ideas

The philosopher must speak in terms of simple impressions. But, even when he does so in the present context, he is still baffled. For apparently no one has an impression of causing. The observer does not perceive p causing q to move away. Strictly speaking, the most that a person sees is p moving in q's direction; he next sees the contacting, and he then sees q move away. So far, there is no knowledge of a causal relation. But, when he sees this sequence occur frequently, by an association of ideas, which Hume finds to be an important principle of the imagination, he does tend to assume that p causes q to move away. The actual simple impressions present are (1) contiguity (p and q are contiguous) and (2) priority in time (p's movement being prior to q's). Though these impressions alone would not give the feeling of a causal relationship, these plus the regularity of the experience and the constancy of the conjunction could do so. The expectation of an event, given the prior conditions, is strong and grows in strength with the increase in experience, until, finally, the observer feels that one *must* cause the other. There is a necessity in the causal relation; yet, the necessity is not now objective. It is a subjective necessity only, a necessity for the imagination controlled by the association of ideas. The observer must believe that p causes q to move.

Causation and belief

The argument throws light, Hume thought, on the nature of belief. Belief is having a present *impression*, for instance of p moving, and associating with it an *idea* of q's moving, so that, before one sees q moving, one believes it will move. In this sense, one may be said to know the causal relation and only in this sense. Knowledge of cause and effect, therefore, is not a rational intuition nor a rational demonstration, but a belief determined by imagination and its laws. The much-prized sciences are thus not rational; they in no way rest on rational insights into the objective nature of the world. They rest, instead, on an experience of impressions in a certain constant order and on the beliefs that the imagination is induced to bring into being as a consequence.

Clearly, one cannot accept the Rationalist account of the knowledge of the causal relation and still remain an Empiricist. The Empiricist may concede the possibility of rational intuition, say, in mathematics but not in the natural sciences nor in psychology. The physical existent is what it is, but men do not know what sort of being it has. The theory of representative perception is wholly unnecessary and solves no problem, for what is phenomenal can never represent what is not phenomenal. The principle of causal relationship belongs to the phenomenal world and makes possible a science, but it is only a science of which the necessity is subjective. Finally, knowledge of substantival continuants—*i.e.*, of identities (whether physical objects or persons)—rests solely on the experience of a series of impressions gained on many occasions in a regular order and on the "bestowing of an identity" on the perceptions, thus "producing the fiction

of a continued existence." Whatever the nature of its true existence, a "physical existence" is experienced by man as a recurring series of impressions. Personal identity, too, is explained in the same way. The abiding personality, like the continued existence of external things, is an "illusion of the imagination"; yet, an illusion without which men could not live their lives.

Summary of classical Empiricism

Assessments and recent expressions of Empiricism. The half century from 1690 to 1740 thus witnessed a bold attack on the problems of epistemology. Starting from the dictum that "there is nothing in the intellect which was not previously in the senses" and taking this dictum seriously, conclusions were drawn that were both brilliant and disturbing. Locke interpreted it to mean that a complete reduction of all ideas into simple ideas was feasible and that this reduction would help to show that the most complex ideas had reference, however remote, to what really existed; for they were reducible to simple ideas, and these, he assumed, resembled the real things. Contradictions in sensory experience, however, caused him to doubt whether the ideas of secondary qualities did resemble the qualities of real things, but at least the ideas of primary qualities resembled them. Further, he failed to reduce all complex ideas—for instance, the idea of substance—into simple ideas. Berkeley contended that Locke in his theory of knowledge had attempted the impossible. Complete skepticism was inevitable if knowledge was held to depend on the establishment of correspondences between ideas in the mind and independent material things outside the mind, and the distinction between ideas of primary and ideas of secondary qualities could not save Locke. What was necessary, in Berkeley's opinion, was a revolutionary change of outlook; it was necessary to deny independent matter and assert that what existed consisted solely of mind and ideas. Hume agreed with Berkeley's diagnosis of Locke's failure but rejected the remedy that he proposed. Idealism was unacceptable. Human experience was of the phenomenal only, and no one could say what lay behind the veil of phenomena. Instead of Idealism, Hume offered a phenomenalist account of human knowledge that enabled one to speak significantly of continuing identities of things and persons and of changes in and between them, but it was a knowledge that arose from familiarity with the phenomena and from inductions based on this familiarity. As for sure knowledge of what exists other than phenomena, Hume admitted that he had none.

18th-century assessments. That these consequences of Empiricism were disturbing is clear from many of the writings of the time, two of which may be briefly mentioned. Richard Price, a British moralist, was quite emphatic on one point: that no account of sense perception can be given in terms of sensation alone; for such notions as substance, space, and duration, which are not given in sensation, show the presence of understanding, "the faculty that discerns truth." The understanding is itself "a spring of new ideas," and these ideas are made use of in sense perception and in the comparison and relating of ideas.

Assessments by Price, Reid, and Kant

Another—and fuller—examination of the Empiricists is that of Thomas Reid, founder of the Scottish commonsense school of philosophy. Reid criticized the failure of the Empiricists to distinguish between sensation and perceiving. Sensing is having an impression; but perception is

> first, some conception or notion of the object perceived; secondly, a strong and irresistable conviction and belief of its present existence; and thirdly, that this conviction and belief are immediate and not the effect of reasoning.

More than all he criticized Berkeley and Hume for allowing their speculations to lead them to positions (immaterialism and total Skepticism, respectively) that are obnoxious to common sense.

On the Continent, while recognition of Locke was widespread, few recognized the significance of Berkeley and Hume. Kant, however, did appreciate the importance of Hume's teaching in epistemology and found it necessary, as a consequence, to make radical changes in his Rationalism. In seeking to understand the world, the knower must first wait on experience for he is dependent upon sense-data. He does not construct the concepts that he thinks from nothing. And there is no possibility of his "calculating the universe" in the extreme Rationalist sense. On the other hand, no attempt to reduce intellectual concepts into sensibles can succeed. For, whereas human knowledge is admittedly a matter of ordering the manifold of the senses, it can only be ordered when principles are given that have been gained not in experience but rationally and a priori. Pure Rationalism of the Leibnizian kind and pure Empiricism of the Humean kind both fail. Kant attempted to frame a theory of knowledge that has both Rationalist and Empiricist elements, but he found himself encumbered by the difficulties of both schools. His partial acceptance of Empiricism, for instance, involved him in a representationalist interpretation of ideas, which contributed to his difficulties with an unknowable "thing-in-itself" and an inexperienceable "real self."

Culmination of sensationalist thought in Condillac and the Materialists

The emphasis on sensation in Locke, Berkeley, and Hume influenced various aspects of 18th-century life. It had a profound effect upon the ethical teaching of the age, leading through the moral-sense theory ultimately to Utilitarianism. On the more theoretical side, the extreme teaching of the French sensationalist Étienne Bonnot de Condillac, influential in France and Italy, is significant. He argued that the full life of the human mind emerges out of the power of sensing. Condillac is noted for having imagined a statue that is lifeless until one first superadds to it a sense of smell. If the statue is genuinely able to smell, then it will soon come to desire and to will; if, further, the sensation of touch is superadded, then will follow a consciousness of a real external world, and so on. Given sensation, all the rest of human experience follows. In England the Materialist Thomas Hobbes, a political philosopher, had argued a century earlier not merely that conscious life is a development of sensations but also that the explanation of sensation is a physical one, the affecting of physical organs by physical motions. David Hartley, an 18th-century physician and philosopher, explained the associationist theory, which Hume made central to his epistemology, in terms of brain vibrations, whereas his disciple, the clergyman Joseph Priestley, discoverer of oxygen, made clear the Materialist implications of this theory. These were emphasized, too, by several other French Materialists of the 18th century, one of whom used the analogy of digestion and spoke of the brain as secreting thought. Many of these writers were medical men; their plea, in effect, was for a purely empirical science of physiology, on the one hand, and of psychology, on the other. They found support in Condillac's sensationalism.

Empiricism and Positivism. Along with sensationalism, another offshoot of the Empiricist school was the Positivism of the 19th century. Condorcet had already expressed the spirit of the new movement, and his work influenced Auguste Comte, the founder of the Positivist school. Comte lectured privately in Paris in the 1830s and published his *Cours de philosophie positive* (1830–42), which set down the Positivist principles. He claimed that the development of science, on the one hand, and the Industrial Revolution, on the other, had given birth to a new culture that derived its principles neither from theological dogmatism nor from abstract metaphysics but from science. The methods that had worked so well in natural science needed to be applied to a new science, sociology. In Britain, Comte had an admirer in John Stuart Mill, whose Empiricism and Positivism are apparent in all of his writings, as they are, too, in those of his father, James Mill, and of Jeremy Bentham, known—as were the Mills—for his Utilitarian ethics. John Stuart Mill objected, however, to what he took to be an illiberal and doctrinaire feature of Comte's teaching, viz., that, once sociological laws are established by scientific methods, they are then—like laws of physics—not to be questioned. Mill objected on moral grounds and also on epistemological grounds, because the sciences, as he thought, provide men with beliefs only and never with absolute certainties. Mill accepted the fundamental epis-

Comte, J.S. Mill, and "empiriocriticism"

temological positions of Hume—*i.e.*, the rule of induction, the regular sequence theory of causality, the greater ontological significance of the particular, and phenomenalism. (Mill held that a physical object is a permanent possibility of sensation.)

Mill's doubts about Comte's teaching were shared by Positivists later in the century. Toward its end, in the German-speaking world, a school arose that was Positivist in outlook but critical of the earlier naïveties of the movement. These men questioned the earlier uncritical assumptions of Comte as to the reliability and universal applicability of scientific method. The school included in its ranks Karl Eugen Dühring, author of a Materialistic "philosophy of reality," and Richard Avenarius, the founder of "empiriocriticism"; but the most prominent figure was a physicist, Ernst Mach, at the University of Vienna. For Mach, who later taught philosophy, science is first and foremost a matter of economy, "the completest possible presentation of facts with the least possible expenditure of thought." The facts are known in experience; science is not fact-finding but fact relating; it does not claim to present the absolute truth about the world. Its so-called laws are not absolute but are at best "limitations of possibilities." Thus, the view of the early Positivists that strict adherence to scientific method guarantees truth was not shared by the later Positivists; yet, they were as emphatic as their predecessors had been that metaphysics is to be avoided. The outcome of their thinking was a fairly general Skepticism.

The Vienna Positivists

In the meantime, the pioneers of mathematical logic, Gottlob Frege, Bertrand Russell, and Alfred North Whitehead, had established that an element of necessity is present in mathematics and logic, and this helped a group of new Positivists in Vienna—among them Moritz Schlick, Rudolf Carnap, Friedrich Waismann, and Otto Neurath—to put forward a Positivism that rests on a sure logical basis. It was argued that some statements can be shown to be true or false by appeal to experience and others by appeal to logic and that both classes of statement are significant. But allegedly factual statements about objects beyond experience—*e.g.*, metaphysical and theological statements—cannot be held to have meaning. This new philosophy was advanced forcibly in *Language, Truth and Logic* (1936), by a British Positivist, A.J. Ayer. Many criticisms have been made of Logical Positivism, the most damaging being that of A.C. Ewing, a Cambridge philosopher, that it would appear to make any philosophic statement whatsoever (including the statement of Logical Positivism itself) meaningless. Moreover, granted that the necessity of logic and mathematics is that of tautology, which, however, involves exact synonymy, W.V. Quine, a U.S. logician, questioned the assumption of analysts and tautologists that there is such a thing as complete synonymy. Thirdly, contemporary Positivists disagree about what experiencing is, for some think of it as the observation of colours, tastes, and sounds, others as that of physical objects, and this ambiguity still remains to muddy the waters of Empiricist arguments.

Empiricism and Pragmatism. Finally, in discussing Empiricism and Positivism, reference must be made to Pragmatism, a movement that flourished, mainly in the United States, at the turn of the 20th century. Its leading figures were Charles Sanders Peirce, an engineer and logician, and William James, a psychologist and philosopher. James's charm, liveliness of style, and generosity of spirit made him the better known of the two. In his suspicion of speculative metaphysics, he was a Positivist; thinking is always a means to an end, he held, and the end is practice. He argued that "truth in our ideas means their power to 'work,' " and that "any idea upon which we can ride, so to speak . . . is true *instrumentally*." Replying to outraged critics in *The Meaning of Truth* (1909), he argued that this view does not imply subjectivity; that, on the contrary, his Pragmatism is throughout objective and empirical, for it rests on the awareness of "brute fact"—*e.g.*, "that this paper is white." But brute-fact knowledge is limited and is to be eked out by way of conceptual knowledge; the latter, however, is largely dispositional in character, involving "a procession of mental associates and motor consequences."

The epistemological features of Pragmatism were given a fuller and more adequate treatment in the highly original writings of Charles Sanders Peirce, a gifted logician and painstaking analyst whose interest in practice was less dominating than that of James. He was less concerned, too, with the reality of individuals and concrete particulars and not at all attracted by James's nominalist philosophy of "radical Empiricism." The link between the two lies in the adoption by both of the pragmatic method that Peirce and James, along with other friends, thought out together in Harvard in the early 1870s.

For Peirce, man's knowledge begins with what he observes through his senses and what he is told by others. He may hold tenaciously to what he has so gained. But doubts inevitably occur, and he finds his senses occasionally deceptive. The authority of others, particularly of those whom he deeply respects, may assuage these doubts, at least temporarily. Other philosophers have held that, if the doubts return, he must then appeal to his own powers of intellectual intuition. But Peirce denies that human knowledge is ever intuitive in this sense; all of the evidence shows that it proceeds in another way—not through intuition but through thinking.

Pragmatism and science

Many would agree that the thinking that has given the most satisfaction to mankind (in the sense of enabling man to ward off doubts and so to believe) is scientific thinking. Consequently, the best approach to the understanding of human knowledge is a study of the method and purpose of science. Scientific thinking, however, is conceptual thinking. Hence, some account must be given of the concept. This account provides the core of the Pragmatisms of both Peirce and James. Peirce defined Pragmatism as follows:

> Consider what effects that might conceivably have practical bearings, we conceive the object of our conception to have. Then, our conception of these effects is the whole of our conception of the object.

A person may conceive of a diamond—*i.e.*, he may think of what it does and conceivably can do. The concept, then, is the conception of these actual and conceivable effects. Thus, part of the concept of diamond is of an object that can scratch a glass surface. Scientific thinking, by the method of hypothesis (or "abduction"), originates new concepts and also verifies them in experience and thus enriches the conceptual content of scientific thought and establishes its truth or falsity. The truth is what survives the verification processes of science, not of one scientist but of all. "The opinion, which is fated to be ultimately agreed to by all who investigate, is what we mean by truth." The investigation by the community of scientific inquirers, "if continued long enough," is destined to attain truth. Such is the fundamental nature of science and so of human knowledge at its best. But this account inevitably provokes the question: "How long is long enough?" Peirce seems aware of the possible criticism and confesses that his philosophy is "fallibilist," since "perfect certitude and exactitude" can never be attained.

A century after its birth, no school of Pragmatism survives; but its influence, blended with that of Positivism, remains. John Dewey's instrumentalism owed much to James and Peirce, and their influence is felt, too, in other circles—*e.g.*, in the operationalist Perry Bridgman, and in operationalism generally, and in the conceptualistic Pragmatism of C.I. Lewis. It is notable, too, that there are elements of Pragmatism in W.V. Quine's *Word and Object* (1960) and in his papers.

V. Conceptual thinking

CONCEPTS

In the two schools of epistemology considered up to this point, the role of reason, on the one hand, and that of sense perception, on the other, have been stressed. It would be acknowledged by both schools, however, that there are other factors in the situation that need attention. Both, for instance, would acknowledge that thinking is one such factor. This is not reason; neither is it sense

experience, but it is, nonetheless, part of the whole cognitive experience. Admittedly, this statement would be disallowed by Hegelian Idealists, because their Rationalism admits no final distinction between thinking and knowing: thinking is the self-development of an ideal content, and this is knowing. The more usual view, however, is that thinking may lead to knowledge, may help to extend knowledge—though it need not do so. The question that arises is what "leading to knowledge" and "extending knowledge" signify in this context.

Both reason as intellectual apprehension and sense perception are intuitive, but thinking proceeds mediately through concepts. Thinking involves having concepts. This has been interpreted to mean that concepts are the objects of thinking. Locke took this view at the outset of modern epistemological speculation. For him, the term idea covered concepts, but it also covered the impressions of sensation—*e.g.*, the colour now sensed and the impression of feeling, for instance, of anger. He used the term, he said, "to stand for whatsoever is the object of the understanding when a man thinks." Thinking is directed to an object, and any such object is an idea. The view that the idea is the object of thinking, when widely applied, caused many difficulties in subsequent discussion. To guard against these difficulties, it is necessary, in the first place, not to confuse an impression with a concept and, in the second place, not to assume without question that a concept is an object of thought.

Whether concepts are impressions or objects of thought

A concept is not an impression. A person may now see a red patch, but this red patch is not a concept. Furthermore, this particular red patch, when remembered, is still not a concept. Usually one thinks of a concept as pertaining to a stage of mental activity higher than that of merely sensing or even remembering. It is something intellectual as involving language and as contrasted with the barely imaginative. Yet, it does not seem to be the case that having a concept invariably presupposes the ability to speak. It is true that the phrase having a concept may be defined as an experience possible only for a person who can speak, but this definition is arbitrary. A deaf mute who has never learned to speak may have seen many storks. But seeing this particular stork or remembering a particular stork is not having a concept. Yet, the deaf mute may think of storks, though none is now visible and though he is not now recalling in memory any particular stork. It is reasonable, then, to suppose that the deaf mute could have the concept though he has no language. It is not unusual to use the word concept in this way, and anyone who does so is implicitly rejecting the view that all concepts are necessarily verbal.

But most concepts are verbal. This statement requires interpretation as to whether it signifies that the concept is the object of conceptual thinking and that the word is the concept's name. Locke seems to say something of the kind. The concept (for Locke, "the general idea") that is the object of thinking has a name, viz., the general word. Here, two questions arise. The first is how the name functions. Presumably it functions somewhat as a proper name, designating the object; but this is surely wrong. The second is whether it is correct to speak of the concept at all as an object. It is admittedly not an object in the sense in which this table is an object, for it is in the mind; it is an internal accusative, what the thought is directed to within the mind. One can immediately object, however, that no one, in his thinking, is ever conscious of the existence of such an inner object or accusative. To this claim it may be replied that it must, nonetheless, be there. It is argued, for instance, that, when a person thinks of a transcendent object, he must be thinking of a concept, since the object transcends all experience. Or, again, when he translates the English word liberty into the German *Freiheit*, there exists the concept as well as the two words. In this view, there is a world of material existences and also a world of psychological occurrences; but, in addition, there is a third world, that of concepts existing as objects of the mind.

If it be felt that this multiplication of worlds is to be condemned, an alternative theory must be sought. One such alternative is to regard the concept not as a mental entity but rather as a capacity. This view stems from David Hume's account of abstract ideas, in which he suggested that the abstract idea (as contrasted with impressions and simple and compound ideas) should be thought of not as an entity in the mind but as a disposition of the mind, or, in his own words, as a propensity. This suggestion provides the basis for the alternative theory. The philosopher should speak not of concepts but of having concepts, and his best way of determining whether a person has a concept is not by asking him whether he finds such a concept in his mind but, for example, by observing his behaviour. When he observes heavy clouds, he looks for his umbrella; and his response is the same if, when he is on his way out of the house, somebody tells him, "There are heavy clouds about." Familiarity with the English language, on the one hand, and with the climate, on the other, has disposed him to respond to the statement in that way. In either instance, he has a concept of heavy clouds presaging rain.

Whether concepts are capacities or dispositions

Having a concept is having a disposition or a capacity. This seems to be a more hopeful theory than that concepts are mental entities, but it, too, is not without difficulties. For, in the first place, the investigator can never directly study a disposition but only the consequences of being so disposed, and this makes for vagueness. Secondly, the mind is said to frame concepts; but, if these concepts are capacities, it must be questioned whether it makes sense to speak of the mind framing its own capacities. Finally, it is reasonable to ask whether it really makes sense to say that the concept is just a capacity, whether it would not be better to think of it as a capacity or capacities along with a certain content or core—which is not to be thought of as an internal accusative. Thus, a man might think of the concept in terms of Frege's account of the reference of the logical predicate term. The predicate term, he held, is a general word (or words) that is to be understood in terms of a function of which the values are truth values. Something is said about an object *a*, and the schematic logical form of the statement is "*f a*," in which *a* stands for the logical subject and *f* for the concept. The question, then, is whether there is in this function "*f* . . ." a clue to the nature of the concept in verbal thinking. If, in the open sentence ". . . is a tyranny," a person can use this locution significantly, if he possesses the necessary empirical and linguistic dispositions, then he has the concept of tyranny. The open sentence is not itself a disposition, but a significant use of it presupposes the presence of dispositions in the mind that are essential if this locution is to be used significantly. There is a core, which in this case takes the form ". . . is a tyranny," that has dispositional accretions around it that enable the locution to be used significantly. This approach would explain the nature of concepts in verbal thinking. A like theory could be worked out for concepts in nonverbal thinking. In respect to nonverbal thinking, having a concept would be explained in terms of accretions of dispositions and capacities around images; in respect to verbal thinking, it would be explained in terms of accretions around general words or open sentences.

LANGUAGE

The epistemologist is much concerned with language and, particularly, with the use of general words in conceptual thinking. But, beyond general words, all aspects of language are of interest to him. Much of what is known by each person is known by listening to others, by speaking with them, and by reading what they have written. Language is, first, a means of communicating between men. For the most part, the communication proceeds through statements that purport to state what is the case. But language may be used also to ask questions, to command, to cajole, and to express one's feelings. In addition, one uses it in thinking, and this latter use is the philosopher's main interest. Yet, this approach may give his study of language a slant that may hide a good deal from him.

Logical versus broader uses of language

For instance, exact thinking is logical thinking, and the philosopher may tend to think of language generally as a completely logical instrument obeying logical laws. He will think of statements as strictly logical statements and

of words as fixed logical terms. Thus, he will analyse "Hitler is dead" as follows: "Hitler" is a logical proper name designating one person and one person only, and "being dead" is a precisely defined predicate term the meaning of which is fixed so that "Hitler is and is not dead" is ruled out logically. Here, language is being used in accordance with strict logic, but this is not its only use nor even its usual use. If the philosopher confines his study to this use of language, his account of it will be both narrow and misleading.

It is sometimes said that Ludwig Wittgenstein, a seminal philosopher of language between the wars, gave too narrow an account of the use of language in his *Tractatus Logico-Philosophicus* (1922), first published as *Logische-philosophische Abhandlung* (1921), and that this was one of the "grave mistakes" to which he confessed in the preface to his *Philosophical Investigations* (1953). It should be noted, however, that the *Tractatus* is primarily a study of logic and philosophy. It expresses his interest in what can and what cannot be stated in logically principled factual statements; and this is what can be thought logically, for what cannot be stated cannot be thought. It expresses an interest, too, in the logical principles involved in the making of these statements and holds that these principles are tautologous. Such was Wittgenstein's interest in the *Tractatus*.

But in *Philosophical Investigations* he looked at language in all of its uses and found it to be much more flexible and less restricted than he had held it to be in the *Tractatus*. Early in the *Investigations* he talked of language as a sort of game in which the rules vary according to custom. He who would understand how the game is played can do so only by participating in it. So, too, the meaning of the words used in a language is not immutably fixed; one can only know it by observing how the words are, in fact, used at any time. Obedience to linguistic rules is a matter of "custom, use or institution" rather than of following deep, unchangeable, logical principles. To understand a language means to be master of a technique. Thus, the attitude toward the study of language in the *Investigations* is very different from that in the *Tractatus*. It is Empiricist rather than Rationalist; but it is an Empiricism with a difference, for it is not scientific Empiricism. It does not seek to pass forward from the observation of particular cases to systematic generalizations about language; it is content to observe piecemeal and to bring out the puzzles that arise on reflection upon each new observation. Wittgenstein reflected, for instance, on uses of the utterance "I am in pain," and out of the reflection came the question whether and in what sense a language can be private.

The contributions of linguists

Neither the method of the *Tractatus* nor that of the *Investigations*, however, is the only method of language study. The study by linguists of the general structure of language itself gives rise to puzzles: for instance, whether, as Noam Chomsky, a generative grammarian, thinks, the facts of grammar are such that a distinction must be made between deep structures and surface structures of grammar and whether the phonemic and the semantic components of language are dominated by these deep syntactical components. Furthermore, the exact study of the natural languages by linguists and of speech by psychologists can provide results that are of value to the epistemologist, and, in fact, many scholars consider it regrettable that he does not make greater use of them. In particular, they could be useful in his study of thinking and his attempt to distinguish it from and relate it to knowing.

As has been seen, not all thinking or conception is verbal, though most of it is; and the question arises how language, as an instrument used in thinking, affects the thinking. Natural languages, such as English and French, have certain features in common (though not a common grammar)—for instance, they are conventional in their use of phonemic symbols; they employ analysis and synthesis; and they can pluralize and speak in general terms. The first use of language was for communication; in this use and in the development of language as a means of communication, thinking was already involved; and no hard-and-fast line can be drawn between thinking and using a language. When men became more and more reflective, the use of language as the instrument of thought affected that thought; the techniques of convention, analysis, and generalization were at hand for the thinker. Symbols could be used in new ways to further thought; deductive argument became possible; and thinking could be carried on in "eternal" sentences. But the epistemologist's question—*i.e.*, whether there is any guarantee that such conceptual thinking can ever be used to extend knowledge—remained to be answered. This is a question that the study of language cannot of itself solve, for it involves metaphysical as well as epistemological issues. In particular, it raises the issue of universals, which must now be briefly examined.

UNIVERSALS

Universals, which are expressed in common nouns or terms, may be described—perhaps inadequately—as either recurrences or principles of grouping or classifying. They have been a bone of contention among philosophers throughout the centuries. At various times, by various schools, the universal has been presented as the ultimately real existence, the Form, as a thought or a concept, as a word or series of words, as an identical recurring quality, as a group of qualities that resemble one another, as a class of things, as a genus, as a species, as a principle of classification, and, finally, as what can be predicated of an individual thing, a species, or a genus. In view of this complexity of definition, disagreement is not surprising. Much of the complexity is due to the fact that the theory of universals is advanced to solve a complex problem, viz., (1) to explain and justify grouping, classifying, and the use of the general word; (2) to find a standard by which to establish what is and is not valuable; and (3) to provide a metaphysic in which what is real can be clearly distinguished from what appears.

History of the problem of universals

Socrates and Plato between them set forward the theory of Forms or Ideas (see above *Rationalism prior to Kant*: *Classical Rationalism*: *Theory of Forms in Plato*) that claimed to solve the whole problem in its full complexity: human beings, closely tied to sense perception, think of visible and tangible things as real, whereas, in fact, they are appearances only; the beautiful things known in nature are manifestations of beauty itself; and, when a person knows beauty, he knows what is real, and he has a standard by which to determine what is and what is not beautiful; finally, knowledge of the Form of beauty enables him to group beautiful things together, provides him with a principle of classification, and enables him to use a general word significantly. Aristotle was critical of the view that the Form had this separate existence and found the universal in the common quality.

The argument was passed on to medieval philosophers through Porphyry, one of the founders of Neoplatonism, in the 3rd century and through the late Roman statesman and philosopher Anicius Boethius at the turn of the 5th century; it was hotly debated in the 11th and 12th centuries; and in the 13th century the different theories were neatly formulated by Albertus Magnus, the leading scholar of the century: universals are held by some (*e.g.*, by Plato) to exist before the things that exemplify them, to be *ante rem;* by others (*e.g.*, by Aristotle) to exist in the things, to be *in re;* by still others to exist in thought or conception only as abstractions or even as names only, to be *post rem*. In the 13th century it was the second theory that was most widely accepted, but there was more support for the third in the 14th century. *Ante rem* and *in re* theories were called Realist and *post rem* Nominalist, though in fact the medieval thinkers of this school were, in modern parlance, more often Conceptualists (the universal is a concept) than Nominalists (the universal is a word or set of words only).

In the modern period the Empiricists thought of universals as concepts abstracted from experience and tended to shift the discussion from the nature of the universal to the manner of its abstraction. The Rationalists maintained that some universals are known a priori. In the writings of contemporary philosophers, Realism of an

Aristotelian type and Conceptualism have flourished; but Positivists have advocated Nominalism, while Idealists and members of the mathematical logicist school have advocated a Platonic Realism.

Requisites for a solution

In epistemology the problem of universals is clearly linked with that of the ontological relevance of conceptual thinking. Its solution would seem to require the following: (1) a full understanding of the manner in which general words are used in thinking; (2) a study of qualities to help determine the precise nature of the link between the quality and the thing to which it is said to belong; (3) an examination of the theory of common qualities—asking whether the theory rests on the supposition of the existence of identical qualities or of resembling qualities or of both; (4) a determination of the principal dispositional features that are present, though not overtly expressed, in conception; and (5) a definitive answer to the question of what it is "to have a concept." It would seem that enough is known of these matters to enable one to say that there are universals. There are recurring resemblances between qualities, and there are also identities of qualities. In the second place, there are universals in the sense of principles of grouping or classifying. For the epistemologist the question then arises whether such a theory of universals can provide the necessary foundation for a theory establishing the ontological relevance of human thinking.

VI. Concluding reflections

The scope of the foregoing discussions has been limited by various considerations. In the first place, the article has been concerned solely with the thought of the West. (For the epistemologies of India and of China, see INDIAN PHILOSOPHY and CHINESE PHILOSOPHY.) In the second place, some matters that are in certain respects epistemological are not usually studied under this head. It is not usual, for instance, to discuss the nature of moral consciousness or, again, of aesthetic appreciation in works on epistemology, though such discussion might be illuminating. (See ETHICS and AESTHETICS.) Again, problems that are discussed in epistemological studies, such as knowledge of the self, of other selves, and of God, are not given special treatment here since they are covered in other articles (see MIND, PHILOSOPHY OF and RELIGION, PHILOSOPHY OF).

CONFLICT OF EMPIRICISM WITH RATIONALISM

The present inquiry into epistemology has concentrated on the main flow of Western speculation from the days of the Greeks to the present. As has been seen, two schools of thought are prominent, namely, the Empiricist and the Rationalist, but it is clear that neither of these schools has been able to offer a wholly satisfactory account of knowledge.

The Empiricist thesis is that human knowledge is either directly acquired in sense perception or derived from what is thus acquired. It follows from this that nothing is or can be thought that was not "previously in the senses." For such a theory a satisfactory account of the function of sense perception obviously is a crucial necessity.

Sense experience and the external world

Whether sense perception reveals the external world as it is and shows up its characteristics becomes an important question, though reflection on the contradictions in sensory experience has made it impossible to hold on for long to an affirmative answer to it. A person may observe that the moon he is looking at is covered wholly by a coin held at arm's length; yet, the moon for an observer standing on its surface is a vast object of which he sees a very small part. One concludes that what he now sees does not, in fact, show the moon's real size. Yet, he does see something. If he says that this visible something is not the real moon, he has then assumed a dualism. What he immediately sees is an object given to the senses, a sense-datum or sensum, but it is not the physical object, the real moon. The problem, then, is that of relating the two. It has to be asked how the Empiricist can say that sense perception reveals the real external world if what is immediately seen is a sensum. The dualism of real object and sensum would seem to throw doubt on the very possibility of knowledge of the external world in sense perception. It is, perhaps, possible to argue that the sensum is a representation of the real object or that it represents it in certain selected aspects, so that the real object is in part known. But this is to raise the question of whether and how the claim that the sensum represents, say, such and such a quality or qualities of the real object can be tested. If the difficulties of the representationalist theory have driven philosophers to reject dualism, some might suggest that, in order to re-establish a monist theory of knowledge, one should adopt then an Idealism denying the independent reality of the physical object or affirm that human knowledge is phenomenalist. In the latter view, man is concerned with phenomena only and the question of whether physical objects exist or do not exist beyond the veil of phenomena does not arise. Yet, both the Idealist and phenomenalist accounts, too, are full of difficulties, and it is doubtful whether the original thesis, that all human knowledge of the outer world is directly acquired in sense perception or derived from what is so acquired, can be sustained by the adoption of either account.

Hearsay and abstracted scientific knowledge

There have been philosophers who have held that sense perception is a snare and that it provides no reliable information; yet, this seems extreme. What is objectionable in the Empiricist position is rather the claim that sense perception is the sole provider of information. On the face of it, it seems incorrect to say that all that a person knows of the world around him is known through sense perception. For instance, it may be true that much of what one knows he learns from what others tell him (in speech or writing)—*i.e.*, from "hearsay knowledge." And the surest source of information may well be the knowledge provided by an expert in any field. To this the Empiricist might reply that in both cases the information in question, though not given to the layman in sense experience or derived from what is so given, is nonetheless given in or derived from the sense perception of his informant or of someone else. Thus, a man is told that there are black swans in Australia. He has never seen a black swan and has never been to Australia; yet, if he is satisfied about the reliability of his informant and especially if the latter says, "I saw them there," he accepts this information. The layman's gaining of the knowledge, however, is dependent not only on the informant's sense experience but also on the layman's understanding of what he says; thus, one condition of hearsay knowledge is the successful use of a language. But this, the Empiricist would say, has to do with the medium in which the information is conveyed to another person; the information itself is gained in sense experience.

A more complex case is presented when an inductively established scientific generalization is reported. Though it will be said that this generalization is still empirically based, "based" is an ambiguous word in this context. The information has been gained by the scientist using the methods that he and his fellow workers accept in this field. It involves sense experience or sensory observation together with scientific reasoning. The knowledge is admittedly empirically based, but this leaves open the question whether it is correct to speak in this case of sense experience as the sole provider. The point can be taken a step further. One of the most important features of scientific method is hypothesis making. The scientist, having observed widely and being thoroughly acquainted with the body of knowledge about the matter in hand, has an insight and proffers it as a hypothesis. Such an insight could possibly be described as a perception but certainly not as sense perception. A natural science is an empirical inquiry; it uses information gained in sensory experience; further, it verifies hypotheses by appeal to the senses. Yet, the Empiricist's claim that such knowledge is either gained in sense perception or derived from sense perception must be dismissed as misleading.

Rationalist infallibility

It is generally agreed that the empirical sciences do not give certainty but only probability. To assert this is to assert that there are degrees of knowledge; a person may know a statement P with complete certainty (know "in the strict sense"), or he may opine or believe P without

being certain, holding it to be just probable or probable with a high or low degree of probability. In the traditional Rationalist view, as has been seen, it is man's reason alone that enables him to know at the highest level—to say "This is true absolutely." Absolute truth is not given in sensory experience nor can it be derived from it. But man is endowed with a pure intellectual power that enables him to know truth positively—truth that is not qualified in any way, which is unchanging and necessary. The information presented by sense experience is uncertain, holding relatively with a certain context, so that to build upon it is to build on shifting sand. In contrast, the information that reason provides is unchanging: "once true always true." To know by reason is to know infallibly; and it is on this rock of infallible rational intuition that human knowledge rests.

This doctrine contrasts strongly with Empiricism. It is undoubtedly comforting, but reflection on its claim still generates doubts. The main doubt is the all-embracing one of whether human beings ever have a knowledge that is strictly infallible. Plato thought they do. But only a few, the "true philosophers," have it, and even in their case infallible knowledge is of Forms or Ideas only. Others supposed it to be more widely spread—for instance, every rational creature could see certain mathematical and logical statements to be true beyond all doubt. Thus, the statement, "The interior angles of a triangle are equal to two right angles," is infallibly true and so is the statement, "This figure is a triangle or not a triangle." These are necessarily true statements that cannot possibly be false, because they are tautologous. No one can doubt that *a* is *a*. But, if the Rationalist thesis is taken to mean that reason provides and is the sole provider of infallible knowledge and if this infallible knowledge is of the tautologous, it might appear that reason's contribution is slight. Further, it may be asked whether even the barely tautologous statement is known infallibly.

BLEND OF EMPIRICISM WITH RATIONALISM

The blended theory and its defects

It could be argued that, in order to make the contrast between Empiricist and Rationalist clear, the immediately preceding paragraphs have tended to exaggerate the differences between them. For, when the history of the conflict is recalled, one finds few Empiricists, if any, who do not have some place for reason in their theory of knowledge and few Rationalists who are not prepared to acknowledge the contribution of sense experience. The difference is one of emphasis: the part played by experience is more important in the Empiricist's mind, and that by reason is more important in the Rationalist's mind. But the general view is that human knowledge is dependent on both experience and reason; experience provides the "manifold," or material, of knowledge; reason provides the principles for ordering this material. Such is the general line followed by epistemologists.

If human knowledge is regarded as a blend of experience and reason, it is necessary to ask whether the theory is then acceptable. It is reasonable to ask whether the blending will result in the modification of material given in experience and reason. Sensory experience, it is supposed, is an awareness of the concrete particular; and there could be a danger that the ordering zeal in the blended knowledge will diminish the concreteness of the immediately experienced and so mislead. On the other hand, reason in its purity provides necessary, infallible knowledge. The question, then, is whether the material that it is now called upon to order will be such that no necessary knowledge is henceforward possible.

Problems of this sort arise. They may be dismissed by some philosophers as the consequences of making two abstractions—sense experience and reason—into one thing and of viewing sense experience in this context as something working against generalization and reason as struggling to secure infallibility. It must be admitted that the tendency is strong to think and speak of sense experience and reason as two faculties operating more or less independently in the attempt to increase knowledge.

As against the above criticisms of the blended theory of knowledge, however, two points can be made. In the first place, the assumption that sense experience gives the particular and never the general can itself be questioned. The evidence available suggests that very young children do not distinguish between particular and general. What one begins with, it would seem, is as general as it is particular. It is only later, when the child has reflected, that he comes to conceive a particular thing, isolated, substantial, and enduring. It may be wrong, therefore, to suppose that early experience is of the concrete and particular and that later conceiving generalizes the experience and to a degree falsifies it. In the second place, it can also be questioned whether the function of reason is to provide man with infallible principles by which to order the manifold of experience. It may be that these principles are provided in some other way: they may be stipulations of the thinker, or they may be hypotheses. Mathematics and logic, it is said, do provide complete certainty within a framework of tautologies. But one may then ask whether the function of reason is to grasp the truth of tautologies. It is necessary to question the assumptions of the critics of the blended theory both in respect to experience and to reason.

Rejoinders to the criticisms

There is, further, a double assumption in arguing that man is capable of infallible knowledge and therefore that reason must be one of his faculties, since reason alone knows the infallible. Even if man enjoyed infallible knowledge, it would still be necessary to prove that the possession of the faculty of reason is a requisite for such knowledge; one cannot assume this. Nor can a person assume that man does have infallible knowledge. It might be answered: "But surely he is certain of many things!" This is so, but to be certain of something is not the same as having infallible knowledge of it: it is not the same for the simple reason that a man can be certain, absolutely certain, and yet be in error.

Remaining problems

It is clear that many problems are left for the epistemologist to solve. No one would say that the subject of sense perception is satisfactorily disposed of, in spite of the considerable attention paid to it. Interest in the analysis of conception is comparatively new, but it has become apparent that difficulties abound in this field. Along with the study of concepts goes that of universals, and linked with both is the study of thinking, which in turn involves an examination of language and of its relation to thought. Finally, there looms the problem of reason and of its function in human knowledge and in human life. The study of these and other matters will certainly keep epistemologists busy for the foreseeable future.

BIBLIOGRAPHY. The subject of epistemology is wide and a vast number of books have been written in this field. What follows is a brief selection, mostly of mid-20th-century books, which the student might find useful as an introduction.

General introduction: A.J. AYER, *The Problem of Knowledge* (1956); R.M. CHISHOLM, *Theory of Knowledge* (1966); and BERTRAND RUSSELL, *Problems of Philosophy* (1912). Also A.D. WOOZLEY, *Theory of Knowledge* (1949) and Panapot Butchvarov, *The Concept of Knowledge* (1970).

Sense-perception: Highly recommended is H.H. PRICE, *Perception*, 2nd ed. rev. (1950). The following are further useful studies: A.J. AYER, *The Foundations of Empirical Knowledge* (1940); R.M. CHISHOLM, *Perceiving* (1957); R.J. HIRST, *Problems of Perception* (1959); J.L. AUSTIN, *Sense and Sensibilia*, reconstructed from the manuscript notes by G.J. WARNOCK (1962); D.W. HAMLYN, *Sensation and Perception* (1961); A.R. WHITE, *G.E. Moore: A Critical Exposition* (1958); A.O. LOVEJOY, The *Revolt Against Dualism* (1930); H.A. PRICHARD, *Knowledge and Perception* (1950); M.H. MANDELBAUM, *Philosophy, Science, and Sense Perception* (1964); and WILFRED SELLARS, *Science, Perception, and Reality* (1963), reprinted 1968.

Belief and certainty: One may begin by referring the reader to C.I. LEWIS, *An Analysis of Knowledge and Valuation* (1947); BERTRAND RUSSELL, *Human Knowledge: Its Scope and Limits* (1948); and G.E. MOORE, *Some Main Problems of Philosophy* (1953). For later views, see NORMAN MALCOLM, *Knowledge and Certainty* (1963); JAAKKO HINTIKKA, *Knowledge and Belief* (1962); BRAND BLANSHARD, *Reason and Analysis* (1962) and *Reason and Goodness* (1961); RICHARD I. AARON, *Knowing and the Function of Reason* (1971); and A.C. DANTO, *Analytical Philosophy of Knowledge* (1968). Very relevant, too, are LUDWIG WITTGENSTEIN's last investigations

On Certainty (1969). The collection of papers entitled *Knowledge and Belief*, ed. by A. PHILLIPS GRIFFITHS (1967), is to be highly recommended.

Thought and language: On the logical (or philosophical logic) side, the reader will find much help in W. and M. KNEALE, *The Development of Logic* (1962). Valuable, too, is W.V.O. QUINE, *Word and Object* (1960), and also his *From a Logical Point of View*, 2nd ed. rev. (1961) and *The Ways of Paradox, and Other Essays* (1966). The most influential modern work in this field is LUDWIG WITTGENSTEIN, *Philosophical Investigations*, 2nd ed. (1958, reprinted 1967), with which one may read F. WAISMANN, *The Principles of Linguistic Philosophy* (1965). See also: G. RYLE, *The Concept of Mind* (1949) and *Dilemmas* (1954); H.H. PRICE, *Thinking and Experience* (1953); BRAND BLANSHARD, *The Nature of Thought*, 2 vol. (1939), a work reflecting the influence of Hegelian Idealism; J. HOLLOWAY, *Language and Intelligence* (1951); RICHARD I. AARON, *The Theory of Universals*, 2nd ed. (1967); P.T. GEACH, *Reference and Generality* (1962); and P.F. STRAWSON, *Individuals* (1959).

Schools of epistemology: Elsewhere in this encyclopaedia are biographies of the leading philosophers together with accounts of their principal works. See also the bibliographies of articles on the various epistemological schools and movements mentioned in the text. The reader may also consult further the *Encyclopedia of Philosophy*, ed. by PAUL EDWARDS, 8 vol. (1967); and D.J. O'CONNOR (ed.), *A Critical History of Western Philosophy* (1964). Below are some useful commentaries.

The Greeks: On early Greek philosophy the best general guide for the newcomer is still JOHN BURNET, *Greek Philosophy: Thales to Plato* (1914). On Plato, see the comprehensive *Plato: The Man and His Work*, by A.E. TAYLOR (1926). The standard commentary for Aristotle is W.D. ROSS, *Aristotle* (1923). A number of excellent commentaries are available on individual works by Plato and Aristotle: F.M. CORNFORD, *Plato's Theory of Knowledge* (1935), is noteworthy. See also GREGORY VLASTOS, "The Third Man Argument in the *Parmenides*," *Phil. Rev.*, 63:319–349 (1954). G.E.L. OWEN and H. CHERNISS are leading contemporary scholars in this field; see the latter's *Aristotle's Criticism of Plato and the Academy* (1944) and *Aristotle's Criticism of Presocratic Philosophy* (1935, reprinted 1964). An introductory account of Aristotle's philosophy is D.J. ALLAN, *Philosophy of Aristotle* (1952). The main difficulty with minor Greek philosophic writers is to find out exactly what they say, since it is necessary to depend on fragments. G.S. KIRK and J.F. RAVEN, *Presocratic Philosophers* (1957); H.F. VON ARNIM, *Stoicorum Veterum Fragmenta* (1905–24); and H. USENER, *Epicurea* (1887, reprinted 1966), provide good collections.

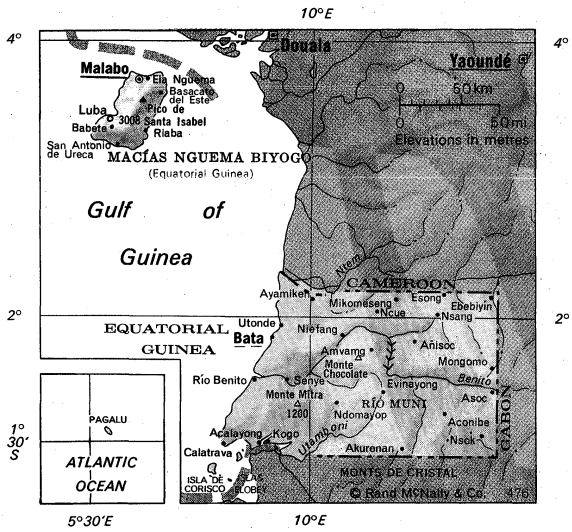
Medieval: Two useful general commentaries are ETIENNE GILSON, *A History of Christian Philosophy in the Middle Ages* (1955); and F.C. COPLESTON, *A History of Philosophy*, vol. 2–3 (1950–53). A good introduction to Aquinas is F.C. COPLESTON, *Aquinas* (1955); a fuller work is ETIENNE GILSON, *Le Thomisme*, rev. ed. (1922; Eng. trans., *The Philosophy of St. Thomas Aquinas*, 2nd rev. ed., 1929).

Modern: Not unexpectedly, the best commentaries on Descartes are in French: see HENRI GOUHIER, *La Pensée métaphysique de Descartes* (1962); and OCTAVE HAMELIN, *Le Système de Descartes* (1921); but there are good introductory studies in English, for instance, S.V. KEELING, *Descartes*, 2nd ed. (1968). On Spinoza, two contrasting works for those beginning to read this philosopher, who is not too easy to understand, are L. ROTH, *Spinoza* (1924); and STUART HAMPSHIRE, *Spinoza* (1951). RUTH SAW has written on *Leibniz* (1954); but BERTRAND RUSSELL, *A Critical Exposition of the Philosophy of Leibniz*, 2nd ed. (1937), may not prove too difficult. General studies of John Locke are D.J. O'CONNOR, *John Locke* (1952); and RICHARD I. AARON, *John Locke*, 3rd ed. (1971); of Berkeley, G.J. WARNOCK, *Berkeley* (1953); of Hume, D.G.C. MACNABB, *David Hume* (1951). The beginner will find Kant difficult and introducing him is not an easy task, but compare S. KORNER's general introduction on *Kant* (1955). On Idealism generally, an excellent study is A.C. EWING, *Idealism* (1934). (R.Aa.)

Equatorial Guinea

The Republic of Equatorial Guinea (República de Guinea Ecuatorial), on the west coast of Africa, is the only independent Spanish-speaking state on the African continent. Formerly Spanish Guinea, a colony of Spain, it consists of two geographically separated provinces—Río Muni, a coastal enclave, and Macías Nguema Biyogo (formerly Fernando Po), an offshore island—whose unity is only political and cultural. This fragmented republic has a total area of 10,831 square miles (28,051 square kilometres) and a population that in 1975 was estimated to be about 310,000.

Río Muni, or continental Guinea, with an area of 10,038 square miles (25,998 square kilometres), is a roughly rectangular territory bounded by Cameroon to the north



EQUATORIAL GUINEA

and Gabon to the east and south. The estuary islands of Corisco (about six square miles), Elobey Grande (less than a mile square), and Elobey Chico (less than a tenth of a mile square) are administratively included in the province of Río Muni, which thus has a total area of 10,045 square miles. The second province, Macías Nguema Biyogo consists of the island of Macías Nguema Biyogo proper—off the coast of Cameroon, with an area of 779 square miles (2,018 square kilometres)—and Pagalu (formerly Annobón), a volcanic island of less than seven square miles that lies south of the Equator almost 400 miles (640 kilometres) to the southwest of Macías Nguema Biyogo.

By any standard Equatorial Guinea forms a small political unit, and it is beset by regional differences, geographic isolation, a fragile economy, a lack of trained personnel, and the incubus of a heavy psychological legacy from the colonial era, which ended when the country obtained its independence on October 12, 1968. The capital of the republic is Malabo (formerly Santa Isabel), on Macías Nguema Biyogo. Bata, on the mainland, is only the administrative capital of Río Muni but aspires to become the national capital. (For coverage of historical aspects, see WEST AFRICA, HISTORY OF.)

Independence

Relief, drainage, and soils. *Río Muni.* The enclave of Río Muni is too small to have a geographic unity of its own. A coastal plain about 12 miles (20 kilometres) wide abuts on the coastal hills, which lead to inland plateaus (called *mesetas* in Spanish) that rise toward the frontier with Gabon. There are several ranges of hills. The central range divides the Río Benito Basin to the north from the southern basin of the Río Utamboni. The Niefang-Mikomeseng range north of the Río Benito is somewhat lower. All these ranges form segments of the Monts de Cristal in Gabon. The province is divided by the Río Benito (known as the Woleu River in Gabon), which runs generally from east to west and is nonnavigable except for the first 12 miles inland. To the north, the Río Campo (called the Ntem in French-speaking Africa) marks part of the frontier with Cameroon. In the south, Río Muni, from which the province takes its name, is not a river but the estuary of various Gabonese and southern Río Muni rivers, among which the Utamboni is the largest. To the east, the border with Gabon follows the meandering course of the Río Kié (Kyé) rather than the legal frontier, which runs along a line 11°20′ east of the Greenwich meridian. Except for some limited use of waterpower on lumbering sites, the rivers of Río Muni are not exploited. The coast

consists of a long stretch of beach with low cliffs toward Kogo to the south. The province has no natural harbour, and Bata, Río Benito, and Kogo are no more than rudimentary ports of call for the ships that infrequently visit the coast.

The coastal plain is overlaid by sedimentary deposits. The hinterland is composed primarily of ancient metamorphic rocks that have undergone a lengthy process of leaching and erosion, so that the resulting soils are mediocre. Exploration for petroleum in offshore waters was discontinued in 1971. Gold, titanium, coal, and iron ores are said to exist inland, but no economic exploitation has begun.

Macías Nguema Biyogo. The main island, Macías Nguema Biyogo itself, is roughly 45 miles long and 22 miles wide (72 by 35 kilometres). Its volcanic cones, crater lakes, and rich lava soils form a contrast with the landscape of Río Muni. In the north, the Pico de Santa Isabel soars to a height of 9,868 feet (3,008 metres); this extinct volcano is now the site of a television transmitter. In the centre of the island, Moca Peak and the Moca Heights present an alpine type of landscape. The southern part of the island, remote and scarcely developed, consists of the Gran Caldera range, which is rugged and indented by torrents. There are two crater lakes, Loreto and Claret.

Agricultural productivity

Despite its tortuous relief, Macías Nguema Biyogo is highly productive agriculturally. Torrents are exploited for hydroelectric power; the Río Musola provides electricity for the township of Malabo. The coast is largely inhospitable, consisting for the most part of a cliff about 60 feet high, broken occasionally by small inlets and beaches. The southern coast is very steep and dangerous to shipping; San Antonio de Ureca, located there, is the most isolated settlement on the island. Malabo has a relatively good harbour, being built on the partially sunken rim of a volcano.

Pagalu is an isolated fragment of the republic, about 93 miles (150 kilometres) southwest of the island of São Tomé in São Tomé e Príncipe and about 400 miles southwest of Macías Nguema Biyogo. Like the latter, it is a volcanic island but is less high; it consists of a conglomeration of cones of which Monte de Santa Mina (about 2,460 feet) is the highest. Not quite four miles long by two miles wide, it is a rugged little island; the only settlement of note is centred on the Catholic mission. The inhabitants are mostly fishermen who speak a Portuguese patois.

Climate. The climate of Río Muni is equatorial, with local variations due to differences in altitude and proximity to the sea. The wet seasons are from February to June and from September to December. Rainfall is higher on the coast than inland. In Bata the rainiest months are September, October, and November, with rainfall averaging more than 94 inches (2,388 millimetres) a year. At Calatrava, farther south on the coast, it sometimes reaches 180 inches (4,572 millimetres). Inland, however, rainfall diminishes; Mikomeseng, for example, receives only about 58 inches (1,473 millimetres). The average yearly temperature is about 79° F (26° C), the maxima being somewhat lower than in Macías Nguema Biyogo. The relative humidity, however, is higher than in Macías Nguema Biyogo, with an average of 86 percent, occasionally rising to 94 percent.

Macías Nguema Biyogo has an extremely debilitating climate. The so-called dry season lasts from November to March, and the rest of the year is rainy. The average annual temperature is 77° F (25° C) with a maximum of 93° F (34° C) and a minimum of 63° F (17° C). Most of the time the sky is cloudy and overcast. Extreme rainfall occurs in the south, with rain brought by monsoon winds amounting to about 450 inches (11,400 millimetres) a year around San Antonio de Ureca.

Vegetation and animal life. Río Muni is covered by a dense jungle that is exploited by a lumbering industry. Over 140 species of wood are found, the most important commercially of which are okume (*Aucoumea klaineana*), African walnut, and various mahoganies. Intensive exploitation close to the coast led the Spanish timber companies to venture deeper into the interior. Reforestation is minimal, and a secondary forest growth has replaced the original rain forest. African farmers clear land by burning off the vegetation cover, after which they grow manioc, beans, yams, roots, and even cash crops such as coffee and cocoa, to the extent that the heavily leached soils allow. Mangroves fringe long stretches of the coast as well as riverbanks.

Macías Nguema Biyogo has a greater variety of tropical vegetation, including mangroves, and—at higher altitudes—vegetable gardens and pastureland.

Varied animal life

Río Muni has a rich animal life that includes gorillas, various rare species of monkeys, leopards, buffalo, antelopes, elephants, hippopotamuses, crocodiles, and various species of snakes, including pythons. Insects, including the tsetse fly and the malaria-bearing *Anopheles* mosquito, as well as hosts of ants, beetles, spiders, and termites, abound. Macías Nguema Biyogo has no big game but has various monkeys, dwarf antelopes, and rodents, as well as the ever-present mosquito and other insects.

The landscape under human settlement. *Río Muni.* Río Muni is sparsely settled by coffee and cocoa farmers who practice traditional methods of agriculture. During the colonial period, Roman Catholic missions did much to encourage the population to construct "corridor" villages by the sides of roads; in most villages the church and the school figure prominently. Spanish plans for building model villages lapsed after independence. Río Muni was never a settler colony, and the few European plantations—mostly Spanish or German—that survived the colonial era have been abandoned. After independence an exodus of Spanish technicians occurred, so that Río Muni has largely reverted to a subsistence economy. While subsistence agriculture sustains the population, it remains to be seen whether the modern sector of the economy, represented by lumbering, coffee growing, and oil palm production, can recover from the crisis of confidence that occurred after independence.

Macías Nguema Biyogo, by contrast, is a plantation island; it retained for several years a larger number of plantation owners and managers and consequently withstood longer than Río Muni the effect of independence upon its economy. Before independence there were about 1,900 plantations (known as *fincas*), which ranged in size from one hectare to more than 2,000 hectares (4,900 acres). The Bubi people, the indigenous population, live for the most part in mission villages in the northern part of the island on the lower slopes of the Pico de Santa Isabel, as well as in their traditional homeland, the Moca Heights. Unused to plantation labour, they gain their living mostly as small farmers and minor civil servants. The workers on the *fincas* were for many years migrant labourers from Nigeria, who served under contract. During the 1960s the Nigerian workers often brought their families, settling in numbers believed to have reached 50,000 to 80,000 by the end of the decade. Political and economic conditions after independence gradually reduced these numbers, despite an agreement with Nigeria in 1972 for the recruitment of new labourers. Reports of virtual slave-labour conditions on plantations and of repressive killings by authorities in 1975 turned this gradual exodus into a flood, with the anticipated effect of further impoverishing Equatorial Guinea's economy.

Nigerian migrant labour

Many of the formerly European-owned plantations were extensive; in 1962 more than 300 plantations occupied over 60,000 hectares (148,000 acres), leaving about 7,000 hectares in the possession of 1,600 African farmers grouped in cooperatives. Some of the larger plantations, employing hundreds of Nigerian labourers and occupying the most fertile land, were local economic powers whose political influence, if subdued, was nevertheless felt by the local Bubi population.

Malabo, both the provincial and the national capital, is a small city standing behind its crater harbour. Created by the British in the 19th century, it was remodelled and developed by the Spanish. A rambling tropical city, it has a distinctly Spanish atmosphere—especially in the European district near the cathedral, the mission, and government house. Farther inland, the African districts have been inhabited mostly by Nigerian and other workers who chose not to return to the mainland. While the

Malabo township and its Ela Nguema (formerly San Fernando) satellite had a total population of about 20,000 in 1960, it is safe to assume that the population has risen to between 25,000 and 30,000. Another town of some importance is Luba, on the southwest coast, linked with the capital by a good tarred road that runs through a series of Bubi settlements. Basilé, on the slopes of Pico de Santa Isabel, provides a cool refuge for heat-weary residents of the capital.

Río Muni was settled much later by the Spanish, so that the township of Bata lacks the amenities of Malabo. Its population was less than 4,000 in 1960 but now numbers perhaps 15,000, as Fang migrants from the interior have built new suburbs around the sprawling port city.

People and population. Population figures are outdated, since the only reliable estimate dates back to 1960, when there were almost 250,000 people, of whom 7,000 were Europeans. It may be assumed that the 3,000 Europeans living in Río Muni have dwindled to a few dozens at most, and that the 4,000 Europeans on Macías Nguema Biyogo have declined to a few hundreds. In 1960 Río Muni had about 180,000 inhabitants and Macías Nguema Biyogo about 60,000 (including 1,400 on Pagalu). The majority of the population is African, but its composition is complex for a political unit so small in size.

Río Muni. The Fang people, who fought their way to the sea in the 19th and early 20th centuries by subjugating the weaker tribes in their path, form about 80 or 90 percent of the population of Río Muni. North of the Río Benito are the Ntumu Fang, and to the south of it are the Okak Fang. Holding political power on the mainland, the Fang tend to migrate to Macías Nguema Biyogo, where their leaders hold most of the levers of political control. Coastal tribes—such as the Kombe, Mabea, Lengi, Benga, and others—have been in contact with European traders much longer, and a limited amount of miscegenation has taken place, especially on the island of Corisco. Spanish ethnographers refer to these coastal tribes as *playeros* (literally, "those who live on the beach"). Both the Fang majority and the *playero* minority are Bantu. Some Pygmies are reported to roam in the vicinity of the Río Campo. In addition to these peoples, there are substantial colonies of Africans from other countries in Río Muni, including Hausa traders in Bata and Ibo, Ibibio, and Efik contract workers from Nigeria who are employed in the lumber camps. There is also a small number of Africans from Cameroon and Gabon, as well as a few Indian shopkeepers in Bata.

The Bubi

Macías Nguema Biyogo. The original inhabitants are the Bubi, descendants of Bantu migrants from the mainland. Contacts with Europeans decimated them, and only a few thousand remained early in the 20th century. They now number about 15,000 and constitute the most pro-Spanish element of the African population, viewing the end of Spanish rule as a signal for the invasion of their island by the Fang. Certainly, numbers of Río Munians, most of them Fang, have flocked to the island since the mid-1960s, seeking to join the civil or military forces or to receive political patronage. In addition to these two groups, there are a few thousand Fernandinos, descendants of former slaves liberated by the British during the 19th century who mingled with other emancipated Africans from Sierra Leone and Cuba as well as with immigrants from West African countries. Formerly constituting an influential bourgeoisie, they lost much of their status when the Spanish acquired the island. The inhabitants of Pagalu are descended from slaves imported by the Portuguese when the island was a dependency of São Tomé; some of them now live on Macías Nguema Biyogo.

By about 1970, all these different strata together constituted a minority on the island, the majority being formed by the mass of Nigerian contract labourers, who lived in compact colonies either in Malabo or on the plantations. The repatriation by Nigeria of an estimated 45,000 workers beginning in mid-1975, following reports of repressive conditions in Equatorial Guinea, could be expected to lead to extensive realignment of the demographic, social, and labour structures of the island and, indeed, of the country. Additional communities on the island are formed by *crioulos* (of mixed Portuguese and African origin) from the formerly Portuguese islands of São Tomé and Príncipe; there are also Cameroonians.

The island's population thus forms a true ethnic kaleidoscope, ruled by a Spanish-speaking group who control the Guardia Nacional, composed of Fang, who are garrisoned on the island.

Language. While each ethnic group speaks its own language, two linguistic influences are at work. The first is Spanish, which is the official language of the republic, is taught in schools and used by the press, and is the only means of communication common to both Río Muni and Macías Nguema Biyogo. The second influence is pidgin English, which forms the lingua franca on Macías Nguema Biyogo and enables the Nigerians to make themselves understood. A Portuguese patois is also spoken both in Macías Nguema Biyogo and Pagalu.

Religion. While about 80 percent of Equatorial Guineans are nominally Roman Catholic, the Bubi and Río Munians have all more or less openly retained traditional forms of worship, which are emphasized in times of crisis. The Mbwiti cult in Río Muni, banned by the Spanish authorities, still has adherents. There are American Presbyterian and English Methodist missions on the mainland. The only Muslims are the Hausa.

The national economy. Equatorial Guinea's economy has depended primarily upon three commodities—cocoa, coffee, and timber. Before independence, the Spanish subsidized cocoa and coffee exports to Spain. Cocoa, which is of high quality, is the mainstay of the economy of Macías Nguema Biyogo, which possesses the right soil and climate for its intensive cultivation. About 90 percent of Equatorial Guinea's cocoa is produced on the island, only about 10,000 hectares (25,000 acres) of land being devoted to cocoa cultivation in Río Muni. Equatorial Guinea's coffee is of poor quality; most of it comes from Río Muni, with Macías Nguema Biyogo's share of production being marginal. The timber companies are entirely European; there were at one time 30 timber concessions in operation in Río Muni. The industry is heavily mechanized and requires a large investment. Friction between the Fang-dominated government and the timber companies, however, led in 1969 to the disruption of the economy of Río Muni.

Cocoa, coffee, and timber exports

Bananas are grown on Macías Nguema Biyogo, where they are exported from the port of Luba. The output of palm oil from Río Muni plantations has been adversely affected by the unsettled state of the country. A Spanish fishing fleet was based on Macías Nguema Biyogo in the late 1960s. Cattle raising in Moka Heights is of minor importance. There is little industry in either of the country's two provinces. Some cocoa and coffee processing takes place locally on plantations and in African cooperatives. There is no mineral production. External trade usually shows a favourable balance, but this is largely because internal consumption of goods and commodities is so low. Since independence the national budget has been balanced chiefly by large Spanish subsidies.

Transport. The road network in Río Muni was adequate for the light traffic it was required to carry before independence, but since local autonomy was granted in 1964, neglect has led to deterioration of the earth roads. Bata is linked with Río Benito by a tarred road. The trans-Río Muni road from Bata to Ebebiyín, near the Cameroon frontier, is partially tarred. There are no railways. On Macías Nguema Biyogo the road system is of a higher standard, with a semicircular tarred road linking Batete to the eastern Bubi villages. The main harbour is Malabo, which is connected to Spanish and other European ports by regular steamer services. There is a regular steamer service between Bata and Malabo, but the service to Pagalu is erratic. Communications are maintained with Calabar in Nigeria and with Douala in Cameroon to transport migrant workers to and fro. There is an international airport at Malabo with links to Madrid, Douala, and Bata as well as weekly flights to Lagos (Nigeria) and Moscow and Odessa in the Soviet Union.

Administration. The system of government is presidential; and while all governing bodies are elected by

universal adult suffrage, the rule of the first president, Francisco Macías Nguema, is highly personal. The Council of Ministers is appointed by the President and is responsible to him. At least one-third of the 10 ministers on the council must be from Macías Nguema Biyogo. The National Assembly of 35 members is the legislative body. Río Muni has 19 deputies, Macías Nguema Biyogo 12, Pagalu two, and the Río Munian islets two. A Council of the Republic, consisting of six members elected by the respective provincial councils, has the function of mediating any dispute between the Council of Ministers and the assembly and between the central government and the two provincial councils, which are also elected by universal suffrage. This complex structure has been devised to protect the rights of the Macías Nguema Biyogo minority. The supreme tribunal in Malabo is the highest judicial authority.

In March 1970, all the political parties that existed before independence were merged into a Partido Único Nacional (Single National Party), which later changed its name to Partido Único Nacional de Trabajadores (Single National Party of Workers), under the leadership of the President, who assumed most of the powers in the country and subsequently was made president for life. Since he is a Fang, and most of the other political figures are also Fang—in addition to the members of the Guardia Nacional—the Fang now constitute the dominant element in Equatorial Guinea.

Cultural life. Despite a veneer of Spanish culture and of Catholic religion that is thicker in Macías Nguema Biyogo than in Río Muni, Equatorial Guineans live largely according to ancient customs, which have undergone a revival since independence. Among the Fang of Río Muni, witchcraft, traditional music (in which the Fang harp, the xylophone, the great drums, and the wooden trumpet are used), gorilla and elephant hunting, and storytelling all do much to relieve the monotony of life in the forest. Among the Bubi farmers of Macías Nguema Biyogo, some ancient customs are still followed.

Role of ancient customs

Education at primary levels was encouraged by the Spanish. In 1970–71 there were more than 6,000 students in secondary schools and technical institutions. At the time of independence, fewer than 30 Equatorial Guineans had completed higher education in Spain.

There is one daily newspaper in Malabo with a circulation of 1,000, and one weekly in Bata with a circulation of 500; both are in Spanish. There is also an official gazette, a monthly, and a Catholic bulletin. There are two radio stations, one in Bata and the other in Malabo. Both are operated by the government, as is the television station that operates from Malabo with programs in Spanish and in African vernacular languages. Cultural life centres on the Catholic mission in Malabo.

Prospects for the future. Equatorial Guinea received independence after a four-year transitional period that could have been used to prepare the small country for its future role but was not. The stability of its fragile economy rests upon the confidence of foreign investors in the Fang leadership; meanwhile, whatever goodwill existed between the local Spanish settler community and the Fang leaders was largely dissipated in the conflicts that occurred in 1969 and after the disturbances of 1970 in Malabo. The situation is complicated by the fact that, while the economic equation includes the necessary presence of tens of thousands of Nigerian migrant workers on Macías Nguema Biyogo, these were being repatriated in 1975–76 because of brutal treatment.

For a variety of reasons—including the reluctance of some Spanish settlers to cooperate with the new leadership, tribalism, and the influence of vested interests—the newly independent country has made a false start. It now struggles with a shortage of trained personnel and capital and is also not yet psychologically prepared for its role as an independent state. Because of its isolation from other West African states, which have been subjected to French and British influences, it is obliged to rely upon Spanish, Soviet, and Chinese help in overcoming the formidable obstacles presented by geographical fragmentation, ethnic diversity, and economic uncertainty. In addition, the strategic position of Macías Nguema Biyogo cannot be discounted in evaluating Equatorial Guinea's future prospects. It has on several occasions (once through its use as a base for a humanitarian airlift during the Biafran conflict) played a role in West African history and may do so again.

BIBLIOGRAPHY

Geography: MANUEL DE TERAN, *Síntesis geográfica de Fernando Poo* (1962), a useful geographical analysis; LUIS BAGUENA CORELLA, *Guinea: Manuales del África Española* (1950), the only detailed compendium of Guinean problems under the colonial regime; RENE PELISSIER, *Les Territoires espagnols d'Afrique* (1963; trans. and updated in 1964, *Los territorios españoles de África*), a handy reference on Spanish Africa; "Spanish Guinea: An Introduction," *Race*, 6:117–128 (1964), the only general review in English; SERVICIO INFORMATIVO ESPANOL, *España y Guinea Ecuatorial* (1968), an official record of developments until independence.

Economy: PRESIDENCIA DEL GOBIERNO, *Plan de desarrollo económico de la Guinea Ecuatorial: años de 1964 a 1967* (1963), the only reliable study of the subject.

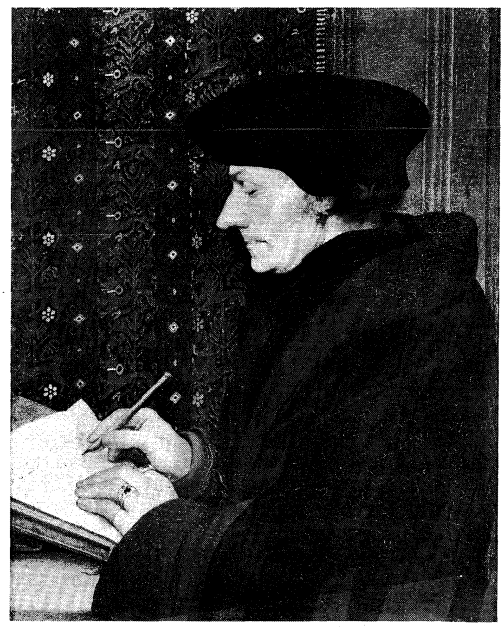
History and politics: ABELARDO UNZUETA, *Geografía histórica de la Isla de Fernando Poo* (1947), *Guinea Continental Española* (1944), *Islas del Golfo de Guinea* (1945), three standard, although poorly organized, works on history; RENE PELISSIER, *Études Hispano-Guinéennes* (1969), the only detailed analysis of the pre-independence period.

(R.P.)

Erasmus, Desiderius

Desiderius Erasmus, Dutch Humanist, scholar of classics and patristics, and the first editor of the Greek version of the New Testament, was the greatest scholar in what became known as the northern Renaissance.

Giraudon



Erasmus, oil painting by Hans Holbein the Younger, 1523. In the Louvre, Paris.

Early life and career. Erasmus was born at Rotterdam or, possibly, Gouda, in the Low Countries, October 26/27, in about 1466. He was the second child of Margaret, a physician's daughter, and Roger Gerard, a priest. Though a romantic story woven by Erasmus around these facts is suspect, the legal impediments of illegitimacy did haunt his later career. He went first to school at Gouda, where Peter Winckel (later one of his three guardians) was his rather obtuse usher (assistant teacher), and spent the years 1475–83, till his father's death, at the school of St. Lebwin's, Deventer (with a short spell as choirboy at Utrecht). There, though he could have had little contact with them, such teachers as John Sintheim (Sinthius) and Alexander Hegius, members of the Brethren of the Common Life, were opening the school to Humanist ideas. In this part of Holland the

influence of the so-called *devotio moderna* ("modern devotion"—a late medieval lay religious movement emphasizing education) was strong, and Erasmus owed much to its practical Christocentric piety, though he was to be repelled by the obscurantism and austerities of its latter end. When their guardians sent Erasmus and his elder brother, Peter, to school at 's Hertogenbosch, Erasmus found the prospect of a cloistered life and its discipline irksome. The brothers, however, were in no position to withstand their guardians' plans, and Peter entered a monastery at Sion, near Delft, while Erasmus became an Augustinian canon at Steyn and he was ordained a priest on April 25, 1492.

Though he now had an opportunity to study the classics and the poets, he felt the constraint of monastic life, which bred in him a passion for personal freedom and an irritation with restraint that became a trait of his complex character. Grasping eagerly at an opportunity to leave, probably in 1494, he became Latin secretary to Henry of Bergen, bishop of Cambrai, only to find that he did not take kindly to the sort of diplomatic career that suited many scholars of the age. He was glad when a friend secured permission for him to study theology at the University of Paris, where he entered the Collège de Montaigu at the time when the rector, the formidable Jan Standonck, was attempting to graft onto Paris the piety of the *devotio moderna* in its most austere form. It was too much for Erasmus, whose health gave way. Nor did his heart lie in the Scholastic theology or in preaching, in which he dabbled at this time. Like other Humanists, he was affronted by the dogmatic theologians, especially of the religious orders, with their party cries and intolerance and their violence and wooden hostility toward new methods. In Paris, however, he made acquaintance with the Humanists, and a commendatory epistle in Robert Gaguin's *De origine et gestis Francorum compendium* (1495) was his first writing to attract public attention. He returned to Paris from a convalescence in Holland and took pupils, first Christian and Henry Northoff from Lübeck and then the Englishmen Thomas Grey and Robert Fisher, for whose instruction he wrote the manuals *De conscribendis epistolis*, *De copia verborum*, *De ratione studii*, and *Colloquia familiaria* (*The Colloquies of Erasmus*), which underwent many revisions and became one of his most famous works.

Early works

First visit to England. What Erasmus really wanted was to be allowed to study in reasonable comfort, and he saw his various employments as of value only to that end. He had gradually to build up a precarious income (which always lagged behind his reputation) from pensions, gifts, and dedications, which in those years involved fulsome touting. His tutorial adventures introduced him to William Blount, Lord Mountjoy, who proved a steadier patron than most and whose invitation to England Erasmus accepted in 1499. Despite his often acid criticisms of England and the English, their barbarism, their weather, their beer, the country fascinated him and drew him back again and again. One reason, no doubt, was the patronage of Archbishop William Warham and John Fisher and even more the congenial friendship of such scholars as William Grocyn, Thomas Linacre, William Latimer, and, above all, John Colet and Thomas More. Of these last he left verbal portraits that have the vivid detail of a Holbein painting. Colet made an early vivid impression on him; his more intimate friendship with More ripened through the years. Though Colet was not the first to turn his thoughts from "good letters" to "sacred letters," he did challenge Erasmus to join him at Oxford in the battle against the Obscurantists and in the exposition of a more directly biblical theology. Erasmus rightly saw that he had not the technical equipment for such intervention, but he was now evidently more deeply concerned for "sacred letters." "I wished," he wrote, "that good letters should find that Christian character which they have lacked in Italy, and which, as you know, ended in glorifying pagan morality." Erasmus' new concern did not diminish his interest in the classical authors, for he stood for a combination of "good" with "sacred letters." He had long been acquainted with such poetic models as Virgil, Horace, Ovid, Juvenal, Statius, Martial, Claudian, Persius, Tibullus, and Propertius and in prose with Cicero, Quintilian, Sallust, and Terence. Throughout his life he edited works by Latin authors (*e.g.*, Pliny, Seneca) and produced translations of Greek classical writings (*e.g.*, Lucian).

The wandering scholar. In 1500 he left England, horrified at having to relinquish his earnings to the customs at Dover, and, in June, worked off some of his disgust by producing a collection of proverbs, the germ of his great *Adagia*. He spent the next months between France and Holland and in this unexciting period began arduously to gain that mastery of Greek that was to become the foundation of his later pre-eminence. His thoughts began to turn toward a great edition of Jerome, the archetype of his own ideal combination of good and sacred letters. At Saint-Omer he learned to know and admire the saintly Franciscan Jean Vitrier, who may have deepened in him a genuine strain of Pauline piety not to be overlooked. One result was the little *Enchiridion militis Christiani* (1503), which reflects some of the most attractive elements in his religion and at the close of which he wrote,

> Make the prophets, Christ and the Apostles your friends. Above all, choose Paul . . . it has long been my cherished wish to cleanse the Lord's temple of barbarous ignorance and to adorn it with treasures from afar, such as may kindle in generous hearts a warm love for the scriptures.

He continued to produce edifying discourses at intervals, though none of them attained the quality of the *Enchiridion*. There followed his *De interdicto esu carnium* (1522), *Exomologesis* (1524), *Modus orandi Deum* (1533), and *Christiani matrimonii institutio* (1526), dedicated to Catherine of Aragon. He commented on certain psalms in 1528 and at the end of his life discussed preaching in a comment on the book of Ecclesiastes.

In the summer of 1504 Erasmus found in the library of the monastery at Park, near Louvain, a manuscript of Lorenzo Valla's *Annotationes* on the New Testament, which criticized the Vulgate and advocated a critical method giving priority to exact, philological exegesis. The discovery was momentous for Erasmus, who published his own edition of this manuscript in 1505. He returned to England (1505–06), where he made his own copy of the Greek New Testament from such manuscripts as he could borrow. When a half-promised benefice failed to materialize, he seized an opportunity to visit Italy as tutor of the sons of Giovanni Battista Boerio, the physician to Henry VII. He took his D.D. at Turin (September 4, 1506) and in the next months saw at first hand the splendour and secularization of the church in Italy and those bloody consequences of papal diplomacy that much offended his temper and his conscience. He moved to Bologna and to Venice, where he collaborated with the great publisher Aldus Manutius. There, in the house of Andrea Asolani, he shared lodgings with the phenomenal young scholar Giralomo Aleandro. At Venice in September 1508 Erasmus published a great edition of his *Adagia*, now swollen to over 3,000 proverbs collected from the classical authors, a work that established his reputation as the foremost scholar in northern Europe. He became tutor to Alexander Stewart, the young archbishop of St. Andrews, and went with him to Padua and Siena. He visited Rome, but though he found friends at the papal court England drew him back, and he returned there to stay with Sir Thomas More. While there he wrote (1509) the *Encomium moriae* (*The Praise of Folly*, 1549) in the Lucianic style that was congenial to both him and More. The *Encomium moriae* drew not only upon ancient and medieval inspiration but also on Erasmus' own wit; it justifies J. Huizinga's comment that "only when humour illuminated that mind did it become truly profound," for the sharp satire became one of the most popular and enduring of his writings. He moved to the University of Cambridge, where he lectured on Greek and on the letters of Jerome. Archbishop Warham gave him the benefice of Aldington in Kent, which he commuted into a pension. But Erasmus could not settle anywhere for very long and was off again in 1514 to Basel, to a new fruitful partnership with the publishing house of

Erasmus in Italy and England

Johann Froben. About this time there appeared a scurrilous satire against the late pope—the *Julius exclusus*. The probabilities were slightly in favour of Erasmian authorship and were reinforced by the curiously evasive character of Erasmus' denials.

A shock came in June 1514, when an old friend Servatius Roger, now prior of Steyn, wrote re-calling him to the monastic life. His reply was a passionate plea for freedom, a defense of his own evident vocation for letters. It now became urgent for him to find authoritative support for his way of life, and he drew up an appeal to the papal chancery in which he put his case under the name of an imaginary Florentius. (This appeal, addressed to "Lambertus Grunnius," together with the letter to Roger and his own *Compendium vitae*, compiled in 1524, are primary sources of the life of Erasmus.) In January 1517 he received two dispensations from Pope Leo X, one allowing him to live in the world, and the other dispensing him from the dress of his order. On his return to England he received these dispensations formally on April 9, 1517, at the hands of his friend Ammonius Andreas, the papal legate.

Edition of the New Testament. In 1516 he had published his most immediately influential work, the edition of the New Testament, which gave priority to the Greek text. He compared such manuscripts as were available to him and various readings of the Fathers, while other scholars assisted with the philological apparatus, especially with Hebrew. It was perhaps less lack of energy that prevented him from mastering Hebrew than it was that he was as instinctively repelled by it as he was drawn by Greek. His general distaste for the Old Testament led him nearer than he knew to a view in which the moralists of the classical world supplied the place of the Old Testament. Although he did not have access to the earliest manuscripts, he provided a much more accurate text than that of the Vulgate. Alongside the Greek text he placed his own elegant Latin version, which greatly attracted scholars; and he appended critical notes, some of which were far from academic, many being as biting as the glosses of later Reformers. His prefatory essay was a noble plea for the study of the Scriptures, including the lines:

Views on knowledge of the Scriptures

> I could wish that every woman might read the Gospel and the Epistles of St. Paul. Would that these were translated into each and every language so that they might be read and understood not only by Scots and Irishmen, but also by Turks and Saracens . . . Would that the farmer might sing snatches of Scripture at his plough, that the weaver might hum phrases of Scripture to the tune of his shuttle, that the traveller might lighten with stories from Scripture the weariness of his journey.

The work was dedicated to Pope Leo X, who accepted the dedication. Nonetheless, it was strongly attacked. There were indeed obvious inaccuracies in the work, many of which were corrected in later editions. To forward-looking scholars the new version offered a more attractive, truer text, whereas its prefaces amounted to a manifesto of the new learning, expounding new critical method, and at the same time transmitting important gleanings from Erasmus' reading of the Fathers. Important too were his paraphrases, first of the Letters, then of the Gospels, the English translation of which had an important and official vogue in the reign of Edward VI. Erasmus has some claim to be regarded as the first New Testament scholar and in this lies his importance as theologian, scholar, and divine.

Years at Louvain. Erasmus spent the years 1517–21 at Louvain, where he took great interest in the new college for the study of the sacred languages founded by Jerome Busleiden. During this period his correspondence greatly increased and he became one of the most prolific letter writers among the Humanists for whom semiprivate correspondence of this kind afforded a prime means of learned conversation. A high proportion of the letters of Erasmus are distinguished from the bulk of Humanist correspondence only by their more polished Latin; but every now and again, writing to some intimate something new appears, pictures of contemporary life wittily observed, that Bruegel-like quality, which in his *Encomium moriae* and in his *Colloquia familiaria* anticipated the writing of a new age.

Years at Basel. In November 1521 he settled at Basel, perhaps the most satisfying to him of his many abiding places. From there he published a great series of works and became a central figure among those scholars for whom the return to the Fathers of the church was an integral part of the renewal of sacred letters. His edition of Jerome in nine volumes (1516) was a great achievement, but others followed: Cyprian (1520), Pseudo-Arnobius (1522), Hilary (1523), Irenaeus (Latin, 1526), Ambrose (1527), Augustine (1528), Chrysostom (Latin, 1530), Basil (1532), Origen (Latin, 1536). In some of the later editions Erasmus took little direct personal share. In Basel, too, he revised and extended the range of the *Colloquia familiaria* into which he contrived to pack an amazing amount of comment on contemporary manners, some of it "replete with malice spiteful."

Erasmus and Luther

The advent of the Reformation ended the Erasmian dream of a golden age of letters. His own criticism of the church had been formidable enough for Aleander to denounce him as the real author of schism and worse than the German reformer Martin Luther. To Erasmus, however, Luther must have seemed a typical dogmatic theologian, violent, aggressive. Luther in his first literary contacts (they never met) was polite, though he soon diagnosed a deep divergence of which the Erasmian preference for Jerome against Augustine was symptomatic.

As the church struggle widened, both sides appealed to Erasmus, who was at one time hailed as the author both of Luther's *De captivitate Babylonica ecclesiae praeludium* (1520) and of Henry VIII's reply. Yet it counted for Luther that in critical months during 1519–21 Erasmus did not come out against him and indeed offered his services and mediation; while in an interview with Frederick the Wise of Saxony, Erasmus himself may have stiffened the resolve of the prince that Luther should not be refused a hearing at the Diet of Worms. In the next years Erasmus was more and more alienated from the Reformers, though some of them, including Huldrych Zwingli, John Oecolampadius, Martin Bucer, and Philipp Melanchthon, had been among his fervent admirers. A long dispute with the French classical and biblical scholar Jacques Lefèvre d'Étaples had shown Erasmus to be hypersensitive to criticism, and in 1523 a bitter polemic with the German Humanist and writer (also a vigorous supporter of Luther's reforms) Ulrich von Hutten resulted in *Spongia Erasmi . . . adversus aspergines Hutteni* ("Erasmus' Sponge Against Hutten's Mire"), the least creditable of all his writings. In 1524 Erasmus yielded at last to the prompting of his patrons and in great haste attacked Luther in *De libero arbitrio*. The work incensed his opponents without much satisfying his friends, and, though an able enough essay in Erasmian moderation, it exposed too his theological limitations. Luther's reply, the *De servo arbitrio* (1525), violent and perverse, is in a more profound dimension. Erasmus worked off his resentment in the tiresome *Hyperaspistes* (1526), but he much improved a second edition, which contains some of his finest mature utterances.

Last years. Though the triumph of the Reformation in Basel under Oecolampadius in 1529 was less violent than elsewhere, Erasmus with other Humanists left and went to Freiburg in Breisgau; there he stayed until 1535 when, aging and unwell, he returned to Basel. Although an imperial councillor, who from the time of writing his *Institutio principis Christiani* (1516) had sought to advise the secular powers, he did not attend the Diet of Augsburg. But his interest in the peace of the empire and of the church brought from him in 1533 *De amabili ecclesiae concordia*, and among those who were trying to heal the breach there were moderate men who were his disciples. A new pope, Paul III, nominated him as dean of Deventer, and at last there was talk of a cardinal's hat. But it was all too late in the day, for Erasmus had outlived his preoccupation with dignities and turned instead to paraphrase a psalm for a humbler but loyal friend, Christopher Eschenfelder, the customs officer at Bop-

pard; to set his affairs in order (he had sold his library in 1534 to the Polish nobleman Johannes à Lasco); and to prepare for an end that could not be far off. He died in Basel on July 12, 1536. That he died without the sacraments shocked Luther, but Bonifaz Amerbach, his heir, who was with him to the end, wrote of his death, "As was his life, so was the death of this most upright of men. Most holy was his living, most holy his dying." Poignantly the last words of the great cosmopolitan, *Lieve God* ("Dear God"), were in Dutch.

MAJOR WORKS

THEOLOGICAL WORKS AND COMMENTS ON TOPICAL PROBLEMS: *Enchiridion militis Christiani* (1503; *The Manuell of the Christen Knyght*, trans. by W. Tyndale, 1533); *Ratio seu compendium verae theologiae* (1518); *De libero arbitrio* (1524; *Discourse on Free Will*); *Hyperaspistes diatribae adversus servum arbitrium M. Lutheri* (1526); *Christiani matrimonii institutio* (1526); *Dialogus, cui titulus Ciceronianus, sive, de optimo dicendi genere* (1528); *De sacrienda ecclesiae concordia* (1533); *Modus orandi deum* (1533).

EDUCATIONAL WORKS: *De ratione studii et instituendi pueros* (1512); *Institutio principis Christiani* (1516; *The Education of a Christian Prince*); *Ecclesiastae sive de ratione concionandi libri quatuor* (1535; *Ecclesiastes; or, the Preacher: An Essay on the Duties of a Public Religious Instructor*, 1797).

BIBLICAL WORKS AND EDITIONS OF THE FATHERS: *Novum instrumentum* (1516); *Omnium operum divi Eusebii Hieronymi* (1516); *D. Caecilii Cypriani opera* (1519); *Sancti Aurelii Augustini opera* (1529); *Sancti Basilii opera omnia* (1532).

OTHER WORKS: *Adagia* (1500; extended edition, 1508); *Encomium moriae* (1509; *The Praise of Folie*, trans. by Sir Thomas Chaloner, 1549; republished 1965); *Colloquia familiaria* (1518; *The Colloquies of Erasmus*); *Compendium vitae Erasmi* (1607); *Opus epistolarum D. Erasmi Roterodami*, ed. by P.S. Allen, H.M. Allen, and H.W. Garrod (1906–58).

BIBLIOGRAPHY. J.A. FROUDE, *Life and Letters of Erasmus* (1895, reprinted 1971), perceptive and still valuable; PRESERVED SMITH, *Erasmus: A Study of His Life, Ideals and Place in History* (1923, reprinted 1962), a useful biography with still more useful and plentiful quotations; JOHAN HUIZINGA, *Erasmus of Rotterdam* (1924, reprinted 1952), a brilliant analysis; P.S. ALLEN, *The Age of Erasmus* (1914, reprinted 1963); ROLAND H. BAINTON, *Erasmus of Christendom* (1969), embodies recent research in a scintillating narrative; AUGUSTIN RENAUDET, *Études érasmiennes* (1939), a basic source for French-reading students; MARCEL BATAILLON, *Érasme et l'Espagne* (1937); ERNST W. KOHLS, *Die Theologie des Erasmus* (1966), the only recent survey of Erasmus's theology; MARGARET M. PHILLIPS, *Erasmus and the Northern Renaissance* (1949), a weak account of theology, but splendidly sympathetic and a good historical study; also by Phillips, *The "Adages" of Erasmus* (1964). Important English editions of Erasmus's work include CRAIG R. THOMPSON, *The Colloquies of Erasmus* (1965), a fine collection of extracts and commentary; E. GORDON RUPP and PHILIP S. WATSON, *Luther and Erasmus* (1969), on the controversy between Erasmus and Luther in 1525 with commentary and essays; and paperback translations of *Praise of Folly*, *Selected Letters*, and *Selected Writings*.

(E.G.R.)

Ericales

The Ericales is an order of about 2,700 species of plants, largely shrubs or small trees, arranged in ten families and about 135 genera.

The number of species used as ornamentals is inordinately large when compared with other plant groups of similar size. Many of the most beautiful and prized horticultural plants throughout the world are found in the Ericales, for example, azaleas and rhododendrons. Blueberries and cranberries are economically significant; there are other species of less commercial value.

GENERAL FEATURES

Structural diversity and distribution. Although predominantly woody shrubs and small trees, the order includes herbs, undershrubs, vines, epiphytes (plants that grow upon other plants), herbaceous saprophytes (nonphotosynthetic plants that obtain nourishment from dead organic matter), and root parasites. A few tree species attain heights of 75 to 100 feet (20 to 30 metres).

Worldwide distribution

Ericads are very widely distributed in the tropics and throughout temperate regions of the Northern and Southern Hemispheres and are a significant component of the sub-Arctic circumpolar flora. A few extend into the Arctic and the Antarctic regions. A number of genera are indigenous to southern Africa, and the large family Epacridaceae is in a sense the Australian segment of the order.

It has been customary to think of the species of the Ericales as inhabitants of temperate and cooler regions, with tropical representatives being confined to the cool, high mountainous regions. A majority of species do occupy these areas, but the recent inclusion of the families Actinidiaceae and Saurauiaceae in the order has extended the group's range into typically tropical situations of Asia and America. As a general rule, ericalean plants prefer acid soils.

Economic importance. Ericads have served as tea substitutes; early explorers of Canada and the eastern and northern regions of the United States, for example, brewed tea from the leaves of Labrador tea, or bog tea (*Ledum palustre*); Lapland rosebay (*Rhododendron lapponicum*); and checkerberry, or teaberry (*Gaultheria procumbens*). The Ojibwa Indians similarly used bog rosemary (*Andromeda glaucophylla*) and leatherleaf (*Chamaedaphne calyculata*).

For centuries the best material for making briar pipes has been wood from burls of *Erica arborea* or related Mediterranean species.

Edible berries

Ericalean plants have been and still are most important to man as foodstuffs and as cultivated ornamentals. Checkerberry (*Gaultheria procumbens*), certain of the bearberries (*Arctostaphylos* species), and creeping snowberry (*Chiogenes hispidula*) produce edible fruits. In Asia the fruit of the tara vine (*Actinidia arguta*) is much sought after. But it is the huckleberries, the blueberries, and the cranberries that are most prized as fresh fruits or as jellies or preserves.

Cranberries (*Vaccinium macrocarpon*) are cultivated in Massachusetts, especially on Cape Cod; in New Jersey; in Wisconsin; and in the Pacific Northwest. They are also harvested from wild stands in these areas. The tart fresh berries are processed with sugar and sold as cranberry sauce or jelly. Cranberries, first cultivated in New England in the early 19th century, are still one of the leading exports of Massachusetts. Cranberry sauce and jelly have come to be thought of as uniquely American, but the Scandinavians hold in high esteem their own native cranberry (*V. vitis-idaea*), the berry of which is spicier than the American fruit.

Huckleberries (*Gaylussacia baccata*) are harvested only from wild stands in the eastern United States and Canada. Although the flesh of the fruit is generally considered to be sweet and delicious, the "berry" is actually a drupe, or stony-seeded fruit, with ten large, hard nutlets, making it less desirable and marketable than blueberries.

Blueberries of many types are harvested from wild stands in New England and the eastern states and from northern California into western Canada. Several species of *Vaccinium* are involved. They range from lowbush to highbush species and from diploid to hexaploid forms (*i.e.*, genetic variants with two to six sets of chromosomes, respectively). Blueberries, with their small and insignificant seeds, are widely considered a delicacy; in constant demand, their commercial production is economically significant, especially in New England.

Ornamental uses

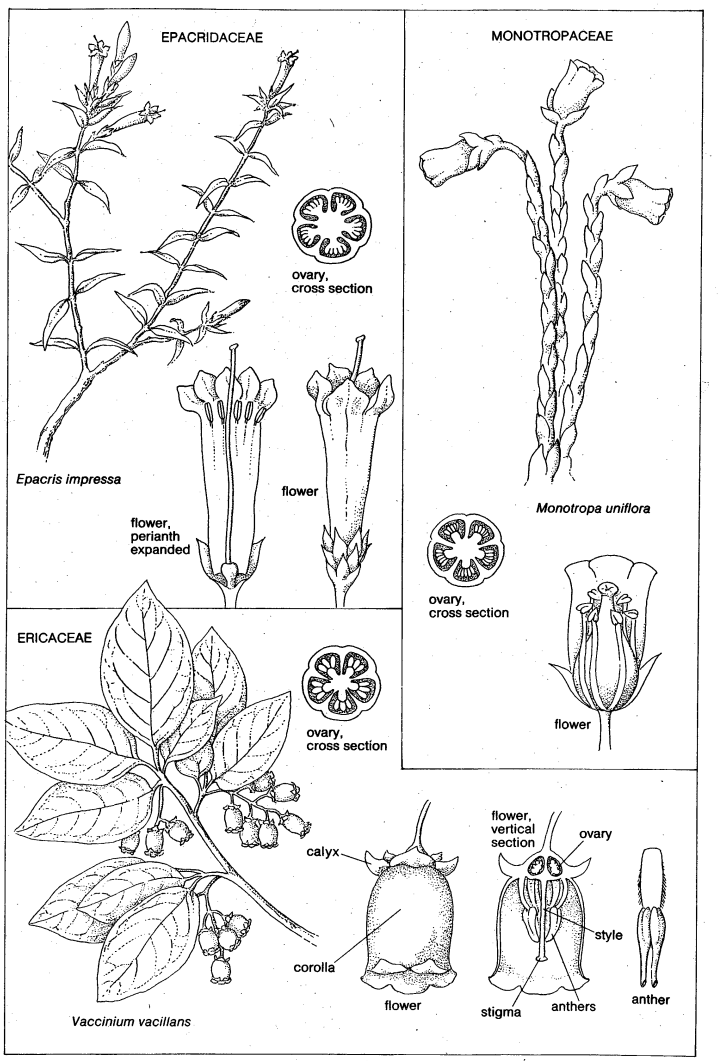
The other major use of ericads is as ornamentals. In Asia some of the vinelike forms (*Actinidia arguta* and *Clematoclethra* species) are cultivated for their deep green foliage. Several species of sweet pepper bush (*Clethra*) are used horticulturally to take advantage of the highly fragrant summer flowers. The leatherwood (*Cyrilla racemiflora*) and buckwheat tree (*Cliftonia monophylla*) are used similarly and also are desirable for their showy autumn coloration of foliage. The sourwood (*Oxydendrum arboreum*), one of the few trees in the order, is also cultivated because of the brilliant colour of its foliage in autumn. In Europe and New England, the heather (*Calluna vulgaris*) and some of the low bushy

heaths (*Erica* species) are used as garden border plants. Many ericads are planted in gardens as novelties or to provide variation in foliage colour and texture.

The most important ornamentals in the entire order, however, are found in the genus *Rhododendron*, the azaleas and the rhododendrons, about 850 species of which are or have the potential to be ornamentals. Some of the most spectacular flower clusters known are produced by these shrubs, and they are widely used not only for the beauty of their blooms but also for the value of the many evergreen species as effective background shrubs. Natural species are cultivated, and many hybrids have originated in cultivation; it is thus difficult to develop a classification that includes all species, varieties, and forms. It is safe to say, however, that there are at least 1,000 varieties of rhododendrons and azaleas in cultivation.

Noxious ericads. The order is not noted as a group of noxious plants, although a few species can be so described. Some contain a toxic substance identified as andromedotoxin. This compound is known to occur in certain species of *Rhododendron*, *Leucothoë*, *Menziesia*, *Ledum*, and *Kalmia*, and it is probably more widespread in the order than is now known. Humans can be poisoned by chewing on leaves and twigs or by sucking nectar from the flowers of these plants. Poisoned honey has been reported in areas in which bees visit large *Rhododendron* or laurel (*Kalmia*) stands, but the honey is so bitter that very little of it can be eaten. The poison causes watering of the mouth, eyes, and nose; vomiting; slow pulse; and depressed blood pressure. Massive ingestion of andromedotoxin results in convulsions and slow and progressive paralysis until death; fatalities, however, are rare.

Several species of laurel (*Kalmia*) long have been known to be poisonous to domestic animals. *Kalmia angustifolia* is known colloquially as sheepkill, lambkill, or calfkill, and one common name of *K. latifolia* is poison laurel. Sheep and cattle may become ill and die from eating foliage of these plants, but deer do not seem to be affected. The course of the disease parallels that in humans who have taken massive ingestion of andromedotoxin—convulsions, progressive paralysis, and death. Laurel poisoning is not a serious problem in sheep or cattle, however, probably because the tough, leathery leaves are not desirable except in the absence of more palatable foliage. Cases of poisoning are more frequent in sheep than in cattle.



Representative plants from three of the principal families of the order Ericales.

Drawing by M. Pahl based on (Epacridaceae, Ericaceae all but ovary) G.M.H. Lawrence, *Taxonomy of Vascular Plants* (1951); The Macmillan Company, (Ericaceae ovary) J. Hutchinson, *The Families of Flowering Plants;* The Clarendon Press, Oxford

NATURAL HISTORY

Pollination. Compared with some of the very highly specialized plant groups, such as the orchids, few unusual or unique features exist in the life cycle of the ericads. There has been only the slightest tendency toward development of irregular flowers, and highly involved and complicated methods of pollination are rare.

Probably most ericads may be pollinated in more than one way, but studies on pollination in the Ericales have been sketchy. In the heather (*Calluna vulgaris*), the nectary in the flower is a continuous, fleshy ring around the base of the ovary (female structure), and the lower parts of the petals and stamen filaments (basal parts of the male structures) are also succulent. An insect forcing its proboscis into the flower shoves the anthers (pollen sacs) apart. Anther chambers open laterally, and hornlike appendages attached to the anthers help deposit pollen on the insect's proboscis by acting as levers. Pollen is carried to another flower by the insect and deposited upon the stigma (pollen receptive surface of the female structure) as the insect probes for nectar in the flower.

Insect pollination

Nectar production decreases near the end of the pollination period. The filaments then elongate and extend the open anthers beyond the confines of the flower; thereafter wind pollination occurs.

Another kind of pollination also takes place in the same heather flower. Certain small insects (*Taeniothrips ericae* [Thysanoptera]) appear to be present at all times in *Calluna* flowers. These tiny insects are very lively, move about actively, and reach parts of the flower inaccessible to larger insects. Pollen discharged during their activity adheres to their bodies, which become sticky with nectar. The males of *T. ericae* are much rarer than the females and cannot fly. Females, therefore, take the aggressive role and fly from flower to flower searching for males. They depart from projecting stigmas, their bodies heavily laden with pollen, and presumably land on stigmas, thereby probably being able to effect both self- and cross-pollination.

The laurels (*Kalmia* species) have two pouches in each of the five partly fused petals. Anthers are retained under tension in these pockets until the flower opens; then the filaments snap the anthers up, and pollen is forcibly ejected. Laurel flowers are visited by bees that almost certainly effect pollination. Presumably elevation of the anthers above the saucer-shaped flowers of *Kalmia* also permits wind pollination.

Mycorhizal relationships. Mycorhizae are structures formed by plant roots and the fungi that live in close association with them. Mycorhizal associations are common and widespread in the Ericales. It has been suggested that probably all ericads are in some mycorhizal relationship. Although considerable research has been done on the nature of the relationship, much of the work has been challenged and is of doubtful validity. In most instances, the species with an obligate relationship and those without cannot be identified with certainty; the relationship is obligate, however, in the few members of the family Pyrolaceae that occasionally lack chlorophyll and in the family Monotropaceae, all of whose members lack chlorophyll. In addition to these families, mycorhizae have been reported in the Clethraceae, Epacridaceae, and

Empetraceae. The phenomenon, which is widespread in the Ericaceae, probably occurs in all families of the order.

The structure of the ericalean mycorhiza has been described as being intermediate between the conditions called ectotrophic and endotrophic, and the term ectendotrophic has been used to describe the mycorhiza of *Monotropa*. Host roots are enveloped by masses of fungal hyphae (filaments of fungus cells) as in ectotrophs, but hyphae penetrate the cells of the host root tissues, as in endotrophs.

The fungi involved in the relationship are members of the fungal classes Deuteromycetes and Basidiomycetes. A number are of the genus *Rhizoctonia*. Little is known as yet of the physiological relationships between the fungus and the plant. The view that species of *Phoma*, a deuteromycetes associated with some ericads, serve to fix free atmospheric nitrogen appears to be unfounded. There are advocates of a theory that fungi may serve in some capacity to synthesize various carbon-containing materials from the soil, which are then passed along to the host plant. This explanation is especially attractive in explaining saprophytic situations of nongreen ericads. It must be assumed that the fungus utilizes organic compounds from the soil and transfers its products in forms useful to the plant.

EVOLUTION AND CLASSIFICATION

Fossil record and phylogeny. Fossil records of ericads are not numerous, especially considering the number of species in the order. All have been found in deposits of the Tertiary Period (2,500,000 to 65,000,000 years ago) and mostly from the Oligocene Epoch (26,000,000 to 38,000,000 years ago) and the Miocene Epoch (about 7,000,000 to 26,000,000 years ago).

Fossil leaves of *Saurauia* have been found in Alaska, and *Actinidia* leaves have been recovered from California. Miocene layers in Oregon have yielded leaves of *Arbutus trainii*, which closely resemble those of the living madrona (*A. menziesii*) of the Pacific Coast. Fossil records of *Arctostaphylos*, *Vaccinium*, and *Andromeda* also have been reported.

Fossil pollen grains

Many fossil pollen grains have been taken from Miocene deposits at Rypin, Poland. In some cases, some of them have been assigned to the Ericales because of structural resemblances; in other cases, they have been so assigned because of structure and the fact that they occur in tetrads (groups of four), a condition common in living ericads. *Cyrilla* appears to be represented by three species. Several pollen tetrads have been assigned to the Ericaceae, but only those of the genus *Rhododendron* are clearly identified.

The fossil record is of little help in tracing phylogenetic relationships within the order or between the Ericales and other orders. Any such relationships must be determined largely from comparative morphological studies of living forms. Close affinities between the order Ericales and the order Diapensiales are recognized, and a common ancestry for the two is postulated in the order Theales. A close relationship of these groups has been recognized for some time.

Classification. *Distinguishing taxonomic features.* Although there are exceptions to most features, ericads generally are shrubs with alternate, simple, leathery leaves. Their flowers have functional structures of both sexes and are regular (radially symmetrical) with a four- or five-parted corolla (collection of petals) of partly fused petals. Stamens number twice the number of corolla lobes and usually are attached directly to the receptacle (expanded stalk tip that carries the flower parts). Anthers open by terminal pores, and pollen is discharged in tetrads. The pistil (female structure) is compound with one style (upper, narrow, elongated part of pistil). The ovules are numerous and are attached along the central axis of the ovary. The only characteristics shared by all ericalean species are that the ovule has but one integument, or covering cell layer, and the nucellus (central part of ovule) is a single cell layer thick.

Variations in the above characteristics provide the bases for establishing families and for determining relationships between them. Major variables of taxonomic significance are: number of floral parts, degree of fusion of floral parts, degree of fusion of floral parts with the ovary, type of anther dehiscence (opening), structure of pollen, structure of ovary, and type of fruit.

Annotated classification. The classification system used below is a recent one that differs from more traditional schemes mainly in the inclusion of the family Grubbiaceae.

ORDER ERICALES

Herbs, shrubs, trees, herbaceous saprophytes, or root parasites. Leaves alternate (also opposite or whorled in Ericaceae; opposite in Grubbiaceae), simple, commonly leathery, without stipules (basal appendages). Flowers mostly bisexual, regular or slightly irregular. Calyx of 4 to 10 (rarely fewer) separate or partly united sepals. Corolla of 4 to 10 (rarely fewer) separate or partly united petals or, in a few instances, lacking. Stamens usually as many or twice as many as petals or sepals, very rarely more numerous, and sometimes partly reduced to staminodia (sterile stamens). Ovary of several, usually 2 to 7, fused carpels (ovule-bearing segments) and 2 to 7 (rarely more) chambers, infrequently with incomplete partitions; rarely with 1 chamber. Ovary superior, partly inferior, or inferior (positioned above, partly enclosed, or enclosed by the other flower parts). Styles united except in rare cases. Ovules usually, but not always, numerous. Ovule attachment usually axile (central in Grubbiaceae). Fruit a berry, drupaceous, or a capsule. Seed with copious fleshy endosperm (nutritive tissue). Ten families, about 135 genera, and some 2,700 species.

Family Saurauiaceae (saurauia family)

Trees or shrubs clothed with bristly hairs. Leaves alternate, simple, frequently serrate (toothed). Flowers mostly bisexual, regular, hypogynous. Sepals 5, separate, greatly overlapping. Petals 5, separate or fused into a short tube at the base. Stamens numerous, attached to petals. Ovary superior with 3 to 5 locules (chambers). Styles 3 to 5, separate or partly to completely united. Ovules numerous. Fruit a 3- to 5-locular berry, rarely somewhat dry and dehiscent. Seeds small. One genus (*Saurauia*) with about 250 species in tropical and subtropical America and Asia.

Family Actinidiaceae (actinidea family)

Trailing or climbing shrubs. Leaves alternate, simple, more or less rounded, sometimes serrate. Flowers bisexual or unisexual; regular. Sepals 5, separate and overlapping. Petals 5, separate. Stamens 10 or more. Ovary 3-locular or more, the carpellary walls sometimes hardly reaching the central axis. Ovules 2 or more in each locule. Styles 5 and completely united or many and spreading. Fruit a dry capsule or a berry. Seed small. Three genera with about 25 species of tropical (a few in temperate) East Asia.

Family Clethraceae (pepperbush family)

Tall shrubs or low trees. Leaves alternate, simple, often serrate. Flowers very fragrant or aromatic, bisexual, regular. Sepals 5, partly fused, persistent about the fruit. Petals 5, separate, forming a saucer-shaped corolla. Stamens 10 (sometimes 12), separate. Pistil with 3 carpels. Ovary superior with 3 locules, mostly 3-lobed. Style 1. Ovules numerous. Fruit a 3-valved capsule. Seed sometimes winged. One genus (*Clethra*) with about 30 species native to eastern North America, Brazil, Mexico, and East Asia.

Family Ericaceae (heath family)

Shrubs; subshrubs; occasionally woody, perennial herbs; or small trees. Leaves opposite, alternate, or whorled; simple; often leathery and persistent. Flowers bisexual, regular or slightly irregular. Sepals 4 to 5, separate or partly fused, usually persistent, sometimes fused with the ovary. Petals 4 to 5, rarely separate, usually partly fused. Stamens as many or more commonly twice as many as the petals, inserted on the outer edge of a disc that surrounds the ovary at its base or higher up. Pistil 4 to 10 carpellate. Ovary superior, partly inferior, or inferior, 4- to 10- (typically 5-) loculate. Ovules usually numerous. Stigma and style 1. Fruit a capsule, berry, or drupe. Seed usually small. Seventy to 80 genera with 1,500 to 1,900 species widely distributed on acid soils throughout temperate Northern and Southern Hemisphere regions, in sub-Arctic regions, and in high mountains in the tropics.

Family Epacridaceae (epacris family)

Shrubs or small trees. Leaves alternate, often crowded, simple, small leathery, usually stiff. Flowers bisexual (rarely unisexual), regular. Sepals 4 to 5, partly fused, persistent. Petals 4 to 5, partly fused, or rarely petals separate. Stamens usually 5, but sometimes 4, alternating with the petals, and sometimes with alternating staminodia. Pistil 4- to 5-carpellate. Ovary superior with 1 to 10 locules often surrounded at the

base by a disc. Ovules 1 to many in each locule. Style 1, stigma capitate. Fruit a 5-valved capsule or a drupe. Twenty-four genera with about 340 species, mostly in Australia, New Caledonia, New Zealand and the Antarctic islands, a few species in the islands of the Pacific, in India, and the Malay Archipelago, and a single species in the mountains of South America.

Family Pyrolaceae (pyrola family)
Evergreen, perennial herbs with creeping rootstocks. Stem above ground short, sometimes slightly woody at the base. Leaves alternate, almost opposite, or in false whorls, simple, leathery, and mostly toothed. Flowers bisexual, regular or slightly irregular. Sepals 5, separate or slightly united. Petals 5, waxy, separate, hypogynous. Stamens 10, separate. Pistil compound, 4- to 5-carpellate. Ovary superior, 4- to 5-loculate. Ovules numerous. Style 1. Fruit a capsule. Seed numerous. Ten or 11 genera with perhaps as many as 45 species of the Northern Hemisphere.

Family Monotropaceae (Indian pipe family)
Saprophytic or root parasitic herbs, almost or, more commonly, completely lacking chlorophyll, usually white, brown, purple, red, yellow, or pink, mostly succulent. Stems single or clustered from matted roots. Leaves short or rarely elongated scales. Flowers borne singly, erect, or nodding, bisexual (very rarely unisexual), regular or slightly irregular. Sepals 2 to 6, separate. Petals 3 to 6, separate or partly united (petals absent in *Allotropa*). Stamens 6 to 12. Pistil compound of 4 to 6 carpels. Style 1. Ovary superior, mostly 4- to 6-loculate, or sometimes 1-celled. Ovules numerous. Fruit a 4- to 6-celled capsule or, rarely, 1-celled, somewhat fleshy. Seed numerous, minute. About 9 genera with about 16 species chiefly, if not all, North American.

Family Cyrillaceae (cyrilla family)
Deciduous or evergreen shrubs or small trees. Leaves alternate, simple, frequently leathery. Flowers bisexual, regular. Sepals 5, separate and overlapping or fused at the base. Stamens 10, in 2 whorls of 5 each, the inner whorl sometimes reduced to staminodia or even missing. Pistil compound, 2- to 4-carpellate. Ovary superior with 2 to 4 locules. Ovules 1 or 2 in each locule. Fruit a dehiscent capsule or a spongy berry. Three genera with about 12 species. Monotypic species (genera with only one species) of *Cyrilla* and *Cliftonia* are indigenous to the southeastern United States. *Costaea* has several species extending from Cuba into South America.

Family Empetraceae (crowberry family)
Evergreen, small, cushion-shaped, heathlike shrubs. Leaves alternate, linear, the lower surface deeply grooved. Flowers usually bisexual, irregular. Sepals 2 to 6, often petaloid, bracteate (resembling bracts, small green structures), sometimes absent, separate, often overlapping, in 2 whorls. Petals absent (inner whorl of sepals interpreted by some to be petals). Stamens 2 to 4, separate, alternating with the sepals. Pistil 1, 2- to 9-carpellate. Ovary superior, 2- to 9-loculate. Ovules 1 in each locule. Style 1, variously branched into 2 to 9 lobes. Fruit a fleshy or dry berry with 2 or more 1-seeded pyrenes (nutlet-like structures). Three genera with 8 species native to the mountains of North and South America extending into the Antarctic, the Arctic, and northern circumpolar regions.

Family Grubbiaceae (grubbia family)
Heathlike shrubs. Leaves opposite, simple, linear or lance shaped, leathery. Flowers bisexual, regular. Perianth (sepals and petals) 1- to 4-lobed of undifferentiated segments. Stamens 8, in 2 whorls of 4 each. Pistil 1, 2-carpellate. Ovary inferior, 1-loculate at maturity, with 2 pendulous ovules. Style 1, stigma slightly bifid (two-parted). Fruit a drupe with a crown composed of the disc and style. One genus (*Grubbia*) with 4 species endemic to southern Africa.

Critical appraisal. Close relationships among the families Clethraceae, Pyrolaceae, Monotropaceae, Ericaceae, and Epacridaceae have been recognized for many years, although taxonomists have not agreed in their treatment of the families. The family Monotropaceae frequently is combined with the Pyrolaceae, and both families are sometimes included in the Ericaceae. The family Vacciniaceae which is composed of those species of the Ericaceae that have partly to wholly inferior ovaries is sometimes recognized.

In any of these manipulations, however, the five "core families" noted above comprise some 2,200 species, or more than 80 percent of the approximately 2,700 species of the order.

Inclusion of the family Empetraceae in the Ericales has become almost universally accepted in recent years, although one important taxonomist retains it in the order Celastrales.

Fairly recently the family Cyrillaceae has been placed in the Ericales, an arrangement that is gaining acceptance. Previously, it was assigned to the Celastrales, and, in some systems, it remains there.

Five principal families stable in all taxonomic systems

The families Actinidiaceae and the Saurauiaceae are obviously closely related to each other, and it is common to find the Saurauiaceae within the Actinidiaceae. These families have affinities with both the orders Dilleniales and Theales, and modern taxonomic treatments are about equally divided in placing them in one or the other order. Referred to the Ericales, as is done here, they are the most primitive families in the order and may be regarded as near ancestral to the families more traditionally comprising the Ericales.

Inclusion of the family Grubbiaceae in the Ericales has been to date quite widely rejected. The family consistently has been placed in the order Santalales for a great many years. The main stumbling block to general acceptance of the Grubbiaceae in the order Ericales is the structure of the pistil. The ovary is inferior and, as it begins its development, is more or less two-locular (chambered). As the ovary continues to mature it becomes unilocular with a standing, free-central placenta that bears two pendulous ovules. This ovular structure is so typical of the order Santalales and so completely atypical of the order Ericales that few taxonomists consider the ericalean characteristics of the Grubbiaceae to outweigh the santalalean structure of the ovary.

(H.T.C.)

Erskine, Thomas Erskine, 1st Baron

Renowned in his own time for an unrivalled forensic skill, Thomas Erskine (1750–1823) made important contributions to the defense of personal liberties during his brilliant career as a British lawyer.

Early life and career. He was born Jan. 10, 1750, in Edinburgh, the youngest son of Henry David Erskine, 10th earl of Buchan. Upon completion of his preliminary education, though he wanted to enter a learned profession because of the straitened financial circumstances of his family, he sought a career in the Royal Navy instead. He became a midshipman in 1764 but left the service in 1768 and purchased a commission in a regiment of the 1st Royals. He added to his education by extensive reading, particularly in English literature. His unsigned pamphlet, "Observations on the Prevailing Abuses in the British Army" (1772), gained a wide audience. Finding opportunities for advancement in the British army no more favourable than in the navy and encouraged by the friendly interest of Lord Mansfield, Erskine decided to

enter the law. He was admitted to Lincoln's Inn in 1775, and in 1778 he received an honorary M.A. degree from Trinity College, Cambridge, after which he was called to the bar.

Erskine, oil painting by Sir William Charles Ross (1794–1860). In the National Portrait Gallery, London.

Professional life. Within a few months, his future was assured by his defense of Capt. Thomas Baillie, lieutenant governor of Greenwich Hospital, who had published charges of corruption in the administration of the hospital. Those accused instituted a proceeding to show cause why Baillie should not be prosecuted for criminal libel. Erskine was retained by Baillie as his junior counsel and in his first appearance at the bar vindicated his client with remarkable eloquence and courage. He very quickly rose to the leading position in the English bar. In the following year, he successfully assisted the defense in the court-martial of Adm. Augustus Keppel. His successful defense of Lord George Gordon on the charge of high treason for instigating the anti-Catholic riots of 1780 substantially destroyed the English legal doctrine of constructive treason—*i.e.*, treason imputed to a person from his conduct or course of actions, though none of his separate actions amounts to treason. Erskine appeared in most of the major cases that arose out of the disruption of commercial relations with France, which had entered the United States War of Independence against Britain in 1778.

Defense of Lord George Gordon

In 1784 he unsuccessfully represented a clergyman defending a charge of criminal libel, but his contention that it is for the jury, not the judge, to determine whether a publication is libellous was vindicated by the passage of the Libel Act of 1792. In 1789 he won an acquittal for a bookseller who was charged with criminal libel for selling a pamphlet criticizing the trial of Warren Hastings, a former governor general of India who was impeached for alleged misconduct. Erskine's speech on that occasion is one of the monuments in the literature of English freedom. His unsuccessful defense of Thomas Paine, whom William Pitt, the prime minister, had caused to be indicted for treason for publishing *The Rights of Man*, cost him his position as attorney general to the Prince of Wales.

His defense of various politicians and reformers on charges of treason and related offenses placed a powerful check on the repressive measures taken by the ministry of William Pitt in response to the insecurity and hysteria engendered in England by the French Revolution and its aftermath. In 1800, by establishing the defendant's insanity, he successfully defended James Hadfield, who had attempted to assassinate George III. Erskine's argument at the trial is an important contribution to the law of criminal responsibility.

Erskine, who was an intimate of the Whig leaders Charles James Fox and Richard Brinsley Sheridan, the playwright, sat in the House of Commons from 1783 to 1784 and from 1790 until he became a peer in 1806. His undistinguished parliamentary career was almost wholly devoid of the forensic triumphs that marked his legal practice. In 1806 he became lord chancellor during the so-called Ministry of All the Talents. Erskine was not well qualified for the position either by training or experience. At the same time, his tenure of 14 months in office was not sufficiently long to permit any outstanding contribution.

Lord chancellor

His latter years were marked by private sorrows and misfortunes, which caused him almost completely to withdraw from public affairs. Toward the close of his life, however, he again achieved widespread prominence by his role in defense of Queen Caroline, whom her husband, George IV, had brought to trial before the House of Lords for adultery in order to deprive her of her rights and title. Erskine died at Almondell, Linlithgowshire (now West Lothian), Scotland, on Nov. 17, 1823.

Erskine's published works include his pamphlet "The Unconditioned Freeness of the Gospel in Three Essays" (1778); a student declamation published in 1794 in a pamphlet entitled "Sketch of Erskine, with Anecdotes: A View of the Causes and Consequences of the Present War with France" (1797); *Armata, a Fragment* (1817), written in the style of *Gulliver's Travels*; a burlesque of Gray's "Bard" entitled "The Barber" in *Poetical Works* (1823).

Published works

Numerous collections of Erskine's courtroom speeches have been published, the most useful of which include a collection edited by James Ridgway in 1847 and another edited by James L. High in 1874.

Assessment. Erskine excelled principally as a jury lawyer. His courtroom speeches are characterized by vigour, cogency, and lucidity and often by great literary merit. They consistently reveal a courageous and passionate dedication to the causes he represented. It was the judgment of Lord Campbell, a later lord chancellor and author of *Lives of the Lord Chancellors,* that, as an advocate, Erskine was "without an equal in ancient or in modern times."

BIBLIOGRAPHY. L.P. STRYKER, *For the Defense, Thomas Erskine* (1947), is a modern biography written in a popular style by a well-known American courtroom advocate. LORD CAMPBELL, *Lives of the Lord Chancellors . . .*, vol. 6 (1845), presents an interesting and anecdotal account of Erskine's life, marred by some inaccuracies. On the historical background out of which Erskine's famous cases arose, see PHILIP ANTHONY BROWN, *The French Revolution in English History* (1918); and CARL B. CONE, *The English Jacobins: Reformers in Late Eighteenth Century England* (1968).

(F.A.A.)

Eschatology

Eschatology (the doctrine about last things) is originally a Western term, referring to Jewish and Christian beliefs about the end of history (or of the world in its present state), the resurrection of the dead, the Last Judgment, and related matters. The term has been extended by historians of religions to cover similar themes and concepts in the religions of primitive peoples, ancient Mediterranean and Near Eastern cultures, and Eastern civilizations.

Eschatological ideas and beliefs played a central role in the development of Judaism; the Kingship of God, "the end of days," "the world to come," the Messiah and the messianic era, the Day of Judgment, and the images of a perfected future were basic concerns in biblical (Old Testament) and rabbinic Judaism.

NATURE AND SIGNIFICANCE

In New Testament Christianity, history is viewed throughout in eschatological terms: the future of God has already begun with the appearance of Christ; the end of history is near; the end time is therefore filled with danger and salvation, faith and unfaith, Christ and Antichrist, and will be consummated through the resurrection of the dead, the judgment of the world, and its salvation through a new creation. Christianity, with this biblical heritage, has influenced many religions, revolutions, and

civilizations through its orientation toward hope in the future. Biblical eschatological archetypes can be found in the various secular liberation movements leading up to the present day.

In the general history of religions, the term eschatology refers to *conceptions of the beyond* that express the destiny of man after his death (immortality of the soul, rebirth, resurrection, migration of the soul). These eschatological concepts stand in a mutual relationship with the experiences of men in the present world, the turning points of life, and the understanding of death. They often pose a contrast to the present experience of suffering within nature and society, within this whole "perverted world." Eschatological themes thrive particularly in crisis situations, whether they serve as consolations for those who hope for a better world or as the motives for revolutionary transformation of the world.

A distinction has often been made between individual (personal) eschatology and collective (social) eschatology. The eschatological expectations of either type, however, are as extensive as the respective believer's interest and involvement in life and his suffering from its miseries. These expectations can embrace individual souls; they can just as easily embrace a people or group, humanity, or the whole cosmos.

ESCHATOLOGICAL THEMES AND FORMS

Origins and last things. Because biblical eschatology is grounded in what are interpreted as uniquely occurring historical events (such as the Exodus of the Hebrews from Egypt in the 13th century BC), certain difficulties occur when the biblical concept of eschatology is translated into the eschatological framework of other religions. In other religions (especially Eastern and primitive religions), cosmic representations of the eternal struggle between cosmos and chaos prevail. Therefore, a distinction must clearly be made between *mythical* eschatologies and *historical* eschatologies. The term mythical refers to the concept of the philosophically conceived truth of the human condition in relation to the realm of the sacred and the profane as defined in nontemporal terms and stories. The term historical, on the other hand, refers to the concept of the philosophically conceived truth of the human condition in relation to the realm of the sacred and the profane as defined in temporal terms and stories.

Mythical eschatologies

Mythical eschatologies emphasize the reproduction of the origin of the world at the end of the world. The end time repeats the primordial time; out of chaos (disorder) there arises anew the cosmos (order). At the origin there stands the cosmogony (creation of order) and the laws that govern the world and the pure order of things. Time is experienced as decay, degeneration, and guilt. Salvation, therefore, is found in a return of the origin or a return to the origin. All historical events are interpreted as representations of an eternal struggle in which the world order is defended against chaos. This struggle occurs as myth in the world of the gods and as history in the world of men. History thus becomes a cultic drama in which priests and kings play out the ritual roles foreordained to them.

The religious symbolism of mythical eschatology can be defined in terms of the "myth of the eternal return." This concept contains not only a cyclical view of history but also a cultic view of the annihilation of the horrors of history itself. In the ever-recurring cultic festivals, the lost time of history is regenerated and eternity is represented. Through the ritualistic repetition of all events in the creation of the cosmos, the impression of transience is proved to be a mere semblance. Everything basically remains in its place. In the framework of the myth of the eternal return, hope is inherent in memory. This basic structure is not limited to the great cultic religions; many messianic and revolutionary movements (such as the nativistic religious movements in Africa and Oceania, and sectarian movements in pre-1917 Russia) also exemplify it. Within a history that is generally regarded as evil, the saving future is depicted as a return to the primordial origin. In the terms of mythical eschatology, the meaning of history is found in a celebration of the eternity of the cosmos and the repeatability of the origin of the world.

Historical eschatology

Historical eschatology, on the contrary, is not grounded in a mythical primal happening but in historically datable events that are perceived as root experiences (past events that are narrative and paradigmatic in the present) and are regarded as fundamental for the progress of history. Biblical and biblically influenced eschatologies are grounded in such a view of historical experiences and are directed toward the historical future inaugurated by them. In this view, such experiences are never universal but always particular; they are not grounded in natural happenings but in historical election. Such events and experiences are not repeatable in cultic forms and rituals but are remembered through the telling of history and the relating of tradition. They do not abolish history; they rather inaugurate a new process (or new age) of history. They are events in which a *novum* (new or extraordinary thing) is perceived, that have a greater future than a beginning. Hope is thus grounded in historical remembrance but goes beyond what is remembered historically.

Because history is viewed as unrepeatable, the future of history is final. History is understood in this context not as the arena of the horrors of chaos but as the field of danger and salvation. The meaning of history is thus not found in its cultic abolishment (as in the case of mythical eschatologies) through the presence of eternity but in its future goal and its fulfillment. The divine or sacred is not experienced in the eternally recurring orders of nature and of the cosmos through ritualistic reenactments. Rather, God's freedom, faithfulness, and promises of the future are known and comprehended in the contingent and irreversible events of history. If here the future is greater than the beginning, hope at the end is more extensive than at the beginning.

Historical eschatologies are found in the faith of Israel and Judaism, which is grounded in the Exodus event (the liberation of the Hebrews from Egypt in the 13th century BC) and which in the course of its historical experiences is more and more directed towards the expected revelation of the glory of God in all lands. Historical eschatologies are also found in the Christian faith, which is grounded in the history of Jesus and in the root experience of his resurrection from the dead. The hope of Christian faith is aimed at the Kingdom of Christ and the Kingdom of God, through which history is ended as well as fulfilled. In both cases the unique occurrence of a historical foundation event serves as a basis for the final goal of the long-awaited and hoped for future. A historically experienced *novum* opens up hope in a new creation that will be more than the reproduction of the primordial condition.

Apocalypticism and messianism. In the sphere of historical eschatology, distinctions should be made between the hopes of messianism, millenarianism, and apocalypticism. Messianic hopes are directed toward a king of the end time who will lead the people of God, now suffering and oppressed, into a better historical future. Millenarian hope is directed toward the 1,000-year Kingdom of Christ and of his own people, in which the ones who are suffering now will rule over their enemies. In political and nativistic messianism, visions of the vengeance and of the equalizing justice on the side of the oppressed are aimed at political and religious leaders. Always at work in these instances are inner and often local historical expectations of a certain fulfillment of history before the end of history. Apocalypticism should thus be distinguished from this point of view. Apocalypticism upholds the view that God will intervene in history on the side of a faithful minority and that the intervention will be accompanied by sudden, cataclysmic events. According to this view, "this world" cannot bear the "justice of God." Therefore, against what is perceived as the perverted world, the followers of apocalyptic views hope for the creation of a new world on the basis of God's righteousness. If this hope is universal, it is, nevertheless, not generally represented by a people

but rather by individual holy men or, perhaps, by an ascetic community.

The negation of the negative and the analogy of the future

Eschatological terminology. Eschatological language ordinarily uses two elements of style in conjunction with each other: the negation of the negative and the analogy of the future. Objective statements about the future that is not yet present are not possible in history. Such statements are possible only in the form of the negation of the negative in this life and this world. An example of this style may be found in Revelation 21:4: "And death shall be no more, neither shall there be mourning nor crying nor pain any more." Thus, the positive aspects of the eschatological future are circumscribed by the negative aspects of the present. If this future is to be meaningfully related to this life, however, this life, despite all its negativity, must also be presently capable of pointing toward or of foreshadowing the future life. Eschatological imagery and language, therefore, constantly use comparisons or analogies from everyday life (such as the several "the Kingdom of God is like . . ." analogies in the New Testament) and employ the hopes and anticipations of people and events from history in analogical ways.

A problem of eschatological language exists because of the necessary connection between negation and analogy. If negation is predominant, the tendency is towards apocalyptical and metaphysical dualism and towards mysticism. If analogy or foreshadowing of the future dominates eschatological language, the tendency is toward a one-sided belief in progress. In both cases the *novum* of eschatology becomes inexpressible. A hermeneutic (methodological interpretive principle) of eschatological traditions must verify the negation of the negative in face of the presently experienced negative, and simultaneously seek the traces of the coming positive in the ambiguous history of liberations. There are always negative and positive signs of the future in history. "Where danger is, the saving also flourishes" (Hölderlin), but "where the saving draws near, danger also grows" (E. Bloch). Eschatology understands history as a growing crisis: the good provokes the evil, and the growing danger makes the action of redemption necessary. Authentic eschatology is neither world denying nor faith in progress but rather it can be seen as anticipation of freedom in the midst of slavery and of salvation in the midst of lostness and alienation.

VARIETIES OF ESCHATOLOGY IN THE RELIGIONS OF THE WORLD

The end of the order of the world

Primitive religions and nativistic movements. Eschatological motives must be understood in their religious and cultural contexts. According to the eschatological views of the people of the Andaman Islands, at the command of the god Puluga an earthquake will destroy the earth and the bridge of heaven; the souls and spirits of the dead will arise and be reunited. Then men will lead happy lives in power, without sickness, death, and marriage. Even the animals will appear again in their present form. The impatient spirits of the underworld are already now shaking the roots of the palm tree, which supports the earth, in order to bring about the end of this present world and the resurrection more quickly. The Semang pygmies in Malacca hold a somewhat different eschatological view:

> In the beginning of the ages there was still absolutely nothing. Then Ja Pudeu [the highest being] blew with her mouth causing storms to rage over the earth. This was the means by which stars, water, trees, and everything came into being. At the end of the ages when all men shall have died, she will destroy everything with the same storms; a great flood will complete the destruction and the bones of men will swim together. Finally, the bones will rise.

The Australian aborigines claim that the end of the world will come when the moral world order legislated by the gods is no longer upright.

The Gabonese Pygmies in West Equatorial Africa believe that once Kmvum (the original man) lived with them faithfully. Then their guilt brought on the day of separation. He will come again, however, and bring back with him joy, abundance, and happiness. Among the Altaic Tatars of Central Asia there is an eschatological belief that Tengere Kaira Khān (the "graceful emperor of heaven"), who once lived on earth with men, will return at the end of the world in order to judge men according to their works. At his departure from earth he sent a mediator who remains faithful to him. At the end of the world the mediator will be victorious over evil. The Salish Indian tribes of the Pacific Northwest of North America believe that the creator god, before he vanished from the earth, promised the "elder" or "chief" his return at the end. When earth (a female figure) has become old, the coyote will return as the first sign of the world's end. This will be followed by the "chief" himself returning to earth. "After this there will no longer be a land of the spirits. All men will live together, the earth will receive her natural form and will live as a mother among her children. Then all things will be made right and happiness will reign."

Such mythical themes arranged around the origin–fall–return motif are experiencing a revival as primitive peoples suffer cultural shock in their encounters with Western civilization and Christianity. These themes are particularly reflected in various nativistic movements. In part, they take over biblical-messianic hopes and turn against the church. Cultural catastrophes are viewed as signs of the nearing end. The end is expected to bring about the return of the old gods and the eternal orders of creation. The presently "perverted world" is turned upside down. "The blacks become white and the whites become black. The whites will work for us just as we must now work for them." The Mamaia prophets on Tahiti in 1832 prayed for the second coming of Jesus so that he would drive all whites and missionaries out of the land. In the case of the Dayaks on Borneo there is a similar expectation. The Dayaks believe that the white officials and missionaries, when their time has run its course, will become slaves of the free Dayaks. Nativistic and messianic movements are a regular occurrence in acculturations. The self-consciousness of the oppressed is restored in them, and they can be easily politicized. In the 20th century, therefore, large numbers of nativistic–messianic cults have arisen and are continuing to do so in Africa and Asia.

Eschatological views within nativistic movements

Religions of the East. Buddhism has four "noble truths"—the fact of human suffering, the understanding of the origin of suffering, the removal of the causes of suffering, and the path to the transcendence of suffering —and is partly therefore a religion of redemption. According to the Buddhist world view there is a macrocosm composed of innumerable worlds. In recompense for good and evil deeds, creatures are reborn in an unceasing process in the region that they deserve. Beyond all worlds is found Nirvāṇa ("bliss" or enlightenment), "the indescribable goal," whose attainment means redemption from the cycles of existence. Each one of the innumerable worlds passes through periods of destruction and recreation. There is no soul migration because there is no soul substance. Rather, each new existence is defined by *karman*, the deeds of the earlier existence. Only insofar as this is true can one speak of continuity in the reincarnations.

Buddhist and Hindu "eschatological" views

If anything at all in Buddhism can be considered as eschatological it is the yearning for an ultimate redemption from the cycle of rebirth and the final abolishment of the suffering bound up with it. In the religious community founded by the Buddha this yearning finds its peculiar way, the "eightfold path," on whose highest step occurs illumination or enlightenment. This illumination or "life beyond grief and woe" (Nirvāṇa) is a condition of eternal peace that cannot be conceived or described in ordinary terms. Rather, it comprehends even the worlds and their cycles themselves: "I do not know the end of suffering if we have not reached the end of the world" (Gautama, the Buddha).

According to Hīnayāna (the Lesser Vehicle, or Southern) Buddhism, the individual believer must strive after redemption for himself through the exertion of his powers of being. At the centre of Mahāyāna (the Greater

Vehicle, or Northern) Buddhism, on the contrary, stands the concept of the redemption of all living creatures which will occur through the sympathetic assistance of a redeemer figure.

In Hinduism the world of Brahman (the Universal Soul) is created by demiurges (creator beings) in egg-form and contains numerous zones and levels around the golden world mountain Meru. It passes through a series of temporal cycles, and every temporal cycle ends with the destruction of the world followed by a new creation under a new demiurge. Man is now living in the dawn of the last, worst Kali *yuga* (age) of such a cycle. Through migration of the soul, man is drawn into the circle of the animals and plants. Rank and kind of birth are determined by the individual *karman* (acts and their consequences). The *karman*, which accompanies the soul and even has an effect on the destruction of the world, determines the following existence. After death, the soul returns to earth or it goes the "gods' way" (*devayāna*) of redemption. Redemption occurs when *karman* can no longer be produced, or it can happen through a divine act of grace that blots out the existing *karman*. Redemption is popularly viewed as entrance into the highest heaven of the god worshipped, where the redeemed one awaits a spiritual reflection of earthly joy. In modern Hinduism the soul that is identical with God is redeemed through a recognition of the organic wholeness that has vanished from consciousness because of the soul's imprisonment in matter. Self-recognition (*Ātman*) then leads to identity with the absolute being (Brahman). Redemption lies in the accomplishment, or rather recognition, of the *Ātman*-Brahman identity, for it already frees man from the chains of *karman* and *saṃsāra* (cycle of rebirths).

Buddhism and Hinduism do not have a historical eschatology. They rather emphasize an ultimate redemption from the cycles that have no beginning. Their redeemer figures are impersonal transparencies of the ultimate-universal.

Religions of ancient civilizations. In the religions of the West, there is a tendency to understand time as irreversible and therefore the end as occurring once and for all, as ultimate. The final judgment will be followed by the creation of a new and sacred world that is eternal. Origins of this kind of eschatological thinking are found in ancient Egypt in texts such as the "Shipwrecked Sailor" and the "Conversation between Atum and Osiris." The idea of an eschatological individual judgment of the dead is developed here in the strongest sense. Ancient Greek and Roman eschatological views depict a shadow life for the individual departed soul in Hades. Other than this focus on the individual, however, the cyclical concepts of periodic world destruction and world renewal are also found in these religions.

Zoroastrianism and Islām

Religions of the West. In Parsiism (Indian Zoroastrianism), the end-time struggle between the forces of the good against the forces of evil is the ruling element in its eschatology, and Parsis look toward a "wonderful creation" (*frashokereti*) at the end. Under biblical influence, the concept of the resurrection of men is given rich embellishment in Islām. The Antichrist and ʿĪsā (Jesus) play important roles. ʿĪsā will usher in Islām as the world religion. Before him, however, will appear a mahdī (divinely guided one) who is to establish the Islāmic ideal state and fulfill the divine law. After the appearance of ʿĪsā, the last judgment will begin: the good will enter paradise; the evil will fall into hell. Heaven and hell possess various goals and steps of recompense for good and evil. The time before the end is viewed pessimistically: God himself will abandon the godless world. Ka'bah (the great pilgrimage sanctuary of the Muslim world) will vanish, the copies of the Qur'ān will become empty paper, and its words will disappear from memory. Then the end will draw near.

Judaism. The real inception of historical eschatologies stems from the Old Testament. Israel's faith in God there is rooted in the historical experience of the Exodus, and because of this experience of liberation it contains a hope in the guidance and the promises of God in history. The basic structure of this faith is found in the law of promise and fulfillment. The eschatology of the Old Testament is grounded in the identity of faith in God and hope in the future (Gen. 12:1ff.). It has its beginning in the promise of a "good and broad land, a land flowing with milk and honey" (Ex. 3:8). In the Pentateuch (first five books of the Old Testament) the promise is broadened to the increase of people and possessions, the blessing of God and the victorious presence of God (Gen. 49:8–12; Num. 23; Deut. 33:13–17; Num. 23:21). The history of the occupation of the land of Canaan (Palestine) and the victory of the Hebrews is to be understood as "realistic hope." Through the experiences of Israel's own disobedience to the laws and the will of God and defeats at the hands of its enemies, the concept of the "day of the Lord," which is to bring salvation and victory, came into existence. The happiness of the establishment of the Kingdom by David in the 10th century BC led to a hope in the future Messiah (Anointed One) of God from the house of David (II Sam. 7).

Concept of the "day of the Lord"

In the midst of the political catastrophes of the 8th century BC, the great prophets took up the concept of the "day of the Lord" and proclaimed it as a day of judgment (Amos 5:18) over the disobedient people and also over all other peoples. It was through such a process that the day of the Lord concept became the bearer of eschatological hopes. Isaiah also viewed salvation in an eschatological light as happening only after the universal judgment (Isa. 4:3; 6:13; 11:11; 37:31) and combined it with the presence of a messianic mediator of salvation (7–12).

In face of the political destruction of Israel (8th century BC) and Judah (6th century BC) the prophetic hope kept Israel alive religiously. This prophetic hope was aimed primarily at a comprehensive and total new creation, a new heart, a new covenant (Jer. 31; Ezek. 36; Isa. 41; Isa. 51). Through the vicarious atonement of the servant of God (either the people of Israel or a messianic figure) this hope was to include not only Israel but also the Gentile world (Isa. 42:6; 49:6). The future of Israel is thus bound up with the future of all peoples and of the whole earth.

In the incipient apocalyptic views of the prophet Daniel (2 and 7), hope is transcendent. His apocalyptic eschatological hope expects the "Kingdom of the Son of man" following the consummation of evil in the fourth and final kingdom of the world. Since that time, hope in a Messiah and hope in a Son of man have been bound to a kind of eschatology that unites the fulfillment of the history of Israel with the end of world history.

Individual eschatology emerges only on the periphery of the Old Testament. Amazingly, there were in Israel no known death cults and no vivid conceptions of life after death. The late expectation of the resurrection from the dead to judgment (Dan. 12:2) is not a yearning for salvation but hope in the victorious righteousness of God. Rabbinical messianism continued this same line of thought.

Christianity. If for Judaism the peculiar eschatological event lies in the future, this future of God, according to the New Testament, has already begun with Christ ("Today this scripture has been fulfilled in your hearing." [Luke 4:21] "The Kingdom of God is at hand." [Mark 1:15]). New Testament eschatology differentiates between the eschatological present and the eschatological future. Yet they are both one unique event: the presence of Christ is the anticipation of the future of God, and the future of God is the fulfillment of the presence of Christ. God has reconciled the world in Christ but not yet redeemed it. Faith saves, but the believers are saved in hope (Rom. 8:24). At the centre stands the hope in the "Kingdom of God," in which God comes to his lordship and his right in the world.

Eschatological present and eschatological future

Individual eschatology and collective eschatology are constituent parts of the theocentric (God-centred) hope in the coming God. Jesus proclaimed the Kingdom of God and brought it through his words and deeds as grace and joy to the poor and the lost. He united the Kingdom of God with his person in such a way that he is under-

stood as the incarnated Gospel of the Kingdom. His word calls men to eschatological decisions and makes the end judgment a present concern. His Crucifixion in loneliness and alienation is understood as the presence of salvation among the unsaved and as revelation of the divine righteousness. In God's raising of Jesus from the dead, the Easter witness recognized the exaltation of Jesus as Lord of the end time, and they saw in this action the anticipation of the coming resurrection of men and the new creation of the world.

The memory of Jesus and the Christ-event (cross and Resurrection) is the basis of primitive Christian eschatology in its many variations. Its object is the Parousia (Coming Presence) of the crucified one in the glory of the coming God. The Parousia brings the visible presence and indwelling of God in his new creation. It brings the freedom of the "children of God" and thus the new humanity. It brings the liberation of the whole creation, which "waits with eager longing" (Rom. 8:19) for its release from the power of death to participation in the glory of God and the participation of the new man in peace and freedom.

Eschatology, in primitive Christianity, developed within the process of the interaction between the memory of Christ and new experiences in the world. A primary controversial issue was the *particularity* or *universality* of hope for salvation. The primitive congregation in Jerusalem understood itself as a messianic community, but remained in the sphere of Judaism. Only after the awakening of Israel—according to its beliefs—would the Gentiles be allowed to come into the community of faith and hope. In the Hellenistic congregations (Antioch, Corinth), on the contrary, the Gentiles came to faith without having first become Jews. "Spirit and freedom" were understood as already universally existent.

Early controversial Christian eschatological concerns

A second controversial issue was the *presentness* or *futurity* of salvation. Primitive Christian enthusiasm viewed salvation as already present in the possession of the Spirit. The Gospel of John also emphasizes the present eschatological possession of salvation in faith. The theology of Paul, however, is dominated by the tension between the presence and the future of salvation. Faith gives a ground for hope and prevents it from being superfluous for the reconciled are not yet redeemed; they wait together with the unredeemed creation for the "day of Christ," the freedom from death, and the unhindered participation in the presence of God ("that God may be everything to every one"; I Cor. 15:28). The letters of John, Hebrews, and the Revelation of John also emphasize the future, the universality, and the bodiliness of salvation.

ESCHATOLOGY IN MODERN TIMES

Times of hope and times of fulfillment have alternated with each other in the history of Christianity. During the first three centuries the eschatological views of the martyrs stood in the foreground. But since the time of the Roman emperor Constantine (died 337) the political recognition of Christianity has been understood as a realized hope in the Kingdom of Christ. Futuristic eschatology continued to exist in the suppressed underground sects. The consequent history of state Christianity and of the established churches is interlaced with an abundance of adventistic and millenarianistic sects (those awaiting the coming Kingdom of God). Such sects appeared among the leftwing groups of the Reformation. They were also active in the English Revolution. They were conspicuous in the awakening and revivalistic movements of the "Christian century" (19th century), particularly in so-called "Christian nations." The more established Christian churches excluded eschatology as meaningless or as an insignificant myth. The more these hopes and visions emigrated out of Christianity the more they were invested in revolutionary movements. The history of revolution in Europe, Russia, and North America is dominated by the motives and images of a secularized eschatology. Here eschatological expectation radically transforms itself into revolutionary action, as it sometimes did during the Reformation.

Revolutionary eschatology

Since the exegetical (interpretive) works of Johannes Weiss and Albert Schweitzer around 1900 (school of "consistent eschatology") and dialectic theology (Karl Barth, Rudolf Bultmann), eschatology has again become a principal theme of academic Christian theology. The crises in the Western countries have led to a renewed activization of eschatological hopes. In church struggles, this was expressed in terms of distinctions between Christianity as a state religion and congregations with eschatological orientations. On its margins, Western civilization contains a series of mystical and apocalyptical "anticultures." Initial attempts to combine eschatology and philosophy, hope, and social practice, and thus overcome the difference between the church and the sects, as well as the church and the modern age, are found in Ernst Bloch's philosophy of hope (*Das Prinzip der Hoffnung*, 1959), the writings of P. Teilhard de Chardin, and in the "theology of hope" (J. Moltmann, W. Pannenberg, H. Cox, L. Dewart, etc.). Eschatology is one of the main focuses of Christianity. Therefore, its most important theological decisions about theory and practice must take eschatological concerns seriously, as seriously as the many and varied revolutionary groups (both religious and secular) have done in the 20th century.

Eskimo-Aleut Languages

Eskimo and Aleut, once neighbour languages on the Alaska Peninsula, are related but quite distinct; together they form the Eskimo-Aleut language family.

Eskimo is spoken in Greenland by a native population of about 40,000, in Arctic Canada by 15,000 or more, in Alaska by some 25,000 native inhabitants, and on the coast of the Chukchi Peninsula in northern Siberia by fewer than 800 of the Siberian Eskimos (1970). In Green-

land, Eskimo is used in the schools, in the church, and on the radio; in Canada and in Alaska the language is employed mainly as a means of religious education. It is the language of instruction in the first grade of primary school in the Soviet Eskimo area. There are numerous Eskimo dialects; between them there is a more or less clear-cut break at the Bering Strait and at Norton Sound in Alaska. Within each of the dialect chains the neighbouring dialects are mutually intelligible, but the cumulative differences impede or prevent understanding between the dialects at the geographical extremes.

Intelligibility of dialects

Aleut, now greatly reduced in number of speakers, is the smallest branch of the family. It is spoken in the Aleutian Islands and in the Pribilof Islands in the Bering Sea, settled in the 1820s, by fewer than 1,000 Aleuts; on the Soviet Commander Islands, settled in 1826, there are fewer than 100 Aleut speakers (1970). Three mutually intelligible Aleut dialects are left, although one is nearly extinct. The Eskimo language is unintelligible to the speakers of Aleut, and vice versa.

Classification. The Eskimo dialects are usually classified into two main branches—an Inuk, or Inupik, branch, which spreads eastward from the Bering Strait and the Norton Sound, and a twofold Yuk, or Yupik, branch, consisting of Asian (Siberian) and Alaskan varieties. This grouping is based on the dialectal forms of the term for people or real people that most Eskimos use to refer to themselves. The exact interrelationship of the dialects remains to be clarified.

The term Aleut, introduced by Russian traders from Kamchatka in northeastern Siberia after 1741, is commonly used both for the Aleuts proper, who call themselves Unangan (or, on the island of Atka, Unangas), and for the Eskimos of former Russian Alaska. The linguistic relationship between Eskimo and Aleut, sensed as early as the 1820s by the Danish linguist Rasmus Rask, could be proved only through a fairly advanced analysis of both languages. The proposed relationship of Eskimo-Aleut with other language families, such as Chukchi-Kamchadal, Uralic, and/or Indo-European, remains speculative.

Relationship between Eskimo and Aleut

Alphabets and orthography. The first book in Eskimo was published in 1742 by Hans Egede, a Dano-Norwegian missionary to Greenland. It was printed in the Roman alphabet, with the letter *r* used to represent the Eskimo uvular fricative (a sound involving friction in the airstream, made at the back of the mouth with the appendage known as the uvula). The Greenlandic orthography was systematized in 1851 by Samuel Kleinschmidt, a German of the Moravian Brethren. He introduced a small capital ʁ to distinguish the uvular stop, made with stoppage of the airstream by contact of the uvula and the back of the tongue (also written *q*), from the velar sound *k*, made with the back of the tongue touching the velum, or soft palate (like the English *k*). Three accents were introduced to differentiate long sounds from short ones; *e.g.*, *anâna* (equivalent to *anaana*) "mother," *mâna* (equivalent to *manna*) "this," *mãna* (equivalent to *maanna*) "now." That is, the circumflex, ^, marks a long vowel, the acute accent, ´, indicates a long consonant following the marked vowel, and the tilde, ~, notes a long vowel and a long succeeding consonant. The Kleinschmidt orthography is still used today, and similar orthographies have been employed by the Moravian Mission in Labrador since 1800.

In Russian Alaska, an adequate Cyrillic alphabet was designed for the Aleut language by the Orthodox missionary Ivan Veniaminov in about 1830. In 1848 it also became used for southern Eskimo. Books in both languages were published by the Russian Orthodox Church in America until 1903.

Adaptation of the Cree syllabary

In 1878 the syllabic characters originally designed for the Cree Indians were introduced to the Eskimos of central Canada by the Rev. Edmund J. Peck of the Church Missionary Society. Since 1953 this form of writing has also been used in an Eskimo periodical sponsored by the Canadian government, alongside a new, tentative orthography in the Roman alphabet.

The ordinary Roman alphabet was used for Alaskan Yupik by Moravian missionaries from Pennsylvania in the 1920s. From 1948 on, Protestant missionaries in northern Alaska developed an alphabet with seven additional letters. In 1961 a program was started at the University of Alaska, with the active participation of Yupik Eskimos, for working out a systematic Eskimo orthography in the Roman alphabet to be used in Alaskan public schools from 1971 on. In the Soviet schools for Asian Eskimos a Roman alphabet with two additional letters was introduced in 1932, but it was replaced by the Russian Cyrillic alphabet in 1937.

Phonological characteristics. Eskimo and Aleut have relatively simple systems of distinctive sounds. The accent (stress) depends upon the length of the syllables and never has independent value as in English.

In Eskimo there are four distinctive vowels. Three of them, usually written as *a, i, u,* vary considerably in pronunciation according to the consonants that follow or precede. These three vowels occur both short and simple, and combined into long vowels and diphthongs. The vowel combinations result primarily from the loss of former intervocalic consonants; *e.g.*, Greenlandic *ûvoq*, the equivalent of *uu-vuq* "is burnt," is related to the Asian Yupik form *ugu-*, which has a fricative *g* sound between the two vowels. The fourth Eskimo vowel is represented in Yupik by a short *e* and is pronounced somewhat like the vowels in "but" or "bird." In the Inupik area it has become identical with the vowel written *i*. The Aleut language has only *a, i,* and *u* in both short and long varieties. The fourth vowel has become identical with one of the first three or has been dropped from the language.

The consonantal system

Of consonants, Eskimo has from 13 to 21, depending on the dialect. The stop sounds include the uvular *q*, the velar *k*, the dental *t*, made with the tip of the tongue touching the back of the upper teeth, and the labial *p*, made with the lips; in Alaskan Yupik there is also a palatal *c* (like English *ch*), to which an *s* corresponds in the other dialects. In parts of Canada this has changed to *h*. The nasal sounds, made with the breath passing through the nose, include ŋ (as in "sing"), *n*, *m*, and, in Asian Yupik, also a voiceless *n*, made without vocal cord vibration. Voiced and voiceless varieties of the continuant consonants *r, g, l,* and *v* are distinctive sounds in the western dialects but in eastern Inupik they are only variants. In addition to *j*, pronounced as *y* in English "year," some dialects have sounds similar to English *r* or *z* or to *sh* (in Greenlandic written *ss*). Corresponding to *ss* in Aleut there is a fricative *d* (pronounced as the *th* in "that"); *e.g.*, Aleut *da-* "eye" is related to Eskimo *izi* and *ii* and to Greenlandic *isse*. Aleut shares with Eskimo most of the consonants articulated with the tongue, including *c* (the English *ch* sound) and *s*, but has *p* and labial fricatives (*f* and *v*) only in loanwords from Russian or English. Aleut *m* corresponds with both Eskimo *m* and *v;* to Eskimo *p* corresponds the Aleut *h* (in initial position) and the Aleut aspirated nasal sound *hm* (in noninitial positions)—*e.g.*, Aleut *hum-* "to swell" corresponds to Eskimo *puvi-*; Aleut *ahmat-* "to ask" is cognate with Yupik *ap(e)t-*. (An aspirated sound is one pronounced with an accompanying puff of air.)

In initial position, Inupik uses only a single stopped consonant (*i.e., p, t, k,* or *q*), or *s, n,* or *m* (rarely *l*); between vowels it employs at most two consonants, including double ones. In contrast, Yupik and Aleut have initial consonant clusters, resulting from the loss of a vowel in the first syllable from an older historical form; *e.g.*, Yupik and Aleut *sla* "weather," Inupik *sila.*

Grammatical characteristics. Eskimo has a great number of suffixes but practically no prefixes or compounds. In Aleut the word forms are simpler, but the syntactic constructions (the way the words are arranged in sentences) are more complicated. Suffixes are often accompanied by changes in the stem, especially in Eskimo; *e.g.*, *nanuq* "polar bear," dual *nannuk* "two polar bears," plural *nannut* "several polar bears"; *inuk* "person," dual *innuk,* plural *inuit; umialik* "owner of boat (*umiaq*), chief," dual *umiallak,* plural *umialgit* (North Alaska dialect). Note the doubled consonants in the dual and plural

forms of some terms, and the other consonant and vowel alternations.

Grammatical numbers—singular, dual, plural—combine with suffixes for person—*e.g.*, *ulu-ga* "my knife," and *ulu-t-ka* "my knives," in which *-t-* means "several" and *-ga* or *-ka* "my." The possessor of someone or something occurs in the so-called relative, or subordinative, case—*e.g.*, *umialgum pania* "the chief's (his) daughter," in which *pani-a* means "his or her daughter"; this is distinguished from the reflexive *panni* "his or her own daughter" and the stem *panik*.

Personal pronouns

The personal pronouns consist of a stem and person suffixes—*e.g.*, Aleut *ti-*ŋ "I, me," with the ending -ŋ as in *ada-*ŋ "my father"; Eskimo *uva-*ŋa "I, me," with a demonstrative stem (*uva*) as in *uva-ni* "here." Corresponding to the separate personal pronoun forms in Aleut are the Eskimo suffixes for the 1st, 2nd, and reflexive 3rd persons (himself, etc.). These indicate the subject of an intransitive verb or the object of a transitive verb—*e.g.*, *-*ŋ*a* means "I" in *uqaqtu-*ŋ*a* "I said," and "me" in *uqautigaa-*ŋ*a* "he told me." A noun that would be the subject of "said" (the intransitive verb) or the object of "told" (the transitive verb) is in the absolute case (it is not marked with a suffix), whereas the subject of a transitive verb (*e.g.*, "tell") occurs in the subordinative case. For example, compare the unmarked form for "chief," *umialik*, in *umialik uqaqtuq* "the chief said" with its corresponding form *umialgum* in the subordinative case in *nukatpiarzuk umialgum uqautiga-a* "the young man (object), the chief told him" (*-a* "he - him"). With a 3rd person object ("him, them"), a transitive verb has largely the same suffixes as a noun—*e.g.*, the *-t-* and *-ka* in *ulu-t-ka* "my knives" and *tigu-gi-t-ka* "I took them" (*-gi-* is indicative) and the corresponding Aleut forms, *-ni-* and -ŋ in *ukina-ni-*ŋ and *su-ku-ni-*ŋ.

Eskimo nouns and pronouns have six adverbial cases, expressing relations such as "in," "to," from," "along," "with," and "like"—*e.g.*, *iglu-mi* "in the house," *iglu-pti*ŋ*-ni*, "in our house." In the Yupik dialects there are only five such adverbial cases. These are reduced to two (in/to, from/along) in Aleut and are limited to pronouns and relation words—*e.g.*, *ula-m nag-a-n* "of house (*ula-m*) in its (*-a-*) interior"; this corresponds to Eskimo *iglu-m ilu-a-ni* "in the house."

Verbal modes include indicative ("he goes"), interrogative ("did he go?"), imperative ("go!"), optative ("may he go"), participles ("going, gone"), and other forms corresponding to subordinate clauses in English—*i.e.*, clauses beginning with "if," "when," etc. Other modal relations and tenses are specified by derivational suffixes, and in Aleut also by auxiliary verbs; *e.g.*, *haqa-l sara-nar* "coming he slept" is equivalent to "he came yesterday." An Eskimo derivative form may also correspond to an English complex sentence—*e.g.*, $tikit_1$-$qaar_2$-$mina_3$-it_4-ni_5-ga_6-a_{7-8} is "he $(A)_8$ $said_{5-6}$ that he $(B)_7$ would not_4 be $able_3$ to $arrive_1$ $first_2$," or, in exact Eskimo order, "to arrive first be able would not said him he."

Vocabulary. A remarkable feature of the vocabulary is the great number of demonstratives, about 30 in western Eskimo and in Aleut. For example, in Aleut there is *hakan* "that one high up there" (as a bird in the air), *qakun* "that one in there" (as in another room), and *uman* "this one unseen" (heard, smelled, felt).

The vocabulary naturally has its local particularities, the various groups having lived under very different conditions. The Eskimo word that means "meat" from Greenland to Siberia means "fish" south of Norton Sound and also in the Aleut language. Word taboo has also played its part, as in East Greenlandic, in which the general Eskimo-Aleut word for "eye" (*da-*, *izi*, see above) has been replaced by *uitsatai* (*ui-sa*+*uta-i*) "those by which he keeps gazing."

Word formation by derivation

Eskimo-Aleut derived words (*e.g.*, similar to English "winter-ize" or "anti-dis-establish-ment-ari-an-ism") correspond quite often to simple, nonderived English words. The possibility of derivation is virtually unlimited in the languages, and the number of word stems is comparatively small; *e.g.*, there are fewer than 2,000 in well-known West Greenlandic. Examples of derivatives are: *nalu-voq* "is ignorant," *nalu-vâ* "does not know it," and *nalu-na-er-* "make not (*-er-*) to be (*-na-*, *-nar-*) ignored," which is equivalent to "communicate." *Nalunaer-asuar-ta-ut* "that by which (*-ut*) one communicates habitually (*-ta-*, *-tar-*) in a hurry (*-asuar-*)" is the form for "telegraph," a term coined in the 1880s.

In Greenlandic there are four loanwords from medieval Norse; from the colonial period after 1721 there have been surprisingly few borrowings until recently. In Aleut and in the Eskimo of former Russian Alaska there are many borrowings from Russian, and there are several in Asian Eskimo from English, and many from Chukchi, a Paleo-Siberian language. Notable Eskimo contributions to the vocabulary of English and other European languages are "igloo" (or *iglu*) and "kayak" (*qayaq*).

(K.B.)

Espírito Santo

The State of Espírito Santo (Estado do Espírito Santo), a small coastal state of eastern Brazil, is bounded on the north by the State of Bahia, on the east by the Atlantic Ocean, on the south by the State of Rio de Janeiro, and on the north and west by the State of Minas Gerais. It has a total area of 17,605 square miles (45,597 square kilometres), including the uninhabited offshore islands of Trindade and Martin Vaz; the state is about 250 miles from north to south and about 75 miles from east to west. At the start of the 1970s the population was over 1,600,000, almost double the figure of 860,000 recorded in 1950. Vitória, the port and capital city, stands on an island in the Baía do Espírito Santo (Bay of Espírito Santo), the only bay on the coast.

History. Espírito Santo formed part of one of the captaincies given by the Portuguese crown to the explorer Vasco Fernandes Coutinho, who, on May 23, 1535, first landed on the future site of Vitória. In 1799 Espírito Santo became an independent captaincy, in 1824 a province of the Brazilian Empire, and in 1889 a state of the newly formed federal republic.

Physical geography. The relief is characterized by the low mountain ranges of the Serra dos Aimorés on the western border and by isolated groups of hills on the eastern coastal plains. The most important rivers—the Doce, São Mateus, and Itapemirim—flow eastward from Minas Gerais across the state to the ocean; navigation on these rivers is hampered by their irregular rate of flow, as well as by falls, rapids, and sandbars.

The country is today sparsely forested, as most of the forests that formerly supplied Brazil with a substantial proportion of its exports of rosewood and other cabinet woods have now been destroyed.

Soils and climate

With the exception of the sandy plains and swamps of the coastal strip, the soil is generally fertile. Repeated plantings of the same crops have, however, exhausted some soils, and many fields have been converted to pasture land.

The climate of the coastal zone and the valleys is hot and humid. In the highlands the temperature is lower, and the climate more comfortable. Rainfall, which averages about 50 inches a year, is heavier from October to March.

Population. The population is predominantly white, but Negroes, mulattoes, and caboclos (of mixed European and Indian ancestry) are also found in high proportions. The population is unevenly distributed.

The largest and most populous cities and towns are Vitória (122,000), Itaquari (65,000), Cachoeiro de Itapemirim (59,000), Colatina (46,000), and Vila Velha (43,000).

The overwhelming majority of the population are Roman Catholic, although Protestants of all denominations and Spiritualists are also represented. Portuguese, the mother tongue of almost the entire population, is generally spoken.

Administration and social conditions. Legislative power is held by the state assembly, while the executive power is vested in the governor. The state is divided into 36 judicial districts and 53 municipalities.

Campaigns against infectious diseases have been successfully pursued. Yellow fever and smallpox have been eliminated, and malaria has been virtually eradicated. The inroads of tuberculosis have also been greatly reduced. Between 1950 and the early 1970s, the death rate dropped sharply.

Primary education is administered by the state but is largely subsidized by the federal government. The adult literacy rate is about 72 percent. In the early 1970s the state embarked on an extensive school-building program, as well as on a vigorous literacy campaign. Secondary schools are distributed throughout the state; there are two medical schools in Vitória (one privately run, the other affiliated with the Federal University of Rio de Janeiro).

Agriculture remains the leading economic activity; coffee, cocoa, sugarcane, rice, and corn (maize) are the principal products. Cattle raising is important, with beef cattle generally being raised in the north and dairy cattle in the south. Poultry farming is becoming increasingly important, and industry, especially food processing, is making progress.

Transportation

Espírito Santo has two railways—one connecting Vitória with Rio de Janeiro to the southwest and one that moves iron ore from the mines of Minas Gerais for export through the port of Tubarão near Vitória. The state is crisscrossed by an extensive road network, and Vitória airport is capable of handling small jet aircraft.

There are 11 radio stations and one television station in the state; Vitória has several cultural institutions. Local festivals usually have a religious meaning, and local folklore is deeply rooted in Portuguese and African traditions.

BIBLIOGRAPHY. FERNANDO DE AZEVEDO, *A Cultura Brasileira*, 2nd ed. (1944; Eng. trans., *Brazilian Culture*, 1950), is by far the most valuable work for understanding the manifold aspects of Brazilian culture. There are three important books for an adequate study of the history of Brazil: PEDRO CALMON, *História da Civilização Brasileira* (1933); J.F. DA ROCHA POMBO, *História do Brazil*, 10 vol. (1905); F.A. DE VARNHAGEN, *História Geral do Brazil*, 2nd ed., 2 vol. (1877). JOSE TEIXEIRA DE OLIVEIRA, *História do Estado do Espírito Santo* (1951), is the best historical work on Espírito Santo; while MARIA STELLA DE NOVAES, *História do Espírito Santo* (1970), is a highly informative study. AUGUSTE DE SAINT-HILAIRE, *Segunda Viagem ao Interior do Brasil, Espírito Santo* (1936), is a narrative of travels in the state of Espírito Santo by the French naturalist.

(D.N.daC.)

Este, House of

The House of Este was an Italian princely family that ruled in Ferrara from the 13th to the end of the 16th century and in Modena and Reggio from the later Middle Ages to the end of the 18th century. It played a significant role in Italian history, and its influence on the political and military events of the peninsula is second only to that of the House of Savoy, which produced the Italian kings of the 19th and 20th centuries.

The Estensi were of ancient Lombard descent. They had first settled in Lombardy as a branch of the great 10th-century dynasty of the Obertenghi, which held power and wealth in Lunigiana, Genoa, and Milan and which also gave rise to the feudal houses of the Malaspina, the Pallavicini, and the margraves of Massa and Parodi. Subsequently, after various vicissitudes, the members of this dynasty removed to the lands of the Venetians, where they had estates at Este, Monselice, Rovigo, and Friuli. The Estensi took their name from the township and castle of Este, 17 miles (27 kilometres) southwest of Padua, and the true founder of the family was the margrave Alberto Azzo II (died 1097). From his son Welf IV, duke of Bavaria, there began a related branch that gave origin to the dukes of Bavaria, Brunswick, and Lüneburg, as well as the electors of Hanover. Another son, Ugo, tried without success to establish in France, while a third son, Folco I (died *c.* 1136), became second in line in the House of Este. Neither he nor his successor, Obizzo I (died 1193), however, achieved any great distinction, beyond the offices and titles that fell naturally to the upper feudal families; but it was during the lifetime of Obizzo I that the Estensi first acquired political importance in Ferrara, through his marriage to a member of one of the two great and rival families of Ferrara. His successor, Azzo VI, acquired considerable authority in the city, though his premature death in 1212 left the family temporarily weakened. Not until 1240 did a descendant, Azzo VII, return to power in the city, in alliance with the Guelf league formed by Pope Gregory IX. This marked the true beginning of Este rule in Ferrara.

Founding of the House of Este

In 1264 Azzo's heir, Obizzo II (1264–93), was created perpetual lord by the people of Ferrara under the pressure of Guelf strength. The Pope, lawful lord of the Ferrarese territory, at first did not oppose this action, but afterward began to contest the Estensi government. Obizzo II's power was growing, however, and he had himself chosen lord of Modena in 1288 and of Reggio in 1289. In the 14th century the House of Este went through difficult, stormy periods, not only because of its controversies with the Pope but also because of domestic dissensions, sometimes very hazardous. The house succeeded, nevertheless, in strengthening its position, and, under Nicolò II (1361–88), called the Lame, there was built the famous Este Castle, the work of the architect Bartolino da Novara, which became a symbol of the power of the duchy and a sure defense against external dangers. To the brother and successor of Nicolò II, Alberto V (1388–93), is due the erection of the University of Ferrara, destined for lasting fame; it was obtained by Pope Boniface IX as a concession in 1391.

Involvement in Italian politics

The reign of Nicolò III (1393–1441), son of Alberto, marked the strengthening of Estensi domination in Ferrara and the introduction of Estensi influence generally in Italian politics. After having defeated an attempt by the Paduans to achieve hegemony in Ferrara, the Estensi duke became intermediary in the political and military contests in the Italian states and extended his dominions. Personally, Nicolò was known for his sensuality; a Ferrarese saying runs, "On both sides of the River Po they all are Nicolò's sons." He had his son Ugo and his young second wife Parisina Malatesta beheaded because they were found guilty of adultery together. But he devoted himself to the exterior manifestations of the religious faith—going on a pilgrimage to the Holy Sepulchre and to Vienna's Saint Anthony, and playing host to the ecumenical council in 1438 that represented a fruitless attempt to bring together again the Western and Eastern churches. (This council was afterward transferred to Florence.) He even seems to have come close to obtaining the succession of an Estensi heir to the Milanese states, but he died suddenly, perhaps poisoned, on December 26, 1441.

Whereas Nicolò III raised the Estensi state to high position in Italian politics in spite of its territorial and financial limits, his bastard son and chosen successor Leonello (1441–50) gave Ferrara considerable distinction in the fields of art and culture. Leonello had been educated by the humanist Guarino Veronese, called to Ferrara by his father; and the period of his reign was one in which Ferrara represented a lively centre of culture and humanism, filled with painters (Pisanello, Jacopo Bellini, van der Weyden, Mantegna), architects (Leon Battista Alberti), and scholars (centring on Guarino Veronese). Leonello's brother and successor, Borso (1450–71), notwithstanding some military failures, not

only maintained his state and increased its aesthetic and cultural prestige but also received from the Holy Roman emperor Frederick III the title of duke of Modena and Reggio (1452) and from Pope Paul II the title of duke of Ferrara (1471).

The long rule of Leonello's and Borso's half brother Ercole I (1471–1505) marked one of the most important periods for the history of the House of Este and of Ferrara. He succeeded in obtaining considerable political support with his marriage to Leonora, the daughter of the King of Naples. These were troublous times, however. Ercole had to defeat the attempt of a nephew, Nicolò, son of Leonello, to usurp the throne; and then he had to face the hostile coalition of Venice and Pope Sixtus IV, which brought war nearly to the walls of the city (1482–84). The subsequent Peace of Bagnolo, however, though not entirely satisfactory, did free Ferrara from immediate dangers.

Ercole's crucial problem became one of consolidating his own political position through marriages that would bind him to the principal Italian powers: of his three daughters, Lucrezia was married to Annibale Bentivoglio (of Bologna), Isabella to Francesco Gonzaga (of Mantua), and Beatrice to Ludovico Sforza (of Milan). His eldest son, Alfonso, was married first to Anna Sforza (of Milan) and then to the famous Lucrezia Borgia, the daughter of Pope Alexander VI. In spite of these difficult affairs of state, Ercole was able to continue his dynasty's patronage of the arts, taking the poet Boiardo as his minister, extending his favour to the poet Ariosto, espousing the theatre and musical arts, and enlarging and beautifying Ferrara to such an extent as to make it one of the first cities of Europe.

His son Alfonso I (1505–34), rough and rude when he was young, proved wise and sure of himself once he had taken the reins of government. First he foiled a plot of a stepbrother, Giulio, and another brother, Ferrante, against him and sentenced them to perpetual imprisonment. Then his attention was completely attracted by the war against Venice (1509), in which his skill in mechanics and artillery design was proved. He was victorious in the naval battle of Polesella and won back the Polesine of Rovigo (which had been lost by Ercole I). At the same time, however, papal ambitions of territorial expansion became threatening. By consistent adherence to the French interest in Italy, Alfonso came into collision with Pope Julius II and was deprived of Modena (1510) and Reggio (1512) and was excommunicated. The Medici popes, Leo X and Clement VII, were both determined on the destruction of the Estensi, but the first-mentioned pope was frustrated by death, the second by political weakness, and Alfonso was able to recover Reggio in 1523 and Modena in 1527. He died in 1534. His succession was assured not only by his legitimate children but also by the issue of his lover Laura Eustochia Dianti, from whom derived the future dukes of Modena and Reggio.

During the reign of his son and successor Ercole II (1534–59), the military events proved less interesting (though the wars of 1557–58 were difficult) than the personal ones. He married Renée, daughter of King Louis XII of France; and in Ferrara she came to embrace the Lutheran religion, becoming its ardent defender and establishing at her court a meeting place for the most famous heretics and liberal thinkers of the day. Ercole, who was the pope's vicar in Ferrara, tried restraining her, even to the point of temporary imprisonment, but to no avail. Next to rule was his first-born, Alfonso II (1559–97), the fifth and last duke of Ferrara. He also tried, vainly, to be elected king of Poland and to organize a crusade against the Turks. More important for the dynasty, however, was the fact that, though he had three marriages, he had no children; and Pope Pius V in 1567 expressly forbade having illegitimate children rule in ecclesiastical lands. Alfonso was so disappointed and discouraged that he let the conditions of his state decay. At his death he bequeathed the duchy to his cousin Cesare (1562–1628), but Pope Clement VII refused to recognize the settlement, declaring Cesare illegitimate; in 1598 direct papal rule was established in Ferrara. The main branch of the Este family had come to an end.

End of the main line of Estensi

Cesare kept Modena and Reggio, but with him the Estensi ceased to play so important a part in Italian politics, and the court was culturally inferior to its brilliant predecessors. Among the several Modenese dukes who followed in the 17th century, Francesco I (1629–58), who came to the throne during the stormy period of the Thirty Years' War, was perhaps the most important. His people were able to survive the famous plague of 1630. In the wars he was first allied to Spain, then to France, whose alliance he thought would best sustain his claims to Ferrara. Later on, he attempted reconciliation with Spain, but ironically it was on the scene of battle, fighting the Spaniards, that he died of malaria. He was a man with enormous aspirations, and, though inclined toward treachery in politics, he gave art his patronage, favouring men of letters and collecting works of art (there is an extraordinary portrait of him by Diego Velasquez and a beautiful bust by Gian Lorenzo Bernini).

Among his successors, the one most deserving to be remembered is Rinaldo I (1694–1737), whose marriage to Charlotte Felicitas of Brunswick-Lüneburg reunited the long-separated branches of the House of Este. Throughout his reign he engaged in imperial politics. His son Francesco III (1737–80), known as a libertine, received the governorship of Lombardy from Empress Maria Theresa of Austria. Ercole III (1780–96), gentle and affable, abandoned Modena in 1796 when the Revolutionary French Army invaded it.

End of the male line

After the Napoleonic Wars, Duke Francesco IV (1814–46), son of Maria Beatrice d'Este (the only surviving daughter of Ercole III) and of Archduke Ferdinand of Asburgo-Lorena, son of Maria Theresa, came back to Modena. He founded the Austro-Este line in Modena, which, however, ended with his son Francesco V (1846–59) when Modena revolted in order to join Sardinia-Piedmont and then Italy.

Childless, Francesco V selected as his universal heir Francis Ferdinand, heir to the Austrian throne, who was murdered at Sarajevo in 1914. Today, the rightful holder of the surname and heraldic bearings of the Estensi is considered to be Archduke Robert, the second-born of Charles of Asberg and Zita of Borbona-Parma. In 1953 he married the princess Margherita of Savoy-Aosta.

About the Signoria of Estensi in Modena and Reggio: O. ROMBALDI, *Gli Estensi al governo di Reggio dal 1523 al 1859* (1959); M.C. NANNINI, *Gli Estensi di Modena* (1959); and L. AMORTH, *Modena capitale* (1961). The most recent study, provided with rich bibliography, is L. CHIAPPINI, *Gli Estensi*, 2nd ed. (1970).

(L.Ch.)

Estonian Soviet Socialist Republic

The Estonian Soviet Socialist Republic, one of the 15 republics of the Soviet Union, was proclaimed on July 21, 1940, and became a member of the Soviet Union on August 6, 1940. On the north and west the republic is bounded by the Baltic Sea and on the east by Lake Peipus (Chudskoye Ozero) and the Narva River; in the south it borders on Latvia and the Russian S.F.S.R.

Estonia has an area of 17,400 square miles (45,100 square kilometres), of which 9 percent is made up of some 800 islands and islets. The larger islands are Saaremaa (1,048 square miles) and Hiiumaa (373 square miles). The capital is Tallinn. For the history of Estonia, see BALTIC STATES, HISTORY OF THE.

The landscape. *Relief.* The Estonian landscape bears traces of glacial activity; the south is covered with moraine (glacial deposit) hills, and the central part abounds in elongated hills with flat tops. They are usually ar-

Glacial landforms

ranged in groups in the direction of glacial movement, for the most part from the northwest to the southeast. The northern part of Estonia is characterized by long narrow swells consisting of deposits left by glacial rivers that formed during the melting of ice. Extensive sandy areas mark what was once the glacier's edge.

The Estonian relief is thus generally undulating, with small hills and numerous lakes, rivers, and forests lending the scene mildness and picturesqueness, particularly in the south.

The mean absolute altitude is 160 feet, only one-tenth of the territory lying at altitudes exceeding 300 feet above sea level. In the southeast is the Haanja elevation containing Mt. Munamägi (1,042 feet [318 metres]), which is the highest point in Estonia.

During the postglacial period a considerable part of Estonia was flooded by the Baltic Sea. Later, large areas emerged from under water as a result of the elevation of the mainland—a process still observable, particularly in the northwest, where a rise of approximately five feet in a hundred years has been recorded.

In northern Estonia is a low limestone plateau that falls abruptly to the sea. The sheer cliff stretches along the southern shore of the Gulf of Finland from Tallinn and continues beyond the republic's borders. It rises to its maximum height (544 feet, or 166 metres, above sea level) at Pandivere.

Rivers and lakes

Estonia abounds in rivers, which carry their water to the gulfs of Finland and Riga and into Lake Peipus. The longest rivers are the Pärnu (88 miles, or 142 kilometres) and the Pedja (81 miles). Lakes occupy about 5 percent of the republic's territory. The largest lake is Peipus, with a surface area of 1,370 square miles (3,548 square kilometres).

Climate. The temperate and humid climate of Estonia differs sharply from the climates of many regions of the Soviet Union situated at the same latitude but in the depth of the continent. The republic lies in the path of air masses brought in by cyclones born in the northern Atlantic that carry warm air in winter and cool air in summer. The mean temperature in February is 23°–43° F (–5° to +6° C) and in July 61°–63° F (16°–17° C). Annual precipitation is 24–28 inches (610–711 millimetres), which, coupled with negligible evaporation and plain relief, leads to waterlogging. The Estonian climate is generally favourable to agriculture.

Flora and fauna. Mixed forests, with about 90 species of trees and shrubs, cover 3,404,000 acres (1,378,000 hectares), or 30.5 percent of Estonia's territory. Most widespread are pine, fir, birch, and aspen; less common are oak, lime, maple, elm, and ash. Meadows occupy a considerable area, as do marshes and swamps.

About 60 species of mammals live in Estonia. The elk is the largest; roe deer, red deer, and wild pigs are also found. In the deep forests of the northeast, bear and lynx are encountered. Foxes, badgers, otters, rabbits, hares, and—along the riverbanks—mink and nutria (coypu) are fairly common. Among the sea animals, seals and fishes (cod, salmon, eel, plaice, and others) are of commercial importance. Birds are very numerous; 295 species have been identified, of which 60 are year-round residents.

Minerals. The most important mineral is bituminous shale; the output of Estonia accounts for 80 percent of the shale produced in the Soviet Union. Reserves and production of peat also are substantial, and large deposits of high-quality phosphorites, limestone, dolomites, marl, and clay exist.

The people. Estonians belong ethnically and linguistically to the Baltic-Finnish group of Finno-Ugric peoples. The population was 1,429,000 in 1975; at the census of 1970 Estonians comprised 68.2 percent, and 24.7 percent were Russians, 2.1 Ukrainians, 1.4 Finns, and 1.4 Belorussians. The average density of population was 82 persons per square mile. Town dwellers comprised 67 percent of the population.

The development of Estonia's economy has been attended by a considerable internal migration. The population in the northern, industrially advanced part of the republic has increased appreciably since the mid-1950s at the expense of the southern and western regions, which are basically agrarian. There has also been extensive immigration from other territories of the Soviet Union, particularly the Russian S.F.S.R.

Towns

There are 33 towns and 26 urban settlements in Estonia. The capital—Tallinn—has a population of 392,000. The other major towns are Tartu, Kohtla-Järve, Narva, and Pärnu, with populations ranging from 25,000 to 100,000.

The economy. Estonia is basically an industrial region, with agriculture also making a contribution.

Fuel and power. About 20 percent of the industrial workers of Estonia are employed in producing bituminous shale and phosphorites or in the power industry. Estonia, the only area of the Soviet Union that has a large shale processing industry, produces about 75 percent of the Soviet Union's artificial gas, much of which is transported by pipelines extending from Kohtla-Järve to Leningrad.

More than 90 percent of the electricity produced in the republic is generated by thermal power plants fired with bituminous shale. One station near Narva, the Estonskaya, which began to operate in 1968, accounts for more than 60 percent of the electricity produced in the Soviet Baltic republics. Other major power plants include a hydroelectric station at the Narva falls and a peat-fired plant at Ellamaa. The electrical power industry has great significance both for the economy of Estonia and for the whole northwest Soviet Union.

Manufactures. Estonia's industry uses both local resources and imported raw materials, those utilizing imported raw materials accounting for 50 percent of the gross industrial output. About 20 percent of the industrial labour force is engaged in engineering and metalworking activities that provide oil-refining equipment, agricultural implements, mining machinery, gas pipes, and excavators. Technical and scientific instruments and electronic apparatus are also produced.

The chemical industry

Shale processing underlies a developing chemical industry centred in Tallinn and Kohtla-Järve. Such products as benzene, adhesives, tanning agents, resins, formaldehyde, and detergents are made.

Estonia's natural resources provide a base for the production of building materials, including cement, mural blocks, and panels made either from shale ash or reinforced concrete. The main centres of this industry are Tallinn, Kunda, Tartu, and Aseri.

Timber and woodworking make up one of the oldest industries of Estonia. As a result of a disorderly exploitation of woodlands in former times the total wooded area decreased more than 15 percent. Many thousands of acres of new trees have been planted, but in order to satisfy its needs Estonia is nevertheless obliged to import from the northwestern regions of the Soviet Union about one-fourth of its requirements. Paper, pulp, plywood, matches, and furniture are among the republic's wood products. The main centres of production are Tallinn, Tartu, Narva, Pärnu, Kehra, Kuressaare (Kingissepp), and Viljandi.

Among consumer goods industries, textiles are the most developed. Seventy percent of all cotton cloth produced in the Soviet Baltic republics is manufactured in Estonia. The republic also produces wool, silk, and linen. Knitted and woven garments and shoes are also produced.

Agriculture. After 1945 Estonia's agriculture was collectivized. Instead of the former 120,000 small peasant farms there were by the mid-1970s more than 300 collective farms and about 150 state farms. Agriculture accounts for 20 percent of the gross national product and engages 26 percent of the labour force.

The land is generally fairly difficult to farm. Large areas have to be cleared of stones, and 70 percent of the natural pastures require draining. Cattle and pigs account for about two-thirds of the Estonian S.S.R.'s agricultural production.

Fodder crops for animal husbandry account for more than 45 percent of total crop production. Grain crops, legumes, and potatoes represent most of the balance.

An increased level of mechanization and the application

of more advanced methods of work in agriculture have resulted in a considerable increase in labour productivity and in agricultural incomes.

Transport and communications. Transport systems in Estonia include railways, roads, rivers, and pipelines. Most of the republic's freight (68 percent) is carried by railways; the share of road transport is 30 percent, that of sea transport 2 percent. River transport is of local significance only.

Estonia is connected by air with Moscow, Leningrad, the capitals of the union republics, and the Black Sea resorts.

Administrative and social conditions. *Constitutional and political framework.* Estonia has a state emblem, flag, and national anthem. It is a socialist republic, and its constitution (1940) declares it to be a sovereign entity, though in fact it has no power to carry on relations with foreign countries. The highest organs of state power are the Supreme Soviet, elected for a four-year term, and the Presidium, selected by the Supreme Soviet. The highest executive and administrative organ of government is the Council of Ministers. In the provinces government is effected through local soviets.

Communist Party of Estonia

All political life in the republic is under the direction of the Communist Party of Estonia, which in 1974 had some 79,000 full and candidate members. The party concerns itself with the political and ideological education of the population, establishes policy for the development of the economy, and directs the activities of the Young Communist League of Estonia (Komsomol; created in 1921), which in 1974 had a membership that totalled 128,000.

Trade union membership totalled some 618,000 in 1970. Unions do not, as in the West, represent the workers in negotiations with management; their efforts are directed more to providing incentives for increased production, maintaining labour discipline, and serving as an instrument of Communist Party policy.

Welfare and culture. As a result of the development of industry and agriculture, the economic and social welfare of the population has increased substantially compared to the period immediately after World War II. Over the decade 1960–70 the national income doubled, permitting advances to be made in such areas as pensions, education, medical care, and housing.

Scientific research in the republic is centred on the Academy of Sciences of the Estonian Soviet Socialist Republic (founded in 1946), which has three departments: physics, mathematics, and technical sciences; chemistry, geology, and biology; and social sciences. In the 1970s the academy supervised about 12 institutes and 11 other establishments employing approximately 900 scientific workers.

More than 40 newspapers are published in Estonia, some with a circulation of more than 1,000,000 copies. Book publishing also flourishes, the output in 1973 comprising 1,966 titles and 13,120,000 copies.

Estonian radio broadcasts diversified programs. The system possesses a mixed chorus, a symphony, and a variety orchestra. The republic has had a television centre since 1955, and television broadcasts from Moscow and Leningrad are also received in most areas.

Literature

The scope and importance of Estonian literature has steadily increased since the period of national awakening in the 19th century. The greatest achievements in the first half of the 20th century were made in the genres of realistic novel (Anton Tammsaare) and imaginative poetry (Marie Under, Betti Alver). Open to cultural and literary influences of western Europe, Estonian literature developed a diversity of styles, ranging from Neoclassicism to bold experimentation. Since World War II, the dominant theme has been Soviet reality, expressed in the form of Socialist Realism especially in the prose writings of Soviet Estonian authors (Juhan Smuul). During the 1960s, a younger generation of exceptionally talented poets (Paul-Eerik Rummo, Jaan Kaplinski) brought about a revival of Estonian poetry that continued into the '70s (Jüri Üdi). A new and sophisticated genre, the so-called short novel, deals primarily with psychological problems (Enn Vetemaa, Mati Unt), sometimes projecting them into history (Jaan Kross). New developments can also be found in drama and short story. Both Estonian classics and the works of contemporary authors have been translated into many languages.

The beginning of professional theatrical art in Estonia is closely connected with the creation of the Vanemuine Theatre in Tartu in 1870. Tallinn has five theatres, including an opera and ballet theatre, a drama theatre, a youth theatre, and a puppet theatre. There are also professional theatres to be found in Pärnu, Viljandi, and Rakvere.

Tallinn is famed for its song festivals. There is an enormous stage for popular mass performances, and tens of thousands of singers and up to 200,000 spectators come to take part in these events.

Prospects. Natural resources, investment funds, and a qualified body of workers and specialists are the foundation of the future development of the national economy of the republic. The ninth Soviet Five-Year Plan, adopted in 1971, laid down the following directives for the Estonian economy: major emphasis was to be given to those branches of machine building that do not consume much metal, particularly the electrotechnical and the instrument-building industries; the light industries and meat and dairy production were also to be given increased emphasis.

During the five-year period, gross industrial production was planned to increase 36–38 percent. The output of shale was to reach 26,000,000 tons annually, necessitating the building of associated plants.

The output of electricity was expected to increase 1.4 times, construction of the Estonskaya power station was to be completed (it became fully operational in 1973), and work was to start on building the Tallinn thermoelectric station.

The fish catch was expected to increase, and the production of the fish-processing industry was expected to expand almost one and a half times.

Estonia's agriculture, it was anticipated, would become still more specialized, with attention focussed on meat and milk production, pig breeding, and potato growing. There were plans to drain 519,000 acres (210,000 hectares) of swampy regions; to further improve land quality over 370,000 acres (150,000 hectares); and to create productive meadows and pastures covering some 320,000 acres (130,000 hectares).

(A.A.Ke./V.J.T./Ed.)

Estuaries

An estuary is a partly enclosed body of water that forms where river water is mixed with and diluted by seawater. In a general sense, the estuarine environment is one that is defined by salinity boundaries rather than geographic boundaries.

Many coastal features that are designated by other names are, in fact, estuaries. The lower reaches of rivers such as the Hudson, Thames, and St. Lawrence are estuaries. Other river systems with large deltas are actually estuaries at their seaward end; the Mississippi is an example. Certain coastal embayments, such as Chesapeake Bay and Galveston Bay, also are estuaries because fresh and salt water undergo considerable mixing. In addition, most of the fjord systems in the world are estuaries (*e.g.*, Oslofjorden, Hardangerfjorden, and fjord systems in the Pacific Northwest of North America). Large, semi-enclosed tidal flat regions and coastal marshes, such as Pamlico Sound, the Waddenzee area of The Netherlands, and those of New England, also may be termed estuaries.

The adjective estuarine can be applied to aqueous environments where seawater has become somewhat diluted by fresh water. For example, the northernmost Pacific Ocean in the vicinity of the Bering Sea and Gulf of Alaska has estuarine characteristics because of the great quantity of fresh water that flows into this region. The same holds true for the Baltic Sea, Gulf of Bothnia, Gulf of Finland, the southeastern section of the North Sea, and the coastal zone around Norway. In these regions

high amounts of precipitation and runoff dilute the coastal seawater until it has estuarine characteristics. Ocean areas off the mouths of the Mississippi, Amazon, and Columbia river systems also become estuarine during the rainy seasons when the river discharge increases and dilutes the coastal waters.

Importance to man

Estuaries have long been important to man as harbour sites and centres of commerce. Some of the oldest continuous civilizations have flourished in such estuarine environments as the lower region of the Tigris and Euphrates rivers, the Po River Delta region of Italy, the Nile Delta, the Ganges Delta, and the lower Hwang Ho Valley. As civilizations developed, it was logical that the seaports were founded at the seawardmost point of the major river systems. In this way commerce could move cheaply and relatively safely down the rivers and be loaded onto ships to be moved to more distant ports. Cities including London (Thames River), New York (Hudson River), Montreal (St. Lawrence River), Baltimore (Chesapeake Bay Estuary), New Orleans (Mississippi River), Houston (Galveston Bay), San Francisco (San Francisco Bay), Hamburg (Elbe River), Liverpool (Mersey River), and Bordeaux (Gironde Estuary) have developed on estuaries and have become important centres of commerce in the modern world.

The world's fishing industry is somewhat dependent on the estuarine environment, either directly as an area of fishing or indirectly as a region where the species spend a portion of their life cycle. In the United States alone, the Pacific salmon, anadromous trout, shrimp, and menhaden fisheries provided the majority of the total weight of fisheries' products landed by United States fishermen. These species are all estuarine dependent for part of their life cycle.

This article treats the formation and maintenance of estuaries, their general hydrology, and the ecology of estuarine life. For further information on relevant physical factors, see WATER WAVES; TIDES; RIVERS AND RIVER SYSTEMS; and HYDROLOGIC CYCLE; see also OCEANS AND SEAS; GULFS AND BAYS; COASTAL FEATURES; RIVER DELTAS; SWAMPS, MARSHES, AND BOGS; and AQUATIC ECOSYSTEM for a description of the nature and the biota of neighbouring environments.

THE FORMATION OF ESTUARIES

Changes of sea level. The geologic processes that form an estuary are extremely complex and varied, but it is clear that the existence of an estuary or estuarine environment is largely dependent on the position of sea level relative to the freshwater discharge. The estuarine brackish water zone is relatively narrow in width and is located at the margins of the continents. If sea level were lowered, the estuarine zone would migrate seaward at the interface of the marine water and the edge of the newly exposed land area. Such migration has occurred in the past as a consequence of the Earth's several continental glaciations. For each glaciation the primary source of moisture has been the oceans. Whenever sea level fell, the estuarine environment at the continental margin was forced to migrate in a seaward direction. Areas of marine water became brackish and supported fauna that were typically estuarine rather than marine. Empty shells of the oyster *Crassostrea virginica* are found in two bands at 70-metre and 50-metre depth on the Atlantic shelf of the United States, for example. Today these oysters are only found in estuarine waters shallower than ten metres, in which the salinities are much lower than in the open ocean. In addition, bottom sampling of the continental shelf off New England often reveals past deposits and intertidal sediments that are indicative of a previous estuarine environment.

Relation to former ice ages

Approximately 18,000 years ago the Wisconsin Glaciation attained its maximum, and glacial melting began. The seas rose, forcing the estuarine environment to migrate back up the continental shelf. During the period of lowered sea level, some rivers had become entrenched in the continental shelf and deepened their valleys. These valleys were soon flooded by the rising marine waters, forming a typical drowned river estuary. In areas such as Norway and parts of the coast of British Columbia, valley glaciation had served to deepen river valleys. These narrow drowned glacial valleys became the modern fjord estuaries as sea level rose.

When sea level rose, the coastal plains and deltas near the outer edge of the continental shelf were the first to be submerged. The shoreline moved over the shelves into the valleys of river systems that previously had transported sediments far across the continental shelf. The physical boundaries of the estuary then became more complex as brackish water filled the former tributaries of recently drowned river systems. In some cases entire broad valleys were filled by the rising of sea level, and in this way some large, shallow estuaries, such as Chesapeake Bay, were formed.

Geomorphology of estuaries. The geomorphology, or form, of an estuarine basin is usually developed by fluvial erosion, fluvial and marine deposition, glacial erosion, or tectonic activity. These processes are associated with four types of basins, namely, fluvial, depositional, glacial, and tectonic.

Fluvial basins. Drowned fluvial valleys are probably the most common type of estuarine basin. Where the valleys were simple and straight with few tributaries, drowning has simply raised the level of water on the valley walls. This is true of the Hudson and St. Lawrence rivers, for example.

In other river systems, especially those that were developed on softer, more unconsolidated rocks, the rivers were quite complex and have an elaborate tributary system. When these regions are flooded, the resulting estuary exhibits an extremely crenulated border that follows the contours of the former tributary valleys. An example of this type is Chesapeake Bay on the eastern coast of the United States (Figure 1).

Depositional basins. Some estuarine basins are formed when barriers that separate the ocean and river waters develop. This has occurred off Galveston and Corpus Christi bays, where barrier islands have, in effect, created an estuarine environment sandwiched between the inner Texas coast and the offshore islands. The Vadehavet, the Danish tidal area, and the Wadden Zee of The Netherlands also have offshore barriers that in part act as a permeable wall behind which the estuary has formed.

Natural levees, spits, and bars also can restrict inlets and thus permit the establishment of estuarine environments in coastal indentations that were formerly open to the sea. Spits commonly form at seaward ends of large estuarine systems and further restrict free exchange between the open ocean and the river water. This has happened to the Swan Estuary of Western Australia.

Fjords as estuaries

Glacial basins. Probably the most picturesque of all estuaries are the fjords. Fjords are deep, narrow, U-shaped gorges that were cut in bedrock by tongues of glacial ice during former ice ages. Many of the fjords were former river valleys that were deepened and widened by ice action. Because of the thickness and weight of the ice, the glaciers were able to erode far below sea level. In addition, the seaward end of the fjord is usually marked by a bedrock or depositional sill that forms an internal basin. This means that the fjords are extremely deep and narrow with a shallow restrictive entrance. The shallow depths of the sills prevent free exchange of the oceanic water outside the sill and the water in the basin. Because of this lack of renewal of oceanic waters to the basin, many fjords have become oxygen deficient and will not support life in their deeper layers.

Tectonic basins. Continental tectonics, or movement of the land surface, may also create estuaries. A common form is the graben, or downfaulted block; Tomales Bay, off the northern California coast, is a graben-controlled estuary.

Broad local subsidence of portions of a coast also can create estuarine environments because its effect is equivalent to a rise in sea level. The San Francisco Bay region, which has had a complex geologic history, is in this category.

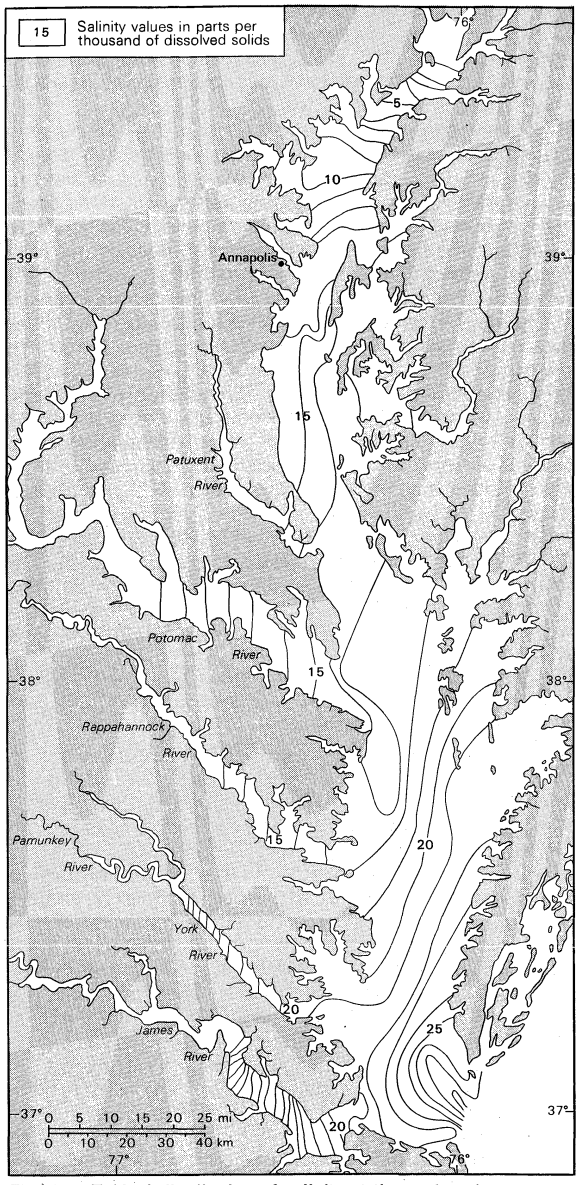

Figure 1: Typical distribution of salinity at the surface in Chesapeake Bay.

Factors tending to destroy estuaries. There are four major factors that tend to destroy the estuary: these are sediment influx, vegetation encroachment, relative changes in sea level, and the activities of man.

Sediment influx. The most natural enemies of the estuary are the river and marine sediments that tend to fill it. In the river environment the current velocity is directed downstream and sediment is constantly moving along; the movement is rapid during flood season and periodical during the quieter water of low discharge periods. When river sediment reaches the estuary, the coarser fraction tends to settle out, often forming deltas. Even the finest clays are affected by the brackish water of the estuary and may begin to flocculate and accumulate. The net effect of this sedimentation is a gradual loss of estuarine area and a decreasing mean depth of the estuarine system. Rates of sediment deposition are variable, but one to three metres per thousand years is probably an average figure.

Infilling by sedimentation and vegetation

Vegetation encroachment. As a natural consequence of sedimentation, vegetation will develop in the estuary. The increase of the vegetable cover depends on the local climate, salinity of the estuary, river drainage, and available types of vegetation. In a broad, shallow estuary that is undergoing deposition in a temperate climate, *Spartina* grasses are one of the first and hardiest of the forms of vegetation to begin filling the estuary. Shoal areas that are exposed during the tidal cycle initially become colonized, and once the plants gain a foothold they act as anchoring devices to stabilize the sediments. Vegetation also acts as a dampening agent to currents and waves, creating areas where finer sediments can settle out. As the vegetation spreads, more sediment is trapped and deposited, and soon the tidal flat is a series of tidal channels separated by expanses of vegetation. The vegetation thickens and grows upward, often creating peatlike deposits below the surface. As the vegetation and peat continue to build up, the region is less influenced by the daily tidal cycle and before long gives way to species of plants that utilize fresh water. The former tidal flat is then relatively divorced from the marine environment.

In tropical estuaries, the vegetation sequence is dominated by mangrove trees, whose densely interwoven systems of stems and roots rapidly build up a swampy shore. With time, the substrate may build up above the reach of the tide, and the mangrove swamp may give way to oak, mahogany, and other hardwood trees. One of the greatest mangrove swamps in the world exists in southwestern Florida where the brackish estuarine water forms ideal environmental conditions. Although the estuaries may lose area, valuable land is often built up by mangrove growth. In the last 40 years in the Biscayne and Florida Bay regions, some 1,500 acres of new land have formed as a direct result of mangrove growth.

Relative changes in sea level. Relative changes in sea level also can modify or shift the estuarine environment. Certain areas of the world that were depressed by ice loads during glacial times, for example, are now rising out of the sea. Some Scandinavian shorelines have risen as much as 300 metres since deglaciation in an attempt to re-establish equilibrium. The brackish water estuarine environments of the Gulf of Bothnia, Gulf of Finland, and even the Baltic Sea are in part related to the former depression of the Earth's crust in these areas by glacial ice. In time these regions will become less marine as they are uplifted relative to world sea level.

Activities of man. Man's effect on estuaries can be dramatic. Dams or locks built on rivers may prevent some estuarine deposition, but upstream deposition will be increased. In the three years following World War II, when the locks of the Rochefort Basin of France were destroyed, some seven metres of sediment accumulated in the estuarine portion of the Charente Estuary. As a result of cultivation, plowing, and deforestation, more sediment is now transported into the estuaries than ever before. In Madagascar, on the Betsiboka Estuary, deforestation has increased the sediment load and deposition to such an extent that an entire harbour built in World War II is now completely filled.

Effects of dams and locks

In general, estuaries are fragile environments that can respond dramatically to minor changes in the sediment load, vegetation, and sea level. True estuarine sedimentary rocks are rare occurrences, and this suggests that estuaries in the past also have been only temporary environments that responded to minor fluctuations of various processes and factors.

HYDROLOGY AND SEDIMENTATION IN ESTUARIES

Factors controlling and affecting estuarine circulation. *The tides.* The tides have a very important effect on the circulation within an estuary. The volume of water within the estuary between high and low tides is known as the tidal prism. The currents generated by this volume of water flowing in and out of the estuary depend on the geometry of the tidal basin and the tidal range (distance sea level rises from maximum ebb tide to maximum flood tide). In estuaries where the tidal range is large, the tidal currents have the ability to mix both the inflowing river water and ocean water in the estuarine basin. In estuaries with smaller tidal ranges and lower current velocities, the river water may remain relatively unmixed within the basin and form a low-density layer that floats on the surface of the denser salt water.

River discharge. The quantity of freshwater inflow is important in determining the nature of the estuary. During periods of high river discharge, fresh water may force most of the salt water out of the estuary. During other seasons when river discharge is low, the estuary may be more akin to an extension of the ocean rather than an estuarine environment. Moderate river discharge may stratify, or layer, the estuary, with the low-density brackish waters on top and the denser, more saline waters below.

Wind. Wind can strongly affect the mixing of estuarine waters by creating local waves that break down water stratification. In addition, through stress on the surface, the wind can cause a net transport of surface water and thus reinforce or retard the normal tidal flow.

Ice. The formation of ice within estuaries can act in many ways to affect the estuarine circulation. If large portions of the estuary are covered by ice, local wind-generated waves will have little effect in mixing the surface and bottom waters. In contrast, restricted channels caused by ice blockage may locally increase the tidal currents and mixing of the waters. Melting of estuarine ice in the spring also provides water that is of lesser density than normal estuarine water and may lead to stratification.

Physical dimensions. The physical dimensions of an estuary are extremely important with respect to the hydrology. Broad, shallow estuaries like Great Bay, New Hampshire, are much more susceptible to the effects of wind mixing by local waves than are deeper estuaries. Narrow, constricted entrances in some estuaries create a Bernoulli effect, wherein the tidal current increases as the water passes through the narrow region. The currents under Golden Gate Bridge in San Francisco Bay are an example. Certain fjords with restrictive sill depths at the seaward portion of the estuary inhibit circulation and mixing to such an extent that the lower waters in the estuary become devoid of oxygen.

Fresh and brackish water and the saltwater wedge

Types and examples of estuarine circulation. In most estuaries there is a certain amount of to-and-fro motion of the waters as the tides flush in and out the basin. Besides this, however, there is a net circulation pattern within estuaries that is a function primarily of the mixing of the fresh and salt water in this complex area. This is termed estuarine circulation

Highly stratified estuary. Most highly stratified estuaries occur in regions where the tidal range is low and river discharge into the estuary is high. In these cases, the less dense surface water of the river will float over the salt water, forming stratification, or layers of water, within the estuary. The fresh river water that forms the surface layer quickly becomes brackish as it mixes with the estuarine waters.

It is possible that internal waves develop at the interface between brackish surface water and the underlying salt water. The formation of these waves would cause some of the underlying salt water to mix with the overlying, lighter brackish water. This means that some salt water would be transported seaward in the upper layer and, as a net result, means a slow movement of salt water along the base of the estuary up the river. This type of estuary often is called a salt-wedge variety because of the wedge of salt water that intrudes at depth (Figure 2). The lower end of the Mississippi River is an example of this type of estuarine circulation.

Conditions leading to highly stratified estuaries are enhanced in regions where there is high river discharge and low tidal flow. In addition, highly stratified estuaries are more likely to develop in deep, narrow, drowned river valleys.

Moderately stratified estuary. As tidal flow increases, or as river discharge decreases, more mixing takes place between the upper and lower waters in an estuary. The sharp salinity gradient, called a halocline in highly stratified estuaries, is more diffuse in a moderately stratified estuary. The greater amount of tidal mixing adds a larger volume of salt water to the upper layers than in the salt-wedge type of estuary. The net flow in this system is still primarily two layer, with the surface water moving seaward and the bottom water moving landward. Now, however, because of mixing, circulation is much greater and there is more flow both in the upper and the lower salt waters. The volume of water circulation in this type of flow far exceeds the salt-wedge type. For example, the seaward flow in the surface layer may be 30 times the river discharge whereas the inflowing water at the base of the estuary is 29 times the river flow (Figure 3). Moderately stratified estuaries include the James River, the Thames River, Chesapeake Bay, and portions of the Strait of Juan de Fuca.

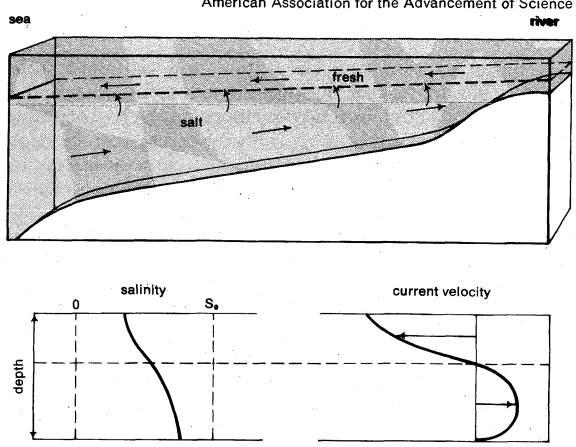

Figure 3: *Partially mixed estuary with entrainment and mixing.* (Top) Section along estuary. (Bottom) Typical salinity and velocity profiles.

Vertically homogeneous estuary. As mixing increases due to tides and wind, the water becomes less stratified and ultimately reaches a point at which its properties from top to bottom are relatively constant at any one location within the estuary. Although the vertical gradient is erased, a strong horizontal gradient extending from brackish water near the head of the estuary to salt water near the mouth still exists.

Coriolis effect and circulation

In certain broad, shallow estuaries there is a lateral salinity gradient across the estuary as a function of the Coriolis effect. In the Northern Hemisphere lower salinity water moves on the right side of the estuary whereas oceanic water enters the system on the left. The net effect is still to maintain vertical homogeneity, but a counterclockwise circulation is established within the estuary. Some estuaries of this type are the relatively wide portions of Delaware Bay and the Raritan Estuary in New Jersey.

In smaller estuaries of this type, the lateral gradients and cyclonic circulation may not exist. In these estuaries there may be net flow seaward at both the surface and the bottom. The exact mechanism of this water move-

ment is poorly understood, however. Perhaps the closest natural example is provided by parts of the Severn Estuary of England.

Fjords. Fjords are somewhat unique estuaries, and it is difficult to classify them according to the above scheme. The freshwater source is usually concentrated at the head, and there is a strong halocline that exists within the fjord during most seasons. The brackish water flows out in the upper layers and in the process entrains some salt water. The salt water enters the estuary over a restrictive sill and fills up the basin with waters of fairly constant salinity. Most of the mixing and entrainment occur at a fairly shallow depth; consequently, the lower waters of the deep, narrow fjords are sluggish and rarely mixed. With time, decaying organic matter falling into the basin uses up the oxygen, and the bottom waters become anoxic (without oxygen) and toxic to life-forms. Many of the fjords found in Norway and British Columbia are of this variety.

Other estuaries. Many other estuaries tend to defy classification. Certain bar-built estuaries have very restrictive inlets with extremely shallow basins, for example. A wind-driven circulation may be the most important factor involved in water transport within these estuaries.

In other estuaries tidal mixing occurs only in portions of the estuarine system where land barriers, islands, or similar features cause currents to increase as they move across or through the barriers. In this case the estuary changes type both up the estuary and through time within the tidal cycle.

Other estuaries change through time as rivers are dammed up, harbours become dredged, or siltation occurs. Some estuaries may become nonestuarine as basins are blocked by hurricanes or by man-made efforts to create freshwater environments.

Relation of estuarine circulation and sediment transport. The motion of the tides have a pronounced effect on the river flow into a typical estuary. In the lower reaches there is a to-and-fro motion of the surface water over the tidal cycle. Proceeding upstream, however, the river becomes more dominant until a point is reached at which the tides no longer can reverse the river current. At this point the water usually is fresh from top to bottom. From this zone seaward the salt content in the lowermost waters increases. If tidal mixing is not too great in this region, the river water, being less dense than the seawater, rides up over the salt water and may actually lose contact with the riverbed. At this ideal stage, a two-layer system exists with the lower water acting as a barrier or cushion to the overlying "fresh" water. This zone is not fixed but will migrate to-and-fro with the tides. If the effect of the tides is removed by averaging the to-and-fro motion, there will be a boundary between the surface and lower waters along which there is little actual motion. This region where the downstream estuarine circulation is balanced by the upstream circulation has been called the level of no motion.

Tidal versus fluvial transport

A river may introduce sedimentary particles of several sizes, including sand, silt, and clay. A sedimentary particle of sufficient size and density may settle down through the fresher surface water moving seaward. As it settles into the saltwater layer, however, its direction of travel will be changed, and it may be transported back up the estuary along the bottom. Assuming the particle is carried in suspension, it may even be entrained in the surface water again, and again continue on its seaward journey. The process could be repeated again and again before the particle finally came to rest or was carried out to sea.

Because of the cyclic nature of this suspended-sediment transport, there exists a turbid zone near the head of the estuary where these fine particles are recycled in suspension. The sizes of the particles contained in the maximum turbidity zone is not known in great detail, but fine silt and some clay probably are present. If a particle is too fine, it will not settle through the upper layer to the lower zone. Instead the particle will be transported seaward and finally escape from the estuary. On the other hand, if a particle is too coarse, it will settle through both the surface and lower layers and consequently it will form a bottom deposit.

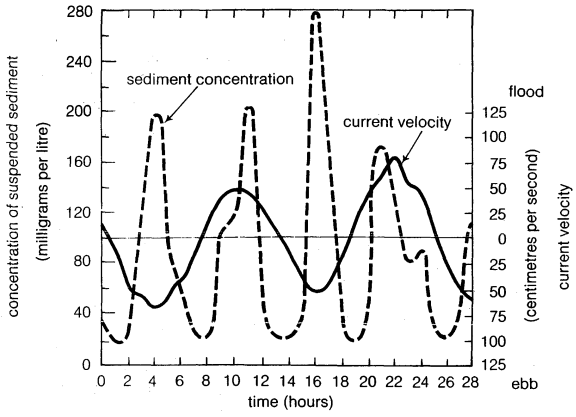

Figure 4: Relationship between suspended sediment near the bottom of an estuary and the tidal current velocity.
From J.R. Schubel, *Science*, vol. 161, p. 1014, © 1968 by the American Association for the Advancement of Science

Sources of estuarine sediments. In many estuaries the main sources of sediment are the associated rivers. In the Rhône Delta region of southern France at least four-fifths of the sediment is derived from the Alps. The Vigo River Estuary, Spain, contains estuarine sediments primarily derived from the erosion of continental weathering products. In the upper Chesapeake Bay region, over 80 percent of the total suspended sediments are thought to be due to discharge from rivers emptying into the bay. Most of this sediment is carried in by the Susquehanna River during high river discharges in the early spring. In the Gulf of Mexico, the Apalachicola and Mobile estuaries contain clays that are typical of those found inland from the coast, and this suggests that the rivers are major sources of sediment.

Estuarine sediment also can be derived offshore and then transported landward in the intruding salt water. Investigations of the Lek Estuary of The Netherlands shows a displacement of sand from the offshore region into the estuary. Work on the Wadden Zee has shown that most of the sediments were derived from marine erosion and transported inshore. Investigations on the Schelde Estuary at the Belgian–Netherlands border have shown that most of the fine silts have originated from the southern North Sea region. There is also evidence from the lower Seine Estuary in France that most of the sediments are of marine origin. This is supported by the fact that in a single year more than 9,500,000 cubic metres of sediment were deposited in the Seine, whereas only 1,000,000 cubic metres were brought down by the river.

Marine derivation in the North Sea area

The ability of tidal currents to erode and resuspend the amount of organic detritus in the suspended matter within the estuary also can be an important factor. In estuarine marshes off Georgia, some 90 percent of the total material in suspension is of organic origin. Most of this is from the breakdown of *Spartina* species. In the upper portions of the Chesapeake Bay region approximately 25 percent of the suspended material is organic.

In summary, then, there are many sources contributing sediment to an estuarine environment. Many of these sources change with the seasons. For example, during the spring and other rainy seasons high river discharge may be the most important source of sediment to the estuary. In the summer, local plant productivity may cause a tremendous input of "suspended sediment" into the estuary. In the fall storms may stir up the bottom and increase the turbidity over short periods of time. The sources of sediment are almost as varied as the types of estuaries themselves.

The concept of flocculation. Fine-grained clay sediment remains in suspension in river waters if the current velocity and turbulence are high enough to keep the par-

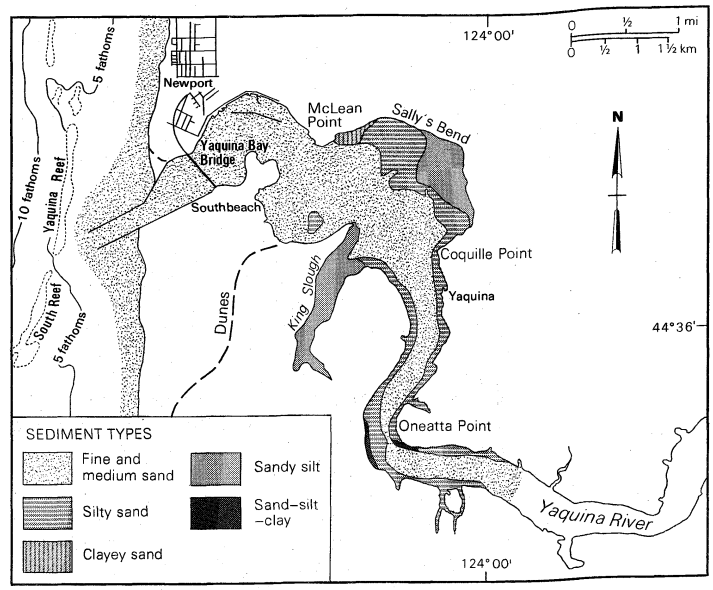
ticle from settling. Each of these very small, flat clay particles settles through a water column at a rate proportional to its density, size, and shape; the molecular viscosity of the water; and other factors. Clay particles in fresh water have a negative electrical charge that attracts and holds dipole water molecules around it. The clay particle then is surrounded by a "hydrated" shell of water that prevents contact with other clay particles.

Creation of larger sedimentary particles

As the clay particle moves from the river to the estuarine environment, it begins to encounter measurable quantities of sea salt. Sea salt cations, especially magnesium and calcium, tend to selectively replace the dipole water molecules surrounding the clay particle. The net effect is that the "hydrated" shell thickness is reduced and particles may come into contact and stick to one another. These aggregated clay particles are called flocs and the process is called flocculation. In sedimentation, the main effect of flocculation is to create larger sized particles, the aggregate weight of which will permit them to settle in the estuarine environment. The process of flocculation is probably reversible; particle aggregates carried back into fresh water by the underlying saltwater intrusion will tend to disassociate.

Distribution of bottom sediments in an estuary. The most landward portion of the estuary is characterized by dominance of fluvial or river sediments. In many estuaries, the point where the river first enters the estuarine basin is marked by deltaic deposits, primarily sands and silts. Farther seaward, where the estuarine circulation patterns are better developed, finer grained deposits of silts and clays commonly occur on the sides of the estuary and coarser sand deposits in the tidal channels. The finer grained material on the sides of the estuary reflect quieter zones of deposition whereas the estuarine channels are regions of higher current velocities that keep all but the coarsest sediment from settling out. The shoreward portion of the tidal flat regions of the estuary are often marked by marsh growth and encroachment of vegetation into the estuary.

Farther seaward, the marine influence becomes increasingly dominant. Quite often tidal deltas are found at the mouth of the estuary extending both seaward and landward from the restricted entrance. The higher tidal currents associated with the entrances are reflected in the coarser sediments found in this region. In addition, coarse-grained materials from outside the estuary from beaches and offshore deposits are often washed into this zone and dominate the bottom sediments. Figure 5 shows a typical estuary and the type of sediments that are found in the various portions. (F.E.A.)



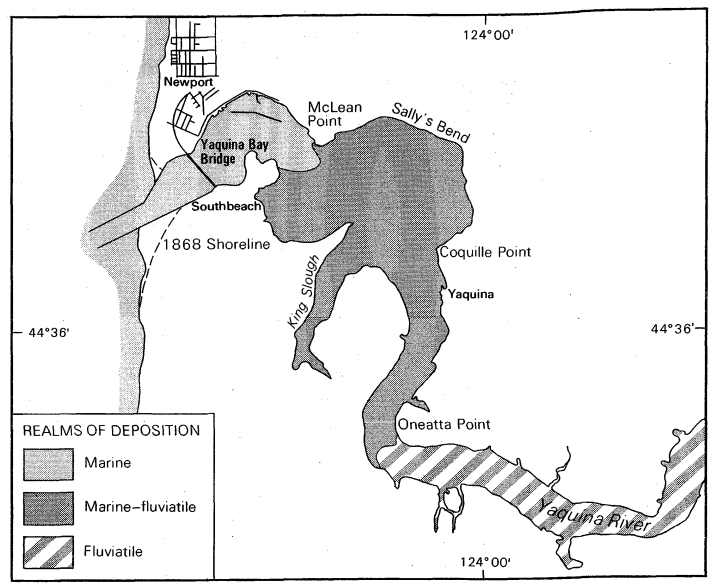


Figure 5: Sediment types and realms of deposition in Yaquina Bay, Oregon.

LIFE IN ESTUARIES

The estuary as a biological environment. Estuarine organisms must cope with the most variable environment on Earth. While other environments may be more extreme in terms of heat or cold, or even salinity, none changes as rapidly, or in so many ways, as an estuary. The salinity at any one point may vary from that of fresh water to that of seawater during the course of a single tidal cycle. At one moment a tidal bore may rush into the estuary; a few hours later the water may be so calm that fine particles of mud can settle. Where the tidal range is great, large areas exposed at low tide may be subjected to the full effects of the sun at midday and to frosts at night.

Environmental gradients

Within an estuary are two major environmental gradients that result from periodic tidal flushing. The first is a longitudinal gradient from fresh water to the sea, the major variable being salinity, subsidiary variables being wave action and current speed. The second is a transverse gradient, which is best shown in estuaries with a large tidal range. The transverse gradient is more complex than the longitudinal: salinity, currents, exposure, temperature, and deposits all vary along the transverse gradient. Low on the estuarine shore the salinity is more variable than it is higher up. When the tide comes in over the lower part of the shore, the outflow of the river is first pushed back, rising slightly over the shore, and is then replaced by water of higher salinity as the sea penetrates into the estuary. High on the shore the salinity is less variable, as it is covered only for a short period, either by fairly high salinities, if the estuary is not stratified, or by fairly consistent low salinity, if the estuary is of the type in which a layer of fresh water flows out over the top of a penetrating tongue of seawater. The lower parts of the shore are also subjected to stronger currents, and this in turn influences the fineness of the deposits. The smaller the particles, the longer the time required for them to settle. Coarse sand settles within a few seconds, but fine mud may take several hours to settle. The finest muds are usually deposited fairly high on the shore, where the currents are slowest.

Habitats of plants and animals

The two gradients, longitudinal and transverse, produce a variety of habitats within the estuary. Each habitat has its own characteristic plants and animals. Low on the shore, where there is bare sand or mud, the majority of animals are burrowers. The bare surface is too exposed for most animals and not stable enough for the attachment of seaweeds, so that there is no shelter from predators. The only escape is to burrow beneath the surface. Various worms, mollusks, and crustaceans make burrows differing in shape and complexity. For instance

the lugworm (*Arenicola marina*) makes a U-shaped burrow with an open tail shaft, but the head shaft is filled with sand that slowly sinks down as the worm eats it from below for suspended food. This sinking of the sand down the head shaft leaves a shallow conical depression in the surface of the sand. At intervals the worm moves backward up the tail shaft and defecates onto the sand above, leaving the sandy casts that are often abundant on estuarine beaches.

For many estuarine animals the burrow is a part of the feeding mechanism. A current of water is passed through the burrow, and small particles in suspension are trapped and eaten, often by elaborate mechanisms, which may involve hairy fringes and mucus nets. The current of water flowing through the burrow also serves for respiration and carries away stagnant water.

The bivalve mollusks use tubular siphons to make contact with the water above the mud. *Scrobicularia plana*, for example, lives several inches below the mud surface. Its two siphons can be extended to ten inches or can be retracted into the shell if danger threatens. This is basically the same as living in a U-shaped burrow, but instead the body of the animal has become modified to enable water to flow through and supply food and oxygen.

Filamentous algae and various unicellular forms, such as *Euglena* and diatoms, are found on bare mud and sand. The filamentous algae help to stabilize the surface and provide food for a number of microscopic animals. Both *Euglena* and the diatoms move up to the surface when uncovered by tides, accounting for the green and yellow patches on bared estuarine muds.

Wherever rocks or stones provide shelter, the estuarine fauna changes. Barnacles can withstand quite low salinities but need something solid to which they can attach themselves. Some of the amphipod crustaceans spend a large part of their time hiding under stones. Mussels, also, are influenced in their distribution and abundance by the presence or absence of a sufficiently firm substratum for attachment. Once a few mussels become attached, they in turn provide surfaces for the attachment of other mussels and shelter for a whole host of smaller animals. The mussel attaches itself by secreting a bundle (byssus) of numerous tough threads that adhere to solid objects. Oyster reef communities also provide a stable bed upon which other organisms can attach.

Colonizing plant communities

The upper parts of the estuarine shore often support rooted vegetation, the most characteristic form in temperate regions being the salt marsh. This flourishes best above the high watermark of neap tides, so that the plants of the marsh have periods of several days every two weeks when they are not covered by water.

Several different plants may act as primary colonizers on estuarine shores. Contrasting examples are *Spartina* and *Salicornia*. *Spartina* is a tall grass with a creeping rootstock from which a series of stout, vertical roots descend and another series of horizontal roots spreads out into the surrounding mud. A rooting system of this sort is very effective in binding soft mud. Once the plant has become established, its dense tussocks slow water currents, allowing the settlement of more mud. Areas colonized by *Spartina* are thus rapidly built up above surrounding areas. Where the water is fresher, *Spartina* tends to be replaced by tall reeds, such as *Phragmites*.

Salicornia, a small plant compared with *Spartina*, has no distinct leaves but only swollen leaf bases around the stem, and it has shallow roots. It is a rapid colonizer of regions with slow currents.

Behind the primary colonizers a range of plants may form a dense sward or general salt marsh, with its characteristic animal life, including both terrestrial and aquatic forms. The latter must tolerate periodic exposure to air, while the former must either leave the marsh at high tide or tolerate submergence for several hours at a time. In the tropics the salt marsh is replaced by mangrove communities, in which the most important trees are the red mangrove (*Rhizophora*) and the black mangrove (*Avicennia*), whose tangled roots and branches provide shelter for numerous animals.

The open waters of estuaries have their own characteristic animals. Floating animals (zooplankton) are usually restricted to relatively few species but can be quite abundant and widespread. Some copepods, such as *Eurytemora velox* and *Acartia tonsa*, are found in estuaries over a large part of the Northern Hemisphere. Sometimes one species replaces another seasonally. For instance, *Acartia tonsa* tends to be abundant in summer, while *Acartia clausi* is generally more abundant in winter; such differences can be related to the interaction of temperature and low salinity on the survival and reproduction of the two species.

The mysids, or possum shrimps, can sometimes be seen as a dense band about a yard wide at the edge of the water as it rises over estuarine mudbanks. They feed by filtering out small particles from the water and in turn act as food for a variety of fish.

Adjustments to estuarine living. An animal living in an estuary must reproduce in such a way that its young can remain in the estuary. An excellent example is given by the ragworm (*Nereis diversicolor*), which belongs to a group of worms that normally produce larvae that float in the plankton. Such a mode of life would be hazardous in an estuary: the larvae would get washed out to sea, away from the habitat to which they are best adapted. The ragworm adapts by producing larvae that do not float but remain on the bottom among the surface layers of the mud.

A high proportion of estuarine animals are crustaceans of the orders Amphipoda and Isopoda, which do not lay their eggs freely into the water but carry them in pouches on the undersides of the females. The young hatch as miniatures of their parents and so avoid the dangers of the floating planktonic life. The burrowers, such as *Corophium*, often liberate their young inside the burrow, and the young then form their own subsidiary burrows.

Adaptation to the stress of salinity

Variation in salinity imposes the greatest stress upon the organisms living in estuaries. A marine animal normally has blood as salty as seawater. If such an animal is placed in fresh water, its tissues take up water by osmosis and the animal swells and dies. Estuarine animals have developed means of controlling such effects and are able to withstand sudden changes in salinity. Some animals develop a tolerance to changes in the salt concentration of their blood. This method is used by the sea slater (*Ligia oceanica*), which can, if necessary, allow the salt concentration of its blood to double.

In general, however, it is more efficient for an aquatic animal to develop a less permeable skin and thus reduce the stress caused by variation in external salinity. The general principles can be illustrated by a consideration of the Chinese woolly-handed crab (*Eriocheir sinensis*), which has been introduced into Europe and is now widespread in many of the larger rivers. This species is capable of living in both fresh water and seawater. When in seawater, the blood has the same osmotic pressure as the surrounding water. When in fresh water, the concentration of the blood is about half that of seawater but still well above that of fresh water. The crab regulates the amount of salt in its blood by taking up salts in its gills from the small amounts present in fresh water. *Eriocheir* is one of the most impermeable crabs. When it is in fresh water, the osmotic inrush of water is severely restricted, and it produces about the same amount of urine in both fresh water and seawater. The common shore crab (*Carcinus maenas*), however, is somewhat more permeable. When in seawater, it produces urine at a rate of 4 percent of its body weight per day. If *Carcinus* is transferred to a mixture of half seawater and half fresh water, the rate of urine production increases up to about 20 percent of body weight per day. This increase is adequate to cope with the osmotic inflow of water that would otherwise dilute the blood.

Biological productivity. Although the estuarine environment is variable and difficult, it is also very productive, for several reasons. One, the river constantly brings down fresh supplies of nutrient salts, especially by pollution from towns built near the head of the estuary. The constant, repeated invasion by the sea also improves the nutrient situation. The basic source of production in estu-

aries lies in the salt marshes. The amount of material that can be harvested from a *Spartina* marsh, for example, is considerably greater than that produced by an average rice field, three times that of the best hayfields, and 50 times that of short grassland areas with low rainfall.

The food-supply chain

The economy of an estuary depends on the major supply of food from the salt marsh. Organic debris from this source supports the growth of bacteria, and the combination of debris and bacteria supports huge populations of invertebrates, which in turn are preyed upon by migratory populations of fish and birds. In most estuaries the production of floating plants (phytoplankton) in the open water is not very important because the water is often too turbid with silt to allow for photosynthesis more than a short distance into the water. Plants growing in the marsh, however, are covered by the water for a few hours at most each day and may remain uncovered for several days at neap tides.

The salt-marsh plants eventually die and decay, the bits of debris being dispersed over the estuary. Certain bacteria aid in the decomposition and add to the nitrogen content of the plant debris. This combination of debris and bacteria forms the basis of the estuarine food web. Nearly all the invertebrates that occur in large numbers in estuaries feed on fine debris and its associated bacteria collected either from suspension in the water or from deposits on the surface of the mud.

A single square metre of estuarine mud may contain a thousand burrowing bivalves and several thousand ragworms. These immense populations of invertebrates provide food for large numbers of fish and birds.

Many fishes move into the estuary on the high tide, feed on invertebrates that live in the mud, and then retreat on the ebb tide. Some estuarine fishes eat plants, and a surprising number include organic debris in their diet. Gray mullets (*Mugil cephalus*) in particular are great consumers of mud, from which they strain out edible material. They also browse on algae growing on stones or on mangrove trees in the tropics. Some of the smaller fishes, such as the gobies, are permanent residents in estuaries, living in creeks and salt-marsh pools where they feed on the rich invertebrate life.

Estuarine shores provide ideal feeding grounds for vast numbers of birds. The rich supply of invertebrates is combined with open expanses that give no cover for bird predators. The most characteristic estuarine birds are the waders, which often occur in flocks of thousands and feed particularly on the fauna of sand and mud, in some places competing with man. Pelicans, cormorants, herons, egrets, mergansers, and kingfishers subsist mainly by fishing. Geese and ducks show a variety of feeding habits. Some of the geese are almost entirely plant eaters, while some of the ducks feed largely on invertebrates. The shelduck (*Tadorna tadorna*), for instance, includes a high proportion of the small snail *Hydrobia ulvae* in its diet.

In a quantitative study of the amounts of energy involved in the various links of the estuarine food web, it was found that *Spartina* produced a net amount of 6,580 kilocalories per square metre per year. The most important consumption of this accumulated energy was through the decomposing activities of bacteria, which accounted for 3,890 kilocalories per square metre per year. Of the total energy accumulated in the salt marsh by the growing plants, about 55 percent was consumed by organisms within the marsh, leaving 45 percent available for utilization in the estuary itself. This underlines the importance of salt marshes in the economy of estuaries, particularly those that are turbid and poor in phytoplankton. Any measure that reduces the area of adjoining salt marsh will reduce the productivity of an estuary.

(J.Gre.)

MAN AND ESTUARIES

Land reclamation. The Netherlands has always been a region faced with a shortage of agricultural land and an expanding population. The rise of sea level since the last glaciation, combined with a gradual sinking of the general area, has produced broad, shallow estuarine waters near or slightly below sea level along much of the coast.

In the Middle Ages land reclamation consisted primarily of marsh drainage, but as population increased land became scarce. Dikes were erected to push back the seas, and former tidal areas were reclaimed chiefly as pastureland and farmland. These broad, flat zones are known as polders and are usually crisscrossed by the canals for which the Dutch are so famous.

Creation of the IJsselmeer

The largest land reclamation project was the conversion of the Zuiderzee into the freshwater lake IJsselmeer by the construction of a great barrier dam between the Wadden Zee and the IJsselmeer. The barrier dam was completed in 1932 and isolated approximately 2,700 square kilometres of shallow estuarine waters. Almost at once the salinity of the former estuary began to drop to that of fresh water. Of course, with the drop in salinity many estuarine species of organisms were no longer able to survive. This included herring, anchovies, shrimp, edible mussels, soft-shelled clams, some crabs, etc. Although the former estuarine fishing industry was eliminated, new species of organisms, including pike, perch, bream, and roach, took over the IJsselmeer environment. In addition, a few estuarine species survived; the eels, for example, form one of the principal commercial species today.

The creation of the IJsselmeer had several advantages. The lake provides the northern Netherlands with a supply of fresh water that is important during dry periods. The land that borders the IJsselmeer is no longer in danger of flooding as when it was open to the Wadden Zee. Creating land from a freshwater lake is much easier than from a former tidal region, where the land must be desalted before it becomes completely productive. Finally, although the net fisheries production decreased by approximately 9,000,000 kilograms when the IJsselmeer was created, over 70,000,000 kilograms of pork was raised on the land reclaimed from the former estuarine environment.

The Netherlands is also studying the possible conversion of other estuarine areas into freshwater environments; plans include the damming of portions of the Haring Vliet, Grevelingen, and Ooster Schelde estuaries and their eventual conversion to fresh water.

Most estuaries bordering population centres have been used in minor land reclamation projects. Some sanitary landfill projects have eliminated vast acreage of wetland estuaries and at the same time created valuable coastal real estate. Boca Ciega Bay, on the west coast of Florida, is an example of an estuary where extreme dredging and filling has reclaimed land to such an extent that scientists are afraid that the estuary may no longer be a suitable breeding and nursery ground for the fisheries population of the region. The Florida region has long been used for reclamation sites primarily for real estate developments in coastal regions. Of Florida's 796,000 acres of estuarine water less than six feet deep, some 60,000 of these valuable acres of nursery and breeding areas have been lost to landfill and dredging.

Estuaries as recreation sites. As technology increases, more and more leisure time will be available to man. Estuaries will provide sites for two major forms of recreation: boating and sport fishing. Many boaters prefer the estuary for both sailing and motorboating primarily because the semi-enclosed basin usually has relatively calmer seas than the open ocean. Puget Sound and Chesapeake Bay in the United States, both major estuarine systems, may support the world's largest flotillas of small pleasure boats.

Estuarine fishing is also an important form of recreation. The great abundance of food sources for fish in estuarine waters make them relatively productive fishing grounds for the recreational angler.

Because of the great quantity of suspended matter in estuaries and the abundance of soft mud near shore, estuaries are less important as swimming areas; however, where high energy environments exist in the estuary and where artificial beaches have been developed, swimming is an important pastime.

Ebb and flow in estuaries

Tidal power. The first record of tide mills is from England and Wales around the 11th century. These early mills were crude affairs consisting of a floodgate that let water in on the rising tide but closed on the ebbing tide. The water then trapped in the tidal basin was forced to drive a waterwheel, usually an undershot type. Today, the tidal flow in estuaries can be used as a clean, cool source of hydroelectric power. In November 1966, the world's first major hydroelectric plant that uses tidal energy was opened on the Rance River Estuary in northern France. This plant can produce over 500,000 kilowatts of electrical power.

The Rance River Estuary was chosen as a site primarily because of the high tidal range (nine to 14 metres) that exists in this region. The power is generated both when the tide is flooding and ebbing through the water turbines. Although the initial cost and operating expenses are somewhat greater for a tidal power plant, in the long run the cost disadvantage is outweighed by low environmental pollution and the cheap power source.

Tidal power sites, however, are limited to those regions with a high tidal range and relatively close proximity to the consumer. In Great Britain the Severn River Estuary has been studied for a possible power station. In North America, the Passamaquoddy Bay region of Maine seems the most likely spot for a tidal hydroelectric plant. In the world, there are nearly 100 estuarine sites that could be harnessed for tidal hydroelectric power.

Estuarine pollution. Many of the world's largest metropolitan areas border estuarine environments; *e.g.*, Buenos Aires, Osaka, Los Angeles, Tokyo, London, New York, and Shanghai. Total population of these seven areas alone approaches 90,000,000 people. These cities are highly industrialized, and all make use of the estuary as a waste disposal site to a greater or lesser extent.

There are many ways man can pollute estuaries. Some are subtle, with no apparent short-term effects, while others are immediately disastrous with large wildlife kills.

Siltation, the natural enemy of harbours and estuaries, is a form of the subtle pollutants. Each year rivers wash more and more of the tilled soil away from the continents, and estuaries become filled with these silts and clays. In some cases, construction and farming have so increased the estuarine sedimentation rates that natural estuarine biologic populations are "smothered" by layers of silt and clay.

Thermal and inorganic pollutants

Thermal pollution can change the ecology of the estuary. Both fossil fuel and nuclear power plants require vast amounts of cooling water in their power output. In the United States alone it is estimated that some 200 × 10^9 gallons of water per day will be required by the electric generating plants. Many of these plants will be constructed on estuaries, where a large steady supply of water is available.

Pesticides that man has been using to control insect population both on inland crops and around marshes will eventually wash off the land into the rivers, then into the estuaries, and eventually into the ocean. Human and animal wastes are another principal form of estuarine pollutants. The high organic content of wastes can use up oxygen in estuarine waters as the wastes decay and thus cause the estuary to become anoxic and essentially devoid of life.

The list of pollutants in an estuary is as varied as the industries that surround it. Heavy metal concentrations, especially zinc, copper, and lead, have been shown to be particularly harmful to some estuarine organisms in high concentrations. Oysters and clams have been studied that can concentrate zinc in their systems over 100,000 times that found in the natural water.

Although estuarine pollution is one of man's more serious problems, there is an indication that he is now aware of the problem and taking steps to combat it. Effects of pollution can be reversed. San Diego Bay, off the coast of California, was one of the most polluted estuaries on the western coast of the United States. The waters were a brownish gray and practically devoid of life. Coliform bacteria counts were high, and the waters were considered a health hazard to bathers. After a decade of concentrated efforts by state and local officials to eliminate raw sewage and discharge effluents into the area, San Diego Bay's waters are again blue, and fish and other forms of wildlife are beginning to return. As man becomes increasingly aware of this environment, he will better understand the role of estuaries in coastal ecology. With this understanding he will be able to preserve this unique and geologically ephemeral environment. (F.E.A.)

Ethics

Ethics is the branch of philosophy that is concerned with what is morally good and bad, right and wrong; a synonym for it is moral philosophy. Traditionally, ethics has undertaken to analyze, evaluate, and develop normative moral criteria for dealing with moral problems. In recent years, however, pervasive current in Anglo-American ethics has come under the influence of a new conception of the proper methods and capacities of philosophy in general, viz., that its task is the analysis of language; and on this basis it has come to hold that the concern of the moral philosopher should be restricted to the analytic task, or to "meta-ethics." This task consists in the logical analysis of the meanings of moral concepts and of the methods of supporting moral judgments and thus stands in contrast to the more traditional view, which combined such analytic studies with normative ethics, the view that authentic standards exist. The relation between these two conceptions, to be discussed more fully following the outline below, is an example of the controversies that have always divided moral philosophers on a large variety of basic issues arising not only from within their subject matter but also from opposed views about their very study of it.

The article is divided into the following sections:

I. Nature, types, and relations of ethics
  Types reflecting intra-ethical differences
    Meta-ethics and normative ethics
    Different analyses of the concept of morality
  Types reflecting relations to other disciplines
    Relations to the philosophical disciplines
    Relations to the humanistic and social disciplines
II. Meta-ethical theories
  Intuitionistic cognitivism
    Moore's axiological intuitionism
    Prichard's deontological intuitionism
    Ross's distinction between prima facie and actual duties
    Critical evaluation
  Naturalistic cognitivism
    Ancient Greek and medieval naturalisms
    Varieties of contemporary naturalism
    Ontological difficulties of naturalism
    Valuational difficulties of naturalism
  Noncognitivism
    Concern with language and verifiability
    Moral statements as "commending"
    Moral statements as "commanding"
    Function of moral judgments
    Cognitive undecidability of moral issues
III. Normative ethical theories
  Principal issues of normative ethics
    Three traditional questions
    The central question

Deontological theories of normative ethics
Material deontological ethics
Formal deontological ethics
Teleological theories of normative ethics
General considerations
Egoism
Utilitarianism
IV. Good reasons theories

I. Nature, types, and relations of ethics

Meaning of ethics

The word ethics signifies not only a certain branch of philosophic study but also the object or subject matter of that study. "Ethics" and "ethical" are often used synonymously with "morals" (or "morality") and "moral," as when reference is made indifferently to the ethics or to the morality of a person or a group, to their ethical or moral virtues or qualities. This synonymy has a clear etymological basis, for the Greek word *ēthos*, from which "ethics" is derived, and the Latin word *mores*, from which "morals" is derived, both mean habits or customs. The ethics or morality of persons or groups, however, consists not merely in what they habitually or customarily do but in what they think it is fitting, right, or obligatory to do. Men's actions are often, but not always, a sign of what they believe: their actions may diverge from their beliefs, and both actions and beliefs may differ from what men say they ought to do or believe. Morality contains an ineluctable normative element. Whereas a person may engage in habitual and customary conduct without any reflective thought, ethics always involves reflective evaluation or prescription concerning the conduct in question. Even when "customary morality" is spoken of, the reference of the term is not merely to the customs as such—in the sense of regular, repeated sequences of behaviour—but also to the view, at least implicitly held by the participants, that what they regularly do is in some way right; it is not merely what is done, it is also what is to be done.

The central concern of moral philosophy, then, has always been the double task (1) of meta-ethics, of analyzing the meaning and nature of this normative moral element in man's action, thought, and language, and (2) of normative ethics, of evaluating this element by presenting and appraising criteria for justifying rules and judgments of what is morally right and wrong, good and bad.

Logical relation between normative and meta-ethics

Because in meta-ethics the logic of normative ethics in its various phases is studied, these two parts of moral philosophy are intimately connected. Contemporary philosophers have disagreed, however, about the precise logical nature of this connection—particularly on whether meta-ethics is or can be neutral with respect to normative ethics. This question, in turn, raises two subquestions: whether holding a specific meta-ethical doctrine logically commits one to holding a specific normative ethical doctrine, and vice versa.

Some philosophers have given negative answers to these subquestions, pointing out that various sorts of combinations have, in fact, occurred among moral philosophers: some intuitionists (stressing the direct grasp of moral qualities) in meta-ethics have been teleologists (stressing goals) in normative ethics, others have been deontologists (stressing obligations), and so forth. These philosophers have also contended that there is a difference in logical type between meta-ethical and normative ethical statements, that the former are logical and conceptual analyses of the latter, and that, hence, the meta-ethical statements do not, as such, make any normative moral assertions.

Other philosophers have given affirmative answers, pointing out that the meta-ethical doctrines of cognitivists —those who affirm that ethical statements are a kind of knowledge—are concerned to bring out just those meanings of "good" or "ought," and just those methods of justifying moral judgments, that fit their normative ethical doctrines. Hence, there is a direct logical sequence from their normative ethical doctrines to the meta-ethical doctrines derived from the analysis of their normative doctrines. Proponents of an affirmative answer have also contended that, although the noncognitivists, qua philosophers, present no normative ethical doctrines, their noncognitivist meta-ethical positions sometimes have logical implications for normative ethical judgments concerning the psychological or other conditions required for moral goodness.

Although this issue cannot be gone into further here, it can be argued that each side may be partly right and partly wrong. The negative answer is at its strongest when the most abstract possibilities of the relations between the two fields are at issue, and the affirmative is strongest when specific philosophers or doctrines are being considered.

Moral philosophers have pursued this double task of meta-ethics and normative ethics in a large variety of ways and with a large variety of emphases, a variety that has two main dimensions—one contained within ethics itself, the other deriving from the relation of ethics to other branches of philosophy, to science, or to human experience in general. Although these two dimensions are in some respects distinct, the question of the precise or proper relation between them itself reflects important divergences among moral philosophers.

TYPES REFLECTING INTRA-ETHICAL DIFFERENCES

Cognitivists versus noncognitivists

Meta-ethics and normative ethics. The first, the intra-ethical dimension consists primarily of the various doctrines that have been upheld in both meta-ethics and normative ethics. In meta-ethics, philosophers have differed over the logical status of moral concepts and judgments. Some philosophers, the naturalistic descriptivists, have held that moral concepts describe natural or supernatural entities in the world. Others, the nonnaturalistic descriptivists, while agreeing that moral concepts are descriptive of entities in the world, have held that these entities are entirely unique in kind. Still other philosophers have been nondescriptivists, holding that moral concepts function primarily not to describe anything but rather to express attitudes or emotions, to command or prescribe, or to commend or condemn. These various groups of philosophers have held corresponding views about the logical status of moral judgments: either the judgments, as in cognitivism, are capable of being true and false and of constituting a kind of knowledge, natural or nonnatural, or, as in noncognitivism, they are not capable of being true or false or of constituting knowledge but function rather to express attitudes or give commands. There have also been differences over whether moral judgments are objective or subjective, absolute or relative—concepts the various meanings of which are best developed in contexts that allow elucidation with greater precision.

Deontologists versus teleologists

In normative ethics the main division has been between deontologists and teleologists, who differ on what constitutes the primary criteria by which actions are to be evaluated as morally right and wrong, and the ground of their difference derives from what they take to be the basic concepts of moral discourse and justification. The deontologists (Greek: *deontos*, "of the obligatory") take as basic such concepts as right and ought, and they hold that other moral concepts are definable in terms of these concepts or, at least, that moral judgments using other moral predicates are to be justified by means of judgments based on these deontic concepts. The teleologists (Greek: *teleios*, "brought to its end or purpose"), on the other hand, take as basic such axiological concepts (Greek: *axios*, "worthy" or "valuable") as good and value; they hold that the deontic concepts are to be defined in terms of these concepts and that moral judgments are to be justified by reference to the goodness of the purposes or consequences achieved by the actions. This difference largely determines their views of what makes certain kinds of actions morally right. Deontologists typically hold that certain kinds of actions are inherently right or right as a matter of principle because of their being the kinds of actions that they are or because of their conforming to some formal principle. Teleologists, on the other hand, typically hold that actions are right because of the goodness of their consequences. Another group of philosophers, related to but distinct from teleologists, are called axiologists; they hold that certain actions

are right because of the value or goodness that they inherently contain, such as happiness or pleasure, not merely because of the goodness of their consequences. Both the axiologists and the teleologists take goodness and value as the basic moral concepts, but the axiologists emphasize intrinsic goodness itself, whereas the teleologists emphasize the calculation of consequences in order to ascertain where, among various alternative actions, the preponderance of intrinsic goodness lies.

Different analyses of the concept of morality. In addition to these differing views about the logical status of moral judgments and the criteria for justifying them, philosophers have been concerned to analyze the concept of morality itself (in the sense in which moral is contrasted with nonmoral rather than with immoral). Thus, they ask how moral rules and judgments differ from nonmoral ones and what the difference is between something's being morally good or right and its being good or right in some other respect, such as prudentially, legally, aesthetically, intellectually, or religiously. And social scientists sometimes ask how moral feeling or how the institution of morality differs from other feelings of persons or from other institutions of society. Insofar as the question concerns the difference between moral and nonmoral rules, judgments, and criteria, however, it falls within ethics. Though the question seems in many respects to belong to meta-ethics rather than to normative ethics, some of the main considerations in answering it have derived from the normative distinction between deontological and teleological criteria.

Formal versus material conditions

The main division has been between philosophers who hold that, for a judgment, rule, or consideration to be a moral one, it must fulfill only certain formal conditions and those who hold that it must fulfill a certain material condition. The formal conditions that have been proposed include that the proponents of the judgments or rules must regard them as prescriptive, as universalizable, or as having overriding importance or authority; the material condition is that the rules, judgments, or considerations must bear on the interests or welfare either of society as a whole or at least of persons other than the judge or agent. It can be seen that the upholders of the formal conditions are closer to the deontologists, because they emphasize that what makes them moral are certain features of the judgments themselves or of the judges' views concerning them. The upholders of the material condition, on the other hand, are closer to the teleologists and axiologists, because they emphasize the bearing of the judgments on basic human goods or purposes.

The impact of the distinction between deontological and teleological criteria on differing interpretations of the concept of morality can also be seen in a related distinction that goes back to the ancients—that morality is constituted either by laws, rules, or commands or by the pursuit of human happiness or well-being. In the former, deontological view—found in the Ten Commandments and in Kant's categorical imperative—morality is regarded primarily as controlling and even repressing natural human tendencies. In the latter, teleological view—found in Aristotle and in the Utilitarians, beginning at least with David Hume, an 18th-century Scottish Skeptic—morality is regarded primarily as developing and fulfilling natural human tendencies. These two views were variously combined in Plato and in the New Testament (and also, in one form, in Kant); they held (like the law and rule view) that certain rules are unconditionally obligatory, even though they may lead to this-worldly disaster, but (like the happiness or well-being view) that obedience to the rules will lead to well-being in a future life.

What virtues or values are moral

One upshot of this difference between definitions of morality emerges in divergent conceptions of what virtues and other goods or values are moral (as against nonmoral) ones. Kant declared the deontological view that only goodness of will consisting in obedience to duty is "good without qualification," as against the various components of "happiness," consisting in "talents of the mind" and "gifts of nature or fortune," which may all become morally bad in the absence of a good will. On the other hand, Aristotle, in upholding the axiological view, listed as "moral" virtues many traits of character that, from at least one deontological point of view, would not count as moral virtues at all: *e.g.*, cheerfulness, wittiness, and "magnificence." These traits are moral virtues for Aristotle because they contribute to individual or social happiness. Belonging to this same tradition, Hume insisted that to try to distinguish moral "virtues" from mere "talents" is to engage in a merely "verbal dispute," because all of these form part of "personal merit." On this ground Hume, too, listed as moral virtues a large number of qualities that strike the contemporary reader, influenced by the deontological-law view, as dubiously moral, such as pride, tranquility, and wealth.

The disagreement between these two views of morality is both conceptual and normatively moral. It concerns the conceptual question of what is to count as moral (in opposition to nonmoral). But this distinction is itself of normative moral significance, for, when certain qualities are regarded as moral, they are viewed as being of greater importance for human life than if they were regarded as nonmoral.

TYPES REFLECTING RELATIONS TO OTHER DISCIPLINES

A further variety of doctrines arises, not within ethics itself but from the relations of ethics to other branches of thought and experience.

Relations to the philosophical disciplines. As a branch of philosophy, ethics has both influenced and been influenced by other parts of philosophy.

Linguistic Analysis, Existentialism, Phenomenology

Recent philosophical schools. In the 20th century, three such influences have been especially important. One has been the development of Linguistic Analysis, which has led to a new sensitivity to logical and conceptual issues in ethics. The methods of careful definition and clarification espoused by this school are traceable, however, back to the dialectical explorations presented in Plato's dialogues and have been utilized in many other eras of ethical inquiry. A second influence has been that of the emphasis placed by such Existentialists as the Danish Christian Søren Kierkegaard and the French atheist Jean-Paul Sartre on authenticity, autonomy, and decision. The Existentialist emphasis focusses primarily on the standpoint of the agent who is actually confronted with a moral problem, rather than, as with the Linguistic Analysts (until recently), on the standpoint of the critic or spectator who makes judgments about the agent or his actions. Although this focus is of the greatest importance, a serious difficulty is posed by the Existentialists' disavowal of general moral rules or principles. This denial of a rational basis of morality echoes the voluntarisms (will-centred views) of such late medieval philosophers as Duns Scotus and William of Ockham, as well as earlier skeptical positions. A third influence has been that of the Phenomenological approach of the Göttingen ontologist Nicolai Hartmann and the French philosopher Maurice Merleau-Ponty, which emphasized the concrete data of moral experience. Though in this position the focus of the Linguistic Analysts on moral judgments has been combined with that of the Existentialists on moral action, the main emphasis has been on the accurate description of man's preconceptual, pre-analytic involvements with morality. Antecedents of this approach can be found in Joseph Butler, an 18th-century bishop of Durham, in his description of the compelling authority of conscience.

Closely related to these philosophic influences on ethics has been the strong concern of philosophers, newly manifested in recent years, with the theory of human action. Ethics is largely concerned with how men ought to act, and this raises questions about the nature and limits of action. Insofar as moral judgments are addressed to persons, it is assumed that the persons addressed can in some sense act voluntarily or intentionally. Questions then arise as to just what such action consists of, how it differs from mere bodily movements and reflexes, and, in the light of the determinism that has often seemed to ground the natural sciences, how men can be held to act voluntarily. For, if determinism is universally true, then all of men's actions are the effects of causes outside themselves;

and what men take to be their autonomous reasons for their behaviour are then simply causes that move them in certain ways. Some of the ramifications of these questions will be mentioned later in relevant contexts.

Relation to metaphysics

Fundamental areas of philosophy. Many ethical doctrines bear a close relation to metaphysics, the study of the general nature of being or reality. The question of determinism just mentioned is an obvious example, deriving, as it does, from the impact of the nature of things on the possibilities of human action within that nature. In a more specific way, the various meta-ethical positions discussed above reflect metaphysical theses about what kinds of entities there are in the world. The naturalistic and nonnaturalistic cognitivists both assert that the world contains entities referred to by moral terms, whereas the noncognitivists deny such entities. Many philosophers, beginning with Plato, have held that moral criteria of what is good or right are to be based on subsistent metaphysical objects or relations, which range from Plato's Idea of the Good to Plotinus' One, the Stoics' right reason, Augustine's God, and Thomas Aquinas' nature and natural law. These last two in particular have had a long subsequent influence, and all of them raise meta-ethical issues (see below *Naturalistic cognitivism: Ancient Greek and medieval naturalisms*).

Moreover, a Materialistic metaphysics, like that of Epicurus, an ancient Greek moralist, and Thomas Hobbes, a 17th-century political and moral philosopher, has had ethical implications of two sorts. One is negative: the philosophers deny that the objective world of matter in motion has any place for moral goods; and they often tend also to deny, though sometimes with qualifications, that this world leaves any place for freedom of the will. The other implication is positive: moral concepts are held to express men's reactions to the impact of material particles on those parts of their sense organs that cause them to experience desires and aversions. Hence, good and evil in this second view are not in the world per se; they are rather men's internal and variable reactions to the ways in which they are stimulated by the world. As Hobbes put it:

> Whatsoever is the object of any man's appetite or desire, that is it which he for his part calleth *good;* and the object of his hate and aversion, *evil;* and of his contempt, *vile* and *inconsiderable.* For these words of good, evil, and contemptible are ever used with relation to the person that useth them: there being nothing simply and absolutely so; nor any common rule of good and evil, to be taken from the nature of the objects themselves.

Relation to logic and epistemology

Moral philosophy has also had a close relation both to logic and to epistemology (theory of knowledge). The meta-ethical enterprise consists in certain applications of these disciplines to moral concepts, judgments, and arguments. In addition to the direct applications (considered in detail below), there are other developments of both logic and epistemology that are closely relevant to ethics. One such development, work on which has greatly increased in recent years, is the elaboration of deontic logic and the logic of imperatives (see LOGIC, APPLIED: *Deontic logic* and *The logic of commands*). In deontic logic the philosopher studies the logical relations between the concepts of the obligatory, the prohibited, and the permitted and tries to set up calculi for inferring from certain axioms the formulas that predicate these concepts. In the logic of imperatives he tries to show how inference can proceed from premises containing at least one imperative sentence to an imperative conclusion; it is particularly relevant to those meta-ethical theories that hold that moral judgments either are or entail imperatives. In one respect, the lineage of these attempts goes back to Aristotle's work on the practical syllogism, whereby, from certain empirical and valuational statements, a conclusion is held to follow consisting in an appropriate action. Like other parts of logic, these theories have incurred various paradoxes.

Insofar as moral philosophy is a quest for ethical knowledge, whether conceptual or normative, it bears a close relation to the more general views elaborated by philosophers about the nature of genuine knowledge and the methods of attaining it. The specific bearings of this relation for cognitivist and noncognitivist theories in meta-ethics will be considered in detail below (II. *Meta-ethical theories*).

There have also been important historical influences. For example, the Cartesian doctrine of representative perception, which from the 17th century on has led philosophers to hold that men cannot directly perceive the external world, had strong repercussions for ethics. Some can be seen in Hume, for example, when he defined moral qualities not as existing or perceived in the world per se but rather as resulting from an impartial spectator's feelings of approval. Just as Hume held in his general epistemology that sense qualities cannot be known to exist in the absence of a perceiver, so he held in his moral epistemology that moral qualities require, for their very existence, the presence of a spectator. Without the spectator, men's characters and actions could not rationally be held to have any moral qualities at all. Many moral-sense theories in addition to Hume's have derived from this epistemological doctrine that qualities cannot rationally be held to exist unless they are in some way sensed or perceived.

Relations to the humanistic and social disciplines. Such humanistic disciplines as religion and history, as well as psychology and the social sciences, have significant interrelations with ethics.

Religion and history. Moral doctrines have been central to religion. All of the great religions prescribe obedience to the Golden Rule, and all set forth many other precepts about the way men ought to live and the kinds of characters they ought to have. The main difference between the religionists' prescriptions of ways of life and those given by moral philosophers—from Socrates through the Stoics and Epicureans to such more recent thinkers as Kierkegaard—consists not in the adherence of the religions to supernatural entities (lacking in Buddhism but present in Kierkegaard) but rather in the degree of conceptual and rational elaboration set forth by the philosophers. On the question of how religion bears upon moral criteria, the dominant view, presented in Plato's *Euthyphro* and in Kant, has been that reference to God is logically dispensable. The relation between God and moral rightness, according to these philosophers, is that God approves of certain actions because they themselves are morally right, not that they are morally right because God approves of them. Hence, the moral validation of the rightness or wrongness of actions is logically independent of any appeal to God. This view does not, however, deny that belief in God may be of practical moral significance, and it is a view, moreover, with which the medieval voluntarists mentioned above strongly disagreed. But the alternative that they upheld leaves moral criteria contingent on the arbitrary will of God.

God and morality

Insofar as philosophy is part of the culture of a civilization, its history belongs to the history of civilizations. In moral philosophy this historical dimension is especially prominent, because men's conceptions of moral character and right action have often reflected the dominant institutions of their society. This reflection has not always, however, been positive; it has sometimes consisted in reactions against severe problems faced by those institutions. In any case, it is possible to trace many correlations between the history of moral philosophy, especially on its normative side, and the history of society. In the ancient world of the West, this history ranged from the probing dialectic of Socrates questioning the unexamined beliefs of the Athenians through the aristocratic doctrines of Plato and Aristotle focussed on the values of small city-states, to the quietistic concern with moderate pleasures among the Epicureans faced with severe social instability, and to the Stoics' universalist emphasis on a universal law of right reason attributing a certain equality of dignity to all men, whether slaves, such as Epictetus, or emperors, such as Marcus Aurelius. The medieval concern with theological ethics, epitomized in Augustine, was followed by the rediscovery of Aristotle in the 13th century, which thus led Thomas Aquinas and others to reinstate a modest naturalism, as against the antecedent su-

pernaturalistic criteria based on God. In the modern world the developments from the Renaissance and Protestant Reformation to the Industrial Revolution and the various political revolutions have gone hand in hand with deontological and teleological emphases in normative ethics, which vary from egoism to Utilitarianism, individualism to Socialism, and elitism to egalitarianism.

Psychology and the social sciences. Psychology and the social sciences have had two main kinds of relations to ethics: explanatory and normative. In fulfilling their explanatory role, they have made empirical studies of moral phenomena in which they have pursued such questions as the nature and origins of men's moral beliefs and the ways in which such beliefs function in individual and social life. These studies have been concerned, among other things, with the differences and similarities between morality and other phases of human life and institutions; but they have focussed not primarily on the conceptual aspects of moral rules, judgments, or criteria as such but rather on their empirical genesis and effects. Among the familiar theories that have been elaborated in this sphere are the Darwinian view, continued by the anthropologists, that moral ideas serve to foster evolutionary or social adaptation; the Marxist doctrine that moral ideas are parts of the ideological superstructure that reflects and subserves the interests of the economically dominant class in any society; and the Freudian conception of moral ideas as the results of parental and societal conditioning aiming at the repression of vital impulses. Some scholars feel that theories such as the last two, though their lineage goes back to the ancient Greeks (as in the first two books of Plato's *Republic*), often view the moral ideas to which they refer in a rather restricted way. Both Marx and Freud, they argue, were so strongly attached to such moral ideas of their own as those urging the removal of exploitation and dishonesty, that they exempted their own moral ideas from the general diagnosis they had made of those of other persons.

Normative role of the social sciences

In their other, normative relation to ethics, the social sciences have tried in various ways either to set forth or to implement norms or criteria for moral actions, characters, and institutions. These norms have ranged from the psychologists' concern with mental health to the doctrines propounded by economists, political scientists, and legal theorists on the requirements and possibilities of justice in the economic, political, and legal spheres. In such endeavours the respective scholars are themselves engaged in moral discourse. Whereas the empirical findings on which they base their moral recommendations are often necessary conditions of morally right policies in their respective areas, they are not sufficient conditions in the absence of independent moral scrutiny. The logical or meta-ethical problems that confront such endeavours are not different in principle from those that face the metaphysical doctrines mentioned earlier. The ways in which moral philosophers have dealt with these problems will be considered in the subsequent sections of this article.

II. Meta-ethical theories

As was noted above, the cognitivist and the noncognitivist are two main varieties of meta-ethical doctrines on the meanings of ethical terms and judgments and the methods of supporting the judgments. The cognitivist doctrines affirm and the noncognitivists deny that moral terms signify qualities in the world and that moral judgments are a kind of knowledge.

Cognitivist theories fall into two groups: intuitionism (or nonnaturalism) and naturalism. The basic difference between them is that the intuitionists affirm and the naturalists deny that the objects that moral terms signify and the knowledge that moral judgments constitute are unique to ethics and hence irreducible to the objects and knowledge found, for example, in the natural sciences.

INTUITIONISTIC COGNITIVISM

According to the intuitionists, the basic moral term or terms signify a nonnatural, indefinable quality of things. G.E. Moore, one of the fathers of Linguistic Analysis, held that the basic term is "good"; two of his critics, the Oxford philosophers H.A. Prichard and W.D. Ross, held that it is "ought"; thus, their views on this point were, respectively, axiological and deontological. All three held that the meaning of the basic term is grasped by direct inspection; *i.e.*, the term's meaning consists in its denoting a certain objective property, that is itself grasped by immediate intuition.

Moore's axiological intuitionism. Moore distinguished three different meanings of the question "What is good?" One meaning is that the question asks: "What is the nature of the property goodness?" On this question Moore held that goodness is a simple, indefinable property, to be grasped by intuition.

Meanings of "What is good?"

A second meaning of the question is: "What things are good in themselves or intrinsically good?" This question, in turn, means: "To what things does the simple property good immediately or directly attach?" This question, too, Moore held, could be answered only by immediate intuition; for, because goodness is indefinable and unanalyzable, there is no way to answer the question by analyzing goodness to see whether it attaches to something. And, presumably, if one had to analyze the objects to see whether goodness attaches to them, then goodness would not attach to the object directly or to the whole of the object but only to a part of it.

The third meaning of the question "What is good?" is: "What things are instrumentally good or good as means to other things?"; *i.e.*, "What things are the causes of other things to which goodness attaches directly?" If, for example, personal affection, aesthetic enjoyment, and knowledge are good in themselves (as Moore held), then what can bring these goods into existence? Moore maintained that this third question is identical in meaning with the question: "What ought one to do?" Hence, he held that "ought" is definable in terms of "good": to say, "I ought to do x," is to say, "My doing x will bring about more intrinsic goodness—that is, the existence of more things to which goodness directly attaches—than will my doing anything else that it is open to me to do." Ought judgments, then, according to Moore, are capable of argument and proof, as against judgments of intrinsic goodness. On this point, he is an ideal Utilitarian: a Utilitarian insofar as he holds that one's duty is to bring about as much good as possible; ideal insofar as the goodness in question is quite general—as against, for example, views in which goodness is regarded as consisting in pleasure or happiness.

Indefinability of good. It can be seen that, of Moore's three questions, the first, on the nature of goodness, is the most basic, for the other two both depend on his answer to the first question: that the property goodness is simple, hence, indefinable and unanalyzable. This answer and the one main argument that he gave for it were of crucial importance for the subsequent development of meta-ethics.

The argument involved an appeal to what Moore called the naturalistic fallacy. He sometimes said that the naturalistic fallacy consists in confusing a nonnatural object, such as good, with a natural object, which must exist in space and time and be empirically observable. But he also insisted that, even if good were a natural object, any attempt to define it would still commit the naturalistic fallacy. The main point of this fallacy consists, according to Moore, in making two other confusions. One is to confuse a simple, indefinable object with a complex, analyzable object; since good is simple, any attempt to define it commits this fallacy. But how is it known that good is simple and hence indefinable? To prove that it is, Moore indicated still a third version of the naturalistic fallacy, according to which any attempt to define good confuses the "is" of identity (which figures in a definition) with the "is" of predication (which figures in a proposition asserting one thing of another). In other words, persons who claim to give definitions of "good" are confusing Moore's first and second questions, namely, "What is the nature of goodness?" and "What things are good?" The first question is to be answered by a definition, expressed in a sentence the copula (equational verb) of which is the "is" of identity; the second question is to be answered by

Naturalistic fallacy

a proposition, expressed in a sentence the copula of which is the "is" of predication. As Moore put it, when a person says that an orange is yellow, he is not saying that yellow is identical with orange or is the nature, meaning, or definition of orange; he is saying, rather, that yellowness is predicated of orange, that yellowness pertains to orange but is not identical with it. To give a definition of "good" as meaning, for example, pleasant or conducive to survival is to make this confusion between the "is" of identity and the "is" of predication; it is to assume that, because what is good is also pleasant or conducive to survival, therefore, goodness is identical with pleasure or conduciveness to survival.

Moore also held, however, that this confusion is logically inevitable no matter what definition one tries to give of "good"; the problem is thus not merely that goodness is not definable by some other concepts but rather that it is not definable by any other concepts. His argument consisted in the appeal to what he called the open-question test: no matter what concepts or qualities a man uses to try to define "good," one can always significantly ask, concerning those qualities, whether they are themselves good. Because it is thus an open question whether goodness attaches to them, those qualities cannot be identical with goodness nor constitute its definition. For, if they were thus identical, it would not be an open question whether those qualities were good. If, for example, good is defined as meaning pleasant, it can always be meaningfully asked whether what is pleasant is good, which is an open question. But, on the proposed definition, this question would mean the same as the question whether what is pleasant is pleasant; and this is not an open but, rather, a closed question: for there is no point or significance in asking it.

Open-question test

Stated somewhat more formally, Moore's argument is as follows: If a person considers any proposed definition of good (G) in terms of some property (P); that

(1) $G =_{df} P$,

in which $=_{df}$ means "is defined in terms of," then he can always ask, with significance,

(2) Is P G?

And this question does not mean the same as

(3) Is P P?

But question (2) would have to mean the same as question (3) if (1) were a genuine definition. As it is, (2) is an open question, whereas (3) is not. Hence, (1) is not a genuine or correct definition.

Bearing on the nature of definition and antinaturalism. This famous and influential argument raised many questions about the nature of meaning and definition. It assumed that every definition of some term must be completely intersubstitutable with that term, not only with no loss of truth but even with no loss of meaning, because the definition must mean the same as what it defines. This assumption ignores, however, an important aspect of definitions. According to Moore, when one term is predicated of another in a question, only two differences between the terms can cause that question to be open and not closed. One is a difference of extension: one of the terms does not denote or refer to the same entities or objects as does the other term. The second and more important difference is one of intension: one of the terms does not connote the same property or properties as does the other term. Moore held that the fact that an open question could always be asked about any proposed definition of good proves that there is always this difference of intension and that the definition is thus not a genuine one. For in a genuine definition the definiendum (to be defined) and the definiens (defining expression) must have the same intension as well as the same extension.

Extension and intension

There is, however, a third possible difference between terms, which Moore overlooked: a difference in clarity between the term defined and its definition. The term defined may, as such, be a vague general idea, and the definition then makes that idea more definite and precise, without thereby changing either its extension or its intension. In the definition of circle, for example, as "a plane figure each point on which is equidistant from a fixed point at the centre," there is no difference either of extension or of intension between the definition and the term that it defines, but there is a difference of clarity, since the definition articulates or explicates what was only vaguely understood in the original idea of the term circle. Because of this difference in clarity, the open question can be asked of this definition, "Is a circle a plane figure each point on which is equidistant from the centre?" But the fact that this question can be asked, with significance, about circles—the fact that this question does not mean the same as the question, "Is a plane figure each point on which is equidistant from the centre a plane figure each point on which is equidistant from the centre?"—does not at all prove that the predicate of the former question does not constitute a definition of its subject.

Moore assumed that all definitions must constitute or be reducible to explicit tautologies of the form "A is A." In such a tautology, however, the predicate simply repeats the subject without bringing in the conceptual analysis or clarification of the subject that a definition provides. It seems, then, that Moore's argument, if it were valid against proposed definitions of good, would rule out most, if not all, definitions.

Another important issue about Moore's contention that good is indefinable concerns its bearing on his antinaturalism; *i.e.*, on his doctrine that goodness is a nonnatural quality. Despite his efforts to establish the indefinability of good, there is no necessary logical connection between that contention and antinaturalism. The indefinability of some concept or quality does not mean that it is nonnatural, for, according to Moore, natural qualities, such as yellow and pleasant, are also simple and indefinable. Indeed, it might even be held that Moore's argument for the indefinability of good does not establish its simplicity. For good might have parts and yet be indefinable because the specific combination of the parts might be unique, so that to enumerate them would not constitute a definition of good; good might consist in the unique, indefinable way in which the parts are combined. In any case, Moore's antinaturalism is rather the result of a further interpretation that he makes concerning the indefinability of goodness: that intrinsic goodness is *sui generis*, uniquely different from all other concepts, and, hence, *a fortiori*, from all natural concepts. This interpretation is the basis of Moore's view that ethics is an autonomous study, different in kind from the natural sciences, and that to apprehend goodness requires a nonempirical intuition.

Prichard's deontological intuitionism. As Moore was an intuitionist with regard to the definition of good and to the question of what things are intrinsically good, so Prichard, an Oxford philosopher of the first third of the 20th century, was an intuitionist with regard to the apprehension of ought. Prichard's position is especially important because he tried to provide for the autonomy of normative ethics conceived not primarily axiologically or teleologically, as with Moore, but rather deontologically. He held that judgments about what one morally ought to do are not analyzable or provable in terms of any other considerations, including self-interest or general utility.

Underivative nature of obligation. In his most famous essay, "Does Moral Philosophy Rest on a Mistake?," Prichard answered his question affirmatively: the mistake consists in the attempts by moral philosophers to give an answer to the question "Is there really a reason why I should act in the ways in which hitherto I have thought I ought to act?" Such attempts are mistaken because the question's demand for a reason is improper. No reason can be given for a person's moral duty or obligation to perform some action. The reasons to which philosophers have appealed have all been some sort of goodness: either the selfish good of the agent or some general good consisting either in the consequences of the action or in the motive of the action. But none of these appeals to goodness can ground any obligation. One's selfish good rests on one's desires or inclinations, and these are obviously different from moral obligations, which operate rather to constrain inclinations. Nor can consequences for the general good provide the ground for moral obliga-

Mistaken quest for reasons

tions. The most basic reason Prichard gave for this denial is a cardinal statement of the irreducibility of deontological considerations to considerations of any other sort: "An 'ought,' if it is to be derived at all, can only be derived from another 'ought.' " This principle of nonderivability at once cuts the ground from under all attempts to justify obligations by means of any other considerations.

Another of Prichard's arguments against grounding the obligation to perform some action on its consequences for the general good also had important ramifications for the theory of justice. His argument was that the obligation to act justly is indifferent to and may even be inimical to good consequences. As for the intrinsic goodness of actions, consisting in the motive from which a person acts, this cannot be the ground for moral obligation, because a person may fulfill his moral obligation to perform some action even if he acts from bad motives. One's moral obligation is simply to do a certain act, not to do it from a certain motive.

The upshot of these considerations, according to Prichard, is that man's sense of obligation to do some action of a particular kind is "absolutely underivative or immediate." Certain preliminary inquiries may be needed in order to appreciate that an action is obligatory or right, but these entail simply getting clear about the precise nature of the action: one may need, for example, to trace out certain consequences of a proposed action in order to see that it will involve hurting someone's feelings. But once a person sees that it is an act of this kind, his perception of his obligation with respect to it is direct or immediate; *i.e.*, it is not mediated by any other consideration, such as goodness.

Objections and rejoinders. Prichard was aware of the apparent dogmatism of his position and tried to answer the resulting objections. To the criticism that obligations cannot be self-evident because men disagree as to what is obligatory, he replied that persons differ in their degree of moral development, that they sometimes fail to carry out the required preliminary inquiries because of lack of thoughtfulness, and that even the best men are therefore "blind" to many of their obligations. To the objection that obligations may conflict, so that one self-evidence will be in opposition to another, Prichard replied that obligation does indeed admit of degrees, so that one has to decide on which obligation is greater. Prichard did not, however, indicate how apart from intuition this decision should be made, although he insisted that, in any case, it is not a matter of calculating which alternative produces the greater amount of good.

Charge that the question of obligation is tautologous

One aspect of what Prichard took to be an improper question might seem obvious. If the question of whether there is any reason for acting the way one thinks he ought is interpreted as meaning, "Why ought I to do my duty?" or "Why should I carry out my obligation?," an obvious objection to it would be that the question is tautologous. Because "one's duty" or "one's obligation" means what one should or ought to do, to ask "Why ought I?" or "Why should I?" would be the same as asking "Why ought I to do what I ought to do?" and to ask this is like asking "Why is *A A*?" (which is a senseless or, at least, a pointless question). In this interpretation, Prichard's point would be analogous to Moore's: he would be saying that a certain question is mistaken because tautologous, just as Moore said that a certain purported definition is mistaken because it is not tautologous.

Two considerations must be noted in this connection. First, the basis of Prichard's own objection to the question that he regarded as improper was not that it is tautologous in the way just indicated. His version of the question was not, "Why are certain acts that are my duty my duty?" but rather, "Why are certain acts that I have believed to be my duty really my duty?" Prichard regarded this question as analogous to that raised by the classical theory of knowledge, "Why are certain things that I believe I know things that I really know?" For each question the point was to obtain some criterion, reason, or guarantee that what a person believes, he is fully justified in believing; that apparent or believed duty or knowledge is real or genuine duty or knowledge. And, in each instance, Prichard held that this quest for a justifying reason was in principle mistaken. But the mistake did not consist in asking a merely tautologous question; it consisted rather in asking for a reason for what was self-evident and, hence, admitted of no reason or of no justification.

"Ought only from ought" versus noncontradiction

A second, closely related consideration concerns an implication of Prichard's argument. Holding that the statement that one ought to do something is not provable or derivable from any statement about what is good, Prichard went on to argue that a statement about ought is derivable only from another statement about ought. But also holding that statements about ought are self-evident, he concluded that no derivation of them from any other statements is needed. This line of reasoning, however, overlooked at least one important alternative. Particular ought statements might be derivable from some general ought statement, some universal moral principle that would serve to ground and explicate all particular moral duties. This principle, in turn, would be derived not from some still more general moral principle but rather from certain principles of reason, involving especially the principle of noncontradiction. Kant's categorical imperative, "Act only on that maxim through which you can at the same time will that it should become a universal law," is the most famous example of such a universal moral principle; but there are other, perhaps more viable possibilities. The advantage of such an alternative over Prichard's position may be that it would show the rational justification of men's moral obligations in a way that avoids both his anti-Utilitarian strictures and his own dogmatic intuitionism. It might also clarify the problem of conflicting obligations, which he left unresolved.

Ross's distinction between prima facie and actual duties. Prichard's doctrines were carried on in amended form by another Oxford moral philosopher, W.D. Ross. The most important amendment was Ross's distinction between prima facie duties and actual duties. An action is a prima facie duty if it tends to be a duty but is not necessarily one's actual or full-blown duty, if it results from some one component of the total nature of the action—*e.g.*, that the action is an instance of keeping a promise or telling the truth. The whole nature of the action, however, may be such that to perform that action is not one's actual duty—*e.g.*, because telling the truth in the given situation will bring harm to some innocent persons. Whether some action is one's actual duty, then, depends on the total nature of the action; whether it is a prima facie duty depends only on some salient part of the total nature of the action.

Conflicts of duties and self-evidence

By this distinction between prima facie and actual duties, Ross was able to cope somewhat more adequately than Prichard with some of the difficulties confronting their common doctrine. One such difficulty concerns conflicts of duties: how they arise and how they are to be resolved. Ross's distinction explains how a certain action may be a duty and yet also not be a duty; the prima facie duty of keeping a promise may be defeasible (not an actual duty) because the action generates another prima facie duty opposed to the former duty, that of preventing harm to innocent persons. The question then arises as to how the conflict between these prima facie duties is to be resolved; *i.e.*, how in such a case a person is to determine what his actual duty is. Ross recognized that his position, like Prichard's, provides no principle that would resolve the conflict; but he also said that Utilitarianism is in no better position and that in any case there is no basis for anticipating that every duty is a duty for the same reason. Thus, Ross repeated Prichard's pluralism of duties.

Another difficulty on which Ross's distinction sheds some light is that of how duties can be self-evident and yet not be acknowledged by many persons. He held that prima facie duties are self-evident to all "thoughtful and well-educated people" who "have reached sufficient mental maturity and have given sufficient attention" to them. With respect to propositions expressing prima facie duties, such as that a person ought to keep his promises, to return services rendered, to effect a just distribution of good, or to promote the good of others, Ross wrote:

> The moral order expressed in these propositions is just as much part of the fundamental nature of the universe (and, we may add, of any possible universe in which there were moral agents at all) as is the spatial or numerical structure expressed in the axioms of geometry or arithmetic.

On the other hand, judgments of actual duty, because of the complexities they involve, are neither self-evident nor logical conclusions from what is self-evident.

Critical evaluation. The crucial difficulties of intuitionism are both epistemological and ontological (on the kind of being or existence). Epistemologically, the claim that men have intuitions of right or ought just as they have sensations of colours has seemed implausible to many scholars, both in itself and in its failure to account for conflicting intuitions. After all, moral conflicts are far more prevalent than disagreements about colours. To other philosophers, however, intuitionism has seemed to provide an indispensable basis for moral argument. They have held, for example, that to engage in moral argument with some person is impossible if that person does not even see the relevance of certain considerations, such as that the action would cause pain, to the desirability or undesirability of actions. For some philosophers, such considerations are part of the very definition of morality. In this way, intuitionist views continue to exert influence as bearing on conceptual or definitional issues of morality. There still remain problems, however, of conflicting intuitions and of rational principles for resolving the conflicts.

Ontological difficulties

Intuitionism also encounters severe ontological difficulties. Basic moral words have been held to signify indefinable moral qualities that are part of the world and yet not empirical or natural. To some philosophers, such a Platonism is difficult enough in itself, but it also raises the question of how these nonempirical moral qualities are related to the empirical actions to which they are attached, as when a person says, for example, that keeping one's promise or telling the truth is right or a duty. The moral qualities have been said to be consequential on the empirical qualities, but the nature of this relation has been left quite unclear. Critics, such as P.F. Strawson, an Oxford "ordinary-language" philosopher, have pointed out that the relation could not be definitional in the sense that the empirical qualities define the moral ones; for the intuitionists held that the latter qualities are indefinable. Nor could the relation be causal, such that the empirical qualities cause the moral ones. For, in order to ascertain a causal relation between two entities, one must be able to have an independent awareness of each; but the intuitionists held that there is no independent awareness of the moral qualities because they are always seen as dependent on the empirical qualities.

NATURALISTIC COGNITIVISM

Naturalism as a meta-ethical theory is, in important respects, an attempt to surmount the difficulties of intuitionism. It accords with intuitionism in its view that moral words or concepts signify real qualities in the world, that moral judgments may be true of the world, and that such judgments thus constitute knowledge. But naturalists seek to avoid the dogmatism and seeming obscurantism of the intuitionists' appeal to nonempirical intuitions and nonnatural qualities by directly identifying moral attributes with empirical qualities. There is no separate ontological realm inhabited by moral qualities, they hold, nor is a separate kind of cognition required to ascertain them. On the contrary, moral judgments are empirical statements verifiable by the same methods of natural science or experience as are other empirical, scientific statements. It follows also that moral knowledge is a part of natural science and not sharply separate from it, as the intuitionists hold.

Naturalism versus nonnaturalism and supernaturalism

In the sense in which Moore distinguished naturalism from his own theory, naturalism may include any position holding that moral qualities are not completely unique in kind. On the basis of this definition, even a theory that held moral qualities to be supernatural and that, for example, defined good as what God commands would still be naturalistic. According to the interpretation most widely accepted in the 20th century (the one to be followed for the most part here), naturalism is opposed, however, to supernaturalism as well as to nonnaturalism or intuitionism. In this more specific interpretation, naturalism holds that moral words signify only natural, empirical qualities, not also supernatural ones.

Ancient Greek and medieval naturalisms. The above characterizations of naturalism have used words like natural, scientific, and empirical. It is important to recognize, however, that the reference imputed to these words in any period will vary with the philosophic and scientific views prevalent in that period. The view of nature that obtained in the ancient and medieval worlds differed in important respects from that of the modern world since Galileo and Descartes (died mid-17th century). The most obvious difference is the widespread removal of final (or purposive) causes, either transcendent or immanent. In the Platonic and Christian doctrines, all things are products of supernatural causes and are fashioned to achieve purposes imposed on them from without by those causes.

Plato, Aristotle, and Aquinas. In important respects, however, the Platonic doctrine is closer to intuitionism than to naturalism, as so far defined. For Plato distinguished between intelligible reality and sensible appearance. The former was the realm of the eternal, unchanging Ideas or Forms, and especially of the Idea of the Good, the ultimate principle of all other Ideas. The sensible, on the other hand, was the realm of changing, empirical, natural objects, which are real and intelligible only insofar as they participate in the eternal Ideas. Hence, just as the intuitionists distinguished between nonnatural moral qualities and the natural empirical qualities to which they are somehow attached but which do not as such constitute moral realities, so Plato distinguished between the evanescent empirical qualities and the unique Idea of the Good, from which alone, by participation, they derive whatever goodness they might achieve.

Transcendent versus immanent forms

Aristotle, on the other hand, rejected this distinction between transempirical Ideas and changing empirical objects. He held, like Plato, that there are forms that give intelligibility and fixity to things; but, unlike Plato, he regarded these forms as being in the things themselves, not separate from them. These forms are ultimately one with the ends or final causes that constitute the good of each kind of thing, in the sense of its perfect functioning and complete development as a member of its species. Indeed, the nature of each kind of thing is identical with its form and end and hence with its good; and natural science attempts to ascertain these natures and their consequent properties by an empirical, inductive process that culminates in an intuitive grasp of the defining essence of each kind of thing. Hence, Aristotle's ethical doctrine is thus far naturalistic in at least two respects. First, goodness is an objective characteristic that belongs to each kind of natural thing; it is of the same kind as other natural characteristics—although in one respect it is more general than they, since objects in each category of things (substance, quantity, relation, and so forth) have their characteristic good. Second, the goodness of each kind of thing can be ascertained by empirical, inductive methods similar to those of all other scientific inquiries.

Thomas Aquinas, living in the 13th century, took over this basic Aristotelian position. As a Christian he believed, of course, in a transcendent God; but, unlike Augustine and his followers who had dominated much of medieval thought, Thomas did not simply absorb all goods and all realities into God's creative power as the first cause of all things. Instead, Thomas emphasized the importance of what he called second causes: the specific, immanent forms that constitute each kind of thing making it what it is. Hence, Thomas declared that good and being, or reality, are the same in each thing, differing only in that the goodness of the thing consists in the perfection that it strives to attain. To the objection that some realities are bad, Thomas replied that they are bad only insofar as they lack some part of their full perfection.

Difficulties in the doctrine of final causes. Some scholars have discerned severe difficulties in this Aristotelian–Thomistic doctrine of immanent final causes and perfections. It may be granted that for frogs and dogs it is easy to ascertain whether they have achieved their full development, the criteria of which are certain kinds of biological functioning. But how does this judgment apply to human individuals? In what respect does a Hitler or a Stalin not represent the complete development of the human form, whereas a Schweitzer or a Gandhi does? In what way does the concept of complete development account for criteria of moral goodness?

Ontological versus practical moral philosophy

To examine how Aristotle might deal with this difficulty, it must be recognized that there is a difference between his general ontological account of goodness (summarized in the preceding section) and the account of moral goodness or virtue that figures in his ethical philosophy. The difference derives from the sharp distinction he drew between theoretical and practical philosophy. Theoretical philosophy—which includes physics, biology, psychology, and metaphysics—deals with objects whose natures or essences are invariant and independent of human action or production. Practical philosophy, which includes ethics, deals with objects that vary because they depend for their existence and salient characteristics on human action. Such varying objects consist not of fixed essences but of human habits or dispositions and of institutions that are the effects of human contrivance.

Hence, human goodness or moral virtue, which is a habit or disposition, cannot be read off from the essence of man in the way in which the goodness of natural entities, which are independent of human contrivance, can be read off from their essences. On the contrary, since human goodness or virtue depends on human action, it will have an important variable feature. The matter of which the moral virtues are composed is human actions and emotions; this matter—*i.e.*, men's actions and passions—develops into virtues when a certain rational pattern is regularly imposed on them. This pattern appears as a mean between extremes and is determined by rational appraisal and ultimately by a kind of intuitive perception. It is in this way that the man of practical wisdom determines what is the right amount of fear to have in each dangerous situation, what is the right amount of food to eat in each gustatory situation, and so forth. In each case the formula is: neither too much nor too little but just the right intermediate amount, and this varies from one person to another and from one time to another. Aristotle also applied this formula, although with some modifications, to justice.

Intuitionist and naturalist strains in Aristotle

It is not entirely clear how Aristotle conceived the relation between this double determination of moral virtue or goodness (1) by a rational pattern or principle and (2) by intuitive perception and his more general ontological conception of goodness as consisting in subsistent final causes. In the sense in which he used "nature" in the *Nicomachean Ethics*, moral virtue for the most part is not natural but results rather from habituation. Hence, Aristotle was not a naturalist in the sense in which a naturalist holds that moral qualities exist as natural qualities and are knowable by the empirical methods of natural science. His position is in one respect closer to intuitionism; for, although he elucidated the rational, moral grasp of the means between excess and defect by analogy with the processes of the arts, he also insisted that the moral virtues are unique qualities quite different from those found in works of art. There was, nonetheless, a deep naturalistic strain in Aristotle insofar as he held that the nature of man, in the sense of his final cause, is to live in society and to have the corresponding virtues, especially that of justice. Thus, he referred, at one point, to natural justice, and in the *Politics* he declared that "the nature of a thing is its end" and that "man is by nature a political animal."

Varieties of contemporary naturalism. In the modern era, the idea of immanent final causes or perfections as part of the natures of things, for the most part, has been relinquished. The consequence for the theory of goodness or value can be seen in the statement of George Santayana, a 20th-century aesthetic Materialist, that "apart from ourselves, and our human bias, we can see in such a mechanical world no element of value whatever." Nevertheless, in some modern naturalisms, analogues can be found of the doctrine that goods are part of the essential natures of things.

An initial broad division can be made between objective and subjective naturalism. According to objective naturalism, goodness belongs to certain objects simply by virtue of their own natures or relations, regardless of whether the objects are known or desired. Such goodness depends upon the natural constitution of the objects and consists in what is required for those objects to achieve the perfect functioning or development of which they are capable. Santayana referred to such an objective goodness when he said that there are "natural relations that make one thing good for another." Food, for example, is good for an animal independently of whether it is known or desired by the animal.

According to subjective naturalism, on the other hand, goodness belongs to things in virtue of some sort of knowledge, desire, or interest. To call such naturalisms "subjective" does not mean that they hold the goodness or value of things to be merely apparent or unreal; rather, the point is that they regard value as pertaining to objects by derivation from the knowing or valuing subject, so that the value consists in or results from a relation between the object and the subject. But, once this relation obtains, the value genuinely exists; it is not mere illusion or appearance.

Epistemic versus nonepistemic subjective naturalism

There are two main kinds of subjective naturalism, epistemic and nonepistemic. Epistemic naturalism holds that goodness or value arises from the application of certain cognitive procedures to objects or experiences. Thus, according to John Dewey, "Without the intervention of thought, enjoyments are not values but problematic goods . . . enjoyment becomes a value when we discover the relations upon which its presence depends." Nonepistemic naturalism holds that goodness or value arises rather from certain desires, interests, or emotions of the organisms. There is an important distinction, however, between those nonepistemic naturalisms that are normative and those that are positive.

The normative variety imposes certain restrictions on the kinds of interests that generate goodness or value. Thus, Santayana recognized that "there are desires for what is bad," but he insisted that such desires are merely "incidental phases of consciousness" and, hence, represent only "momentary and partial interests." Opposed to these are "constitutional interests," which derive from the basic natures of human animals; these interests are "more comprehensive" than the former, and it is they that determine what is really good. He wrote:

> It is in reference to such constitutional interests that things are "really" good or bad; interests which may not be fairly represented by any incidental conscious desire. No doubt any desire, however capricious, represents some momentary and partial interest, which lends to its objects a certain real and inalienable value; yet when we consider, as we do in human society, the interests of men, whom reflection and settled purposes have raised more or less to the ideal dignity of individuals, then passing fancies and passions may indeed have bad objects, and be bad themselves, in that they thwart the more comprehensive interests of the soul that entertains them.

The positive variety of nonepistemic naturalism, in contrast, imposes no restrictions or requirements on the desires or interests that generate goodness or value. Thus, Ralph Barton Perry, a Harvard Realist philosopher, defined value as "any object of any interest"; he said that "any object, whatever it be, acquires value when any interest, whatever it be, is taken in it."

Realistic and descriptive status of naturalistic ethics

For all these varieties of naturalism, goodness and other valuational and moral qualities pertain to things themselves, either directly or in virtue of their relation to some condition of persons or other organisms—this condition being cognitive, conative, or emotional. Moral judgments, which predicate a moral quality of some subject, are hence descriptive, empirical propositions that are either true or false. It has already been argued that nat-

uralism does not incur the logical fallacy attributed to it by Moore and other intuitionists. Whether it incurs a different kind of logical fallacy, however, will be discussed below (*Noncognitivism: Moral statements as "commending"*). Nevertheless, many scholars hold that naturalistic theories face some serious difficulties. They are of two interrelated kinds, ontological and valuational.

Ontological difficulties of naturalism. The ontological difficulty pertains most directly to the objective variety of naturalism. How can goodness or value, one may ask, belong to things themselves irrespective of any desires or knowledge on the part of anyone? It must be emphasized that, in much ordinary thinking and talking, such objectivity of value is assumed. A distinction is sometimes drawn, for example, between men's preferences and their well-being; what men prefer is often not what is really good for them. Obvious examples are smoking and ingestions of heroin or of excessive liquor, in contrast to a moderate amount of food, drink, and rest. This distinction is held to be an objective one, in that what is and what is not for the good of an organism can be ascertained independently of its or anyone else's desires or preferences; the good consists in what contributes to the organism's effective and prolonged functioning as an organic whole.

For this distinction to be tenable as an ontological one, however, it would have to apply indiscriminately to all organisms. Thus, the food that is good for humans is not good for the beasts and plants that are destroyed, as the distinctive organisms that they are, in the process of becoming food for men. Germs are not good for human beings, but similarly human beings are not good for the germs they try to destroy. It seems, then, that what is good can be ontologically good in the way upheld by objective naturalism only at the cost of being made completely relative to each kind of organism. This much was already recognized and accepted by Aristotle in his immanent specific teleology. But Aristotle also upheld a natural hierarchy according to which some organisms are inherently superior to others in virtue of the superior functions they can perform. The criteria of such superiority he held to be quite objective: they include especially the ability to know more things and to know them more deeply in respect to their causes and the ability to engage in moral relations. But these criteria obviously raise many problems; as they stand, they suggest an anthropocentric approach that begs at least part of the question at issue.

Valuational difficulties of naturalism. The valuational difficulties faced by naturalism revolve around the question whether the definitions of goodness or value that its various versions claim to provide can account for moral goodness or value. It is significant that most 20th-century naturalists, like many earlier ones, concern themselves more directly with the general notion of value than with specific moral notions, especially deontic ones. The reason derives from three interrelated factors. First, naturalists see continuities between human and nonhuman nature, and corresponding continuities between their respective sources of value, especially in natural desires or impulses. Since, however, moral considerations do not pertain to nonhuman nature, the naturalists' general approach to value is, as such, nonmoral. Second, the naturalists regard value as affirmatively related to human nature rather than as negatively related—as concerned with the development rather than with the repression of natural tendencies. Insofar, then, as morality involves restraints on natural impulses rather than their fulfillment, the naturalistic approach to value does not, as such, provide for morality. Third, the naturalists consider value as pertaining to each organism or to each human being separately. But, insofar as morality concerns the interrelations among persons, it is not accounted for by naturalism.

Reasons for general concern with values

James's and Perry's ethics of demands and interests. With respect to each of the last two points. however, it is important to note that many naturalists supplement their general, nonmoral definitions of value by further criteria of moral value that include social and interpersonal relationships. The Pragmatist William James, for example, having said that "the essence of good is simply to satisfy demand," recognized that demands may conflict with one another. His solution was a simple, aggregative one, reminiscent of the Utilitarians:

> The guiding principle for ethical philosophy [must be] simply to satisfy at all times *as many demands as we can.* . . . There is but one unconditional commandment, which is that we should seek incessantly, with fear and trembling, so to vote and to act as to bring about the very largest total universe of good which we can see.

James did not, however, deal with the difficulties of this purely quantitative or aggregative doctrine, despite the fact that earlier in the same essay he had recognized the specific problem of justice.

Perry, having defined value as "any object of any interest," then faced the problem of how to ascertain "what is *really* valuable" and how to account for "the case in which an interest or its object is morally condemned." His reply was that the general definition of value must be distinguished from the solution of special problems of value and that in the special case of moral judgments, these "are concerned with organizations of values . . . with the relation of interests to the comprehensive purposes in which they are incorporated." This reference to "comprehensive purposes" suggests a quantitative approach to morality similar to that of James, with its corresponding difficulties. Subsequently, however, Perry tried to deal with the problem of justice by means of what he called "the postulate of concurrence," according to which "we have found a solution when, and only when, the wills of all are so attuned that each is content with a situation in which provision is made for all." This postulate obviously departs considerably from Perry's general definition of value, for it requires not merely that as many interests as possible be satisfied as fully as possible but that there be unanimous consent, even at the cost of lesser satisfaction of some interests. Nevertheless, this postulate can be accommodated to his naturalistic framework, since all of its concepts can be defined empirically.

General definition versus special problems of value

Dewey's ethics of intelligent action and enjoyments. The complex naturalistic doctrine of John Dewey took a somewhat different approach to these problems. He set himself in explicit opposition to Perry's equation of value with any object of any interest, declaring that this equation omits the normative aspect of value: it ignores "the difference between the enjoyed and the enjoyable, the desired and the desirable, the satisfying and the satisfactory." To account for this difference, an additional factor must be introduced. The enjoyments in which fulfillment of desires or interests directly consists must be subjected to experimental, operational tests in order to ascertain their consequences. Hence, Dewey advocated "defining value by enjoyments which are the consequences of intelligent action. . . . Enjoyment becomes a value," he held, "when we discover the relations upon which its presence depends."

This position, with its reference to enjoyments and consequences, is reminiscent of Utilitarianism. But Dewey did not indicate just how the consequences must be related to the initial enjoyments in order to yield a judgment of value. Perhaps he had in mind the sort of situation in which a person tests whether his enjoyment of smoking, for example, is a genuine value by ascertaining through statistical or other empirical methods what are its likely consequences. Here, however, a standard of value is already assumed: the maintenance of physical health. But suppose, instead, that one is testing the enjoyment derived from inflicting pain on innocent persons. By what standard does he test its consequences? The moralist may subject such enjoyment to "intelligent action" by ascertaining its consequences. But Dewey presents no way of showing that, when the consequences include increased suffering for others, the value of the enjoyment is removed, and it is rendered a moral disvalue. His naturalistic definition of value as "enjoyments which are the consequences of intelligent action" hence fails, not because it does not pass Moore's open-question test but rather because it fails to meet a simpler exten-

Relation of enjoyments to consequences

sional requirement: it would entitle the moralist to regard as genuine values sadistic or other acts that are unquestionably moral disvalues.

A possible solution of this problem in Dewey may be found by considering first his conception of the kind of intelligence that he insisted must be brought to bear on enjoyments before they can be considered to be values. He regarded science as the fullest development of intelligence, and science in its own right is both practical and valuational: "This element of direction by an idea of value applies to science as well as anywhere else. For in every scientific undertaking, there is passed a succession of estimates; such as 'it is worth treating these facts as data or evidence; it is advisable to try this requirement.'" The values here in question, however, are purely scientific or intellectual; how, then, do they bear on moral values? Dewey answered this question by emphasizing that scientific values, like moral ones, are interpersonal and intersubjective: the scientist must put his opinions to the test of scrutiny through free inquiry by other scientists using methods whose application and results are available to all. Dewey suggested that, in this respect, there is a potential alliance between scientific and democratic method:

Alliance of scientific and democratic methods

> It is of the nature of science not so much to tolerate as to welcome diversity of opinion, while it insists that inquiry brings the evidence of observed facts to bear to effect a consensus of conclusions—and even then to hold the conclusion subject to what is ascertained and made public in further new inquiries. I would not claim that any existing democracy has ever made complete or adequate use of scientific method in deciding upon its policies. But freedom of inquiry, toleration of diverse views, freedom of communication, the distribution of what is found out to every individual as the ultimate intellectual consumer, are involved in the democratic as in the scientific method.

The question still remains, however, whether these analogies between science and democracy, in respect of their methods of reaching conclusions, are sufficient to remove the possibility of the immoral (or undemocratic) use of scientific method. It might be held that all such uses are really abuses of the libertarian, egalitarian features of scientific method. But, even if scientific and democratic methods exhibit certain freedoms and equalities in their respective spheres and are to that extent similar to one another, this does not answer the question of whether science ought to be used to extend men's freedom and equality generally. Science and democracy may well be similar to one another in the ways indicated by Dewey; but this does not prove that science may not be used for undemocratic purposes. Hence, Dewey's appeal to the operations of scientific intelligence as the way to convert enjoyments into genuine values does not suffice to prevent his definition of value from being compatible with serious moral disvalues.

NONCOGNITIVISM

Although the main development of noncognitivist theories has occurred since the first third of the 20th century, their lineage can be traced back to various emphases in philosophers such as Hobbes and Hume and even to some points in Aristotle and in the medieval voluntarists.

Denials and avowals of noncognitivism

In contrast with both the intuitionists and the naturalists, the noncognitivists deny that moral terms have descriptive meaning, either at all or primarily. They also deny that moral judgments are propositions that state facts about the world or that reason or any other intellectual faculty can prove or justify any moral principle or, more generally, that there can be any conclusive justification of a moral judgment, as the intuitionists and the naturalists had assumed because of their assimilation of such judgments to knowledge certified either by intuition or by empirical methods.

Complementing these negative theses, the noncognitivists hold that moral words and sentences have various kinds of nondescriptive meaning; they express feelings or emotions; they evince attitudes; they exert an influence; they have a certain magnetic force; they issue commands or prescriptions; they guide choices; they commend, recommend, condemn, or disparage.

Concern with language and verifiability. An initial important characteristic of all of the contemporary noncognitivists, in contrast with the cognitivists, is their great concern with language. This concern is indicated in the titles of some of their chief books: A.J. Ayer's *Language, Truth and Logic* (1936; rev. ed. 1946), Charles Stevenson's *Ethics and Language* (1945), R.M. Hare's *The Language of Morals* (1952).

The reasons for this linguistic emphasis are similar to those that motivated the earlier emphases on language by Hobbes and Locke in the 17th century. In general, an explicit, direct study of language can help to clarify philosophic issues. But, more specifically, the philosophers in question hold that it is only by reference to language that the philosopher can account for many of the so-called entities or objects that, according to earlier Rationalistic or ontologically inclined thinkers, comprise an important part of the existing universe. Just as for Hobbes and John Locke the "intelligible forms" and "real essences" that Scholastic Rationalists had held to exist were mere words, whose purported ontological reference was to be accounted for by the philosophers' misuses of language, so, for the noncognitivists, the nonnatural or natural objects that the cognitivists had held to be the referents of "good" and "ought" are to be explained in terms of these philosophers' misinterpretations of the meaning or use of ethical words. There are no such objects in the world, or, at any rate, philosophers have no warrant for asserting that there are; there is only the use of language in certain nondescriptive ways. It is because the cognitivists have interpreted moral judgments as being descriptive that they have held that goodness or obligation is a real quality of things. Once it is seen that the only or the primary meaning of moral judgment is nondescriptive, this view of the ontological or objective reference of moral words must be relinquished.

Another way in which the noncognitivists' concern with language bears on their ethical theory is through their application of the verifiability principle to ethics. Earlier noncognitivists, such as Ayer and Stevenson, were strongly influenced by the Logical Positivists, philosophers such as Moritz Schlick and Rudolf Carnap, one of whose main tenets was that, for a sentence to be cognitively meaningful, it must be verifiable, at least in principle. They further held that there are only two mutually exclusive means of verification and hence only two kinds of cognitively meaningful sentences: (1) analytic sentences, verifiable merely by the meanings of their terms, and (2) synthetic sentences, verifiable by consideration of empirical data. Ethical sentences, however, are of neither of these kinds. For, if they were, then disputes over moral matters could be settled as readily as can disputes over analytic sentences (settled by logic or mathematics) and over synthetic sentences (settled by empirical observations, including those performed by experimental scientists). The fact is, however, that men may agree on all of the empirical facts and logical rules and still disagree on some moral issue. Thus, ethical sentences are not verifiable; hence, they are not cognitively meaningful. The earlier Logical Positivists tended to say, on the basis of this argument, that ethical sentences are not meaningful at all, that they are mere noises or ejaculations, as when one says, "Hurrah!" or "Ugh!" The later Logical Positivists, however, especially Stevenson, admitted that ethical sentences are indeed meaningful, but, since their meaning could not be cognitive, they invented a new rubric, "emotive meaning."

Cognitive meaning through verifiability

Moral statements as "commending." In addition to this argument from the cognitive undecidability of moral disputes, the noncognitivists supported their rejection of the cognitivist doctrines by several other kinds of argument. One was an appeal to Moore's open-question test. Ayer and Stevenson repeated this test in a form that was quite similar to Moore's; hence their views were vulnerable to objections similar to those given above. R.M. Hare, an Oxford "ordinary-language" philosopher, however, put the argument into a new form directly linked to his own noncognitivist thesis.

Value-terms have a special function in language, that of

commending; and so they plainly cannot be defined in terms of other words which themselves do not perform this function; for if this is done, we are deprived of a means of performing the function.

Analysis of attempts to define values

One of the examples that Hare gives to illustrate this impossibility of a "descriptive" or "naturalistic" definition of value terms is the attempt to define the goodness of a strawberry as meaning that the strawberry has such descriptive characteristics as being sweet, juicy, firm, red, and large. But, as Hare writes, "we sometimes want to say that a strawberry is a good strawberry because it is sweet, etc. This—as we can at once see if we think of ourselves saying it—does not mean that a strawberry is a sweet, etc., strawberry because it is sweet, etc. But, according to the proposed definition, this is what it would mean."

This argument can be formally presented in a way parallel to the presentation of Moore's open-question argument given above. Someone may define the goodness of a strawberry in terms of sweetness and other descriptive characteristics (*DC*):

(1) $G =_{df} DC$

If one now wants to say that a strawberry (*S*) is good (*G*) because it is sweet, etc. (*DC*); *i.e.*,

(2) *S* is *G* because *S* is *DC*,

then, according to the definition in (1), in saying (2) he would be saying:

(3) *S* is *DC* because *S* is *DC*.

There are two points here. One is similar to Moore's point: (3) is a tautology, but (2) is not a tautology, as it would have to be if (1) were a correct definition. Moore's emphasis in this connection had been that (3) does not capture the meaning of (2) because the property held to be synonymous with and definitive of goodness is seen by inspection not to be synonymous with it—so that the point concerns the nonidentity of two properties. Hare's emphasis, however, involves the quite distinct point that "good" does not signify any property at all, because a person in saying, "This strawberry is good," is commending the strawberry, not describing it, and this commending function is quite different from uttering the mere tautology that (3) is.

This argument of Hare's raises several important issues. One concerns what it means to refer to the function of words and sentences (see below *Function of moral judgments*). Another issue bears on the basic contention that the function of "good" and other value terms is exclusively or primarily prescriptive or commendatory, not descriptive. In connection with this issue, two questions must be distinguished: (1) Is the function of describing different from the function of prescribing (or commending)? and (2) May the same word or judgment perform both functions? At one point, Hare gives an affirmative answer to both questions: "Although prescription and description may be combined in the same judgment, description is not and never can be prescription." If, however, the same judgment can be used to perform both functions, some scholars have wondered what becomes of Hare's argument just presented. May not a man then use "This strawberry is sweet, juicy, firm, red, and large" to commend the strawberry, to urge others to taste it (or one like it), to guide persons' choices with regard to strawberries, and so forth? And may he not then define "good" and other value terms by means of descriptive terms such as "sweet," "juicy," etc., because these terms can be used to commend, prescribe, or guide actions?

Description versus prescription

In answer to the argument that to give such a descriptive or naturalistic definition of the goodness of strawberries is to incur the penalty of reducing a commendatory or prescriptive judgment to a tautology, one can again argue as above against Moore. The definition may be held to explicate or analyze the complex meaning of the value words; hence, because there is a difference in clarity between the word to be defined and its definition, the one cannot be directly substituted for the other so as to yield a tautology, for such substitution ignores the explicative function of the definition.

Moral statements as "commanding." Moral statements may be interpreted not only as commending but also as commanding.

Guides to action. More generally, it can well be argued that most descriptive words, which can be given descriptive definitions, may be used for prescriptive or action-guiding purposes. ("To commend," Hare says, "is to guide choices.") The Pragmatic philosophers, from Charles Sanders Peirce to C.I. Lewis, had indeed held that a bearing on action is basic to all descriptive language, in that to define any descriptive word, such as door, or to verify any descriptive statement, such as "This is a door," one, at least in principle, would have to refer to various relevant operations, such as turning a knob or pushing. Or, in order to ascertain what are the descriptive statements that a person believes to be true, one would have to examine what actions he performs or would perform in relevant situations. Hence, it is impossible to separate the meanings of descriptive words from the ways in which they either guide actions or are guided by actions.

Action-guiding function

Even without going the full length of the Pragmatic position, it is clear that descriptive words and statements can serve to guide action. An obvious example is, "There is a fire in the next room." Hare recognizes this point when he says: "Even plain judgments of fact may be action-guiding. For example, if I say 'The train is just about to depart,' this may guide a person who wants to catch the train to take his seat." But it is difficult to reconcile this recognition with statements that Hare makes when he is pressing his noncognitivist or prescriptivist thesis, as when he says: "A statement, however loosely it is bound to the facts, cannot answer a question of the form 'What shall I do'; only a command can do this."

For a statement of fact to guide action, it must in some way be related to the wants, desires, or interests of the person whose action is to be guided. If someone in St. Louis, for example, should be told, "A tree fell yesterday in central Siberia," this statement is quite unlikely to have any impact or bearing on his action, unless he perchance should have some interest in it. This factor of interest also operates on commands. If someone is told, "Go jump in the lake," such a command will not even tend to guide his action if he has no interest in jumping in the lake or in obeying the person who gives the command. To generalize, for any person's action to be guided by words or sentences in any use of language—prescriptive, descriptive, or other—what is said in those words or sentences must have a bearing on that person's wants or interests, and he must recognize and accept that bearing.

Commands versus statements. Hare also tries, however, to distinguish between commands and statements (the grammatical analogues of prescriptive and descriptive judgments, respectively) in terms of what is involved in sincerely assenting to each of them. To assent to a statement is to believe it to be true; but to assent to a second-person command addressed to oneself is "to do or resolve to do what the speaker has told us to do." Here, through the difference between belief and action, there would seem to be the basis for Hare's doctrine that descriptive statements, as such, present only what is to be believed, not what is to be done, so that moral judgments, because of their action-guiding function, cannot be descriptive.

Lack of parallelism

The contrast between statements and commands, as Hare here gives it, seems to rest, however, on an important lack of parallelism. He stipulates that the commands must be second-person ones, but he does not in parallel manner stipulate that true–false statements must also be second-person ones concerning the intentional action of the person addressed, of the form "You are doing *x*" or "You will do *x*" or "You did do *x*." But, in fact, to assent to such second-person statements about one's own intentional actions is either to be doing *x* or to resolve or intend to do *x* or to have done *x*. Even if it be admitted, as it should be, that to assent sincerely to a statement is to believe it to be true, it is impossible to believe in the truth of a second-person statement about what one will in the future do without intending to do it. And, because second-person commands concern the (directly or remotely) future actions of the persons to whom they are

addressed, the proper analogue of these imperatives is the true–false statement that the person addressed will perform some intentional action. But sincerely to assent to such a statement is to resolve to do the action, just as to assent to a second-person imperative is to do the action. In this respect, then, the purported distinction between what is involved in assenting to statements and to imperatives does not hold up. Insofar as statements describe one's own intentional future actions—and to be parallel to second-person commands they must be of this sort—assenting to them commits one to action just as does assenting to commands. Yet, it may still be contended that there is a difference between such statements and commands. It lies in the intention of the person who issues each kind of utterance; *i.e.*, the difference is not on the side of the hearer or addressee but rather on the side of the speaker.

Function of moral judgments. The contention that there is a difference between assenting to statements and complying with commands reopens the basic issue of the function of moral judgments and the relation of that function to meaning.

Austin's locutionary distinctions. Some philosophers have tried to clarify this issue by means of an important, though controversial, set of distinctions presented by the Oxford "ordinary-language" philosopher J.L. Austin. (The summary that follows cannot be completely faithful to Austin's position because of persisting unclarities as to what he meant by what he said.)

Locutionary, illocutionary, and perlocutionary
