the United States, which continued during the 1960s. By the end of that decade not only was the postwar monetary system facing new difficulties but inflation also began to grow bigger and less controllable. Internationally, the renewed strength of the European and Japanese economies, coupled with U.S. balance of payments deficits, had made the parities between the main currencies increasingly unrealistic. The dollar was palpably overvalued in terms of gold and other currencies, and the mark and the yen in particular were undervalued; but any revaluation threatened the high exports upon which West German and Japanese economic growth depended.

The main characteristic of economic development in the advanced industrial countries was thus the apparent overcoming of the trends toward stagnation of the 1930s. War and war preparations, impressive technological changes, the increased role of government policy to maintain growth, and full employment offered continuous opportunities for new profitable investment. Best equipped to take advantage of these opportunities were the big corporations, and so, especially in the most modern industries, the field tended to be dominated by a few giant firms. Mergers and take-overs became familiar occurrences, and American corporations moved into the European market.

Internationalism. *The Common Market.* The European Economic Community, or Common Market, was in the first place a customs union whose members reduced (and were finally to abolish) duties on their own trade while a common external tariff was to be maintained against imports. The original signatories of the Treaty of Rome—France, West Germany, Italy, Belgium, The Netherlands, and Luxembourg—also intended to develop policies to achieve full economic integration. It was hoped that the establishment of a unified market area would yield benefits comparable to those gained by the United States. The history of the Common Market is inseparable from the political trends of the period. While Gen. Charles de Gaulle was in power in France (1958–69), he opposed the development of supranational policies and opposed two attempts at entry into the Common Market by Britain. In 1959 Britain and six other European countries formed the European Free Trade Association (EFTA), which reduced tariffs on imports received from member countries until they were finally eliminated in 1970.

The Treaty of Rome

International corporations. The giant international firm was another focal point of public interest. Although the big British, French, German, and other firms were also operating internationally and the Japanese were extending their international connections, the majority of the "multinationals" had their headquarters in the United States. These firms were particularly strong in the industries that were in the vanguard of technical progress, such as computers, motor vehicles, and electronics.

Luxury goods and the tertiary sector. As incomes in Europe and Japan rose, so more was spent on luxury goods, and the extent to which a country was equipped with different types of such goods became a good index of its per capita income. Even advanced European countries were poorly equipped with washing machines, refrigerators, vacuum cleaners, and the like after World War II, and thus a big field was open for new investment and large-scale production, with U.S. capital often taking a leading part. As a result, European consumption moved closer to U.S. patterns. Europeans also spent more on services of various kinds, so that there was a continuous growth of the "tertiary" sector in Europe as well as the United States, and industrialization itself resulted in a fall in the proportion of the occupied population working in manufacturing industry.

The uncertain future. The 1960s—a period clouded by the war in Vietnam and continued high military expenditure—saw a long period of uninterrupted expansion in the United States that ended in a recession in 1969–70. The Japanese economy boomed through most of the decade, as did those of the Common Market countries. Britain faced a series of balance of payments crises and had to devalue the pound sterling in 1967. Moreover, in Britain, in Italy, and then more widely in Europe, as well as in the United States, unemployment began to rise, and the rate of economic growth began to fall. The combination of these phenomena with continued, and even accelerated, inflation, as well as the increasing strains on the world monetary system, seemed to indicate that the economy of the industrialized countries was changing course. In December 1971, the U.S. devalued the dollar by 8.57 percent, but its balance of payments deficit continued, and a further devaluation was necessary in 1973.

THE DEVELOPING NATIONS

Until recently, economic history has been written mainly from the standpoint of those countries in western Europe and North America that, in the 19th and 20th centuries, achieved relatively high per capita incomes as a result of industrialization. The rest of the world was seen as a source of raw materials and as a market for manufactured goods. Since World War II a great change has come about. The disparity between the rich and the poor countries has become a matter of international concern, and the question of economic growth and development has become a major branch of economics.

The developing countries entered the world market as colonies or economic dependencies of the leading capitalist countries. Despite wide differences, certain fundamental characteristics can be distinguished that make them "developing." Of primary importance is the fact that they entered the modern period without the possibility of autonomous economic growth because of their colonial or semicolonial status. Their economic history, therefore, was not a delayed repetition of that of the developed countries but had distinctive features.

The economic and technical superiority of the European capitalist countries enabled them to dominate most of the globe. The development of other areas of the world was determined by the needs of the advanced capitalist countries. Their role in the world market was to supply minerals and plant and animal products to the industrializing countries. Outside capital opened ports for tradè, built transport links into the hinterland, made investments in mining and plantations, and created a labour force of native or immigrant labourers. A modern sector—essentially a geographical extension of the European metropolis or of American capitalism—was inserted into the existing economy; the result was a dualistic economy in which this modern sector existed alongside, or within, a precapitalist peasant economy.

The position of the modern sector

The phase of economic atrophy. European administrators, concession seekers, traders, and investors were not interested in promoting balanced growth or development, and the social side effects were only of concern if they threatened public order and the safety of investments. Although the developing countries differed greatly, they were all dependent on the world market. They remained primary producers, with their economies hinged to the world demand for one or two minerals or export crops. The scope for industrialization was limited, because as the home market grew, the demand for manufactured goods was met largely by imports. When these were cut off during World War I, an impetus was given to manufacturing industry in such countries as India and Brazil. The catastrophic fall in exports during the Depression of the 1930s, followed by another world war, gave further encouragement to local production, but industrialization remained slow and uneven, despite state encouragement during and after World War II.

At the outbreak of World War I, European colonialism was at its height; virtually the whole globe had been divided by the great capitalist powers. After the defeat of Germany its somewhat meagre share of the colonial spoils was disposed of to the other powers as "mandates" of the League of Nations. Britain and France extended their interests in the Middle East, of growing importance as a source of petroleum.

Wartime conditions had generally encouraged faster industrial development in the dependent countries, but the main stimulus was felt by primary producers. The wartime increase in productive capacity proved greatly in ex-

cess of the needs of the market for most of the interwar period. Consequently, what had been the main if not the only engine for growth—rising exports—faltered and stopped. All primary producing countries faced problems of excess capacity, except those with oil.

The emergence of the native bourgeoisie. The most important social change in the developing countries in the interwar period was the emergence of a native bourgeoisie that became increasingly self-conscious and active in seeking home rule or independence. It was strengthened by the increasing opportunities for local investment in trade and industry and sought to extend them by removing the restrictions and restraints arising from colonial or semicolonial status. After World War I the Western-educated intelligentsia became increasingly articulate in formulating political demands and in expressing the aspiration for material improvement in such countries as Indonesia, India, and Indochina. At the same time, the rise of the modern sector, the accelerated disintegration of the traditional society, and the population explosion produced movements of mass discontent and the threat of revolution.

When the national bourgeoisie joined forces with the masses, the national movement in the colonies became a force to be reckoned with, as in India in the 1920s. During and after World War II, nationalist movements took root in many colonial countries, accusing colonialism of deliberately retarding economic development and claiming independence as a precondition for social advance and higher production and material standards. Industrialization became the battle cry of awakened nationalism in the colonial and semicolonial countries, and it was their main policy goal after independence. The equation of colonialism with poverty and of independence with improved living standards was a powerful factor in the success of the nationalist movements. At the same time, the weakened condition of the European colonial powers after World War II made it impossible to hold down all the colonies by force.

India and Burma became independent in 1947 and 1948, the former being at once partitioned into the Indian Union and the new state of Pakistan. In the following years most of the former colonies acquired their independence, in most cases by a peaceful transition. Colonialism of the old type thus steadily disappeared; the winds of change blew over Africa; new states appeared in Southeast Asia. The Latin American states, although developing, had been politically independent since the early 19th century, and this suggests that political sovereignty could not of itself remove economic dependence. What was sometimes called the Third World—to distinguish it on the one hand from the advanced capitalist countries and on the other from the noncapitalist states of eastern Europe, the Soviet Union, and China—was still greatly involved with the capitalist world market.

The disappearance of colonialism

Links with the capitalist world. This involvement took a number of forms. First, there was the stake of foreign capital in mines, oil wells, plantations, and even manufacturing industry. Short of measures of expropriation, these forms of economic colonialism remained. Thus, the newly independent states not only continued to export mainly primary products but also control of their production and sale, and therefore the profits, remained with the extra-territorial companies based in the United States or in the old colonial metropoles. Second, new industries and economic growth usually required foreign participation, if not control. Practically every newly independent state sought foreign private capital and thus had to offer guarantees against expropriation.

Moreover, the political aspects of the question were complicated by the victory of the Chinese Communists in 1949 and by the wars in Malaysia, Korea, and Indochina. Military and economic aid, especially by the United States, became part of the policy of containment intended to keep the former colonies and semicolonies within the orbit of world capitalism and to strengthen resistance to "Communist aggression." This often meant supporting regimes that resisted the kind of changes involved in development policy.

While direct government aid had an overtly political motive, private capital flowed more or less according to economic opportunity. It was attracted predominantly by the existence of raw materials, especially nonferrous metals and petroleum. Developing areas lacking such resources found it difficult to attract private capital; and, in any case, countries undertaking development required imports of machinery and materials and, in some cases, foodstuffs, involving chronic balance of payments deficits that could only be covered by outside aid and investment. Their economies were thus crucially underpinned by capitalist governments and corporations whose motives have primarily been to ensure supplies of raw materials on favourable terms, to sell commodities in a privileged market, and to open up profitable fields for investment. Industrial growth and industrialization in the developing countries have thus depended primarily upon the initiative of their own governments.

The example of India. Although there is no typical developing country, India epitomizes in a dramatic form many of the problems of development and economic growth. After 1951 India launched a series of five-year plans intended to modernize agriculture and establish an industrial base with a large measure of state participation ostensibly designed to establish a "Socialist pattern of society." In the early 1970s India contained about one-sixth of the human race, its population was growing at about 20 percent each decade, and its per capita income was one of the lowest in the world. Something like 70 percent of the population was occupied in agriculture or living off the land. Despite the existence of modern industrial plants, only about 2 percent of the population was employed in industry. While the masses remained illiterate, there was a highly educated elite and an old established industrial and commercial bourgeoisie. Agriculture was still mainly carried on by primitive methods, while the village, the caste, and the traditional culture provided the framework for the lives of the rural masses.

India's five-year plans

Indian planning has differed fundamentally from the Soviet in that, although it has set targets, it has been able to influence directly only that part of industry under state control. The major part of the economy remains privately owned and unplanned in the sense that the resources it will absorb, the foreign exchange it will require, and its contribution to total income cannot be foreseen. Industrialization depends upon capital accumulation, and in India it requires the import of capital equipment, especially in the early stages, and tends to increase dependence upon the world market both for materials and for markets for manufactured goods. Since it has not been possible to produce a sufficient surplus for investment in India or to direct the surplus produced into the requisite channels, development has continued to depend upon a flow of foreign capital and aid. Foreign capital, therefore, remains of great importance, some of the most modern sections of industry being foreign owned or joint enterprises with foreign firms.

Under the five-year plans there has been a considerable industrial expansion, and optimists feel that a basis has been laid for future industrialization. But, the rapid rate of population increase has meant that per capita income may have fallen during the 1960s. In some areas there has been a significant improvement in cultivation methods, favouring the larger and richer farmer; but the fact that there has not been much change in the agrarian system remains a severe handicap. The spheres of state and private capital have been determined pragmatically. Although some say that Indian planning has subserved the profit-making interests of the private sector, others believe it has inhibited private enterprise. In any case, there is little doubt that private capital has found rewarding outlets in trade and finance as well as in industry.

The Indian experience remains the most impressive attempt to industrialize a developing, former colonial country, without the expropriation of capitalists and landlords, while conserving the forms of parliamentary government. Its success or failure will be of importance not only to Indians but also to the increasingly awakened peoples of the Third World everywhere.

The experience of Latin America. Although each Latin American country has a unique history, the area as a whole provides an interesting comparison with India. Becoming independent in the early 19th century, Latin American states developed economically as suppliers of export staples to the developing world market dominated first by Britain and later by the United States. Where the production of the exports gave rise to urbanization and the growth of a labour force and a local bourgeoisie, a domestic market for manufactured goods came into existence. A basis therefore existed for factory industry, notably in textile production. At the same time, the richer segment of the population was able to afford more sophisticated manufactured imports.

The effects of the Great Depression on Latin America

Latin America was strongly affected by the Great Depression, which reduced world demand for primary products. Cutting off earning power stimulated a number of countries to industrial activity that was essentially producing substitutes for imports without necessarily reducing the previous forces favouring industrialization. The situation during World War II tended in the same direction, and a general expansion of the home market was made possible by the renewed demand for primary exports. The more advanced countries, such as Brazil and Argentina, displayed such trends most clearly.

Since World War II most Latin American countries have had serious economic difficulties, the extent and nature of which has varied according to the country's primary exports. In the 1950s, for instance, stagnation in the agrarian–pastoral economy of Argentina and Uruguay led to balance of payments difficulties and a low growth rate in the manufacturing sector. But other countries, such as Brazil, also had acute instability and inflation problems. The shift toward industry has been too slow to increase per capita income in view of the rapid rate of population growth. Thus, despite a considerable absolute increase in manufacturing output, the region as a whole suffers from under-development. In particular, while there is a reasonably prosperous urban middle class to provide a market for manufactured consumer goods, the great mass of the peasantry and urban wage earners exist in poverty. This duality of the market limits the economies of large-scale production and causes sharp social tensions.

Problems of dependence on primary products

The Latin American economies continue to depend on the export of one or two primary products and are variously dominated by U.S.-based foreign corporations that account for a good deal of manufacturing production serving the higher income groups in the home market. Profits are either used to expand local plants or repatriated to the United States. Industrialization tends, therefore, to be extremely lopsided, despite some state-encouraged investment in capital goods industries. The great mass of the population has benefitted little if at all from industrialization. Their poverty limits the possibility for home market growth and helps to explain the Latin American countries' disappointing economic performance in the 1960s. The general picture is one of great social contrasts in which modern factories and urban areas coexist with primitive agriculture and mass poverty aggravated by a high rate of population increase. Powerful vested interests both in the traditional ruling class and the newly emergent elite are opposed to structural change. The U.S. corporations and the U.S. government are also opposed to political changes necessary to break the social deadlock.

Africa. By 1914 Africa had been divided up between the European powers and brought into the world market through the development of rail and water transport and the establishment of port and harbour facilities. There was great unevenness of economic development reflecting the type of primary product being exploited and the extent of white settlement. In some colonies production of export staples was in the hands of peasant farmers; in others, of plantations established with European capital. Where mineral resources were developed the pattern was to recruit black labour, usually by near coercive methods. Economic control of the African colonies was firmly in the hands of extra-territorial companies, and as trade grew it was often conducted mainly by immigrants, such as Indians in East Africa or Syrians on the west coast. The scope for the emergence of a native bourgeoisie in black Africa was therefore limited.

Primary production in Africa followed the price fluctuations in the world market: stimulated by World War I, production declined during the Depression but expanded during World War II and the postwar boom. Periods of boom encouraged further investment, most of which concentrated on minerals production, largely in the countries of white settlement—the Rhodesias and South Africa. The rise of largely European urban communities created a home market that encouraged industrialization. At the same time, black labour was cheap and abundant, and, under the pressure of a developing money economy, indigenous tribal society was undermined, and a large, uprooted urban proletariat came into being.

Economic development over Africa as a whole was extremely uneven down to World War II, many areas remaining backward and primitive. With the outbreak of the war a new era in African history began, still marked by great unevenness but bringing it rapidly into a world economy with an unlimited and apparently permanent demand for African exports. Inevitably, however, the existing political and social structure had much to do with the way in which this new prosperity was distributed and used. In the countries of white supremacy, existing patterns were confirmed and maintained by policies of discrimination against Africans. In the black African colonies, on the other hand, nationalist movements grew in importance, led by the educated elite that colonial governments had reared and drawing support from the developing bourgeoisie and the peasantry. During the 1950s and 1960s the British, French, and Belgian colonies gained independence, while Portugal continued to maintain its colonial hold despite nationalist movements.

The growth of nationalist movements in Africa

The frontiers of the new black African states corresponded with those of the former colonies. That meant fragmentation, and tribal rivalries within the new states, such as Nigeria and the Congos, could break out into civil war. The states were weak politically and economically and remained dependent upon markets and capital in the advanced capitalist countries. Despite postwar changes and economic expansion, they remained primary producers and, despite a boom in exports, still lacked the basis for rounded economic development. Meanwhile, they experienced all the problems of development, which were aggravated whenever world demand for their staple exports slackened.

The outlook for the future. The less developed countries will undoubtedly become of growing significance in the closing decades of the 20th century. Political independence has not enabled them to industrialize rapidly nor to adapt inherited structures to the modernization of their societies. It has failed to break their economic dependence on a world market dominated by the advanced capitalist countries in which they must sell a small number of specialized primary products. For more rapid growth a number of conditions have to be satisfied. Industrialization—the means to rising incomes—requires capital, either domestically generated or obtained from the more advanced countries. Agricultural output has to be increased to feed a growing population, and masses of the rural unemployed and underemployed must be provided with more productive work. Population increase must be controlled. Education has to be improved and technical skills disseminated on a wide scale. Markets for the produce of these countries have to expand, and a place has to be found on the world market for growing exports of manufactured goods if their industrialization is to succeed.

As the developing countries have found out, such objectives are not easy to achieve. They require coherent programs and plans; they are opposed not only by the old property-owning classes and traditional vested interests but also by those of the bourgeoisie that are satisfied with the existing relationship with foreign capital. Thus, more rapid change may require a social revolution, but the fear of social revolution frightens off foreign capital or may invite retaliatory measures by the extra-territorial corporations or by foreign governments. The problems of

development, therefore, are basically political problems, the key to which is not to be found exclusively in the developing countries themselves.

The ability of the new nations to overcome hunger, disease, and illiteracy, let alone to provide for the mass of the people a level of material existence considered tolerable in the advanced countries has not yet been proven. The economic history of the rest of the 20th century undoubtedly will be concerned very much with their struggle to do so. In particular, different methods of development are under test, as are the possibilities of overcoming the problems of development without social revolution in the developing countries and a fundamental change of approach in the advanced countries.

(T.Ke.)

BIBLIOGRAPHY

From c. 1500 to c. 1750: The most satisfactory survey at a readable level is HERBERT HEATON, *The Economic History of Europe*, rev. ed. (1948). *The Cambridge Economic History of Europe*, vol. 4, *The Economy of Expanding Europe in the Sixteenth and Seventeenth Centuries*, ed. by E.E. RICH and C.H. WILSON (1967), treats the context of expansion in greater depth (population, discovery, prices, science, government policy, economic ideas, etc.). CARLO M. CIPOLLA (ed.), *The Economic Decline of Empires* (1970), usefully brings together a collection of essays on the phenomenon of national decline, including that of Italy, Spain, and The Netherlands in this period. On European agriculture, B.H. SLICHER VAN BATH, *De agrarische Geschiedenis van West-Europa, 500–1850* (1960; Eng. trans., *The Agrarian History of Western Europe, A.D. 500–1850*, 1963), is both comprehensive and original, linking agrarian development closely to price and demographic movements. Mercantilist ideas and policies in Europe are the subject of ELI F. HECKSCHER, *Der Merkantilismus*, 2 vol. (1932; Eng. trans., *Mercantilism*, 2nd ed., 2 vol., 1955); though dinted by criticism, this remains a classic, especially on French and German history. HENRI SEE, *Les Origines du capitalisme moderne* (1926), is a valuable and pithy French contribution to the evolution of commercial, industrial, and finance capitalism. Though nearly half a century old, GEORGE L. BEER, *The Old Colonial System, 1660–1754*, 2 vol. (1912), remains an excellent reference book on early European colonial rivalries. VIOLET BARBOUR, *Capitalism in Amsterdam in the Seventeenth Century* (1950), gives a valuable domestic view of Dutch growth that can be complemented by the vivid study of their overseas empire in CHARLES R. BOXER, *The Dutch Seaborne Empire, 1600–1800* (1965). For the Low Countries as a whole, see J.A. VAN HOUTTE, *Economische en Sociale Geschiedenis van de Lage Landen* (1964). For the most recent and highly detailed study of Antwerp, see HERMAN VAN DER WEE, *The Growth of the Antwerp Market and the European Economy*, 3 vol. (1963). FRIEDRICH LUTGE, *Deutsche Sozial- und Wirtschaftsgeschichte* (1960), is useful for all aspects of German economic history. JAIME VICENS VIVES, *Apuntes del curso de historia económica de España* (1955; Eng. trans., *An Economic History of Spain*, 1969), is the best general survey of Spanish economic problems. For the now classic view of the impact of American silver, see E.J. HAMILTON, *American Treasure and the Price Revolution in Spain, 1501–1650* (1934). A good general survey of France during the *ancien régime* is provided by the *Histoire économique et sociale de la France*, vol. 2, written by a distinguished team of French historians and edited by FERNAND BRAUDEL and ERNEST LABROUSSE (1970). Professor Braudel also wrote the remarkable study of southern Europe in the 16th and 17th centuries, *La Méditerranée et le monde méditerranée à l'époque de Philippe II* (1949). The relationship of French economic development and government policy is the subject of several studies by the American scholar CHARLES W. COLE. The two most important are *Colbert and a Century of French Mercantilism*, 2 vol. (1939, reprinted 1964), and *French Mercantilism, 1683–1700* (1943, reprinted 1965). CHARLES WILSON, *England's Apprenticeship, 1603–1763* (1965), deals with all aspects of England's development leading to the Industrial Revolution. The influence of commercial policy is the special concern of LAWRENCE A. HARPER, *The English Navigation Laws* (1939, reprinted 1964); while P.G.M. DICKSON, *The Financial Revolution in England, . . . 1688–1756* (1967), is the most recent study of an often neglected but vital subject—public finance.

From c. 1750 to 1914: The literature on industrial change and economic development is enormous, and any selective bibliography must of necessity slight important aspects of the subject. A good overview of the process, with heavy quantitative emphasis, is provided by SIMON S. KUZNETS in *Economic Growth and Structure: Selected Essays* (1965) and *Modern Economic Growth: Rate, Structure and Spread* (1966). For the history of technology proper, see MELVIN KRANZBERG and CARROLL W. PURSELL, JR. (eds.), *Technology in Western Civilization*, 2 vol. (1967), offering an uneven but invaluable array of specialized essays. Also useful, though more impressionistic, is SIGFRIED GIEDION, *Mechanization Takes Command* (1948, reprinted 1969). There are a number of works that treat of development on a comparative basis: thus DAVID S. LANDES, *The Unbound Prometheus: Technological Change and Industrial Development in Western Europe from 1750 to the Present* (1969); and WILLIAM ASHWORTH, *A Short History of the International Economy, 1850–1950*, 2nd ed. (1962). W.W. ROSTOW (ed.), *The Economics of Take-off into Sustained Growth* (1963); and M.M. POSTAN and H.J. HABAKKUK (eds.), *The Cambridge Economic History of Europe*, vol. 6, *The Industrial Revolutions and After*, pt. 1–2 (1965), also provide material on the experience of different countries, set side by side, however. On the relations between population and economic change, the best international coverage is provided by DAVID V. GLASS and D.E.C. EVERSLEY (eds.), *Population in History* (1965). There are also important studies of different national experiences: On Britain, PETER MATHIAS, *The First Industrial Nation: An Economic History of Britain, 1700–1914* (1969); PHYLLIS DEANE, *The First Industrial Revolution* (1965); ERIC J. HOBSBAWM, *Industry and Empire* (1968). PHYLLIS DEANE and W.A. COLE, *British Economic Growth, 1688–1959*, 2nd ed. (1967), strongly emphasizes the analysis of statistical time series. DONALD N. MCCLOSKEY (ed.), *Essays on a Mature Economy: Britain After 1840* (1971), is a valuable collection of essays in the so-called new economic history and stresses the analysis of Britain's alleged economic decline in the last part of the 19th century. On the European economy, the old classic of JOHN H. CLAPHAM, *Economic Development of France and Germany, 1815–1914*, 4th ed. (1936), is still useful. It should be supplemented by the articles from European writers that have been translated into English and edited by FRANCOIS CROUZET, W.H. CHALONER, and W.M. STERN, *Essays in European Economic History, 1789–1914* (1969). Some of the essays in ALEXANDER GERSCHENKRON, *Economic Backwardness in Historical Perspective* (1962), are helpful in organizing the data on the European experience. Also interpretative is TOM KEMP, *Economic Forces in French History: An Essay on the Development of the French Economy, 1760–1914* (1971). RONDO CAMERON, *France and the Economic Development of Europe, 1800–1914* (1961), is a study in the migration of capital and entrepreneurship. On the economic history of central Europe, the best sources are not in English: PIERRE BENAERTS, *Les Origines de la grande industrie allemande* (1933); RUDOLF BRAUN, *Industrialisierung und Volksleben*, 2 vol. (1960); WOLFRAM FISCHER (ed.), *Wirtschafts- und Sozialgeschichtliche Probleme der frühen Industrialisierung* (1968). A good general introduction to agricultural economics and change is to be found in the old but still useful JOHN A. VENN, *The Foundations of Agricultural Economics*, 2nd ed. (1933). The best overall history is B.H. SLICHER VAN BATH (*op. cit.*). On the agricultural changes of the 18th and 19th centuries, English historians have made the greatest contribution. See, for example, J.D. CHAMBERS and G.E. MINGAY, *The Agricultural Revolution: 1750–1880* (1966); also E.L. JONES (ed.), *Agriculture and Economic Growth in England, 1650–1815* (1967). MICHEL MORINEAU, *Les Faux-semblants d'un démarrage économique, agriculture et démographie en France au XVIII^e siècle* (1971), is a skeptical view of alleged agrarian advances in France in the 18th century and a useful comparison of the French with the British experience. Overall histories of transportation tend to be popularizations. The classic study of WILLIAM T. JACKMAN, *The Development of Transportation in Modern England*, 2 vol. (1916; 2nd ed. 1 vol., 1965), is still useful. Perhaps the best study of this kind for the United States, though dealing with a limited aspect of the subject, is LOUIS C. HUNTER, *Steamboats on the Western Rivers* (1949). The most exciting works in this field in recent years have been the monographs of the new economic historians, which have tended to minimize the contribution of the railroad to American economic development: ROBERT W. FOGEL, *Railroads and American Economic Growth* (1964); ALBERT FISHLOW, *American Railroads and the Transformation of the Ante-Bellum Economy* (1965). These studies have given rise to controversy and further research; the final results are not yet in. On banking, both RONDO CAMERON *et al.*, *Banking in the Early Stages of Industrialization* (1967); and RAYMOND W. GOLDSMITH, *Financial Structure and Development* (1969), offer comparative perspectives. LELAND JENKS, *The Migration of British Capital to 1875* (1927), remains a classic, for both content and style. The most substantial study of European banking and economic development is by MAURICE LEVY-LEBOYER *Les Banques européennes et l'industrialisation internationale dans la première moitié du XIX^e siècle* (1964). There is no overall treatment of the social consequences of industrialization. A few

works, however, may be cited for either their originality or quality of presentation. The student of labour history will still find much of value in SIDNEY and BEATRICE WEBB, *Industrial Democracy* (1897, reprinted with slight changes 1920). Dealing with an earlier period and stimulating and provocative for its moral indignation is EDWARD P. THOMPSON, *The Making of the English Working Class* (1963). On the French side, GEORGES DUVEAU, *La Vie ouvrière en France, sous le Second Empire* (1946), gives a comparably personal evocation of working class life. JOHN R. KELLETT, *The Impact of Railways on Victorian Cities* (1969), deals with a previously neglected aspect of the relationship between economic change and the condition of life.

The diffusion of the Industrial Revolution from its original centre in western Europe to the rest of the world is a subject in itself. For some of the countries treated in this article, the following works are useful: On the United States, H.J. HABAKKUK, *American and British Technology in the Nineteenth Century: The Search for Labour-Saving Inventions* (1962); and NATHAN ROSENBERG (ed.), *The American System of Manufactures* (1969). For Japan, WILLIAM W. LOCKWOOD (ed.), *The State and Economic Enterprise in Japan* (1965), is the best overall treatment; more quantitative and less interpretative in emphasis is HENRY ROSOVSKY, *Capital Formation in Japan, 1868–1940* (1961). For Russia, two recent studies place special emphasis on the diffusion of technology: WILLIAM L. BLACKWELL, *The Beginnings of Russian Industrialization, 1800–1860* (1968); and JOHN P. MCKAY, *Foreign Entrepreneurs and Russian Industrialization, 1885–1913* (1968). There is a growing literature on the economics of technical change. See, for example, the book of that title edited by NATHEN ROSENBERG (1971); also EDWIN MANSFIELD, *The Economics of Technological Change* (1968); W.E.G. SALTER, *Productivity and Technical Change* (1960); and JACOB SCHMOOKLER, *Invention and Economic Growth* (1966). Finally, the reader should be directed to two works that it is easy to omit because they are so obvious: ADAM SMITH'S *Wealth of Nations*, and vol. 1 of KARL MARX'S *Capital*.

1914–70: SHEPARD B. CLOUGH and THOMAS and CAROL MOODIE (eds.), *Economic History of Europe: Twentieth Century* (1968), a useful collection of documents with explanatory text for the period 1914–46; WILLIAM A. LEWIS, *Economic Survey, 1919–1939* (1949, reprinted 1969), still the best brief account of this period for the student; HEINZ W. ARNDT, *Economic Lessons of the Nineteen-Thirties*, 2nd ed. (1963), a pioneer study of the causes and consequences of the world economic depression; INGVAR SVENNILSON, *Growth and Stagnation in the European Economy* (1954), an influential study made under the auspices of the United Nations by a Swedish economist—a diagnosis of Europe's economic ills between the wars; PAUL ALPERT, *Twentieth Century Economic History of Europe* (1951), one of the first textbooks covering the first half of the century; JOHN MAYNARD KEYNES, *The Economic Consequences of the Peace* (1919, reprinted 1971), a prophetic attack on the Versailles settlement by an economist who was to become one of the most important intellectual forces of the period; A.G. KENWOOD and A.L. LOUGHEED, *The Growth of the International Economy, 1820–1960* (1971), basic facts and explanation of the world trading and monetary system for the student; CARLO M. CIPOLLA, *The Economic History of World Population* (1962), an interesting study of the population problem by a well-known economic historian for the nonspecialist; SIDNEY POLLARD, *The Development of the British Economy, 1914–1967*, 2nd ed. (1969), the fullest account of the problems of the world leader of pre-1914 years under pressure and in decline; LOUIS M. HACKER, *The Course of American Economic Growth and Development* (1970), the last four chapters provide a useful account of the period; SUMNER H. SLICHTER, *Economic Growth in the United States* (1963), a critique of Keynes and the stagnationist thesis; JOHN KENNETH GALBRAITH, *The Great Crash, 1929* (1955), a brilliantly written description of the gyrations of the stock market in 1929 and the sequel; MAURICE H. DOBB, *Soviet Economic Development Since 1917*, 6th ed. (1966), a very full study of Soviet industrialization, with apologetic overtones; ALEC NOVE, *An Economic History of the U.S.S.R.* (1969), a more critical view with emphasis on recent developments; WILLIAM W. LOCKWOOD (ed.), *The State and Economic Enterprise in Japan* (1965), a collection of essays that provides an introduction to the reasons for Japan's spectacular emergence as an industrial giant; ANGUS MADDISON, *Economic Growth in Japan and the U.S.S.R.* (1969), a summary picture and comparison with statistical backing—makes a good starting point for the student; CELSO FURTADO, *The Economic Development of Latin America* (1970), the problems of underdevelopment in historical perspective; GUNNAR MYRDAL, *Asian Drama*, 3 vol. (1968), a massive study of the poverty of nations by a renowned scholar—poses the problems in a generally pessimistic framework; MICHAEL M. POSTAN, *An Economic History of Western Europe, 1945–1964* (1967), the postwar recovery and economic boom as seen by the doyen of British economic historians (a pioneer work); ROBERT LEKACHMAN, *The Age of Keynes* (1966), the life and times of the man who, more than any other, set his mark on the economic policies of the capitalist countries in the period since the depression of the 1930s.

Economic Planning

This article deals with central economic planning by governments, and not with the economic plans of individuals and business firms. It is divided into the following sections:

I. The nature of economic planning
II. Economic planning in Communist countries
  Origins of planning in the U.S.S.R.
  Structure of the Soviet planning system
  Planning in other Communist countries
  Assessment of Soviet-type planning
III. Economic planning in developed non-Communist countries
  Origins of planning in the West
  Objectives of planning
  Stages of planning
  Assessment of planning in developed countries
IV. Economic planning in developing non-Communist countries
  Approaches to development planning
  Difficulties in development planning

I. The nature of economic planning

The various forms of planning

By the late 1960s the majority of the world's countries conducted their economic affairs in the framework of a national economic plan. This was a far-reaching change from a generation earlier, when national economic planning existed only in the Soviet Union and, to some extent, Nazi Germany. It should be emphasized that planning takes various forms. In the Soviet Union it is based on state ownership of the means of production, while in western Europe it is thought to be consistent with a large degree of private ownership. The essential idea behind economic planning is that certain key economic decisions should be made, or at least influenced, by some central authority, rather than left to the free play of market forces. In theory it would be perfectly possible to have a high degree of central economic planning in an economy in which everything was privately owned. It would also be possible in theory to have an economy in which, though the means of production were owned by the state, there would be practically no central economic planning in the usual sense of the word. The basic point—that state ownership is not the same as economic planning, and that private ownership is not the same as laissez-faire—is an important one for understanding the history of the idea of economic planning and also for understanding the attitudes toward planning in the modern world.

For the purposes of this article, distinction is made between economic planning in Communist countries, in developed non-Communist countries, and in developing non-Communist countries. Historically, the idea of economic planning was associated with the criticism of capitalism as a system of anarchy and greed. The critics did not give much thought to how the economy would be run after capitalism had been abolished; most of them professed to see no difficulty in organizing the society that would follow. When in 1917 the new Soviet government found itself the owner of all the means of production, it had no blueprint as to what to do next. The evolution of central economic planning in the Soviet Union was largely a pragmatic affair; methods were tried and discarded, and new ones were introduced. The decision in 1927 to undertake rapid and large-scale industrialization required the centralizing of control, since only the government could undertake the task of marshalling the productive resources of the country to achieve its ambitious aims. In western Europe economic planning is adapted to, and can benefit from, the existence of a diversified economic structure, a dynamic class of business managers, and a long tradition of political and economic

liberty. Consequently, although planning implies an extension of the economic responsibilities and activities of the state, the mainspring of economic growth remains the private sector. Only rarely does the state intervene directly in the affairs of individual firms. Economic planning remains indirect and takes the form of collaboration between the public and the private sectors. Producers and consumers are free to adapt their activities to changes in market conditions and relative prices.

Communist methods of planning since the mid-1950s have been in a state of flux, and the highly centralized administrative type of planning inherited after the war from the U.S.S.R. by all the newly established Communist states has undergone considerable modifications. In Yugoslavia planners have followed policies very different from those of the Soviet model, and differences also exist in the practice of other eastern European countries. In the Soviet Union itself, a debate concerning the most appropriate means for implementing plans has been under way for some years, but by the early 1970s, despite numerous efforts on the part of the government to reorganize the machinery of planning, fundamental obstacles had still to be overcome.

The knowledge of these difficulties has given rise in the developing non-Communist countries to a repugnance to Soviet planning methods, while the methods used in the developed non-Communist countries are felt to be not directly applicable, either. There is no settled planning doctrine in these countries, and the approach of governments has remained empirical. In practice, this has meant that the state played a major role in setting up new industries and in modernizing agriculture, particularly in countries of recent independence. The state budget was a major source of savings, supplemented frequently by the local currency counterpart of foreign aid. But the absence of a highly qualified civil service placed limits upon the extent and efficacy of state action. Thus, in urban areas, privately owned businesses continued to supply most local consumer goods. In agriculture, peasant proprietorship or large private estates—particularly for export products—remained the general rule. (Jo.Hac.)

II. Economic planning in Communist countries

ORIGINS OF PLANNING IN THE U.S.S.R.

Soviet improvisations

The kind of economic planning that is practiced in the Soviet Union and in most other Communist countries developed during the 1920s and 1930s in the struggle to industrialize the U.S.S.R. The Bolsheviks had seized power in 1917 without any clear notion as to how an economy should be run. No guidance was to be found in the writings of Karl Marx other than the assertion that a socialist society would operate the economy for the common good, which suggested that it would create organs of economic administration to replace the market system of capitalism. In the future Communist society there would be no money, no profit motive. No wages would be necessary to stimulate effort. It would be "from each according to his ability, to each according to his needs." Economics, a science of exchange relationships or value, would wither away or be replaced by a kind of higher management. "People will be able to manage things very simply, without the intervention of the famous 'value'," wrote Marx's collaborator Friedrich Engels in *Anti-Dühring* (1877–78). In the same tradition, the Bolshevik leader N.I. Bukharin wrote in 1920: "As soon as we deal with an organized national economy, all basic 'problems' of political economy, such as price, value, profit, etc., simply disappear . . ., for here the economy is regulated not by the blind forces of the market and competition but by the consciously implemented plan."

The leader of the Bolsheviks, Lenin, shared these somewhat utopian expectations. It is not clear from his pre-1917 writings just what kind of economic organization he had in mind for Russia should he achieve power. As it turned out, the revolution of October 1917 was accompanied by economic breakdown, a refusal of cooperation from officials and managers, civil war, and uncontrollable inflation. Partly under the stress of these circumstances, partly from ideology, the Bolsheviks moved to establish thoroughgoing state control over industry and trade, nationalized all economic property including land, declared all private enterprise illegal, and demanded that the peasants deliver all farm surpluses to state procurement organs. Money lost all value.

On paper, this period of "war communism" was one of centralized planning. All economic units, except the peasant producers, were subjected to orders from the governments's Supreme Council of National Economy (V.S.N.Kh.). But this initial essay in planning was a failure—except insofar as it facilitated the concentration of the few available resources for the civil war fronts. Rationing functioned spasmodically, there was famine, and output fell drastically.

From Lenin to Stalin

The controversies of the 1920s. In 1921 Lenin introduced the New Economic Policy (NEP). Small-scale private manufacturing, private trade, and free sale of peasant surpluses became legal once again, while the state retained the "commanding heights" (large-scale industry, foreign trade, banking, transport, etc.). The state sector continued to be operated under the aegis of V.S.N.Kh. by trusts and enterprises with state-appointed managers. In 1921 the State Planning Committee (Gosplan) came into existence to advise the government and its economic alter ego, the Council of Labour and Defense; but planning was still a shadowy process. Trusts and enterprises had considerable autonomy and were free to make agreements and grant credits to one another. The planners made forecasts, and government policy decisions influenced the level and direction of state investments; but there was no integrated system of production and allocation planning, even in the state sector, while the private sector was not directly planned at all. In 1924 only 35 percent of the national income, 1.5 percent of agricultural production, less than half of all retail trade, and three-quarters of industrial output were "socialized"; the rest was private.

In 1926–28 a vigorous discussion raged about the future basis of planning. Two schools of thought developed, one advocating "genetic" and the other "teleological" planning. The former, composed of the more moderate and cautious planners, believed that plans should be based on existing trends in the economy and reasonable projections thereof. The latter considered that drastic measures were necessary to speed up the industrialization of the country, and this "teleological" school produced extremely ambitious drafts of the First Five-Year Plan. The radicals conceived the plan as taking precedence over all previous economic decisions so as to enable a sharp break with the past. It was their view that won.

Priority for heavy industry

First Five-Year Plan. The First Five-Year Plan (1928–1932), which was later said to have been carried out in four years, called for immense investments in heavy industry; for example, steel output was to be more than doubled by 1932. Amid great confusion, the planning mechanism was overhauled, and gradually a "command economy" was established. In this system, subordinate units of the economy (*e.g.*, industrial enterprises) operated in accordance with administrative instructions, and they did not decide their inputs or outputs by negotiation with other enterprises, these being determined by the planners. The sole effective criterion of management decision became conformity to plan; *i.e.*, to the instructions issued by the central administrative planning organs (see below). In this way, the political authorities achieved a high degree of control over resource allocation and were able to enforce their priorities. Consequently, when the First Five-Year Plan ran into trouble, the government was able to insist on the fulfillment of most of the plans for key sectors of heavy industry, at the cost of a drastic fall in availability of consumers' goods.

STRUCTURE OF THE SOVIET PLANNING SYSTEM

Control from the top

A rearrangement of the planning system was the necessary consequence of the new tasks it was called upon to perform. In 1932 three People's Commissariats (for heavy, light, and timber industries) replaced the V.S.N.Kh; these were further split, and by 1939 the industries of the U.S.S.R. were run by 21 People's Com-

missariats (the numbers varied in subsequent years). Each commissariat (renamed ministry in 1946) controlled a branch of industry, either directly or through a ministry in one of the union republics. (There were also purely local, small-scale industrial establishments, controlled by republican or local soviets.) The ministries issued instructions to "their" enterprises, organized the supply of materials and components, and also disposed of the output. This organization according to sectors facilitated the handling of problems common to each separate industry, but necessarily put a heavy burden on the coordinating organ, Gosplan.

At the apex of the system stood, and still stand, the leaders of the Communist Party, who decide the policy objectives in economic as in other matters and who make choices as to the means of achieving those objectives. It was the party leaders who decided, in 1957–58, to make drastic changes in fuel policy, to launch the virgin-lands campaign in Siberia (1954), and to greatly expand the chemical industry (1963). The government's role is to carry out the decisions of the party. All key appointments in the economic hierarchy are made or confirmed by appropriate party committees.

The work of Gosplan. It is Gosplan's task to "translate" the politically determined objectives into a consistent set of plan targets. There must be coherence between production and supply at all times, as well as between investment plans and the current production of capital goods. Foreign trade must also be taken into account, as a drain on available resources (exports) and as a source of needed goods (imports). The planners proceed by drawing up a series of material balances, which express anticipated supply of, and demand for, all key commodities. The successive versions of the plan are revised until a general balance is attained, since it is no use planning an increase in production of any item if the necessary additional machinery, raw material, and fuel cannot be made available. The task is of especial complexity in the short term (*i.e.*, within a period of a year), since the plan must take the form of millions of consistent instructions to thousands of enterprises to produce, deliver, transport, and process millions of commodities of a great many shapes, sizes, and types.

Balancing supply and demand

Needless to say, all these decisions must be made somewhere in all economic systems. The Soviet type of "command economy," however, developed under Stalin, provides no criterion for decentralized decision making such as is provided, however imperfectly, by the market mechanism in Western capitalist countries. Consequently, the coordination of all these decisions must be consciously achieved by the planners. The enterprises and other local organs can put forward their own plans and suggestions, as well as applications for material inputs, and this certainly influences what the planners do and know; but in the last analysis, only the centre can be aware of the needs of the economy as a whole. This became apparent after the reforms of May 1957 scrapped the industrial ministries and sought to base planning on territorial economic councils (*sovnarkhozy*) in the republics and regions, with Gosplan as the coordinating body. The object, insofar as it was economic, was to strengthen inter-industrial coordination, regional, republican, and national, at the expense of ministerial industrial "empires." It was soon found necessary to tighten central control, and the resultant proliferation of coordinating agencies and state committees greatly complicated an already highly complex planning process. This led in 1965 to the abolition of the territorial councils and the restoration of the industrial-sector ministries. In the 1960s there were vigorous and far-reaching discussions of reforms in the system, designed to overcome some of its known weaknesses, which spring essentially from the sheer volume of decision making. The latter had led to a considerable de facto dependence on low-level decisions and also on information that it often suited the enterprise management to withhold: For example, since bonuses and promotions depend on plan fulfillment, it "paid" management to argue for a modest plan, to conceal potential, and to hoard materials and equipment (in case supplies did not match production plans, which, owing to the fragmentation of the planning mechanism, they quite often did not).

Proposed reforms. The growth of the economy, itself evidence of the success of the system as an engine of growth, has led to greatly increased complexity. The fact that various components of the plan, originating in different offices, often fail to match one another gives subordinate organs a choice as to which orders to obey.

Reformers in the 1960s were concerned, first of all, with finding ways of adapting the newly developed electronic computer and programming techniques to the tasks of the planners, both in the process of allocation and in making rational choices between alternatives; they were also concerned with seeking criteria for decentralization. They hoped to achieve the latter by utilizing the profit motive and by making prices reflect in some measure supply and demand conditions and opportunity cost, instead of being based on average costs of some previous year. Discussions and cautious experiments were continuing, though no fundamental changes had been attempted by 1971. Detailed production and supply planning was still to a great extent centralized, and prices still failed to reflect supply and demand conditions. The idea of a socialist market or competitive price system remained unacceptable. Speeches at the 24th Party Congress (March–April 1971) reaffirmed the refusal of the leadership to make the basic changes in the centralized "directive planning" system, while seeking to make it more efficient and technologically advanced. The amalgamation of enterprises into large industrial associations, or trusts, was expected to improve matters. The reformers were not silenced, however; in particular, the mathematical economists continued to urge a combination of computerization and the market system.

Agricultural planning

Agricultural planning has had a peculiarly difficult history. With priority given to industrialization, agriculture during the regime of Joseph Stalin was essentially treated as a source of cheap food and materials for the cities. The peasants were, in fact, expropriated by force in the period 1930–35, and the bulk of them were compelled to join collective farms (*kolkhozy*), which were nominally a form of voluntary cooperation. While in Soviet ideology, state farms, operated like factories with wage labour, were preferred to collective farms, they remained of relatively minor importance until after 1954. Mechanization was for many years confined to a very few crops and especially to grain growing. The entire system was primarily designed to ensure deliveries of produce at low prices, and the planners and administrators concentrated on procurements, while production plans were seldom, if ever, fulfilled. Under Nikita Khrushchev in the late 1950s and early 1960s there was a substantial change of policy, with greatly improved prices and a major investment program designed to restore agriculture to health. After initial successes, especially in the period 1955–58, reality again fell far short of planned growth. Endeavours to stimulate output on collective and state farms often took the form of centrally organized campaigns, which led to the imposition by party officials of practices and crop patterns that were unsound or harmful in particular areas. After the fall of Khrushchev, farm prices and incomes were increased and arbitrary intervention was diminished, with resultant gains in output. Peasant incomes greatly improved, but at the same time costs of production rose. Since, for political reasons, retail prices were not increased, a very large subsidy had to be paid out of the state budget (over $13,000,000,000, at the official rate of exchange, in 1971).

PLANNING IN OTHER COMMUNIST COUNTRIES

In other European Communist-ruled countries the Soviet system was extensively copied, even in minor details, until 1956. After that date it is not possible to generalize. In Poland there was talk of drastic reforms in the direction of a looser, market type of socialism, but shortages and low productivity checked the would-be reformers. Alone among this group of countries, the Poles did not collectivize the peasants, and so Polish agriculture was dominated by the private sector. In Czechoslovakia, a de-

centralizing reform, launched in 1958, was followed by some disorganization, caused partly by difficulties in foreign trade, on which that country is very dependent; and in the period 1960–64 the economy underwent a severe crisis, with growth virtually at a standstill. At the end of 1964 the Czechoslovaks adopted a sweeping reform, which went further toward decentralization. Attempts to work out a form of market socialism similar to that in Yugoslavia were halted by the Soviet intervention of 1968.

Efforts to decentralize

Yugoslavia. The Yugoslav Communists developed their own conception of socialist planning after their break with Moscow in 1948. The collectivization of agriculture was abandoned in the early 1950s. The control of the state-owned enterprises was given to workers' councils that would decide their own production programs according to profitability, with prices subject to negotiation. Investments were partly controlled by the enterprises themselves out of profits or by the central planners, partly financed from bank credits. An economic crisis in 1966–67 led to still greater measures of "liberalization," despite some dangerous growth in unemployment. The central authorities still retain a measure of overall economic control through their power to regulate the supply of money and bank credit, and through taxes. The authorities also have some control over price levels, including the power to fix a few key prices. The fact remains that Yugoslavia has for long had substantially more of a market system, and much less of administrative regulation, than other Communist countries.

Hungary. In 1968 Hungary adopted a system of market socialism that, while not going as far as Yugoslavia's, left each enterprise management very largely free to determine its own production program. The central planners were no longer to set obligatory production targets. While some prices remained controlled, others were set free. Enterprises were also given some freedom to buy and sell abroad, and efforts were made to link Hungarian prices with those on world markets. Profits became the principal measure of managerial success, and bonuses based on profits had an appreciable effect on managers' and workers' incomes. Large-scale investments were still controlled by the central planners, but the enterprises were required to finance roughly 40 percent of all investments out of their own resources.

The Soviet type of planning ran into serious difficulties in foreign trade, not least in trade arrangements between Communist-ruled states. Since each country planned centrally, and since (apart from Yugoslavia) none had, by the mid-1960s, a price system that reflected scarcities or needs, trade planning encountered a double obstacle—on the one hand, comparative cost calculations were all but impossible, and on the other hand, the necessary coordination required a supranational authority that could enforce a "socialist international division of labour," and no such authority existed. Efforts to create an effective international planning body encountered opposition from the less developed countries, notably Romania, which refused to accept any limitation on its own industrialization plans. A further difficulty arose when some countries adopted market-oriented reforms and others did not. A Council for Mutual Economic Assistance (Comecon or CMEA) had existed since 1949, supposedly coordinating the planning and trade of the European Communist states, but their trade remained predominantly bilateral rather than multilateral. A resolution adopted by Comecon in August 1971 aimed once again at integrating the plans, prices, and economies of the member countries.

China. Chinese Communist planning at first also followed the Soviet pattern. In 1958, however, came the "great leap forward," an effort to speed up progress by shifting rural manpower into manufacturing. This failed, and later it was admitted that production statistics in industry and especially agriculture had been greatly exaggerated. The quarrel with the Soviet Union contributed to industrial difficulties (the U.S.S.R. had been by far the largest supplier of capital equipment to China) and led the Chinese Communist leadership to devise its own planning methods, adapted to a vast country with poor communications and a low stage of economic development. In the mid-1960s the government stopped publishing regular economic statistics, and knowledge of Chinese economic performance was still scanty in the early 1970s. Production was thought to have been adversely affected by the internal political struggles of the late 1960s known as the Cultural Revolution.

ASSESSMENT OF SOVIET-TYPE PLANNING

The Soviet type of planning grew up under the special conditions prevailing in the U.S.S.R. and was adapted to the task of speedy industrialization of a poor country, with strong emphasis on heavy industry, explicable partly by the logic of industrialization (steel and machinery are more conducive to industrial growth than textiles and jam), partly by concern for military potential. The system made it easy for the authorities to attain a high rate of forced saving and investment and a rapid buildup of basic industries, though at the cost of neglecting for many years the elementary needs of the citizens. The plans were backed up politically by a one-party state and Stalin's system of terror.

Advantages and disadvantages of Soviet planning

Planning of the Soviet type has certain advantages compared to other systems of economic organization. The growth of the Soviet economy in the early 1930s, for example, was in striking contrast to the situation of the "capitalist" world at that time. Through their control over the level of economic activity, financial institutions, and personal incomes, the planners should be able to avoid inflation, the bugbear of economic development in many other countries. In their investment planning, they should be able to avoid the type of wasteful duplication that sometimes occurs under private enterprise through lack of knowledge of other people's investment intentions. The system should also make it possible to reconcile the conflict between short-term sectional profitability and long-term advantage. Insofar as the investment plans of most basic industries depend in the last resort on a quantitative estimate of future demand, the Soviet system is better adapted to making such estimates, since so much of the additional demand is a consequence of the planners' own decisions.

In practice, of course, Soviet-type planning is not always able to realize these potential advantages. There have been repeated instances of overinvestment, followed by the abandonment or freezing of partly finished projects. Inflation, with large, unplanned increases in prices and incomes, affected the U.S.S.R. in the 1930s, though price stability was reasonably well maintained during 1950–67. Experience has also shown that the separate administrative units into which a nationalized economy must be divided can take as narrow and short-term a view as any capitalist entrepreneur. Thus, the most easily accessible forests have been cut, the richest sources of iron ore exhausted, and fallow land put under the plow in order to fulfill current plans, with little consideration of the consequences. A centralized system of material balances is not insurance against erroneous forecasting; the demand for coal was greatly overestimated at the beginning of the 1950s in eastern and western Europe alike. The material-balances approach exercises a conservative influence, perhaps because it is simplest to plan on the assumption that the various technical coefficients will remain constant. The economy grows, but preserves its existing pattern, until the need for change has been overwhelmingly demonstrated. Thus the Soviet planners were very slow to turn from solid fuels to oil and gas and to shift from natural materials to synthetics and plastics. When change does come, it often has to be ordered by the top party leadership, and a political campaign is launched to catch up on arrears caused by past neglect. One must bear in mind, of course, that Western economies also have many imperfections. A theoretical model of centralized planning works as smoothly and as efficiently as a theoretical model of a perfectly competitive market, but neither exists in the real world.

Following the death of Stalin in 1953, the Soviet economic system was presented with new problems. It

showed itself unable to cope effectively with the finer adjustments required in a sophisticated industrial economy. It dealt very clumsily with the satisfaction of consumer demand, though this became more important in the changed political conditions, not only in the Soviet Union but in most of its European allies. The system was in urgent need of reform to save it from being overwhelmed by the complexities inherent in an attempt to base decision making on plans; *i.e.*, on command. Yet Soviet experience may have a marked appeal to those in developing countries (see below) who seek to achieve rapid and drastic changes. Insofar as rapid industrialization involves social and political coercion, the fact of such coercion in the history of Communist countries may be a source of attraction rather than revulsion. (A.No.)

III. Economic planning in developed non-Communist countries

Planning in a capitalist framework

Non-Communist countries that practice some explicit form of economic planning include Belgium, Finland, France, Germany, Ireland, Italy, The Netherlands, New Zealand, Norway, Portugal, Spain, Sweden, Great Britain, and Japan. Planning in these countries differs from the Soviet type of planning in that the economies are predominantly run by private enterprise, and the planning authorities seek to guide and influence private decision making rather than to make the decisions themselves.

ORIGINS OF PLANNING IN THE WEST

Until World War II there was no serious attempt at economic planning outside the Soviet Union. During the depression of the 1930s, many governments were forced to intervene vigorously in economic affairs, but in a manner that amounted to economic warfare; this intervention took the form of giving increased protection to domestic producers against competition from abroad; of acquiescing in the formation of cartels and other arrangements among producers to raise prices and reduce competition; and of higher levels of government spending, some of it for relief and some of it for armaments.

At the end of the war there was a shift to the left in the politics of some of the countries, and with it a turn to more positive forms of government intervention. In Great Britain the Labour Party secured a large majority in Parliament in 1945, and with it a mandate for policies aiming at more social equality. In Scandinavia, particularly in Sweden, moderate left-wing traditions in government made a transition to planning politically acceptable. In France, left-wing groups, including the Communist Party, emerged as the dominant political force after 1945 with programs of far-reaching social reform. More important, a group of eminent public servants, engineers, and business leaders—continuing a tradition of French 19th-century capitalism known as Saint-Simonianism—were in favour of the state taking a leading role in economic affairs.

While the initial impulse to planning came from the political left, actual decisions by governments to plan were based on practical considerations rather than on political doctrine. The decision to plan most often followed a crisis in a country's economic affairs, as was the case in France after World War II, when there was an urgent need to reconstruct and modernize the economy. In the United Kingdom, the setting up of a medium-term plan accompanied the emergency measures taken to deal with a balance of payments crisis in July 1961; and the Labour government's National Plan of September 1965 was formulated in similar circumstances. In Belgium and Ireland dissatisfaction with the past performance of the economy was a major reason for planning. Belgium had not shared in the European prosperity of the 1950s, and accordingly, in 1959, the government adopted a plan aimed at an increase of 4 percent a year in the gross national product, practically double the rate achieved from 1955 to 1960. Its planning methods were modelled on those of France (see below).

The French example also influenced planning in other European countries. In Great Britain, a Conservative government undertook, during a balance of payments crisis in July 1961, to set up a National Economic Development Council to draft a five-year economic plan that would emphasize much more rapid economic growth. The Netherlands, which had been very successful since the war in achieving balanced economic growth, initiated five-year plans in 1963 through the medium of the Central Planning Bureau, which had for some years been advising on national budgetary policies. Italy had first turned to planning in the 1950s, when a plan for the development of southern Italy was launched; later, attempts were made to extend this example of regional economic planning into a plan for the national economy. Even in West Germany, where the Christian Democratic governments had emphasized a policy of strengthening the free market, a need for some central management of the economy was increasingly recognized.

It may be said in general that planning in the developed countries does not represent an attempt to apply preconceived doctrines. Although left-wing parties are more ready to propose increased intervention by the state in economic affairs than are the more conservative ones, the attitudes and responses of governments in the 1950s and 1960s were mainly determined by practical considerations. The key factors were dissatisfaction with the performance of the national economy as compared with the economies of other countries, and the emergence of serious obstacles to a continuation of the upsurge that had begun in the late 1940s.

OBJECTIVES OF PLANNING

Growth, balance, and consistency

The plans drafted in the developed countries all postulate target rates of growth that are high by historical standards (usually 4 or 5 percent annually). They require that a choice be made in allocating rates of increase to the various kinds of expenditures on available goods and services (private and public consumption, social investment, directly productive investment, stocks, and exports). Further, as the plan has to be balanced, the total of these components of overall demand must fall within the probable total available supply of goods and services, after allowing for the desired level of the current balance of payments surplus. The rates of increase of some types of demand—directly productive investment and stocks in particular—are fixed within fairly narrow limits by technological considerations once the overall rate of growth of output has been chosen. But an important area of choice concerns the respective rates of growth of private consumption by individuals and what has come to be called collective consumption; *e.g.*, education, health, urban facilities, provision for culture.

Another planning objective that has become very prominent (and that figures in the plans of Great Britain, The Netherlands, France, and Italy, to mention only a few) is the correction of imbalances in regional development.

One of the most important functions of economic planning is to achieve consistency among different economic objectives. Some desirable goals are likely to conflict with others. While it may be possible, for example, to stimulate the economy so as to obtain sharply higher levels of output and employment, the measures required to do this may also produce rapidly rising prices, which in turn will lead to rising imports and falling exports; the result may be a balance of payments crisis.

STAGES OF PLANNING

Public discussions of objectives

Choosing the targets. One of the chief merits of national planning is that it publicizes the choices before a country and encourages discussion of them. In France, the Parliament is consulted on the broad outline of the five-year plan, which is presented in terms of a number of alternative balanced sets of objectives. More government spending on social services, for example, can be shown as implying a slower rise in individual incomes after taxes, or—a rather more difficult choice to make explicit—a higher growth rate can be shown as requiring greater willingness on the part of producers and consumers to adapt themselves to changes in markets and technology. Since 1964 the French government has pre-

sented the Parliament with an outline of the main options it favours for economic policy during the coming period. The document is appraised by an advisory body drawn from business, agriculture, the trade unions, and the professions and then submitted to a vote in Parliament. A year later, the complete plan, drafted according to the guidelines approved by the Parliament, comes back again for a final vote.

In other countries, the choice of objectives may be left to the government, which thus makes the plan a part of the program upon which it will stand or fall at the next election. Or the government may prefer to detach itself almost entirely from the plan. In West Germany, where planning is less explicit, projections of economic trends are set out in a technical document that does not have the formal status of a government draft and circulated to the governments of the *Länder* (states) and to employers and trade unions. Such projections are thought to have some influence on public thinking and on the expenditure plans of business and government. In Great Britain, since the Conservatives returned to power in 1970, there has been less enthusiasm for public discussion of planning objectives than there was under the preceding Labour government. The Dutch procedure is to leave the main responsibility for drafting projections of economic trends to the Central Planning Bureau. In that country, however, business and labour have generally been ready to take account of such projections when drawing up their own plans. In Belgium, after the period of strained relations between the main language groups during the 1960s, regional considerations have been very much to the fore in all planning discussions. In 1970 the institutional setting of the new plan for the years 1971–75 included three regional economic councils whose views were influential in the establishment of the national targets.

An important issue for the European countries in the 1970s has been the impact on their economies of the European Economic Community (Common Market). The British government's reluctance to commit itself to economic targets for several years ahead arose from uncertainty as to whether Britain would join the EEC. The French planners gave this same uncertainty as one of their reasons for keeping the targets in the plan for 1971–75 few in number.

Bringing the public into the planning process

Detailed drafting. Since targets in this type of planning do not constitute orders to producers and consumers to do or not to do particular things, the plan has to take account of what private firms say they intend to do, or could do, during the period of the plan. Drafting a plan, therefore, requires arrangements for bringing the representatives of the private sector—both employers and workers—into the planning process. This is usually done by setting up a tripartite body (the High Planning Council in France, the Council for Economic Planning in Sweden, for example) where representatives of the private sector are brought together with representatives of the government. These bodies have much greater responsibility for economic policy making than the older consultative committees that exist in all developed countries. In exchange, the representatives of the private sector are expected to commit their organizations to helping carry out the decisions made.

Detailed discussions on planned targets and ways of achieving them are frequently entrusted to tripartite committees, one for each major sector of activity. The French have 21 such committees, called modernization commissions, some of which—the horizontal commissions—deal with specific topics such as investment and its finance, regional policy, or manpower questions, the others being specialized by sectors of industry. In the United Kingdom, similar committees for major branches of industry were set up after 1963. It is important, although difficult, to ensure that the targets of the branches as regards investment, employment, and output do not conflict with each other and are consistent with the targets for the economy as a whole. The French try to avoid such conflict by giving each planning commission an outline of the overall plan as a starting point for its own projections. This procedure is said to facilitate coherence, since the individual commissions all work toward the same targets.

Government departments in most countries draft programs several years in advance for expenditure on such public projects as education, road building, urban improvement, and hospital construction. But it often happens that these programs are not mutually consistent. One of the advantages of an overall plan is that the confrontation and coordination between the various programs has to be done in an explicit manner. The task can be difficult; watertight administrative compartments are not always easy to break down.

Efforts to incorporate into the plan all that can be known about the intentions of the private and public sectors need to be supplemented by more general economic analysis. As has been stressed already, the plan should be, above all, coherent; and the best way of ensuring this is to build up the planned targets within the framework of the national income accounts. Since World War II, such accounts have been drawn up on an annual basis in all the developed countries. From this it is only a step to projecting the national accounts for several years ahead.

Recent innovations in planning

Earlier types of economic planning leaned heavily upon the method of economic balances. This consists of setting out the quantities of economic resources that will be available during the plan period and comparing them with the quantities demanded by the plan. Four balances are of key importance: the demand for and supply of goods and services; of savings; of manpower; and of foreign exchange. The notion of balance is a valuable one in planning, since no plan can be successful if it outruns the available resources. The method has its difficulties, however, because of the numerous interactions between different sectors of the economy, with the consequence that an adjustment in one set of balances requires adjustments in the others—a complex and time-consuming process. The method of balances is also unable to throw light upon a more fundamental aspect of economic decision making, the need to choose among alternative courses of action on their own merits.

Other methods of planning that have in varying degree replaced the method of balances include mathematical model making and cost–benefit analysis. A mathematical model consists of a series of equations that describes the structure and working of the national economy, enabling various sets of targets to be "tried out" by feeding their values into a computer. It is too early, however, to claim for economic models any clear superiority over the more pragmatic method of economic balances. The most systematic use of models has been in The Netherlands and France. In the Scandinavian countries, a strong mathematical tradition among economists has favoured their adoption.

Cost–benefit analysis, sometimes known as the planning–programming–budgetary system (PPBS), represents an effort to improve the planning of government expenditures. Starting from the fact that public expenditures are not sensitive to the economic considerations of price and profitability but that they nevertheless use up scarce resources that have economic value, PPBS attempts to provide rules of calculation when deciding upon the allocation of these resources. A first step is to break down public expenditure into its main functions and to divide each of the latter into programs that can be identified with government policy objectives. Then an effort is made to evaluate the effectiveness of each program in achieving its declared objectives, together with a consideration of alternative ways of achieving the same objectives and the costs of those alternatives. The United States government pioneered in the application of PPBS to government activities in the 1960s. Great Britain introduced it in the Ministry of Defence in the late 1960s and then began to extend it to other departments, particularly in education and science. In France, the government decided to apply the system in 1968, first in the Ministry of Defense and then in relation to energy, town planning, and such departments as posts and telegraph.

By the early 1970s PPBS had become an integral tool of national economic planning.

Carrying out of plans. In their planning, all the non-Communist countries leave a large margin of initiative to individual producers and consumers; *i.e.*, they rely upon market mechanisms rather than upon direct controls. There is no contradiction between this state of affairs and the existence of a plan. First, as already noted, the fact of associating the private sector with the drafting of the plan encourages its representatives to be dynamic in their behaviour, a prerequisite for any successful growth policy. Second, when a plan is drafted in this way, all sectors are encouraged in making their own plans to adopt the same general assumptions about the growth of the economy. In France, this aspect of planning is called "generalized market research." Third, participation in drafting the plan can help to make the representatives of the employers and workers more conscious of existing obstacles to growth and encourage them to find constructive solutions for overcoming them.

Problems of flexibility

But the government is not freed from participating actively in carrying out the plan. The government's budget and its monetary policy must be used in such a way that overall demand rises as steadily as possible along the desired growth path. The problem of avoiding checks to growth caused by balance of payments difficulties is likely to call for more direct means of influencing the private sector of the economy. That is why governments in developed countries are increasingly seeking to work out "incomes policies" to prevent undue increases in costs and prices. In some countries, planning and incomes policy tend to be linked.

If certain objectives in the plan are not likely to be achieved, it may be necessary to revise some of the targets. In Great Britain the overall growth target in the 1965–70 plan had to be abandoned as early as 1966 because the estimates of productivity growth had been set too high. The Fifth French Plan (1966–70) had to be revised following the social upheavals in May 1968. Ireland and Italy have also had to revise plans because of unanticipated crises.

Direct government intervention

There is no easy solution to the problem of how to reconcile five- or six-year plans with the need to adjust economic policy to the phases of the business cycle. In Japan, a country that has experienced several sharp though brief recessions since the end of the postwar reconstruction period, governments are willing to cut back their public expenditure programs and to take restrictive fiscal and monetary measures because they believe that the economy will soon rebound once the restrictive measures have done their work. Japan's remarkable economic growth has borne out this confidence. In the less flexible economies of western Europe, governments are more circumscribed in their action. France, Germany, and The Netherlands have instituted systematic reviews of their plan targets every one or two years and are quite prepared to revise the targets if necessary.

In addition to these general measures for implementing plans, some governments attempt to influence more directly the behaviour of private firms by granting depreciation allowances for investments and tax exemptions for some activities, such as expenditure on research. In France, which has gone further than most countries in using such measures to implement planned targets, large requests for medium-term credit from the banks are granted after consultation with the planning office, and private firms have to receive the permission of the Ministry of Finance before issuing debentures on the capital market.

But it is in the field of regional development policy that governments intervene most actively to influence the decisions of the private sector of the economy. There is widespread use in western Europe of tax incentives and grants from public funds to encourage private firms to expand in less developed regions. Frequently, permission to set up a new factory, or to expand an existing one, in already congested areas where labour shortages are acute is refused. In addition, governments endeavour to stimulate growth in the less developed areas by improving transport facilities, housing, and urban infrastructure generally. These efforts have not shown any significant success in raising incomes or reducing unemployment in the less developed regions. This does not mean that the regional policies have been without effect, however, for without them the regional disparities might have worsened. Present-day plans for regional development attempt to concentrate on a few selected "growth points" where it is thought that favourable geographical characteristics or the presence of raw materials or other advantages offer the most hope of success.

ASSESSMENT OF PLANNING IN DEVELOPED COUNTRIES

Economic growth as an object of policy

The acceptance of economic planning in a large number of countries and by a variety of political parties and governments indicates that it is now a permanent feature of national policy in many of the developed industrial countries. By the 1970s planning had become more flexible and selective than in earlier years. The general consensus was that the government should seek to create conditions in the private sector of the economy that would encourage growth; this would include measures to establish and maintain competition. The corollary was that governments should try to avoid applying detailed controls over the private sector in peacetime, since these lead to reduced efficiency.

Some critics of planning have charged that the planners put too much emphasis on measures to accelerate economic growth, overlooking the social costs involved. A difficulty with simple growth targets is that they do not measure the increase in side effects such as pollution, noise, and the destruction of nature; on the contrary, they show the expenditures on combatting these effects as part of the growth itself. (For example, expenditures on conservation or smog abatement are included in the statistics of national income and gross national product.) Similar contradictions are found in the easy equation of economic growth with the general welfare: it is possible for income per head of the population to rise while the incomes of certain groups fall; quite frequently, some groups, such as the aged, handicapped, unemployed, and certain ethnic groups, do not share in the increasing prosperity of their country. The general welfare obviously includes elements such as health, housing, education, and economic opportunity as well as economic growth. This concern with the qualitative aspects of economic growth has left its mark upon the objectives written into the economic plans, which increasingly spell out general social aims.

Governments have also adopted a more flexible approach to the setting of targets. During the 1960s, mainly under the influence of French practice, targets for the private sector were often spelled out in detail. But experience showed that elaborate targets were rarely achieved, although they were likely to be considered by public opinion as representing firm commitments by the government. Since then, care has been taken to distinguish between firm targets and estimates. The firm targets are set only for areas over which governments have a considerable degree of control. While the government may have some influence on output in manufacturing industry, this depends more directly upon such things as the state of business conditions abroad, the purchasing habits of consumers, trends in prices and incomes, and so on. It is noteworthy that Japan, which holds the record for economic growth since World War II, has never used detailed output targets in its multiyear plans. (Jo.Hac.)

IV. Economic planning in developing non-Communist countries

Since the end of World War II, it has become an accepted practice among the governments of the developing countries to publish their "development plans." These are medium-term plans, usually for a five-year period. The aim is to select a period long enough to include projects spanning a number of budget years but not so long as to delay periodic assessment of the development effort stretching over a series of plans. The development plan attempts to promote economic development in three

Why poor countries plan

main ways: (1) by increasing the overall rate of investment; (2) by carrying out special types of investment designed to break bottlenecks in production in important sectors of the economy; and (3) by trying to improve the coordination between different parts of the economy. Of these, the third is perhaps the most important and the least understood function of economic planning. The other two functions of planning cannot be efficiently carried out without effective economic coordination between the different government departments and agencies within the public sector and the private sector. In order to improve coordination it is necessary to spread reliable economic information to indicate the future course of the government's economic intentions and activities so that the people concerned, both in the public and the private sectors, may make appropriate plans of their own to bring them in line with the government's plan. In fact, this may be regarded as the main reason for publishing development plans, although this point is not always clearly appreciated by the governments that issue them.

APPROACHES TO DEVELOPMENT PLANNING

From simple to comprehensive planning

Listing of development projects. The newly independent countries, just starting to plan their economies, usually begin with a simple type of development plan. In most cases this is merely an ad hoc list of individually conceived social and economic projects that the various government departments have submitted for the plan. So long as the projects are well selected (say, to break some obvious bottlenecks in production) and are well designed in a technical sense, such a simple plan may be quite serviceable. But it tends to suffer from a number of weaknesses arising from insufficient coordination. (1) Since the projects are drawn up on a piecemeal basis in separate government departments, there is usually no systematic attempt to compare the relative costs and benefits of the schemes proposed by the different departments on a uniform basis. As a consequence, the collection of projects included in the plan may or may not represent the most productive pattern of investing the available resources of the government. (2) A lack of coordination frequently leads to wasteful duplication and a failure to take advantage of complementary relationships between individual projects. (3) A simple listing of the projects does not provide a clear-cut system of priorities in their implementation. Typically, the projects that are relatively easy to implement are pushed far ahead of others that, although requiring a longer time to prepare and implement, may contribute more directly to the expansion of national output and government revenue. This can have serious budgetary consequences when the projects that are easier to implement generally happen to be in the field of social welfare, education, and health and—although they may indirectly contribute to economic development in the longer run—entail an increasing stream of recurring government expenditure after their completion.

Integrated public investment plan. An obvious way of remedying these defects is to formulate a more systematic plan of the public investment program as an integrated whole. In order to do this, it is necessary to begin by making a careful estimate of the total amount and time pattern of the financial resources that the government expects to receive during the plan period from domestic sources and from external loans and aid. Next, it is necessary to make realistic estimates of the costs and benefits of the alternative investment projects within the public sector as a whole so as to select the most productive combination of projects, taking into account significant complementary relationships between the different projects. In selecting the best combination of projects to be included in the plan, it is necessary to pay special attention to the time pattern of costs and benefits. A poor country, with limited sources of government revenue, would have to discount future benefits heavily relative to the more immediate benefits and would have to give priority to the type of project with quicker returns in the form of expansion in output and tax yields over the type of project that may promise higher rates of return, but only in the more distant future.

The problems of carrying out an integrated public investment program serve to emphasize the crucial role of the annual budget in development planning. At the aggregate level, with a given amount of external aid, the stream of the total investable funds available to the government during the plan period depends on its ability to raise revenue (and borrow from domestic sources) and, equally important, to control its nondevelopment, or "consumption," expenditure year by year during the plan period. At the individual project level, the fact that a project requires a number of budget years to complete does not dispense with the need for annual budgetary controls to ensure that it is being implemented in stages, according to the timetable as originally planned. Indeed, it is only through the discipline of annual budgetary controls that a medium-term development plan is likely to be kept nearer the course as originally planned.

Planning the whole economy

Comprehensive planning. Few developing countries have submitted themselves to the budgetary discipline necessary for implementing an integrated public investment program. This has not deterred them, however, from jumping from a simple type of development plan to "comprehensive" economic planning, embracing both the public and the private sectors and regulating both the aggregate level of economic activity and its detailed composition. The drive toward comprehensive planning arises from various causes: from a distrust of the automatic working of the market mechanism and its ability to promote economic development; from a desire to assert national economic independence by government control of foreign trade and investment; and from the theories of economic development, fashionable during the 1950s, that emphasize the need for a "big push" to overcome technical indivisibilities and the need for a simultaneous setting up of a number of mutually supporting projects to enjoy the benefits of technical complementaries. The economic development plans published by the developing countries in the 1960s were fairly elaborate. The trend to "quantitative" planning encouraged the use of elaborate statistical estimates and projections even when the primary statistical sources on which these computations were based were often unreliable or conjectural. Advanced mathematical techniques were also increasingly employed.

Basically, there are three parts to such a development plan: (1) the target figures for increase in per capita income and consumption to be attained at the end of the plan (with estimated figures for the intermediate years during the plan); (2) estimates of the quantities of various resources, such as capital, manpower, and foreign exchange, needed to implement the target figures (including the time profile of the rate at which these resources will be required during the plan); and (3) parallel but independent estimates and projections of the quantities and the time pattern of these resources expected to be available both to the government and to the economy as a whole during the plan period. The elaborate planning documents issued by some developing countries may be described as attempts to quantify as far as possible the information required under the three heads and to test the formal consistency of the plan. This essentially consists in asking (a) whether the total amount of available resources is sufficient to meet the total requirements of resources as set by the target figures, and (b) whether the allocation of resources planned for different sectors is consistent with the detailed target figures for the increased output of different goods and services required for consumption and investment. When the resources required by some industries are intermediate goods (the output of other industries), input–output tables are frequently used to check whether the outputs of different industries are sufficient to supply not only the target figures for final use in the form of consumption and investment but also the "indirect use" required by other industries. The more advanced planning models using programming techniques then attempt to solve the further question (c) whether the planned pattern of allocat-

ing resources is the most efficient; *i.e.*, whether it minimizes the resources needed to meet the target figures as compared with other patterns.

DIFFICULTIES IN DEVELOPMENT PLANNING

In spite of increasing professionalism in the formulation of development plans on paper, the practical performance of the developing countries in implementing development plans of any complexity has not been very encouraging. Development plans, however elaborately formulated on paper, rarely get beyond the first and most obvious practical hurdle, viz., how to equate the total amount of investable resources required to fulfill the target rates of economic development set by the plan with the total supply of investable resources. This arises from the practice of starting with some minimum "politically acceptable" target rate of economic growth while optimistically assuming that the problem of providing the necessary resources will somehow look after itself. This is the opposite of realistic planning, which should start from the supply of available resources and find out the maximum possible rate of economic growth that can be got out of these resources. Sometimes, also, the plan may be deliberately drawn up larger than can be sustained out of the available domestic resources as an elaborate window-dressing exercise to obtain a greater amount of external aid. When external aid fails to fill the planned gap in resources, the typical reaction is not to reduce the size of the plan but to take the politically less painful (and the administratively simpler) expedient of keeping to the publicly declared target rates of the plan and then trying to fill the gap in resources out of "forced saving," which it is hoped will be generated by budget deficits and inflation. Unfortunately this "forced saving" approach has not worked in most developing countries, because the public soon loses confidence in the stability of the purchasing power of money as prices tend to rise in step with increases in government expenditure. The pressure of domestic inflation increases the pressure of demand for imports, while rising domestic production costs discourage expansion of exports.

The need for realistic targets

The balance of payments problem. This disequilibrium situation may be eased by raising the rate of interest to reduce the demand for investable funds and to encourage saving, and by devaluation of the currency to discourage imports and encourage exports. But the governments of the developing countries generally prefer to maintain artificially low rates of interest (lower than the prevailing rates in the advanced countries during the 1960s) and to supply cheap loans to the public sector and to some favoured sections of the private sector engaged in modern manufacturing industry. They are also reluctant to devalue for fear of further raises in prices through speculation and the higher costs of imported goods. Thus they tend to rely heavily on detailed administrative controls and import licensing to ration the scarce supply of investable funds and foreign exchange. The attempt to control the entire economy in detail through a network of direct administrative controls inevitably results in inefficiency and delays, aggravated by the inadequacy of the administrative machinery and a shortage of competent civil servants. The closer the "integration" planned between different sectors of the economy, the greater the damage to efficient coordination, since delay in one sector causes widespread delays in others.

The overlooking of qualitative factors. The main weakness of the formal "quantitative" economic development plans is that they distract attention from various qualitative factors, such as the practical capacity of the administrative machinery to implement the plan, the degree of political stability, and the extent of public confidence in the government's willingness and ability to carry out stated aims, which are crucial for the practical success of planning. The developing countries that are not well provided with these crucial qualities may do much better with a less comprehensive type of planning, making a greater use of indirect controls through the market mechanism and concentrating attention on the breaking of bottlenecks, particularly to the expansion of production in agriculture and export industries. Some developing countries have in fact succeeded in attaining rapid rates of growth just by concentrating on these vital sectors of the economy without an elaborate paraphernalia of planning. (H.My.)

BIBLIOGRAPHY

Developed countries: The best general introduction to the development of economic planning in western Europe is M.M. POSTAN, *An Economic History of Western Europe 1945 to 1964* (1967). Of a more technical nature are: B. HICKMAN (ed.), *Quantitative Planning of Economic Policy* (1965); and JOAN MITCHELL, *Groundwork to Economic Planning* (1966). The best general treatment of planning in Japanese context is G.C. ALLEN, *Japan's Economic Expansion* (1965). An assessment of three European experiments in planning from a rather critical standpoint is GEOFFREY DENTON, MURRAY FORSYTH, and MALCOLM MACCLENNAN, *Economic Planning and Policies in Britain, France and Germany* (1968). Three aspects of planning that are very much in the foreground of present-day discussions of planning are dealt with in HAROLD A. HOVEY, *The Planning-Programming-Budgeting Approach to Government Decision-Making* (1968); E.J. MISHAN, *The Costs of Economic Growth* (1967), a critique of excessive preoccupation with growth; and E.B. SHELDON and W.E. MOORE (eds.), *Indicators of Social Change* (1968), a discussion of the techniques of measuring social aspects of economic growth.

Communist countries: General works on the Soviet-type system of planning include: A. NOVE, *The Soviet Economy*, 2nd ed. (1969); and H.J. SHERMAN, *The Soviet Economy* (1969). Very useful, though somewhat introductory in character, are M.C. KASER, *Soviet Economics* (1970); and R. CAMPBELL, *Soviet Economic Power*, 2nd ed. (1967). For the history of Soviet planning, see A. NOVE, *Economic History of the U.S.S.R.* (1969); and the highly detailed and well-documented work of E.H. CARR and R.W. DAVIES, *Foundations of the Planned Economy*, 1926–29, 2 vol. (1970). A guide to discussions of economic reform in the Soviet Union is G.R. FEIWEL, *The Soviet Quest for Economic Efficiency* (1967). Much useful material is contained in two collections of studies prepared for the Subcommittee on Foreign Economic Policy of the Joint Economic Committee of the Congress of the United States, *New Directions in the Soviet Economy* (1966), and *Recent Trends in the Soviet Economy* (1970). For the mathematical approach to central planning, see L.V. KANTOROVICH, *The Best Use of Economic Resources* (1965; orig. pub. in Russian, 1959); V.V. NOVOZHILOV, *Problems of Cost-Benefit Analysis in Optimal Planning* (1970; orig. pub. in Russian, 1967); A. ZAUBERMAN, *Aspects of Planometrics* (1967); and J.P. HARDT *et al.* (eds.), *Mathematics and Computers in Soviet Economic Planning* (1967). Works on planning in central and eastern Europe include: A. ZAUBERMAN, *Industrial Progress in Poland, Czechoslovakia and East Germany, 1937–62* (1964); OTA SIK, *Plan and Market Under Socialism* (1967), a critique of central planning by the former head of the Czechoslovak planning commission; M.C. KASER and J.G. ZIELINSKI, *Planning in Eastern Europe* (1970). For planning in Yugoslavia, see B.N. WARD, *The Socialist Economy* (1967); T. WILSON and G.R. DENTON, *Economic Reform in Yugoslavia* (1968); and J.T. CRAWFORD, "Yugoslavia's New Economic Strategy: A Progress Report," in studies published by the Joint Economic Committee, Congress of the United States, *Economic Developments in Countries of Eastern Europe* (1970). A general comparative survey is N. SPULBER, *Socialist Management and Planning* (1971).

Developing countries: The best introduction to economic planning in the developing countries is W. ARTHUR LEWIS, *Development Planning: The Essentials of Economic Policy* (1966). It explains with arithmetical illustrations the various stages of drawing up a consistent development plan, but rightly emphasizes that economic policies are more important than formal planning techniques. ALBERT WATERSTON, *Development Planning: Lessons of Experience* (1965), gives a well-documented survey of development plans in various countries and is particularly good on the administrative and fiscal problems of development planning. A useful general survey of criteria for allocating investment resources is in G.M. MEIER, *Leading Issues in Economic Development*, 2nd ed., sect. 6 (1970). The general theoretical issues of balanced growth and the critical minimum size of development programs are discussed in H. MYINT, *The Economics of the Developing Countries* (1964). W.F. STOLPER, *Planning Without Facts* (1966), combines a case study of development planning in Nigeria with a pragmatic general approach to development planning.

(A.No./Jo.Hac./H.My.)

Economics

No one has ever succeeded in neatly defining the scope of economics. Economists used to say, with Alfred Marshall, the great English economist, that economics is "a study of mankind in the ordinary business of life; it examines that part of individual and social action which is most closely connected with the attainment and with the use of the material requisites of wellbeing"—ignoring the fact that sociologists, psychologists, and anthropologists frequently study exactly the same phenomena. Another English economist, Lionel Robbins, has more recently defined economics as "the science which studies human behaviour as a relationship between (given) ends and scarce means which have alternative uses." This definition—that economics is the science of economizing—captures one of the striking characteristics of the economist's way of thinking but leaves out the macroeconomic approach to the subject, which is concerned with the economy as a whole.

What economists do

Difficult as it may be to define economics, it is not difficult to indicate the sort of questions that economists are concerned with. Among other things, they seek to analyze the forces determining prices—not only the prices of goods and services but the prices of the resources used to produce them. This means discovering what it is that governs the way in which men, machines, and land are combined in production and that determines how buyers and sellers are brought together in a functioning market. Prices of various things must be interrelated in a certain manner; how does such a "price system" or "market mechanism" hang together, and what are the conditions necessary for its survival?

These are questions in what is called "microeconomics," the part of economics that deals with the behaviour of such individuals as consumers, business firms, traders, and farmers. The other major branch of economics is "macroeconomics," in which the focus of attention is on aggregates: the level of income in the whole economy, the volume of total employment, the flow of total investment, and so forth. Here the economist is concerned with the forces determining the income of a nation or the level of total investment; he seeks to learn why full employment is so rarely attained, even in industrialized countries, and what public policies should be followed to achieve higher employment or more stability.

But these still do not exhaust the range of problems that economists consider. There is also the important field of "development economics," which examines the attitudes and institutions supporting economic activity as well as the process of development itself. The economist is concerned with the factors responsible for self-sustaining economic growth and with the extent to which these factors can be manipulated by public policy.

Cutting across these three major divisions in economics are the specialized fields of public finance, money and banking, international trade, labour economics, agricultural economics, industrial organization, and others. Economists may be asked to assess the effects of governmental measures such as taxes, minimum-wage laws, rent controls, tariffs, changes in interest rates, changes in the government budget, and so on.

The size of the profession

In the 19th century, economics was the hobby of gentlemen of leisure and the vocation of a few academicians; economists wrote about economic policy but were rarely consulted by legislatures before decisions were made. Today, there is hardly a government, international agency, or large corporation that does not have its resident economist. According to an estimate of the National Science Foundation (U.S.), for instance, there were 11,000 economists in the United States in 1966. Clearly, much depends on how one defines the job of an economist: the list of the National Science Foundation is confined to persons whose chief competence is in any one of the recognized economic specialities. Of the 11,000 professional economists, about 4,500 were employed as teachers of economics; the rest worked in various research or advisory capacities, either for themselves, for industry, or for government. This leaves out of account many others employed in accounting, commerce, marketing, and business administration; they may think of themselves as economists, but their professional expertise falls within other fields. There are perhaps another 10,000 economists in the rest of the world—their numbers have never been counted. It would be reasonable to estimate the total number of professional economists in the world in 1970 at 20,000, a number that was apparently growing at about 5 percent per year. There were about 75 English-language journals in economics and another 25 in various foreign languages, with new ones appearing every year. This implies the publication of about 1,500 scientific papers per year, not to mention the 700 new books on economics published every year. This is indeed "the age of economists," and the demand for their services seems insatiable.

MAIN CURRENTS IN THE DEVELOPMENT OF ECONOMIC THOUGHT

The work of Adam Smith

The effective birth of economics as a separate discipline may be traced to the year 1776, when the Scottish philosopher Adam Smith published *An Inquiry into the Nature and Causes of the Wealth of Nations.* There was, of course, economics before Adam Smith: the Greeks made significant contributions and so did the medieval scholastics; from the 15th to the 18th century, an enormous pamphlet literature appeared that developed the implications of economic nationalism, a body of thought now known as "mercantilism"; for a brief period in the 18th century the French "physiocrats" developed a fairly sophisticated economic model; and several other 18th-century figures can compete with Smith for the title of "first economist." Nevertheless, Adam Smith wrote the first full-scale treatise on economics and, by his magisterial influence, founded what later generations were to call the "English School of Classical Political Economy."

Analysis of the market. The *Wealth of Nations,* as its title suggests, is essentially a book about economic development and about policies that promote or hinder development. In its practical aspects it is an attack on the protectionist doctrines of the mercantilists and a brief for free trade. But in the course of attacking "false doctrines of political economy," Adam Smith was led to analyze the workings of a free-enterprise system as a governor of human activity. In a competitive market each individual, being one among many, can exert only a negligible influence on prices; each must take prices as they come and is free only to vary the quantities bought and sold at given prices; yet the sum of all individuals' separate actions determines prices. The "invisible hand" of the market, as Adam Smith was fond of saying, assures a social result that is independent of individual intentions and thus creates the possibility of an objective science of economic behaviour. Adam Smith believed that he had found, in the competitive market, an instrument capable of converting "private vices" (like selfishness) into "public virtues" (like maximum production). But this is only true if the competitive system is embedded in an appropriate legal and institutional framework, an insight that Adam Smith developed at length but that was largely forgotten by later generations. Within this great tome on the theme of rich and poor nations was contained a simple theory of value (or prices), a crude theory of distribution, an even cruder theory of international trade, and a primitive theory of money; but with all their imperfections, these were the building blocks of classical and modern economics. The book's very fecundity gave it strength because it left so much for disciples to tidy up.

The later classical economists

Construction of a system. David Ricardo's *Principles of Political Economy and Taxation* (1817) was, in one sense, simply a critical commentary on the *Wealth of Nations;* in another sense, it gave an entirely new twist to the developing science of political economy. Ricardo invented the concept of the "economic model," a tightly knit logical apparatus consisting of a few strategic variables, an apparatus that was capable of yielding, after a bit of manipulation, results of enormous practical im-

port. At the heart of the Ricardian system is the notion that economic growth must sooner or later be arrested, owing to the rising cost of growing food on a limited land area. An essential ingredient of this argument is the Malthusian principle—enunciated in Thomas Malthus' *Essay on Population* (1798)—that population tends to increase up to the limits set by the existing supply of food, thus holding down wages. As the labour force increases, extra food to feed the extra mouths can be produced only by extending cultivation to less fertile soil or by applying capital and labour to land already under cultivation (with diminishing results because of the so-called law of diminishing returns). Although wages are held down, profits do not rise proportionately because tenant farmers outbid each other for superior land. The chief beneficiaries of economic progress, therefore, are the landowners.

Since the root of the trouble, according to Ricardo, is the declining yield of wheat per unit of land, one obvious solution is to import cheap wheat from other countries. Eager to show that Britain would benefit from specializing in manufactured goods and exporting them in return for food, Ricardo hit upon the "law of comparative costs" as proof. He assumed that, within countries, labour and capital are free to move in search of the highest returns; between countries, however, they are not. In these circumstances, Ricardo showed, the benefits of trade are determined by a comparison of costs *within* each country, rather than by a comparison of costs *between* countries. It pays a country to specialize in the production of those goods that it can produce *relatively* more efficiently and to import everything else; although India may be able to produce everything more efficiently than England, India is nevertheless well advised to concentrate its resources on textiles, in which its efficiency is relatively greater, and to import British capital goods. The beauty of the argument is that if all countries take full advantage of the territorial division of labour, total world output is certain to be larger than it will be if some or all countries try to become self-sufficient. Ricardo's law became the fountainhead of 19th-century free-trade doctrine, which would have been enough, if he had said nothing else, to give him a place in the economists' pantheon.

Ricardo's influence

The influence of Ricardo's treatise was felt almost as soon as it was published, and for over half a century the Ricardian system dominated economic thinking in Britain. In 1848 John Stuart Mill's restatement of Ricardo's thought in his *Principles of Political Economy* brought it new authority. After 1870, however, most economists turned their backs on the range of problems that had concerned Ricardo and began to re-examine the foundations of the theory of value; that is, they became interested in the theory of why goods exchange at particular prices, so that for a while they devoted almost all of their efforts to the problem of resource allocation under conditions of perfect competition.

Marxism. A few words must first be said, however, about the last of the classical economists, Karl Marx. The first volume of *Das Kapital* appeared in 1867; the second and third after his death, in 1883 and 1894. For a generation, therefore, the competitive market theorists jostled with the followers of Marx. By 1900 the intellectual battle was over, and thereafter professional economists largely lost interest in Marx. Despite the Russian Revolution, despite what amounts to official endorsement of Marxism in one-third of the world, and despite the lingering influence of Marx's ideas, Marxian economics has been moribund ever since Marx's death in 1881. If Marx may be called "the last of the classical economists," it is because to a large extent he found his economics not in the real world but in the teachings of Smith and Ricardo. They had espoused a "labour theory of value," which holds that products exchange roughly in proportion to the labour costs incurred in producing them. Marx worked out all the logical implications of this theory and added to it "the theory of surplus value," which rests on the axiom that human labour alone creates all value and hence constitutes the sole source of profits. It is an axiom in the sense that it cannot be established in terms of the theory itself: it must be imported from without. To say that an economist is a Marxian economist is in effect to say that he shares the value judgment that it is socially undesirable for some people in the community to derive their income merely from the ownership of property. Since few professional economists in the 19th century accepted this ethical postulate and most were indeed inclined to find some social justification for the existence of private property and the income derived from it, Marxian economics fell on deaf ears. The Marxian system, moreover, culminated in three great generalizations: the tendency of the rate of profit to fall, the growing impoverishment of the working class, and the increasing severity of business cycles, of which the first is the linchpin of all the others. Marx's exposition of the "law of the declining rate of profit" is invalid; with it all of Marx's other predictions fall to the ground. In addition, Marxian economics had little to say on some of the practical problems that are the bread and butter of economists in any society. This is enough to suggest why Marxian economics failed to make many converts among academic economists. Marxists will reply that the reason is simply that academic economists have always been "lackeys of the capitalist class." Perhaps so, but the fact remains that Marx has had virtually no effect on modern economic thought.

The three generalizations of Marxism

The marginalists. The marginal revolution was essentially the work of three men: Stanley Jevons, an Englishman; Anton Menger, an Austrian; and Léon Walras, a Frenchman. Their contribution was the replacement of the labour theory of value by the marginal utility theory of value; their explanation of prices began with the behaviour of consumers in choosing among increments of goods and services (see UTILITY AND VALUE, ECONOMIC). The idea of emphasizing the marginal or last unit proved in the long run to be more significant than the introduction of utility. It was the consistent application of marginalism that marks the true dividing line between classical theory and modern economics. The classical political economists saw the economic problem as that of predicting the effects of changes in the quantity of capital and labour on the rate of growth of national output. The marginal approach, however, focussed on the conditions under which these factors tend to be allocated with optimal results among competing uses—optimal in the sense of maximizing consumers' satisfactions.

Throughout the last three decades of the 19th century, the English, Austrian, and French contributors to the marginal revolution largely went their own way. The Austrian school dwelt on the importance of utility as the determinant of value and vehemently attacked the classical economists as completely outmoded. A brilliant second-generation Austrian economist, Eugen von Böhm-Bawerk, applied the new ideas to the determination of the rate of interest, putting his stamp for all time on capital theory (see CAPITAL AND INTEREST). The English school, led by Alfred Marshall, sought a reconciliation with the doctrines of the classical writers. The classical authors, Marshall argued, concentrated their efforts on the supply side in the market; marginal utility theory was concerned with the demand side, but prices are determined by both supply and demand, just as a pair of scissors cuts with both blades. Marshall, seeking to be practical, applied his "partial equilibrium analysis" to particular markets and industries.

The leading French marginalist was Léon Walras, who carried the approach furthest by describing the economic system in general mathematical terms. For each product there is a "demand function" that expresses the quantities of the product that consumers demand as depending on its price, the prices of other related goods, the consumers' incomes, and their tastes. For each product there is also a "supply function" that expresses the quantities producers will supply as depending on their costs of production, the prices of productive services, and the level of technical knowledge. In the market, for each product there is a point of "equilibrium"—analogous to the equi-

librium of forces in classical mechanics—at which a single price will satisfy both consumers and producers. It is not difficult to analyze the conditions under which equilibrium is possible for a single product. But equilibrium in one market depends on what happens in other markets (a "market" in this sense being not a place or location but a complex of transactions involving a single good), and this is true of every market. There are literally millions of markets in a modern economy, and therefore "general equilibrium" involves the simultaneous determination of partial equilibria in all markets. Walras' efforts to describe the economy in this way led the historian of economic thought Joseph Schumpeter to call his work "the Magna Carta of economics." Walrasian economics is undeniably abstract, but it provides an analytical framework for incorporating all of the elements of a complete theory of the economic system. It is not too much to say that nearly the whole of modern economics is Walrasian economics. Certainly, modern theories of money, of employment, of international trade, and of economic growth are all Walrasian general equilibrium theories in a simplified form.

The neoclassical era

The years between the publication of Marshall's *Principles of Economics* (1890) and the Great Crash in 1929 may be described as years of reconciliation, consolidation, and refinement. The three national schools gradually coalesced into a single mainstream. The theory of utility was reduced to an axiomatic system that could be applied to the analysis of consumer behaviour under various circumstances, such as a change in income or price. The concept of marginalism in consumption led eventually to the idea of marginal productivity in production, and with it came a new theory of distribution in which wages, profits, interest, and rent were all shown to depend on the "marginal value product" of a factor. Marshall's concept of "external economies and diseconomies" was developed by his leading pupil, Alfred Pigou, into a far-reaching distinction between private costs and social costs, thus laying the basis of welfare theory as a separate branch of economic inquiry. There was a gradual development of monetary theory, which explains how the level of all prices is determined as distinct from the determination of individual prices, notably by the Swedish economist Knut Wicksell. In the 1930s the growing harmony and unity of economics was rudely shattered, first by the simultaneous publication of Edward Chamberlin's *Theory of Monopolistic Competition* and Joan Robinson's *Economics of Imperfect Competition* in 1933 and then by the appearance of John Maynard Keynes's *General Theory of Employment, Interest and Money* in 1936.

The critics. Before going on, it is necessary to take note of the rise and fall of the German Historical school and the American Institutionalist school, which levelled a steady barrage of critical attacks on the orthodox mainstream. The German historical economists, who had many different views, basically rejected the idea of an abstract economics with its supposedly universal laws; they urged the necessity of studying concrete facts in national contexts. While they gave impetus to the study of economic history, they failed to persuade their colleagues that their method was invariably superior. The institutionalists are more difficult to categorize. "Institutional economics," as the term is narrowly understood, refers to a movement in American economic thought associated with such names as Thorstein Veblen, Wesley Clair Mitchell, and John R. Commons. These writers had little in common aside from their dissatisfaction with the abstract theorizing of orthodox economics, its tendency to cut itself off from the other social sciences, and its preoccupation with the automatic market mechanism. They failed to develop a theoretical apparatus that would replace or supplement the orthodox theory. This may explain why the phrase "institutional economics" has become little more than a synonym for "descriptive economics." The hope that institutional economics would furnish a new interdisciplinary social science proved stillborn. (This is perhaps not surprising, because it was by abstracting purely economic forces from the totality of social interactions that economics got so far ahead of the other social sciences in theoretical rigour.) Although there is no longer an institutionalist movement in economics, the spirit of institutionalism is alive in such works as the Harvard economist John Kenneth Galbraith's *The Affluent Society* (2nd ed., 1969) and *The New Industrial State* (1967).

Returning to the innovations of the 1930s, the theory of monopolistic or imperfect competition remains somewhat controversial to this day. The older economists had devoted all their attention to two extreme types of market structure, that of "pure monopoly," in which a single seller controlled the entire market for one product, and that of "pure competition," characterized by many sellers, highly informed buyers, and a single, standard product. The theory of monopolistic competition gave recognition to the range of market structures that lie between these extremes, including (1) markets having many sellers with "differentiated products," employing brand names, guarantees, and special packaging that cause consumers to regard the product of each seller as unique; (2) "oligopoly," markets dominated by a few large firms; and (3) "monopsony," markets with a single monopolistic buyer and many sellers (see MONOPOLY AND COMPETITION). The theory produced the powerful conclusion that competitive industries in which each seller has a partial monopoly because of product differentiation will tend to have an excessive number of firms, all charging a higher price than they would if the industry were perfectly competitive. Since product differentiation—and the associated phenomenon of advertising—seems to be characteristic of most industries in developed capitalist economies, the new theory was immediately hailed as injecting a healthy dose of realism into orthodox price theory. Unfortunately, its scope was not great enough. It failed to provide a satisfactory theory of price determination under conditions of oligopoly. In advanced economies many of the manufacturing industries are oligopolistic. The result has been to leave a somewhat undigested lump at the centre of modern price theory, a constant reminder of the fact that economists still lack an adequate explanation of the conditions under which the giant firms of rich countries conduct their affairs.

Keynesian economics. The second major breakthrough of the 1930s, the theory of income determination, was primarily the work of one man—John Maynard Keynes. Keynes asked questions that in some sense had never been asked before; he was interested in the level of national income and the volume of employment rather than in the equilibrium of the firm or the allocation of resources. It was still a problem of demand and supply, but "demand" here means the total level of effective demand in the economy, and "supply" means the nation's capacity to produce. When effective demand falls short of productive capacity, the result is unemployment and depression; when it exceeds the capacity to produce, the result is inflation. The heart of Keynesian economics consists of an analysis of the determinants of effective demand. If one ignores foreign trade, effective demand consists essentially of three spending streams: consumption expenditures, investment expenditures, and government expenditures, each of which is independently determined. Keynes attempted to show that the level of effective demand so determined may well exceed or fall short of the physical capacity to produce goods and services: that there is no automatic tendency to produce at a level that results in the full employment of all available men and machines. This fundamental implication of the theory came as something of a shock to exponents of the traditional economics who had been inclined to take refuge in the assumption that economic systems tend automatically to full employment. By keeping his attention focussed on macroeconomic aggregates, like total consumption and total investment, and by a deliberate simplification of the relations between these economic variables, Keynes achieved a powerful model that could be applied to a wide range of practical problems. His system subsequently underwent considerable refinement—some

have said that Keynes himself would hardly have recognized it—and became thoroughly assimilated into the body of received doctrine (see INCOME AND EMPLOYMENT THEORY). Still, it is not too much to say that Keynes is perhaps the only economist to have added something really new to economics since Walras and perhaps since Ricardo.

Keynesian economics as conceived by Keynes was entirely "static"; that is, it did not involve time as an important variable. But a disciple of Keynes, Roy Harrod, soon developed a simple macroeconomic model of a growing economy; in 1948 he published *Towards a Dynamic Economics,* launching an entirely new speciality, "growth theory," which absorbed the attention of an increasing number of economists.

Developments after World War II

Mathematical economics. In the 25-year period following World War II, economics was so totally transformed that those who studied it before the war might as well have lived in another world. First of all, there was an enormous increase in the use of mathematics, which came to permeate virtually every branch of economics. Previously, few economists had made use of mathematics other than differential and integral calculus. Matrix algebra became important with the advent of "input–output analysis," an empirical method of reducing the technical relations between industries to a manageable system of simultaneous equations; it was an attempt to put quantitative flesh on the bones of a general equilibrium model of the economy. A closely related phenomenon was the development of "linear programming" and "activity analysis," which opened up a whole host of industrial problems to numerical solution and introduced economists for the first time to the mathematics of "inequalities" rather than exact equations. Likewise, the emergence of "growth economics" promoted the use of difference and differential equations.

Hand in hand with the spread of mathematical economics went an increasing sophistication of empirical work under the rubric of "econometrics," comprising a combination of economic theory, mathematical model building, and statistical testing of economic predictions. The development of econometrics had an impact on economics in general, since those who formulated new theories began to cast them in terms that allowed them to be empirically tested.

The postwar years also saw a renewal of interest in the underdeveloped countries. Economists became aware that they had too long neglected "an inquiry into the causes of the wealth of nations." There was also a conviction that economic planning of one variety or another was needed to close the gap between the rich and poor countries. Out of these concerns came the field of development economics. Regional economics, urban economics, health economics, and the economics of education are other offshoots of the mainstream since 1945.

The postwar tendencies in economic thought were best exemplified, not by the emergence of new techniques or by the addition of new parts to the economics curriculum but by the disappearance of divisive "schools," by the increasingly standardized professional training of economists all over the world, and by the transformation of the science from a rarefied academic exercise to an operational discipline geared to practical advice. This transformation brought prestige to the profession but also a new responsibility: now that economics really mattered, economics had to reckon with the conflict that so often exists between analytical precision and economic relevance.

The question of relevance was at the centre of a "radical critique" of economics that developed along with the campus revolts of the late 1960s. The radical critics declared that economics had become a defense of the status quo and that its practitioners had joined the power elite. The marginal techniques of the economists, ran the argument, were profoundly conservative in their bias, and encouraged a piecemeal rather than a revolutionary approach to social problems; likewise, the tendency in theoretical work to ignore the everyday context of economic activity amounted in practice to the tacit acceptance of prevailing institutions. The critics said that economics should abandon its claim of being a value-free social science and address itself to the great questions of the day—those of civil rights, poverty, imperialism, and nuclear war—even at the cost of analytical rigour and theoretical elegance.

It is true that the study of economics encourages a belief in reform rather than revolution; economics as a science does not provide enough certitude for any thoroughgoing reconstruction of the social order. It is also true that most economists tend to be deeply suspicious of monopoly in all forms, including state monopolies, and to favour competition between independent producers as a way of diffusing economic power. Finally, most economists prefer to be silent on large questions if they have nothing to offer beyond the expression of personal preferences: most economists as economists are fundamentally concerned with the professional standards of their discipline, and this may mean in some cases frankly conceding that economics has as yet nothing very interesting to say about these questions. (It does not mean, however, that they desire to justify the status quo.) Yet the radical critique of modern economics was not to be lightly dismissed. The radical economists were posing issues that were important. At the very least it could do the economic researcher no harm to think about the social and political relevance of his work.

ECONOMICS AS A SCIENCE

The role of value judgments

Economists are sometimes confronted with the charge that their discipline is not a science. Human behaviour, it is said, cannot be analyzed with the same objectivity as the behaviour of atoms and molecules. Value judgments, philosophical preconceptions, and ideological biases must interfere with the attempt to derive conclusions that are independent of the particular economist espousing them. Moreover, there is no laboratory in which economists can test their hypotheses.

This argument raises issues for all of the social sciences. Only a very general reply can be given here. Economists are wont to distinguish between "positive economics" and "normative economics." Positive economics seeks to establish facts: Will a subsidy to butter producers lower the price of butter? Will a rise in wages in the automobile industry reduce the employment of automobile workers? Will devaluation improve the balance of payments? Does monopoly foster technical progress? Normative economics, on the other hand, is not concerned with matters of fact but with questions of policy, of "good" or "bad": Should the goal of price stability be sacrificed to that of full employment? Should income be taxed at a progressive rate? Should there be legislation in favour of competition?

Positive economics in principle involves no judgments of value; its findings may be as impersonal as those of astronomy and meteorology, two natural sciences that are also denied the advantage of conducting laboratory experiments. As the British philosopher David Hume argued 200 years ago, there is no logical way to deduce "ought" from "is" or prescriptions from descriptions; all statements of fact are ethically neutral. In that sense a value-free economics is possible (at least in principle): if economics is about the application of means to achieve given ends, there would seem to be no reason why one cannot analyze the allocation of means to achieve *any* end. This is not to deny that most of the interesting economic propositions involve the addition of definite value judgments to a body of established facts, that ideological bias creeps into the very selection of the questions that economists investigate, that what is a means from one point of view may be an end from another, nor even that much practical economic advice is loaded with concealed value judgments, the better to persuade rather than merely to advise. This is only to say that economists are human. The commitment of economists the world over to the ideal of value-free positive economics (or to the candid declaration of personal values in normative eco-

nomics) serves as a defense against the attempts of special interests to bend the science to their own purposes. The best assurance against bias on the part of any particular economist is the criticism of other economists. The best protection against special pleading in the name of science is the professional standards of scientists.

Methods of inference. But how, one may ask, are facts established in a science that cannot conduct experiments? In essence, the answer is: by means of statistical inference. Economists typically begin by describing the area under study according to what they feel to be important. Then they construct a "model" of the real world, deliberately repressing some of its features and emphasizing others; they abstract, isolate, and simplify, thus imposing order on a world that at first glance appeared disorderly. Having evolved an admittedly unrealistic representation of the real world, they then manipulate the model by a process of logical deduction, arriving eventually at some prediction or implication that is of general significance. At this point, they return to the real world to see whether or not the prediction is borne out by observed events.

But the observable events that are available to test a theory never exhaust the population of all such events: they are merely a sample of it. This raises the problem of statistical inference; namely, what can be inferred about a population from a sample of the population? The theory of statistical inference is simply an agreed-upon procedure for making such inferences, but in the nature of the case it never succeeds in removing all elements of judgment from an inference. Thus the empirical truths of economics are invariably surrounded by a band of doubt, and economists speak of them as "probable" or "likely"; they are propositions in which economists have "a certain degree of confidence" because it is unlikely that they could have come about by chance.

It follows that judgments are at the heart of both positive and normative economics. It is easy to see, however, that judgments about "degrees of confidence" and "statistical levels of significance" are of a totally different order from those that crop up in normative economics. When men say that every individual should be allowed to spend his income as he likes, that people should not be free to control material resources and to employ others, or that governments must offer relief for the victims of inexorable economic forces, they are making the kind of value judgments that laymen have in mind when they accuse economists of producing personal preferences in the guise of scientific conclusions. There is no room for such value judgments in positive economics.

Testing theories. In the past some economists tended to claim too much for their propositions. Economic models were said to be based on fundamental axioms and premises about economic behaviour that were absolutely true a priori because they were derived from an examination of one's own economic behaviour. Since the theorems of the model were deduced from these axioms by the laws of logic, the theorems also were held to be true a priori. Economic models did not need to be confronted with empirical evidence.

This extreme apriorist position may be contrasted with the ultraempiricist view, which holds that one must begin and end with observable facts; the latter approach, however, has never appealed to more than a small minority of economists. In the middle ground between these two sharply opposing views is the methodological position that has found increasing acceptance among modern economists. It argues that one must test the predictions or conclusions of a model but without worrying too much about the realism of its premises, axioms, or assumptions. Most assumptions in economic theory cannot be tested directly. For example, there is the famous assumption of price theory that businessmen strive to maximize profits. Attempts to find out whether they do, by asking them, usually fail; after all, businessmen are no more fully conscious of their own motives than other people are. A logical approach would be to observe businessmen in action. But that would require knowing what sort of action is associated with profit maximizing, which is to say that one would have drawn out all the implications of a profit maximizing model. Thus one would be testing an assumption about business behaviour by comparing the predictions of a theory of the firm with observations from the real world.

The problem of validity

This is not as easy as it sounds. Since the predictions of economics partake of the nature of probability statements, there can be no such thing as a conclusive, once-and-for-all test of an economic hypothesis. The science of statistics cannot prove any hypothesis, it can only fail to disprove it. A theory that survives a statistical test is not true as such; it is only provisionally true because it has so far resisted all attempts to falsify it. Attempts to falsify economic hypotheses never yield unambiguous results, and hence economic theories tend to survive until they are falsified repeatedly with new or better data. This is not because they are *economic* theories but because the attempt to compare predictions with outcomes in the social sciences is always limited by the rules of statistical inference.

It is not remarkable that competing theories exist to explain the same phenomena, with economists disagreeing as to which theory is to be preferred. While virtually all economists today agree that theories should be submitted to empirical testing and that the theory is to be preferred that allows predictions that conform, in a probabilistic sense, most closely to observable events, this precept can be very difficult to apply in practice. There have been periods in the history of economics when there was overwhelming agreement in the profession as to which models or theories were "true." But a period of consensus may be followed by a generation of doubt until a new departure is made that succeeds in producing a new consensus. In this, economics is not very different from physics.

Much has been written about the doubtful accuracy of economists' predictions. Of course, economists cannot foretell the future as such; only soothsayers do that. Economists can foretell the effects of specific changes in the economy, but they are better at predicting the direction than the actual magnitude of events. When economists predict that a tax cut will raise national income, one may be confident that the prediction is accurate; when they predict that it will raise national income by a certain amount in three years, however, the forecast is likely to miss the mark. The reason is that most economic models do not contain any explicit reference to the passage of time and hence have little to say about how long it takes for a certain effect to make itself felt. Short-period predictions generally fare better than long-period ones, in part because most economic models rely on propositions about the plans and intentions of economic agents, whereas the data on which the theories are tested are derived from past events. This is disappointing, but it does not mean that economics is not a science.

MICROECONOMICS

The firm and the household

Since Keynes, economic theory has been of two kinds: macroeconomics—or the study of the determinants of national income—and the traditional microeconomics. The latter approaches the economy as if it were made up only of business firms and households (ignoring governments, banks, charities, trade unions, and all other economic institutions) interacting in two kinds of markets—product markets and markets for productive services, or factor markets. Households appear as buyers in product markets and as sellers in factor markets, where they offer men, machines, and land for sale or hire. Firms appear as sellers in product markets and as buyers in factor markets. In each type of market, price is determined by the interaction of demand and supply, and the problem of microeconomic theory is to say something meaningful about the forces that make up demand and supply.

Theory of choice. At first it appears that all one can say is that everything depends on everything else. But firms and households do not behave in a vacuum. Firms face certain technical constraints in producing goods and services, and households have definite preferences for some products over others. It is possible to express the

technical constraints facing business firms by writing down a series of "production functions," one for each firm. A production function is simply a kind of equation that expresses the fact that the output of a firm depends on the quantity of inputs it employs and, in particular, that inputs can be technically combined in different proportions to produce a given level of output. A production engineer could calculate, on the basis of existing technical knowledge, the largest possible output that could be produced with every possible combination of inputs and in this way could define a boundary to the range of production possibilities open to a firm. By itself this does not tell how much the firm will produce or what mixture of products it will make or what combination of inputs it will adopt: these depend on the prices of products and the prices of inputs (or "factors of production"), which have yet to be determined. One may assume that the firm is motivated in a particular way: it wants to maximize profits, which are defined as the difference between the sales value of its output and the money outlays required to obtain its inputs. It will, therefore, select that combination of inputs that minimizes the costs of producing any given quantity of output and will select from the range of possible combinations of products that combination that maximizes its revenues. This is to say that it always tries to move along its production function, along the edge of the boundary of technical possibilities. But where it ends depends, in part, on the demand for its products. This leads to the part played by households in the system.

Households are endowed with definite "tastes" that can be expressed in a series of "utility functions," one for each household. A utility function is an equation like a production function, expressing the fact that the pleasure or satisfaction that households derive from consumption depends on the products that they purchase and on the various ways in which they combine these products in consumption to yield a given level of satisfaction. The utility function need not be specified in the same detail as a production function. One may think of it as a general description of the household's preferences between all the paired alternatives with which it will be confronted. Here, too, it is necessary to assume something about motivation to make any progress: the assumption is that households seek to maximize satisfaction, distributing their given incomes among available consumer goods in such a way as to derive the largest possible "utility" from consumption. Their incomes, however, remain to be determined.

Supply and demand curves

The purpose of production functions in economic theory is to provide an anchor in the bedrock of technology from which to derive the "supply curves" of firms in product markets and the "demand curves" of firms in factor markets. Similarly, the purpose of utility functions is to provide an anchor in subjective "tastes" from which to derive the "demand curves" of households in product markets and the "supply curves" of households in factor markets. All of these demand and supply curves express the quantities demanded and supplied as a function of prices, not because price is the only determinant of economic behaviour but because the purpose is to have a theory of price determination. Much of economic theory is devoted to showing how various production and utility functions, coupled with certain assumptions about behaviour, lead to demand and supply curves in which the quantity demanded is inversely related and the quantity supplied positively related to price. The figure depicts these relationships (curves would be just as suitable as straight lines).

Not all demand and supply curves look alike. The essential point is that most demand curves are negatively inclined, while most supply curves are positively inclined. This may seem a modest result for a great deal of effort, but the argument has powerful implications. The participants in a market will be driven automatically to the price at which the two curves intersect; this price p is called the "equilibrium" price or "market-clearing" price because it is the only price at which supply and demand are equal. If it is a market for butter, any change in the

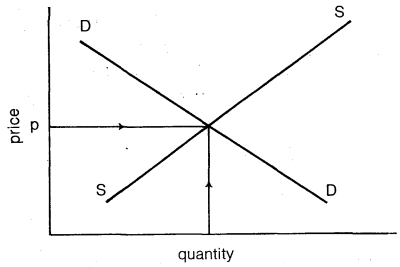

Illustration of the relationship of price to supply (S) and demand (D).

production function of dairy farmers or in the utility function of butter consumers or in the prices of cows, grassland, and milking equipment or in the incomes of butter consumers or in the prices of nondairy products that consumers buy can be shown to lead to definite changes in the equilibrium prices of butter and in the equilibrium quantity of butter produced. Better still, the effects of a government ceiling on the price of butter or of a tax on butter producers or of a price-support program for dairy farmers can be predicted with almost perfect certainty. As a rule, the prediction will refer only to the direction of change (the price will go up or down); but if the demand and supply curves of butter can be defined in quantitative terms on the basis of past data, one may be able to predict the actual magnitude of the change.

Theory of allocation. This analysis of the behaviour of firms and households is to some extent symmetrical: all economic agents are conceived of as ordering a series of attainable positions in terms of an entity they are trying to maximize. For a firm these attainable positions are essentially input combinations; for a household they are product combinations. From the maximizing point of view, some combinations are better than others; the best combination is called the "optimal" or "efficient" combination. The rule for efficient, optimum allocation may now be stated baldly: an optimum allocation is one that equalizes the returns of the marginal or last unit to be transferred between all the possible uses. In the theory of the firm, an optimum allocation of outlays among the factors of production implies that the "marginal physical product" of an additional dollar devoted to hiring the services of any one of the factors is the same for all factors; the so-called law of eventually diminishing marginal productivity, a property of a wide range of production functions, ensures that such an optimum exists. In the theory of consumer behaviour an optimum situation obtains when the consumer has distributed his given income in such a way that the "marginal utility" of each additional dollar spent on any of the products purchased is equal for all products; the "law of eventually diminishing marginal utility," a property of a wide range of utility functions, ensures that such an optimum exists. These are merely particular examples of the "equimarginal principle," which is not only at the core of the theory of the firm and the theory of consumer behaviour but also underlies the theory of money, of capital, and of international trade. In fact, the whole of microeconomics is nothing more than the spelling out of this principle in ever wider contexts.

The equimarginal principle is, of course, applicable to any decision that involves alternative courses of action. Economics furnishes a technique for thinking about decisions, whatever their character and whosoever makes them. Military planners may, for example, consider a variety of weapons in the light of a single objective, that of damaging an enemy; some of the weapons are effective against the enemy's army, some against the enemy's navy, and some against his air force; the problem is to find an optimal allocation of the defense budget, one that equalizes the marginal contribution of each type of weapon. But defense departments rarely have single objectives; along with maximizing damage to an enemy there may be another objective, such as minimizing losses

from attacks. In that case, more than the equimarginal principle is needed for a decision; it is necessary to know how the department ranks the two objectives in order of importance, since different rankings will imply different optima. But a ranking of objectives is simply a utility function or a preference function.

In other words, when an institution pursues multiple ends, decisions about how to achieve them require a weighting of the ends. Every decision involves a "production function"—a statement of what is technically feasible—and a "utility function"; the equimarginal principle is then invoked to provide an efficient, optimal strategy. This applies just as well to the running of hospitals, churches, and schools as to the conduct of a business enterprise, to the location of an international airport as well as to the design of a development plan for an underdeveloped country. This is why economists crop up in what seem to be the most unlikely places, advising on activities that are obviously not being conducted for economic reasons.

MACROECONOMICS

The different approach of macroeconomics

There is, however, an approach to economics in which the foregoing considerations do not apply. That is the field known as macroeconomics. In macroeconomics one is concerned with the aggregate outcome of individual actions. Keynes's "consumption function," for example, which relates aggregate consumption to national income, is not built up from individual consumer behaviour; it is simply an empirical generalization. The focus is on income and expenditure flows rather than on markets. Purchasing power flows through the system from business investment to consumption, but it leaks out at two places in the form of personal and business savings. Counterbalancing the savings are investment expenditures in the form of new capital goods, houses, and so forth, which constitute a source of new injections of purchasing power in every period. Since savings and investments are carried out by different people for different motives, there is no reason why "leakages" and "injections" should be equal in every period. If they are not equal, national income, the sum of all income payments to the factors of production, will rise or fall in the next period. When planned savings equal planned investment, income will be at an equilibrium level, that is, a level at which it can sustain itself; when the plans of savers do not match those of investors, the level of income will go on changing until the two do match. One can complicate this simple model by making investment a function of the interest rate; by introducing the government budget, the money market, labour markets, imports and exports, foreign investment; and so forth. But all this is far removed from the problem of resource allocation and from the maximizing behaviour of individual economic agents.

The result is a kind of intellectual schizophrenia in which the techniques of microeconomics do not carry over fully into macroeconomics and vice versa. This is widely held to be an unsatisfactory state of affairs; economists have in recent years sought to build a bridge between the individual consumer and the overall consumption function and between the individual investor and the behaviour of aggregate investment. Nevertheless, the bridge remains incomplete, and the student of economics must be prepared to work with two boxes of tools.

FIELDS OF CONTEMPORARY ECONOMICS

The following is a bird's-eye view of the main fields of contemporary economics.

Public finance. Since the time of Ricardo economists have been concerned with the incidence of taxes, that is, with determining who it is that really pays a tax. If a corporation faced with a profits tax reacts by raising its prices, it may succeed in making the consumer pay the tax; on the other hand, if sales decline as a result of the rise in price the firm may have to lay off some of its workers, and the burden of the tax will be shared by consumers, wage earners, and shareholders. This simple example shows how complex may be the actual incidence of a tax. A large part of the literature of public finance in the 19th century was devoted to such problems.

Taxes and government expenditures

Keynesian economics brought new dimensions to public finance: the older preoccupation with tax incidence gave way to the analysis of the impact of government expenditures on the level of income and employment (see FISCAL AND MONETARY POLICY). It was some time, however, before economists realized that they lacked a theory of government expenditures, that is, a set of criteria for determining what activities should be supported by governments and what should be the relative expenditure on each. One of the most exciting recent developments in the field of public finance is the attempt to devise such criteria. Decisions on public expenditures have proved to be susceptible to much of the traditional analysis of microeconomics. In the 1960s there developed a technique known as "cost–benefit analysis," which tries to appraise all of the economic costs and benefits, direct and indirect, of a particular activity so as to decide how to distribute a given public budget most effectively between different activities. This technique has been applied to everything from the construction of hydroelectric dams to the control of tuberculosis. Its exponents hope that the same type of analysis that has proved so fruitful in the past in analyzing individual choice may also succeed with problems of social choice.

Money. One of the oldest, widely accepted functions of government is control over the supply of money. The dramatic effects of changes in the quantity of money on the level of prices and the volume of economic activity were recognized and thoroughly analyzed in the 18th century, and monetary economics has ever since constituted one of the principal branches of economics. In the 19th century a complex and somewhat crudely formulated tradition grew up known as the "quantity theory of money," which held that any change in the supply of money can only be absorbed by variations in the general level of prices (the purchasing power of money). In consequence, prices will tend to change proportionately with the quantity of money in circulation. As the growth of fiat paper money gave governments increasingly effective control over the stock of circulating media, the quantity theory of money supplied an apparently simple rationale for the management of the economy: all that was needed to prevent inflation or deflation was to vary the quantity of money in circulation inversely with the level of prices.

One of the targets of Keynes's attack on traditional thinking in his *General Theory of Employment, Interest and Money* was this quantity theory of money. Keynes produced a different theory of the demand for money that implied that the impact of a change in the stock of money on the level of national income is weak and at best indirect; the effect on prices is virtually nil, he maintained, at least in economies with heavy unemployment such as prevailed in the 1930s. He put his emphasis instead on government budgetary and tax policy and direct control of investment. As a consequence, economists lost faith in monetary management and came to regard monetary policy as more or less ineffective in controlling the volume of economic activity.

In the 1960s there was a remarkable revival of the older view, at least among a small but growing school of American monetary economists. They accepted much of Keynesian economics but argued that the effects of fiscal policy are unreliable unless the quantity of money is regulated at the same time. They refurbished the quantity theory of money and tested the new version on a variety of data for different countries and for different time periods, leading to the broad conclusion that the quantity of money does matter (see MONEY).

In the early 1970s the controversy was still raging. It is notable that this debate, unlike previous debates in the history of monetary economics, was characterized by disputes over empirical findings—that is, it was focussed on the testable character of different monetary theories rather than on the manner of their formulation. Progress was made slower by the political overtones of the con-

troversy: in some countries, belief in the efficacy of monetary policy had become a kind of litmus test of political conservatism. Nevertheless, a reconciliation between Keynesians and quantity theorists needed only some agreement as to the magnitude of monetary forces and the degree of stability of the demand for money. Monetary economics seemed at last to be coming of age as an empirical discipline.

International economics. The foundations of international economics were firmly established in the 19th century. The subject has consisted ever since of two distinct but connected parts: (1) the "pure theory of international trade," which seeks to account for the gains obtained from trade and to explain how these gains are distributed among countries, and (2) the "theory of balance-of-payments adjustments," which analyzes the workings of the foreign exchange market, the effects of alterations in the exchange rate of a currency, and the relations between the balance of payments and the level of economic activity.

In modern times, the Ricardian pure theory of international trade has been reformulated by the American Paul Samuelson, improving on the earlier work of two Swedish economists, Eli Heckscher and Bertil Ohlin. The so-called Heckscher–Ohlin theory explains the pattern of international trade as determined by the relative land, labour, and capital endowments of countries: a country will tend to have a relative cost advantage in goods requiring the intensive use of the country's relatively abundant factor of production (thus land-rich Canada exports wheat) and to import goods requiring the intensive use of the country's relatively scarce factor (thus capital-poor Canada imports American automobiles). This theory absorbs Ricardo's law of comparative costs but goes beyond it in linking the pattern of trade to the economic structure of trading nations. It implies that foreign trade is a substitute for international movements of labour and capital —which raises the intriguing question of whether or not foreign trade may work to equalize the prices of all factors of production in all trading countries. Whatever the answer, the Heckscher–Ohlin theory provides a model for analyzing the effects of a change in trade on the industrial structures of economies and, in particular, on the distribution of income between factors of production. Much of the recent effort of specialists in international economics has gone toward refining the Heckscher–Ohlin model and testing it on an ever wider range of empirical evidence.

Labour. Like monetary and international economics, labour economics is an old economic speciality. It gets its raison d'être from the peculiarities of labour as a commodity. Labour itself is not bought and sold; rather, its services are hired and rented out. But since people cannot be disassociated from their services, various nonmonetary considerations play a role in the sale of labour services as contrasted with the sale of machine time or the rental of land. Yet, the bulk of the literature in labour economics was until recently concerned solely with the demand side of the labour market. Wages, the textbooks all said, were determined by the "marginal productivity of labour," that is, by the relationships of production and by consumer demand. If the supply of labour came into the picture at all, it was merely to allow for the presence of trade unions; unions could only raise wages by limiting the supply of labour.

The economics of labour and industry

After a long period of neglect, the supply side of the labour market began, in the 1960s and 1970s, to attract the attention of economists. First, attention shifted from the individual worker to the household as a supplier of labour services; the increasing tendency of married women to enter the labour force and the wide disparities and fluctuations observed in the rate that females participate in a labour force drew attention to the fact that an individual's decision to supply labour is not independent of the size, age structure, and asset holdings of the household to which he or she belongs. Second, the new concept of "human capital"—that people make capital investments in their children and in themselves by incurring the costs of education and training, the costs of searching for better job opportunities, and the costs of migration to other labour markets—has served as a unifying explanation of the diverse activities of households in labour markets. In this way, capital theory (see CAPITAL AND INTEREST) has become the dominant analytical tool of the labour economists, replacing or supplementing the traditional theory of consumer behaviour. The economics of training and education, the economics of information, the economics of migration, the economics of health, and the economics of poverty are some of the by-products of this new perspective. A field that was at one time regarded as rather cut-and-dried has taken on new vitality.

Labour economics, old or new, has always regarded the explanation of wages as its principal task, including the factors determining the general level of wages in an economy and the reasons for wage differentials between industries and occupations. Wages are influenced by trade unions; the impact of their activities is of increased importance at a time when most governments manage the economy with one eye on the unemployment statistics. The prewar fears of chronic unemployment gave way to the postwar fears of chronic inflation at or near levels of full employment. In response to this a vast literature sprang up after 1945 analyzing the inflationary pressures stemming from both the supply side and the demand side of labour markets. Whether prices were being pushed up by the labour unions ("cost push") or pulled up by excess purchasing power ("demand pull") became the issues in this 20-year long debate on inflation, a controversy that is, of course, intimately related to the quarrels in monetary economics mentioned earlier.

Industrial organization. The principal concerns of this field are the structure of markets, public policy toward monopoly, the regulation of public utilities, and, of late, the economics of technical change.

The monopoly problem, or, more precisely, the problem of the maintenance of competition, does not fit well into the received body of economic thought. Economics started out, after all, as the theory of competitive enterprise, and even today its most impressive theorems require the assumption of numerous small firms, each having a negligible influence on price. Yet the typical market structure of manufacturing today is that of oligopoly—competition among the few—and some industries are dominated by firms so large that their annual sales volume exceeds the national income of the smaller countries of western Europe. It is tempting to leap to the conclusion that oligopoly is deleterious to economic welfare, on the ground that it leads to the misallocation of resources. But some economists, notably Joseph Schumpeter, have argued that economic growth and technical progress are brought about not through free competition but through large firms and the destruction of competition. According to this view, monopoly has its origin in the need of business firms to protect themselves from the risks associated with the introduction of new products, new techniques, and new methods of marketing. The giants compete not in price but in successful innovation, and this kind of competition has proved more effective for economic progress than the price competition described in orthodox textbooks.

Although this thesis smacks of *post hoc ergo propter hoc* ("after this, therefore because of this")—giant firms have prospered in rapidly growing economies; therefore, growth is due to giant firms—it makes the merits of "trust busting" and cartel dissolution somewhat less compelling. The question is what sort of competition is socially most desirable. If each of four or five large firms in an oligopolistic industry finds it necessary to compete in terms of the quality of its products and its research or by means of better technology and superior merchandising, the performance of the industry may well be more satisfactory than if it were reorganized into a price-competitive industry. But if the four or five giants settle down to a quiet life and concentrate their rivalry on sales promotion techniques, the verdict must be less favourable. One cannot, it seems, draw facile conclusions about

the competitive results of different market structures; it is necessary to approach the monopoly problem with a generous dose of pragmatism.

The reason why there is so much uncertainty in the economic discussion of policies toward big business is the lack of a general theory of oligopoly. There are dozens of special theories applying to special cases, but there is no single, organizing framework with testable implications about the behaviour of oligopolists in general.

Agriculture. Farming has long provided economists with their favourite example of a perfectly competitive industry. But with increasing government regulation of agriculture, it also provides striking examples of the effects of price controls, income supports, output ceilings, and marketing cartels. Agricultural economics commands attention wherever governments wish to stimulate farming or to protect farmers—which is to say, everywhere.

Agricultural economists generally have been closer to their subject matter than other economists. In consequence, more is known about the technology of agriculture, the nature of farming costs, and the demand for agricultural goods than is known about any other industry. The student of economics who wants to learn how to estimate a production function or a demand curve is well advised to go to the literature on agricultural economics.

The underdeveloped countries have furnished a new laboratory for agricultural economics. Many such countries have a "subsistence agriculture," in which the farmer produces mainly for his own family consumption and brings to market only what is left over. Subsistence farmers are only tenuously linked to the money economy. They are more reluctant than commercial farmers to take the risks entailed in experimenting with new seeds, fertilizers, and farming methods: given the vagaries of the weather, they prefer to operate on the basis of the worst weather that can be expected rather than the best or even the average. While the pessimism of subsistence farmers is perfectly rational, it makes the task of predicting their response to new prices or new methods doubly difficult. The economist must also recognize that every agricultural area presents its own production, processing, and marketing problems. To suggest changes that will raise agricultural productivity in these circumstances is no easy task, and agricultural economists often find themselves warning governments not to intervene too vigorously, since much intervention in the past has been shown to be wrong or inappropriate.

The problem of economic development in Africa, Asia, and Latin America centres on the agricultural sector; one of the abiding questions is how far industrialization can proceed without there first being an agricultural revolution. For this reason, if for no other, agricultural economics has a large future.

Growth and development. The study of economic growth and development is not a single branch of economics but falls, in fact, into two quite different fields. The two fields—"growth" and "development"—employ different methods of analysis and are indeed addressed to two distinct types of inquiry.

Development economics is easy to describe. It is one of the three major subfields of economics, the other two being microeconomics and macroeconomics. Development economics resembles economic history in that it seeks to explain the changes that take place in economic systems with the passage of time (see ECONOMIC DEVELOPMENT).

The subject of economic growth is not so easy to characterize. It is the most technically demanding field in the whole of modern economics, impossible to grasp for anyone who lacks differential calculus. Its focus is the properties of equilibrium paths, rather than equilibrium states. One makes a model of the economy and puts it into motion, requiring that the time paths described by the variables be self-sustaining in the sense that they continue to be related to each other in certain characteristic ways. Then one can investigate the way economics might approach and reach these steady-state growth paths from given starting points. Beautiful and frequently surprising theorems have emerged from this experience, but as yet there are no really testable implications nor even definite insights into how economies grow.

Growth theory began with the work of Roy Harrod in England and Evsey Domar in the United States. Their joint product has been known ever since as the Harrod–Domar model. Keynes had shown that new investment has a multiplicative effect on income and that the increased income generates extra savings to match the extra investment, without which the higher income level could not be sustained. One may think of this as being repeated from period to period, remembering that investment, apart from raising income disproportionately, also generates the capacity to produce more output that cannot be sold unless there is more demand, that is, more consumption and more investment. That is all there is to the model. It contains one behavioral condition—that people tend to save a certain proportion of extra income, a tendency that can be measured. It contains one technical condition—that investment generates additional output, a fact that can be established. And it contains one equilibrium condition—that planned saving must equal planned investment in every period if the income level of the period is to be sustained. Given these three conditions, the model generates a time path of income and even indicates what will happen if income falls off the path.

More complex models have since been built, incorporating different saving ratios for different groups in the population, technical conditions for each industry, definite assumptions about the character of technical progress in the economy, monetary and financial equations, and much more (see ECONOMIC GROWTH).

Mathematical economics. Differential calculus has long been the traditional tool of mathematical economics. Many economic problems, particularly in microeconomics, take the form of maximizing some variable (such as profits) subject to a constraint (such as the production function), for which calculus supplies the simplest technique. Traditionally it was applied to problems in comparative statics. These problems include so-called endogenous variables, the values of which are determined within the model, as well as constants that originate outside the model and are called "exogenous variables" or "parameters." The object is to discover the effects of changes in one or more of the parameters upon the equilibrium situation. The latter is a situation in which all of the endogenous variables are simultaneously in a state of rest. If the value of some of the parameters is changed, the result is a new equilibrium state.

The application of mathematical methods

Much economic analysis, even when it is expressed in words, is simply the method of comparative statics. But comparative statics has its limitations: it tells the investigator *where* the system will arrive, but it does not tell him *when* it will arrive or what will happen along the way; and it cannot tell him whether, once driven out of the way, it will ever get back to its destination. In other words, comparative statics ignores the process of adjustment from the old equilibrium state to the new one, and it entirely neglects the time element in that adjustment process. The study of this process of adjustment over time is called "economic dynamics," and one may think of it as the economics of disequilibria.

Just as differential calculus is the mathematics of comparative statics, difference and differential equations are the ideal tools for handling dynamic problems. Difference equations deal with time as a discrete variable—changing only from period to period—whereas differential equations treat time as a continuous variable; the choice between them is simply one of convenience. They enable one to ask such questions as: if the system is pushed out of equilibrium, perhaps because one of the parameters of the model has changed, will economic forces drive it toward a new equilibrium position or away from one, will the time path described by the endogenous variables be steady or fluctuating, and if fluctuating, will the move-

ments be damped down or will they increase and become explosive?

Economic dynamics is one of the newer developments of mathematical economics, and often it falls short of the ambitious demands made on it. Dynamic models, for example, are typically formulated in terms of linear equations, not because the world is linear but because nonlinear equations can be very difficult to solve. Likewise, the coefficients of difference and differential equations are usually taken to be constants, again for the sake of making the mathematics of the analysis manageable. This means that if the economic environment changes as the model runs its course, its predictions will be false. An abiding danger in all mathematical economics is the tendency to adopt economic assumptions for the sake of mathematical convenience. The way to meet this danger is for economists to acquire enough mathematical sophistication so that they will not be dazzled by displays of mathematical technique.

Econometrics. Like mathematical economics, econometrics is something economists do rather than a special area of interest. Econometrics refers to the study of empirical data by statistical methods, the purpose of which is the testing of hypotheses and the estimation of relationships suggested by economic theory. Whereas mathematical economics considers the purely theoretical aspects of economic analysis, econometrics attempts to falsify theories that are expressed in explicit mathematical terms. But frequently the two go together.

The classic technique for estimating an economic relationship is that of "least squares," which is a method of fitting a trend line to a scatter of observations that minimizes the square of the deviations of the observed points from the line. To take a simple example: the Keynesian theory assumes that consumers' expenditures depend principally on income; one may interpret this to mean that consumption depends *only* on income and then test the hypothesis by trying to fit a trend line to a series of observations of income and consumption over a period of time. In so doing, one is really saying that the observations that fall to either side of the line are due either to errors in measuring the variables or to errors in specifying the relationship between consumption and income. It is essential to the method of least squares that these "errors" be randomly distributed or at any rate distributed in known ways. When this condition is violated, least squares estimates are unreliable. It is sometimes difficult to tell with economic data just how the errors are randomly distributed, and it is precisely for this reason that an econometrician is needed rather than an ordinary statistician.

A still more significant trend in recent econometrics is the tendency to move from single-equation estimates (such as the relationship between consumption and income) to systems of simultaneous equations. While consumption depends on income, income also depends on consumption; this kind of interdependence requires two equations rather than one. More generally, most economic variables are the result of demand and supply forces that simultaneously determine quantities and prices. To estimate a demand curve for butter from a single-equation regression (by relating the price of butter to the quantities of butter consumed, the incomes of consumers, and the prices of near substitutes for butter) is likely to produce a biassed answer because the price of butter is also influenced by supply conditions in the dairy industry. This creates the so-called identification problem, namely, the question of whether it is possible to identify a demand curve or a supply curve from observed price–quantity data. The use of simultaneous equation models to estimate economic relationships is by now perhaps the best way of distinguishing econometrics from economic statistics.

The foregoing discussion covers only nine major branches of economics. There are many other fields in economics, including economic history, comparative economic systems, business cycles, economic forecasting, national income accounting, managerial economics, business finance, marketing, the economics of natural resources, economic geography, consumer economics, and regional economics. The reader who wishes to investigate them will find references in RELATED ENTRIES under ECONOMICS in the *Ready Reference and Index*.

BIBLIOGRAPHY. The best introduction to methodological issues in economics is still L. ROBBINS, *The Nature and Significance of Economic Science*, 2nd ed. (1935). The modern position on empirical testing is well conveyed by M. FRIEDMAN in *Essays in Positive Economics* (1953); and by R.G. LIPSEY and P.O. STEINER, *Economics*, 2nd ed. (1969), an elementary textbook. The best way to learn about economics is to browse through an introductory textbook. The best known is P.A. SAMUELSON, *Economics: An Introductory Analysis*, 8th ed. (1970); another is A.A. ALCHIAN and W.R. ALLEN, *University Economics* (1964). There are several good histories of economic thought: H.L. HEILBRONER, *The Worldly Philosophers*, rev. ed. (1953), a pleasure to read; O.H. TAYLOR, *A History of Economic Thought* (1960), arranged chronologically; and E. WHITTAKER, *A History of Economic Ideas* (1940), arranged topically. J.A. SCHUMPETER, *History of Economic Analysis* (1954); and M. BLAUG, *Economic Theory in Retrospect*, 2nd ed. (1968), are advanced references. Excellent bibliographical articles on the great economists, as well as superb but sometimes quite difficult essays on all the leading branches of modern economics may be found in the *International Encyclopedia of the Social Sciences*, 16 vol. (1968). Further readings for advanced students are those published by the American Economic Association: *Survey of Contemporary Economics, I*, ed. by H.S. ELLIS (1948); *A Survey of Contemporary Economics, II*, ed. by B.F. HALEY (1952); and *Surveys of Economic Theory*, 3 vol. (1965).

Each branch of economics has its own text; the following list is highly selective. Microeconomics: C.E. FERGUSON, *Microeconomic Theory*, 2nd ed. (1969); K.J. COHEN and R.M. CYERT, *Theory of the Firm: Resource Allocation in a Market Economy* (1965). Macroeconomics: G. ACKLEY, *Macroeconomic Theory* (1961); T.F. DERNBURG and D.M. MCDOUGALL, *Macroeconomics*, 3rd ed. (1968). Development economics: C.P. KINDLEBERGER, *Economic Development*, 2nd ed. (1965); B.H. HIGGINS, *Economic Development*, 2nd ed. (1968). Public finance: R.A. MUSGRAVE, *The Theory of Public Finance* (1959). Monetary economics: A.G. HART and P.B. KENEN, *Money, Debt and Economic Activity*, 3rd ed. (1961); L.V. CHANDLER, *The Economics of Money and Banking*, 5th ed. (1969). International economics: C.P. KINDLEBERGER, *International Economics*, 4th ed. (1968). Labour economics: A.M. CARTTER and F.R. MARSHALL, *Labour Economics: Wages, Employment, and Trade Unionism* (1966); L.C. HUNTER and D.J. ROBERTSON, *Economics of Wages and Labour* (1969). Industrial organization: E.H. CHAMBERLAIN (ed.), *Monopoly and Competition and Their Regulation* (1954); J.S. BAIN, *Industrial Organization* (1959). Agricultural economics: T.W. SCHULTZ. *The Economic Organization of Agriculture* (1953), and *Transforming Traditional Agriculture* (1964). Growth economics: R.G.D. Economic Systems

An economic system may be defined as the sum total of institutions and patterns of behaviour that organize economic activity in society. This is the sense in which one speaks, for example, of a private-enterprise system or of a centrally planned socialist system. The production and distribution of goods in a modern industrial economy is a process in which millions of people must cooperate. For the sake of greater efficiency their functions are specialized so that none of them makes a whole product, and they are all mutually dependent. Working together, they are able to create a social product that is many times greater than the aggregate result of their isolated individual efforts would be. But the interdependence of millions of people in this gigantic process of cooperation raises a number of problems, which different economic systems solve in different ways.

The first problem is to determine what goods are to be produced, and in what quantities. Although productive

The basic economic problems

resources can be combined in an infinite variety of ways, technology and manpower set ultimate limits to the total size of the final output. Particularly important is the division of the national product into investment goods and consumption goods. A greater allotment to investment will permit increased future consumption but at the cost of a reduction of present consumption.

A second problem is that many thousands of interdependent production processes must be properly balanced if the economy is to function smoothly. The complexity of this is staggering. Let one integral part of this cooperative process of social production lag behind, and potentially all other parts will be affected.

A third problem of every economy is the way in which the common product is to be distributed. This has much to do with reward for effort. Since human beings are not simply creatures of instinct or of habit, they must be induced to perform the right functions in the right place and at the right time, whether they be farmers, industrial workers, or managers. To the extent that society relies on self-interest rather than coercion or inspiration, the promise of reward for effort becomes decisive.

Modern economic systems can be distinguished by the ways in which they solve these problems. Essentially, the differences among systems have to do with three main characteristics: (1) the degree of public or private ownership of the means of production, (2) the relative emphasis on planning, and (3) the prevalence of public or private decision making. These characteristics are interrelated. Where the ends of the economy are determined by the government rather than by the individual, central planning will tend to prevail together with public ownership of the material means of production (capital and land); where the demand decisions of consumers guide production, a market process must exist.

These distinctions must not be exaggerated, however. The centrally planned system can include a substantial amount of individual freedom and will have to make at least some use of market forces, while the private enterprise system will not only contain a large public sector but will likely seek to influence the working of the private sector through government fiscal and monetary policies. Nevertheless, it is helpful to approach comparative economic analysis through a separate study of the principles of the centrally planned and the competitive private enterprise economies. Only after the essential features of these two main types have been fully understood can the study of the existing systems of different countries become fruitful; only then can judgments be made as to whether their aims and policies are compatible and their economic structures internally consistent.

ARCHETYPAL ECONOMIC SYSTEMS

The private enterprise economy. *Its theoretical model.* The theoretical model of the private enterprise economy is built upon private ownership and control of the means of production, free choice of occupation, and consumers' sovereignty. Private enterprises, or firms, translate consumer demand for commodities and services into a demand for labour, capital, and other factors of production. The consuming units receive their income from the sale of productive services to the firms, and spend most of it on consumption. Thus money flows from the firms to the people and back to the firms in a continuous circle. This money flow is maintained even if a part of the national income is saved, that is, not spent on consumption, provided that the savings are borrowed by firms and spent on investment goods or borrowed by other consumers to be spent on additional consumption. Should the saved portion of the national income remain unspent, however, the circular flow of money would be interrupted, with serious consequences in terms of inadequate demand, reduced production, and unemployment.

Price and cost relationships decide what each firm produces in the various markets of the economy. Where demand has not been fully met, product prices will exceed production cost per unit, and the resulting profits will then call forth increased production. If supply exceeds demand, losses will result in reduced production. The market processes of the private enterprise economy involve a series of price relations that tend to lead to a state of equilibrium at full employment. In this state all resources will be employed wherever they are paid the highest price that equates supply and demand. This is so because they shift from one employment to another in response to consumer demand as expressed through the market.

Technical change and prices

The working of the price mechanism can be shown by assuming a disturbance to a given state of equilibrium resulting from a change in the techniques of production. The substitution of a newly invented machine for labour —for example—increases productivity, lowers costs, lowers the price of the product (under competitive conditions), and initially reduces the demand for labour. Lower prices permit the purchase of larger quantities of the commodity; alternatively, other commodities may be bought in increased quantities. In either case the demand for labour will increase again, though it will not always be easy to shift workers from one industry to another. All changes in the demand for products and for productive factors alter the prices on the various markets and lead to a chain reaction of adjustments until a new equilibrium is reached.

Thus self-interest, working through competitive markets, theoretically enables the private-enterprise economy to solve the problems of the social economy without the aid of a central plan. The government's sphere is limited to functions that private enterprise cannot perform, for example, the satisfaction of collective wants for which a market price cannot be charged (such as police protection or flood control). But once the government does not tell the citizen what to consume, where to work, or what to produce, the private-enterprise system offers a degree of economic freedom that cannot be matched by a centrally planned economy.

Three major criticisms. The private-enterprise system is usually subjected to three principal criticisms. The first applies both to theory and to practice; the other two address themselves only to practical applications of the system.

(1) Since private incomes are determined by prices of the factors of production and by individual ownership of these factors, the national income of the private-enterprise economy is very unequally distributed. Furthermore, individual incomes cannot be equalized to any large degree by tax and other government policies because the working of the system depends on private ownership of the material means of production and on wage differentials. The system claims the advantages of consumer's sovereignty, but since the market counts the dollars of the rich and the poor alike, the system does not maximize the satisfaction of wants for the economy as a whole.

(2) The market mechanism of the private-enterprise economy rests on competition. The growth of monopoly opens the way to exploitation, suppresses private initiative, and may damage, through price rigging, the working of a system that must rely on free price movements. Again, it is difficult for the government to rid the market of monopolistic impediments since these are, to a large extent, the outgrowth of modern mass-production techniques.

(3) Experience has shown that the private-enterprise economy does not always maintain high levels of employment. Productive resources may be wasted in depression and stagnation, and the national income may remain far below its potential maximum. Fortunately, it is generally agreed that high employment can be maintained through the application of modern fiscal and monetary policies, which have nothing in common with central planning or with the nationalization of major industries. The government merely sees to it that demand deficiencies in the private sector of the economy are counterbalanced by an expansion of public spending so that sufficient aggregate demand permits the full use of productive resources.

The centrally planned economy. The most thoroughgoing form of the centrally planned economy ("authoritarian socialism" or "command economy") features the public ownership of, or control over, all productive resources, including labour, and the direction of the economy by command from the centre according to an all-inclusive plan. But this extreme form of central planning is not likely ever to exist in real life, nor can it be assumed that any government would insist on distributing national income without allowing any choice on the part of consumers. Even the most autocratic and totalitarian governments have always placed considerable reliance on markets for consumer goods and have allowed some freedom in the choice of occupation.

The centrally planned economy should rather be seen as a system that seeks to combine public ownership of the *material* means of production (land and capital) and central planning, with as much personal freedom as this framework permits in terms of occupation and consumption. These concessions to economic freedom have important consequences. If workers are not simply commanded to perform the work that the plan requires, they must be induced to do so by wage differentials. This means that the centrally planned economy cannot achieve equal income distribution and that labour markets in the centrally planned and the private enterprise economies must be similar.

Limited consumer choice

Consumers in the centrally planned economy are permitted to choose among commodities and services; this makes it necessary to have consumer goods markets but does not require that production adjust itself automatically to changes in consumer demand. A central plan is not flexible enough to permit such automatic adjustments through price and cost signals.

The centrally planned economy meets the problems of a social economy as follows. The major goals of the economy are determined by the government and then translated into the details of the central plan. Since, at full employment, new investment competes with consumer goods production for the nation's resources, the plan must be all-inclusive. The details will depend on the ends to be achieved, the availability of productive resources, the techniques of production, and the need for proper balance. Balance might conceivably be achieved by input-output equations; in practice it is reached by approximation through trial and error.

The central plan does not rest on price and cost calculations and does not permit major independent decisions by decentralized enterprises. The plan sets output quotas that must be met on the basis of fixed allocations of productive resources. Managers who have technical know-how must obey commands issued by planners who lack knowledge. Indeed, the planners depend on information sent to them by men who may be tempted to influence the centre's decision in their favour by misrepresenting their enterprise's capacity, thus making it easier to fulfill the ensuing plan.

The central plan rests on material or physical balances, that is, on a system of relationships between, say, the total supply of steel needed for the fulfillment of production quotas in all steel-consuming industries and the total input of the various resources needed to reach the output quota for steel. Not all balances can be material balances. When dissimilar things (such as labour, fuel, and transportation services) must be added together, monetary balances are needed. Monetary balances are indispensable, furthermore, because workers are paid wages and the public makes its purchases with money.

The use of money in the centrally planned economy does not mean that the plan follows the guidance of market prices. All prices are set by the government and are but rarely changed. They serve for balancing and accounting purposes. Monetary transfers between enterprises help check plan fulfillment.

The chief criticism of the centrally planned economy is that it is not able to allocate its resources efficiently. Planners and managers cannot base their decisions on prices that reflect the real costs of goods and services. The authorities do, however, have the power to determine the rate of investment, and since the rate of investment is decisive for the rate of growth of the economy, the centrally planned system may be able to compensate for its relatively poor performance in factor allocation by its command over the rate of investment—at the cost of relatively low consumption.

Liberal socialist economies. *Consumer sovereignty.* Liberal socialists reject the authoritarian features of the centrally planned command economy. They insist on the guidance of production by the consumer; they want real consumer sovereignty, and not merely a choice among an assortment of commodities produced in accordance with the government's wishes. They also believe that consumer sovereignty makes more sense in a socialist than in a private-enterprise economy because public ownership of the material means of production will result in a more equal income distribution. Free choice of occupation, however, and the use of wage differentials admittedly exclude full equality.

Liberal socialists generally reject the command economy because of its overcentralization. They want managers of enterprises to make their own decisions on the basis of price signals. They argue that it is impossible to allocate productive resources efficiently unless this is done on the basis of a consistent and correct price structure that expresses the relative scarcities of factors and products. Liberal socialists, therefore, do not oppose all of the features of a private-enterprise economy.

Decisions on basis of price signals

Problems and difficulties. The main problem of liberal socialism stems from the fact that public ownership of the means of production eliminates genuine markets for investment goods, unless it is assumed that the managers will be permitted to compete freely for productive resources. To accomplish this it will be necessary to set million of prices correctly, so that they are consistent, correspond to the relative scarcities of products and factors, and equate prices and costs.

Another difficulty concerns the motivation of the managers. How are they to act, particularly if the decisions of the planning authorities happen to conflict with the wishes of the consumers? Some socialists have suggested that the managers should act very much as private businessmen would in a perfectly competitive market. They should produce just enough to equate prices and costs. To re-create the conditions of perfect competition in a private-enterprise economy, all accounting would have to be done *as if* the prices were independent of the manager's decisions.

The Polish socialist and economist Oskar Lange believed that "the real danger of socialism is that of the bureaucratization of economic life and not the impossibility of coping with the problem of allocation of resources." Bureaucratization will flourish, however, precisely because real markets will no longer exist for all transactions between public enterprises. As in the centrally planned economy, the problem is that the centre lacks the omniscience that would be required to set correct prices; and that the enterprise managers, who are on the spot and have the know-how, will be most reluctant to treat the prices that the planners are setting *as if* they were correct.

WESTERN-TYPE MARKET ECONOMIES

The private-enterprise system (or capitalism) is not very old. Emphasis on private enterprise developed in reaction to mercantilism, which involved, as Adam Smith said, the "attempt to direct private people in what manner they ought to employ their capitals." Adam Smith believed that every individual, intending only his own gain, is "led by an invisible hand to promote an end which was no part of his intention"—the interest of sociey. Smith was often wrongly accused of having advocated completely private enterprise with no government intervention. It is true, however, that under his influence the pendulum did swing from an emphasis on the most minute government regulation of trade to the ideal of minimum interference.

This attitude, too, proved untenable, for the market process alone is only an instrument and not an end. Left to itself, the market economy permitted the growth of monopoly, produced crises of mass unemployment, and favoured an income distribution that many did not consider socially "just."

The achievements of capitalism

Yet 19th-century capitalism could claim to be a highly productive economic system, as testified by Karl Marx who wrote that "the bourgeoisie, during its rule of scarce 100 years, has created more massive and more colossal productive forces than have all preceding generations together." On the whole, the system worked well enough to induce the countries of the West to return to it after World War I. Only prolonged stagnation and mass unemployment in the early 30s led to the complete reappraisal known as *Keynesian* economics.

John Maynard Keynes argued that while classical teaching "embodied some permanent truths of great significance . . . we cannot now accept them without much qualification." His main criticism was that classical economics taught that the market economy would always tend to a state of full-employment equilibrium and that savings would always be invested. Keynes argued that an increased desire to reduce spending and to hold liquid balances (for example, in expectation of falling prices) would raise interest rates, reduce investment spending, and create unemployment. He also considered it realistic to assume that wages and prices had lost much of their downward flexibility under monopolistic market conditions. If the market economy requires price variations as signals and if downward price movements are becoming increasingly sticky, only two possibilities remain. Either the system works on the basis of differentiated price changes upward, which means inflation, or (if the authorities try to stabilize the general price level by a tight monetary policy) there will be unemployment, since fixed commodity prices and rising costs will force business into contraction. Keynes held that vigorous government intervention was required to maintain the economy at a high level of employment.

In the leading countries of the West the governments now accepted the responsibility for maintaining high employment levels. Instead of balancing the budget each year, governments are willing to incur a (temporary) deficit either through increased spending or through lower taxes when necessary to maintain aggregate demand. These policies are complicated and the countries of the West have been using them in different "mixes" and with varying success, particularly so far as the simultaneous achievement of full employment and monetary stability is concerned. All of these fiscal and monetary policies have this in common, however, that they differ radically from Soviet-type central planning. Even socialist governments in the West appear to have lost much of their interest in the nationalization of major industries and in central planning, because the private-enterprise system seems to work reasonably well so long as aggregate demand is maintained without too much price inflation.

There are differences among Western economies in the rate of growth of the public sector, but this does not alter their basic similarity since both private and public demand are met chiefly by the output of private enterprise.

THE SOVIET-TYPE ECONOMIC SYSTEM

The main problem of the Soviet economy has lain in the complexities of the central plan. After Stalin's death the conviction grew that something was wrong with the organization of the system. Nobody suggested that the central plan itself be abolished, but it was said that the incentive system was faulty, that managers needed more independence, and that planners could not cope with the allocation problem. Reformers attempted to improve the relationship between centre and periphery through an incentive system that would make the managers support rather than obstruct the plan and spur production of the goods consumers really want.

According to Professor Yvsey Liberman of Kharkov, the system practically required the managers to misinform the planning authorities as to the true potential of their enterprises and to press for excessive supplies of materials and capital. Since the managers thus could not be trusted, they had to be kept under strict supervision; and the task of controlling tens of thousands of enterprises from the centre put too heavy a burden on the planning authorities, who necessarily lacked the technical knowledge that the managers possessed. Premier Kosygin agreed with Liberman when he admitted that "it is necessary to abolish excessive regulation of economic activity of enterprises" and asked for the establishment of "firm legislative guarantees for the expanding rights of enterprises."

The question of incentives

The solution proposed by Liberman was to revise incentives so that "what is profitable for society, as represented by the state, must be profitable for every collective of the enterprise and every member of that collective." The managers would still be required to fulfill production quotas. Furthermore, prices, investments, and "all the value, labour and major physical indices of rates and proportions in the sphere of production, distribution and consumption" would still be centrally determined. Nevertheless, "the petty tutelage of centralized planning over enterprises" would be replaced by reliance on "economic levers." The chief lever was a "profitability rate"—*i.e.*, enterprise profits expressed as a percentage of the monetary value of working capital—to be compared with a "profitability norm" that the authorities would establish as a benchmark for every branch of production. Liberman's emphasis on profits (in which the enterprise would share) was designed to prevent the managers from wasting capital by asking for larger allocations than they really needed. Their fear that good performance would only lead to stiffened norms was to be met by maintaining the norms for up to five years. The introduction of new products and techniques was to be encouraged by the setting of low profitability norms in high-priority industries.

The effort to reform the central-planning process through a decentralized use of economic levers logically required a system of prices that would mirror the relative scarcities of capital assets, productive resources, and commodities. Profit rates make no sense if they are figured on the bases of wrong prices and capital values. So far nobody has shown how the central authorities (whose limitations are now recognized where physical production planning is concerned) can correctly set and revise many millions of prices.

Another difficulty lay in the working out of the operational plans of the enterprises. It was not clear whether the managers were to compete for investment funds and would be permitted to use any input mix that promised to lower costs, nor, if they did, how their decisions would be made to conform to the quantity-assortment targets of the government.

The hybrid economy of Yugoslavia. The Yugoslav economy, as it evolved in the 1960s, seemed to demonstrate that a socialist system decidedly different from the Soviet model could be made to operate with a degree of decentralization that exceeded by far the Soviet concessions in that direction.

Under the Yugoslav system of workers' management, workers were authorized to select from their own ranks a workers' council and a managing board. The director of the enterprise, who is supposed to run it in accordance with the wishes of the workers, is not subject to them entirely; as a representative of the local community, he is entitled to set aside the workers' wishes if they are considered to be in violation of existing laws and regulations.

The impact of the workers' councils on the management of the enterprises has been considerable. Not only do the workers share in the enterprise's profits; they are able to raise wages at the expense of capital investment and, where there is monopolistic pricing, at the expense of the consumer. Furthermore, a firm may refuse to hire new workers who would be difficult to lay off and whose pay would reduce the profit shares of those already employed.

In Yugoslavia a series of reforms has reduced the national economic plan to the establishment of broad production targets. However, it is more than a mere projection of past trends; the government has the power to influence decisively the rate of capital accumulation and economic growth. The enterprises are not given production quotas or fixed allocations of materials. They formulate their own operational plans according to price signals and profit considerations.

The federal government in Belgrade does not allocate investment funds on the basis of purely market criteria but with political considerations in mind. Furthermore, the prices that govern the actions of the enterprises are in many instances either controlled or set by the government to induce the enterprises to meet the targets of the plan. Since such policies are also used in Western economies, for example in France's experiment with "soft" or "indicative" planning, the difference between Yugoslavia and some Western economies has in many respects become a matter of degree rather than of principle.

Neither Yugoslav nor French planning relies solely on the market economy. Yet, once the functioning of the economy has been largely entrusted to markets and the profit motive, misallocations and inconsistencies may develop if credit and price controls prevent the market forces from working properly. But at the same time, because they have no central plan, the market-planned economies may also suffer from inflation and unemployment.

MIXED ECONOMIES IN DEVELOPING COUNTRIES

If market forces alone were always sufficient, every country with a potential for economic growth would now have developed that potential. Obviously something more is required. The process of growth in less-developed countries must be stimulated by some form of government action that creates the conditions for growth. This does not mean, however, that a positive correlation exists between government action and the rate of growth. The reverse may be true. Results may be better, once the main barriers to development have been overcome, if the government succeeds in bringing market forces and private initiative into play.

Central planning will exceed the capacity of the bureaucracy, for such planning requires a strong, competent, and incorrupt administration, which is just what no backward country possesses. In the absence of such administration it may be better that governments should avoid planning rather than pretend to plan.

Nevertheless, some government initiative is indispensable if existing barriers to development are to be removed. The main barriers are, as a rule, a degree of poverty that does not permit sufficient private or corporate saving, the absence of monetary incentives, and inadequate government services. A clarification of the policies by which economic development can be fostered is urgent. A mixed system does not lend itself to a simple program. If the policies are not to be those of a Soviet-type economy, then whatever increased economic activity the government may undertake must have as its aim the creation and maintenance of a strong private economic sector.

Three main problems

The government will have to solve three main problems: (1) It will have to set investment priorities with respect to education, health, transportation, electric power, and many other parts of the neglected "infrastructure" of the economy. The allocation of very limited resources of capital and administrative talent among these competing demands will be difficult.

(2) The government, therefore, must try to keep its activities limited and leave as much as possible to the private sector. For this purpose it must create market conditions that permit private enterprise to work efficiently. Monetary incentives must be strengthened and investment funds directed into the most productive channels. A correct price and cost structure must be developed to serve this allocation process.

(3) The government must seek to attain the highest level of aggregate investment compatible with monetary stability and must abstain from using an excessive share of the investment funds for the public sector.

The administrations of developing countries are exposed to many temptations to do the wrong thing. For example, a government may try to use excess agricultural labour in the production of capital goods without realizing that major obstacles must be overcome before this absorption of "disguised unemployment" in rural areas can be achieved: consumption in agriculture must be kept from increasing after the labour force has been reduced; the released labour force must be supplied with capital goods; the labourers must be willing to respond to monetary incentives; and administrative or private initiative is needed to organize these changes. Furthermore, "disguised unemployment" must not be confused with the mass industrial unemployment of developed economies and therefore should not be attacked through deficit spending or by embarking on big industrial projects requiring large amounts of capital. Increased spending may do little to move workers from agriculture to industry and, in failing to raise productivity, may only create price inflation. Furthermore, an emphasis on capital-consuming investment projects violates the basic principle of factor allocation. Employment-creating projects in overpopulated poor countries should be prevailingly labour consuming; poor countries are ill-advised when they try to imitate the rich countries by show-case industrialization.

WILL ECONOMIC SYSTEMS CONVERGE?

A casual observer of more recent changes in Western and in Soviet-type economies may be tempted to conclude that they are converging. In Western economies there is a continuing growth of the public sector and increasing concern with the maintenance of a high level of economic activity at reasonably stable prices. In Soviet-type economies there is a trend toward decentralization and the use of profit incentives.

Economic systems must all deal with the same fundamental problems, and it is not surprising that they have many features in common. Modern industrial processes, which are essentially the same everywhere, also account for similarities in otherwise different economic systems. As time goes by and wealth increases there are strong pressures for more freedom for consumers in centrally planned economies and for more collective consumption in the private-enterprise economies. If these similarities constitute convergence then convergence exists. However, if convergence is taken to mean a coalescing of market forces and central planning, with a uniform system emerging that combines what was good and rejects what was bad in the original opposites, one must say that convergence is not occurring. Attempts to decentralize planning on the one hand, or to control the market on the basis of arbitrarily set prices on the other, have yet to show much success; they may in fact, lead to undesirable mixed systems in which the production processes are no longer properly guided either by central command or by private decisions.

BIBLIOGRAPHY

General texts: This article follows the arguments as presented in G.N. HALM, *Economic Systems: A Comparative Analysis*, 3rd ed. (1968). Other selected texts include: G. GROSSMAN, *Economic Systems* (1967), the most compact introduction to the subject; W.N. LOUCKS, *Comparative Economic Systems*, 8th ed. (1969), with an institutional orientation; A.R. OXENFELDT and V. HOLUBNYCHY, *Economic Systems in Action*, 3rd ed. (1965), a realistic comparison of the economies of the United States, the Soviet Union, and France; C. LANDAUER, *Contemporary Economic Systems: A Comparative Analysis* (1964), a liberal socialist approach.

Readings volumes: W.A. LEEMAN (ed.), *Capitalism, Market Socialism, and Central Planning: Readings in Comparative Economic Systems* (1963); M.I. GOLDMAN (ed.), *Comparative Economic Systems: A Reader* (1964); M. BORNSTEIN (ed.), *Comparative Economic Systems: Models and Cases*, rev. ed. (1969).

Central planning: The literature on central planning is as

enormous as the literature on the Soviet economy. For the special purpose of a comparison of different economic systems see: M.H. DOBB, *Soviet Economic Development Since 1917* (1948); P.M. SWEEZY, *Socialism* (1949); H. WELLISZ, *The Economies of the Soviet Bloc: A Study of Decision Making and Resource Allocation* (1964); F.D. HOLZMAN (ed.), *Readings on the Soviet Economy* (1962); M. BORNSTEIN and D.R. FUSFELD (eds.), *The Soviet Economy: A Book of Readings*, rev. ed. (1966).

Liberman discussion: On the Soviet side see M.E. SHARPE (ed.), *Planning, Profit, and Incentives in the USSR*, vol. 1, *The Liberman Discussion: A New Phase in Soviet Economic Thought*, vol. 2, *Reform of Soviet Economic Management* (1966). On the Western side see G.N. HALM, "Mises, Lange, Liberman: Allocation and Motivation in the Socialist Economy," in *Weltwirtschaftliches Archiv*, vol. 100, no. 1 (1968).

Liberal socialism: The most important discussion of the liberal socialist economy may be found in O.R. LANGE and F.M. TAYLOR, *On the Economic Theory of Socialism* (1938; reprinted 1969); and H.D. DICKINSON, *Economics of Socialism* (1939).

The Yugoslav economy: G. MACESICH, *Yugoslavia: The Theory and Practice of Development Planning* (1964); and S. PEJOVICH, *The Market-Planned Economy of Yugoslavia* (1966).

Economic policies in Western economies: Full employment and other modern economic policies in the developed countries of the West are discussed in all modern texts on economics.

Mixed economies in developing countries: While the number of books and articles on economic development is very large, the basic problem of planning and market has been rather consistently ignored. For an exception see H.G. JOHNSON, "Planning and the Market in Economic Development," *Pakistan Economic Journal*, 8:44–55 (1958), reprinted in M. BORNSTEIN (ed.), *Comparative Economic Systems*.

(G.N.H.)

Economic Systems, Primitive

Primitive economic systems are those that apply in so-called primitive societies. Although anthropologists have not quite succeeded in removing the word primitive from their vocabulary, they endeavour to do so because of the value connotations of the word. Some of the economies labelled as primitive represent a high degree of human adaptation, make use of extraordinary skill, and are highly complex in areas of life that in an industrialized society tend to be simplified. If anthropologists have had difficulty in getting rid of the word primitive, the general public has had even greater difficulty, and hence the phrase remains as the most common and easily recognizable in use.

One of the reasons for this is that most other labels similarly lack accuracy. Primitive economies have been called subsistence economies because in them the household produces a very high proportion of its own needs; nevertheless, there is an important component of exchange and often of trade. They have also been described as the economies of "simple societies" or economies with a "simple technological base." But it is often difficult to think of the kinship and religious aspects of Australian aboriginal society (which affect the economy) except as complex. The technology is of course simple by comparison with industrial society, yet components of it (such as highly involved methods of removing poisons from foodstuffs or the production of ornaments) can be highly complex. Perhaps the one universal characteristic (if some peasant societies are excluded) is that the peoples concerned were, at least until the advent of the West and its communications, nonliterate. Thus, "the economies of nonliterate cultures" would perhaps be the most accurate way of defining the topic.

The study of such systems is primarily the subject matter of economic anthropology, the branch of social and cultural anthropology that focusses on the nature of economizing (including the implications of such economizing for institutions and cultural values) and that endeavours to offer interpretations systematically and compare the results both temporally and cross-culturally. Some anthropologists attempt to apply general, abstract principles, mostly derived from economics, to the vast variety of human experience. Others deny the universal validity of such propositions and work through the classification of ideal types of institutions. The probability is that both approaches have their uses.

Much hinges on the application of the idea of economizing to nonliterate cultures. All peoples economize, in the sense in which the term is used in economics. That is, whenever they act they must choose to use limited resources for purposes that are chosen among competing ends. (Ends are competing in the sense that one cannot do everything at once and hence must choose what to do now and what to leave for another time.) It must be remembered that time is a resource: hence conversation and ritual are economic acts. There is nothing in this definition to imply that in some sense the economic is equated with the material: copyright, and its primitive equivalent, the right to perform an initiation song, is a resource; services are as important as material goods; the ideas of a culture are among the tools it has to use; iron in the ground can hardly be counted as a resource if people do not know it is there or have no ideas about its use.

Compared to modernized societies, nonliterate societies have a high proportion of events in which choice is severely constrained—constrained by such matters as ritual, lack of resources, restricted ideas and goals. They are not wholly and inflexibly ruled by custom, however, for myth, ritual, and custom can be manipulated to enable individuals and groups to gain their objectives; nonliterate societies can be flexible, changing, adjusting, even if the change is usually slow.

"Primitive money"

Such societies have sometimes been called nonmonetary, although there are frequently objects identified as "primitive money," such as ornaments of high value (shell-bead necklaces in New Guinea) or durable, countable objects (cowrie shells in Africa). Where money begins and nonmoney ends is difficult to determine, and from a theoretical point of view it may be that the question is meaningless. What is important to determine is what fulfills the functions of money. Ideally, money is a liquid medium of exchange; it consists of things (objects or symbols) that can be transferred freely from one party to another for value received. Its degree of liquidity depends on various restrictions, such as administrative rules (exchange regulations), physical difficulties of transfer (houses), lack of durability (some foods), lack of divisibility for small transactions (heirlooms), customary restrictions upon exchange use, lack of confidence, and so on. Nonliterate societies have many items that enter into exchange, and the current form of questioning about them is to ask: to what degree and for what purpose are they liquid? It thus turns out that in New Guinea the display ornaments once thought of as "money" are in fact limited to certain types of ceremonial exchange, whereas some relatively durable foodstuffs (yams) and tobacco are much more liquid. But no item approaches the universal liquidity represented by the abstract entries in a bank balance in modern industrialized societies.

Production. Why do men produce? First let it be said that the variety of nonliterate societies is considerable: it is much greater in many respects than the variety of Western and Oriental societies since Christ. Thus, any general, short statement concerning primitive economic systems must do violence to the facts as they apply to some particular primitive economies.

Reward or motivation. Under some conditions, such as those of desert bushmen, Australian aborigines, or Eskimos, men live so close to a perilous nature that they must adapt to it, almost become one with it, to survive. Their actions, their will to live, are dominated by their environment. But this is never the whole story and in most instances is but a tiny part of it. The goals, values, and ambitions toward which people orient their production are seldom wholly material. They include status, prestige, and the respect of one's fellow men. They include ritual and religious satisfaction, often in the form

of security against supernatural manipulation. They also have included territorial aggrandizement.

Reward for the fulfillment of production goals can thus come about in several ways. The simplest is production for direct consumption. In nonliterate societies, however, the kin connections used for production go far beyond the small nuclear family—that is, parents and their children. Since an isolated individual would have a difficult if not impossible time living on his own, everyone is part of a family; and the principle of mutual dependence, or reciprocity, becomes the element binding everyone together in production and exchange units. Its extension and reinforcement, indeed, become a major motivation in the minds of the ambitious, and a prime one for those whose very survival depends upon cooperation with others.

Thus, although production is usually much more direct and less "roundabout" than in a modern complex economy, it does not follow that incentives and rewards are simple, material, and direct. If the Western observer examines only one given transaction—for example, the growing of yams in a Melanesian garden or the construction of a canoe—he may be misled by the apparent absence of immediate material wages given to those who work. Only more complex analysis will reveal that the production is to assist kinsfolk or affinal (*i.e.*, marital) relatives in complex ceremonial transactions: the rewards are strictly long term, balanced through networks of mutual dependence, with nonmaterial considerations often predominating.

Division of labour and differentiation of social roles. In many material production tasks, the work of nonliterate societies is relatively unspecialized from family to family. All families can turn their hands to agriculture, domestic work, house building, and fishing. The division of labour tends to be based instead on sex or age categories, though within such categories, of course, skills emerge that can be called upon for special occasions. The production of nonmaterial services, on the other hand, can be crucial in the differentiation of social roles. A shaman, orator, lineage leader, or navigator may have knowledge and skills as important as wealth, resources, and power in giving him specific roles in the division of labour.

The influence of social structure

Both social structure and individual decision making and choice are important in analyzing production. The social structure helps to determine the normative goals of economic activity and embodies the organizational principles. And it influences means as well as ends: a proposed production goal, for instance, may be discarded because it would interfere with the social structure, or, alternatively, a production goal may be adopted or modified to take advantage of methods embodied in the social structure. On the other hand, although the social structure is a charter for action, it is a charter flexible enough to be manipulated in the interests of self and family. A Fijian producer, for example, has a wide choice of possible helpers: members of his household, of households belonging to neighbouring patrilineages, of lineage organizations linked to other households in his village, or lineages linked to women who by marriage have entered his family. Each one of these choices may be justified by the ethos of the social structure. The producer is faced with such choices when he is building a house or a canoe, organizing a fishing expedition, or putting together land, labour, and materials for agriculture. Whether he be African, Asian, an Indian of the Americas, or an islander of Oceania, he is in this sense a coordinating entrepreneur faced with the need to decide between alternatives.

In reference to specialization and division of labour, it should also be noted that between communities there may develop geographical specialties (such as production of ornaments or pottery) leading to trade. Although such geographical specialization may sometimes be found to be historically rooted in some comparative advantage—in the sense that one community has an advantage over another or that trade is more economical than unspecialized production—once a division of labour of this kind becomes institutionalized and customary, it may persist long after the conditions of advantage have changed or disappeared.

Exchange, distribution, and wealth. It should be evident from the discussion about that production, whether of material goods or nonmaterial services, has as its goal the satisfaction not only of subsistence needs but also of those requirements necessary to lead a "good life" as perceived in the community, including the maintenance and reinforcement of the social organization. This principle can be seen most clearly in the study of exchanges and transactions that take place in the course of relations between families, lineal groups, clans, and other units of a social structure. Such relations are, in nonliterate society, frequently, though not completely, expressed in a context of ritual, ceremonial, and conventional codes.

Important examples of such economic exchanges occur during so-called rites of passage accompanying birth, the attainment of adult status, marriage, and death, since on such occasions the familial and lineage links of the main parties require considerable emphasis. On some such occasions, exchanges are relatively simple, but on others they may involve scores or hundreds of participants and preparations lasting months. Some such occasions may have a predominantly religious or political character. It is not normally true to say that such exchanges are "wasteful," for usually the exchanges constitute a major production incentive and hence bring forth a supply of goods that would otherwise be lacking; they often have at their centre durable items; they are the occasion for capital investment; and they are responsible for redistribution of goods through a considerable social network, thus in a certain sense replacing trade.

The central place of gift and ceremonial exchange in nonliterate economies has given rise to a literature that has analyzed the socially compelling consequences of gift giving and the various obligations involved. To give a gift puts the recipient in a position of debt, a debt that may be a requirement for specific repayment or, more symbolically, an emotive and social obligation. This principle is at the heart not only of the economy but of the social system, and its consequences have implications even for modern society (as at Christmas, in marriage, and in business men's clubs).

Even in those societies in which trade and markets have developed, transactions are hardly ever impersonal. Trade partners tend to be selected and symbolized through a process of gift giving, and in market situations each successful transaction tends to reinforce subsequent bonds. Normal supply-and-demand influences on prices are often overruled by personal considerations, and regularity, security, and maintenance of the relationship are more to be valued than taking a maximum profit.

The anthropologist's notion of value, in short, tends to be ethically and philosophically oriented; whereas the economist's use of the term value is ethically neutral, denoting the degree of utility or demand associated with a given object or goal. Insofar as anthropologists do identify values in the economist's sense, their awareness of the wide range of goals that govern action in nonliterate society suggests to them that limited material indicators of standards of living are misleading. Such indicators fail to acknowledge that a society may be prepared to limit material growth in order to gain, for example, increased religious satisfaction or satisfaction derived from kinship relations. Unless such noneconomic values are taken into consideration, one might seriously underestimate or misunderstand the satisfactions, performance, and directions characterizing a particular society. The idea of a "profile of culture" is intended to take such cultural matters into account.

Such considerations lead one to examine more closely the nature of wealth. Westerners are accustomed to thinking of wealth in monetary terms as consisting of accumulated units of purchasing power or of capital. Although nonliterate societies vary in their degree of acquisitiveness and in their conceptions of which kinds of ac-

quisitiveness are ethical and which are unethical, even in those societies classed as materially acquisitive (such as in Melanesia) individuals do not appear very successful at accumulation. Variations in individual property or material holdings are not great, and differences in life style from one person to another are very small.

Where there is lack of continuous accumulation, there is often a lack of durable capital objects that can be passed on from generation to generation. Although durable capital items are never wholly lacking, their ability to call forth production may be restricted, and hence their capital function is also restricted. There are, however, other reasons for limiting accumulation; most nonliterate societies somehow recognize that the accumulation of material wealth carries with it power and political weight, which can upset the traditional or conventional balance of forces. There thus exist conventions and mechanisms to control and check such accumulation. These include symbolic redistribution or even destruction of accumulated material wealth (potlatch being the most famous example) and the use of sorcery and witchcraft to bring unduly ambitious men to heel.

Sometimes, although material accumulations may be frowned upon, there may be respected means of accumulating control over other resources, such as personal services and obligations. If an ambitious man obtains material objects, such as foods, ornaments, pottery, and mats, beyond his immediate requirements, he may escape the threat of sanctions by redistributing the goods as ceremonial or personal gifts. Each time he does this, however, he creates counterobligations. He can thus accumulate wealth, not in the form of a material stock but in the form of obligations to him. The ambitious entrepreneur can call on such obligations as he needs them, gaining prestige, the reputation for wealth, social influence, and economic and political control as he does so. The wealthy man under such conditions is a man without a bank or a warehouse. Wealth consists in the accumulation of obligations that imply powers of control.

Property. No human society exists without property and ownership in some form, and in no case can property rights be conceived of if one considers only a single individual. For property rights are an expression of recognized social relations. Theoretically, property emerged with the first objects of material culture. If a man using a tool prevents others from using it, he exercises or creates a property condition. If he shares it, he defines the property conditions in a different manner. In sharing it, he and others define the terms of sharing and the class of persons included in or excluded from sharing (such as those within or outside the family or kin group).

Such considerations affect all material objects. In traditional nonliterate societies, the relation of a person or group to the land is of course paramount; and whether the society is nomadic, pastoral, or agricultural, a prime element in social relations consists in the norms of interaction, with land as the physical referent. The patterns of land use, and the rights and obligations defining who has a say in the use and product of the land are a result of complex historical and ecological adjustments.

Mythological sanctions for property

Existing rights and practices frequently are justified by reference to history as expressed in myths, tales of origin, accounts of warfare, and the like. Such charters tend to be highly manipulated oral documents, with a strong component of religious and ritual content. Typically, they infer or explain the position of the defined social groups, such as lineages. The family or individual relates his property position to the general social charter and to the more recent specific history of interactions that can be related to it. The specificity of the family or individual position varies according to whether the need to define landed property is specific or general: thus hunting bands may not need to define individually exclusive rights within the total group rights, whereas agriculturalists and shifting cultivators must.

Observation of land use, including the way in which it is justified by reference to right and to historical transactions, usually reveals a pattern much more complex than that suggested solely by the formal social structure or mythology. The interplay of lineal and affinal relatives, the ability to gain access to land through a number of kinship channels, the holding of such land over long periods and the gradual acquisition of rights of disposition, the use or relinquishment of land as an aspect of wider reciprocal exchanges, and the acquisition of political power-carrying rights of general land administration are all factors that can lead to a much more complex crisscrossing of interests in land than might otherwise be deduced.

In addition to rights and obligations with respect to material objects and land, there are others that are rather like copyright, or property in ideas or skills. Knowledge is a significantly scarce resource in any society, and in nonliterate societies it has special manifestations. The right to use symbols (as with totem poles), to make use of a ritual song, to use a tale or a dream as a charter, to exercise a skilled craft such as that of manufacturer of shell ornaments are each examples. In very many instances, such rights (and the obligations that go with them) can be inherited and can even be traded or exchanged, though usually through ritualized forms.

Transformation. There is an extensive literature on the transformation and adaptation of economics under conditions both of traditional patterns of change and of the massive pressures of modern capital, trade, and political and religious action. From all the studies, however, there has as yet been relatively little successful theoretical synthesis or practical application. The best laid theories, when translated into applied projects of change or development, have more often than not been failures. In large measure this can be traced to the fact that change is complex, whereas the tools available to induce change tend to be simplistic, partially applied, out of tune with the values and ambitions of the people, and open to political or moral suspicion.

The difficulties of deliberately inducing change can be so great that many frustrated reformers have tended to find the explanation in the irrationality of traditional society and the dead hand of "custom." This is now normally recognized to be a misunderstanding. Traditional society is rational within its goals, and many reformers do not understand the basis of those goals and the rationality that flows from them and are hence misled. Also, within its own terms, traditional society can be highly adaptable. But if one does not understand this, it is easy to agree with the early analysts, who up to the late 1950s (with echoes still today) tended to feel that progress was only possible through the destruction of traditional values and social organization, opening up the way for individualism and materialism to take charge of events.

Today there are enough examples of successful change, expansion, and modernization based upon a non-Western core of values and social organization to indicate that a policy of destruction is more likely to hinder change (by creating oppositions) than to speed it, and that modernization has many forms. It is true that to date the most successful examples can be drawn from such countries as Japan, Taiwan, and India, which can hardly be described as traditionally nonliterate. Nevertheless, the growing cities, agricultural complexes, and industries of Nigeria, Zaire, Fiji, and other countries working from a traditionally nonliterate base, are well on the way to success as measured in terms of industrialized societies. And it is now clear that their modern form will be far from a mirror image of Detroit, the Midlands, Moscow, or the Ruhr. Adaptation and variety are likely to survive the creation of the computerized world village.

BIBLIOGRAPHY. Two recent reviews of the general issues are M. NASH, *Primitive and Peasant Economic Systems* (1966); and C.S. BELSHAW, *Traditional Exchange and Modern Markets* (1965). Some of the more important specialist articles on this subject have been collected in G. DALTON (ed.), *Tribal and Peasant Economies* (1967); and E.E. LeCLAIR and H.K. SCHNEIDER (eds.), *Economic Anthropology*, including a good bibliography (1968). On gift exchange and money, classic references are M. MAUSS, *The Gift: Forms and Func-*

tions of Exchange in Archaic Societies (1954; orig. pub. in French, 1925); P.M. BLAU, *Exchange and Power in Social Life* (1964); and P. EINZIG, *Primitive Money* (1949). General statements on change and development are contained in C.S. BELSHAW, *The Conditions of Social Performance* (1970); E.E. HAGEN, *On the Theory of Social Change* (1962); B.F. HOSELITZ, *Sociological Aspects of Economic Growth* (1960); and J.H. KUNKEL, *Society and Economic Growth* (1970). Ecosystem

To understand the meaning of the word ecosystem and to appreciate the role this word plays in communicating man's increasing concern about his environment, it is well to consider the holistic concept that underlies the term. Holism, in this connotation, is based on the theory that living components (organisms, including man) and nonliving components (the physical environment) function together as a whole according to well-defined physical and biological laws. Also fundamental to such a holistic concept is an important generalization variously known as the theory of integrative levels or the theory of hierarchical controls. By this is meant that as components are added together to create larger functional units, additional attributes come into focus, attributes not present or not evident from the behaviour of the components functioning separately. When hydrogen is combined with oxygen in a certain manner, for example, water, which is distinct from both of its components, is formed. Similarly, when trees evolve together, they form forests, with an entirely new set of attributes. To understand fully water or forests, therefore, knowledge about the functional wholes as well as the parts is required. The importance of the ecosystem concept is the emphasis it places on the overriding necessity for understanding the large units of nature in which man, his domestic organisms, and his energy-demanding machines are interdependent components, along with other essential components that maintain the total life-support system.

The underlying holistic concept

The word ecosystem is a contraction of ecological system. Ecology, in turn, is derived from the Greek word meaning "house." Persons all over the world, seizing on the root meaning of ecology, have broadened its scope from former rather narrow academic confines and use it to refer to the study of the totality of man and environment, or to the whole "environmental house," as it were. The word system has been defined as regularly interacting and interdependent components forming a unified whole. An anthropocentric, or human centred, definition of ecosystem, therefore, could be: man as a part of, not apart from, a life-support system composed of the air, water, minerals, soil, plants, animals, and micro-organisms, all of which function together and maintain the whole (Figure 1). A more formal definition is: any unit —including all the organisms (biological factors)—interacting with the environment (physical factors) so that a flow of energy within a system leads to a clearly defined trophic (nutrient-requiring) structure, to biotic diversity, and to an exchange of materials between living and nonliving sectors.

The size of an ecosystem

There is no size limit implied in the definition of an ecosystem. It may be a square kilometre of jungle, a square metre of desert, a pond, a woodlot, a city, a farm,

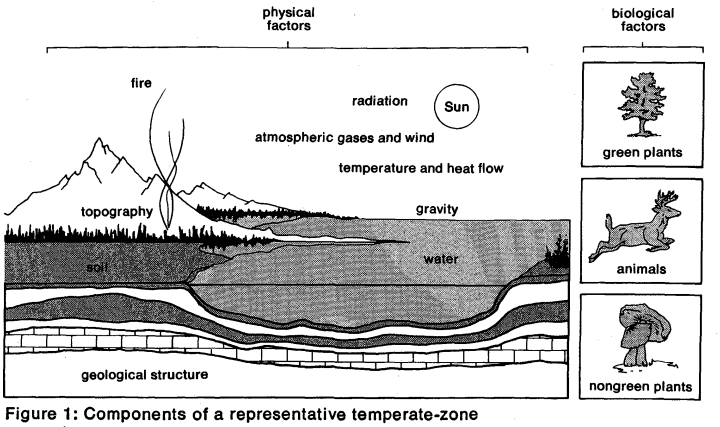

Figure 1: Components of a representative temperate-zone ecosystem.
From *Biological Science: An Inquiry into Life*, 2nd ed. (1968); Harcourt Brace Jovanovich, Inc., New York; by permission of the Biological Sciences Curriculum Study

or a closed container of small organisms (*e.g.*, an aquarium or a vivarium). The largest ecosystem is the biosphere, the entire world of life, and its associated geosphere, the inanimate earth (see BIOSPHERE); because of its magnitude, this ecosystem is often referred to as the ecosphere. Only in man-made ecosystems are the boundaries clear; natural ecosystems blend together at overlap areas called ecotones, as at the edge of a forest or at the seashore.

Historical review of the ecosystem concept. Although the term ecosystem was first proposed by a British ecologist, Arthur George Tansley, in 1935, the concept is much older. Allusions to the idea of the unity of organisms and environment—as well as the oneness of man and nature—can be found far back in written history and often as a basic part of many religions. Anthropologists and geographers, long concerned with the impact of man on his environment, early debated the extent to which man's continuing trouble with deteriorated environments stemmed from the fact that human culture tends to develop independently of the natural environment. A Vermont writer, George Perkins Marsh, produced a classical treatise on this theme in 1864, in which he analyzed the causes of the decline of ancient civilizations and forecast a similar doom for modern ones unless man takes what would now be called an ecosystematic view of man and nature. In the late 1800s essays began to appear on the unity of nature, interestingly enough in a roughly parallel manner in German, English, and Russian. Thus a German, Karl Mobius, in 1877, wrote about the community of organisms in an oyster reef as a biocoenosis. In 1887 an American biologist, Stephen Alfred Forbes, wrote a significant essay on "The Lake as a Microcosm." A pioneer Russian ecologist, V.V. Dokuchaev, and his disciple, G.F. Morozov, placed great emphasis on the concept of biocoenosis, a term later expanded to geobiocoenosis, or biogeocoenosis, which can be considered a synonym of the word ecosystem.

No one has expressed the relevance of the ecosystem concept to man better than did an American ecologist, Aldo Leopold, in his essays on the land ethic. In 1933 he wrote: "The Golden Rule tries to integrate the individual to society; democracy to integrate social organization to the individual. There is as yet no ethic dealing with man's relation to the land," which is "still strictly economic, entailing privileges but not obligations." Leopold argued that without the last, the little progress that has been made with the other two ethics will surely be lost.

Although the idea of the ecosystem was accepted for a long time, before the 1960s it was not in any way applied to man's affairs. Up to this time, applied science consisted largely of managing components as more or less independent units. There was forest management, wildlife management, water management, agriculture, soil conservation, and pest control, but no real planning and management of the whole environmental complex; that is to say, mankind had not yet practiced true ecosystem management. Controlled management of the human

population, together with the resources and the life-support system on which it depends as a single, integrated unit, now has become the greatest and certainly the most difficult challenge ever faced by human society. During the closing decades of the 20th century, mankind shall witness a historic revolution in the way people look at their environment for the very simple reason that for the first time in his short history man is faced with ultimate rather than merely local limitations.

The components of the ecosystem. An ecosystem has two components that are usually partially separated in space and time: (1) an autotrophic, or self-nourishing, component—largely green plants—in which light energy is used to build up complex organic substances from simpler inorganic ones; and (2) a heterotrophic, or "other nourishing," component, in which complex organic substances are utilized, rearranged, and ultimately decomposed. Natural ecosystems, therefore, consist of an upper green belt, which receives incoming solar energy and which overlaps with a lower brown belt, in which organic matter accumulates and decomposes in soils and sediments. The vegetation canopy comprises the autotrophic layer in terrestrial and shallow-water ecosystems, and the soil represents the heterotrophic layer, in which the necessities of life are regenerated in forms usable by green plants. Similarly, in deepwater ecosystems, such as the ocean, the layer of floating algae in the upper, lighted zone is the green belt; and the lower dark zone, with its sediments, is the brown belt.

The green and brown belts of natural ecosystems

It is convenient for purposes of analysis to recognize two layers, six structural components, and six processes as comprising the ecosystem according to the following outline:

A. Layers
  1. autotrophic layer (green belt): the buildup of complex substances predominates
  2. heterotrophic layer (brown belt): the decomposition of complex materials predominates

B. Components
  1. inorganic substances involved in material cycles
  2. organic compounds that link biotic and abiotic sectors
  3. climatic regime (*e.g.*, temperature, rainfall)
  4. producers: chiefly green plants that manufacture food from simple substances and light energy
  5. consumers: animals that ingest other organisms or particulate organic matter
     a. primary consumers: animals that eat plants
     b. secondary consumers: animals that eat other animals
  6. decomposers: chiefly micro-organisms that break down complex compounds with release of products that are recycled by plants or that affect other biotic components

C. Processes
  1. energy flow
  2. food chains (trophic relationships)
  3. diversity patterns in time and space
  4. water and mineral (nutrient) cycles
  5. development and evolution
  6. control (cybernetics)

As with any classification, such subdivisions are arbitrary, but they provide a useful beginning for analysis. Often the components are grouped under abiotic, or physical factors (1–3) and biotic, or biological, factors (4–6). In the holistic viewpoint all components are operationally inseparable; in practice different methods are required to delimit structure on the one hand and to measure rates of function on the other. The ultimate goal of study at any level of organization, however, is to understand the relationships between structure and function. In this article the emphasis is on major functions; the reader is referred to textbooks and review articles (see below *Bibliography*) for details on ecosystem components.

Energy flow and nutrient cycling. The two overriding processes that determine the nature and productivity of an ecosystem relate to energy flow and nutrient cycling. Figure 2 shows in a diagrammatic manner how the one-way flow of energy (clear channels) drives the movement of vital materials (shaded channels) in circular pathways

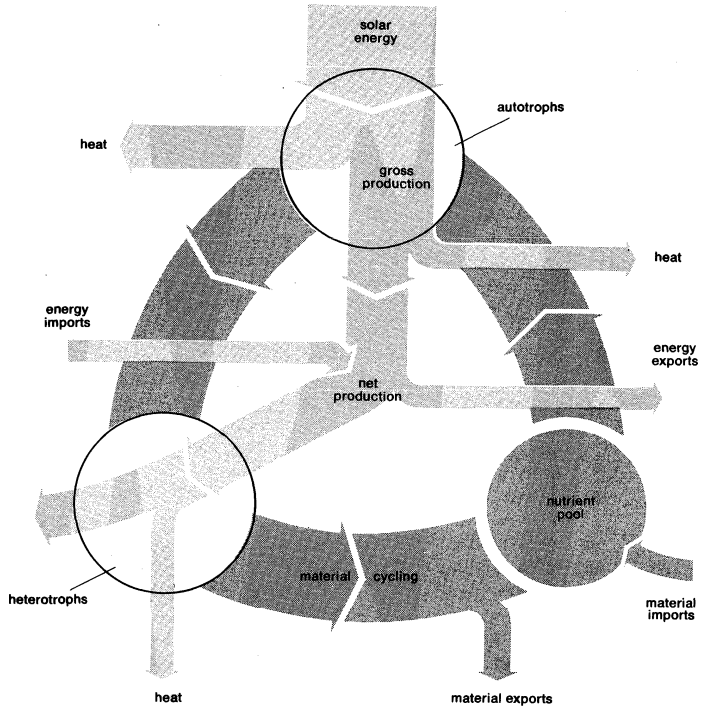

Figure 2: Relationship of energy flow to ecosystem productivity (see text).

(except for importation and exportation of certain matter). The ultimate source of energy that runs the ecosystem is solar radiation. Some of this radiation is converted into organic matter by the autotrophs; it is this primary production that provides the entire food supply of the entire earth community, including man. The sequence of transfer of food energy from one group of organisms to another is known as the food chain, or, if complex, as a food web (Figure 3). At each transfer a large part of the energy (as kilocalories) is lost to the system as heat (the respiration, or R-flows), in agreement with the second law of thermodynamics. In general, 1 to 5 percent of solar energy is fixed by the autotrophic layer (organisms requiring only carbon and nitrogen to synthesize all food requirements); 10–20 percent is transferred from one heterotrophic layer (requiring complex organic compounds) to another. These efficiencies can be increased somewhat, at least for short periods of time, by introducing into the system additional energy in the form of organic matter, cultivation, irrigation, and fertilization, as is done in agriculture; but experience shows that any increase in production or production-transfer efficiency above that which has evolved in nature results in additional thermodynamic disorder (*e.g.*, pollution, disruption of nutrient cycles), which must be taken into account before it can be concluded that a given strategy really has a net benefit in production.

Food chains and food webs

A forking pattern of food chains is shown in Figure 3, a model that relates more directly to the two-layered structure of ecosystems as described earlier. When living plants are consumed by herbivorous animals (grazers), which in turn are eaten by predators, the sequence can be designated conveniently as the grazing food chain. If, on the other hand, plants are not consumed until they die and fall into the heterotrophic stratum, in which decomposing micro-organisms play a major role, the situation is described as the organic detritus food chain. In mature ecosystems, such as forests, less than 10 percent of net primary production is consumed by grazers; the rest goes into the detritus food chain. In what can be termed youthful systems (see below *Ecosystem development*), such as most agricultural systems or fertilized fishponds, 50 percent or more of net primary production flows along the grazing pathway. Experience with pastures (grass–cow–man food chains) has shown that if more than about 40 percent of the annual net primary

production is grazed future productivity may be jeopardized; apparently, a large part of each year's production must be left in the system if moisture retention and nutrient-cycling capacity are to be maintained. In most natural ecosystems there exist feedback mechanisms that prevent overgrazing; unfortunately, man's economic systems, which are based on the short-term profit motive, tend to encourage overgrazing (and overuse of resources generally), since it is often possible to obtain increased yields for several years by overuse. The Table summarizes a nine-year study in which pastures were grazed at three different levels. It can be seen that it paid to overgraze (*i.e.*, to use more than 50 percent of yearly net production) for about five years in the sense that a larger amount of beef was produced. After nine years, however, the overgrazed pasture was so damaged that its yield was but a fraction of the pastures grazed in a moderate manner.

The value of analytical models

The bulk of incoming solar energy is dissipated in the work of driving the water and other physical cycles, in powering weather systems, and in maintaining a gradient of temperature conditions to which various kinds of organisms are adapted. From the global standpoint, one of the most important cycles is the water, or hydrologic, cycle shown in Figure 4, in terms of a picture model and a systems model derived from it. The advantage of the systems model is that it shows the steps that require solar energy to drive the cycle and the steps that release energy for useful work in operating the biological components of the ecosystem. Such a diagram also is the first step in translating energy flows and amounts into computer language for simulating and testing total ecosystem behaviour.

Grazing Intensity Model*

production efficiency	intensity of grazing		
	light (1 cow per 21 acres)	moderate (1 cow per 15 acres)	heavy (1 cow per 9 acres)
Forage utilization (percent of vegetation grazed)	37	46	63
Condition of range (end of 9-year period)	improved	unchanged	deteriorated
Annual beef production (lbs per acre)			
First 5 years	15	18	32
Next 3 years	15	15	18
Ninth year	20	17	9

*A nine-year study of a South Dakota range.

Until recently, man tended to take for granted this immense amount of "free" work of nature and scarcely bothered to measure the energy drive or the flux rate of water movement between different compartments of the ecosystem. As industrial power flows are greatly increased by releasing energy from fossil fuels and atomic sources, it becomes clear that stability of vital natural cycles and energy flows can be adversely affected; for example, the thermodynamic-disorder consequences of rapid burning of fuels, namely the release of CO_2 and dust into the atmosphere, may now already be affecting the heat balance of the Earth. Carbon dioxide tends to act as a heat trap, warming the Earth, whereas dust tends to reflect incoming energy, thus cooling the Earth. Even small changes either way can influence the amount of water available as liquid, which in turn could greatly alter sea levels and climates.

In contrast to the water cycle, the cycling of nitrogen is largely controlled by the biological community rather than by strictly physical forces. A key role is played by specialized micro-organisms, many of which are sensitive to poisoning by man-made chemicals and other wastes. The study of biological nitrogen fixation and recycling is of such vital importance to man that intensive and worldwide interdisciplinary ecological studies have been launched, as, for example, those supported by the International Biological Program.

Systems ecology. If man is to cope adequately with the ecosystem level of organization in the sense of developing a new applied science of ecosystem management, the models, as shown in Figures 1–4, must be formalized in terms of mathematics. The formalized, or mathematical model, approach to populations, communities, and ecosystems is known as systems ecology; it has become a major science in its own right for two reasons: (1) extremely powerful tools are now available in terms of mathematical theory, cybernetics, and electronic data processing; (2) formal simplification of complex ecosystems provides the best hope for solutions to man's environmental problems, which can no longer be trusted to trial and error or to one problem-one solution procedures that have been employed in the past. Although the formal models thus far are rather crude and as yet have limited predictive value, the following eight points have emerged as a result of modelling the whole of nature:

1. Since available energy declines with each step in a food chain, a system can support more herbivores than carnivores. For this reason, fewer meat eaters than vegetarians, including man, are supported by a given food base. Materials, however, often become concentrated

with each step in a food chain; failure to anticipate the possible biological concentration of pollutants, such as DDT or long-lived radioisotopes, has caused serious problems in man's environment.

2. It has become increasingly evident that high biological productivity (in terms of energy yield per unit area) in both natural and agricultural ecosystems is usually achieved with the aid of energy subsidies from outside the producing system. Energy subsidies take the form of wind and rain in a rain forest; tidal energy in an estuary; or the fuel, animal, or human work energy used in the cultivation of a crop. Comparisons of the productivity of different systems should take into consideration the complete budget—not just solar input.

Energy subsidies

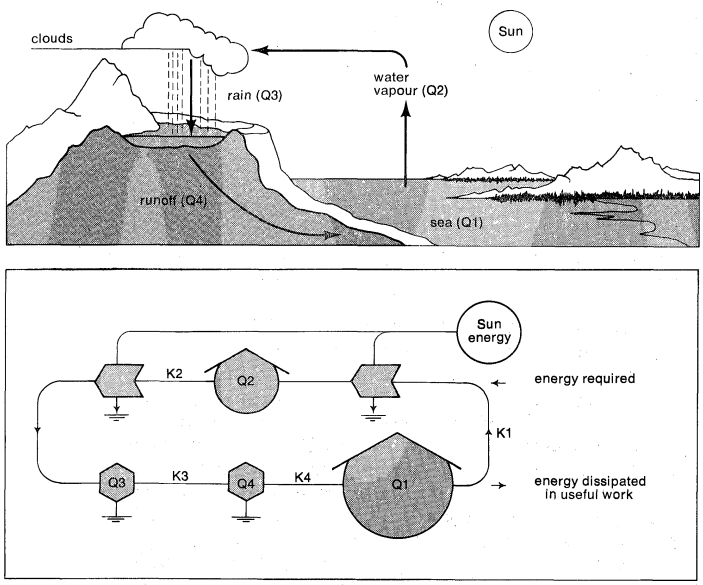

Figure 4: Conceptual models of the water cycle. The symbols are mathematical shorthand for energy movement.

3. It has become evident that both harvest and pollution are stresses that reduce the energy available for self-maintenance of an ecosystem. Man should be aware that he will have to pay the costs of added maintenance, or "disorder pumpout." Attempts to force too much productivity, or yield, from the landscape—the aim of the so-called green revolution—are dangerous because very serious ecological backlashes can result from the following: pollution caused by heavy use of fertilizers and insecticides and the high consumption of fossil fuels; unstable or oscillating conditions created by one-crop systems; genetic vulnerability to disease of highly bred plants because their self-protection mechanisms have been "selected out" in favour of high yield; and social disorder created by rapid shift of rural people to cities that are not prepared to house or employ them. The tragedy of the last point is that industrialized agriculture can result in increased food per acre, but it can also widen the gap between rich and poor, so that increasing numbers of people are increasingly unable to buy the food produced.

4. Although production and decomposition are generally thought of as being balanced in the biosphere as a whole, this balance has never been exact; rather, it has fluctuated from time to time in geological history. Throughout evolution, production has slightly exceeded decomposition, so that an atmosphere with a high oxygen content has replaced the original (reducing) atmosphere of the Earth. Man, of course, now tends to reverse this trend by increasing decomposition (burning of fuels) at the expense of production.

5. The diversity of living things is apparently directly correlated with stability, and perhaps inversely correlated with productivity, at least in many situations. Most ecosystems contain a larger number of species than would seem necessary to maintain basic energy flows and cycling; models indicate that variety may be a necessity in the evolution of natural systems. Thus, it is possible that the preservation of diversity in the ecosystem is important.

6. At the population level, it is now clear that the growth form of the human population does not conform to the simple model, in which density levels off below carrying capacity, or the peak ability to support persons. Since there will always be a time lag in the effects of crowding, pollution, and overexploitation of resources, growth will not automatically level off, as do populations of yeasts in a confined vessel. Instead, it is probable that the human population will exhaust some vital resource unless man can anticipate the effects of overpopulation and reduce growth rates before the deleterious effects of crowding are actually felt. Intelligent behaviour would seem to be the most effective control mechanism in view of the fact that the extent of such restraints as disease and famine have been greatly reduced—at least for the time being.

7. Some of the most important developments in ecology have been in the area of biogeochemical cycling and recycling. Since recycling of water and minerals will eventually become a major goal of human society, such pathways in nature are of great interest. At least four major ones occur, which vary in importance in different kinds of ecosystems: (1) recycling via microbial decomposition of detritus; (2) recycling via animal excretion; (3) direct recycling from plant back to plant via micro-organisms, such as the fungal mycorrhizae associated with roots; and (4) autolysis, or chemical recycling, in which no organisms are involved. The third pathway seems to be especially important in the humid tropics, which suggests that tropical agriculture might be redesigned to include food plants with mycorrhizae.

Recycling

8. The principles inherent in limiting factor analysis and in human ecology can be combined to formulate the following tentative overview: In an industrialized society, energy (*e.g.*, power, food) is not likely to be limiting, but the pollution consequences of the use of energy and of the exploitation of resources are limiting. Thus, pollution can be considered the limiting factor for industrialized man—which may be fortunate since pollution is a visible signal to man.

Ecosystem development. Principles concerned with the development of ecosystems are most relevant, in view of man's present situation, and for that reason are summarized here. In older textbooks this general subject is usually called "ecological succession."

In broad view, ecosystems develop through a rapid growth stage that leads to some kind of maturity or steady state (climax), usually a fluctuating steady state. The early successional growth stage is characterized by a high production to respiration (P/R) ratio, high yields (net production), short food chains, low diversity, small size of organism, open nutrient cycles, and a lack of stability. In contrast, mature stages have a high biomass (total mass of living matter) to respiration (B/R) ratio, complex food webs, low yields, high diversity, and stability. In other words, major energy flow shifts from production to maintenance (respiration) as an ecosystem reaches maturity.

The general relevance of the development sequence which has been described above to land-use planning can be emphasized by general contrast of young and mature ecosystems: young ecosystems display production, growth, and quantity, while mature ecosystems display protection (of production), stability, and quality.

Young versus old ecosystems

Since all of these characteristics are desirable in the aggregate, two possible solutions to the dilemma can be suggested. A compromise can be obtained so as to provide moderate quality and moderate yield on all the landscape, or the landscape can be compartmentalized so as to maintain simultaneously highly productive and predominantly protective types as separate units subjected to different management strategies. If ecosystem development theory is valid and applicable to land-use planning (total zoning), then the so-called multiple-use strategy, about which much has been written and said, will work only through one or both of these cases be-

cause in most cases projected multiple uses conflict with one another.

The general failure of land-use planning and zoning, as presently carried out, appears to result from, first, a failure to recognize conflicts between different uses that can not be resolved by continual compromise and, second, a failure of the economic system to place a monetary value on that part of the environment that functions as the life-support apparatus.

BIBLIOGRAPHY. EUGENE P. ODUM, *Fundamentals of Ecology*, 3rd ed. (1971), is a comprehensive college textbook and reference, designed also for the citizen, educator, and political leader; see also the same author's "The Strategy of Ecosystem Development," *Science*, 164:262–270 (1969). Three paperbacks that emphasize the ecosystem approach to ecology are: EUGENE P. ODUM, *Ecology* (1963); EDWARD J. KORMONDY, *Concepts of Ecology* (1969); and ROBERT H. WHITTAKER, *Communities and Ecosystems* (1970). HOWARD T. ODUM, *Environment, Power, and Society* (1971), is a semipopular introduction to systems ecology, with emphasis on technological, political, and economic solutions to man's environmental problems. *Ecosystem Structure and Function* (1971), contains the proceedings of the 31st Biology Colloquium, in which five authors deal with ecosystem concepts. ALDO LEOPOLD, *A Sand County Almanac, and Sketches Here and There* (1949), is an environmental classic, with near poetic essays on "The Land Ethic," "Wilderness," and "Conservation Esthetic," all imbued with the place of man in ecosystems.

(E.P.O.)

Ecuador

Ecuador, a republic situated in northwestern South America, is, after Uruguay and Guyana, the smallest state in South America. It is crossed by the Equator, from which it derives its name. Its possession of the Archipiélago de Colón, or the Galápagos Islands, which have an area of 3,075 square miles (7,964 square kilometres), brings its total land area to 109,483 square miles (283,561 square kilometres), of which continental Ecuador amounts to 101,429 square miles (275,597 square kilometres). The population, early in the 1970s, was about 6,000,000.

Ecuador is bounded by Colombia to the north, Peru to the south and east, and the Pacific Ocean to the west. The border with Peru, established by the Rio de Janeiro Protocol of 1942, has never been accepted by Ecuador, which claims a larger portion of the Amazon Basin. The country is traversed from north to south by the Andes mountains. The capital city is Quito.

Although Ecuador is rich in natural resources, rapid and sustained economic growth has not yet begun. The subsoil, especially in the east, is virtually unexplored. The economy is basically agricultural, with bananas and coffee constituting the two most important products. The exploitation of petroleum deposits has begun in the northeast, and copper is produced from mines in Azuay Province. It is hoped that these mineral resources will help to stimulate the economic development of the country.

(For associated physical features, see ANDES MOUNTAIN RANGES; GALAPAGOS ISLANDS; for historical aspects, see ECUADOR, HISTORY OF.)

THE LANDSCAPE

Physiography. *Relief.* Three parallel chains, or cordilleras, of the Andes Mountains, the eastern, central, and western—all running approximately north to south—divide the country into three main regions: the coastal region; the sierra, or mountain, region; and the east.

The three regions

The coastal region is composed of lowlands extending from the Pacific Ocean to the western edge of the mountains and rising from sea level to an altitude of 1,650 feet. In the centre of these lowlands—the location of the Guayas and Manabí provinces—a small mountain range of volcanic origin rises to 2,600 feet. It is variously known as the Colonche, Chongón, Paján, or Puca Mountains. The range is surrounded by a slightly undulating plain that stretches northward to the Colombian border. In the south, the lowlands were primarily formed by the silt deposits of the rivers that empty into the Gulf of Guayaquil. Puná, in the Gulf of Guayaquil, is the major coastal island.

The western and central ranges of the Andes bordering the sierra region constitute the country's highest and most continuous mountain chains. Many peaks are volcanic or snow covered; these include Cayambe, 18,996 feet (5,790 metres); Antisana, 18,717 feet (5,705 metres); Cotopaxi—the world's highest active volcano—19,360 feet (5,897 metres); Carihuairazo, 16,752 feet (5,106 metres); Chimborazo, 20,556 feet (6,267 metres); Tungurahua, 16,420 feet (5,005 metres); Altar, 17,277 feet (5,266 metres); and Sangay, 17,158 feet (5,230 metres). The two ranges are connected at intervals by transversal mountain chains of volcanic origin, much as individual stairs connect a staircase. Between the transverse mountains are large, isolated valleys or basins, called *hoyas*, that are named for the main river running through them.

The eastern region begins with the eastern spur of the central range, which extends to the border with Peru. This region is crossed by the eastern, and least important, cordillera of the Andes, which is also comprised of three sections—the Cordillera de Galeras, which includes the northern mountains; the Sierra de Cutucú, which borders the Upano Valley and includes the central peaks; and the Cordillera del Cóndor to the south, which borders the Zamora Valley. Beyond this eastern cordillera, again to the east, is the Amazon River Basin.

Drainage. As the annual thawing of snow occurs in the mountains, numerous rivers arise, pass through the *hoyas* of the Sierra, and flow either west to the Pacific coast or east to the Amazon River.

The river system

The coastal region is primarily drained by the Río Guayas Basin. Formed by the juncture of the Daule and Babahoyo rivers and their affluents, the Río Guayas is navigable for the greater part of its course. The rivers that also flow to the ocean include the Santiago and Cayapas and their tributaries; the Esmeraldas; the Jubones; and the Santa Rosa.

In the sierra region the rivers, torrential in their upper courses, become calmer in the plains areas but remain, nonetheless, unnavigable.

The majority of Ecuador's rivers, found in the eastern region, carry the greatest volume of water and are the most navigable of the nation's waterways. The most important is the Napo River, which receives the Coca and Aguarico rivers as well as other large tributaries as it takes its course towards Peru, where it joins the Amazon River (*q.v.*).

Climate. Despite the fact that Ecuador lies on the Equator, the climate is modified by the Andes Mountains and by a branch of the cold Peru or Humboldt Current that flows along the coast.

The coastal region is warm; temperatures rise slightly away from the sea and average between 73° and 77° F (23° and 25° C). Rain falls from January to May. Affected by the Peru Current, annual precipitation varies between 16 inches and 78 inches.

In the sierra region, the climate varies with altitude and is modified by winds. Climatic conditions run the gamut from glacial cold at the perpetual snow line to tropical temperatures in certain *hoyas*. Among inhabitants of Vilcabamba in Loja Province, famous for its exceptionally healthy climate in which the temperature varies between 63° and 68° F (17° and 20° C), it is not unusual to find individuals of 120 years or more. Using 79° F (26° C) as a median temperature at sea level, it may be said that the temperature decreases by 1.8° F (1° C) with every 660-foot increase in the altitude.

The east is the warmest and most humid region of Ecuador. Median temperatures range between 73° and 81° F (23° and 27° C), rainfall can reach 236 inches annually, while humidity as high as 90 percent may be sustained for several months.

Tropical rain forest areas

Vegetation and animal life. The wet lowlands of the east and the northern and southern corners of the coastal region are covered with tropical rain forest, containing various trees, lianas (climbing vines rooted in the ground), and many epiphytes (plants that grow nonparasitically on other plants, deriving their nutrients from

the air and the rain). This forest thickens as it approaches the zone of maximum rainfall, which occurs between 4,000 and 5,000 feet above sea level. In the Guayas Valley, the forest contains balsa, which is exploited for its light lumber; in the eastern forest the cinchona trees were a valuable source of quinine before synthetic equivalents reduced demand for it. The trees of the coastal region are fast disappearing because of exploitation, while the east remains untouched.

In the coastal region between Esmeraldas and the Gulf of Guayaquil, where the climate is affected by the Peru Current, the rain forest gives way to deciduous and semi-deciduous woodland. There, scattered palms produce the ivory-coloured nuts used in making buttons, while the hat carludovica (*Carludovica palmata*) furnishes the fibre used for Panama hats. Areas of swampy coast and the river floodplains are covered by thick mangrove forest.

In the sierra region, the vegetation of the *hoyas* resembles the rain forest. Above the valleys, the *ceja de la montaña* ("eyebrow of the forest") consists of dense moss-covered woodland that at 10,000 to 11,000 feet gives way to tall, strawlike grasses known as *elichu*. In the highest regions, only lichens grow where there is no snow cover.

In the rain forest live a wide variety of monkeys, as well as such carnivorous mammals as the jaguars, ocelots, foxes, weasels, otters, skunks, raccoons, coatis (members of the raccoon family), and kinkajou (a tree-dwelling nocturnal animal with a prehensile tail). Hoofed mammals include tapir, deer, and peccary, an animal related to the pig. There are many species of rodents and bats.

Birdlife

About 1,500 species of birds have been identified; different species of birds are associated with the various types of vegetation. Among many types of North American birds that migrate to Ecuador for the winter are the Virginia rail, the kingbird, the barn swallow, and the scarlet tanager.

The fish population is similar to that of the Amazon River although in the west the electric eel and the piranha are not found. All major groups of reptiles are represented, including dangerous snakes; two types of marine turtle are hunted for their meat and shells.

Numerous insects include butterflies, moths, grasshoppers, bees, and ants. A giant beetle grows to five inches in length; some other beetles emit phosphorescent light.

Settlement patterns. *Traditional regions.* The traditional regions of Ecuador coincide with the country's three physical regions of the coast, the mountains, and the Amazon Basin. The highest proportion of peoples of Indian descent lives in the isolated mountain basins. The east is thinly inhabited by indigenous peoples.

Rural settlement. The coastal region is the site of banana plantations; its other tropical products include cacao, tobacco, yucca (a fibre-bearing plant of the lily family), and fruit. Most of the population lives in grass or cane houses with roofs of palm leaves or zinc. The sierra is the granary and cattle centre of Ecuador. Grains, beans, and peas are grown in small patches that, from the air, give the land the appearance of a giant, multicoloured chessboard. The peasants occupy houses of adobe (brick made of sun-dried earth and straw) roofed with straw. A small amount of settlement has taken place in the east, where grain is grown on land reclaimed from the rain forest.

The land tenure system

The rural peoples lead lives characterized by poverty and hard labour. Some of them own small patches of land, or *minifundios*, the products of which are insufficient even for subsistence. Others work as tenant farmers, or *huasipongueros*, on the haciendas (large estates). In return for their labour, they receive a house and a small plot of land on which they may cultivate wheat and raise domestic animals. The large landowners generally live in the cities and only occasionally visit the haciendas. An agrarian reform program has been launched to attempt to improve conditions through the agency of the Ecuadorian Institute of Agrarian Reform (IERAC).

Urban settlement. Quito (population 530,000), the national capital, known for its distinctive architecture, is one of the most beautiful cities in Latin America. Guayaquil (population 795,000) is the principal port and national commercial centre. Cuenca (population 77,000) is known for its traditional culture and for its growing industry. Other notable urban centres include Riobamba, Ambato, Loja, and Ibarra.

The main cities are increasing their populations at an accelerated rate. Quito houses most of the country's government officials; state salaries are not high, and most civil servants live from day to day. In Guayaquil, however, the majority is engaged in commerce, and economic opportunities are greater. Social and cultural life is intensified in the main urban areas. On weekends people often go to the countryside, or attend such sporting events as football (soccer) matches, bullfights, or horse races.

THE PEOPLE

Composition. Ecuador has long been mistakenly represented as either a predominantly Indian country or as a land of headhunters. In effect its population is ethnically mixed, with mestizos—persons of mixed Indian and European (white) origin—forming the majority.

The Indian population

The Indians, whose numbers are decreasing, form the second largest ethnic group. They are divided into a number of groups, including Otavalos in Imbabura; Salasacas in Tungurahua; and the descendants of the Puruhá in Chimborazo, who represent the largest and the poorest Indian group. Other Indian groups are the Cañari in Cañar and Azuay provinces; the Saraguros in Loja; the Cayapas in Manabí; and the Colorados in Pichincha Province.

The white population, third in order of size, is largely descended from Spaniards who arrived in Ecuador from the 16th to the early 19th centuries. Other white emigrants travelled from North America and Europe during the 20th century. The blacks were brought from Africa as slaves during the colonial era and are mainly found

in the northern coastal province of Esmeraldas. There is also a small black community in the Chota Valley of Imbabura Province, as well as a few families living in Catamayo. Mulattos, or *zambos*—people of mixed black and white parentage—are found living throughout the coastal region.

The Jívaro, who form the main Indian group in the eastern region, consist of small tribes or family units; they are gradually being assimilated into Ecuadorian society. They originally engaged in headhunting, a practice now extinct. Shrunken heads sold to tourists today are generally imitations fashioned by talented artisans from goat or other animal skins. Other eastern Indians include the Záparos, Cofanes, and Aucas.

Linguistic patterns

Spanish, the official national language, is spoken by nearly all the population. Quechua, an Indian language, is also spoken within Indian groups, while the Jívaros and Colorados use dialects of their own.

The overwhelming majority of the people are Roman Catholic; Protestants comprise less than 1 percent of the population.

Demography. The total population of Ecuador was estimated at 6,384,000 inhabitants in 1971. In quantitative order, the population is composed of mestizos, Indians (except for Jívaros), whites, blacks, mulattos, and the Jívaro Indians. About 51 percent of the people live in the sierra region, 46 percent in the coastal region, and 2 percent in the eastern region (the remainder in the Galápagos).

The annual birthrate is 45 per 1,000 inhabitants, and the infant mortality rate is 86 per 1,000. The annual population growth rate of 3.4 percent is not appreciably affected by immigration or emigration rates, which are low and variable.

THE ECONOMY

While Ecuador is a country of tremendous economic potential, it has never experienced a period of sustained development. The agricultural possibilities of El Oro Province and the sierra have been well-developed, but the mineral wealth of the mountains remains untouched. The eastern region, with its rich, virgin land, is now being settled, but there are thousands of acres of undeveloped jungle that represent an unknown reserve potential. The majority of Ecuadorean land remains uninhabited, and technological methods of agriculture are used only on the banana plantations of the coastal region.

Natural resources. *Mineral resources.* Since the birth of the republic almost 150 years ago, no comprehensive scientific exploration of Ecuador's mineral wealth has been undertaken. The extent and depth of deposits of white clay, marble, coal, and sulfur remain unknown because they have been examined only superficially if at all. In the late 1960s, however, the government at last showed interest in its mineral wealth and began to contract for its exploitation. Oil, found in northwestern Oriente Province, is being extracted by the Texaco-Gulf Oil Corporation, which constructed a pipeline to Esmeraldas. Copper mines at Chaucha are operated by a Japanese company. Deposits of silver and molybdenum have also been located.

Oil and copper resources

Forest resources. Pines are cultivated in the sierra region, where there are also natural forests of romerillo (herb yielding a yellow dye), walnut, and cedar. Large eucalyptus forests occur in all three regions.

Power resources. The Andes Mountains present vast possibilities for hydroelectric development. The present small hydroelectric plants are inadequate for industry, or even for domestic use. At the instigation of the Ecuadorian Centre of Economic Reconversion, a Canadian firm carried out a study along the Río San Pablo, an affluent of the Paute River, and subsequently proposed the installation of a hydroelectric station with a capacity of 1,050,000 kilowatts. The Ecuadorian Institute of Electricity (Instituto Ecuatoriano de Electrificación), a government agency, is responsible for the development of power resources.

Sources of national income. *Agriculture, forestry, and fishing.* Agriculture employs about 56 percent of the working population. The chief products are bananas and coffee; other products include barley, cocoa, cottonseed, corn, potatoes, rice, wheat, kidney beans, chickpeas, lima beans, and fruit.

The forests supply the domestic needs of the construction and cabinetmaking industries. Fishing provides work and a subsistence diet for small coastal settlements. The tuna, sardine, and shrimp industries in Guayaquil and Manta produce over 26,500 tons annually.

Stock raising is extensive in the sierra and coastal regions, and is growing in importance in the eastern region. In the early 1970s, Ecuador's livestock resources amounted to about 2,400,000 cattle, 1,900,000 sheep, 240,000 horses, and 110,000 mules.

Mining and quarrying. The mining and quarrying industries are still nascent. Annual production includes about 770 pounds of gold, 3 tons of silver, 40,000 tons of salt, 150 tons of sulfur, and small quantities of zinc and marble. The production of crude oil—about 300,000 tons annually—and of copper increased considerably in the 1970s.

Industry. The major industrial centres in Ecuador are Quito, Guayaquil, and Cuenca; the other cities have experienced only slight industrial development. The main industrial products of the country include textiles, shoes, tires, processed foods and beverages, galvanized pipes, vehicle frames, pharmaceutical and chemical products, cement, and oil derivatives.

Financial services and foreign trade. *Financial services.* The Central Bank and the National Bank of Promotion, both state controlled, have branches in all of the provincial capitals. The former is the government depository and controls the monetary system, while the latter handles agricultural and industrial credit. Private or commercial banks are both foreign and domestic. The bank supervisory board is a technical organization that monitors all banking activities.

Government and private banking

Foreign trade. Exports include bananas (47 percent of the total), coffee (25 percent) and cacao (11 percent); these products are sold primarily to the United States,

Japan, West Germany, Belgium, and Luxembourg. Imports include motor vehicles, food and chemical products, consumer goods, and machines and primary materials for industry. They are mainly bought from the United States, Japan, West Germany, the United Kingdom, Belgium, The Netherlands, and Luxembourg. In 1970 all exchange restrictions on international transactions except those relating to foreign loans and investments were ended. Tax allowances were provided for exports, while surcharges on imports were abolished. In the same year Ecuador began the exportation of specified products to Bolivia, Chile, Colombia, and Peru on a duty-free basis.

Management of the economy. The government regulates national production through various organizations, such as the Planning and Coordination Council, which deals with economic and social developmental planning; the Central Bank; and the National Developmental Centre. The private economic sector includes a large part of agriculture and stock raising, as well as business and industry.

All of the provincial capitals have their own commercial, industrial, and agricultural associations, or *cámaras;* they are composed of persons associated with various economic sectors, and protect the interests of their membership. Each association is autonomous and is locally influential.

The Ministry of Finance collects taxes on income and commercial transactions through the General Director of Revenues; taxes on rural and urban property are collected through the municipalities. The Ecuadorian taxation system was being reformed in the 1970s in order to attempt to ensure a more complete tax collection.

Transportation. Because of difficult topography and lack of economic development, Ecuador has only a partially developed road system. The farmer, or *campesino,* who wishes to take his products to market frequently must resort to horse or mule transport, or must even backpack to reach motorized transportation. These circumstances reduce the profits earned and constitute an obstacle to production in many areas. The problem is most acute in the southern sierra and in the eastern regions.

Road system

There are about 13,000 miles of roads of which 1,800 miles are paved. The Pan-American Highway crosses the country from north to south through the sierra region. Other important roads connect the port of Guayaquil with Quito, Cuenca, Loja, and the port of Salinas. Machala and Puerto Bolívar are linked to Huaquillas and Cuenca, and there is a narrow road from Pallatanga to Bucay (situated 54 miles east of Guayaquil on the Guayaquil–Cuenca Road). In the east, the main roads lie within the Andes region and radiate from Ambato, Cuenca, and Loja.

Railroads total about 700 miles. The principal lines connect Quito with Guayaquil and Cuenca through the railway junction at Sibambe. There is also a line from Quito north along the mountains and across the coastal plain to the port of San Lorenzo. Service is slow and poor, and the railways are used more for the transport of freight than for passengers.

Guayaquil, with its modern facilities at Puerto Nuevo, is the country's chief port. Other ports of importance are San Lorenzo, Esmeraldas, Manta, and Puerto Bolívar. All have a port captaincy (an administrative district under the command of a captain) as well as customs and immigrations offices; all are linked with the interior by road or railway.

Most of the major cities have airports. There are several national airlines, and the main international airline is *Ecuatoriana de Aviación.* Nine international airlines stop at Quito and Guayaquil, but the airports at Cuenca, Loja, and Riobamba lack the necessary facilities for larger aircraft.

ADMINISTRATION AND SOCIAL CONDITIONS

Government. *Administration.* Ecuador is a sovereign democratic republic. The president and vice president are elected for four-year terms by popular, direct, and secret voting. The State Council of 19 members has a consultant function, and the chief executive is aided by an 11-member cabinet. Legislative power is vested in the national congress, which is made up of two houses—the senate, with two representatives from each province, and one from the Archipiélago de Colón, as well as 15 "functional" senators elected by special economic or cultural groups—and the House of Deputies, whose members are chosen from each province according to population distribution.

The chief executive appoints as his representatives the provincial governors, political chiefs in each of Ecuador's 19 provinces, which are divided into *cantones* (regions), which in turn are divided into parishes. The chief executive also appoints the political chief in each *cantón,* and a political lieutenant in each parochial district. Every province also has a provincial council presided over by the provincial prefect.

Each *cantón* constitutes a municipality, the governing of which is in the hands of a *cantón* council. The council of each province capital is headed by a mayor.

Politics. Literate, native-born, or naturalized Ecuadorians over 18 years of age have the right to vote in all elections by direct, secret ballot. Political groups include on the right of the spectrum, the Conservative Party, the Social Christian Movement, and the Nationalist Revolutionary Action Party of Ecuador. Parties on the left include the Liberals, the Socialists, and the Communists. A large part of Ecuadorian politics, however, revolves around the caudillos, or political leaders. The Concentration of Popular Forces Party, for example, was led by Asaad Bucaram. The Velasquista Party centred on José María Velasco Ibarra, five-time president of the republic. These two parties drew members from nearly all of the other political parties.

Political parties and groups

Justice. The constitution provides for free access to justice for all. The Supreme Court, with its seat in Quito, has national jurisdiction. Eight superior courts are located in the provincial capitals, and there are also provincial tribunals, *cantonales* or regional courts, and criminal and transportation courts. Special tribunals handle cases concerning the press and radio, and the protection of minors. Constitutionally, no judgement may be appealed more than three times.

The armed forces. The armed forces consist of the national army, the air force, and the navy. The army consists of six divisions and some small operational forces; the navy has a small number of frigates, gunboats, patrol vessels, and other craft; the air force has about 60 aircraft. The National Civil Police have the responsibility of maintaining internal security and order. With the exception of Guayaquil, which has an autonomous transportation commission, the police also control traffic. The rural police, a division of the national civil police, exist only in the small towns and the interior. The police force throughout the country is below strength because of a lack of funds.

Social conditions. *Education.* Education is free and is obligatory at the primary level for all children ages six to 12. All state schools are nondenominational, but private schools—which also receive state funds—are divided into nondenominational and religious schools.

In the early 1970s there were about 7,000 primary schools, about 360 high schools, and almost 240 technical schools, of which about 40 were teacher-training schools.

There are 14 institutions of higher learning. They include the Central University of Ecuador at Quito, the University of Guayaquil, the University of Cuenca, the University of Loja, the Technical University of Manabi, the National Polytechnic School of Quito, and the Polytechnic School of the Litoral at Guayaquil. Church-affiliated universities include the Pontificate Catholic University at Quito, the Catholic University of Guayaquil, and the Catholic University of Cuenca.

Welfare services. All public and private employees are affiliated with the National Social Security Institute. In return for a monthly deduction from employees' salaries, the agency provides such services as medical and

hospital insurance coverage, state-run clinics and dispensaries, low-interest loans for surgery and mortgages, retirement pensions for civil and state employees, and pensions for widows and child dependents.

The Social Welfare Program, a division of the Ministry of Public Health, maintains public hospitals in all of the provincial capitals and in the principal *cantóns*. The Anti-Cancer Society and the Anti-Tuberculosis Society are also part of the ministry. Only a very small percentage of the national budget is, however, devoted to public health programs. As a result, research institutions lack funds, and health conditions are generally poor. There are a number of endemic diseases including goitre, typhoid fever, and tuberculosis.

Salaries are not related to a cost-of-living index, and low wage scales present a problem that daily becomes more acute. Minimum wages established by law are not always paid. In an attempt to provide minimum wage security, a work administration was created, but by the early 1970s it had not yet proved effective.

The national press frequently focusses on social problems. *Vistazo* Magazine from Guayaquil has denounced the imbalance between work performed and salaries paid. Some governmental employees, for example, may receive more than 50,000 sucres monthly, while others do not even receive the lawful minimum monthly wage of 750 sucres (25 sucres = $1 U.S.; 60 sucres = £1 sterling, on December 1, 1970).

Economic divisions

The traditional social divisions based on family lineage are being translated into economic terms, thus allowing for greater mobility. Alongside the opulent few, however, a large percentage of the population lives under almost subhuman conditions, for example in some city ghettos and in some Indian communities, especially in Chimborazo Province.

Cultural life. Despite an illiteracy rate of almost 33 percent and a poor economy, Ecuador nevertheless maintains a generally high cultural level. A tendency to erudition is evident, and music forms an integral part of Ecuadorian life. Many people play musical instruments, accompanying their own songs. The various art forms are distinctive for their treatment of the themes provided by the landscape or Ecuadorian folklore. National literature often focusses on the Andes or on Indian themes. Perhaps the best example of Ecuadorian art is the poem *Boletín y elegía de las mitas* ("Record and Elegy on Indian Forced Labour") by the late Cuencan poet, César Dávila Andrade.

Ecuadorian music is characterized by its sadness. Among folksong types, the *yarabí* evokes the immense solitude of the Andes and the pain of the oppressed Indian. Paradoxically, many tunes, through their sadness, lighten Ecuadorian fiestas and popular dances.

The most important cultural institution in the country is the House of Ecuadorian Culture (founded in 1944), the aim of which is to direct and preserve all aspects of national culture. It has 14 provincial branches. The National Library, the National History Archives, the Museum of Colonial Art, the Pedro Traversari Musical Instrument Museum, and the Pío Jaramillo Alvarado Museum all constitute subdivisions of this central institution. Other institutions include the Centre for the Promotion of Popular Art, as well as the Ecuadorian Institute of Artisans and Manual Artists, which has workshops for applied art, ceramics, painting, and weaving. Each of the major cities has French and North American institutes, as well as representative agencies from other countries.

Major newspapers include *El Comercio*, *El Tiempo*, and *Ultimas Noticias*, all published in Quito; *El Universo* and *El Telégrafo*, published in Guayaquil; *El Mercurio* and *El Tiempo* in Cuenca; *El Heraldo* in Ambato; *La Opinión del Sur* and *La Verdad* in Loja; and *Diario Manabita* in Manabí. The most widely circulated magazine in the country is *Vistazo*, published in Guayaquil.

There are more than 200 radio stations in the country. Major cultural stations include Radio Nacional del Ecuador (which is state-run); La Voz de los Andes; and Radiodifusora Casa de la Cultura in Quito. Commercial stations include Radio Atahualpa and Radio Quito in Quito; Atalaya and Cadena Radiodifusora Ecuatoriana in Guayaquil; and Radiotelevisora Ondas Azuayas in Cuenca. Each of the major cities has two or more television stations.

Prospects for the future. A common expression that is traditionally attributed to Baron Alexander von Humboldt, the German geographer and naturalist, who visited Ecuador in 1802, still remains relevant:

> The people are the strangest in the world. They live in poverty on mountains of gold; sleep tranquilly at the foot of volcanoes; and cheer themselves with sad music.

Despite the mineral wealth enclosed in the Andes Mountains, and despite a considerable potential for hydroelectric power, many Ecuadorians continue to live in poverty. The Andes Mountains themselves, despite their beauty and their influence in modifying the climate, continue to obstruct communication and development, and also symbolize the latent danger of earthquakes. As recently as 1949, Ambato and 50 other towns were destroyed by an earthquake.

Ecuador's future depends upon further development, both in industrialization and in the improvement of its agricultural economy. Disparate standards of living that parallel social divisions, past and present, are becoming increasingly apparent and represent a source of political tension that can only be lessened by the development of a trend towards the establishment of more equitable conditions.

WATKINS (ed.), *Expanding Ecuador's Exports: A Commodity-by-Commodity Study with Projections to 1973*, prepared by the Surveys and Research Corporation (1967), are also helpful in their fields.

(H.P.V.)

Ecuador, History of

In 1551, when Francisco Pizarro's lieutenant Sebastián de Belalcázar conquered what is now called Ecuador, he found an area that had been part of the Inca empire for about half a century. The last Inca emperor, the tragic Atahuallpa, was born near Quito.

In the mountainous Andean area of central Ecuador (the sierra), the Spaniards established a colony of large estates worked by Indian peons. People lived in semi-autonomous Indian villages or in Spanish and mestizo administrative and religious centres such as Quito, Ambato, and Cuenca. The making of rough textiles in primitive sweatshops was the only industry. Life was rural, hierarchical, and slow to change.

On the Pacific coastal plain (the tropical costa), there were fewer Indians to do the work, and the area was extremely unhealthy until the advent of modern medicine. As a result, the coast was neglected during the colonial period, although there was some shipbuilding and exporting of cacao from the port of Guayaquil. The small coastal population of mixed races, with plenty of vacant land and little coercion of labour, developed a very different culture from that of the sierra (see further LATIN AMERICA AND THE CARIBBEAN, COLONIAL).

On the eastern slopes between the Andes and the headwaters of the Amazon (the oriente), recalcitrant Indians and the equatorial climate prevented settlement, and the only Spaniards who attempted to live there in any numbers were missionaries. Later, this demographic vacuum was to cause Ecuador many problems.

The country's fourth major subdivision, the Galápagos Islands (in the Pacific Ocean about 580 miles [933 kilometres] west of the mainland), were little more than pirate nests during the colonial period; but they were to achieve world fame in the 19th century because Charles Darwin made there a major portion of his observations that led to his theories on evolution and the *Origin of Species*.

The people of Quito, the Ecuadorian capital, claim that it was the scene of the first Ecuadorian patriot uprising against Spanish rule (1809). Invading from Colombia in 1822, the armies of Simón Bolívar and Antonio José de Sucre came to the aid of Ecuadorian rebels, and on May 24 Sucre won the decisive Battle of Pichincha on a mountain slope near Quito, thus assuring Ecuadorian independence.

Early national history (1830–c. 1925). Ecuador's early history as a nation was a tormented one. For some eight years it formed, together with Colombia and Venezuela, the confederation of Gran Colombia. But in 1830, after a period of protracted regional rivalries, Ecuador seceded and became a separate, independent republic.

Liberal–Conservative hostilities. An increasing rivalry and ideological difference between the sierra and the costa usually focussed on the two leading cities—Quito, the capital, in the sierra, and Guayaquil, the country's principal port. Quito was the home of a landed aristocracy, whose positions of power during this early period were based on large, semifeudal estates worked by servile Indian labour; it was (and to some extent has remained) a conservative, clerical city, resistant to changes in the status quo. Guayaquil, on the other hand, by the 19th century had become a bustling, cosmopolitan port, controlled by a few wealthy merchants; these men and those around them were influenced by 19th-century liberalism; interested in trade, they favoured free enterprise and expanding markets; some were anticlerical. Their bourgeois attitudes conflicted sharply with the more aristocratic beliefs of the sierra elites. These early rivalries tended to be exacerbated by the nature of the two cities. The people of Guayaquil, the nation's breadwinner and the home of Ecuador's industry and trade, felt that a disproportionate part of the state's tax income was spent in Quito by government bureaucrats. Those in Quito complained that their exports had to pass through the monopolistic bottleneck of Guayaquil, which acted as a traditional middleman and, by adding to the price of sierra products, reduced their competitiveness in the world market.

Development of Guayaquil

Rivalry between Flores and Rocafuerte (1830–45). Ambitious generals and politicians have played on this Quito–Guayaquil rivalry since the foundation of the republic in 1830. During the period 1830–45, two generals from the wars of independence—Juan José Flores and Vicente Rocafuerte—struggled for power; Flores found much of his support in Quito, Rocafuerte in Guayaquil. Hostility was not constant, and for a few years the rivals agreed to alternate in the presidency. They were not simply personalist dictators; Rocafuerte in particular had a coherent ideology of government and did much to improve the educational institutions of the main cities. Both, however, were capable of obnoxious conduct in their efforts to retain or regain power, inviting foreign armies to enter the country and assassinating opponents and hostile journalists; Flores, on one occasion, even invited the Spaniards to return.

Breakdown of national government (1845–60). The rivalry between Flores and Rocafuerte was a struggle between two strong leaders. Between 1845 and 1860, however, the nation went through a period of chaos in which a series of squabbling, weak leaders (usually self-proclaimed liberals) fought for the presidency with little regard for the nation's integrity or development. This period reinforced the already close ties between the military and the national government.

The regime of García Moreno (1860–75). The next years (1860–75) saw one of Latin America's most extraordinary experiments in autocracy, during the presidency of Gabriel García Moreno. As a young man García Moreno, a religious intellectual and conservative, had witnessed the chaos in Ecuador and the selfish struggles of the various cliques. He had also seen the European revolutions of 1848 and had developed an abhorrence of liberalism and of uncontrolled violence. A careful analysis of Ecuadorian society led him to conclude that the young nation lacked unifying factors; it had no great tradition, suffered from regional resentments, and was sharply divided by class and between whites and Indians who did not even share a common language. García Moreno concluded that the only social "cement" was religion—the general adherence of the population to the Roman Catholic Church. He felt that in time, nationalism could be created and that more social cohesion would emerge as a result, but that meanwhile Ecuador needed a period of peace and strong government. When he became president, therefore, he based his regime on two factors—strong authoritarian personal rule and the Roman Catholic Church. All education and welfare, and the direction of much government policy, were turned over to clerics. Other religions were harshly discouraged. All opposition was ruthlessly suppressed, and some leading liberals spent many years in exile.

Although many aspects of García Moreno's regime were negative, it did mark the first period of genuine progress for Ecuador. Roads, schools, and hospitals were built. A start was made on a Quito–Guayaquil railroad, to tie together the costa and the sierra. García Moreno encouraged the planting of eucalyptus trees from Australia to combat erosion in the sierra, where the original ground cover had been cut down for fuel by the impoverished Indians. Other agricultural reforms slowly raised production. By the end of his regime a strong feeling of nationalism had been created among the urban classes.

In the 19th century, however, this authoritarian, clerical government seemed an anachronism, and liberal opposition grew both at home and abroad. When García Moreno was assassinated on the steps of the government palace in 1875, a liberal intellectual and pamphleteer Juan Montalvo proclaimed from exile, "My pen has killed him."

Shift to liberalism (1875–97). García Moreno's death, as he himself might have forecast, brought a period of near anarchy. Conservatives and Liberals struggled for power. But Ecuador had become part of the world market; the importance of the coast slowly increased, and the Liberals of that area more and more dominated the economy.

A new Liberal hero emerged from the lower classes as

the leader of the coastal reaction to sierra conservatism and clericalism. A man of great personal magnetism, Gen. Eloy Alfaro led a march against the sierra in 1895 and after a year became constitutional president. Eloy Alfaro served two terms as president (1897–1901 and 1906–11). Much of the administrative structure of the García Moreno era was dismantled. The anticlerical Liberals gradually removed the church from state education; they instituted civil marriage and burial, proclaimed freedom of religion, permitted divorce, and eased controls on the press. The church's tithe was abolished, and many of its large estates were confiscated by the state (some estates passing into the hands of Liberal leaders).

The leadership of Eloy Alfaro

In many ways, however, in spite of political manifestos to the contrary, the Liberals of this era shared the basic ideas of the previous period. They advanced García Moreno's road- and railroad-building programs; the Quito-Guayaquil railroad was completed in 1908 during Eloy Alfaro's second term. Moreover, central government did not lose its authoritarian caste; Alfaro, the Liberal strong man (caudillo), was as abitrary and ruthless as his Conservative predecessor. In the sierra and on the coast, power remained in the same hands. The problem of the great haciendas was not touched, and the change to liberalism presumably meant little to the great masses of impoverished Indians and peasants.

Eloy Alfaro's overthrow, like that of García Moreno, was brought about by his stubborn attempts to perpetuate himself in office. A coalition of Conservatives and dissident Liberals forced him and his clique from the presidency in August 1911, but when the next president died in office shortly thereafter, the aging and increasingly unpopular Alfaro returned from exile and tried to recapture his following. The leaders of the Liberals rejected him, and after some fighting he was arrested in Guayaquil. He and his lieutenants were sent to a model prison in Quito, built years before by García Moreno. There, on Jan. 28, 1912, a lynch mob broke in, dragged the prisoners through the streets, and burned the bodies.

Problems of the early 20th century. The Liberals remained in office, although the various factions quarrelled constantly. The real power in the nation continued to be the wealthy merchants and bankers of Guayaquil. During World War I and the short boom that followed it, this powerful clique further extended its influence and diversified its capital with a view to owning the agriculture of the coastal plain. Cacao was the dominant export crop, as in the colonial period, but sugar and rice became increasingly important.

A depression followed in the early 1920s. The price of food increased and exports in general declined. The sucre —the national unit of currency—fell rapidly in value. At the same time, the nation's cacao plantations became infected with a blight known as "witchbroom" disease, and production sagged. These crises brought urban discontent, the formation of trade unions in Guayaquil, riots, and massacres by the army. Hundreds died during riots and shootings in November 1922.

In 1925 the army stepped into this turbulent situation, claiming that it wished to restore national unity and blaming many of the country's problems on the merchant bankers of Guayaquil. Like most Latin American revolutions the one of 1925 brought little change in social and economic structures, but it did replace one governing clique with another.

Recent history (since c. 1925). The period between 1925 and 1948 was one of greater turbulence than Ecuador had ever known. Increasing involvement in the world market and in international politics meant that the nation could no longer escape entanglements and the consequences of world ideological conflicts. Yet during this crucial period, when the tempo of events was accelerating, Ecuador's internal disunity prevented the modernization of its social structure, land tenure system, education, and communications. Thus, the country was badly equipped to face the demands of the age.

Economic development and loss of territory in the 1940s. Ecuador was still suffering from the effects of the great depression when it became involved in World War II. It sided with the allies and allowed the United States to build military bases on its territory, but it played little direct part in the war. Under Pres. Carlos Arroyo del Río, Ecuador drew some benefit from the higher prices for raw materials caused by the war. Nazi infiltration never reached the proportions it did in other parts of South America, and the early years of the war were ones of relative prosperity and tranquility.

World War II

World War II had a serious secondary effect on the nation, however. Because of lack of capital and people, Ecuador by 1940 had not effectively settled its vast Amazonian territories. In July 1941, after long diplomatic bickering and a series of border incidents, the Peruvian army invaded, siezed much of the disputed Amazonian area, and devastated El Oro province (Ecuador had lost territory to each of its more powerful neighbours during its troubled history). The Ecuadorian forces, poorly trained and equipped, were easily defeated, and the national disgrace caused the overthrow of Carlos Arroyo del Río. The United States and the other major powers were too preoccupied with the war to allow such small conflicts to destroy allied unity or to disrupt the production of vital raw materials. A peace conference was hastily called in Rio de Janeiro in 1942, and Ecuador was forced to relinquish title to much of the Amazonian region to which it had claims. Subsequently, Ecuador made repeated attempts to reopen the question, claiming that the "Protocol of Rio" was imposed by force and that the new borders were therefore invalid. This constant Ecuadorian irredentism, although having a strong legal and moral base, nevertheless, caused the country much harm, because it was used repeatedly by demagogues and ultranationalists to distract attention and effort from urgent internal problems.

Domination of Velasco Ibarra (post-World War II). Politics and government after World War II presented a paradox. Except for one interlude of army government (1963–66), Ecuador enjoyed constitutional government and relatively free elections following the election to the presidency of Liberal Party leader Galo Plaza (1948). Yet the period was dominated by the presence of one of the last of Latin America's great caudillos—José María Velasco Ibarra.

By 1970 Velasco had been president of Ecuador five times but had completed only one of these terms. He seemed able to win any election, such was his popularity with the masses; but his terms of office were marked by sudden switches in policy, contradictory economic programs, wild personal outbursts, temporary suspensions of civil liberties, military interventions, and public strife. Some critics claimed that Velasco drew clandestine support from Communist groups; others saw him as little more than the puppet of powerful business groups in Guayaquil; but neither these nor other groups were able to control the erratic Velasco for long.

His political presence may have inhibited the development of coherent political parties and programs for changing the nation's antiquated social and economic structure. His appeal, personal and charismatic, cut across parties and ideologies. The traditional parties—the Liberals and the Conservatives—were thrown into disarray by Velasco's incursions, and the growth of newer parties such as the Socialists and the Social Christians was retarded. Opponents alleged that Velasco made economic progress impossible because constructive measures undertaken by the governments of such presidents as Galo Plaza (1948–52) and Camilo Ponce Enríquez (1956–60) were halted or even reversed by the chaotic Velasco interludes.

Ecuador in the 1970s. Of the many problems faced by Ecuadorians during the 1970s, the most important was how to achieve rapid and just economic development. Most of the population was still rural, although the cities were growing rapidly. One of the highest birthrates in the world ate into per capita gains in productivity and income. Illiteracy, malnutrition, and infant mortality remained huge problems. Many of the people, especially in the sierra, clung to the remnants of their pre-Columbian cultures and played no real part in the national econ-

omy either as consumers or as producers; and because they exerted little political pressure, their incorporation into the nation was talked about constantly but never achieved. Thus, the gap between rich and poor remained vast. The middle class was small and confined to the cities. Large haciendas still dominated the land tenure pattern in the Andean countryside. These estates—undercapitalized and largely unmechanized—were owned by Spanish-speaking white or mestizo city dwellers, while much of the work was performed by Indian sharecroppers or hired labour. Large land reform projects remained unimplemented.

The Ecuadorian economy in the 1970s still suffered from a chronic lack of developmental capital, an unskilled labour force, and, in spite of the opening of many new roads, poor communications. Per capita income was about $200 per year. To worsen the economic picture, the export economy was caught in a monocultural squeeze; the cacao industry of the 1920s had been replaced by banana plantations, but beginning in the early 1960s the country's banana export industry was challenged by a stagnating world market, combined with new competition from Colombia and the Caribbean. The predominance of one export crop also placed the welfare of the nation at the mercy of the world price of bananas. The government had tried to diversify industry to lessen its dependence on bananas, but successes were few. The most promising developments were large oil strikes in the 1960s near the Putumayo River along the Colombian border (see further ECUADOR: *The Economy*).

Ecumenism

Ecumenism, a term of recent origin, was first given wide currency in connection with the Roman Catholic council known as the second Vatican Council (1962–65) and denotes in an admittedly vague manner the awakened conscience of the Christian Church towards its universal aspects as well as towards its rekindled sense of mission and service. Being etymologically a derivative of the Greek words *oikos* ("household") or *oikoumenē* ("inhabited earth") and historically of the ecumenical councils of the distant past and of the ecumenical movement of modern times, ecumenism represents a movement towards church unity that its advocates claim deserves to be studied, heeded, and encouraged.

NATURE AND SIGNIFICANCE

The quest for unity. The nature and the significance of the ecumenical movement in the 20th century lies in the longing of Christians for a greater and more effective role in the affairs of the modern world. Granted that unity and mission belong to the essence or nature of the church—as Christians for centuries have proclaimed—many modern Christians in increasing numbers now assert that they can no longer justify the duality of what they consider to be a beautiful faith on the one hand and an ugly and contradictory life—*i.e.*, a divided church—on the other. Church unity—or the quest for it—is considered by modern ecumenists to be the echo of the spirit calling for the reacceptance by Christians of the One Church. Participants involved in modern theological and ecumenical deliberations often speak out for the need to chart a converging course, which, through mergers and regroupings of churches and denominations, they hope might lead ultimately to unity.

The urge for unity is believed in part to be the result of the pent-up frustrations of Christians who view what they take to be the impotence and the failure of the church to exert an influential impact on social ethics and to recapture the heart and mind of the unbelieving man. The ecumenical dialogue may then be seen as the attempt of the church to re-engage modern believers in a search for that which constitutes the soul or essence of Christianity. Participants in this dialogue place their hope in the revival of the ecumenical Christian community, which they believe once stood and ideally would stand again as the fulfillment of the promised Kingdom of God, and in which a conscientious belief in God would be attendant with peace and good will.

The church as the ecumenical community. The definition of the church by St. Paul in his 1st-century-AD letters as *to sōma Christou* ("the Body of Christ") dominates modern ecumenical thinking, and his premise that the diversity of spiritual gifts or of ministries does not permit a schism in the body seems to force denominational doctrinal positions or confessional theology (based on statements of belief by particular church bodies; *e.g.*, The Augsburg Confession of the Lutheran churches) into a reappraisal of the theology held by the early church, which is viewed as having been undivided. On the basis of this approach the ecumenical movement may be credited with encouraging the churches towards an ecumenical theology even in respect to a recommended study of all "theologies"—*i.e.*, the doctrinal views of the various churches. The ecumenical movement, thus, can be viewed as being of parallel significance with modern theological studies and movements. The healing of the deep wounds of schism inflicted by persons or segments of ancient and medieval Christianity that exhibited divisive qualities may be realized, according to ecumenical enthusiasts, through a revitalized ecumenical theology or the restudy and re-examination—in the light of what is believed to be historical truth—of the true nature and significance of ancient theological and ecclesiological precepts and doctrines.

Diversity in the church

Schisms and heresies, brought about either by disciplinary, moralistic, or philosophical actions leading towards independence of particular segments of ancient Christianity, were seen as disruptive of the unity, rather than of the theology, of the church. Ecumenical adherents believe that through a united or ecumenical theology the unity of the church will be restored. They hold that the unity of the church cannot be supported by sophisms; it can survive only by direct and undisputed theological affirmation.

History counts innumerable conciliar efforts undertaken at one time or another by the ancient church, and it records many ecumenical or provincial councils called at intervals to deal with schismatic or heretical actions or with ecclesiastical "coup d'etat" situations (*i.e.*, illegal or uncustomary assumptions of ecclesiastical offices). Modern chroniclers, however, would find it difficult to count even one collective or partly collective effort of the church to heal or confront any divisive action and situation in the life of modern Christianity. Thus, the ecumenical movement is believed by its advocates to be the only agency in which unity-minded Christians may hope that a truly representative ecumenical council of the church universal may be convened in order to reorder Christian priorities, that such a council or synod will be the first and the last that will accomplish the recomposition and the resurrection of the One Church, and that it will claim all Christians—irrespective of national, racial, or cultural origins and backgrounds, though respecting fully their local disciplines and liturgical traditions.

HISTORY

Ecumenism's early origins. Christian ecumenism can be traced to various roots: to the command of Christ to his Apostles (*i.e.*, to preach the gospel to all nations and

Ecumenism in the New Testament

to baptize persons in the name of the Father, Son, and Holy Spirit, as it is described in all three Synoptic Gospels [Matthew, Mark, and Luke]); to the miracle of the Pentecost (Acts) in which the disciples received the gift of the Holy Spirit; to the founding of the primitive church (Acts); to the Apostolic Synod, also called the Council of Jerusalem (Acts); and to the first ecumenical decree to send forth missionaries (Acts).

During the 1st and 2nd centuries the church was composed of many local and area units with a wide variety of organizational forms: monarchical episcopates (jurisdictional units presided over by a single bishop with sole authority in ecclesiastical matters); colleges of presbyters (ecclesiastical units presided over by several priests with shared authority, with one of their number serving as president of the group); local units that were somewhat democratically organized; and other forms. During the 3rd century the organizational form of the church moved more and more in the direction of the episcopate. In addition to different organizational forms, there were variations in theological interpretation. Four Gospels (Matthew, Mark, Luke, and John) were utilized in varying degrees of importance in the various churches, according to certain theological viewpoints: Mark, with its practical bent, by the Roman Church; Matthew, with its Jewish orientation, by the church in Palestine; John, with its philosophical orientation, by the Greek Church; and Luke, with its universal appeal, by churches throughout the Greek and Syrian East and the Latin West. Despite the lack of uniformity in theological and organizational matters, the churches accepted the view that they were One Church in their faith in Christ, and the church was

Unity in diversity

viewed as having unity in its diversity, even in the face of the intense nationalistic desires within the Roman Empire that affected believers and nonbelievers alike. When, in the edict of Milan (AD 313), the emperor Constantine (d. 337) granted toleration to Christianity within the Roman Empire, a new era for the church began. The goal of unity, however, was marred by theological controversy, and Christianity, which, many had hoped, would be the "cement of the empire," was itself lacking in consensus theologically, and eventually organizationally. In spite of the conflicts, the first ecumenical Council of Nicaea (325) affirmed that the church was one, holy, catholic, and apostolic. This council and the ones that followed were convened in order to define, fortify, and preserve the unity of faith.

Ecumenical contacts between the Eastern and Western churches: 5th to 19th centuries. Ecumenism proper (recognition that the church is not one in organization or mission) entered history with the Byzantine (Eastern Roman) emperor Zeno's *Henotikon* (482), a document aimed at the reunion of the religious and political separatist movements of his time with the religious and political *oikoumenē*, *i.e.*, the Byzantine Church and Empire. During the reign of one of Zeno's successors, Justinian the Great (527–565), ecumenism lost the identity just described and acquired a new meaning: that of religious and political orthodoxy in which the true faith of the church coincides with the true interests of the state. In view of this change in emphasis and the rising influence of the papacy and Western nations, ecumenism—especially after the East–West Schism (beginning in 1054) and the Reformation (16th century)—meant little other than Roman Catholicism in its autocratic and temporal connotations. Because of its position within nations that rose to greater and greater power politically, economically, and culturally, Roman Catholicism held councils that it called ecumenical, though, in reality, they were Western. These councils—especially the fourth Lateran Council (1215), the second Council of Lyons (1274), the Ferrara-Florence Council (1438–45)—though they included some representation from the Eastern churches, indicate that ecumenism was not at that time viewed from the standpoint of the conscience, mission, and service of the church.

Ecumenism within Eastern Christianity, however, has been viewed as a matter of conscience directly related to the survival of the church itself. This is because of Eastern Christianity's long centuries of isolation following the Great Schism (1054) and the subjugation of the East by the Muslims during and after the 7th century. Captive under Muslim political overlords and isolated from Western Christianity, the Church of Constantinople (the traditional centre of Eastern Christianity) attempted to breach the thick walls of its forced isolation. It went as far as Lyons in 1274, Ferrara in 1438, and Florence in 1439 to seek to repair the damages wrought by the Crusades. The Church of Constantinople made approaches to a responsive sister church, the church of Rome, in hopes of restoring unity, but without success. The catastrophic fall of the Byzantine Empire in 1453 obliterated all such hopes in the hearts of the Christians of the East. Though the years of apparent hopeless mourning seemed to have reached an end when the Roman Church sent its Jesuits (monks belonging to the Society of Jesus) into Poland and the Ukraine during the 16th and 17th centuries, the hope was short-lived; it was soon obvious that the Jesuits were not liberators, but conquerors, who, through the program known as the Unia (Union with Rome), induced many Poles and Ukranians to leave the Orthodox Church. Eastern Christians viewed these actions by Roman Catholics as subjugating the feeble spiritual freedom that the Eastern Christians had upheld during more than a century of enslavement to the Muslim Turks (see also ROMAN CATHOLICISM, HISTORY OF; EASTERN RITE CHURCHES).

Ecumenism and the survival of the church

Thus, when the Church of Constantinople received the messenger and the message of the Protestant Reformation leaders in the 16th century—who attempted to reawaken "the dormant conscience of the church" in the hope that their revolt against what they viewed as the abuses of Rome could unite all those Christians who at one time or another were abused by the temporal authority of the pope—it appeared as though the hope for unity might become an actuality. An historic correspondence between Leipzig (Germany) and Constantinople—which began in 1555 between Luther's follower Philipp Melanchthon and Patriarch Joasaph II of Constantinople and reached its apex when the Lutheran Augsburg Confession of 1530 was sent to Joasaph's successor Patriarch Jeremias II by Jacob Andreas, the chancellor of the University of Tübingen—came to an inglorious end with the rejection of the Confession by Jeremias in 1576. An attempt to revive Lutheran–Orthodox relations by the Lutheran theologians Martin Crucius, Jacob Andreas, Lucius Osiander, and Stephen Gerlach, who met in Wittenberg in June 1580 to prepare a reply to Jeremias' thesis, did not fare any better. Jeremias responded in 1581 that it would be useless to continue such a futile correspondence.

Reformation ecumenical relations

Constantinople's ecumenical hopes, nevertheless, remained unaltered and alive. The third Western Church with which the Church of Constantinople came into a series of theological contacts was the Church of England. The Ecumenical Patriarchate (Constantinople) decided to attempt certain semiofficial contacts with the Anglican Church in the 17th century based upon the assumption that the sympathetic attitude displayed by Anglican chaplains in Constantinople, Hunt (1627–38), William Gotobet (1642) and Thomas Smith (1668–70), was an indication of their friendly concern. The first approaches were made by Cyril Lucaris, the alleged Calvinist patriarch of Constantinople, through two youthful ecclesiasts, Metrophanes Critopoulos and Nathaniel Conopius (early 17th century). Joseph Georgarinis, bishop of Samos, who travelled to Britain in 1676 to organize the first Greek Orthodox parish, entered into actual theological discussions with Anglican theologians. His return to Samos in 1685 in no way ended the mutually desired contacts between the two churches. Callinicus II, patriarch of Constantinople during three periods from 1688–1702, replying to an invitation to send students to England, obliged by sending a number of them. All were forced, however, to return, because of what they described as poor food and lodging. Relations were again resumed officially in 1701 when Neophytus, the Bishop of Philippopolis, was invited to be accorded an honorary degree

of doctor of divinity at Oxford. Following the ceremonies, Bishop Neophytus was received by Archbishop Tenison of Canterbury, who in turn introduced him to Dr. John Covel, master of Christ's College at Cambridge, for the purpose of discussing certain doctrines. The deliberations—the apparent aim of which was for the Anglicans to obtain an Orthodox confession of faith that accurately reflected Orthodox beliefs after the persistent confusion over Patriarch Lucaris' "confession," which was Protestant in tone—came to an end when a "synodical" letter sent to the lovers of the Greek Church in England, signed by Patriarch Dionysius IV, was delivered to the Anglican theologians in 1672. Talks on intercommunion (allowing members of both churches to receive the Lord's Supper in either church) that were encouraged by both churches soon ended because of the internal split in the life of the Anglican Church caused by the appearance of the nonjuror movement (a schism concerned with episcopal succession) in the early 18th century (see also ANGLICAN COMMUNION).

Relations between the Orthodox and Old Catholic churches

Another Western Church with which the Church of Constantinople entered into ecumenical relations through correspondence and legation was the Old Catholic Church, which came into existence (in Germany, Switzerland, and Holland) as the result of the decrees of the Roman Catholic Council known as the first Vatican Council (1870). Although the new church had eloquent and forceful exponents, it was lacking both in organization and self-confidence. Along with the Jansenist Church of Holland (a movement that broke with the Church of Rome), in the 18th century, it developed into what is known today in Europe as the Old Catholic Church and in Poland and the U.S. as the Polish National Catholic Church. The letters and the contacts exchanged between Bonn (the headquarters of the German Old Catholic Church) and Utrecht (headquarters of the Jansenist Old Catholic Church) on one part and Constantinople on the other ended with the feeling of ecumenical proximity and hopeful of a "close and intimate friendship" (see also OLD CATHOLIC CHURCHES).

Ecumenical contacts between the Church of Constantinople and the other Orthodox churches. Constantinople's enthusiasm for ecumenism was not always shared by the other Orthodox churches. Its failure to achieve some form of communion or communication between East and West resulted in a new effort or approach on the part of Constantinople—*i.e.*, promoting more frequent meetings and cooperation with the other Orthodox churches, which had no easy means of contact under the new rulers (Muslims) of the former Byzantine Empire. The endeavours of the Ecumenical Patriarchate to bring about Orthodox unity through "Pan-Orthodox synods" proved to be unsuccessful because of continuing political confrontations.

Five Pan-Orthodox synods were convened, and a sixth Pan-Orthodox synod was proposed. None, however, was truly pan-Orthodox, for full representation from Orthodoxy proved to be totally impossible. They were the Synod of Constantinople (1482–84), the Council of Jassy (1642), the Synod of Jerusalem (1672), the Synod of Moscow (1690), the Synod of Constantinople (1772), and the proposed Pro-Synod of Mount Athos (1922)—none of which lived up to expectations. Patriarch Meletios Metaxakis issued invitations to all the Orthodox churches to attend the Pro-Synod of Mount Athos, but because he was forced by the Turkish government to resign it never materialized.

Ecumenical conferences

Ecumenism in the 20th century. Ecumenism in the early part of the 20th century derived much of its impetus from three movements: international missionary conferences (Protestant), beginning with the Edinburgh Conference (1910) and led by a Scottish church leader J.H. Oldham and the International Missionary Council (1921) led by an American missionary leader John R. Mott; the Faith and Order Conferences (dealing with doctrines and practices) beginning with the conference at Lausanne, Switzerland, in 1927 and including both Protestant and Orthodox leaders; and the Life and Work Conferences (dealing with social and other practical problems) beginning with the Stockholm (Sweden) Conference in 1925. These three movements gradually were incorporated into the World Council of Churches (founded in 1948). The second and the third quarters of the 20th century are claimed by many leaders of the ecumenical movement to exemplify ecumenism because of the ecumenical role played by religiously associated organizations (some established in the 19th century) in promoting an evangelistic, nonconfessional understanding of Christianity. Among the more important of these organizations are: the British and Foreign Bible Society, established in England (1804); the Young Men's Christian Association (YMCA) of England, initiated in 1844—which ultimately led to the creation of the World's Alliance of YMCAs; the World Student Christian Federation (1895, Sweden); and the International Missionary Council (founded 1921), which was based upon actions of the International Missionary Conference (convened in Scotland, 1910). Giving new summation to the ecumenical idea that was assuming more and greater importance and influence were ecumenists such as the Swedish Lutheran archbishop, Nathan Söderblom; the Anglican archbishop William Temple and G.K.A. Bell (bishop of Chichester); the Greek Orthodox metropolitan (archbishop) Germanos of Thyateira; the Dutch leader of the World Council of Churches, W.A. Visser t'Hooft; and Hamilcar Alevizatos (professor of canon law, University of Athens), who are mainly responsible for the creation of the World Council of Churches in Amsterdam in 1948.

Modern Orthodox-initiated ecumenical attempts

Of no less significance is the ecumenical spirit that animated the Church of Constantinople in its ecumenical endeavours both before and after the fall of the Byzantine Empire. As noted, that church's many contacts with Lutherans as well as with Anglicans, Calvinists, and Old Catholics attest to the ecumenism of Eastern Christianity. An encyclical letter of Dorotheos (1920) stands out as the most ecumenical document of the early 1920s. The ecumenism that was in the minds and hearts of the Orthodox citizens of Muslim-dominated Byzantium regained much of its former quality and dynamism. As a result, the Church of Constantinople not only associated itself with the World Council of Churches from its inception but it also played the role of protagonist in convincing other Eastern European Orthodox churches to join the council, (as they did at the 3rd General Assembly of the World Council of Churches in New Delhi, November 1961) and in reopening communications with Rome in 1959, when Ecumenical Patriarch Athenagoras I sent his first emissary (Archbishop Iakovos) to Pope John XXIII at the Vatican.

Ecumenism in the 1960s owed much to the second Vatican Council, which, under the leadership of popes John XXIII and Paul VI and through the writings and initiative of the German theologian Augustin Cardinal Bea, promulgated—after thorough discussion and enlightening exchanges of ideas—a noteworthy decree on ecumenism that has helped to make possible many new contacts and visits among high-ranking ecclesiastical leaders, including the encounters between Patriarch Athenagoras and Pope Paul and the unprecedented journeys that they and other religious leaders have made in the cause of the ecumenical movement. The ecumenism of today could well be defined as the centrifugal movement of the conscience of the church universal, aiming at nothing less than the recapturing of the sense of its oneness, holiness, catholicity, and apostolicity, all of which constitute the true essence of Christian ecumenism.

The Pan-Orthodox Synod

The less than successful results of the six abortive Orthodox synods from 1484 to 1922 may indicate to many Orthodox Christians a need for a truly Pan-Orthodox Synod that they hope will be realized before 1980. Such a synod would define more clearly that which appears to need redefinition or reaffirmation in matters of church teachings and would also re-examine and redefine discipline and ecumenism. In the view of many Orthodox leaders, if the ecumenical movement is destined to serve the cause of unity, the Orthodox churches need to present themselves as one, not only in faith but, what is more important, in terms of attesting or witnessing to the Ortho-

dox faith through adequate policy and polity in today's ecumenical, ecclesiastical, political, and social affairs.

CURRENT AGENCIES AND EXPONENTS OF ECUMENISM

The World Council of Churches. Though by its nature it is consultative and conciliar, the World Council of Churches (since its inception in 1948) serves as the chief agent and exponent of ecumenism. By absorbing and enhancing the goals and activities of its forerunners—the Faith and Order Conference in 1948, the Life and Work Conference in 1948, and the International Missionary Council in 1961—the World Council of Churches has moved to become a theological catalyst and, subsequently, the Protestant and Orthodox organ of modern ecumenism. Its ecumenical activities include theological studies as well as commissions on world evangelism; through interfaith colloquiums, seminars, and meetings, directly or indirectly sponsored by the council; it promotes ecumenical consciousness and universal Christian one-mindedness.

Because of Visser t'Hooft, who developed and advanced the global dimensions of ecumenicism and broadened its role from that of a cooperative body to a potent ecumenical force, the World Council of Churches is no longer a loose confederation of churches as it was initially envisioned but is an active and dynamic expression of their concerns and of their anguish. The range of the council's interests begins with ecumenical praying and culminates in church mergers and unions (many already accomplished) that the council silently but effectively guided and inspired.

Protestant and Orthodox agencies in the U.S. The National Council of Churches of Christ in America (1950) is another ecumenical expression of Christian concern. Though it owes its creation to the cooperative initiative of 12 original interdenominational agencies, the council now comprises the large majority of the Protestant and Orthodox churches in the U.S. Through its multiple divisions, departments, and committees that study and analyze national and international issues, the National Council of Churches serves the ecumenical intent in a broad sense.

The Consultation on Church Union

The Consultation on Church Union, another American church unit, envisages the realization of ecumenicity through multiple national mergers. The movement, which was initiated in 1960, in the 1960s and early 1970s encompassed nine Protestant churches (Episcopal, Methodist, United Church of Christ, United Presbyterians Church in the U.S.A., Disciples of Christ, Presbyterian Church in U.S. [Southern], African Methodist Episcopal, African Methodist Episcopal Zion, and Christian Methodist Episcopal). Its goal and plan is to be united in a "Church of Christ Uniting."

Roman Catholic agencies. The Secretariat for the Promotion of Christian Unity is the Roman Catholic equivalent of a faith and order and of life and work commission. Conceived by Pope John XXIII in 1959 and organized by Augustin Cardinal Bea in 1961, it is the guiding ecumenical agency of the Roman Catholic Church. Its major significance lies in the fact that the second Vatican Council—contrary to the first Vatican Council—recognized for the first time in Roman Catholic history the existence not only of separated brethren but also of separated churches, of which it speaks with reverence and solicitude. The Secretariat, furthermore, accepts the theory of unity in diversity and insists not upon the return of the estranged but on the need of a dialogue that would eventually lead Christians and their churches to unity, not with Rome but with one another in Christ with Christian love (agape) and with understanding. The Secretariat seems to understand "unity" as a unity that binds Christians in the fundamentals of the faith but allows them liberty in what may be called the nonessentials.

Orthodox agencies. The Pan-Orthodox Conference is the ecumenical agency of the Orthodox churches acting collectively. Organized in 1961 through the initiative of Patriarch Athenagoras I, it adopted a lengthy and all-important agenda, starting with the definition of dogma and concluding with the detailed list of theological, sacramental, and socioreligious subjects to be discussed with Roman Catholics, Anglicans, Old Catholics, and Lutherans. In its three meetings the Pan-Orthodox Conference designated a theological commission as well as dialogue committees that would elaborate on the ecclesiological problems between Eastern and Western Christianity. Another committee is working on the Great Pan-Orthodox Synod, tentatively scheduled for 1973, which it is expected will set forth in precise terms the Orthodox standards, presuppositions, and positions for the eventuality of reunion with any Christian Church of the West or with any of the ancient Oriental Monophysite churches, *i.e.*, those that broke with Constantinople over the doctrine of the nature of Christ.

The Standing Conference of the Canonical Orthodox Bishops in the Americas (SCCOBA) may also be listed as an ecumenical agency for American Orthodoxy. Organized in 1960 through the initiative of Archbishop Iakovos, the exarch of the Ecumenical Patriarchate of Constantinople, which has jurisdiction over the Greek Orthodox Archdiocese of North and South America, the conference has succeeded through its Ecumenical Commission in representing a united Orthodox view in ecumenical meetings and in embarking upon important conferences and clarifying bilateral concerns with the Anglican, Roman Catholic, Lutheran, and Reformed churches in America.

THE NEW ECUMENISM

Ecumenism of underground churches

A new ecumenism that is in opposition to some of the traditional ecumenical concepts underlies the thinking of the underground churches that are now found especially among the younger generations of the established Christian churches and, most interestingly, in the indigenously emerging Christianity of the emancipated African and Asian nations. New ecumenical currents and countercurrents combine in this movement and have become verbalized in strong words of indignation against what its proponents consider to be an institutionalized and fossilized church—which, it is believed, needs to be liberalized and humanized. Various writers associated with this new ecumenism imply that the church, while it should rediscover its spiritual power, should divest itself of any and all glory and human weaknesses and prove itself to be what it should always be: the Holy Spirit in action. Such writers also speak of a secular ecumenism founded on the doctrine of recreation. In view of such comments a special document, prepared for and presented to the July 1970 meeting of the Lutheran World Federation in Evians-Les-Bains, France, introduced a tripartite ecumenism (pastoral, practical, and social) as an answer to the predicament of a stalled ecumenism.

The new ecumenism, though secular and unconventional in nature, is considered by its devotees, and by those who find merit in it, "as not peripheral to theological unity." If, however, it sanctions violence on behalf of love for the oppressed, it may become a divisive rather than a unifying force, which would impede the progress of the ecumenical movement. Such a new ecumenism, according to the estimate of those associated with what may now be called traditional ecumenism, might meet the ecumenical standards of such things as the Socialist-oriented Prague Peace Conference or the demands of militant and radical Christians but not the requirements of those Christians who continue to believe in the pre-eminence of faith, hope, and love expressed in I Corinthians that sums up the essence and mission of a united Christianity.

BIBLIOGRAPHY. WALTER M. ABBOTT (ed.), *The Documents of Vatican II* (1966), is a documentary account of the historic actions decided upon by Vatican II. GEORGE F. LEWIS, *Toward Anglican-Roman Catholic Unity* (1962), points to the confessional as both encouraging and discouraging Anglicans as well as Roman Catholics in their understanding of ecumenism. IAN HENDERSON, *Power Without Glory: A Study in Ecumenical Politics* (1967), is a good analysis of the many-sided (Protestant-Orthodox-Catholic) post-Vatican II ecumenism, focussing its attention on spiritual power as the principal factor that should underlie the pursuit of Church union. ARTHUR MICHAEL

RAMSEY, *God, Christ and the World* (1969), places emphasis on theology as the only way towards reuniting Christianity. GEOFFREY FRANCIS FISHER, *The Archbishop Speaks* (1958), reflects an understanding of ecumenism as an invitation to an objective re-evaluation of the theology of the particular Christian churches. N. GOODALL in his *The Ecumenical Movement* (1961), records the personal feelings and thoughts of a man committed to world evangelism as a means of achieving true ecumenism. JOHN COLEMAN BENNETT, *Foreign Policy in Christian Perspective* (1966), is an analysis of the Christian perspective of foreign policy by a theologian committed to religious and political or international ecumenism. S.C. NEILL, *Towards Church Union, 1937–1952* (1952), is a record and chart of theological mores affecting, and the steps that should be taken in gaining, a clearer perspective of the theological dimensions of modern ecumenism. DENO JOHN GEANAKOPLOS, *Emperor Michael Palaeologus and the West, 1258–1282* (1959), studies in depth the political overtones and motivations of the reunions negotiated and agreed upon in Lyon and Florence-Ferrara. R. ROUSE and S.C. NEILL, (eds.), *A History of the Ecumenical Movement 1517–1948* (1954), stands out as the most scholarly work in the series of ecumenical literature to be consulted in understanding both the division and the imperative of bringing about a united Christendom. ERNST BENZ, *Geist und Leben der Ostkirche* (1957; Eng. trans., *The Eastern Orthodox Church*, 1963), gives an objective analysis of the openness of the Eastern Church, vis-a-vis the ecumenical orientation of modern times. STEVEN RUNCIMAN, *The Great Church in Captivity* (1968), reveals the abandonment of the Eastern center of Christianity, resulting from the westernization and alleged self-righteousness of Christianity, pointing to the need for a new evaluation of unity, both as a demand of God and of history.

(I.)

Eddington, Sir Arthur Stanley

Astronomer, physicist, and mathematician, Sir Arthur Stanley Eddington was a pioneer in the fields of relativity, cosmology, and the dynamics and internal constitution of the stars. He was also a notable expositor of new scientific ideas and their philosophic significance.

He was born on December 28, 1882, the son of the headmaster of Stramongate School, an old Quaker foundation in Kendal near Lake Windermere in the northwest of England. His father was a gifted and highly educated man who died of typhoid in 1884. The widow took her daughter and small son to Weston-super-Mare in Somerset, where young Eddington grew up and received his schooling. He entered Owens College, Manchester, in October 1898, and Trinity College, Cambridge, in October 1902. There he won every mathematical honour, as well as Senior Wrangler (1904), Smith's prize, and a Trinity College fellowship (1907). In 1913 he received the Plumian Professorship of Astronomy at Cambridge and the following year became also the director of its observatory.

From 1906 to 1913 Eddington was chief assistant at the Royal Observatory at Greenwich, where he gained practical experience in the use of astronomical instruments. He made observations on the island of Malta to establish its longitude, led an eclipse expedition to Brazil, and investigated the distribution and motions of the stars. He broke new ground with a paper on the dynamics of a globular stellar system. In *Stellar Movements and the Structure of the Universe* (1914) he summarized his mathematically elegant investigations, putting forward the thesis that the spiral nebulae, cloudy structures seen in the telescope, were galaxies like the Milky Way.

Eddington.

During World War I he declared himself a pacifist. This arose out of his strongly held Quaker beliefs. His religious faith also found expression in his popular writings on the philosophy of science. In *Science and the Unseen World* (1929) he declared that the world's meaning could not be discovered from science but must be sought through apprehension of spiritual reality. He expressed this belief in other philosophical books: *The Nature of the Physical World* (1928), *New Pathways of Science* (1935), and *The Philosophy of Physical Science* (1939).

During these years he carried on important studies in astrophysics and relativity, in addition to teaching and lecturing. In 1919 he led an expedition to Príncipe Island (West Africa) that provided the first confirmation of Einstein's theory that gravity will bend the path of light when it passes near a massive star. During the total eclipse of the sun, it was found that the positions of stars seen just beyond the eclipsed solar disk were, as the general theory of relativity had predicted, slightly displaced away from the centre of the solar disk. Eddington was the first expositor of relativity in the English language. His *Report on the Relativity Theory of Gravitation* (1918), written for the Physical Society, followed by *Space, Time and Gravitation* (1920) and his great treatise *The Mathematical Theory of Relativity* (1923)—the latter considered by Einstein the finest presentation of the subject in any language—made Eddington a leader in the field of relativity physics. His own contribution was chiefly a brilliant modification of affine (non-Euclidean) geometry, leading to a geometry of the cosmos. Later, when the Belgian astronomer Georges Lemaître produced the hypothesis of the expanding universe, Eddington pursued the subject in his own researches; these were placed before the general reader in his little book *The Expanding Universe* (1933). Another book, *Relativity Theory of Protons and Electrons* (1936), dealt with quantum theory. He gave many popular lectures on relativity, leading the English physicist Sir Joseph John Thomson to remark that Eddington had persuaded multitudes of people that they understood what relativity meant.

Relativity theory

His philosophical ideas led him to believe that through a unification of quantum theory and general relativity it would be possible to calculate the values of universal constants—in particular involving the number 137 (the fine-structure constant), the ratio of the mass of the proton to that of the electron, and the number of atoms in the universe. This was an attempt, never completed, at a vast synthesis of the known facts of the physical universe; it was published posthumously as *Fundamental Theory* (1946), edited by Sir Edmund Taylor Whittaker, a book that is incomprehensible to most readers and perplexing in many places to all but which represents a continuing challenge to some.

Eddington received many honours, including honorary degrees from 12 universities. He was president of the Royal Astronomical Society (1921–23), the Physical Society (1930–32), the Mathematical Association (1932), and the International Astronomical Union (1938–44). He was knighted in 1930 and received the Order of Merit in 1938. Meetings of the Royal Astronomical Society were often enlivened by dramatic clashes between Eddington and Sir James Hopwood Jeans or Edward Arthur Milne over the validity of scientific assumptions and mathematical procedures. Eddington was an enthusiastic participant in most forms of athletics, confining himself in later years to cycling, swimming, and golf. He died on November 22, 1944.

Contributions to astrophysics

Eddington's greatest contributions were in the field of astrophysics, where he did pioneer work on stellar structure and radiation pressure, subatomic sources of stellar energy, stellar diameters, the dynamics of pulsating stars, the relation between stellar mass and luminosity, white dwarf stars, diffuse matter in interstellar space, and so-called forbidden spectral lines. His work in astrophysics is represented by the classic *Internal Constitution of the Stars* (1925) and in the public lectures published as *Stars and Atoms* (1927). In his well-written popular books he also set forth his scientific epistemology, which he called "selective subjectivism" and "structuralism"—*i.e.*, the interplay of physical observations and geometry. He believed that a great part of physics simply reflected the interpretation that the scientist imposes on his data. The better part of his philosophy, however, was not his metaphysics but his "structure" logic. His theoretical work in physics had a stimulating effect on the thought and research of others, and many lines of scientific investigation were opened as a result of his work.

BIBLIOGRAPHY. A biography by A. VIBERT DOUGLAS, *The Life of Arthur Stanley Eddington* (1956), contains a list of his books and scientific papers. A popular discussion of Eddington's work is contained in J.R. NEWMAN, *Science and Sensibility*, vol. 1 (1961). His place in the history of physics is described in EDMUND T. WHITTAKER, *From Euclid to Eddington: A Study of Conceptions of the External World* (1949). For his philosophical ideas, see HERBERT DINGLE, *The Sources of Eddington's Philosophy* (1954). Technical discussions of his work are C.W. KILMISTER, *Men of Physics: Sir Arthur Eddington* (1966); and NOEL B. SLATER, *The Development and Meaning of Eddington's "Fundamental Theory"* (1957).

(A.V.D.)

Edentata

Edentata, an order of mammals, includes 31 living species distributed among the armadillos, true anteaters, and tree sloths, as well as eight extinct families of ground sloths and armadillo-like animals. The living families and six of the extinct families comprise the suborder Xenarthra. A second suborder, Palaeanodonta, consists of two extinct families. The entire evolutionary history of the edentates is restricted to the Western Hemisphere and the majority of the living species occur today in South America.

GENERAL FEATURES

Edentata means lacking teeth, though in reality only the true anteaters are toothless. The majority of edentates have simple, peglike cheek teeth that lack enamel; canine-like teeth do occur in some forms. Certain armadillos may have as many as 100 teeth. Edentates possess specialized traits, such as reduced dentition, a long sticky tongue, powerful, clawed, forefeet, associated with their insect diets. They also have primitive traits, such as the possession of five toes on the hindfeet, a simple uterus, and small, uncomplicated brain, which place them close to the primitive stock that gave rise to the infraclass Eutheria, which includes all placental mammals.

A persistent myth holds that any kind of armadillo, in defense against enemies, can roll itself into an impregnable armour-plated ball. In fact, only the three-banded armadillo (*Tolypeutes tricinctus*) is able to perform this feat. Most armadillos contort themselves into a reasonable facsimile of a ball, but some only slightly increase the convexity of the dorsal shell (carapace) while flattening against the ground. Individuals of some species flee to burrows or attempt to burrow right on the spot but may freeze and feign death when flight and rapid excavation are somehow prevented. Misconceptions about other edentates also exist. The toothless, weak-jawed anteaters seem to be sucking in ants and termites through a small tube, when, in fact, it is the sticky product of the greatly enlarged submaxillary glands covering the lengthy extensible tongues that facilitates the capture of these insects. The slow-moving arboreal sloths, typically depicted as moving upside down along a branch, really spend only about 10 percent of their time moving at all.

The armadillos and anteaters are important ecologically, helping to control many kinds of abundant insects, especially ants and termites. Armadillos feed on some carrion and thus play a small part in cleaning up the environment. Although some armadillos may become agricultural pests, and the armour of several species is made into purses and other curios, edentates are generally of little economic importance. Generally, the greatest interest in edentates lies in their bizarre appearance.

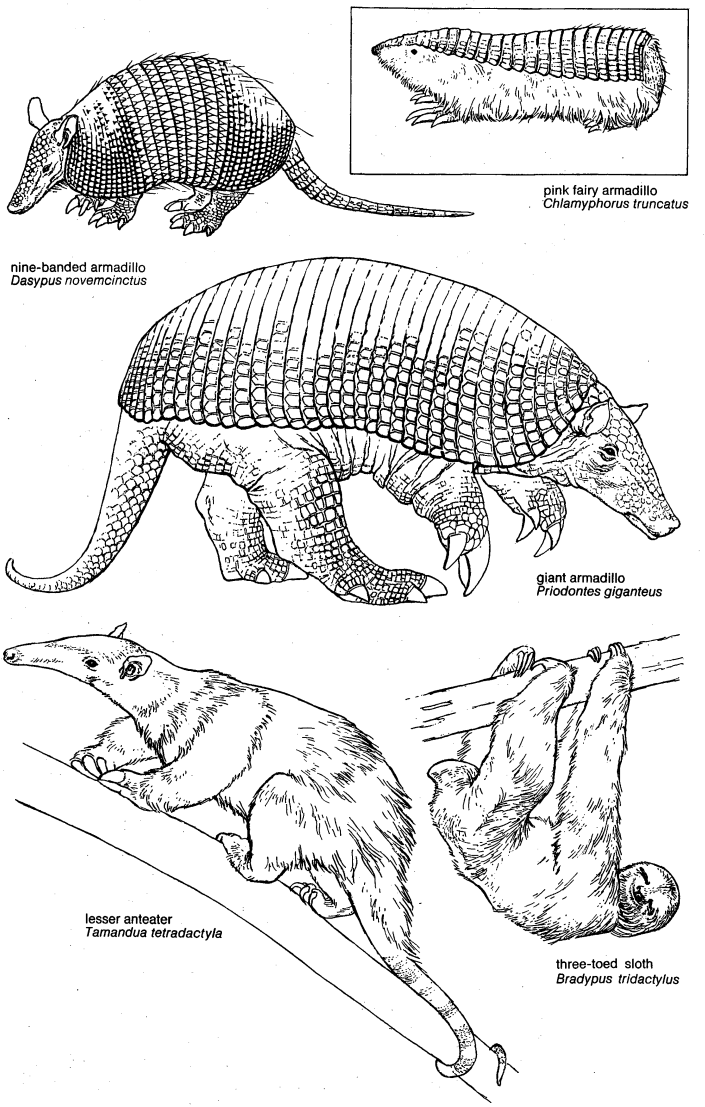

Figure 1: Edentate body plans.
Drawing by J.C. Barberis

Living edentates range in size from the tiny pink fairy armadillo or "lesser pichiciego" (*Chlamyphorus truncatus*) of Argentina, measuring about 16 centimetres (6.5 inches) in length and weighing little more than 100 grams (a few ounces), and the slightly larger two-toed or silky anteater (*Cyclopes didactylus*), just over 37 centimetres (15 inches) long and weighing about 325 grams (12 ounces), to the 60-kilogram (125-pound) giant armadillo (*Priodontes giganteus*), nearly 1.5 metres (5 feet) long, and the giant anteater (*Myrmecophaga tridactyla*), which weighs up to 25 kilograms (55 pounds) and may be over 2 metres (6 feet) in length. Among extinct forms, an Oligocene armadillo, *Prozaedyus proximus*, had a skull under 8 centimetres (about 3 inches) in length and was only somewhat larger than the smallest of the living armadillos. The Pleistocene ground sloth, *Megatherium americanum*, was 6 metres (20 feet) long and was larger than a modern elephant; a Pleistocene glyptodon (*Doedicurus clavicaudatus*) was more than 4 metres (13 feet) long and 1.5 metres (5 feet) high. Both flourished in South America about 500,000 years ago.

Anteaters, tree sloths, and armadillos are strikingly dif-

ferent in appearance, but within each of these families, there is only a modest diversity of structure. The toothless anteaters vary from strictly arboreal to terrestrial forms that are characterized by progressively more elongate tubular mouths. The arboreal species have only two (*Cyclopes*) or three (*Tamandua*) clawed toes on the forefeet, whereas the terrestrial giant anteater has four. In addition, the arboreal species have prehensile tails. At a casual glance, the two genera of herbivorous (plant-eating) tree sloths (*Bradypus, Choloepus*) differ from each other in general appearance only in the number of toes on the forefeet (two in *Choloepus* and three in *Bradypus*) and in pelage coloration. The armadillos (Dasypodidae) are distinguishable on the basis of relative size and on the distribution, flexibility, and pattern of the bony shields that form their body armour.

The anteaters, essentially a tropical family, occur from northeastern Argentina and northern Uruguay to the extreme northern part of the state of San Luis Potosí, Mexico. Tree sloths are restricted to forests from northern Rio Grande do Sul, Brazil, to southeastern Honduras. Armadillos are found from the northern part of the province of Santa Cruz, Argentina, to south-central Kansas. Most living edentates are fairly common in their preferred habitats, although several species have disappeared from parts of their range largely because of habitat destruction and excessive hunting by man. These endangered species include the giant anteater, the three-toed sloth (*Bradypus torquatus*), the three-banded armadillo, the giant armadillo, the pink fairy armadillo, and Burmeister's armadillo (*Burmeisteria retusa*).

NATURAL HISTORY

Behaviour. Anteaters eat termites, ants, and occasionally other insects. They may forage in trees (two-toed), on the ground (giant *Myrmecophaga*), or in both situations, as does the lesser anteater (*Tamandua tetradactyla*). Their prey is usually located by smell, the sense of which is better developed in these animals than are those of eyesight and hearing. With the long, powerful foreclaws, the anteaters rip open anthills and termite mounds, into which they then insert their long sticky tongues. The tongue, covered with prey and debris, is then drawn into the tubular mouth. When frightened, the giant anteater usually flees at a slow clumsy gallop, but if forced it will fight, using its claws to rip the enemy. *Cyclopes and Tamandua* also use their foreclaws for defense, anchoring themselves to a branch with their prehensile tails. When alarmed, these two emit shrill calls.

Anteaters travel solitarily or as mother and young and do not seem to have permanent resting places. The giant anteater chooses a secluded spot such as a hollow log or the abandoned burrow of some other animal and then curls up to rest, with its long bushy tail covering its head and body. The arboreal anteaters find shelter in trees. The two-toed and lesser anteaters are mainly nocturnal, but the giant anteater is both nocturnal and diurnal. In areas remote from civilization, the giant anteater is most active during the day, whereas in heavily populated regions it is primarily nocturnal.

Food habits of sloths

Tree sloths are strictly herbivorous, but the absence of enamel on their teeth suggests that the group perhaps was once insectivorous. The lack of enamel could pose serious problems relating to tooth wear for animals eating such abrasive food as vegetation. The difficulty, however, is alleviated by continuous growth of the teeth, which have an outer covering of hard cement. As is typical of herbivores, tree sloths have large multichambered stomachs in which the slowly digesting plant material steeps. Constantly filled, the stomach and its contents constitute about 30 percent of the sloth's body weight. A meal may take up to a week to digest. Every two to eight days, the sloth descends to the foot of its home tree and passes a large amount of excrement.

The diet of the two-toed sloth consists of a variety of leaves, stems, and fruits. The three-toed sloth, on the other hand, eats only the leaves of the cecropia tree. The sloth locates its food by touch and smell and then hooks a branch with its curved claws and pulls it to the mouth. Although colour vision is present, the eyesight and hearing of sloths are not very well developed, and they orient themselves mainly by touch.

In the wild, the hair of the sloth's body is inhabited by algae, which flourish in the jungle humidity. A variety of mites, beetles, and small moths live as commensals (harmless companions) in the hair, feeding on the algae.

Activity. Tree sloths are normally solitary creatures and spend the days and most of the nights sleeping. The little time that remains is spent eating, resting, and moving. This "laziness" contributes greatly to their survival, because their diurnal sleeping posture (hanging from a branch with feet bunched together and head tucked in on the chest) and their coloration give them the appearance of a bunch of dead leaves, rendering them virtually invisible. At night, when they are active, their slow movements do not attract the attention of nocturnal enemies. In addition, sloths have a thick skin and the ability to tolerate strong poisons and severe injuries.

When angered or otherwise disturbed, the three-toed sloth utters a high-pitched cry that sounds like "ai," whereas the two-toed sloth snorts and hisses. Normally, sloths are docile and in the presence of danger remain still, relying on their protective coloration to conceal them. If molested, however, they bite savagely and strike out furiously with the sharp foreclaws.

Burrowing by armadillos

Armadillos are primarily nocturnal, spending the daylight hours in their burrows, in expanded nest chambers lined with grasses and leaves. The burrow is also used for the escape from enemies and as a food trap. When using a burrow, in an emergency, some species are able to flex their bony back plates and brace with the feet in such a manner as to become firmly wedged in the tunnel and virtually impossible to pull out. When in danger away from a burrow, armadillos will draw in their feet and lie so that the edges of their armour touch the ground, or will run, burrow rapidly, or even defend themselves with their claws. The three-banded armadillo can roll itself into a ball with feet inward and the head and tail protected by special shields. If captured, an armadillo usually reacts by "playing dead," either stiffening or relaxing, but in either case remaining perfectly still for a brief period. If this course of action does not result in release, the captive armadillo begins kicking vigorously, often facilitating escape. Several kinds of sounds are reported to have been made by fleeing or otherwise agitated armadillos. The peludos (three species of *Chaetophractus*) make snarling sounds, the mulita (*Dasypus hybridus*) repeatedly utters a guttural monosyllabic sound reminiscent of the rapid fluttering of a human tongue, and other species emit a series of grunts or buzzes when alarmed.

The act of burrowing involves the forelimbs, hindlegs, and tail. The heavy claws on the forefeet are used for scraping and loosening the dirt, pushing it toward the rear. The hindlimbs throw the dirt out behind while the tail elevates the rear end of the animal so that the hindlegs may kick more freely. In this manner, burrows from 0.6 to six metres (two to 20 feet) long, from 0.3 to 1.5 metres (one to five feet) underground and with as many as 12 entrances, may be constructed in a relatively short period. Occasionally, other small animals share these burrows. In North America, rabbits (*Sylvilagus*) and cotton rats (*Sigmodon*) have been found living in the burrows of the nine-banded armadillo.

Armadillos eat insects, mollusks, frogs, small reptiles, carrion, and some plant material and will burrow underneath an animal carcass to obtain maggots and other insects. An acute sense of smell enables some armadillos to detect grubs and other insects up to 12 centimetres below the surface of the earth. The peludo is reputed to make conical holes with its snout in the earth in search of food. It first inserts its snout and then rotates its body so that it literally drills the hole. It is able to hold its breath under such circumstances for up to four minutes. Armadillos have relatively good hearing and vision.

Locomotion. The giant anteater walks with a shuffling gait bearing the weight of its foreparts on the side of the fourth (outermost) digit on the front foot. When hard pressed, this species breaks into a slow, clumsy gallop. It

is also a good swimmer. The tamandua walks rather clumsily on the sides of its forefeet when on the ground, in a manner similar to that of the giant anteater. The tamandua is an agile climber, aided both by its foreclaws and hindclaws and by its prehensile tail. Two-toed anteaters are strictly arboreal and are thus very strong climbers. They also have a prehensile tail.

The claws of tree sloths, which are quite similar to those of their terrestrial forebears, have become adapted to a strictly arboreal life. On the ground, a tree sloth is nearly helpless and cannot move at all unless there is something to grasp, then it is able to drag itself along with its claws. Most of the time sloths simply hang upside down, but when they do move they use a slow hand over hand motion both on horizontal and upright branches. Interestingly enough, they are excellent swimmers.

Generally, armadillos walk on the tips of the claws of their front feet and on the soles of the hindfeet; occasionally, they rear up and walk bipedally on their hindlegs. They trot with a stiff-legged gait. At a gallop, some species can outdistance a man. Because of their heavy dermal armour, armadillos have a specific gravity so high that they would normally sink in water. To overcome this problem, they gulp quantities of air that give them the buoyancy needed for swimming. Under some circumstances, armadillos seemingly take advantage of their specific gravity and cross small streams simply by walking under water on the bottom.

Habitat. Edentates occur in a variety of habitats, in temperate, subtropical, and tropical environments. Giant anteaters are found in savannas and in wet forests, where they feed either at night or in the day, ripping the terrestrial mounds of termites and ants apart with their powerful foreclaws. Lesser and silky anteaters are both arboreal, the latter totally so. Lesser anteaters prefer tropical forests, parklands, and, to a lesser extent, savannas, in which they forage mostly in trees on ants, termites, and various other insects. They are predominantly nocturnal but may be active at twilight as well. Silky anteaters, which are nocturnal, are found in tall humid tropical forests usually high up in the trees, where they feed almost exclusively on termites. The herbivorous tree sloths occur only in dense tropical rain forests. Armadillos frequent grasslands, parklands, open and even thick forests. They may live largely in subterranean burrows (pink fairy armadillo) in grasslands or dig burrows for temporary shelter in forests (*Dasypus* species). The shape of the burrow entrance is often diagnostic of the cross-sectional shape of the owner; the nine-banded armadillo (*Dasypus novemcinctus*), for example, which has a high rounded carapace, digs a nearly circular entrance. The six-banded armadillo (*Euphractus sexcinctus*), which is compressed from top to bottom, digs a burrow with an entrance that is wider than it is high. The habitat preference of the three commonest armadillos in Uruguay illustrates the ecological diversity of this group. *Dasypus hybridus*, the smallest of the species, prefers grassland and most of its burrows are found there. The six-banded armadillo burrows near streams in open woodlands and grasslands where it occasionally overlaps with the former species and with the nine-banded, which most frequently makes its burrows in woodlands.

Reproduction. The gestation period of those edentates for which it is known ranges from 65 days in the hairy armadillo (*Chaetophractus villosus*) to 263 days in the two-toed sloth. The protracted gestation period of the sloth is attributed to delayed implantation. The very early embryo, consisting of but a few cells, lies free in the uterus without developing further for several months, before becoming imbedded in the uterine wall, at which time normal embryonic growth recommences. Anteaters and tree sloths normally bear single young. Most armadillos give birth to one or two young, although some species demonstrate polyembryony (the birth of from 2 to 12 identical embryos, which develop initially from a single fertilized ovum) and delayed implantation (attachment of the ovum to the uterine wall after a variable delay period). The nine-banded armadillo has both of these phenomena. The delayed implantation is seasonal, the stages occurring at fixed times of the year, related to environmental influences. In the Northern Hemisphere, young of this species are born in March and April. Breeding occurs between June and September, but, regardless of when breeding occurs, implantation is delayed until November and the postimplantation pregnancy is between November and March. Delayed implantation is presumably beneficial because birth does not take place until spring, when food is plentiful.

Little information is available on the birth and early life of many edentates. A recent study of the two-toed sloth (*Choloepus didactylus*) revealed that the young is born as the mother hangs upside down. The baby emerges head first and face upward, and, as soon as its forelimbs are free, it grasps the abdominal hair of the mother and pulls itself up on her chest. The mother may assist in birth by pulling on the young. Subsequently, the female breaks the umbilical cord with her teeth.

The young sloth's eyes and ears are open at birth. It suckles for about five months but does not leave the mother until the ninth month, when adult proportions, but not size, have been attained. Adult size is reached at from two and one half to three years. Young anteaters also cling to their mothers for several months to a year after birth. The giant anteater rides on its mother's back, the two-toed anteater on its mother's tail.

Armadillo young are born with soft leathery skins, which harden as they grow older. In the six-banded armadillo, the eyes do not open for several days after birth, but in the nine-banded armadillo, the young are born with their eyes open. Young armadillos are able to walk when only a few hours old. In the nine-banded armadillo, physical maturity is achieved at six months, but females do not have their first litter until they are two years old. In captivity, the giant anteater has lived 14 years, the two-toed sloth 19 years, the peludo 15½ years, and the three-banded armadillo 11 years.

FORM AND FUNCTION

External appearance. Anteaters (Myrmecophagidae) have elongate heads; tubular muzzles with no teeth; and long, sharp claws. Their toes vary in number from two to four on the forefeet and from four to five on the hindfeet, depending on the species. The thick coat of the giant anteater is gray with lateral white-bordered blackish stripes, and the hair is long and straight, especially on the characteristically stiff bushy tail. Tamanduas, or lesser anteaters, have short hair, which is usually cream-coloured to brownish, with a black vestlike area over the upper thorax. The entire underside of the tail, as well as the tip, is naked. The two-toed anteater (*Cyclopes*) has soft silky fur, usually golden yellow in colour. In this species, only the underside of the prehensile tail is naked. Males and females are of approximately equal size in *Cyclopes* and *Tamandua*, but males are much larger in *Myrmecophaga*. All anteaters have enormously developed salivary glands that supply the sticky saliva that covers their long extrusible tongues.

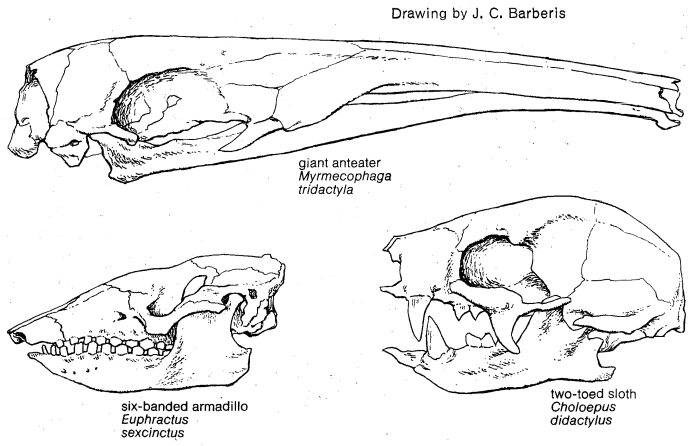

Figure 2: Edentate skulls.

The shaggy pelage of tree sloths grows from the belly toward the back on the body and toward instead of away from the body on the limbs (*i.e.*, downward, when the animal is suspended beneath a branch), thus facilitating the shedding of rain. Tree sloths have pale faces with darker eye rings. The body hair is yellowish to brownish, but the individual hairs are fluted and contain a growth of algae that gives a greenish cast to the entire animal, especially in the rainy season. In the drier conditions of captivity, the algae die and the animal loses the natural coloration. The legs are long, with the forelimbs longer than the hindlimbs, and are designed for suspension of the body rather than for "column-like" support.

Armadillos are characterized by a dorsal bony carapace made up of scapula (shoulder), dorsal, and pelvic shields, separated by a series of movable bands. A bony cephalic (head) shield is also present. The tail is typically armoured as well, except in the naked-tailed armadillos of the genus *Cabassous*. The body hair is greatly reduced, but some, such as the pink fairy armadillo, have dense fur on their sides and underparts. A sparse growth of hair also occurs among the bony plates of all species.

Specializations of internal anatomy. Female edentates have a common urogenital sinus (*i.e.*, both reproductive and excretory functions involve a single chamber) and a simple uterus (a single uterine cavity rather than a branching two-chambered organ). The placenta (the uterine connection between the mother and embryo) is discoid in shape. In other words, the actual areas between which gases, food, and nitrogenous wastes are exchanged are restricted to a single disc-shaped region. The placenta is also deciduous; *i.e.*, it is shed at the time of birth. Females have one or two pairs of mammary glands that are located just lateral to the "armpits," on the chest or on the abdomen. In males, the testes are abdominal and the length of the penis is associated with the degree of difficulty encountered in copulation. In tree sloths, where the partners hang abdomen to abdomen, it is quite small, whereas in armadillos, in which the carapace prevents the partners from getting very close to one another, the penis is long and pendulous.

In general, edentates have poor temperature control. Definitely related to the conservation and manipulation of heat are the extensive anastomoses (fusions) of the veins and arteries (termed retia mirabilia) in the limbs and tails of most species. These structures conserve heat, transferring heat from the arterial components carrying warm blood outward along the limbs to the veins lying adjacent for return to the trunk. At the same time, the appendages are cooled.

Tree sloths are heterothermic (*i.e.*, have imperfect control of body temperature) and under experimental conditions their body temperature, normally ranging between 28° and 35° C, may drop to 20° C. At this temperature, the animals become torpid. Temperature control is likewise relatively poor in armadillos. The fact that it builds a subterranean leaf-lined nest has aided the nine-banded armadillo in the northward expansion of its range into the United States. Nonetheless, many individuals of this species perish during severe winters.

EVOLUTION AND PALEONTOLOGY

The ancestry of the order Edentata is believed to be rooted in some unknown but probably generalized insectivore (order Insectivora). The oldest known members of the two presently recognized suborders of edentates were already too specialized for either group to have given rise to the other. Members of the extinct suborder Palaeanodonta, a group restricted to North America, by the time of their first appearance in the fossil record had already developed specializations that eliminate them as possible direct ancestors of the suborder Xenarthra, which flourished throughout the Tertiary in the then isolated South American landmass.

The palaeanodonts

The palaeanodonts, which lived from the late Paleocene until the beginning of the Oligocene, comprised two families, Metacheiromyidae and Epoicotheriidae. The most completely preserved form in the former family is *Metacheiromys*, an archaic mammal about 45 centimetres (18 inches) in length, reminding one somewhat of an armadillo lacking armour. This animal possessed an assemblage of clearly edentate traits, including the near absence of teeth (except for the enlarged bladelike canines), long compressed foreclaws, and a slight inward twist of the wrist, which is typical of virtually all members of the order. Other metacheiromyids did not show the strong development of the canines. *Palaeanodon*, known from the upper Paleocene and probably ancestral to *Metacheiromys*, had a series of four or five peglike cheek teeth that lacked enamel. The Epoicotheriidae, which had a skull that in outline is reminiscent of that of a small armadillo, were apparently small aberrant forms, highly specialized for a fossorial (digging) livelihood. When the palaeanodonts passed from the scene at the end of the Oligocene, they left no descendants.

The second suborder, Xenarthra, by far the more successful group of edentates, enjoyed an evolutionary history independent from that of the palaeanodonts because North and South America were separated throughout most of the Tertiary, not becoming rejoined until the Pliocene. Contemporaneous with the earliest palaeanodonts of North America was the first South American xenarthran, *Utaetus*, already recognizable as a primitive armadillo and thus sufficiently advanced to eliminate any possibility that known palaeanodonts might be directly ancestral to xenarthrans. The fact that primitive armadillos are the first known members of the suborder strongly suggests that the other xenarthran families are in some way derived from the Dasypodidae.

The Tertiary radiation of edentates in South America resulted in several more or less separate lineages, which are conveniently arranged in three infraorders. The first of these infraorders, Loricata, includes the armadillos (Dasypodidae) and their relatives, the extinct glyptodonts (Glyptodontidae) or so-called turtle armadillos, distinguished from the former especially by their possession of a rigid carapace. Armadillos flourished in South America in the Tertiary and were abundant by the Miocene. In the Pleistocene, some species had moved northward as far as what is today the central United States.

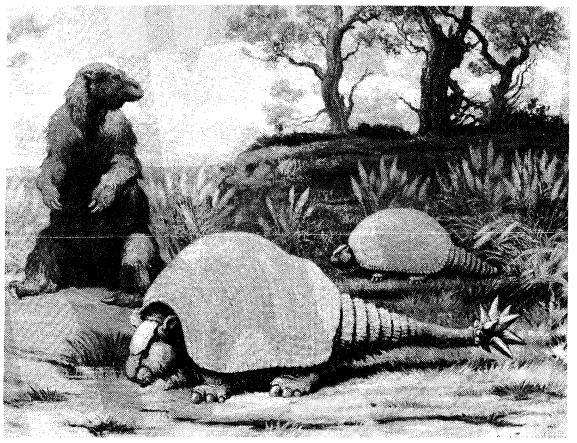
Fossil armadillos

Four distinctive lines developed in the Dasypodidae, comprising the subfamilies Dasypodinae, the Stegotheriinae, the Pampatheriinae, and the Chlamyphorinae (including only the living genera *Chlamyphorus* and *Burmeisteria*). The Dasypodinae includes most of the living genera of armadillos as well as *Utaetus*. The fossil members of this group varied in size from that of a small contemporary armadillo to animals as large as the South American Pliocene form *Macroeuphractus* that had a skull nearly 28 centimetres (11 inches) long. The head and body of the latter must have been almost two metres (6 feet) long. The fossil members of this subgroup all seemed to favour invertebrates in their diets, but they probably ate carrion and some plant material as well. This distinguished them from the extinct Stegotheriinae, a subfamily whose members were highly specialized for a strictly insectivorous diet. *Stegotherium* of the lower Miocene of South America had an elongate anteater-like skull with much reduced cylindrical cheek teeth.

The Pampatheriinae, known from the late Miocene to the Pleistocene, was a group characterized by great size. At least one form, *Pampatherium*, a nearly complete skeleton of which was recovered from a Pleistocene deposit in Texas, was nearly as large as a rhinoceros. This animal and its closest relatives were apparently adapted to an herbivorous diet. Both insect- and plant-eating groups are thus included among the true armadillos.

The genus *Peltephilus* and several other closely related genera of aberrant armadillo-like creatures have been placed in their own family, Peltephilidae, because, among other characteristics, they possessed at least one pair of hornlike protuberances on the muzzle. These animals, which appeared in the Oligocene and disappeared in the Pliocene, were apparently specialized for flesh eating.

The glyptodonts (Glyptodontidae) evolved from primitive armadillos, first appearing in the fossil record in the Eocene with the genera *Glyptatelus* and *Lomaphorelus* but remaining relatively uncommon until the beginning



(Left) Ground sloth (*Megatherium*) and (right) glyptodonts (*Doedicurus*). Painting from fossil skeletons by Charles R. Knight. By courtesy of Field Museum of Natural History, Chicago

of the Miocene. Subsequently, they experienced a radiation of their own and by the Pleistocene several kinds had spread into North America. Throughout their history, they demonstrated an increase in size culminating in the Pleistocene giant, *Doedicurus*. They became extinct before the end of that epoch.

The second infraorder, Pilosa (hairy) includes the sloths, both the living arboreal forms (Bradypodidae) and the fossil ground dwellers of the families Megatheriidae, Megalonychidae, Mylodontidae, and Orophodontidae. There are no fossils of tree sloths, but they appear to be structurally related to the ground sloth families Megatheriidae and Megalonychidae. The oldest fossils of ground sloths belong to the Megatheriidae and come from Oligocene deposits in South America. By the early Miocene, primitive members of this group were rather common. One form, *Hapalops*, although typical of that time, was of relatively small size for a ground sloth. It had a slender body about 1.3 metres (4.5 feet) in length and had five toes with developed claws on both its forefeet and hindfeet. *Hapalops* had a moderately elongated skull with slender premaxillae (bones of the upper jaw), and a process resembling a spout that protruded from the lower jaw and may have supported horny plates for cropping. This animal had five upper teeth and four lower teeth in each jaw, the first upper pair of which resembled canines. The small Pleistocene ground sloth *Nothrotherium* apparently was a descendent of *Hapalops* and the two comprise a branch of the Megatheriidae, which throughout its history was given to small size. This stock differed greatly from the main stem of the family, which had no specialized "canines" and had the two inner toes reduced, represented by the Pleistocene *Megatherium*, a massive ground sloth larger than an elephant.

The megalonychids, although related to the megatheriids, were distinguished from them by their definite canine-like teeth and lack of the spoutlike process on the lower jaw. The megalonychids ranged in size from one island-dwelling animal no bigger than a domestic cat to the mainland ox-sized *Megalonyx*. Both the Megalonychidae and the Megatheriidae reached southern North America by the Pleistocene, but they became extinct on the Continent at the end of the epoch. Some megalonychids invaded the West Indies, however, and experienced a minor radiation in Hispaniola, Puerto Rico, and Cuba. One or more species may have flourished there to within a few hundred years of the present.

Distinct from the megatheriid–megalonychid line of ground sloths were the Mylodontidae, which first appeared in the Oligocene; from the Pliocene until their extinction at the end of the Pleistocene, they were the dominant South American group of ground sloths. The mylodonts differed from the other ground sloths in their partially developed upper canines, reduced first toe of the hindfoot and rounded ossicles (bony tubercles) in their skin. The mylodonts followed the trend of other ground sloth families toward great size and awkwardness, which in this group culminated in the Pleistocene giant, *Glossotherium*, which was the size of a large ox. As with other xenarthran groups in the Pleistocene, the mylodonts extended as far north as the southwestern United States.

The other family of ground sloths, the Orophodontidae, is known only from the Oligocene of South America. This briefly-lived side group is represented by *Orophodon* and *Octodontotherium*, both of which were rather small sloths that do not seem to have left any descendants.

The final infraorder, Vermilingua, comprising the anteaters (Myrmecophagidae), is known no earlier than the Miocene. The fossil myrmecophagids, as represented by the Pliocene form *Palaeomyrmedon*, were already completely toothless and presumably well adapted to an insectivorous diet. The Myrmecophagidae first appeared in South America in the early Miocene and apparently only fairly recently have spread to Central America.

CLASSIFICATION

Distinguishing taxonomic features. The degree of development of certain sets of structural characteristics taken in concert defines the Edentata and its subgroups. None of these features is universally distributed throughout the order. The most important are as follows: (1) in addition to the normal zygapophyses (protuberances), the occurrence of supplementary articular surfaces called xenarthrous articulations between the arches of sequential posterior trunk vertebrae; (2) development of certain projections of the scapula bone, or shoulder blade, called the acromion and coracoid processes; (3) articulation of the ischium bone of the pelvis with the proximal caudal (tail) vertebrae, forming an elongate sacrum; (4) length and massiveness of limb bones; (5) fusion of distal limb bones; (6) hyperdevelopment of claws; (7) development of forefeet and hindfeet; (8) a skull characterized by a small brain housed in a long tubelike brain case, typically with a reduced premaxilla (*i.e.*, elongate palate), often an incomplete zygomatic arch, and a reduction in number of teeth and their enamel covering.

Annotated classification. The classification presented here combines those proposed by the two paleontologists R. Hoffsteter and Alfred S. Romer. The features given below are only those that distinguish each group from the others. Groups indicated by a dagger (†) are known only as fossils.

ORDER EDENTATA

Placental mammals with reduced dentition, often lacking enamel; heavily clawed forelimbs for burrowing. Coracoid process of the scapula more strongly developed than in other eutherian mammals. About 31 recent species.

†Suborder Palaeanodonta

Fossil only. Bony carapace and the xenarthrous articulations on the vertebrae lacking; no fusion between the ischium and caudal vertebrae; simple teeth, usually single-rooted and lacking enamel; slight inward twist to the forelimbs.

†*Family Metacheiromyidae.* Upper Paleocene to lower Eocene. Small, lightly built edentates with sharply pointed somewhat laterally compressed canines; postcanine teeth reduced or lacking; armadillo-like feet with 4 to 5 digits; the lateral digits reduced, the inner greatly so. North America.

†*Family Epoicotheriidae.* Lower Eocene to lower Oligocene of North America. Very small burrowing edentates, with a domed skull having a depressed snout and possessing a zygomatic arch; having 6 slightly differentiated cheek teeth, nearly cylindrical, lacking enamel, and single-rooted.

Suborder Xenarthra

Some extinct and all living edentates; all with xenarthrous posterior trunk vertebrae. Lack teeth or have only poorly differentiated cheek teeth, lacking enamel and having single roots. Fusion (symphysis) between the ischium and the anterior caudal vertebrae in all except the 2-toed anteater (*Cyclopes*).

Infraorder Loricata

Bony plates covered with horny plates, forming a protective carapace over the trunk.

Family Dasypodidae (armadillos). Lower Eocene to Recent in South America; Pleistocene to Recent in North America; forests, savannas, and plains; primarily in the tropics and sub-

tropics. Teeth more than $\frac{6}{6}$ (6 above and below on each side); top and sides of the body covered with horny scutes over a bony, flexible carapace.

†*Family Peltephilidae.* Upper Oligocene to lower Pliocene (questionably) in South America. Teeth $\frac{7}{7}$; short, broad skull; hornlike structures on the head armour.

†*Family Glyptodontidae* (glyptodonts). Mid-Eocene to Pleistocene in South America; upper Pliocene to Pleistocene in North America. Fusion of bony plates on the back into a solid turtle-like carapace; teeth $\frac{8}{8}$ with 3-lobed pattern.

Infraorder Pilosa

Incomplete zygomatic arch (bony ridge below eye); 4 or 5 simple cheek teeth; expanded acromion, which unites with the coracoid region.

†*Family Orophodontidae.* Oligocene in South America. Bilophodont teeth, $\frac{5}{4}$, made of a mass of compacted dentine; highly specialized astragalus (ankle bone). Small to medium body size.

†*Family Megalonychidae* (ground sloths). Upper Pliocene to Pleistocene in South America; middle Pliocene to Pleistocene in North America; Pleistocene in West Indies. Ground sloths. Large canine-like teeth in the upper and lower jaws and no spoutlike terminus on the lower jaw.

†*Family Megatheriidae* (ground sloths). Upper Oligocene to Pleistocene in South America; Pleistocene in North America. Partial development of upper "canines"; spoutlike terminus on the lower jaw.

†*Family Mylodontidae* (ground sloths). Upper Oligocene to Pleistocene in South America; Pleistocene in North America. Distinguished by a partial development of upper "canines," triangular-shaped cheek teeth, and a hindfoot with the 1st toe reduced.

Family Bradypodidae (tree sloths). South and Central America; tropical forests; no fossil record. Dental formula of $\frac{5}{4\text{-}5}$; 6 to 9 cervical vertebrae.

Infraorder Vermilingua

Toothless and hairy edentates.

Family Myrmecophagidae (anteaters). Lower Miocene to Recent in South America; Recent in Central America; tropical forests and savannas. Teeth lacking; tubular mouth with a small terminal opening.

Critical appraisal. The edentates are a natural assemblage of several seemingly rather diverse groups. Given that the oldest known representatives of the palaeanodonts and the xenarthrans are too advanced for either to be ancestral to the other, it would be of great interest to find the common ancestor of both groups, as well as the insectivore precursor of this ancestor. To date, no good fossil candidates have been unearthed in either category.

Authorities disagree on the relationships and degree of distinctness of some groups of fossil edentates. The palaeanodonts are believed by some to be closer to the Old World pangolins (order Pholidota) than to the New World edentates. The armadillo-like *Pseudophorodon* from the upper Oligocene of South America is sometimes placed in its own family but is considered here to belong in the Peltiphilidae. The palaeopeltids, known especially from polygonal plaques of bone, are considered by some to have been aberrant glyptodonts but are considered by Romer to have been the distinct superfamily Palaeopeltoidea. The unusual Miocene ground sloth *Entelops*, due to the presence of teeth on the premaxillary bone, is sometimes separated from the Mylodontidae as sole member of the family Entelopsidae.

The degree of relatedness of sloths and anteaters has been the subject of disagreement. It has been shown that despite certain adaptations of the front limbs and digestive tract for insect eating, anteaters are close to the most primitive xenarthran edentates in many characteristics of the forefeet and hindfeet. Hofstetter has suggested that the evolutionary lines that produced the modern Myrmecophagidae and Bradypodidae separated early and that, therefore, the two families are not closely related but should be placed in separate suborders.

The origin of the tree sloths and the relationship of the currently recognized two genera is a question of some interest. As mentioned above, the two genera may be independently derived from two extinct families of ground sloths. *Choloepus* shows affinities to the megalonychids and *Bradypus* is more like the megatheriids.

At one time, the Old World scaly anteaters or pangolins (order Pholidota) and the South African aardvarks (order Tubulidentata) were included in the Edentata. The adaptations for an insectivorous diet that these two groups seem to have in common with the New World anteaters and the armadillos are most assuredly a result of convergent evolution, and not a reflection of any close phylogenetic relationship.

BIBLIOGRAPHY. The following works, although broad in scope, are particularly rich in information on this group: J.C. BARLOW, "Edentates and Pholidotes," in S. ANDERSON and J.K. JONES, JR. (eds.), *Recent Mammals of the World* (1967), a discussion of the taxonomy of this order and its families; J. DORST, *South America and Central America: A Natural History* (1967), many fine photographs of edentates; E.R. HALL and K.R. KELSON, *The Mammals of North America*, 2 vol. (1959), descriptions and distributional information on North and Central American members of this order; R. HOFFSTETER, "Xenarthra," and R. SABAN, "Palaeanodonta," in J. PIVETEAU (ed.), *Mammifères evolution*, pt. 6, vol. 2 of *Traité de Paleontologie* (1958), detailed accounts of early edentates; and E.P. WALKER, *Mammals of the World*, 2nd ed., vol. 1 (1968), an account of the natural history and distribution of every genus in the order.

(J.C.B.)

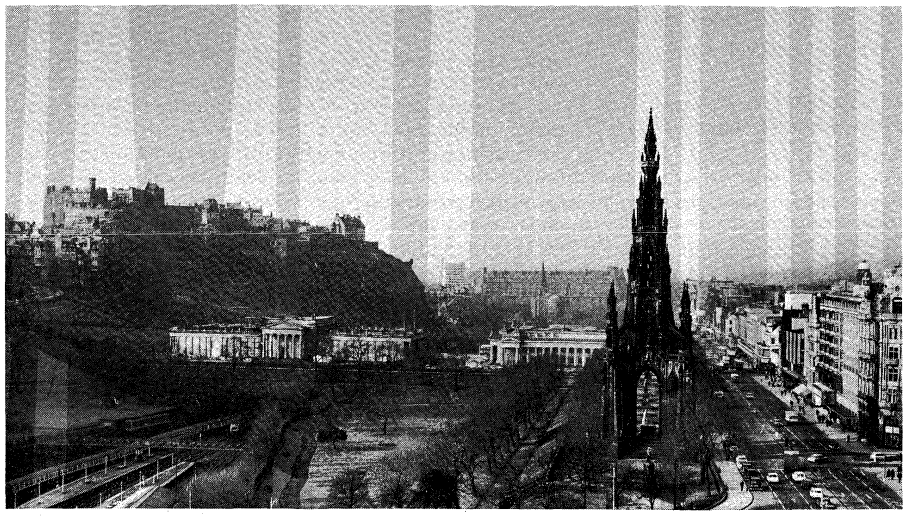
Edinburgh

Edinburgh, the capital of Scotland, like many of its northern European counterparts, is a dramatic and spacious city. While its character may seem lacking in warmth, it exhibits a striking, if somewhat aloof, nobility. The dramatic qualities of the city lie in its site: a rough valley, punctuated by upthrusting crags (there are five extinct volcanoes within the city limits) and scoured by Ice Age glaciers, slopes down to the port of Leith, two miles away on the southern shore of the Firth of Forth, an irregularly diminishing arm of the North Sea that thrusts westward into the heart of the Scottish lowlands. The wind, frequently whistling in from the sea and the abrupt heights, sounds a wild note among the urbane expanses of the modern city.

The city, seen from on high, still gives the impression of being rather sparsely strewn amid open country, although its population had reached almost 500,000—nearly 10 percent of the inhabitants of Scotland—by the 1970s. Only a little more than half of the area of the district, 64,000 acres (26,000 hectares), is occupied by buildings; there are more than 550 miles of city streets, and some of the free space remains relatively untamed hill and moorland. Within the confines of Edinburgh there exist entirely rural villages such as Duddingston, sited beside a loch behind the 824-foot (251-metre) hill known as Arthur's Seat.

Edinburgh Castle, 443 feet (135 metres) above sea level, dominates the central city from atop basalt cliffs, which themselves drop a sheer 270 feet to a grassy valley planted with trees and flowers, the drained North Loch. On the opposite shore of this former lake, northward toward the sea, there rises an elegant gray Georgian town of the 18th century. On either side of the valley, east–west thoroughfares, one called the Royal Mile, the other named Princes Street, form the main axes of Edinburgh. The Royal Mile descends Castle Hill, a spur of rock linking the castle with the Palace of Holyroodhouse; the towering, 16th-century-style tenements of the original burgh, the Old Town, are pressed together on this crest.

Changes in light and weather make for a constant and subtle shift in the vistas stretching away across the valley separating the Old Town from the New. The ravine itself, drained in 1816, now houses the Princes Street Gardens, one of the most remarkable of urban parks, with main railway lines running deep along its centre. To the south of the castle, beyond the Meadows, which occupy the site of the drained South Loch, there are additional splendid views of the Pentland Hills (1,898 feet [579 metres] high), formed of igneous rocks heaved up by



Princes Street, showing Castle Rock overlooking the city, the Scott Monument (foreground), the National Gallery of Scotland, and the Royal Scottish Academy, Edinburgh.
A.G. Ingram Ltd., Edinburgh

earth movements and leading to the Southern Uplands beyond. Although Edinburgh absorbed surrounding villages and the Firth of Forth ports between 1856 and 1920, the mood of the whole is still generated within the small compass of the Old Town and New Town, the former huddled high as a result of medieval fears of attack, the latter serenely spread out in a magnificent succession of streets, crescents, and terraces, somehow reflecting the optimism of the 18th-century Enlightenment.

"This profusion of eccentricities, this dream in masonry and living rock is not a drop-scene in a theatre," wrote Robert Louis Stevenson, the 19th-century Scottish novelist, essayist, and poet, who was born in the New Town, "but a city in the world of reality." The contrasts that make Edinburgh unique also make it typically Scottish, for, despite its reserved exterior, it is also a city capable of great warmth and, upon occasion, gaiety, while its history demonstrates that its citizens have also been capable of great passion, especially in matters royal or religious. In 1736 the burgh almost lost its royal charter following the lynching of one John Porteous, captain of the city guard. This occurrence can be viewed as a violent gesture common to the history of most old cities, yet, even in this moment of conventional madness, the city manifested its complex character: needing a hanging rope, the mob descended on a shop and bought one.

A wealthy city by European standards, Edinburgh shuns ostentation. As far back as 1820, Stendhal, one of the greatest of French novelists, noted that the city had "emancipated itself from the mean omnipotence of gold." In a society relatively unmarked by modern class conflict, one in which public politeness and private consideration still prevail, it is not necessarily held against a man that he has had a head start in life. Having for centuries been a bulwark of free education for all, and endowed with a traditionally superior state school system, the Edinburgh of the 1970s still had a greater proportion of private school students than any other city of the British Isles—20 percent of the school population, including children of families with very modest means.

Long history of free education

A city long renowned for a somewhat inflexible respectability—when west Princes Street Gardens were turned over to the general public in 1876, smoking was forbidden—Edinburgh concurrently maintained a fascinating netherworld of ribaldry and drunkenness. A poet or jurist of sufficient distinction might succeed in inhabiting both worlds. Such "Edinburgh characters" abounded during the flourishing neoclassical period of the 18th and 19th centuries known as the Augustan age, when the city's authors, critics, publishers, teachers, physicians, and scientists formed an intellectual elite of world influence. With the subsequent relapse of the city into a more provincial role, such noted eccentrics have become virtually extinct. Since 1947, Edinburgh has shone anew as an international focal point for the arts during the three weeks of its annual summer festival. Almost 100,000 visitors come for the theatre, ballet, music, films, art expositions, and the general excitement, which closes with a skirl of the Scottish bagpipes before the castle gate.

Regular attendance at church is still common to the citizens of Edinburgh, although Sabbath observances are less austere than those molding the social life in previous centuries. Even in the later years of the 19th century, a noted foreign visitor leaving church was advised not to proceed too fast, "lest people think we are just out for a walk." Men, whose costume during the week may well be a sombre business suit, sometimes dress for church by donning the kilt, once prohibited by the English. The kilt is seen on other days of the week on soldiers of the Scottish regiments (the army has its national Scottish headquarters in the city) and is also worn by visitors from the Highlands and islands. As late as 1970, services at Tolbooth St. John's in the Old Town were still being conducted in Gaelic, the fast-diminishing native tongue of Scotland. A measure of the relaxation of sabbatarian severity is evidenced by the number of ladies who now attend church hatless, while Sunday cricket and soccer matches are allowed on the municipal playing fields after 2:00 PM, weather permitting. Costumes other than the workaday or the tartan are rarely seen on the streets of Edinburgh except during the important high tourist season: of only marginal industrial importance, the city has not attracted the great numbers of Commonwealth immigrants who have been drawn to other leading British cities. A cosmopolitan group around the university has nevertheless leavened Edinburgh society to some extent. The medical school, in particular, has attracted overseas students, and one of the first Africans to take a medical degree in Britain, Dr. James Africanus Beale Horton, was graduated from there in 1859. This tradition has found its latest expression in the Centre for African Studies, established in 1963.

Social observances and the kilt

GROWTH AND TOPOGRAPHY

The castle and the earliest period. The Roman invaders of Britain established a camp on the shores of the Firth of Forth, where the little Almond River debouches, and the village of Cramond on this site, together with the port of Leith and other, smaller, settlements, became part of expanding Edinburgh in 1920. There is no evidence that the legions installed themselves at Castle Rock, four miles further inland, where the towering crag was to become the nucleus of the city. The Gaelic name Dun-eideann means "hill fort of Eiden," and, as far as historical records indicate, fortifications have existed on the rock since at least the 6th century AD. The oldest surviving construction is 11th century; the impressive cliffhanging ramparts, with attendant sentinel towers, are large-

ly of 18th-century origin. The history of the rock and of its stony spine trailing off to the east is, for the first thousand years, not only the history of a city but also that of the Scottish nation, a nation successively seeking to be born, to defend its independence, and to preserve its identity.

The king of the castle in the 11th century was Malcolm III Canmore (1058–93), whose father, Duncan, had been murdered by Macbeth, the dark event providing the inspiration for the Shakespearean tragedy. Malcolm's Saxon queen, St. Margaret, erected a small, square chapel in the castle grounds at the highest point of the rock. Rebuilt a century later, the simple building is the oldest to survive in the city. It was not harmed when Edward I of England (1239–1307), after an assault with stone-slinging engines, took the place by storm in 1296 at the start of the bloody Wars of Independence (the Scots took it back 16 years later). When the Scottish king Robert I, the Bruce, (1274–1329)—who granted Edinburgh's first extant charter in the year of his death—ordered the castle razed for military reasons, he specifically spared the chapel, in which the saint had heard her dying mass in 1093. Services are still occasionally conducted there.

Nearby are the massive ruins of David's Tower, erected by David II in 1367–79. The tower's ruins are now entirely enclosed by the Half-Moon Battery (1574), from which a modern 25-pounder fires the daily one o'clock signal. Simultaneously, a white ball drops from the top of the 102-foot-high Nelson monument, three-quarters of a mile away on Calton hill. Since this firing began, in 1858, it has been an Edinburgh pleasantry to pretend to admire the gunnery of the castle cannoneers.

Palace Yard, or Crown Square, occupies much of the summit of Castle Rock and is surrounded on three sides by the 16th-century royal palace, with the Scottish National War Memorial (1927) completing the closure on the north. On the south side, the Great Hall, restored in 1888, preserves the features of an imposing medieval banqueting hall, and ceremonial gatherings are still held under the original richly carved hammer-beam roof. On the east, in the King's Lodging, the "Honours of Scotland" (royal crown, sceptre, sword of state, and other 16th-century regalia), hidden from 1707 to 1817 after the Union with England, are on public view, as are the royal apartments. These include the quarters of Mary of Guise (Lorraine), who died, it is said, when she scanned the Forth for sight of a French fleet and saw instead an English one. Her daughter Mary, Queen of Scots (1542–87), gave birth in 1566 to James VI (James I of England) in a room unregally tiny but extraordinarily secure, with a single window giving onto the perpendicular cliff. The Scottish United Services keep a museum of Jacobite relics and Highland weapons and uniforms in the palace.

The extensive precincts of the rock are not all given over to sight-seeing: in addition to the regional command offices of the army and the small guard, the Piobaireached Society continues the School of Piping. Outside the gates is the bare, broad Esplanade, from which tourist buses and parked cars are banned during traditional military displays. A corner near the drawbridge contains Nova Scotian soil, as mandated by Charles I (1600–49). To attract Scottish settlers to the North American colony, baronetcies were offered for sale. Before such title had legal force, each new baronet was obliged to take seisin —*i.e.*, to accept a morsel of his lands from the crown—hence the alien soil on Scottish ground. In the northeast corner of this open space a metal wellhead marks the spot where 300 or more alleged witches were burned at the stake between 1479 and 1722.

Importance of sight-seeing

The medieval Old Town. The original burgh of Edinburgh, now known as the Old Town, rose under the castle walls on the slopes of the ridge to the east, bounded by streams on north and south. At the same time (during the reign of David I [1124–53]), the Augustinian Abbey of Holyrood was founded at what is now the eastern end of the Royal Mile. The King granted canons the right to erect their own burgh, which, under the name of Canongate, remained a self-governing entity until its incorporation into the city of Edinburgh in 1856.

The embryonic town had suffered with the castle under the ravages of the Wars of Independence, and it was razed again during the invasion of Richard II in 1385. Only during the reign of James II (1437–60), who was born and crowned at Holyrood, did Edinburgh begin to emerge as the Scottish capital. It became the usual meeting place of the national Parliament, and developed a municipal administration, together with the beginnings of a power struggle, between craft guilds and merchants, that was typical of evolving European cities of that period. The first city wall was constructed, and a second street, the Cowgate, was built on the southern slope of the ridge, parallel to the main street. In the next century, after the terrible defeat of Scottish arms at Flodden in 1513, another wall, thicker, and of wider compass—it reached halfway down the Royal Mile—was hastily thrown about the town as protection against an imminent threat of assault, which did not materialize.

The Flodden wall

In spite of religious and political turbulence—there was further destruction by an English army in 1544, and the tragic reign of Mary—the 16th century was a period of consolidation. In 1505 the Royal College of Surgeons was chartered and the practice of dissection legalized. Little use was made of this privilege for two centuries, after which Edinburgh became one of the great medical teaching centres of the Western world. The College of Justice was founded in 1535, and, in 1560, the first General Assembly of the Church of Scotland convened in the Magdalen Chapel in Cowgate, which still stands. Further, in 1583, James VI settled the squabbling between the craft guilds and the merchants' party over the composition of municipal government, giving it a form it was to keep for 250 years. A year earlier the council had given orders for the construction of the "Toun's College" at the site of the ancient collegiate church of St. Mary in the Fields ("Kirk o' Field"), scene of the unsolved gunpowder murder of Lord Darnley, Queen Mary's husband. The college of 80 students, under a single teacher, was to grow into Edinburgh University.

The church, the law, national and municipal legislatures, and advanced learning were thus all established in Edinburgh when James VI also became James I of England. He moved his court to London in 1603, two years after the union of crowns. There followed a precipitate fall in the prestige and prosperity of Edinburgh, but in 1633 Charles I declared the burgh an episcopal see and made the ancient church of St. Giles a short-lived Episcopal cathedral. Five years later there came the National Covenant, signed—sometimes in the blood of the signatory—by nobles and commoners alike in Greyfriars churchyard. While loyal to the King as their monarch, the signatories rejected his policy of enforcing the Anglican Episcopacy on Presbyterian Scotland. Edinburgh escaped the battles that subsequently flared under both Stuarts but did not escape the dire consequences. From June to September 1679, more than 1,200 Covenanters, captured in the battle of Bothwell Bridge, were imprisoned in the same churchyard where the Covenant had been signed. Many died from starvation and exposure; others were sold into West Indian slavery, and 100 were executed in the Grassmarket.

After the Union with England in 1707, resulting in the abolition of the Scottish Parliament, the town again declined, and riots were common. The town was nevertheless to emerge into its "Golden Age" by the mid-18th century. Then a city of 50,000 people, Edinburgh had grown from fewer than 8,000 inhabitants 100 years earlier and only 25,000 some 50 years before. Almost all these 50,000 were squeezed behind the Flodden walls, in buildings that climbed ever higher. Then, in the 1760s, the old city vaulted its valleys and spread to both the north and the south (see below *The Meadows and the university; Princes Street Gardens;* and *The New Town.*

The Royal Mile bears several names on its way to Holyrood: Castle Hill, Lawnmarket, High Street, and Canongate. The cliff-face of houses is broken by wynds—narrow, winding, stone lanes leading down either side of the ridge, sometimes not much more than long staircases, some with a left-handed spiral that favoured defending

swordsmen—and closes or vennels—entranceways into courtyards, around and behind which are yet more buildings, towering and beetling. Everything was jammed together to make space where there was none, ". . . piled deep and massy, close and high," as Sir Walter Scott, the nation's leading writer, described the area.

Only the wealthiest could afford to occupy one of the heavy-timbered and gabled houses fronting directly on the street, and the closes and courtyards harboured not only families but also workshops, taverns, and clubs. At Anchor Close the parents of Sir Walter Scott lived until 1777, the editor and writer William Smellie brought out the first serials of *Encyclopædia Britannica* in 1768, and the Anchor Tavern provided food, drink, and fellowship. In James' Court, off the Lawnmarket, lived one of the leading 18th-century philosophers, David Hume. In the same building the diarist and biographer James Boswell entertained Samuel Johnson, in 1773, regretting, after the latter's remark on the smells of High Street, that although the magistrates "enforce city laws against throwing foul water from the windows . . . there being no covered sewers the odour still continues." In the same year, Robert Fergusson, one of the leading figures of a renascent Scots poetry, cited "the morning smells that hail our street" where "clarty [filthy] Odours fragrant flow." "Auld Reekie," the affectionate name for Edinburgh, may thus not have referred exclusively to the smoke and sea mist mantling the town.

Water supply was a great problem until it was piped in, in 1681, to serve street wells, which, when they became contaminated under later, more crowded, conditions, spread epidemics of typhoid and cholera. The linkboys, who ran errands and carried jugs of water up to householders, were called "caddies," a Scotch version of the French *cadet*. The name survives on golf courses.

Once the city had spread off the hill, although the town council moved effectively to end overcrowding and to institute modern municipal services, the Royal Mile decayed badly. Courts, the church, and the city government nevertheless remained in place on the ancient thoroughfare, and in the mid-20th century the council and private persons resolved to restore it. Five of the old buildings are now museums, while others are used as offices or for educational purposes. Tenements have been razed, ugly courtyards scoured, and the splendid old courts restored to their original state and made into desirable dwellings.

The High Kirk

In the case of St. Giles, the National Church of Scotland, an earlier, but less thoughtful, generation of rescuers had already (1829) paved the exterior with good intentions. Happily, the magnificent 15th-century crown tower, an open spire with eight flying buttresses supporting a sculptured turret, was left untouched. Many of the church's chapels are authentically late medieval. The official city guide says, "The High Kirk of Edinburgh is the very heart of Scotland." Still in use, it has been a parish church, a collegiate church, and for two short periods (1633–38, 1661–89) an Episcopal cathedral.

Behind St. Giles is Parliament House, built by the Town Council (1632–39), with the aid of private contributions, when Charles I threatened to move the law courts elsewhere. The Scots Parliament met there from 1639 to 1707. The supreme civil and criminal courts of Scotland now sit in the building, administering Scots law, which has been characterized as somewhere midway between the Anglo-American school of legal thought, deriving from English common law and equity, and the continental school, based on Roman law.

Opposite the cathedral are the City Chambers, which is the venue of the City of Edinburgh District Council (from May 1975), consisting of 64 popularly elected members, one from each of the city's wards. Intended to be the Royal Exchange, the building was erected in 1753, using the designs of John Adam, the Neoclassicist architect.

At the foot of the castle crags, on the south slope, the Cowgate emerges at its western end into a broad, tree-planted square, the Grassmarket, where until 1911, cattle and grain were sold weekly. On the north side is the White Hart Inn, patronized by such figures as the poets Robert Burns and William Wordsworth. A flight of steps on the southwest corner is enclosed on the left side by a stretch of the Flodden Wall; on the other side is George Heriot's Hospital, built in 1628, following designs of Inigo Jones, the founder of the classical school of British architecture. This school is not only one of Edinburgh's noblest buildings but also its oldest privately endowed educational charity. Tanner's Close once stood on the same corner of Grassmarket. Here, in 1828, the "Resurrectionists" Burke and Hare purveyed cadavers for dissection to Dr. Robert Knox of the Medical School. At first they robbed graves, then took to obtaining cadavers wholesale, by murder, and their trial was one of the most celebrated in Scots criminal annals. The nearby graveyard of Greyfriars Church still has iron trellises on some tombs to foil body snatchers, as St. Cuthbert's burial ground has a watchman's tower in heavy stone.

The Meadows and the university. Southeast of this neighbourhood, close to the edge of the Meadows (the drained South Loch), the architect James Brown developed a Neoclassical square (1766), which he named George for his brother. This was the first move in developing the town southward beyond the old walls. Today the university's new (1966–75) complex occupies three sides of the square, with a row of Georgian houses preserved along the other. The university's old quadrangle, some 300 yards closer to the Royal Mile, was started in 1789 and completed in 1834. The 1854 Royal Scottish Museum is adjacent, and the nearby Cowgate houses the city's central library, across the street from which is the 1854 National Library of Scotland (3,000,000 volumes, founded 1682), abutting Parliament House.

Holyrood. Away from the crowded buildings, at the lower end of the Royal Mile, is Holyrood. The now-roofless abbey was founded in 1128 and rebuilt about 1220. The substantial remains are impressive examples of the bold, imaginative work of the period. The Palace of Holyroodhouse, which shouldered the abbey aside, is intact in its early 16th-century wing and in the 1671 extensions. It was to this palace that the widowed Mary, Queen of Scots came from France, to find herself the symbol of Catholicism and continental refinement opposed by (among others) the fiery John Knox of St. Giles Kirk, who represented the new Calvinism and the old, rugged Scottish ways. The rooms in which Mary's Italian secretary was dragged from her side and murdered are now on public view, as are the State apartments used during royal visits to Edinburgh. Bonnie Prince Charlie also stayed here during the attempted Stuart restoration of 1745. Its 110 royal portraits, from "Fergus I, 330 AD" to "James VI (1566–1625)," were all painted by the Dutch artist Jacobus de Wet.

Royal traditions

The abbey's monks began making beer in the 12th century, and today the tradition is maintained by a nearby commercial brewery, sharing Holyrood's soaring view of the Salisbury Crags and Arthur's Seat. These two eminences are among the five in the 648-acre (262-hectare) Holyrood Park, which also embraces three lochs.

Princes Street Gardens. The 37 acres (15 hectares) of the Princes Street Gardens, lodged between the Old and New Towns, have a distinct character. The old North Loch, which had been created out of a swamp by James II (1437–60) as the castle's northern defense, was the sump for sewage draining from the Old Town. Doctors clamoured for its destruction long before it was achieved in 1816. Flowers are set out in beds changed 10 or 12 times a year, and a floral clock (1903, first in the world), which embowers a quarter-hour cuckoo, has some 24,000 plants in its 36-foot circumference. Among the lawns, flower beds, and groves are recreational areas, a bandstand, an outdoor dance floor, and numerous memorials, the most conspicuous of which is an 1844 Gothic spire, 200 feet high, that rises above a statue of Sir Walter Scott and his hound, Maida.

The floral clock

For the first 100 years of its existence, west Princes Street Gardens was the private amenity of Princes Street proprietors. In 1876 this tract was opened to the public, which had always had access to the east gardens. The

Mound, a causeway of rubble and earth from New Town construction, which crossed the ooze of the recently exposed lake bottom, forms the division between the two gardens. On the Mound stand two neo-Grecian temples to the arts: the Royal Scottish Academy (1832) and the National Gallery of Scotland (1859). These buildings are now seen to be lightly tinged with ochre, but for more than a century they were soot black: locomotives passed under the Mound, railroad tracks—now almost concealed by landscaping—having been laid through the middle of the gardens in 1847. The rails terminated in the east end of the Park at Waverly Station, which covered some 25 acres, most of it under glass.

There were other attempts to bring progress (as envisaged during the 19th century) to the gardens, notably those to erect buildings on the park side of Princes Street. The fights were hard and bitter, but public-spirited citizens eventually prevailed over private interest.

The New Town. The town council approved plans for the New Town in 1767. Its members broke with tradition in planning a town at all, but exceeded even that act of courage and imagination by planning the converse of the Edinburgh that had existed for 600 years. The architect, James Craig, envisaged a grid five streets deep and seven streets wide, its broad central axis terminating in grand squares at each end. St. George's Church would anchor the western end of the scheme, St. Andrew's the eastern. St. Andrew's Square boasts a column in Roman style, topped by a statue of Henry Dundas, 1st Viscount Melville. A member of his family, Sir Laurence Dundas, refused to let St. Andrew's Church be built on the spot he had selected for his mansion. There was no argument, for Sir Henry was the uncrowned king of Scotland, serving as the English prime minister's proconsul in the Scottish capital. Under him, the corrupt Town Council concealed the fact that the city was bankrupt at the end of the 18th century, a state of affairs not divulged until years later. The Dundas house, a fine design of 1772, later became the headquarters of the Royal Bank of Scotland. Extension schemes by other architects were coupled onto Craig's New Town: in 1804 the original plan was reproduced as well as the terrain to the north allowed, while in 1822 there evolved a sumptuous ensemble around a crescent, an oval, and a polygon, connected by short streets. Later expansion developments lacked the Georgian élan, and elegant style was replaced by unimaginative convention. By the 1970s, a scattering of modern glass-fronted structures had replaced grand residences ill-adapted to the contemporary requirements of, for example, the Stock Exchange or the Scottish Widows' Fund and Life Assurance Society. Robert Adam's superb Charlotte Square (1791), the showpiece of New Town, remains intact. Princes Street (originally it trailed an apostrophe, being named after two sons of King George III of England) became the shopping street and the principal thoroughfare of the city, and there is scarcely one original building behind the shop fronts.

Architectural styles of Calton Hill

At the east end of Princes Street is another of the city's extinguished volcanoes, Calton Hill (355 feet [108 metres] high). Its summit proclaims the passion for the classical that gripped Edinburgh architecture in the first half of the 19th century, before Gothic styles became dominant. With the exception of the Nelson monument (1806–16), a structure exhibiting neither Greek nor any other known architectural style, the hilltop monuments are all of Attic extraction. A small temple gracefully honours the memory of the philosopher Dugald Stewart (1753–1828). A porticoed fortress with cupolas is an observatory designed by Robert Adam for the university but completed by the municipality when the original funds were exhausted in 1792. Within the Adam central enclosure, a cruciform structure, with four pedimented facades supporting a dome, is an observatory that W.H. Playfair designed in 1812 for a local astronomy group (the Royal Observatory, 1859, is across town on Blackford Hill). The 12 stark columns, standing like a ruin from some vanished Aegean civilization, are the beginnings—and remains—of Playfair's Parthenon, a project launched with fervor in 1822 as a memorial to Scots who served in the Napoleonic Wars but tagged "Scotland's Pride and Poverty" when the money ran out in 1830.

In a niche in the hill's south flank is an adaptation (1829) of the Temple of Theseus in Athens. This housed the Royal High School (founded at Holyrood in the 11th century) before it moved to suburban Barnton in 1968.

Across the road from the high school is St. Andrew's House (1937), architecturally undistinguished but politically powerful, containing the administrative centre of government in Scotland.

CONTEMPORARY DEVELOPMENTS

Edinburgh entered the 1970s with 159,099 inhabited dwellings, 48,170 of which had been built by municipal housing authorities, almost 20,000 of them less than a dozen years earlier. Ranging from small cottages, through reconstructed historic precincts, to multi-story complexes, they have been conceived with unusual sympathy for the needs of the inhabitants, the character of the neighbourhood, and the requirements of the site. By far the greatest number have been erected on the periphery, between three and four miles from the city centre. Planning is complete for several renewal projects in older central districts. Some of the recent installations house employees at Sighthill Industrial Estate, where about 45 light industries have been established and more are planned.

The urban economy. In the 1970s, manufacturing employed only one-quarter of the people who worked in Edinburgh. The three main manufacturing groups were food, drink, and tobacco; engineering (including ship repairing and marine engineering), electrical goods, and electronics; and paper, printing, and publishing. The capital is Scotland's centre of medicine, law, banking, insurance, and investment and is second only to London as a United Kingdom tourist city.

The port of Leith, about 30 miles from the open sea, has been part of the six-port Forth Ports Authority since 1968 and handles nearly 2,000,000 tons of cargo annually. Grain, foodstuffs, and wood products were the principal incoming products; outbound shipments being coal, whiskey, iron, and steel. Extensive modernization was completed in the early 1970s. Granton, Edinburgh's other port town, is also under the authority, with special facilities for rapid loading and unloading; a sizable industrial estate to service North Sea petroleum is also under development there, and it is the home port for the Firth of Forth fishing fleet.

Population. In 1801 the city had 67,288 inhabitants: the urbanization associated with the Industrial Revolution stimulated growth to 228,357 by 1881. Significant extensions of the city boundary, to facilitate incorporation of surrounding settlements, occurred in 1896, 1900, and 1920, and the population had grown to 439,010 by 1931. By 1974 it had reached 449,910, and the Edinburgh City District, created in 1975, annexed another 25,000 persons.

Administration and services. Until the reorganization of local government of Scotland in May 1975, the Town Council performed most local governmental functions; its successor, the City of Edinburgh District Council, has somewhat more restricted responsibilities—housing, primarily, as well as local planning, libraries, museums, and sports grounds. Under the new scheme, the Lothian Regional Council has primary responsibility for education, transportation, social services, environment, and police, fire, and water services. The famous Edinburgh teaching hospitals, Western General and Royal Infirmary, are undergoing extensive rebuilding as part of a regional National Health Service scheme, costing over £60,000,000 ($144,000,000) and destined for completion in the 1980s. In the early 1970s, there were eight general hospitals, two maternity hospitals, one children's, and one orthopedic hospital—handling some 2,675,000 in- and out-patients. In addition, there were 29 child health clinics, 14 day nurseries, 33 play centres, and extensive facilities for home visits. The birth rate was 12.1 per 1,000, and the death rate 13.3 per 1,000 (with a low infant mortality rate of 16.6 per 1,000 live births).

The medical tradition

The city is served by Britrail, the national system. Princes Street railroad station was closed in 1965, but Waverly (second largest in Britain) and Haymarket remain. Local, regional, and national bus services are also extensive, and there is a civil airport located at Turnhouse, six miles to the west of the city. By the 1970s, the annual number of licensed motor vehicles in Edinburgh reached 100,000, 80 percent of them private vehicles, with all the attendant problems of parking and congestion.

Edinburgh has a remarkable proportion of recreational facilities per head of population. In addition to the expected spectator sport facilities, it has within its boundaries nine miles of coastline for boating, with a fair number of beaches; six public and 16 private courses for golf, which has been played there since 1457; 50 public bowling greens and as many private ones; 104 public football and hockey fields; 20 public cricket pitches; 113 public tennis courts; 28 public putting greens and short hole golf courses; plus a vast multisport centre constructed for the 1970 Commonwealth Games.

Education. By 1970, Edinburgh University, whose origins have already been described, had nearly 11,000 students from 90 countries, enrolled in 150 departments of study. The nearby Heriot-Watt college, dating from the earliest days of the Industrial Revolution, achieved university status in 1966, becoming one of the first of Britain's new technological universities. This institution, installed in the university area and at Grassmarket, has a 200-acre satellite campus just over the city line at Riccarton, Currie. Other establishments of higher education in the city include the Moray House College of Education; Craiglockhart College of Education, for Roman Catholic women; Dunfermline College of Physical Education, for women; Leith Nautical College, training ship's engineers, cooks, radio operators, and pursers. State nursery, primary, and secondary schools offered, by the early 1970s, some 2,700, 45,000, and 21,000 places, respectively.

The Edinburgh College of Art, in addition to its fine arts faculties, also has, under a faculty of Environmental Studies formed jointly with Heriot-Watt, schools of town and country planning and of architecture.

New College, Church of Scotland, is the largest postgraduate theological college in Scotland. William Henry Playfair, whose Greek galleries are just below on the Mound, designed the twin towers (1846) that glare down on the gardens from Castle Hill, solid, upright, and uncompromising, characteristics that have been of strong—but not overwhelming—significance in molding the life of the entire city.

BIBLIOGRAPHY

General: GEORGE SCOTT-MONCRIEFF, *Edinburgh*, 3rd ed. (1965), a detailed account of every aspect of the city, illustrated from photographs, prints, and paintings; IAN NIMMO, *Portrait of Edinburgh* (1969), the city and its inhabitants, their way of life, and culture; WILLIAM GORDON SMITH, *Edinburgh* (1967), text and photographs by author, the principal districts of the city today and yesterday; ERIC LINKLATER, *Edinburgh* (1961), a personal, essayist treatment of the city in its variety.

Special topics: ROYAL COMMISSION ON THE ANCIENT AND HISTORICAL MONUMENTS AND CONSTRUCTIONS OF SCOTLAND, *An Inventory of the Ancient and Historical Monuments of the City of Edinburgh* (1951), a detailed, illustrated catalog for each district of the city, including a list of monuments the commissioners deemed most worthy of preservation; DAVID KEIR (ed.), *The City of Edinburgh*, vol. 15 of *The Third Statistical Account of Scotland* (1966), a close examination of the life of the city in the second half of the 20th century; ROBERT CHAMBERS, *Traditions of Edinburgh*, new ed. reprinted (1967), written to preserve the stories of some of the characters who lived in Edinburgh at the beginning of the 19th century, first published in 1824, uses the author's final revision of 1868.

(B.E.)

Edison, Thomas Alva

One of the outstanding geniuses in the history of technology, Thomas Alva Edison included among his 1,093 patents the incandescent electric lamp, the phonograph, the carbon telephone transmitter, and the motion-picture projector. In addition, he created the world's first industrial-research laboratory.

Edison was born in Milan, Ohio, on February 11, 1847, the youngest of four children of Samuel Ogden and Nancy Elliott Edison. When Thomas was seven years old his family moved to Port Huron, Michigan. There the boy received his only formal schooling, which ended abruptly after three months, when the schoolmaster expelled him as "retarded." For the next three years his mother, a former schoolteacher, tutored him. "She instilled in me the love and the purpose of learning," Edison later recalled.

By courtesy of the Edison National Historical Site, West Orange, N.J.

Edison demonstrating his tin-foil phonograph, photograph by Mathew Brady, 1878.

First experiments and inventions. Curiosity was his dominant trait. When he was ten, his mother aroused his interest in an elementary physical science book, and in the cellar of his home he set up a small chemical laboratory. He found the study of chemistry and the production of electrical current from voltaic jars especially absorbing; soon he operated a home-made telegraph set.

A mettlesome child, he was given to pranks calculated to frustrate his father, who regularly beat him and on one occasion whipped him before the townspeople in the village square. The boy's middle-ear deafness, which had resulted from scarlatina, also contributed considerably to his troubles.

Early interest in science

As his father was a poor provider, Edison went into "business" for himself at the early age of 12, selling newspapers and candy on the new railroad between Port Huron and Detroit. He installed his little laboratory in a baggage car, where he occupied himself during train layovers. He later described this as "the happiest time" of his life. Because people had to raise their voices above the train's roar, he could hear them speaking, and at the stations he could follow the high click of the telegraph. His impaired hearing disposed him to enjoy solitude that gave him the opportunity to read and work in his laboratory. He also managed to train himself in telegraphy, and from 1863 to 1868 he roamed as a "tramp telegrapher," filling casual jobs in Midwestern and Southern cities, sometimes behind the battlefronts of the Civil War. Though living in the bohemian style of the roving telegraphers, he read all the scientific journals he could find, and in cheap furnished rooms of slum quarters ex-

perimented with modifications of the telegraph that would increase its speed and capacity. His earnings went mostly for electrical equipment and chemicals.

In 1868 he obtained a position in Boston as an expert night operator for Western Union Telegraph Company; by day he slept little, however, for he was gripped by a passion for manipulating electrical currents in new ways.

Influence of Michael Faraday

Soon after his 21st birthday he bought a used copy of Michael Faraday's journals, *Experimental Researches in Electricity*, which he promptly read without stopping. It marked a turning point in his life. The experiments of the self-taught English scientist were set forth so clearly that Edison instructed himself by performing all of them. He had already won the notice of his companions by his unusual powers of observation and his ability to "cure" balky instruments. Now, under the inspiration of Faraday, his experimental work became more painstaking, and he began to keep laboratory notebooks of his findings. By this time he had serious projects in view. Borrowing a small sum from an acquaintance, he gave up his job in the autumn of 1868, and became a free-lance inventor, taking out his first patent for an electrical vote recorder. Although the invention worked well when exhibited before a committee of Congress, no one bought it—a lesson Edison never forgot.

In the summer of 1869 he was in New York, sleeping in a basement below Wall Street, a typical, impecunious inventor. At a moment of crisis on the Gold Exchange caused by the breakdown of the office's new telegraphic gold-price indicator, Edison was called in to try to repair the instrument; this he did so expertly that he was given a job as its supervisor. Soon he had remodelled the erratic machine to such effect that its owners, the Western Union Telegraph Company, commissioned him to improve the crude stock ticker just coming into use. He performed this task by creating the Edison Universal Stock Printer, which, together with several other derivatives of the Morse telegraph, brought him a sudden fortune of $40,000. With this capital he set himself up as a manufacturer in Newark, New Jersey, producing stock tickers and high-speed printing telegraphs. Edison was married in 1871 to Mary Stilwell of Newark, a gentle but undereducated woman. Two sons and a daughter were born of this union, but the often distracted father tended to neglect them.

Western Union, then owned by the Vanderbilts and J.P. Morgan, ranked as America's leading electrical enterprise at the time. A group of talented inventors, including Elisha Gray and J.B. Stearns as well as Edison, was retained to develop its several electrical devices. Their knowledge of the field, like Edison's, flowed from an evolving technological environment. The young inventor's skill in eliminating "bugs" became legendary; he could also describe his electrical researches with considerable imagination. In order to gain permission to work all night at Western Union headquarters, he explained that he "wanted to feel the pulse of my patients." The company's operating chief called him a "genius" and "fiend for work" and remarked upon his unfailing self-confidence. When the financier Jay Gould set up a rival telegraph company to harass Western Union, Edison sometimes served under him also, acting as a scientific soldier of fortune in the camps of the warring "robber barons." His quadruplex telegraph in 1874 was his most ingenious invention of those earlier years: it doubled the capacity of the existing duplex of Stearns, simultaneously sending two messages in each direction over one wire.

In his Newark factory, Edison set aside a room equipped with a few scientific instruments, where he could plan and perform experiments according to his own fancy, unrelated to his duties at Western Union. It only served to sharpen his appetite; and in 1876, asserting that he feared he would be turned into a mere "bloated Eastern manufacturer," he gave up the Newark factory altogether and moved to the village of Menlo Park, New Jersey, to set up a laboratory where he could devote his full time to inventive work.

Years at Menlo Park. In a rectangular wooden-frame structure that looked like a rural meeting house he installed a quantity of fine measuring instruments, such as a galvanometer and an electrometer; supplies of storage batteries, induction coils, copper wire, chemicals, and metals; a Brown steam engine; photographic equipment; and a forge. He also established there a library of scientific publications. The equipment at Menlo Park, costing him $40,000, had few rivals even at the leading universities. About 20 of the skilled clockmakers and machinists whom he had employed at Newark were persuaded to settle, with their families, in his secluded "scientific village," to which in due time he also added a mathematical physicist.

The Menlo Park laboratory

Before moving to Menlo Park, Edison had told one of his scientific friends that his would be an "all-purpose research laboratory" and an "invention factory," and he promised that he would turn out a minor invention every ten days and a "big trick" every six months. He also proposed to "make inventions to order." Before long he had 40 different projects going at the same time and was applying for as many as 400 patents a year. Unlike his contemporaries, who worked alone in an attic, Edison depended in great measure on exact instruments and operated with an organized team of specialists whose tasks were allotted to them by their master—then still in his 20s. The German historian Werner Sombart later wrote that Edison was an example of a man "who made a business of invention." Menlo Park was, in fact, the first industrial-research laboratory, to be imitated 20 years later by giant corporations in both Europe and America.

The rough-hewn Edison used to declare that he was no scientist but a "commercial inventor" who worked for the "silver dollar." What he meant was that he consciously directed his studies to devices that could satisfy real needs and come into popular use. Indeed, it may be said that in applying himself to technology, he was fulfilling the ideals of democracy, for he centred his attention upon projects that would increase the convenience and pleasure of the multitude.

At Menlo Park, Edison, now in his 30s, experienced his finest hours. An astonishing number of new products bearing the mark of his originality were developed systematically from the inventor's growing reservoir of knowledge of various arts and industries. When Alexander Graham Bell won the race for the "speaking telegraph" in 1876, Edison was commissioned to improve the device and quickly added the carbon transmitter, markedly increasing the instrument's audibility. But he also had the gift of serendipity: when some unexpected phenomenon was observed, he did not hesitate to halt work in progress and turn off course in a promising new direction. This was how, in 1877, he achieved his most original invention, the phonograph, based on a fresh observation of the dynamics of sound. The phonograph was also an example of what has been called the wonderful simplicity of many Edison devices. Up to this time he had enjoyed a high repute among American technicians, but the phonograph made Edison internationally famous.

The electric light

Europe was well in advance of the United States in developing dynamos and also the electric arc light, which was the sensation of the Centennial Exposition at Philadelphia in 1876. In September 1878, after having viewed William Wallace's exhibition of a series of eight glaring 500-candlepower arc lights, Edison boldly announced that he would invent a safe, mild, and inexpensive electric light that would replace the gaslight in millions of homes; moreover, he would accomplish this by an entirely different method of current distribution from that used for arc lights.

Edison's past achievements commanded respect for his boastful prophecy. A syndicate of leading financiers, including Morgan and the Vanderbilts, advanced him $50,000 for research and development work on the incandescent electric light, which had been the despair of inventors for 50 years. The contracting parties went so far as to establish the Edison Electric Light Company, one of very few occasions when capital has backed an unachieved invention. There followed the prodigious dragnet search, lasting 14 months, for a suitable filament for his proposed lamp. The gifted physicist Nikola Tesla, who once

worked for Edison, called this his "needle-in-the-haystack" method of experimentation. The newspapers also reported that Edison proposed to connect his lights in a parallel circuit by subdividing the current, so that failure of one light bulb would not cause a whole circuit to fail. Some eminent scientists, including Sir William H. Preece, in a paper read before the Royal Society in London, predicted that such a circuit could never be feasible. On October 21, 1879, Edison demonstrated the carbon-filament lamp, supplied with current by his special high-voltage dynamos. The pilot light-and-power station at Menlo Park glowed with a circuit of 30 lamps, each of which could be turned on or off without affecting the rest. Three years later, the Pearl Street central power station in downtown New York City was completed, initiating the electrical illumination of the cities of the world.

One of the accidental discoveries Edison made in his laboratory in 1883 was beyond his comprehension, as it was beyond that of contemporary scientists. In one of his vacuum bulbs he observed a mysterious force that manifested itself by a flow of current between a hot and a cold electrode; later, this was shown to be due to thermionic emission of electrons from the hot electrode. He patented the bulb, describing what became known as the "Edison effect"; studied by other scientists a few years later, it became the basis of the electron tube and laid the foundation for the electronics industry.

After the death of his first wife in 1884, Edison married Mina Miller of Akron, Ohio, a woman half his age, but of genteel background and firm character. She took the heretofore incorrigible, tobacco-chewing eccentric in hand and made him presentable in polite society, which he had tended to avoid. Two sons and a daughter were born of the second marriage, one of the sons, Charles Edison, later becoming secretary of the navy and governor of New Jersey.

Later life. The second half of Edison's life was active and eventful but brought fewer big surprises. Most of the time he occupied himself with promoting and marketing his many products through companies he formed, such as the Edison General Electric Company, which manufactured his lamps and a variety of central station equipment. Eventually, Edison lost control of this major company which, in 1892, was merged into the General Electric Company.

The Edison laboratory

In 1887 he moved his workshop from Menlo Park to West Orange, New Jersey, where he built the Edison Laboratory (now a national monument), a facility ten times larger than the earlier one. In time it was surrounded with factories employing some 5,000 persons and producing a variety of new products, among them his improved phonograph using wax records, the mimeograph, fluoroscope, alkaline storage battery, dictating machine, and motion-picture cameras and projectors. The motion picture, with which he is so closely identified, was not Edison's invention, but with his rare power of going straight to a practical end he brought it to practical, operational success when many others had failed. The mass entertainment industry that he fathered yielded him rich profits, which, by the turn of the century, he badly needed, for he had overextended himself in the development of a magnetic ore-separating process for low-grade iron deposits. When, after five years, he decided to write off this venture, he found that he had lost the entire fortune of $4,000,000 earned by his electric-light system. His reaction was typical: "Well, it's all gone, but we had a hell of a good time spending it!"

In one important episode his limited knowledge of theoretical science told heavily against him. Toward 1890 the more advanced electrical scientists were introducing alternating current at high voltages for long-distance transmission. Edison, having chosen direct current, launched a press campaign to alarm the public about the alleged hazards of the high-voltage system. As a consequence, he lost the contract for the great Niagara Falls hydroelectric site to the rival entrepreneur George Westinghouse.

Other ventures, such as in engineering a more efficient form of cement kiln and in the poured-concrete structure designed for low-cost housing, were more fruitful. During World War I, the aged inventor headed the Naval Consulting Board and directed research in torpedo mechanisms and antisubmarine devices. It was largely owing to his agitation that Congress, in 1920, established the Naval Research Laboratory, the first institution for military research.

Achievements. Edison's career, the fulfillment of the American dream of rags-to-riches, through hard work and native intelligence, made him a folk hero to his fellow countrymen. He was attractive in appearance, although negligent in dress; in temperament he was an uninhibited egotist, at once a tyrant to his employees and their most entertaining companion, so that there was never a dull moment with him. His shafts at the expense of the "long-haired" fraternity of theorists sometimes led formally trained scientists to deprecate him as anti-intellectual. Yet he employed as his aides, at various times, a number of eminent mathematical physicists, such as Tesla and A.E. Kennelly.

The full record of his 3,400 notebooks shows that he had a wide understanding of the principles of science, as known in his time, and a tremendous faith in the method of scientific experimentation. The mathematician Norbert Wiener characterized Edison as a transitional figure in late 19th-century science, who arrived on the scene after the crude mechanical inventors had done their part, when systematic experiment and research were about to be undertaken by organized groups of specialists. The little industrial-research laboratory at Menlo Park may, therefore, be seen as his greatest invention. Edison was in the forefront of those who pressed on, for better or worse, toward the Age of the Machine. Though he grew up in an era of great acquisitors, his own instincts were predominantly creative, as shown by the manner in which he flung away fortunes, only in order "to invent more," as he said. He continued to work even in his 80s, devoting his last years to efforts to develop rubber latex from domestic weeds. He died in West Orange, New Jersey, on October 18, 1931.

BIBLIOGRAPHY. MATTHEW JOSEPHSON, *Edison: A Biography* (1959), is based on the correspondence and laboratory notebooks of Edison in the Edison Laboratory archives, West Orange, New Jersey. F.L. DYER, T.C. MARTIN, and W.H. MEADOWCROFT, *Edison: His Life and Inventions*, 2 vol. (1929), an authorized biography, done in part with Edison's collaboration, records his career to the 1920s. W.K. and L. DICKSON, *The Life and Inventions of Thomas Alva Edison* (1894), contains a detailed account of early motion picture experiments by a former laboratory assistant. THOMAS A. EDISON, *Diary and Sundry Observations*, ed. by D.D. RUNES (1948), is autobiographical, with fragments and random notes. See also G.P. LATHROP, "Talks with Edison," *Harper's Magazine*, 80: 425–435 (1890); FRANCIS JEHL, *Menlo Park Reminiscences* (1936); and THOMAS A. Education, Economics of

The economics of education has a long ancestry. Distinguished economists, from the time of, and including the founders of the science, have alluded to the importance of the growth of human knowledge through formal educational processes and to the significance that this plays in the development of the economy. Only in comparatively recent years, however, has a body of specialized knowledge worthy of note been developed.

Educational investment and return. *Economic input.* In recent times education has come to take more and more years of an individual's life span. In North America and western Europe it is not uncommon for a child to enter a nursery school or kindergarten at the age of two or three and to emerge from the educational process only after he has completed studies for a higher degree, as much as 20 years later. Frequently, during the years of his working life, he will attend refresher courses and other postdoctoral courses in order to bring his knowledge up to date. In the developing countries, where once only a small proportion of the community entered into formal education, universal primary education is a high-

priority matter. The latter half of the 20th century has truly been called the period of universal education.

Education as a percentage of GNP

In developed economies, normally between 5 and 7 percent of the Gross National Product may be spent on formal education. As will be seen later, this figure is exclusive of significant additional costs, notably the earnings forgone by students when they are undergoing education, and education that is not organized—*i.e.*, not part of the formal apparatus of schools and colleges. Some authorities, indeed, have estimated that the proportion of a developed country's Gross National Product devoted to education in the broadest sense might be as much as 10 percent. This figure compares with figures of 1 or 2 percent for the latter part of the 19th century in a significant number of advanced industrial countries and with figures of between 2 and 3 percent in many of the currently developing nations. What is significant about the percentage is that it is increasing more rapidly than many other parts of the national income. This large proportion of the national income is, in most countries, channelled through the public budget at central and local levels; in many countries the proportion of the public budget devoted to education may be as high as one-fifth. In real terms education is an industry relying more on labour than on capital, and it thus uses a high proportion of the qualified manpower available.

One major part of the study of the economics of education is the careful calculation of the amount of resources devoted to education.

Economic output. Corresponding to these inputs are the outputs, or consequences, of the educational system. Here, a major problem is posed by the evaluation of the outcomes of education. In part, these outcomes are intangible; in other respects—in terms of examination results or of the differentials in lifetime earnings that may be attributed to education—they are fully measurable. Thus, a student is supposed to forgo the earnings that he might have made between the ages of 16 and 23 in order to earn a higher salary than he otherwise would have done in his later years. Part of these additional earnings may, of course, be due to innate ability, race status, social class, parental background, or other factors besides education. Techniques have now been developed for differentiating between these elements so as to permit the allocation of an appropriate part of the outcome to education.

Individual and social benefits of education

For the individual it is possible that the major part of the economic outcome of education can be measured by extra income, but it does not follow that these are the only benefits of an economic nature that can be said to accrue because of education. If the model society were one in which all incomes were equal, it would still not follow that education had no economic benefit, because the extra skills and abilities resulting from education would still yield outcomes that were beneficial to the community. Thus there is a distinction between the benefits to the individual and those to the community as a whole. The difference may be positive or negative.

Investment and consumption. It is customary to study the consequences of education and the motivation that leads people to undergo education in terms of either investment or consumption. That is to say, people may undertake education purely for its own sake, as when a middle-aged person undertakes the study of a foreign language for recreational purposes. If he decides to devote a portion of his income to this study, the decision to do so is, in principle, no different from a decision to spend more on food or on clothing or on any other item of personal consumption. Part of the demand for education represents collective family decisions to allocate resources in this way. For some people, learning in itself is something that gives pleasure and a sense of achievement.

But in another respect, education can be viewed as an investment in the future. A society that deliberately devoted a high proportion of its resources to improving the skills and abilities of its young people would expect to see a change in its economic and social performance in the years ahead. The same, of course, is true of the family and of the individual.

In this respect, therefore, expenditure on education may be understood as a forgoing of present enjoyment in order to increase the future flow of benefits. The analogy is with the process of investment in physical capital, when current consumption is forgone in order to increase the stock of capital goods that will, in the future, yield a flow of consumption benefits. It is possible, therefore, to examine the process of educational expenditure over a period of time as a process of investment in the future of an individual or of a community. Part of this investment will be merely the replacement of an older generation and its skills by a younger generation and its skills, but another part of it will be genuinely new investment—that is, a net addition to the stock of "human capital." There are, of course, grave dangers in pressing the analogy too closely but within limits it has some merit.

Factors of production. In classical economic theory, human labour added to land produced the final product. In Neoclassical economic theory, land and labour had to be differentiated from physical capital, that is the outfit of plant, equipment, and buildings used in the productive process. It was held that the contribution of each factor of production—land, labour, or capital—could be distinguished from the contribution of others. In recent years the contribution of labour has been further divided into the contribution of labour pure and simple and the contribution of acquired human ingenuity and skill. The latter factor, termed human capital, is widely regarded as one of the most important factors in the process of production.

Human capital

This formulation has significance for a number of aspects of economic theory, notably for the theory of economic growth. It used to be thought that the accumulation of physical capital was the key to economic development. More recent studies have suggested that the contribution of human capital is at least as significant and that a considerable amount of the growth rate can be explained as the yield on human capital. It follows, therefore, that if the accumulation of human capital can be accelerated, the rate of growth will be increased.

Work on the economics of human capital has been extended to cover not only the effects of formal education but of on-the-job training and other methods of skill acquisition, as well as of scientific research and technological development. The development of the new concept of human capital has helped to explain the residual gap that was left after the contributions of land, labour, and capital had been accounted for, a gap which had hitherto remained a mystery. The policy consequences of this change in economic theory are important because they point to additional expenditures on education and on-the-job training and on research and development, rather than on physical capital. In many countries this offers a relatively more simple solution to the problem of growth than the more traditional solutions.

DEMAND AND SUPPLY OF EDUCATIONAL SERVICES

The increasing demand for educational services. Since about 1950 there has been a rapid acceleration in the rate of growth of demand for educational services at all levels, the most notable at the level of higher education in college and university but affecting primary and secondary education, adult education, and other out-of-school educational activities of all kinds. Projections of future demands suggest that while there may be, in some countries, a slowing up in the rate of increase, there is no reason to suppose that the demand will, in any reasonable period of time, reach a plateau.

Population growth. A major cause of the rise in the demand for education is the increase in the size of the child population. In the world as a whole the rise in the number of children and young people has been due first to a marked decline in infantile mortality rates and second to a tendency in a number of countries for the average size of the family to increase. Even in those parts of the world in which the average size of family has

fallen in recent years, the improvement in child health has been such that the size of the child population has nevertheless tended to increase. Most recently the size of the child population in northwestern Europe and North America has tended to stabilize or, even, to decline slightly; but rapid increases in child population continue to be observed throughout Asia, Africa, and Latin America. It is probable that the rate of increase will tend to slow down if the standard of living rises. One aspect of the rise in the standard of living is an increased spread of education. The spread of education tends to raise the cost of having children for each family—in part by diminishing the supply of child labour—and thus gives an additional incentive for family limitation. It has been suggested that this was a major cause of the fall in the size of the family noted in northwestern Europe and North America in the last quarter of the 19th century.

The lengthening of school life

Social demand for education. The rise in the child population has been a major cause of the increased demand for educational services. But added to this in the developed countries is probably the most important single cause of the increasing demand for education: the increase in the length of school life. At a certain level of national income per person, education becomes widespread, and universal, compulsory primary education is introduced. In the developing countries, since about 1950, the process of decolonialization and spread of the concept of economic and social development have led to a demand for universal primary education in all countries, and this demand is in process of realization.

Preceding this process of universal primary education, however, and superimposed upon it has been a demand for more education for children from favoured social groups. The average length of school life has increased, decade by decade, in almost every country. Those parents who have themselves received some education are often those who demand most education for their children. Thus, in countries in which there is wide educational opportunity, the spread of education has been accompanied by a rapid increase in educational provision for those groups—often the most affluent—with the highest degree of experience of education. This feedback or spiralling effect of education means that education has become a self-perpetuating process.

Economic growth and technological development. To some extent the growth in population, and to a great degree the increase in the demand for education arising from growing prosperity, reflects the process of economic growth and technological development. As technology changes and economic growth occurs, the growing complexity of the economic process requires a growing and diverse range of skills. Thus, the production necessary for a highly diverse and complex society based on an industrial and scientific complex requires a broad range of skills, not only in the labour force but among consumers in the ordinary daily process of life. All of this rests on a complex process of instruction and socialization, which implies a highly articulated, complex, and diverse educational structure.

The process of technological and economic change manifests itself first in the growing experience of the working force and of consumers. This is an almost automatic and almost unconscious process in many instances, and over a long period a substantial amount of new knowledge about technical processes is thus acquired by workers and consumers. Then there are formally arranged training procedures in industry and agriculture, of which the most common is the apprenticeship in which young people work alongside master craftsmen. There is also technical education outside industry. Underlying technical education is, of course, the general process of education.

The links between the different kinds of education and training are loose, but the development of a whole series of formal skills, at the more advanced levels, involves a widespread educational background, and the countries with a deep educational background are able to adjust quickly to the demand for new skills and techniques.

The uncertain supply of educational services. *Demographic imbalance.* Educational services respond only comparatively slowly to new demands. It is common for acute shortages of educational facilities to exist in the face of mounting demand. The causes of this imbalance are manifold. Because of different sized age groups, a large child population may be taught by people drawn from smaller age groups within the adult population. In industrialized countries particularly, and in areas in which there is significant urban development, the population may be highly mobile, causing regional imbalances. Further, rapid shifts in the demand for different specialties within education may cause a surplus of teachers in one subject and a shortage of teachers in another subject; and, finally, education is so closely connected with the religious, social, and ethnic background of the community that it is perfectly possible for acute shortages of teachers to arise in one ethnic group, while there are surpluses in another.

Since teachers form so high a proportion of the total stock of educated people, the increase in the demand for educated people for other occupations must tend to reduce the supply of potential teachers.

Competition from other occupations. There tends to be, in the more advanced countries, a persistent trend toward higher salaries in the educational system. Traditionally, because the provision of teacher training facilities has often been accompanied by fairly adequate scholarship programs and free or reduced tuition, the teaching profession has been an avenue of academic and social advancement for clever children from poorer homes. But as the general level of affluence rises in the developed countries, teaching becomes less an avenue of advancement than previously it had been.

Alienation from teaching. As a result of the development of the educational system, something like 20 or 25 percent of the population of advanced countries will be employed full time in the educational system, either as teachers or as taught. In such circumstances teaching may become less a prestige occupation than a mass-production exercise. Because of this the more ambitious may often be deterred from entering it.

Uneven development. Educational systems develop almost inevitably at an uneven rate, so that although in an ideal system there ought to be a balance between the first, second, and third levels and appropriate teachers and buildings should be supplied for each, in fact, because of fluctuations in population structure and social demand and because of varying pressures on the educational system to provide new skills, the levels of education tend to become out of balance. The supply of buildings, teachers, and other facilities may not necessarily be coordinated with each other, so that in some places there may be empty buildings with no teachers and in other places, teachers with no place to teach. The normal development of education, therefore, is not one of smooth equilibrium in demand and supply but one of fairly chronic imbalances.

ECONOMIC PLANNING OF EDUCATION

Various approaches to the determination of education expenditure. There are various approaches for determining the desirable level of expenditure on education. If an individual family buys its own education for its own children, then it might seem that the solution to the desirable level of educational expenditure is a simple one; as in the case of any consumer commodity, the choice is left to the consumer and the sum total of all consumers' expenditures equals the demand for the commodity. In the case of education considered as an investment, the family would make the same choices it would if it were buying a house or a long-term consumer durable, it would appropriately discount the future flow of returns. But for a number of reasons this is not a wholly satisfactory answer. Families might make decisions that, between them, were too high or too low from the point of view of the nation as a whole, determined by its legislature or other appropriate institution. A number of fam-

ilies might be unable to buy either enough or any education. The desirability of the market as a mechanism for allocating resources depends ultimately upon the doctrine of the sovereignty of the individual consumer and in the field of education raises the question of whether the parent should be sovereign on behalf of his children.

The application of market criteria

In any event, the greater part of educational expenditure is undertaken by public authorities or firms on behalf of their citizens or their employees. The question thus arises: What principles, if any, should determine the expenditure? The first that has been suggested is that it should be based on the analogy of the market—that is to say, each family should be asked how much education it wishes to consume, and a general idea should thus be given to the policy-making institutions. Further, it should be arranged that the expenditure should be based on consumer decisions (on behalf of children) resting on consumer preference and, especially for older students, on ordinary investment criteria. These criteria depend on a correlation between educational attainment and subsequent earnings. The sum total of earnings over a lifetime has to be added up and discounted to a present value. Since very few data are available relating any individual's earnings to his own income over a period that may be as long as 70 years, present-day educational experience is taken and correlated with present-day earnings profiles. Thus there has to be some degree of approximation in the statistics.

According to pure theory, differences in expected rates of returns should be reflected in differences in the choices that people make in careers and in courses leading to careers. There is some evidence that this is the case, though whether or not the explanation that is given for these choices is the correct one is still a matter for debate and study.

Optimum educational opportunity. A contrasting approach is based on the concept of optimum educational opportunity. Sociological evidence shows that for children with the same measured ability, differences in educational attainment are dramatic. Urban children tend to perform better than children in rural environments. There are significant ethnic differences such as those revealed between black and white children in the United States, and there are major differences between those from families in the upper professional classes and those from the lower manual working classes. According to the view that seeks the attainment of optimum educational performance for each child, if all social disadvantages were removed from those children who appear to be relatively handicapped socially, the level of attainment of the children of the nation as a whole would approximate the level of attainment of those children from the most favoured social classes. This, of course, would lead to dramatic increases in the numbers seeking full secondary and higher education. There is strong evidence that as generation succeeds generation, other social groups tend to emulate those social groups with the most favourable educational experience. They are, to some degree, chasing a receding target; even the highest and most favoured social groups tend to improve their educational performance through time, so that over the 30-year period between 1938 and 1968, the gap between the educational performance of the most favoured and the least favoured social groups in England and Wales did not diminish, despite a striking improvement in the position of the least favoured social group.

Problems involved in equalizing educational opportunity

The assumption underlying this criterion of public expenditure may be both questionable and expensive: expensive for the obvious reason that the number of children who ultimately might be expected to proceed into higher education would be large, reaching eventually well over half the age group, if present-day educational attainments by the most favoured social groups were to be attained, and questionable because it is not necessarily inevitable that the educational experience of the most favoured social group represents the optimum experience possible for all young people. In the first place, from an economic investment point of view, there may not be occupations available in sufficient numbers for all the people who, under this hypothesis, would be educated to expect to work at those jobs. In the second place, it may well be, too, that educational aims of people from different social groups may legitimately be radically different from each other.

Underlying this concept there is an important controversy in sociology and genetics about the relative importance of nature and nurture. Some sociologists have taken the view that the distribution of innate ability, if such a concept has any meaning, would be found to be the same in all social groups if social handicaps were removed. There is controversy about the proposition, and some sociologists and geneticists are willing to argue that the greater part of ability is genetically controlled. If they are right, there will not be many people in the least advantaged social group able to undertake higher education; for presumably they have inherited fewer abilities than have the upper classes, who are better prepared for higher education.

Manpower planning

Maximizing economic growth. The preceding approaches to the economic planning of education depend ultimately on individual choice. Manpower planning is an approach based on the need to promote economic growth and on the view that economic growth depends, probably in substantial part, on the availability of skilled manpower. Thus it is argued that, since from the point of view of the nation as a whole, the optimum availability of skilled manpower is what matters, the main purpose of state intervention in the educational and training system should be to achieve the optimum supply of skilled manpower. The required total of skilled manpower may be derived from a number of exercises. It is necessary, for instance, (1) to establish the educational attainments of the existing stock of skilled manpower, (2) to determine the relations between the possible growth of the national economy and the requirements for skilled manpower, (3) to estimate changing technological relations in the future, (4) to determine how the future demand for skilled manpower may be affected by future mortality and retirement rates, and so forth and so on. The resulting gross demand for skilled manpower expressed in annual rates represents the desirable output of the education system from the point of view of manpower planning. The utilization of this technique requires many approximations of what are in fact only loose relationships, both between educational attainment and subsequent occupational classification and between the level of output and the level of skill input. In addition, the long-range projection of the national income and its various sectors is both complex and uncertain.

Even if manpower projections were accurate, however, and could be neatly related to desirable educational outputs, there would still remain the problem of relating this hypothetical desirable output to individual preferences for specific education. This could be done by propaganda, by altering income and wage differentials, or by direction; all of these techniques have been used in the U.S.S.R., which has partly based its educational program on manpower requirements. In France, where manpower planning has been carried on with a considerable degree of sophistication, the educational system bears little relation to the manpower plans.

International comparisons. Another criterion used for determining desirable levels of educational expenditure is international comparison. Comparisons are based on data regarding educational expenditures in different countries representing similar stages of economic growth. The hypothesis is that countries at similar levels of economic development will tend to spend a similar amount on education and that their educational patterns will resemble each other in certain broad respects. The central problem of this method is that, although countries with roughly similar levels of national per capita income do tend to have *similar consumption* patterns (as do the countries of western Europe and North America, where mutual cultural influences are strong), these countries may very well have considerably *different economic* structures. It

follows, therefore, that insofar as the educational system is related to the economic structure, educational expenditures will differ from country to country. Furthermore, there is no necessary relation between the educational structure and the level of national income; the relation is far more closely affected by different historical circumstances than by the social and economic structures, which differ widely from country to country.

International comparisons of national income are notoriously complex and difficult to make and rest upon questionable assumptions about the comparability of welfare. In addition, despite attempts to achieve an agreed-upon international definition, educational expenditures are in fact defined in different countries in part according to their own educational practices, and therefore the range of expenditure may well reflect more the differences in accounting procedures than differences in actual outlays.

Other approaches. Some of the other approaches to determining a desirable level of educational spending represent a compromise between the different approaches so far discussed. Some educational expenditure is mainly a matter for individual decision; some is related to a policy of raising the level of those with the lowest educational attainments; some, particularly industrial training and technical education, is related to the requirements of skilled manpower; and some is based on international comparisons.

Cost–benefit analysis

There are new approaches to public finance that suggest that there may be further possibilities of calculating optimum levels of educational expenditure. Cost-benefit analysis is an instance. It is suggested that there should be a quantified relation between expected total benefits (including private and social benefits) arising from a given level of public expenditure and the cost of that public expenditure. It is generally agreed, however, that cost–benefit analysis can fully be used only within a sector, such as the educational sector, and that it is not valid as a method of comparison between sectors, such as between formal education and other kinds of welfare programs. Nevertheless, it may be some guide to relative expenditures on different levels of education.

Decisions about educational spending are usually marginal decisions. The greater part of educational expenditure in any one year represents previous commitments and inescapable changes in costs that the system has already agreed to incur—for example, wage increases or rises in the cost of building construction. The area of choice is represented by only a small margin in any one year, though over a period the margin may be considerable. It follows, therefore, that since the greater part of educational expenditure represents a pattern that is the cumulative result of many small decisions, it is difficult to change the pattern radically in any short period of time.

In addition, the greater part of educational policy making concentrates on changes in particular areas of the educational system (for example, primary education or higher education); and although changes at one level inescapably have effects ultimately at all other levels, many of these relations have not been carefully assessed and are only generally considered by policy makers.

Various approaches to determining fees and revenue collection: "consumption" and "investment" issues. Much work in the economics of education deals specifically with the issues of raising revenue for the educational system and with the manner in which expenditure on education is undertaken. The first principle of revenue collection is concerned with the issue of who should bear the cost. One of the principles of taxation is that the cost of a service should be borne by those who ultimately benefit from it. If students ultimately benefit from education, it seems logical that they and their families should pay for it. On the other hand, part of educational expenditure is undertaken not only because it is in the interests of students but also because it is in the interests of the community, either locally or nationally. Ultimately, enterprises both public and private benefit from the availability of skilled and educated manpower. Nor must it be forgotten that among those concerned with education are charitable and, especially, religious foundations: indeed, the origin of education in modern Western culture has largely been due to religious bodies.

The difficulty of trying to recoup the cost of education from students is that they themselves rarely have incomes sufficient to meet the cost of their education, though there is a sense in which they already do bear a major part of educational costs because, while they are studying, they are unable to earn significant amounts. The cost of studying is, in some degree, represented by the earnings that they have forgone by becoming students. If this item were added to the total cost of education, as it sometimes is, it would increase the cost substantially. The families of the students, particularly the more affluent families, sometimes bear the full cost of tuition. For the majority of the population, however, the costs of tuition are mainly or wholly borne by public bodies. It would, in principle, be possible to have this payment through taxation replaced by a system of family loans that would be later repaid out of the enhanced incomes that successful students expect to earn. Loans raise major administrative problems as well as questions of social value, however, because they may discourage potential students, and many people hold the view that, in principle, education should be free. It is difficult, if not impossible, to make education compulsory without at the same time making it free. Loan schemes have generally been attached to those optional parts of education (such as technical and university education) in which the decision to attend is, to a greater degree, a free choice. It has been proposed that the full cost of higher education should be recouped from fees charged to students and that loans should be paid back by a given percentage of earnings over the lifetime—that is to say, in effect, an addition to the income tax for those people who have borrowed money. Thus those groups, such as women who marry and are no longer employed or people who enter low-income professions, such as priests or social workers, would not be faced by large repayments, whereas successful businessmen and professional workers would pay back substantially more than they had borrowed. Merely to state the case is to indicate the political difficulty inherent in it.

Tuitions, taxations, and loans

In some countries with a unitary system of administration, such as France, the cost of education is a national responsibility. In others, such as the United States, there is a division between local and central government with education frequently a local responsibility, with the costs borne locally. This raises serious problems because the financial resources of state and local government are often fairly narrow and often based upon the property tax, which has an inelastic yield and does not rise as fast as national income and tends to be politically unpopular. As society becomes increasingly mobile, education itself is a major factor in geographical mobility, and people pay taxes to communities that have not borne the expense of their education. Increasingly, therefore, education has become a matter for national finance. It has already been said that business represents a major beneficiary of the educational system, and businesses make considerable contributions both to central and local taxation. In some countries, such as France and the United Kingdom, there is additional taxation for broadly educational purposes, represented in the United Kingdom by the levy imposed upon most employers to finance the cost of industrial training. It may well be that this form of taxation will become more popular, particularly as a means of financing technical education.

National and local financing

Churches in many countries have been a major source of educational finance, both through the unpaid labour of teachers in religious orders and through direct expenditures from their own charitable endowments. But as modern education has become more complex and expensive, this source of finance has diminished. Private endowments from foundations have been significant in stimulating educational innovation in particular areas of

an education system. There are also long-standing charitable endowments to individual schools and colleges that are used to subsidize the fees of students.

What form should revenue collection take? Most revenue is collected from taxes, though there are also sources of income from fees and from the yield on capital endowments; and to complicate the picture there are also grants-in-aid, loans, and subsidies among various parts of the educational system. The detailed arrangements vary from country to country and from institution to institution. Much of education is financed by property taxes, particularly at the local level; and therefore because primary education in many countries is mainly a local responsibility, primary education rests in many countries mainly on property tax. Insofar as the central government is responsible for education, the general fund of taxation (which includes most forms of taxation) is the main source of income.

THE BALANCE BETWEEN DIFFERENT FORMS OF EDUCATION

Developed countries. *The consumer society.* There is an educational pyramid ranging from education at the preprimary level up to education at the postdoctoral level. There is also a horizontal division between different types of education—notably the differences between a professionalized and a general education or between different forms of vocational education.

Formal education in its origin was in one sense vocational, since it was concerned with the production of priests and other people who could perform high clerical functions. Training in medieval society largely took the form of apprenticeship; during the 18th and 19th centuries in western Europe and North America the upper class concerned itself primarily with general preparation for entering the high culture, and the other classes concerned themselves with apprenticeship. The middle class took an increasingly vocational education in the modern sense of the word, preparing for specific occupations. During the 19th century there was a spread of elementary education to include children from the poorer classes, and a growing development of technical education in the modern sense, resting on the emerging concepts of engineering and science.

During the 20th century, as the level of national income has risen and as the consumer society has become widespread, the demand has increasingly been for a more general education for all children, such as was formerly the prerogative of the upper and middle class and superimposed upon this has been growing technical specialization enabling more people to enter high-level occupations. During the development of the modern consumer society, the notion of a cultured person has radically changed. There has thus arisen in the public mind a growing confusion about the ends of education, at the same time that the demand for it has become an almost unquenchable thirst. The result is that a large and growing portion of the population is spending a longer part of its life in education, not only during childhood and youth but also during maturity, and this experience of education is in itself radically altering the nature of modern culture. The development of powerful student groups has been noted by many observers as a prevalent feature of modern society, and the concept of man as the perpetual student is not as farfetched as it might once have seemed.

The technological society. The prevalence of a technological society—one that has led to the superabundance of commodities and services available to many in modern society—has required an increasing number of specialists of all kinds, particularly in the fields of science, engineering, and associated areas. Such age-old professions as medicine have also been radically transformed by the growth of modern scientific medicine and by the technological applications associated with it. At the same time, there have arisen entirely new professions, such as that of computer specialists, which are increasingly important in determining the nature and rate of development of modern society. Thus, there is a conflict between the growing concern about general cultural levels and the growing specialization of people's working lives. The long period of preparation that is necessary for people to enter a specialized working life is also the period in which they assimilate cultural values. The problem facing education is that as technology and knowledge change, the content of education also changes; and thus there is a contrast between the desirability of continuity implicit in a mature culture—the need to hand on traditions from one generation to another—which is one of the primary purposes of education, and the need for constant change to keep people up-to-date with rapid technological change. This striking contrast represents a major source of tension in the curriculum and in techniques of teaching. There are other subsidiary contrasts that are equally important; increasingly, education is concerned with freedom of expression by the student, but the close and intimate relation between teacher and taught often contrasts with the authoritarian and hierarchic structure of the work that is undertaken in life.

In the developed countries, education has become a major source of economic development. It is regarded as one of the primary sources of skills and of new ideas; it takes an increasingly important part of the national income; it becomes increasingly a focus of national and individual and family concern. At the same time it is a source of revolutionary discontent and of growing concern with man's condition. It follows, therefore, that the community's attitude toward education is shot through with ambivalence—on the one hand, recognition of its economic importance to the individual and to society and, on the other hand, resentment of many of its aspects of change.

Developing countries. *The aspiring society.* In developing countries many of the same tensions are seen. In all of them without exception—but especially among those that have moved from a colonial status to political independence—the demand for universal literacy has been widespread. The right to free primary education is not only written into the Universal Declaration of Human Rights but is also often embodied in the basic constitutional documents of all developing countries. The result has been an explosion in the demand for universal literacy and particularly for universal primary education. Many countries are therefore devoting substantial amounts of their public resources to the spread of universal primary education and to adult literacy programs. The adult literacy programs have generally been a failure despite repeated experiments to raise the efficacy of various methods of teaching adults to read and write. Generally speaking, attempts to achieve universal adult literacy are a failure unless there is a direct correspondence between the achievement of literacy and its subsequent use in daily life. In many cases the achievement of literacy to a standard enabling a person to pass formal tests has been followed by a lapse into illiteracy. The concept of "functional literacy," in which a person is defined as literate if he is able to fulfill a task for which literacy is required, has achieved widespread popularity.

Literacy programs

The basic attack on illiteracy must ultimately come from the spread of universal primary education. Many countries are now within striking distance of achieving this, though the primary educational system in most countries, judged by the standards of the developed countries, is often inefficient. It is marked by a high level of truancy, old-fashioned teaching methods, and widespread problems of untrained teachers and inadequate buildings. Although the manpower planners suggest that the developing countries should be putting their first efforts into training highly skilled and semiskilled specialists, there is no doubt that the demand for primary education is overwhelming and cannot be resisted.

Indeed, instead of a desire for skills for the purposes of economic development, the demand for secondary and higher education in the developing nations often takes the form of a demand for prestigious education, preparing children of the elite for elite positions. Many highly educated people in the developing nations consciously reject manual labour and technical and scientific skills; the

Elitist versus technical education

emphasis in their education is upon the humanities and especially upon law. It is indeed true that education in the humanities and law is often required to develop a politically conscious elite—one that is able to take over the administration of a country from the previous rulers. But it is also true that the major public services—such as the armed forces, the medical services, together with the whole complex of skills required to service the modern sector of the economy—depend heavily upon expatriates trained in science and technology. The replacement of these expatriates by domestically trained specialists often leads to a fall in the efficiency of services.

In any event, the process of decolonialization is often accompanied by an urgent need to produce highly skilled technical manpower. But much of this technical manpower has to be trained overseas, and the process of training overseas encourages the resulting highly skilled specialists to remain overseas or re-emigrate. Many programs for overseas training have, in fact, accelerated the degree of migration of skill from the developing to the developed countries.

A developing society may therefore almost be defined as a country that is deficient in the technical skills required not only to service it at its present level of development but also to accelerate its development. It follows, therefore, that from the point of view of the economy, one of the urgent requirements of the developing countries is the development of cadres of technically skilled people. The International Bank for Reconstruction and Development (the World Bank) has attached priority in its development plans to the provision of technical specialists. In the developing nations, despite the need to develop cultural autonomy and the priority therefore given to cultural objectives in education, there is no doubt that the highest priority must be given to the development of technical specialists who can lead the country into self-sufficiency in technical, scientific, and other specialist skills. But the emphasis on this aspect of education is dangerous if it leads to an imbalance in the education service, because the development of a high-level training program presupposes a solid basis of secondary and primary education. It is for this reason that there is a need to develop plans that coordinate the different levels of education and the different parts of education, so that the product of one level becomes the proper input of a next higher level. Further, it is necessary to see that these plans are carefully coordinated with other programs of economic and social development, so that the educational system is not out of kilter with the other programs in the development process.

BIBLIOGRAPHY. M. BLAUG, *Economics of Education: A Selected Annotated Bibliography* (1966, periodically revised), a full listing, reasonably annotated, of books and articles in the field; and (ed.), *Economics of Education*, 2 vol. (1969), a collection of readings with emphasis on solutions to the problems of education by applying the market criteria; *The Economics of Education* (1970), a textbook that complements the volumes of readings edited by M. BLAUG; M. LEITE *et al.*, *The Economics of Educational Costing*, 4 vol. (1969–70), represents a complete survey of work in the economics of education; E.A.G. ROBINSON and J.E. VAIZEY (eds.), *The Economics of Education* (1966), a collection of papers read at a conference of the International Economic Association; T.W. SCHULTZ, *Economic Value of Education* (1963), an essay representing the Neoclassical tradition of human capital theory that has come to be associated with the University of Chicago; J.E. VAIZEY, *The Economics of Education*, 2nd ed. (1962), a survey that attempts to cover most of the major topics in a way designed both for elementary and advanced students.

Education, History of

Education can be viewed as the transmission of the values and accumulated knowledge of a society. In this sense, it is equivalent to what social scientists term socialization or enculturation. A child—whether conceived among the African Bushmen, the Renaissance Florentines, or the middle classes of Manhattan—is born without culture. Education is designed to guide him in learning a culture, molding his behaviour in the ways of adulthood, and guiding him toward his eventual role in society. In the most primitive cultures, there is often little formal learning, little of what one would ordinarily call school or teachers; for, frequently, the entire environment and all activities are school, and many or all adults are teachers. As societies grow more complex, however, the quantity of knowledge to be passed on from one generation to the next becomes more than any one person can know; and hence there must evolve more selective and efficient means of cultural transmission. The outcome is formal education—the school and the specialist called the teacher.

As society becomes ever more complex and schools become ever more institutionalized, educational experience becomes less directly related to daily life, less a matter of showing and learning in the context of the workaday world, and more abstracted from practice, more a matter of distilling, telling, and learning things out of context. This concentration of learning in a formal atmosphere allows the child to learn far more of his culture than he could by merely observing and imitating. As society gradually attaches more and more importance to education, it also tries to formulate the overall objectives, content, organization, and strategies of education. Literature becomes laden with advice on rearing the younger generation. In a word, there develop philosophies of education.

This article deals with the evolution of the formal teaching of knowledge and skills in all parts of the world and with the philosophies that have inspired it. The article is divided into the following sections:

I. Education in primitive and early civilized cultures
  Prehistoric and primitive cultures
  Education in the earliest civilizations
    The Old World civilizations of Egypt, Mesopotamia, and North China
    The New World civilizations of the Maya, Aztecs, and Incas
II. Education in classical cultures

I. Education in primitive and early civilized cultures

PREHISTORIC AND PRIMITIVE CULTURES

The term education can be applied to primitive cultures only in the sense of enculturation, which is the process of cultural transmission. A primitive man, whose culture is the totality of his universe, has a relatively fixed sense of cultural continuity and timelessness. The model of life is relatively static and absolute, and it is transmitted from one generation to another with little deviation. As for prehistoric education, it can only be inferred from educational practices in surviving primitive cultures.

The purpose of primitive education is thus to mold the child in the manner in which he becomes a good member of his tribe or band. There is a marked emphasis upon training for citizenship, because primitive people are highly concerned with the growth of individuals as tribal members and the thorough comprehension of their way of life during passage from prepuberty to postpuberty.

Participatory learning in primitive societies

Obviously, because of the variety in the countless thousands of primitive cultures, it is difficult to describe any standard and uniform characteristics of prepuberty education. Nevertheless, certain things are practiced commonly within cultures. Children actually participate in the social processes of adult activities, and their participatory learning is based upon what the American anthropologist Margaret Mead has called empathy, identification, and imitation. Primitive children, before reaching puberty, learn by doing and observing basic technical practices. Their teaching personnel are not strangers but, rather, their immediate community.

In contrast to the spontaneous and rather unregulated imitations in prepuberty education, postpuberty education in some cultures is strictly standardized and regulated. The teaching personnel may consist of fully initiated men, often unknown to the initiate though they are his relatives in other clans. The initiation may begin with the initiate being abruptly separated from his familial group and sent to a secluded camp where he joins other initiates. The purpose of this separation is to deflect the initiate's deep attachment away from his family and to establish his emotional and social anchorage in the wider web of his culture.

The initiation "curriculum" does not usually include practical subjects. Instead, it consists of a whole set of cultural values, tribal religion, myths, philosophy, history, rituals, and other knowledge. Primitive people in some cultures regard the body of knowledge constituting the initiation curriculum as most essential to their tribal membership. Within this essential curriculum, religious instruction takes the most prominent place.

EDUCATION IN THE EARLIEST CIVILIZATIONS

The Old World civilizations of Egypt, Mesopotamia, and North China. The history of civilization started in the Near East about 3000 BC, whereas the North China civilization began about a millennium and a half later. The Mesopotamian and Egyptian civilizations flourished almost simultaneously during the first civilizational phase (3000–1500 BC). Although these civilizations differed, they shared monumental literary achievements. The need for the perpetuation of these highly developed civilizations made writing and formal education indispensable.

Priestly control of Egyptian and Babylonian education

Egypt. Egyptian culture and education were preserved and controlled chiefly by the priests, a powerful intellectual elite in the Egyptian theocracy who also served as the political bulwarks by preventing cultural diversity. The humanities as well as such practical subjects as science, medicine, mathematics, and geometry were in the hands of the priests, who taught in formal schools. Vocational skills relating to such fields as architecture, engineering, and sculpture were generally transmitted outside the context of formal schooling.

Egyptians developed two types of formal schools for privileged youth under the supervision of governmental officials and priests: one for scribes and the other for priest trainees. At the age of five, pupils entered the writing school and continued their studies in reading and writing until the age of 16 or 17. At the age of 13 or 14, the schoolboys were also given practical training in offices for which they were being prepared. Priesthood training began at the temple college, which boys entered at the age of 17, the length of training depending upon the requirements for various priestly offices. It is not clear whether or not the practical sciences constituted a part of the systematically organized curriculum of the temple college.

Rigid method and severe discipline were applied to achieve uniformity in cultural transmission, since deviation from the traditional pattern of thought was strictly prohibited. Drill and memorization were the typical methods employed. But, as noted, Egyptians also used a work–study method in the final phase of the training for scribes, when the trainees were required to take part in actual professional work.

Mesopotamia. As a civilization contemporary with Egyptian civilization, Mesopotamia developed education quite similar to that of its counterpart with respect to its purpose and training. Formal education was practical and aimed to train scribes and priests. It was extended from basic reading, writing, and religion to higher learning in law, medicine, and astrology. Generally, youth of the upper classes were prepared to become scribes, who ranged from copyists to librarians and teachers. The schools for priests were said to be as numerous as temples. This indicates not only the thoroughness but also the supremacy of priestly education. Very little is known about higher education, but the advancement of the priestly work sheds light upon the extensive nature of intellectual pursuit.

As in the case of Egypt, the priests in Mesopotamia dominated the intellectual and educational domain as well as the applied. The centre of intellectual activity and training was the library, which was usually housed in a temple under the supervision of influential priests. Methods of teaching and learning were memorization, oral repetition, copying of models, and individual instruction. It is believed that the exact copying of scripts was the hardest and most strenuous and served as the test of excellence in learning.

North China. In North China, the civilization of which began with the emergence of the Shang era, complex educational practices were in effect at a very early date. In fact, every important foundation of the formation of modern Chinese character was already established, to a great extent, more than 3,000 years ago.

Moral emphases of Chinese education

Chinese ancient formal education was distinguished from the education discussed earlier by the markedly secular and moral character of its educational purpose. Its paramount purpose was to develop a sense of moral sensitivity and duty toward people and the state. Even in the early civilizational stage, harmonious human relations, rituals, and music formed the curriculum.

Formal colleges and schools probably antedate the Chou dynasty of the 1st millennium BC, at least in the imperial capitals. Local states probably had less organized institutions, such as halls of study, village schools, and district schools. With regard to actual methods of education, ancient Chinese learned from bamboo books and obtained moral training and practice in rituals by word of mouth and example. Rigid rote learning, which typified later Chinese education, seems to have been rather condemned. Education was regarded as the process of individual development from within.

The New World civilizations of the Maya, Aztecs, and Incas. The outstanding cultural achievements of the pre-Columbian civilizations are often compared with those of Old World civilizations. The ancient Mayan calendar, which surpassed Europe's Julian calendar in accuracy, was, for example, a great accomplishment demonstrating the extraordinary degree of knowledge of astronomy and mathematics possessed by Maya. Equally impressive are the sophistication of the Incas' calendar and their highway construction, the development of the Maya's complex writing system, and the magnificent temples of the Aztecs. It is unfortunate that archaeological findings and written documents hardly shed sufficient light upon education among the Maya, Aztecs, and Incas. But from available documents it is evident that these pre-Columbian civilizations developed formal education for training the nobility and priests. The major purposes of education were cultural conservation, vocational training, moral and character training, and control of cultural deviation.

The Maya. Being a highly religious culture, the Maya regarded the priesthood as one of the most influential factors in the development of their society. The priest enjoyed high prestige by virtue of his extensive knowledge, literate skills, and religious and moral leadership, and high priests served as major advisers of the rulers and the nobility. To obtain a priesthood, which was usually inherited from his father or another close relative, the trainee had to receive rigorous education in the school, where priests taught history, writing, methods of divining, medicine, and the calendar system.

Priestly control of Maya and Aztec education

Character training was one of the salient features of Mayan education. The inculcation of self-restraint, cooperative work, and moderation was highly emphasized in various stages of socialization as well as on various occasions of religious festivals. In order to develop self-discipline, the future priest endured a long period of continence and abstinence, and, to develop a sense of loyalty to community, he engaged in group labour.

The Aztecs. Among the Aztecs, cultural preservation relied heavily upon oral transmission and rote memorization of important events, calendrical information, and religious knowledge. Priests and noble elders, who were called conservators, were in charge of education. Since one of the important responsibilities of the conservator was to censor new poems and songs, he took the greatest care in teaching poetry, particularly divine songs.

At the *calmecac*, the school for native learning where apprenticeship started at the age of ten, the history of Mexico and the content of the historical codices were systematically taught. The *calmecac* played the most vital role in ensuring oral transmission of history through oratory, poetry, and music, which were employed to make accurate memorization of events easier and to galvanize remembrance. Visual aids, such as simple graphic representations, were used to guide recitation phases, to sustain interest, and to increase comprehension of facts and dates.

The Incas. The Incas did not possess a written or recorded language as far as is known. Like the Aztecs, they also depended largely on oral transmission as a means of maintaining the preservation of their culture. Inca education was divided into two distinct categories: vocational education for common Incas and highly formalized training for the nobility. As the Inca Empire was a theocratic, imperial government based upon agrarian collectivism, the rulers were concerned about the vocational training of men and women in collective agriculture. Personal freedom, life, and work were subservient to the community. At birth an individual's place in the society was strictly ordained, and at five years of age every child was taken over by the government, and his socialization and vocational training were supervised by government surrogates.

Education for the nobility was clearly defined in terms of the curricula and rituals. The Inca nobility consisted of three classes: the imperial *ayllus*; the *curacas*, who

were the tribal chiefs; and distinguished common Indians. The sons of the *ayllus* and the *curacas* received education for four years in learning centres called the *cuzco* schools. In the first year the pupils learned the Quechua language, the language of the nobility. The second year was devoted to the study of religion, and the third year to learning about the quipus, a complex system of knotted coloured strings or cords used for sending messages and recording historical events. In the fourth year major attention was given to the study of history, with additional instruction in sciences, geometry, geography, and astronomy. The instructors were highly respected encyclopaedic scholars known as *amautas*, to whom even the supreme Inca listened. After the completion of this education, the pupils were required to pass a series of rigorous examinations in order to attain full status in the life of the Inca nobility. (N.S.)

II. Education in classical cultures

ANCIENT INDIA

The Hindu tradition. India is the site of one of the most ancient civilizations in the world. About the 2nd millennium BC, the Aryans entered the land and came into conflict with the *dāsas*, or the non-Aryan tribes. They defeated them, spread far and wide in the country, established large-scale settlements, and founded powerful kingdoms. In the course of time, a section of the intellectuals, the Brahmins, became priests and men of learning; another group, nobles and soldiers, became Kṣatriyas; the agricultural and trading class was called Vaiśyas; and finally the *dāsas* were absorbed as Śūdras, or domestic servants. Such was the origin of the division of the Hindus into four *varṇas*, or "classes." By about 500 BC, the classes became hardened into castes. The Brahmins occupied the most venerable position in society.

The Vedic tradition in Hindu education

Religion was the mainspring of all activities in ancient India. It was of an all-absorbing interest and embraced not only prayer and worship but everything—philosophy, morality, law, and government. Religion saturated educational ideals, too, and the study of Vedic literature was indispensable to higher castes. The stages of instruction were very well defined—namely, up to the age of seven at home, from eight to 16 at school, and then at a university. During the first period, the child received primary education at home. Formal schooling, however, began with a ritual known as the *upanayana*, or thread ceremony, which was more or less compulsory for the three higher castes. The Brahmin children had this ceremony at the age of eight, the Kṣatriya children at the age of 11, and the Vaiśya children at the age of 12 years. The *upanayana* ceremony marked the beginning of secondary education. The boy would leave his father's house and enter his preceptor's *āśrāma*, or home, situated amid sylvan surroundings. The *ācārya* would treat him as his own son, give him free education, and not charge anything for his boarding and lodging. The pupil had to tend the sacrificial fires, do the household work of his preceptor, and look after his cattle.

The study at this stage consisted of the recitation of the Vedic *mantras*, or "hymns," and the auxiliary sciences—phonetics, the rules for the performance of the sacrifices, grammar, astronomy, prosody, and etymology. The character of education, however, differed according to the needs of the caste. For a boy of the priestly class, there was a definite syllabus of studies. The *trayī-vidyā*, or the knowledge of the three Vedas, the most ancient of Hindu scriptures, was obligatory for him. During the whole course at school, as at college, the student had to observe *brahmacarya*—that is, wearing a simple dress, living on plain food, using a hard bed, and leading a celibate life.

The period of studentship normally extended to 12 years. For those who wanted to continue their studies, there was no age limit. After finishing their education at an *āśrama*, or forest school, they would join a higher centre of learning or a university presided over by a *kulapati* (a founder of a school of thought). Advanced students would also improve their knowledge by taking part in philosophical discussions at a *parisad*, or "academy." Occasionally, a great king would summon a national gathering or congress to which the representative thinkers of the various schools of thought in the country were invited. Education was not denied to women, but normally girls were instructed at home.

The method of instruction differed according to the nature of the subject. The first duty of the student was to learn by heart the particular Veda of his school. Every word and line of the text had to be learned from the lips of the teachers, and so correct pronunciation was stressed. In the study of such literary subjects as law, logic, rituals, and prosody, comprehension played a very important role. A third method was the use of parables, which were employed in the personal spiritual teaching relating to the *Upaniṣads*, or conclusion of the Vedas. In higher learning, such as in the teaching of *śāstras* ("sciences"), the most popular and useful method was catechism—the pupil asking questions and the teacher discoursing at length on the topics referred to him. Memorization, however, played the greatest role. It could not be avoided even when a topic was thoroughly grasped.

The introduction of Buddhist influences. By about the end of the 6th century BC, the Vedic rituals and sacrifices had gradually developed into a highly elaborate cult that profited the priests but antagonized an increasing section of the people. Education became generally confined to the Brahmins, and the *upanayana* was being gradually discarded by the non-Brahmins. The formalism and exclusiveness of the Brahmanic system was largely responsible for the birth of two new religious orders, Buddhism and Jainism. Neither of them recognized the authority of the Vedas, and both challenged the exclusive claims of the Brahmins to priesthood. Their founders, Buddha and Mahāvīra, taught through the common language of the people and gave education to all, irrespective of caste, creed, or sex. Buddhism also introduced the monastic system of education. Monasteries attached to Buddhist temples served the double purpose of imparting education and of training persons for priesthood. A monastery, however, educated only those who were its members, living under a common roof. It did not admit day scholars. Thus, it was not possible for the Buddhist order to cater to the needs of the entire population.

Buddhism and Jainism in Indian education

Meanwhile, significant developments were taking place in the political field that had repercussions on education. The establishment of the imperialistic Nanda dynasty in *c.* 413 BC and then of the even stronger Mauryas some 40 years later shook the very foundations of the Vedic structure of life, culture, and polity. The Brahmins in large numbers gave up their ancient occupation of teaching in their forest retreats and took to all sorts of occupations; the Kṣatriyas also abandoned their ancient calling as warriors; and the Śūdras in their turn rose from their servile occupations. These forces produced revolutionary changes in education. Schools were established in growing towns, and even day scholars, including married and regular householders, were admitted. Studies were chosen freely and not according to caste, and teachers admitted students of all castes. Taxila had already acquired an international reputation in the 6th century BC as a centre of advanced studies and now improved upon it. It did not possess any college or university in the modern sense of the term, but it was a great centre of learning with a number of famous teachers, each having a school of his own; it included special institutions of law, medicine, and military science.

In the 3rd century BC Buddhism received a great impetus under India's most celebrated ruler, Aśoka. After his death, Buddhism evoked resistance, and a counter-reformation in Hinduism began in the country. About the 1st century AD, there was also a widespread lay movement among both Buddhists and Hindus. As a result of these events, Buddhist monasteries began to undertake secular as well as religious education, and there began a large growth of popular elementary education along with secondary and higher learning.

Classical India. The 500 years from the 4th century AD to the close of the 8th, under the Guptas and Harṣa

The university at Nālandā

and their successors, is a remarkable period in Indian history. It was the age of the universities of Nālandā and Valabhī and of the rise of Indian sciences, mathematics, and astronomy. The university at Nālandā owed its foundation to six generations of the Gupta kings. It housed a population of several thousand teachers and students, who were maintained out of the revenues from more than 100 villages. Because of its fame, Nālandā attracted students from abroad, but the admission test was so strict that only two or three out of ten attained admission. More than 1,500 teachers discussed over 100 different dissertations every day. These covered the Vedas, logic, grammar, philosophy (*sāṃkhya, nyāya,* etc.), astronomy, and medicine. Other great centres of Buddhist learning of the post-Gupta era were Vikramaśīla, Odantapurī, and Jagaddala. The achievements in science were no less significant. Āryabhaṭa in the late 5th century was the greatest mathematician of his age. He introduced the concepts of zero and decimals. Varāhamihira of the Gupta age was a profound scholar of all the sciences and arts, from botany to astronomy and from military science to civil engineering. There was also considerable development of the medical sciences. According to contemporaries, more than eight branches of medical science, including surgery and pediatrics, were practiced by the physicians.

These were the main developments in education prior to the Muslim invasions, beginning in the 10th century. Nearly every village had its schoolmaster, who was supported from local contributions. The Hindu schools of learning, known as *pathasala*s in western India and *tol*s in Bengal, were conducted by Brahmin *ācāryas* at their residence. Each imparted instruction in an advanced branch of learning and had a student enrollment of not more than 30. Larger or smaller establishments, specially endowed by *rajas* and other donors for the promotion of learning, also grew in number. The usual centres of learning were either some king's capital, such as Kanauj, Dhār, Mithilā, or Ujjayinī, or a holy place, such as Vārānasi, Ayodhyā, Kāñcī, or Nasik. In addition to Buddhist *vihāras* ("monasteries"), there sprang up Hindu *maṭhas* (monks' residences) and temple colleges in different parts of the country. There were also *agrahāra* villages, which were given in charity to the colonies of learned Brahmins in order to enable them to discharge their scriptural duties including teaching. Girls were usually educated at home, and vocational education was imparted through a system of apprenticeship.

Indian influences on Asia. An account of Indian education during the ancient period would be incomplete without a discussion of the influence of Indian culture on western and Southeast Asia. It was achieved partly through cultural or trade relations and partly through political influence. Khotān in Central Asia had a famous Buddhist *vihāra* as early as in the 1st century AD. A number of Indian scholars lived there, and many Chinese pilgrims, instead of coming to India, stayed there. Indian pandits (scholars) were also invited to China and Tibet, and many Chinese and Tibetan monks studied in Buddhist *vihāra*s in India.

Indianization of Southeast Asia

The process of Indianization was at its highest in Southeast Asia. Beginning in the 2nd century AD, Hindu rulers reigned in Indochina and in the numerous islands of the East Indian archipelago, from Sumatra to New Guinea, for a period of 1,500 years. These regions were peopled by primitive races, who adopted the civilization of their masters. A greater India was thus established by a general fusion of cultures. Some of the inscriptions of these countries, written in flawless Sanskrit, show the influence of Indian culture. There are references to Indian philosophical ideas, legends, and myths and to Indian astronomical systems and measurements. Hinduism continued to wield its influence on these lands so long as the Hindus ruled in India. This influence ceased by the 15th century AD. (S.N.M.)

ANCIENT CHINA

According to the prehistory records, education in China was early recognized as an important function of the state. Good government consisted of teaching the people the proper conduct so that they would know how to live harmoniously and happily. A good ruler was one who set a good example for the people to follow, and officers of the state were specifically charged with the duty of attending to the instruction of the people.

Ancient Chinese education served the needs of a simple agricultural society with the family as the basic social organization. Paper and the writing brush had not been invented, and the "bamboo books" then recorded to be in existence were of limited use at best. Oral instruction and teaching by example were the chief methods of education.

The molding of character was a primary aim of education. This was done by imparting knowledge of the laws of the land and teaching the acceptable modes of behaviour. Even more important than knowledge was actual participation in the rituals, the prescribed customs, and the music and dance that were actually a part of the rituals. Through such participation correct behaviour was taught and learned.

Ethical teachings stressed the importance of human relations and the family as the foundation of society. Filial piety, especially emphasizing respect for the elderly, was considered to be the most important virtue. Special institutions were designated for the care of the elderly and the performance of rituals reflecting the respect for age.

Education and public service

Two characteristics of Chinese education were already evident in the early period: the emphasis on ethical and moral values and the close link between education and public service. It was the responsibility of government to provide instruction so that the talented would be able to enter government service and thus perpetuate the moral and ethical foundation of society. The selection of educated persons for government service foreshadowed the elaborate examination system of later periods. The basis of selection was usually the recommendation of local officials. It was recorded, however, that a model emperor of the early legendary period personally examined his officers every third year and decided upon their promotion or dismissal after three examinations.

The Chou period. *Early Chou (1122–721 BC).* This was the feudal age, when the feudal states were ruled by lords who paid homage to the king of Chou and recognized him as the "Son of Heaven." The relations between the feudal lords and the king were governed by prescribed rules and rituals assuring the stability of government and society.

Schools were established for the sons of the nobility, but the education of the common people was not neglected. The former were located in the capital city of Chou and the capital cities of the feudal states; within the feudal states there were schools in villages and hamlets that were attended, according to written records, by men and women after their work in the fields. There were elementary and advanced schools for both the ruling classes and the common people. Separate studies were prescribed for girls; they were concerned chiefly with homemaking and the feminine virtues that assured the stability of the family system.

The content of education for the ruling classes consisted of the "six arts"—rituals, music, archery, charioteering, writing, and mathematics. They constituted what may be called the "liberal education" of the period. Mere memory work was condemned. As Confucius said of the ancient spirit of education, "learning without thought is labour lost."

Later Chou (771–221 BC). This was a period of social change brought about by the disintegration of the feudal order, the breakdown of traditional loyalties, the rise of cities and urban civilization, the growth of commerce, and the appearance of scholar-philosophers offering a variety of solutions for the problems of the day. The decline of the authority and prestige of the king was proportionate to the increasing power and arrogance of the feudal states, until the latter practically ignored the royal position and engaged in strife and warfare leading to the collapse of the Chou dynasty.

The instability and the perplexing problems of the times challenged scholars to propose various remedies. The absence of central control facilitated independent and creative thinking. Thus appeared one of the most creative periods in China's intellectual history, when a Hundred Schools of thought vied with one another to expound their views and their proposals for attaining a happy social and political order. Some urged a return to the teachings of the sages of old, while others sought better conditions by radical change. Among the major "schools" of this age were Taoism, Confucianism, Moism, and Legalism (see CHINESE RELIGION; CHINESE PHILOSOPHY). No one school was in the ascendancy. Orthodoxy was yet unknown.

The Hundred Schools of thought

Each major school had its followers and disciples, among whom there was a vigorous program of instruction and intellectual discussion. The breakdown of the feudal system meant the neglect of education by the government, and this period saw the decline of state schools and the growth of private ones. Most active in the establishment of private schools were Confucius and his disciples, but the Taoists, the Moists, and the Legalists also maintained their own teaching institutions.

Another form of educational activity was the practice of the contending feudal states of luring to their domain a large number of scholars, partly to serve as a source of ideas for enhancing the prosperity of the state and partly to gain an aura of intellectual respectability in a land where the respect for scholars had already become an established tradition. The princes and dukes not only provided the scholars with material sustenance and comfort but strove to accord them due respect and honour. The age of political instability and social disintegration therefore turned out to be an age of free and creative intellectual activity. Conscious of their importance and responsibility, the scholars developed a tradition of self-respect and fearless criticism. It was this tradition that Confucius had in mind when he said that the educated person was not a utensil to be used, and it was this spirit that the Confucian philosopher Mencius described when he said that the great man was a man of principles whom riches and position could not corrupt, whom poverty and lowliness could not swerve, whom power and force could not bend.

The teachings of the Hundred Schools and the records of the feudal states meant a marked increase in literature and, consequently, in the materials for instruction. The period of the Eastern Chou (so named from the location of its capital) is the classical age of China, which bequeathed to subsequent periods an intellectual and educational legacy of inestimable value. Its scholars propounded theories of government and of social and individual life that were as influential in China and East Asia as the Greek philosophers of almost contemporary age were in the Western world. The classics that were to become the main content of education until modern times were written or compiled during this period.

The Ch'in–Han period. *Ch'in autocracy (221–206 BC).* Of the various schools of thought that arose in China's classical age, Legalism was the first to be accorded official favour. The policies of the Ch'in dynasty were based on Legalist principles stressing a strong state with a centralized administration. Many of its policies were so different from past practices that they incurred the criticism of scholars, especially those who upheld the examples of the ancient sages. To stop the criticism, the ruler, who called himself the first emperor, acting upon the advice of a Legalist minister, decreed a clean break with the past and a banning of books on history and of classics glorifying past rulers. Numerous books were collected and burned, and hundreds of scholars were put to death for failure to surrender the banned books.

Legalism and banning of books

Though condemned for the burning of books and the persecution of scholars, the Ch'in dynasty laid the foundation for a unified empire and made it possible for the next dynasty to consolidate its power and position at home and abroad. In education, the unification efforts included a reform and simplification of the written script and the adoption of a standardized script intelligible throughout the country. First steps were taken toward uniform textbooks for the primary schools. The invention of the writing brush made of hair, as well as the making of ink, led to the replacement of the clumsy stylus and bamboo slips with writing on silk.

Scholarship under the Han (206 BC–AD 220). The Ch'in dynasty did not last long. Capitalizing on the popular discontent with the short-lived regime, the Han dynasty reversed many of the policies of its predecessor. The most important change was a shift from Legalism to Confucianism. The banned books were now highly regarded, and the classics became the core of education. An assiduous effort was made to recover the prohibited books and to discover books and manuscripts that scholars had concealed in secret places. Much painstaking work was done in copying and editing, and the textual and interpretative studies of the Han scholars accorded a new importance to the study of the classics. The making of paper further stimulated this revival of learning. Critical examination of old texts resulted in the practice of higher criticism long before it developed in the West.

Shift to Confucianism

There were historians, philosophers, poets, artists, and other scholars of renown in the Han dynasty. Deserving special mention is Ssu-ma Ch'ien, author of a monumental history of China from the earliest times to the 1st century BC, whose high level of scholarship earned him the title "Chinese Father of History." An illustrious woman of letters, Pan Chao, was named poet laureate. A bibliographer collected and edited ancient texts and designated them as classics. The first dictionary of the Chinese language was written. Books multiplied; historical and literary works became models of critical scholarship. Since the discovery and interpretation of ancient texts had largely been the work of Confucian scholars, Chinese scholarship from now on became increasingly identified with Confucianism. Most of the Han rulers gave official sanction to Confucianism as a basis of conducting government and state affairs. There was, however, no action to exclude other schools of thought.

There were a variety of schools on the national and local levels. The trend of increasing activity in private education continued, and much of the study of the classics and enriched literature of the day was done in private schools. Of considerable influence in the country and abroad was a national university with an enrollment that soared to 30,000. The classics now became the core of the curriculum, but music, rituals, and archery were still included. The tradition of all-round education in the six arts had not vanished.

Recruiting educated persons for state service had always been important. Now competitive examinations were coming into use, and the combination of examinations with proper recommendation was considered a good way to insure the selection of the worthy for government service.

Introduction of Buddhism. The Han dynasty was a period of territorial expansion and growth in trade and cultural relations. Buddhism was introduced at this time.

Early information about Buddhism was probably brought into China by traders, envoys, and monks. By the 1st century AD, an emperor became personally interested and sent a mission to India to seek more knowledge and bring back Buddhist literature. Thereafter, Indian missionaries as well as Chinese scholars translated Buddhist scriptures and other writings into Chinese, and the way was opened for the spread of the new faith among the people.

Buddhist and Indian influences in China

Indian missionaries not only preached a new faith but also brought in new cultural influences. Indian mathematics and astronomical ideas enriched Chinese knowledge in these fields. Chinese medicine also benefitted. Architectural and art forms reflected Buddhist and Indian influence. Hindu chants became a part of Chinese music. Translation of new ideas and new terms also resulted in new vocabulary and writing forms.

For a couple of centuries after its introduction, however, Buddhism showed no signs of popular appeal. Han scholarship was engrossed in the study of ancient classics

and was dominated by Confucian scholars who had scant interest in Buddhist teachings that were unconcerned with the practical issues of moral and political life. Moreover, the Buddhist view of evil and the Buddhist espousal of celibacy and escape from earthly existence were alien to China's traditions. The Taoist scholars, finding in Buddhism much that seemed not too remote from their own spiritual message, were much more inclined to study the new philosophy, and some of them aided in the translation of Buddhist texts. The Taoists, however, were not in the centre of the Han stage.

The fall of the Han dynasty was followed by a few hundred years of division, strife, and foreign invasions. China was not united again until the end of the 6th century. It was during this period of confusion and disunity that Buddhism gained a foothold in China. Political chaos and foreign invasions produced a widespread feeling of uncertainty and insecurity, and Buddhist asceticism seemed to fit the mood of the times.

The literary efforts of Chinese monks produced a Chinese Buddhist literature, and this marked the beginning of a process that transformed an alien importation into a Chinese religion and system of thought. The non-Chinese characteristics of Buddhism were soon to be submerged under the growth of distinctly Chinese sects. There was much study and teaching of Buddhism by scholars and monks and religious converts, but most of this educational activity took place in monasteries and temples rather than in schools which were attended by the people. The content of the examinations, however, generally reflected the growth of Buddhist thought and Buddhist literature. (T.H.C.)

ANCIENT HEBREWS

Like all preindustrial societies, ancient Israel first experienced a type of education that was essentially familial; that is to say, the mother taught the very young and the girls, while the father assumed the responsibility of providing moral, religious, and handcraft instruction for the growing sons. This characteristic remained in Jewish education, for the relation of teacher to pupil was always expressed in terms of parenthood and filiation. Education, furthermore, was rigid and exacting; the Hebrew word *musar* signifies at the same time education and corporal punishment.

The education of scribes

Once they were established in Palestine—at the crossroads of the great literate civilizations of the Near East, in the beginning of the 1st millennium BC—the Jewish people learned to develop a different type of education—one that involved training a specialized, professional class of scribes in a then rather esoteric art called writing, borrowed from the Phoenicians. Writing was at first practical: the scribe was the man who wrote letters and drew up contracts, who kept accounts, maintained records, prepared orders. Because he could receive written orders, he eventually became entrusted with their execution; hence the importance of scribes in the royal administration, well-attested since the times of David and Solomon. The training given these scribes was not merely technical or utilitarian; it included training of character and instilling the high ideal of wisdom, as would befit the servants of the king.

The evolution of Hebrew schools

Writing found another avenue of application in Israel—in religion. And the scribe again was the agent of education. He was the man who copied the sacred Law faithfully and established the canonical text. He was the one who read the Law to himself and to the people, taught it, and translated it when Hebrew ceased to be the vernacular or "living language" (into Greek in Alexandria, into Aramaic in Palestine); he explained it, commented on it, and studied its application in particular cases. After the downfall of Israel in 722–721 BC and Judah in 586 BC and their subjection to foreign rule, Jewish education became characterized more and more by this religious orientation. The synagogue in which the community assembled became not merely a house of prayer but also a school, with a "house of the book" (*bet sefer*) and a "house of instruction" (*bet ha-midrash*) corresponding roughly to elementary and secondary or advanced levels of education.

The role of writing in this Oriental world should not be exaggerated, of course; oral instruction still held first place by far. Although a pupil might learn to read aloud, or rather to intone his text, his main effort was to learn by heart fragment after fragment of the sacred Law. Alongside this written Law, however, there developed interpretations or exegeses of it, which at first were merely oral but which progressively were reduced to writing—first in the form of memoranda or *aides-mémoire* inscribed on tablets or notebooks, then in actual books. The diffusion of this religious literature called for an expansion of programs of instruction, evolving into diverse stages: elementary, intermediate, and advanced, the latter in several centres in Palestine, later in Babylonia. This religiously based education was to become one of the most important factors enabling Judaism to survive the national catastrophes of AD 70 and 135, involving the capture and subsequent destruction of Jerusalem. In their dispersion, the Jews clung to Hebrew, their only language for worship, for the study of the Law, for tradition, and consequently for instruction. From this evolved the respect with which the teacher was and is surrounded in Jewish communities. Teaching is ennobled by its association with the sacred text; as the Talmud records, "One must have as much respect for the teacher as for God."

ANCIENT GREEKS

Origins. The history of the Hellenic language and therewith of the Hellenic people goes back to the Mycenaean civilization of about 1400–1100 BC, which itself was the heir of the pre-Hellenic civilization of Minoan Crete. Because the Mycenaean civilization consisted of little monarchies of an Oriental type, with an administration operated by a bureaucracy, one may assume an educational system designed for the training of scribes, analogous to those known from the ancient civilizations of the Near East. But continuity did not exist between this education and that which was to develop after an interruption of obscure centuries known as the Greek dark ages (11th to 9th centuries BC). When the Greek world reappeared in history, it was an entirely different society, one headed by a military aristocracy as idealized in Homer's *Iliad* and *Odyssey*. During this period, sons of the nobility received their education at the court of the prince in the setting of a guild companionship of warriors: the young nobleman was educated through the counsel and example of an older man to whom he had been entrusted or had entrusted himself, a senior admired and loved. It was in this atmosphere of virile camaraderie that there developed the characteristic ideal of Greek love that was enduringly to mark Hellenic civilization and to deeply influence its conception of education itself—for example, in the relation of master to pupil. Yet these warriors of the archaic period were not coarse barbarians but already in some sense knights. Their education was not confined to an apprenticeship in arms and horsemanship but gave much attention to sports (which survived, little changed, into classical Greece), to the dance, instrumental music, and oral poetry, and, finally, to the taste for words, the germ of eloquence. There was already a certain refinement of manners, a delicacy that showed itself particularly in the respect accorded to women. More characteristic and perhaps more important was the ethical ideal that characterized this knightly education, an ethic based on the notion of valour (*aretē*). The cult of military or sporting prowess by which one could assert oneself, could outclass others, was a source of prestige and glory. It was an ethic of honour, which made virtues of pride and of jealousy as the inspiration of great deeds and which accepted it as natural that one would be the object of jealousy or of hatred. The cult of Homer, which until the end of antiquity (and in Byzantium even later) was to constitute the basis of Greek culture and therewith of Greek education, would maintain from generation to generation this "agonistic" ideal: the cult of the hero, of

Education in the Greek archaic ages

the champion, of high performance, which found an outlet outside the sphere of battles in games or contests (*agōnes*), particularly in the realm of sports, the most celebrated being the Olympic Games, dating traditionally from 776 BC.

Profound changes were introduced into Greek education as a result of the political transformations involved in the maturing of the city-state. There then developed a collective ideal of devotion to the community: the city (*polis*) was everything to its citizens; the city made its citizens what they were—mankind. This subordination of the individual exploit to collective discipline was reinforced by the strategic military revolution that saw the triumph of heavy infantry, the hoplites, foot soldiers heavily armed and in tight formation.

Sparta. It is in Sparta, the most flourishing city of the 8th and 7th centuries BC, that one sees to best advantage the richness and complexity of this archaic culture. Education was carried to a high level of artistic refinement, as evidenced by the events organized within the framework of the city's religious festivals. The young men and women took part in processions, dances, and competitions in instrumental music and song. Physical education had a like part, equally for both sexes, given status by national or international contests (the Spartans regularly took more than half of the first places at the Olympic games); and military and civic education had a large place, as was proper for the citizen-soldier to be ready to fight and if necessary to die for his country.

Spartan education for a warrior caste

This last aspect became not merely dominant but exclusive from the time (about 550 BC) when a conservative reaction triumphed at Sparta, bringing to power a militarist and aristocratic regime. Arts and sports gave way completely to an education appropriate to men of a warrior caste. The education of girls was subordinated to their future function as mothers; a strict eugenic regime pitilessly eliminated sickly and deformed children. Up to the age of seven, children were brought up by the women, already in an atmosphere of severity and harshness. Education, properly speaking, *agōgē*, lasted from ages seven to 20 and was entirely in the hands of the state.

The male youth of Sparta were enrolled into formations corresponding to successive age classes, divided into smaller units as in modern Scouting, under the authority of comrades of their own age or of young officers. It was a collective education, which progressively removed them from family life and subjected them to garrison life. Everything was organized with a view to preparation for military service: ill-clothed, bedded on the bare ground, the child was poorly fed, told to steal to supplement his rations, and subjected to rigorous discipline. His virility and combativeness were developed by hardening him to blows—thus the role of ritual brawls between groups of boys and of the institution of the *krypteia*, a nocturnal expedition designed both to terrify the lower classes of slaves (helots) and to train the future fighter in ambushes and the ruses of warfare. He was also, of course, directly apprenticed to the military craft, using arms and manoeuvring in close formation. This puritanical education, proceeding in a climate of austerity, had as its sole norm the interests of the state, erected into a supreme category; the Spartan was trained under a strict discipline to obey blindly the orders of his superiors. Curiously, the child was at the same time trained to dissimulation, to lying, to theft—all virtues when directed toward the foreigner, toward whom distrust and Machiavellianism were encouraged.

This implacably logical education enabled Sparta to remain for long the most powerful city, militarily and diplomatically, of the entire Greek world and to triumph over its rival Athens after the long struggle of the Peloponnesian War (431–404 BC); but it did not prevent Sparta's decadence. Not that Sparta ever relaxed its tension: on the contrary, in the course of centuries, the rigour and ferocity were accentuated even as such behaviour became more and more anachronistic and without real use. Rites of initiation were transformed into barbarous tests of endurance, the boys undergoing flagellation and competing in enduring it, sometimes to the very death, under the eyes of tourists attracted by the sadistic spectacle. This occurred in times of complete peace when, under the Roman Empire, Sparta was nothing but a little provincial city with neither independence nor army.

Athens. Beginning at a date difficult to fix precisely (at the end of the 7th or during the 6th century), Athens, in contrast to Sparta, became the first to renounce education oriented toward the future duties of the soldier. The Athenian citizen, of course, was always obligated, when necessary and capable, to fight for the fatherland, but the civil aspect of life and culture was predominant: armed combat was only a sport. The evolution of Athenian education reflected that of the city itself, which was oriented toward increasing democratization—though it should be noted that the slave and the resident alien always remained excluded from the body politic. The Athenian democracy, even in its most complete form, attained in the 4th century BC, was to remain always the way of life of a minority—about one-tenth, it is conjectured, of the total population. Athenian culture continued to be oriented toward the noble life, that of the Homeric knight, minus the warrior aspect, and this orientation determined the practice of elegant sports. Some of these, such as horsemanship and hunting, always remained more or less the privilege of an aristocratic and wealthy elite; the various branches of athletics, however, originally reserved for the sons of the great families, became more and more widely practiced.

Athenian education for a democratic minority

Education of youth. Under such conditions, there arose the need of a collective education—and of the school. It was at first a school of gymnastics, or *palaistra*, under the authority of the boys' coach, or *paidotribēs;* it was for the youngsters what the gymnasium was for the adults. (From 632 BC the Olympic Games added contests for children.) But education also became musical; a second category of specialized teacher appeared, that of the teacher of music, including dance, choral singing, instrumental music on the lyre or the *aulos* (a kind of oboe), lyric music, and finally poetry. By way of this latter poetry, a literary aspect was introduced into education. Certainly the poetry, sung or recited, was at first entrusted primarily to memory, but recourse to reading and writing gradually increased, and there appeared a third type of school—third in time, as in the importance credited to it—in which the child learned to read, write, and count.

The moral aspect of education was not neglected. The Athenian ideal was that of the *kalos kathagos*, the "wise and good" man. The teachers were as much preoccupied with overseeing the child's good conduct and the formation of his character as with directing his progress in the various subjects taught him. Poetry served to transmit all the traditional wisdom, which combined two currents: the ethic of the citizen expressed in the moralizing elegies of the 6th-century lawmaker Solon and the old Homeric ideal of the value of competition and the exploit. But this ideal equilibrium between the education of the body and that of the mind was interrupted before long as a result on the one hand of the development of professional sports and the exigencies of its specialization and on the other by the development of the strictly intellectual disciplines, which had made great progress since the time of the first philosophers of the 5th century BC.

Higher education. With the great Sophists, contemporaries and adversaries of Socrates (*c.* 470–399 BC), one sees the emergence of a system of higher education open to all—to all, at any rate, who had the leisure and necessary money. Until then, the higher forms of culture had retained an esoteric character, being transmitted by the master to a few chosen disciples, as in the first schools of medicine at Cnidus and at Cos, or within the framework of a religious confraternity involving initiate status. The Sophists proposed to meet a new need that was generally felt in Greek society, particularly in the most active cities such as Athens, where political life had been intensively developed. Henceforth the management of public affairs became the supreme occupation engaging

Sophistic education

the ambition of Greek man; it was no longer in sports and elegant leisure activities that his valour, his desire to assert himself and to triumph, would find expression but rather in political action.

The Sophists, professional educators, introduced a form of higher education whose success attested to its social utility and practical efficacy—a commercial success, promoted by an advertising setup: they inaugurated the literary genre of the public lecture, which was to experience a long popularity. It was a teaching process oriented in an entirely realistic direction, the education of statesmen. The Sophists pretended neither to transmit nor to seek for the truth concerning man or existence; they offered simply an art of success in political life, which meant, above all, being able on every occasion to make one's point of view prevail. Two principal disciplines constituted the program: the art of persuasion, or dialectic, and the art of speaking, or rhetoric—the two most flourishing humanistic sciences of antiquity. These disciplines the Sophists founded by distilling from experience their general principles and logical structures, thus making possible their transmission on a theoretical basis from master to pupil.

To the pedagogy of the Sophists there was opposed the activity of Socrates, who, as inheritor of the old aristocratic tradition, was alarmed by this radical utilitarianism. He doubted that virtue could be taught, especially for money, a degrading substance. An heir also of the old sages of former times, Socrates held that the supreme ideal of man and hence of education was not the spirit of efficiency and power but the distinterested search for the absolute, for virtue—in a word, for wisdom.

It was only at the beginning of the 4th century BC, however, that the principal types of classical Greek higher education became organized on definitive lines. This was the result of the joint and rival efforts of the two great educators, the philosopher Plato (*c.* 428–348/347), who opened his school, the Academy, probably in 387, and the orator Isocrates (436–338), who founded his school *c.* 390.

Platonic education

A disciple of Socrates and like him an heir of the aristocratic tradition, Plato had early tried to take advantage of the ambition of men of his social class and to dream of the creation of an elite of men of politics, councillors to the sovereign, or leaders of the people. Blocked by the triumph of democratic ideas in Athens, however, he turned to a more personal conception of the ideal of the Greek man—as a philosopher. Plato's Academy did not take the form of a commercial enterprise but of a *thiasos*, a religious association devoted to the cult of the Muses (and, after the death of the master, to the cult of Plato himself, venerated as a hero). A notion of what his curriculum may have been can be gleaned from the idealized programs offered in the utopias of his books *The Republic* and *Laws*. The curriculum was founded on the traditional education of the Athenian child: for education of the body, it included gymnastics (which was broadened, however, to embrace hygiene and dietetics); for education of the spirit or soul, it included *mousikē*, "the Muses' thing"—dance, choral and solo singing, playing the lyre, and poetry. Then—this was the essential feature—there followed a long preparatory education that was characterized essentially by the study of mathematics and that, in principle, was to last as long as 30 years. Only then, when his intellect had been thoroughly tested and accustomed to moving in the rarefied atmosphere of abstract rational thought, would the disciple be able to attack the study of philosophy itself. Overall, this plan of education was doubly aristocratic: its origins were class-conscious; and its aims were to weed out those persons whose mental capacities and philosophical leanings proved insufficient to the tasks of long years of training.

The education of Isocrates

The rival school of Isocrates—a school open to fee-paying customers and not having an esoteric character like that of the Academy—was much more down-to-earth and practical. If it too aimed at a form of wisdom and claimed for itself the name of philosophy in defining its ideal, it was a wisdom of a much more practical order, based on working out commonsense solutions to life's problems. In contrast to Plato, Isocrates sought to develop the quality of grace, cleverness, or finesse rather than the spirit of geometry. The program of study that he enjoined upon his pupils was more literary than scientific. Besides gymnastics and music, its basics included the study of the classics (the poets first of all, with Homer in the foreground), the great prose authors, the historians, and the philosophers. Its higher levels consisted of an extensive study of the queen of disciplines, rhetoric—a study consisting of five or six years of theory, analysis of the great classics, imitation of the classics, and finally practical exercises. Such was the practical training of the Athenian citizen.

The two parallel forms of culture and of higher education must not be considered totally opposed: both opposed the cynical pragmatism of the Sophists; each influenced the other. Isocrates did promote elementary mathematics as a kind of mental training or mental gymnastics and did allow for a smattering of philosophy to illumine broad questions of human life. Plato, for his part, did recognize the usefulness of the literary art and philosophical rhetoric. The two traditions appear as two species of one genus; their debate, continued in each generation, enriched classical culture without jeopardizing its unity.

Aristotelian education

Before leaving the Hellenic age, there is one other great figure to appraise—one who was a bridge to the next age since he was the tutor of the young prince who became Alexander the Great of Macedonia. Aristotle (384–322 BC), who was one of Plato's pupils and shared some of his opinions about education, believed that education should be controlled by the state, and that it should have as a main objective the training of citizens. The last chapter of his *Politics* opens with these words:

> No one will doubt that the legislator should direct his attention above all to the education of youth. . . . The citizen should be moulded to suit the form of government under which he lives.

He shared some of Plato's misgivings about democracy; but, because he was no recluse but a man of the world acquainted with public affairs, he declared his preference for limited democracy over other forms of government. His worldliness also led him to be less concerned with the intuition of universals, in the Platonic mode, and more concerned with the observation of specific things. His urge for logical structure and classification, for systematization, was especially strong.

This systematization extended to a youth's education. In his first phase, from birth to age seven, he was to be physically developed, learning how to endure hardship. From age seven to puberty, his curriculum would include the fundamentals of gymnastics, music, reading, writing, and enumeration. During the next phase, from puberty to age 17, the student would be more concerned with exact knowledge, not only carrying on with music and mathematics but also exploring grammar, literature, and geography. Finally, in young manhood, only a few superior students would continue into higher education, developing encyclopaedic and intensely intellectual interests in the biological and physical sciences, ethics, and rhetoric, as well as philosophy. Aristotle's school, the Lyceum, was thus much more empirical than Plato's Academy.

The Hellenistic age. Alexander the Great's conquest of the Persian Empire between 334 and 323 BC abruptly extended the area of Greek civilization by carrying its eastern frontier from the shores of the Aegean to the banks of the Syrdarya and Indus rivers in Central Asia. Its unity rested henceforward not so much on nationality (it incorporated and assimilated Persians, Semites, and Egyptians) nor on the political unity soon broken after the death of Alexander in 323 but on a common Greek way of life, the fact of sharing the same conception of man. This ideal was no longer social, communal in character, as had been that of the city-state; it now concerned man as an individual—or, better, as a person. This civilization of the Hellenistic age has been defined as a civilization of *paideia*—which eventually denoted the condition of a person achieving enlightened, mature self-ful-

The concept of *paideia*

fillment but which originally signified education per se. The Greeks succeeded in preserving their distinctive national way of life amid this immense empire because, wherever numbers of them settled, they brought with them their own system of education for their youth, and they not only resisted being absorbed by the "barbarian," non-Hellenic peoples but succeeded somewhat in spreading Greek culture to many of the alien elite. It is important to note that, although Hellenism was finally to be swept away in the Near East by the Persian national renaissance and the invasions originating from Central Asia beginning in the 2nd century BC, it continued to flourish and even expand in the Mediterranean world under Roman domination. Hellenistic civilization and its educational pattern were prolonged to the end of antiquity and even beyond; it was to be a slow metamorphosis and not a brutal revolution that would later give birth to the civilization and education strictly called Byzantine.

The institutions. Hellenistic education comprised an ensemble of studies occupying the young from age seven to age 19 or 20. To be sure, this entire program was completed only by a minority, recruited from the rich aristocratic and urban bourgeois classes. The students were mostly boys (girls occupied only a very modest place), and of course they were usually free citizens (masters, though some slaves were given a professional education occasionally reaching a high level).

As in the preceding era, education continued to be dependent upon the city, which remained the primary frame of Greek life. One of the results of the implantation of Hellenism in the Near East was the foundation of a network of cities or communities organized and administered in the Greek manner. In effect, the creation of vast kingdoms did not eliminate the role of the city, even if the latter was not altogether independent; the Hellenistic state was not at all totalitarian and sought to reduce its administrative machinery to a minimum. It relied upon the cities to assume responsibility for public services, that of education in particular. The city in turn looked to the contributions of the richest and most generous private individuals, either by requiring them to fill magistracies and supply costly services or by appealing to their voluntary generosity; the proper functioning of the Hellenistic city presupposed the willing contributions of "benefactors." Thus, certain educational institutions were supported—and in fact sometimes set up—by private foundations that specified exactly the use to be made of the income from their gift of capital. Many schools were private, the role of the city being limited to inspections carried out by special magistrates and to the organization of athletic and musical competitions and festivals.

Physical education. The Hellenistic school *par excellence* was still the school of gymnastics, the practice of athletic sports and the nudity that they required being the most characteristic feature contrasting the Greek way of life with that of the "barbarians." It consisted of an establishment called in some contexts *palaestra* and in others *gymnasion*. There were, at least in sufficiently large cities, several of these, separately for the different age classes and on occasion for the sexes. They were essentially sports grounds, generally square, surrounded by colonnades in which were set up the necessary services: cloakrooms, washstands, training rooms, massage rooms. At the side there was a track for footraces.

The *palaestra* or *gymnasion*

The foundation of the training always consisted of the sports properly called gymnastic and field. Horsemanship remained an aristocratic privilege. Nautical sports had a very modest role—a curious thing for a nation of sailors like the Greeks, but the fact is that they were by origin Indo-Europeans from the interior of the Eurasian continent. The other sports—ball games, hockey—were considered merely diversions or at best preparatory exercises. As the competition of professional sports grew, however, education based on sports progressively, though no doubt very slowly, lost its pre-eminent position. Although the popularity of athletic sports as spectacle endured, educational sports moved into the background, disappearing altogether in the Christian period (in the 4th century AD) in favour of literary studies.

There was a similar progressive decline, a similar final effacement, of artistic, particularly musical, education, the other survivor from the archaic culture. The art of music continued to flourish, but like sports it became the concern of professional practitioners and a feature of public spectacles rather than an art generally practiced in cultivated circles.

The primary school. The child from seven to 14 years of age went to the school of letters, conducted thither by a special slave, the *paidagōgos*, whose role was not limited to accompanying the child: he had also to educate him in conduct, good manners, and morals and finally to act as a lesson coach. Ignorance—or disdain—of child psychology resulted in the use of teaching methods that were scarcely efficient: flogging was the only aid used, and it was used generously. The teaching of reading involved an analytical method that made the process very slow. First the alphabet was taught from alpha to omega and then backward, then from both ends at once—alpha–omega, beta–psi, and so on to mu–nu. (A comparable progression in the Latin alphabet would be *A–Z*, *B–Y*, and so on to *M–N*.) Then were taught simple syllables—*ba, be, bi, bo*—followed by more complex ones, and then by words, successively of one, two, and three syllables. The vocabulary list included rare words (*e.g.*, some of medical origin), chosen for their difficulty of reading and pronunciation. It took several years for the child to be able to read connected texts, which were anthologies of famous passages. With reading was associated recitation and, of course, practice in writing, which followed the same gradual plan.

The program in mathematics was very limited; rather than computation, the subject, strictly speaking, was numeration: learning the whole numbers and fractions, their names, their written notations, their representation in finger counting (in assorted bent positions of the fingers and assorted placements of either hand relative to the body). The general use of tokens and of the abacus made the teaching of methods of computation less necessary than it became in the modern world.

Secondary education. Between the primary school and the various types of higher education, the Hellenistic educational system introduced a program of intermediate, preparatory studies—a preliminary education, a kind of common trunk preparing for the different branches of higher culture, *enkyklios paideia* ("general," or "common, education"). This general education, far from having "encyclopaedic" ambitions in the modern sense of the word, represented a reaction against the inordinate ambitions of philosophy and, more generally, of the Aristotelian ideals of culture, which had demanded the large accumulation of intellectual attainments. The program of the *enkyklios paideia* was limited to the common points on which, as noted earlier, the rival pedagogies of Plato and of Isocrates agreed, namely, the study of literature and mathematics. Specialized teachers taught each of these subjects. The mathematics program had not changed since the ancient Pythagoreans and comprised four disciplines—arithmetic, geometry, astronomy, and music (not the art of music but the theory of the numerical laws regulating intervals and rhythm). The primary function of the *grammatikos*, or professor of letters, was to present and explicate the great classic authors: Homer first of all, of whom every cultivated man was expected to have a deep knowledge, and Euripides and Menander—the other poets being scarcely known except through anthologies. Although poetry remained the basis of literary culture, room was made for prose—for the great historians, for the orators, Demosthenes in particular, even for the philosophers. Along with these explications of texts, the students were introduced to exercises in literary composition of a very elementary character (for example, summarizing a story in a few lines).

The program of this intermediate education did not attain its definitive formulation until the second half of the 1st century BC, after the appearance of the first manual devoted to the theoretical elements of language, the slim grammatical treatise by Dionysius Thrax. The program then consisted of the seven liberal arts: the three literary

The seven liberal arts

arts of grammar, rhetoric, and dialectic and the four mathematical disciplines noted above. (These were, respectively, the trivium and the quadrivium of medieval education, though the latter term did not appear until the 6th century and the former not until the 9th century.) The long career of this program should not conceal the fact that in the course of the centuries it fell into disuse and became rather largely a theory or abstraction; in reality, literary studies gradually took over at the expense of the sciences. Of the four mathematical disciplines, only one remained in favour—astronomy. And this was not merely because of its connections with astrology but primarily because of the popularity of the basic textbook used to teach it—the *Phaenomena*, a poem in 1,154 hexameters by Aratus of Soli—whose predominantly literary quality was suited to textual explications. Not until about the 3rd and 4th centuries AD was the need of a sound preparatory mathematical education again recognized and put into practice.

Higher education. Higher education appeared in several forms, complementary or competitive. First was the *ephebeia* ("youth" culture), a kind of civic and military training that completed the education of the young Greek and prepared him to enter into life; it lasted two years (from 18 to 20) and corresponded quite closely to the obligatory military service of modern states. It was a survival from the regime of the old Greek city-states, but in the Hellenistic age the absence of national independence erased all reason for this military training; between the 3rd and 2nd centuries BC, the Athenian *ephebeia* (eventually reduced to a single year) was transformed into a peaceful civilian college where a minority of rich young men came to be initiated into the refinements of the elegant life. Military training came to play only a modest role and gave way to sport as such. To this were added lectures on scientific and, above all, literary subjects, assuring the ephebe a polish of general culture. The same evolution took place in other cities: the *ephebeia* became everywhere more aristocratic than civic, more sporting than military. What the Greeks, especially those who had emigrated to the "barbarian" lands, demanded of it was above all that it initiate their sons into Greek life and its characteristic customs, beginning with athletic sports. Especially in Egypt, it was intended to legitimize the privileged status of the Hellene relative to the "native" Egyptian. In any event, the *ephebeia* no longer was the setting for the highest forms of education.

Education in science and medicine

Formal education in science also lacked any institutionalization. There were, to be sure, certain establishments having scientific staffs of high competence, such as the Museum established at Alexandria, richly endowed by the Ptolemies; but, at least initially, it was an institute for advanced studies rather than a university properly speaking. If the savants endowed there were also professors, this meant only that they dispensed instruction to a small circle of chosen disciples. The same informal character of personal training was to be seen in all the special disciplines—medicine, for example, which saw such a fine development between the time of Hippocrates (5th century BC) and that of Galen (2nd century AD). If there were in the Hellenistic era certain "schools" of medicine —old (Cnidus, Cos) and new (Pergamum, Alexandria)— these were less the equivalent of today's medical faculties than simply centres to which the presence of numerous qualified masters attracted a large number of aspirants. Whatever theory these "students" were able to learn, they learned largely through self-training and practice, by associating themselves with a practicing physician whom they accompanied to the bedsides of patients, taking part in his consultations, profiting by his experience and advice.

Philosophy and rhetoric were subjects of education most highly institutionalized. Although philosophy was taught privately by individual masters-lecturers, who could be either itinerants or residents of one place, these teachers were well organized and, in groups, possessed a kind of institutional character. On the model of Plato's Academy, the new Athenian schools of philosophy—Aristotle's Lyceum, Epicurus' Garden, the Porch (*stoa*), which gave its name to the Stoics—were brotherhoods in which the posts in both teaching and administration were passed from generation to generation as a kind of heritage. It was in philosophy that the personalistic character of the Hellenistic era most clearly asserted itself, in contrast to the more communal idea of the preceding period; when philosophy turned to the problem of politics, for instance, it dealt less with the citizens of a republic and more with the sovereign king, his duties and character. The central problem was henceforth that of wisdom, of the purpose that man should set for himself in order to attain happiness, the supreme ideal. The teaching of philosophy was not entirely contemplative: it involved the disciple in a conversion analogous to a religious conversion, a decision implying a revision of his life and the adoption of a generally ascetic way of life. Such a vocation, however, could obviously appeal only to a moral, intellectual, and financially secure elite; philosophers were never to be more than a small number within the Hellenistic (and Roman) intelligentsia.

The prestige of rhetoric

The reigning discipline was thus that of rhetoric. The prestige of the oratorical art outlived those social conditions that had inspired it; political eloquence operated only in the context of an embassy coming to plead the cause of a particular city or pressure group at the court of the sovereign. Legal eloquence did retain its function, and the profession of advocate retained its attractiveness; but it was above all the eloquence of showy set speeches, the art of the lecturer, that experienced a curious blossoming. Also, as a result of the customary habit of reading aloud, there was no sharp line between speech and the book; thus, eloquence imposed its rule upon all literary genres—poetry, history, philosophy. Even the astronomer and the doctor became lecturers.

Hence the importance attached to the teaching of rhetoric, which developed from century to century with an ever more rigorous technicalism, precision, and systematization. The study of rhetoric had five parts: invention (the art of finding ideas, according to standard schemes), disposition (the arrangement of words and sentences), elocution, mnemonics (memory training), and action. Action was the art of self-presentation, the regulation of voice and delivery, and above all the art of reinforcing the word with the expressive power of gesture. Each of these parts, equally systematized to the tiniest detail, was taught with a technical vocabulary of extreme precision. Such an education, which in addition to theory comprised a study of the great examples to be imitated and exercises in practical application, required many years of study; in fact, even in maturity, the cultivated Hellene continued to deepen his knowledge of the art, to drill himself, to "declaim."

A rivalry existed between philosophy and rhetoric, each trying to draw into its orbit the best and the most students. Even in the time of Plato and Isocrates, this rivalry did not proceed without mutual concessions and reciprocal influences, but it remained one of the most constant characteristics of the classical tradition and continued until the end of antiquity and beyond. The long summer of Hellenic civilization was extended under the Roman domination; the great centres of learning also experienced a long prosperity. Athens in particular was the unchallenged capital of philosophy; its *ephebeia* welcomed foreigners to come to crown their culture in the "school of Greece." Its masters of eloquence also had a solid reputation, even though they had competition from such schools of Asia Minor as those of Rhodes (in the 1st century BC) and Smyrna (in the 2nd century AD). Under the later Roman Empire, Alexandria, already famous for medicine, competed with Athens for pre-eminence in philosophy. Other great centres developed: Beirut, Antioch, and the new capital Constantinople. The quality of the teachers and the number of students attending permits one to apply to these centres, without too much anachronism, the modern designation of "universities."

ANCIENT ROMANS

Early Roman education. The quality of Latin education before the 6th century BC can only be conjectured.

Rome and Roman civilization were then dominated by a rural aristocracy of landed proprietors directly engaged in exploiting their lands, even after the establishment of the republic. Their spirit was far removed from Greece and Homeric chivalry; ancient Roman education was instead an education suitable for a rural, traditional people —instilling in youth an unquestioned respect for the "customs of the ancestors."

Education had a technological aspect, involving instruction on how to direct the use of one's lands, how to oversee the work of slaves, and how to advise the tenant farmers or one's steward. It had a legal aspect; in contrast to Athenian law, which relied more on equity than on written law, Roman justice was much more formalistic and technical and demanded much more study on the part of the citizen. Education had a moral aspect, aiming at inculcating rustic virtues, a respect for good management of one's patrimony, and a sense of austerity and frugality. Roman education, however, did not remain narrowly utilitarian; it broadened in urban Rome, where there developed the same ideal of communal devotion to the public weal that had existed in Greece—with the difference that in Rome such devotion would never be called into question. The interests of the state constituted the supreme law. The ideal set before youth was not that of the chivalrous hero in the Homeric manner but that of the great men of history who, in difficult situations, had by their courage and their wisdom saved the fatherland when it was in danger. A nation of peasants, Rome was also a nation of soldiers. Physical education was oriented not toward self-realization or competitive sport but toward military preparedness: training in arms, toughening of the body, swimming across cold and rapid streams, and horsemanship, involving such performances as mounted acrobatics and cavalry parades under arms.

The familial character of Roman education

Differing from the Greeks, the Romans considered the family the natural milieu in which the child should grow up and be educated. The role of the mother as educator extended beyond the early years and often had lifelong influence. If, in contrast to the girl, the boy at seven years of age escaped from her exclusive direction, it was to pass under that of his father; another trait of Roman pedagogy was that it was the father who closely supervised the development and the studies of his son, giving him instruction in an atmosphere of severity and moral exigency, through precept but even more through example. The young Roman noble accompanied his father as a kind of young page in all his appearances, even within the Senate.

Familial education ended at 16, when the adolescent male assumed the toga of manhood, the attire of the adult. He devoted one year to an apprenticeship in public life, no longer at his father's side but placed in the care of some old friend of the family, a man of politics laden with years and honours. Then came military service, first as a simple soldier (it was well for the future leader to learn first to obey), encountering his first opportunity to distinguish himself by courage in battle, but soon thereafter as a staff officer under some distinguished commander. Civil and military, the education of the young Roman was thus completed in the entourage of some high personage whom he regarded with respect and veneration, without ceasing, however, to gravitate toward the family orbit. The young Roman was brought up not only to respect the national tradition embodied in the example of the illustrious men of the past but also, very specifically, to respect the particular traditions of his own family, which too had had its great men and which jealously transmitted a stereotype, a specific attitude toward life. If ancient Greek education can be defined as the imitation of the Homeric hero, that of ancient Rome took the form of imitation of one's ancestors.

Roman adoption of Hellenistic education. Something of these original characteristics was to survive always in Roman society, so ready to be conservative; but Latin civilization did not long develop autonomously.

It assimilated, with a remarkable faculty for adaptation, the structures and techniques of the much further evolved Hellenistic civilization. The Romans themselves were quite aware of this, as evidenced by the famous lines of Horace: "Captive Greece captivated her rude conqueror and introduced the arts to rustic Latium" "Graecia capta ferum victorem cepit et artis intulit agresti Latio" (*Epistles*, II, i, 156).

Greek influence was felt very early in Roman education and grew ever stronger after the long series of gains leading to the annexation of Macedonia (168 BC), of Greece proper (146 BC), of the kingdom of Pergamum (133 BC), and finally of the whole of the Hellenized Orient. The Romans quickly understood what advantages they could draw from this more mature civilization, richer than their own national culture. The practical Romans grasped the advantages to be drawn from a knowledge of Greek, an international language known to many of their adversaries, soon to be their Oriental subjects, and grasped the related importance of mastering the art of oratory espoused by the Greeks. Second-century Rome assigned to the spoken word, particularly in political and legal life, as great an importance as had Athens in the 5th century. The Roman aristocrats quickly understood what a weapon rhetoric could be for a statesman.

Rome doubly adopted Hellenistic education: on the one hand, it came to pass that a Roman was considered truly cultivated only if he had the same education, in Greek, as a native Greek acquired; on the other hand, there progressively developed a parallel system of instruction that transposed into Latin the institutions, programs, and methods of Hellenistic education. Naturally, only the children of the ruling class had the privilege of receiving the complete and bilingual education. From the earliest years, the child, boy or girl, was entrusted to a Greek servant or slave and thus learned to speak Greek even before he was able to express himself well in Latin; he also learned to read and write in the two languages, with Greek again coming first. (Alongside this private tutoring there soon developed, from the 3rd century BC, a Greek public education in schools aimed at a socially broader clientele, but the results of this schooling were less satisfactory than the direct method enjoyed by the children of the aristocracy.) In following the normal course of studies, the young Roman was taught successively by an instructor of Greek letters (*grammatikos*) and then by a Greek rhetorician. Those desiring more complete training did not content themselves with the numerous and often highly qualified Greeks to be found in Rome itself but went to Greece to participate in the higher studies of the Greeks themselves. From 119 or 118 BC onward, the Romans secured admission to the Ephebic College at Athens, and in the 1st century BC such young Latins as Cicero were attending the schools of the best philosophers and rhetoricians at Athens and Rhodes.

The tutoring of Roman children

Roman modifications. The adoption of Hellenistic education did not proceed, however, without a certain adaptation to the Latin temperament: the Romans showed a marked reserve toward Greek athleticism, which shocked both their morals and their sense of the deep seriousness of life. Although gymnastic exercises entered into their daily life, it was under the category of health and not that of sport; in Roman architecture, the palaestra or gymnasium was only an appendage of the public baths, which were exaggerations of their Greek models. There was the same reserve, on grounds of moral seriousness, toward music and dance, arts suitable for professional performers but not for freeborn young men and least of all for young aristocrats. The musical arts indeed became integrated into Latin culture as elements of the life of luxury and refinement, but as spectacle rather than as amateur participation; hence their disappearance from programs of education. It must be remembered, however, that athletics and music were in Greece itself survivals of archaic education and had already entered upon a process of decline.

This education in a foreign language was paralled by a course of studies exactly patterned upon those of the Greek schools but transposed into the Latin language. The aristocracy was to remain always attached to the idea of private education conducted within the family, but social pressure brought about the gradual develop-

ment of public education in schools, as in Greece, at three levels—elementary, secondary, and higher; they appeared at different dates and in various historical contexts.

Roman primary and secondary education

Education of youth. The appearance of the first primary schools is difficult to date; but the use of writing from the 7th century BC implies the early existence of some kind of appropriate primary instruction. The Romans took their alphabet from the Etruscans, who had taken theirs from the Greeks; Etruscans and Latins quite naturally copied the pedagogy of the Hellenistic world: the same ignorance of psychology, the same strict and brutal discipline, the same analytical method characterized by slow progress—the alphabet (forward, backward, from both ends toward the middle), the syllabary, isolated words, then short sentences (one-line moral maxims), finally continuous texts—the same method for writing and the same numeration, rather than computation.

It was only between the 3rd and the end of the 1st centuries BC that Latin secondary education developed, staffed by the *grammaticus Latinus*, corresponding to the Greek *grammatikos*. Since the principal object of this education was the explication of poetry, its rise was hindered by the slowness with which Latin literature developed. The first of these teachers, Livius Andronicus, took as his subject matter his own Latin translation of the *Odyssey;* two generations later, Ennius explicated his own poetic works. Only with the great poets of the age of Augustus could Latin literature provide classics able to rival Homer in educational value; they were adopted as basic texts almost immediately after their appearance. Thereafter, and until the end of antiquity, the program was not to undergo further change, the principal authors being first of all Virgil, the comic author Terence, the historian Sallust, and the unchallenged master of prose, Cicero. The methods of the Latin grammarian were copied directly from those of his Greek counterpart; the essential point was the explication of the classic authors, completed by a theoretical study of good language using a grammar textbook and by practical exercises in composition, graduated according to a minutely regulated progression and always remaining rather elementary. Theoretically, the curriculum remained that of the seven liberal arts, but, as in Greece, it practically neglected the study of the sciences in favour of that of letters.

It was only in the 1st century BC that the teaching of rhetoric in Latin was established: the first Latin rhetorician appeared in 93 BC in a political context, namely, as a democratic initiative to counter the aristocratic education given in Greek, and, as such, was soon prohibited by the conservative party in power. It was not until the end of the century and the appearance of the works of Cicero that this education would be revived and become normal practice; first, Cicero's discourses offered the young Latin the equivalent of those of the Greek Demosthenes, and, second, Cicero's theoretical treatises provided a technical vocabulary obviating the need for Greek manuals. But this instruction was to remain always very close to its Hellenistic origins: the terminology used by the great pedagogue Quintilian (*c.* AD 35–*c.* 100) is much more impregnated with Hellenism, much less Latinized, than that which Cicero had proposed. At Rome, too, rhetoric became the form of higher education enjoying the greatest prestige; as in Greece, this popularity outlived the elimination of political eloquence. More than in Greece, legal eloquence continued to flourish (Quintilian had in mind particularly the training of future advocates), but, as in the Hellenic milieu, Latin culture became predominantly aesthetic: from the beginning of the empire, the public lecture was the most fashionable literary genre, and the teaching of rhetoric was very naturally oriented toward the art of the lecturer as the crowning achievement.

Higher education. Precisely because the oratorical art was incontestably the most popular subject of higher education, the Romans did not feel the same urgency to Latinize the other rival branches of knowledge, which interested only a small number of specialists with offbeat vocations. To be sure, the philosophical work of Cicero had the same ambition as his oratorical work and proved by its existence that it was possible to philosophize in Latin, but philosophy found no successors to Cicero as rhetoric did. There was never a Latin school for philosophy. Of course, Rome did not lack philosophers, but many used Greek as their means of expression (even the emperor Marcus Aurelius); those who, like Cicero, wrote in Latin—Seneca, for example—had taken their philosophy studies in Greek. It was the same in the sciences, particularly in the medical sciences; for long, there were no medical books in Latin except encyclopaedias on a popular level.

The innovation of legal education

On the other hand, Rome created in the school of law another type of higher education—the only one that had no equivalent in Hellenistic education. The position of law in Roman life and civilization is, of course, well-known. Perhaps even more than rhetoric, it offered young Romans profitable careers; very naturally, there developed an appropriate education to prepare them. At first elementary in character and entirely practical, it was given within the framework of apprenticeship: the professor of law (*magister juris*) was primarily a practitioner, who initiated into his art the group of young disciples entrusted to him; these audited his consultations and heard him plead or judge. Beginning in Cicero's time and undoubtedly under his influence, this instruction was paralleled by a systematic theoretical exposition. Roman law was thus promoted to the rank of a scientific discipline. True schools were progressively established and took on an official character; their existence is well attested beginning with the 2nd century AD. It was at this same time that legal education acquired its definitive tools, with the composition of systematic elementary treatises such as the *Institutiones* of Gaius, manuals of procedure, commentaries on the law, and systematic collections of jurisprudence. This creative period perhaps reached its peak at the beginning of the 3rd century AD. The works of the great legal authors of this time, which became classics, were offered by the law professor with much interpretation and explication—very similar to the way in which grammarians offered literature.

Rome, the capital, remained the great centre of this advanced study in law. At the beginning of the 3rd century, however, there appeared in the Orient the school of Beirut. The teaching there was in Latin; and, to hear it and profit by the advantages that it offered for a high administrative or judicial career, many young Greeks enrolled there, in spite of the language obstacle to be overcome. Only a legal career could persuade young Greeks to learn this language that was always regarded by them as "barbarous."

The Roman world became covered with a network of schools concurrent with the Romanization of the provinces. The primary school always remained private; on the other hand, many schools of grammar or rhetoric acquired the character of public institutions supported (as in the Hellenic world) either by private foundations or by a municipal budget. In effect, it was always the city that was responsible for education. The liberal central government of the high empire, anxious to reduce its administrative apparatus to a minimum, made no pretense of assuming charge of it. It was content to encourage education and to favour teaching careers by fiscal exemptions; and only very exceptionally did an emperor create certain chairs of higher education and assign them a regular stipend. Vespasian (AD 69–79) created two chairs at Rome, one of Greek rhetoric and the other of Latin rhetoric. Marcus Aurelius (AD 161–180) similarly endowed, in Athens, a chair of rhetoric and four chairs of philosophy, one for each of the four great sects—Platonism, Aristotelianism, Epicureanism, and Stoicism.

The durable character of Greco-Roman education

Education in the later Roman Empire. The dominant fact is the extraordinary continuity of the methods of Roman education throughout such a long succession of centuries. Whatever the profound transformations in the Roman world politically, economically, and socially, the same educational institutions, the same pedagogical methods, the same curricula were perpetuated without great change for 1,000 years in Greek and six or seven

centuries in Roman territory. At most, a few nuances of change need be noted. There was a measure of increasing intervention by the central government, but this was primarily to remind the municipalities of their duties in regard to education, to fix the remuneration of teachers, and to supervise their selection. Only higher education received direct attention: in AD 425, Theodosius II created a true university in the new capital of Constantinople and endowed it with 31 chairs for the teaching of letters, rhetoric (both Greek and Latin), philosophy, and law. Another notable innovation was that the exuberant growth of the bureaucratic apparatus under the later empire favoured the rise of one branch of technical education, that of stenography, necessary for secretaries—a humble career, no doubt, but one that in that absolute autocracy could lead, through ambition and intrigue, to high responsibilities.

The only evolution of any considerable extent involves the use of the Greek and Latin languages. There had always been only a few Greeks who learned Latin, even though the growing machinery of administration and the increasing clientele drawn to the law schools of Beirut and Constantinople tended on the whole to increase the numerical size of this tiny minority. On the other hand, in Latin territory, late antiquity exhibited a general recession in the use of Greek. The ideal remained unchanged, and high culture always proposed to be bilingual: but, except among those aristocratic elites who clung to the old traditions and among a few other exceptional groups, people generally knew Greek less and less well. This retrogression need not be interpreted solely as a phenomenon of decadence: it had also a positive aspect, being an effect of the development of Latin culture itself. The richness and worth of the Latin classics explain why the youth of the West had less time than formerly to devote to the study of the Greek authors. Virgil and Cicero had pushed back Homer and Demosthenes, just as in modern Europe the ancient languages have retreated before the progress of the national languages and literatures. Hence, in the later empire, there appeared specialists in intercultural relations and translations from Greek into Latin. In the 4th and particularly in the 5th century, medical education in Latin became possible, thanks to the appearance of a whole medical (and veterinary) literature consisting essentially of translations of Greek manuals. It was the same with philosophy: resuming Cicero's enterprise at a distance of more than five centuries, Boethius (*c.* 480–524) in his turn sought with his manuals and his translations to make the study of that discipline available in Latin. Although the misfortunes of Italy in the 6th century, including the Lombardian invasion, did not permit this hope to be realized, yet the work of Boethius was destined later to nourish the medieval renaissance of philosophic thought.

Christian use of Greco-Roman education

Nothing better demonstrates the prestige and the persistent allure of classical culture than the attitude taken toward it by the Christians. This new religion could have organized an original system of education analogous to that of the rabbinical school—that is, one in which children learned through study of the Holy Scriptures—but it did not ordinarily do so. Usually, Christians were content to have both their special religious education, provided by the church and the family, and their classical instruction, received in the schools and shared with the pagans. Thus, they maintained the tradition of the empire after it had become Christian. Certainly, in their view, the education dispensed by these schools must have presented many dangers, inasmuch as classical culture was bound up with its pagan past (at the beginning of the 3rd century, the profession of schoolteacher was among the professions that disqualified one from baptism); but the utility of classical culture was so evident that they considered it necessary to send their children to these same schools in which they barred themselves from teaching. From Tertullian to St. Basil the Great of Caesarea, the Christian scholars insisted on the dangers presented by the study of the classics, the idolatry and immorality that they promoted, but they sought to show how the Christian could nevertheless make good use of them. With the passage of time and the general conversion of Roman society and particularly of its ruling class, Christianity, overcoming its reserve, completely assimilated and took over classical education. In the 4th century, Christians were occupying teaching positions at all levels, from schoolmasters and grammarians to the highest chairs of eloquence. In his treatise *De doctrina Christiana* (426), St. Augustine formulated the theory of this new Christian culture: being a religion of the book, Christianity required a certain level of literacy and literary understanding; the explication of the Bible required the methods of the grammarian; preaching a new field of action required rhetoric; theology required the equipment of philosophy. The synthesis of Christianity and classical education had become so intimate that, when the barbarian invasions swept away the traditional school along with many other imperial and Roman institutions, the church, needing a literary culture for the education of its clergy, kept alive the cultural tradition that Rome had received from the Hellenistic world. (H.I.M.)

III. Education in Persian, Byzantine, early Russian, and Islāmic civilizations

ANCIENT PERSIA

The ancient Persian Empire began when Cyrus II the Great initiated his conquests in 559 BC, and it ended when it was overrun by the Muslims in AD 651. Three elements dominated this ancient Persian civilization: (1) a rigorous and challenging physical environment, (2) the activist and positive Zoroastrian religion and ethics, and (3) a militant, expansionist people. These elements developed in the Persians an adventurous personality mingled with intense national feelings.

Zoroastrian influences

In the early period (559–330 BC), known as the Achaemenid period for the dynastic name of Cyrus and his successors, education, sustained by Zoroastrian ethics and the requirements of a military society, aimed at serving the needs of four social classes—priests, warriors, tillers of the soil, and merchants. Three principles sustained Zoroastrian ethics: the development of good thoughts, of good words, and of good actions (see ZOROASTRIANISM AND PARSIISM). Achaemenid–Zoroastrian education stressed strong family ties and community feelings, acceptance of imperial authority, religious indoctrination, and military discipline.

Education was a private enterprise. Formative education was carried on in the home and continued after the age of seven in court schools for children of the upper classes. Secondary and higher education included training in law to prepare for government service, as well as medicine, arithmetic, geography, music, and astronomy. There were also special military schools.

In 330 BC Persia was conquered by Alexander the Great, and native Persian or Zoroastrian education was largely eclipsed by Hellenistic. Greek practices continued during the Parthian Empire (247 BC–AD 224), founded by seminomadic conquerors from the Caspian steppes. And, thus, truly Persian influences were not restored until the appearance of a new, more sophisticated and reform-minded dynasty, the Sāsānids, in the 3rd century AD. In what has been called the neo-Persian empire of the Sāsānids (AD 224–651), the Achaemenian social structure and education were revived and further developed and modified. Zoroastrian ethics, though more advanced than during the Achaemenian period, emphasized similar moral principles, but with new stress upon the necessity for labour (particularly agriculture), upon the sanctity of marriage and family devotion, and upon the cultivation of respect for law and of intellectualism—all giving to education a strong moral, social, and national foundation. The subject matter of basic education included physical and military exercises, reading (Pahlavi alphabet), writing (on wooden tablets), arithmetic, and the fine arts.

Academy of Gondēshāpūr

The greatest achievement of Sāsānid education was in higher education, particularly as it developed in the Academy of Gondēshāpūr. Here, Zoroastrian culture, Indian and Greek sciences, Alexandrian–Syrian thought, medical training, theology, philosophy, and other dis-

ciplines developed to a high degree, making Gondēshāpūr the most advanced academic centre of learning in the later period of Sāsānid civilization. The academy, to which came students from various parts of the world, advanced, among other subjects, Zoroastrian, Greek, and Indian philosophies; Persian, Hellenic, and Indian astronomy; Zoroastrian ethics, theology, and religion; law, government, and finance; and various branches of medicine. In medicine, two kinds of diseases were recognized —internal and external, caused, according to Sāsānids, by stench and dirt, heat and cold, hunger and thirst, anxiety and old age, intemperance and overindulgence. Health was defined as a state of harmony of elements in the body, sustained by good birth and proper nourishment. The necessary qualifications for the practice of medicine included not only mastery of the science of medicine but also indifference to material benefits and continuous professional improvement.

It was partly through the Academy of Gondēshāpūr that important elements of classical Greek and Roman learning reached the Muslims during the 8th and 9th centuries AD and through them to schoolmen of western Europe in Latin translations of Arabic works during the 12th and 13th centuries.

THE BYZANTINE EMPIRE

The Byzantine Empire was a continuation of the Roman Empire in the eastern Mediterranean area, when the empire was finally divided into eastern and western parts in AD 395. If one takes as its starting point the year 330, when Constantine transferred the capital to Byzantium (Constantinople), the Eastern Empire lasted from 330 to 1453, when the capital fell to the Ottoman Turks under Sultan Mehmed II.

Influences on Byzantine education and culture. Byzantine education, though essentially patronized by Greek Christian Orthodoxy, remained basically a continuation of classical education. Even the emperor Justinian's closing of the Neoplatonic schools of Athens in 529 was more a defensive measure against pagan traditions than an attempt to break away from the Greek classical traditions of learning, particularly on levels of higher education. This is evident particularly in the traditions of Byzantine universities, which remained to a large extent aloof from religious involvements.

Nonetheless, religious orthodoxy, or faith, was Byzantium's greatest strength. It held the empire together, now expanded and again reduced, for more than 1,000 years against eastern invaders. Faith was also the Byzantine culture's chief limitation, choking originality in the sciences and the practical arts. But within this limitation it preserved the literature, science, and philosophy of classical Greece in recopied texts, some of which escaped the plunders of the crusaders and were carried to southern Italy, restoring Greek learning there. Combined with the treasures of classical learning that reached Europe through the Muslims, this Byzantine heritage helped to initiate the beginnings of the European Renaissance.

Results of the division between East and West

The highlights of the development of Byzantine culture and education within the restrictions of Eastern Greek Orthodoxy may be shown by its contrast with Latin, or Western, Christianity. In Greek Christianity the emperor appointed the patriarch of Constantinople and had the power to reduce or remove his jurisdiction. In Latin Christianity the two centres of power, the state and the church, competed for supremacy—the church maintaining, by and large, the upper hand throughout the Middle Ages. Intellectually, the consequences of this division were many. (1) Geographically, it divided Europe between Greek and Latin orthodoxies. (2) Linguistically, it identified Byzantine orthodoxy with the Greek language and Western orthodoxy with the Latin. (3) Jurisdictionally, it put Greek orthodoxy under secular laws, with the emperor appointing and disposing the patriarchs, whereas the Latin church dominated the political fortunes of western Europe into the 13th and 14th centuries. (4) Liturgically, in Greek Orthodoxy, ecclesiastical ornaments, vessels, and vestments became more ornate than in the Western church.

Primary and secondary education. More is known about the development of higher education than about the development of education on the primary and secondary levels in the Byzantine world. The best available information provides, nonetheless, certain limited observations. In general, some type of education seems to have been available for all classes within a rigid class structure, which provided better educational opportunities for upper class children. This aristocratic restriction was considerably reduced after the 11th century. Some provisions were also available for the education of girls. The emperor Julian (361–363) introduced state examinations and enforced state appointments of all teachers. Theodosius II (408–450) went so far as to make it a state offense for any teacher to give public instruction without a state license and saw to it that licenses were given only to conformists of orthodoxy. Schools were subsidized by the government.

In addition to some private tutoring, formal education included the following types of schools. Primary schools were available for a wide variety of middle and upper class children, including both urban and rural schools. Certain rudiments of classical learning formed part of the curriculum, in addition to an emphasis on reading and writing. These schools enrolled pupils variously between the ages of six and eight or eight and ten. On the secondary level, schools were open to pupils between the ages of ten and 16. Here there was stronger emphasis on the study of classics, particularly the works of Homer, in addition to instruction in mathematics, grammar, and religion. In patriarchal schools, which were fully developed by the 11th century, religious studies founded upon the Scriptures were taught by teachers chosen by the patriarch. But even in these schools the tradition of classical Humanism was not overlooked. Instruction in religion was complemented in these schools by the arts, including instruction in grammar and mathematics—combining, in a sense, religious and classical studies into a curriculum of Christian Humanism. The monastic schools were the only schools in the Byzantine culture devoted completely to religious disciplines and ascetic practices with total indifference or even hostility to the Humanistic tradition. These schools were established only for those who vowed dedication to a completely religious life. Children of the secular world were not admitted to them. Biblical studies, hymns, prose, and verse were central features of the curriculum.

Patriarchal schools

Higher education. The Byzantines remodelled the literary Humanism and moral philosophy of classical education to accord with Christian educational aims and came up with Christian Humanism, incorporating into this renovated curriculum such studies as literature, rhetoric, grammar, and philosophy. This classical tradition survived in the empire into the 8th century. In higher learning, important elements of classical culture were preserved in the great universities of larger cities, such as the universities of Constantinople, Alexandria, Antioch, and Beirut.

The Byzantine universities

In 425, under Theodosius II, higher education was reorganized in Constantinople, and there was established a university with 31 teachers, of whom 28 were assigned to instruction in Greek and Latin grammar, rhetoric, and literature, two were assigned to law, and one to philosophy. In 526 the grammarian Priscian wrote an extensive work on Greek and Latin grammar, *Institutiones grammaticae*, which became one of the famous texts in this field throughout the Middle Ages. Through such writers many of the Greek "pagan" classics were copied and taught in the schools of Constantinople, over the protest of churchmen, and remained more or less in vogue to the end of the Byzantine Empire.

For more than a thousand years (425–1453), save for temporary discontinuation, the University of Constantinople remained a rich centre of secular learning, embodying some of the best features of classical education, with periods of decline matched by as many periods of revival and reorganization in the 9th, 11th, 13th, and 14th centuries.

In general, the secular curricula of the major Byzantine

universities were quite diversified. Taken together, they included instruction in humanities, Greek classics, rhetoric and grammar, philosophy as a preparation for theology, secular music founded upon mathematical concepts, geometry, astronomy, logic, poetry in Atticized Greek, religious literature as a secular study, and arithmetic, as well as courses of study leading to the professions of law, medicine, architecture, and civil service. The state depended upon the universities to train qualified men for government services.

Thus, even after the educational centres of Athens had been closed, other universities and teaching centres carried much of the classical tradition through secondary and higher education, with the University of Constantinople and the patriarchal schools surviving as centres of Hellenistic Christian education to the end of the empire.

EARLY RUSSIAN EDUCATION: KIEV AND MUSCOVY

Influences on Russian education and culture. The influence of Byzantium, the Greek Orthodox Church, and other external forces upon early Russian education appears vividly in the light of six broad historical periods in Russia, based largely upon the shifting relations between the forest and steppe zones. Of concern here are the first four periods. The first, or prenational, period ended with Prince Svyatoslav's final attempt to unify a broad area encompassing the Dnieper River (Kiev and Novgorod), the Lower Volga, and the lower Danube. With his death in 972 this temporary empire crumbled, giving way to a gradual Christianization of Russia under Byzantine religious, cultural, and educational influences. Slavic mythology and Indo-European and Iranian themes, folklores, and arts were also contributing factors.

The struggle between the forest and the steppes, which continued into the second period, from 972 to 1240, is characterized by the unsuccessful though damaging efforts of Turkish tribes to subdue the Russians, whose ecclesiastical and political capital lay, at this time, in Kiev. The period was also characterized by further Russo-Byzantine cultural, religious, and educational developments, as well as by influences from Hungarians, Czechs, Poles, and Germans. During this period all the important elements of the Byzantine civilization and culture permeated Russia. Russia was officially converted to the Christian faith sustained by Byzantium but not as yet separate from the West. The gradual separation of Russian culture from western Europe began with the breach between the Byzantine and the Roman churches in the middle of the 11th century and the adherence of Russia to Greek Orthodoxy. This separation further widened and deepened until the end of the 17th century, or the reign of Peter the Great.

During the third period, from 1240 to 1452, the Mongol invasion terminated the struggle between the forest and the steppes, uniting the several Russian states under the domination of the Mongols, or Golden Horde, for about a century.

The two and a half centuries that followed the fall of Constantinople in 1453 were characterized by Russian expansion to the southeast. This expansionism continued with colonization of Siberia, the conquest of Kazan and Astrakhan, the reoccupation of the mouth of the Don, and the capture of Azov by Peter the Great in 1696 and other conquests later. During this period the church fell under the administrative control of the state and was divided into two metropolitan districts, Moscow and western Russia, with the patriarchate established in Moscow. These developments made a significant impact upon education.

Education under Kievan federation. As far back as 988, when the Russian church was officially converted to Greek Orthodoxy, Vladimir, metropolitan of Kiev, had advocated some form of formal elementary education. In 1028 Prince Yaroslav the Wise, the greatest ruler in the Kievan period, sent to Novgorod a request for 300 children's books; and in 1096 Prince Vladimir Monomakh wrote a long letter to his children on the advantages of education. This letter is one of the earliest documents on education in Russia. Schools as formal educational institutions, however, were not introduced into southern Russia until the end of the 16th century; the cultural nerve centre remained in Kiev, which was by then exposed to Western culture. In 1624, for instance, a Kievan religious order, the Lutsk Brotherhood, composed an educational document defining the qualifications of a teacher. They included devotion, judiciousness, humility, gentleness, continence, and sobriety. The good teacher should not be a usurer, a fornicator, a liar, or an envious, ridiculous, or irascible person; he should above all conduct himself with religious piety and never fall into heresy.

Clerical monopoly of learning

By the mid-17th century several types of schools flourished in southwestern Russia. These included elementary church schools, preparing students for religious service; schools founded by various brotherhoods advancing religious instruction; special home instruction in wealthy homes by private "masters"; Latin schools, similar to those established in Poland and Germany; and special schools giving literacy and religious instruction to children of the masses and occasionally to children of the nobility. Instruction was in the native language, reaching a larger number of pupils than some of the older schools. All these types of schools were established and supported by the people without state interference, thus anticipating the foundations of a system of public education. The Lutsk Brotherhood School laid down the strictest and most extensive rules for teaching and teacher conduct, school discipline, and parent–teacher cooperation.

The Lavr School, established in 1631, had an eight-year curriculum similar to some Jesuit schools, although it aimed at combatting the increasing influence of the Jesuits by teaching Greek and Latin, Slavonic, and the doctrines of Eastern Orthodoxy. The school attracted some fine teachers and became known as the Kiev Academy.

Muscovy educational development to 1725. The few elementary schools that existed in Muscovy up to the 17th century taught reading, writing, computation, and religion; and deacons and sextons served as teachers. The schools prepared students to become deacons and priests or government clerks. (Similar educational conditions prevailed in the Ukraine but with improved elementary schools.) Moscow established a divinity college in 1687, with emphasis on Greek language.

By the mid-16th century, the illiteracy of the clergy had become so notorious that it was decreed that schools be established in the homes of the better educated priests to teach church doctrines, singing, reading, and writing to any child, but particularly to students who prepared for the priesthood; the decree, however, was not widely carried out. Throughout the 16th and 17th centuries, home instruction was still largely the prevailing form of instruction. Oddly enough, secondary and higher education developed in Russia much earlier than elementary schools.

Romanov reforms

The Romanov family, which came into power in the early 17th century, ruled continuously until 1917, with absolute power for much of this period. The Romanovs developed cultural and educational relations with Germany, France, and England very early, with Peter the Great (tsar from 1682 to 1725) making systematic efforts to "westernize" Russia, inviting Western specialists to help found several schools of engineering and a naval academy. In a new type of school, called the cypher schools, arithmetic dominated the curriculum. It became compulsory for children of nobility to attend these schools. When the church was ordered by Peter in 1721 to facilitate education, diocesan schools were developed that by midcentury came into vogue, replacing the cypher schools and creating competition between the church and the crown for supremacy in education. Peter the Great also initiated efforts to establish an academy of science, which was finally founded by his widow as the Academy of Sciences in St. Petersburg in 1725.

Another school, the Slavonic–Greek–Latin Academy, had been licensed in 1682 and opened in Moscow in 1687. In 1701 Peter the Great transferred the academy to the state and turned it into a Latin school. Between 1630 and

1680 most Russian schools gradually changed from a Greek–Slavonic to a Polish–Latin orientation.

THE ISLAMIC ERA

Influences on Muslim education and culture. The Greco-Byzantine heritage of learning that was preserved through the medium of Near Eastern scholarship was combined with elements of Persian and Indian thought and taken over and enriched by the Muslims. It was initiated as early as the Umayyad caliphate (661–750), which allowed the sciences of the Hellenistic world to flourish in Syria and patronized Semitic and Persian schools in Alexandria, Beirut, Gondēshāpūr, Nisibis, Haran, and Antioch. But the largest share of Islām's preservation of classical culture was assumed by the ʿAbbāsid caliphate (750–*c.* 1100), which followed the Umayyad and encouraged and supported the translation of Greek works into Arabic, often by Nestorian, Hebrew, and Persian scholars. These translations included works by Plato and Aristotle, Hippocrates, Galen, Dioscorides, Alexander of Aphrodisias, Ptolemy, and others. The great mathematician al-Khwarizmi (flourished 9th century) compiled astronomical tables, introduced Hindu numerals (which became Arabic numerals), formulated the oldest known trigonometrical tables, and prepared a geographic encyclopaedia in cooperation with 69 other scholars.

The Muslim blend of scholastic heritages

The transmission of classical culture through Muslim channels can be divided into seven basic types: works translated directly from Greek into Arabic; works translated into Pahlavi, including Indian, Greek, Syriac, Hellenistic, Hebrew, and Zoroastrian materials, with the Academy of Gondēshāpūr as the centre of such scholarship (the works then being translated from Pahlavi into Arabic); works translated from Hindu into Pahlavi, then into Syriac, Hebrew, and Arabic; works written by Muslim scholars from the 9th through the 11th centuries but borrowed, in effect, from non-Muslim sources, with the line of transmission obscure; works that amounted to summaries and commentaries of Greco-Persian materials; works by Muslim scholars that were advances over pre-Islāmic learning but that might not have developed in Islām had there not been the stimulation from Hellenistic, Byzantine, Zoroastrian, and Hindu learning; and, finally, works that appear to have arisen from purely individual genius and national cultures and would likely have developed independent of Islām's classical heritage of learning.

Aims and purposes of Muslim education. Muslim education endeavoured to achieve two basic aims, religious and secular. The religious aims included the study of the Qur'ān as a source or basis of knowledge and the study of sectarian moral and spiritual disciplines, including the basic articles of faith. Secular aims included the synthesis of secular knowledge and religious belief, the conception and extensive practice of equal educational opportunity, and the establishment of teachers as guides and authorities in forms of knowledge based upon revelation, or direct intuition. These teachers were known as the *mutakallimun*, or *loquentes*.

It is important to emphasize the practical aims of Muslim secular education, which was responsible for the application of technological expertise to the development of irrigation systems, architectural innovations, textiles, iron and steel products, earthenware, and leather products; the manufacture of paper and gunpowder; the advancement of commerce; and the maintenance of a merchant marine. After the 11th century, when denominational interests dominated higher learning, academic freedom and practical studies gave way to religious and literary pursuits, Arabic language and grammar, and intolerance toward scientific innovations, secular subjects, and creative scholarship. These denominational colleges spread throughout eastern Islām from Transoxania (roughly modern Uzbek S.S.R.) to Egypt. Some 75 of them were in existence between about 1050 and 1250.

Varieties of Islāmic schools

Organization of education. There were many types of schools in the Muslim world, among them the *ḥalqah*, or circle schools; the *maktab* (*kuttab*), or writing schools; the palace schools; the *masjid*, or mosque schools; the bookshop schools; the *madrasah*, or schools of public instruction; and the universities.

The simplest type of early Muslim education was the circle, or gathering, school (*ḥalqah*), so named because the teacher was, as a rule, seated on a dais or cushion with the pupils gathering in a semicircle before him. The circle was determined by rank. The more advanced a student, the closer he was seated to the teacher, with the most advanced students or visiting scholars seated next to him. The mosque circles varied in approach, course content, and quality of teaching. Teachers were as a rule looked upon as masters of scholarship, and their lectures were meticulously recorded in notebooks, which were periodically examined, corrected, and approved for use in teaching others. The teacher encouraged students to discuss highlights of lecture notes with each other as preparation for advanced instruction in given areas. Advanced students were also encouraged to debate controversial points with their teachers and to feel free to challenge and even correct the teacher's statements. Every subject was dealt with methodically, beginning with a general survey of a subject, then connecting each day's lesson with previous lectures and a hint of the forthcoming lessons, giving in this manner coherence and continuity to a subject. Students often made long journeys to join the circle of a great teacher.

Writing schools (*maktab*, or *kuttab*), in which pupils learned to read and write, date back to the pre-Islāmic period in the Arab world. After the advent of Islām and the introduction of instruction in religion and the Qur'ān, these schools developed into centres for instruction in elementary Islāmic subjects. Some included in their curriculum the study of poetry, elementary arithmetic, penmanship, ethics (manners), elementary grammar, horsemanship, and swimming. *Maktab*s were quite common in almost every town or village in the Middle East, Africa, Sicily, and Spain.

Schools conducted in royal palaces taught not only the curriculum of the *maktab*s but also social and cultural studies designed to prepare the pupil for higher education, for service in the government of the caliphs, or for polite society. The instructors were called *muʾaddib*s, or instructors in good manners. Oratory, history, tradition, formal ethics, and the art of good conversation were often included in the curriculum.

The longest lasting of the elementary schools in Islām were the *masjid*s, which, as the name in Arabic implies, were attached to a mosque. Mosques increased in number under the caliphs, particularly the ʿAbbāsids: 3,000 of them were reported in Baghdad alone in the first decades of the 10th century; as many as 12,000 were reported in Alexandria in the 14th century, most of them with schools attached. Some mosques, such as that of al-Manṣūr, built during the reign of Hārūn-ar-Rashīd in Baghdad, or those in Isfahan, Mashhad, Ghom, Damascus, Cairo, and the Alhambra (Granada), became centres of learning for students from all over the Muslim world.

The high degree of learning and scholarship in Islām, particularly during the ʿAbbāsid period in eastern Islām and the later Umayyads in western Islām, encouraged the development of bookshops, copyists, and book dealers in large, important Islāmic cities such as Damascus, Baghdad, and Córdoba. Scholars and students spent many hours in these bookshop schools browsing, examining and studying available books, or purchasing favourite selections for their private libraries. Book dealers travelled to famous bookstores in search of rare manuscripts for purchase and resale to collectors and scholars and thus contributed the spread of learning. Many such manuscripts found their way to private libraries of famous Muslim scholars such as Avicenna, al-Ghazālī, and al-Fārābī, who in turn made their homes centres of scholarly pursuits for their favorite students.

Fundamental to Muslim education as were the circle schools, the *maktab*s, and the palace schools, they embodied definite educational limitations. Their curricula were limited; they could not always attract well-trained teachers; physical facilities were not always conducive to a congenial educational environment; and conflicts

between religious and secular aims in these schools were almost irreconcilable. These limitations led to the necessity of initiating a new type of school, the *madrasah*, to create a curriculum of studies more representative of the progressive diffusion of knowledge and to organize a body of better paid and better trained teachers to handle this enlarged curriculum more efficiently. These schools were widely established in Islāmic countries until the end of the 12th century.

The great Muslim universities

The crown and glory of medieval Muslim education were their famous research centres, or universities. Important among them were the universities of Niẓāmīyah and Mustanṣirīyah in Baghdad, which developed during the ʿAbbāsid caliphate, and those that developed in the Spanish cities of Córdoba, Seville, Toledo, Granada, Murcia, Almeria, Valencia, and Cádiz, in western Islām, under the Umayyads. The curricula of these schools offered both comprehensive programs of vocational studies and advanced studies in the professions, including courses in algebra, trigonometry, geometry, chemistry, physics, astronomy, medicine (including surgery, anatomy, pharmacy, and specialized medical branches), logic, ethics, metaphysics, geography, political disciplines, philology, poetry, grammar, prosody, law, jurisprudence, and all branches of theology.

The contribution of Muslim universities to the advancement of knowledge was vast. Muslim scholars calculated the angle of the ecliptic; measured the size of the Earth; calculated the procession of the equinoxes; invented the pendulum clock; explained, in the field of optics and physics, such phenomena as refraction of light, gravity, capillary attraction, and twilight; used the globe in teaching the geography of a round Earth; and developed observatories for the empirical study of heavenly bodies. They made advances in the uses of drugs, herbs, and foods for medication; established hospitals with a system of interns and externs; discovered causes of certain diseases and developed correct diagnoses of them; proposed new concepts of hygiene; made use of anesthetics in surgery with newly innovated surgical tools; and introduced the science of dissection in anatomy. They furthered the scientific breeding of horses and cattle; found new ways of grafting to produce new types of flowers and fruits; introduced new concepts of irrigation, fertilization, and soil cultivation; and improved upon the science of navigation. In the area of chemistry, Muslim scholarship led to the discovery of such substances as potash, alcohol, nitrate of silver, nitric acid, sulfuric acid, and mercury chloride. It also developed to a high degree of perfection the arts of textiles, ceramics, and metallurgy.

The Islāmic renaissance and medieval periods

Major periods of Muslim education and learning. The renaissance of Islāmic culture and scholarship developed largely under the ʿAbbāsid administration in eastern Islām and under the later Umayyads in western Islām, mainly in Spain, between 800 and 1000. This latter period, the golden age of Islāmic scholarship, was largely a period of translation and interpretation of classical thoughts and their adaptation to Islāmic theology and philosophy. The period also witnessed the introduction and assimilation of Hellenistic, Persian, and Hindu mathematics, astronomy, algebra, trigonometry, and medicine into Muslim culture and their modification and adaptation to Islāmic needs.

Whereas the 8th and 9th centuries, mainly between 750 and 900, were characterized by the introduction of classical learning and its refinement and adaptation to Islāmic culture, the 10th and 11th were centuries of interpretation, criticism, and further adaptation. There followed a period of modification and significant additions to classical culture through Muslim scholarship. Then, during the 12th and 13th centuries, most of the works of classical learning and the creative Muslim additions were translated from Arabic into Hebrew and Latin. The decline of Muslim scholarship coincided with the early phases of the European intellectual awakening that these translations were partly instrumental in bringing about.

Creative scholarship in Islām from the 10th to the 12th centuries included works by such scholars as Omar Khayyam, al-Bīrūnī, ar-Rāzī (Rhazes), Ibn Sīna (Avicenna), aṭ-Ṭabarī, Ibn Bājja (Avempace), and Ibn Rushd (Averroës).

Influence of Islāmic learning on medieval and modern Europe. The translation into Latin of most Islāmic works during the 12th and 13th centuries had a great impact upon the European Renaissance. As Islām was declining in scholarship and Europe was absorbing the fruits of Islām's three and a half centuries of creative productivity, signs of Latin Christian awakening were evident throughout the European continent.

The 12th century was one of intensified traffic of Muslim learning into the Western world through many hundreds of translations of Muslim works, which helped Europe seize the initiative from Islām when political conditions in Islām brought about a decline in Muslim scholarship. By 1300, when all that was worthwhile in Muslim scientific, philosophic, and social learning had been transmitted to European schoolmen through Latin translations, European scholars stood once again on the solid ground of Hellenistic thought, enriched or modified through Muslim and Byzantine efforts. (M.K.N.)

IV. The European Middle Ages

THE BACKGROUND OF EARLY CHRISTIAN EDUCATION

From the beginnings to the 4th century. At first Christianity found most of its adherents among the poor and illiterate, making little headway, as St. Paul observed (I Cor. 1:26), among the worldly-wise, the mighty, and those of high rank. But during the 2nd century AD and afterward it appealed more and more to the educated class and to leading citizens. These naturally wanted their children to have at least as good an education as they themselves had had, but the only schools available were the grammar and rhetoric schools, with their Greco-Roman, non-Christian culture. There were different opinions among Christian leaders about the right attitude to this dilemma that confronted all Christians who sought a good education for their children. The Greek Fathers, especially the Christian Platonists Clement of Alexandria and Origen, sought to prove that the Christian view of the universe was compatible with Greek thought and even regarded Christianity as the culmination of philosophy, to which the way must be sought through liberal studies. Without a liberal education the Christian could live a life of faith and obedience but could not expect to attain an intellectual understanding of the mysteries of the faith or expect to appreciate the significance of the Gospel as the meeting ground of Hellenism and Judaism. St. Augustine and St. Jerome also encouraged the use of the secular schools by Christians, maintaining that literary and rhetorical culture is valuable so long as it is kept subservient to the Christian life. The Roman theologian Tertullian, on the other hand, was suspicious of pagan culture, but he admitted the necessity, though deploring it, of making use of the educational facilities available.

Views of the early Christian Fathers

In any event, most Christians who wanted their children to have a good education appear to have sent their children to the secular schools; this practice continued even after 313, when the emperor Constantine, who had been converted to Christianity, stopped the persecution of Christians and gave them the same rights as other citizens. Christians also set up catechetical schools for the religious instruction of adults who wished to be baptized. Of these schools the most famous was the one at Alexandria in Egypt, which had a succession of outstanding heads, including Clement and Origen. Under their scholarly guidance, it developed a much wider curriculum than was usual in catechetical schools, including the best in Greek science and philosophy in addition to Christian studies. Other schools modelled on that at Alexandria developed in some parts of the Near East, notably in Syria, and continued for some time after the collapse of the empire in the west.

5th to 8th centuries. The gradual subjugation of the Western Empire by the barbarian invaders during the 5th century eventually entailed the breakup of the educational system that the Romans had developed over the

centuries. But, despite the political and social upheavals, the methods and program of ancient education survived into the 6th century in the new barbarian Mediterranean kingdoms; for the barbarians were frequently impressed and attracted by things Roman. In Ostrogothic Italy (Milan, Ravenna, Rome) and in Vandal Africa (Carthage), the schools of the grammarians and rhetoricians survived for a time, and, even in those places where such schools soon disappeared, as in Gaul and in Spain, private teachers or parents maintained the tradition of classical culture until the 7th century. As in previous centuries, the culture bestowed was essentially literary and oratorical: grammar and rhetoric constituted the basis of the studies. The pupils read, reread, and commented on the classical authors and imitated them by composing certain kinds of exercises (*dictiones*) with the aim of achieving a perfect mastery of their style. In fact, however, the practice was desultory, and the results were mechanical and poor. Furthermore, Greek was ignored more and more, and attempts to revive Hellenic studies were limited to a dwindling number of scholars.

Amid the general decline, the Christian Church persevered. From the 5th century to the time of Charlemagne in the 8th century, the church was able to provide some teaching of a religious character, especially for its clergy; and on those modest foundations a new educational system took shape gradually and fitfully. Learning that had no religious significance was rarely encouraged. But, even during the darkest days from the 5th to the 8th centuries, there were exponents of wider conceptions of education, and among them were such Christian scholars as Boethius and Cassiodorus in Rome, Isidore in Spain, and Bede in England. There were also monasteries in which the lamps of learning burned brightly. Particularly in Ireland, monasticism made its greatest contribution to the preservation and enrichment of culture during the 6th, 7th, and 8th centuries. In pre-Christian times there had been an educational tradition in Ireland, as in other Celtic regions, which the Irish monks took advantage of by developing schools open to the laity as well as to the clergy. They were keen students of the classics as well as of their native language and literature; and, when they crossed to the Continent as missionaries, they carried with them their knowledge of the literature of Greece and Rome, establishing monasteries, such as St. Gall (in Switzerland) and Reichenau (in Germany), that won renown for their scholarship.

Monastic and episcopal schools

The monastic schools, however, may not be as significant in the history of education as the schools founded by bishops, usually in connection with a cathedral. These bishops' schools are sometimes looked upon as successors of the grammar schools of the Roman Empire, and they are also often regarded as the parents of the grammar school of modern times. First specializing in the development of the clergy, these episcopal schools later admitted young lay people when the small Roman schools had disappeared. At the same time there were bishops who organized a kind of boarding school where the aspiring clergyman, living in a community, participated in duties of a monastic character, learned his clerical trade, and received doctrinal instruction.

The influence of monasticism affected the content of instruction and the method of presenting it. Children were to be dutiful, as the Celtic and English monks Columban and Bede were to remark: "A child does not remain angry, he is not spiteful, does not contradict the professors, but receives with confidence what is taught him." In the case of the adolescent destined for a religious profession, the monastic lawgiver was severe. The teacher must know and teach the doctrine, reprimand the undisciplined, and adapt his method to the different temperaments of the young monks. The education of young girls destined for monastic life was not much different from that of the monks. The mistress of the novices recommended prayer, manual work, and study.

Education of the laity

Between the 5th and 8th centuries, the principles of education of the laity likewise evolved. The treatises on education, later called the "mirrors," pointed to the importance of the four moral virtues—prudence, courage, justice, and temperance. The *Institutionum disciplinae* of an anonymous Visigoth pedagogue expressed the desire that all young men "quench their thirst at the quadruple fountain of the virtues." The author of this treatise also insisted on physical education, corresponding to Germanic standards of education. In the 7th and 8th centuries, the moral concepts of antiquity completely surrendered to religious principles. The Christian Bible was more and more considered as the only source of moral life, as the mirror in which men must learn to see themselves. A bishop addressing himself to a son of the Frankish king Dagobert (died 639) drew his examples from the books of the Old Testament. The mother of Didier of Cahors addressed to her son letters of edification on the fear of God, on the horror of vice, and on penitence.

The Christian education of children who were not aristocrats or future clergymen or monks was irregular. Whereas in antiquity catechetical instruction was organized especially for the adult laity, after the 5th century more and more children and then infants received baptism, and, once baptized, a child was not required to receive any particular religious education. His parents and godparents assisted him in learning the minimum, if anything at all. Only by attending church services and listening to sermons did the child acquire his religious culture.

The Irish and English revivals. During the 5th and 6th centuries there was a renaissance of learning in the remote land of Ireland, introduced there initially by the patron saints of Ireland—Patrick, Bridget, and Columcille—who established schools at Armagh, Kildare, and Iona. They were followed by a number of other native scholars, who also founded colleges—the most famous and greatest university being the one at Clonmacnois, on the Shannon River near Athlone. To these and lesser schools flocked Anglo-Saxons, Gauls, Scots, and Teutons from Britain and the Continent. From about AD 600 to 850, Ireland itself sent scholars to the Continent to teach, found monasteries, and establish schools.

Although the very earliest Irish scholars may have aimed primarily at propagating the Christian faith, their successors soon began studying and teaching the Greek and Roman classics, along with Christian theology. Eventually, there was a rich curriculum of mathematics, nature study, rhetoric, poetry, grammar, and astronomy, all studied, it seems, very largely through the medium of the Irish language.

England was next to experience the reawakening, and, though there were notable schools at such places as Canterbury and Winchester, it was in Northumbria that the schools flourished most. At the monasteries of Jarrow and Wearmouth and at the Cathedral School of York, some of the greatest of early medieval writers and schoolmasters appeared, including the Venerable Bede and Alcuin. The latter went to France in 780 to become master of Charlemagne's palace school.

THE CAROLINGIAN RENAISSANCE AND ITS AFTERMATH

The cultural revival under Charlemagne and his successors. Charlemagne (742/743–814) has been represented as the sponsor or even creator of medieval education, and the Carolingian renaissance has been represented as the renewal of Western culture. This renaissance, however, built on earlier episcopal and monastic developments; and, although Charlemagne did help to ensure the survival of scholarly traditions in a relatively bleak and rude age, there was nothing like the general advance in education that occurred later with the cultural awakening of the 11th and 12th centuries.

Educational reforms of Charlemagne

Learning, nonetheless, had no more ardent friend than Charlemagne, who came to the Frankish throne in 768 distressed to find such poor standards of Latin in his correspondence, the offenders including even bishops and abbots from all parts of his empire; he complained that their letters, though often very correct in sentiment, were very incorrect in grammar. He thus ordered that the clergy be educated severely, whether by persuasion or under compulsion. He recalled that, in order to inter-

pret the Holy Scriptures, one must have a command of correct language and a fluent knowledge of the Latin tongue; he later commanded, "in each bishopric and in each monastery let the psalms, the notes, the chant, calculation and grammar be taught and carefully corrected books be available" (capitulary of AD 789). His promotion of ecclesiastical and educational reform bore fruit in a generation of churchmen whose morals and whose education were of a higher standard than before.

The possibility then arose of providing, for the brighter young clerics and perhaps also for a few laymen, a more advanced religious and academic training. It was perhaps to meet this modest need that a school grew up within the precincts of the Emperor's palace at Aachen. In order to develop and staff other centres of culture and learning, Charlemagne imported considerable foreign talent. During the 8th century, England had been the scene of some intellectual activity; thus, Alcuin, who had been the master of the school at York, and other English scholars were brought over to transplant to the Continent the studies and disciplines of the Anglo-Saxon schools. From Moorish Spain came Christian refugees who also contributed to this intellectual revival; disputations with the Muslims had forced them to develop a dialectic skill in which they now instructed Charlemagne's subjects. From Italy came grammarians and chroniclers, men such as Paul the Deacon; the more formalistic classical traditions in which they had been bred supplied the framework to discipline the effervescent brilliance of the Anglo-Saxons. Irish scholars also arrived. Thanks to these foreigners, who represented the areas where classical and Christian culture had been maintained in the 6th and 8th centuries, the court became a kind of "academy," to use Alcuin's term. There the emperor, his heirs, and his friends discussed various subjects—the existence or nonexistence of the underworld and of nothingness, the eclipse of the Sun, the relationship of Father, Son, and Holy Ghost, and so on. Recognizing the importance of manuscripts in the cultural revival, Charlemagne formed a library (the catalog of which is still extant), had texts and books copied and recopied, and bade every school to maintain a scriptorium. Alcuin developed a school of calligraphy at Tours, and its new script spread rapidly throughout the empire; this Carolingian minuscule was more legible and less wasteful of space than the scripts hitherto employed.

Outside the court at Aachen were to be found here and there a few seats of culture, but not many. The Archbishop of Lyon reorganized the schools of readers and choir leaders; Alcuin in Saint-Martin-de-Tours and Angilbert in Saint-Riquier organized monastic schools with relatively well-stocked libraries. It was necessary to wait for the second generation or even the third to witness the greatest brilliance of the Carolingian renewal. Under Charlemagne's son Louis the Pious and especially under his grandsons, the monastic schools reached their apogee in France north of the Loire, in Germany, and in Italy. The most famous were at Saint-Gall, Reichenau, Fulda, Bobbio, Saint-Denis, Saint-Martin-de-Tours, and Ferrières. Unfortunately, the breakup of the Carolingian Empire, following local rebellions and the Viking invasions, ended the progress of the Carolingian renaissance.

Educational accomplishments of Alfred the Great

Influences of the Carolingian renaissance abroad. In England, at least in the kingdom of Wessex, King Alfred the Great stands out as another royal patron of learning, one who wanted to imitate the creativity of Charlemagne. When he came to the throne in 871, cultural standards had fallen to a low level, partly because of the turmoil of the Danish invasions. He was grieved to find so few who could understand their church services in English or translate a letter from Latin into English. To accomplish an improvement, he called upon monks from the Continent, particularly those of Saint-Bertin. Moreover, he attracted to his court certain English clergy and young sons of nobles. Since the latter did not know Latin, he had translated into Wessex English some works of Pope Gregory the Great, Boethius, the theologian and historian Paulus Orosius, Venerable Bede, St. Augustine, and others. He himself translated Boethius' *De consolatione philosophiae*, Gregory the Great's *Cura pastoralis*, and Bede's *Ecclesiastical History of the English People*. This promotion of learning was continued by Alfred's successors and spread elsewhere in England; and in the reformed monasteries at Canterbury, York, and Winchester, the young monks renewed the study of religious and secular sciences. Among the master scholars of the late 10th century was the Benedictine monk Aelfric, perhaps the greatest prose writer of Anglo-Saxon times. In order to facilitate the learning of Latin for young monks, Aelfric composed a grammar, glossary and colloquy, containing a Latin grammar described in Anglo-Saxon, a glossary in which master and pupil could find a methodically classified Latin vocabulary (names of birds, fish, plants, and so forth), and a manual of conversation, inspired by the bilingual manuals of antiquity.

Among the other Saxons, those of the Continent who presided over the destinies of Germany, there were also significant gatherings of masters and students at selected monasteries, such as Corvey and Gandersheim. In any case, wherever teaching became important in the 10th century, it concentrated largely on grammar and the works of the classical authors. Thus when Gerbert of Aurillac, after a course of instruction in Catalonia, came to teach dialectic and the arts of the quadrivium (geometry, arithmetic, music, and astronomy) at Reims, he aroused astonishment and admiration. His renown helped in his later election as Pope Sylvester II. The first half of the 11th century contained the first glimmerings of a rediscovered dialectic. A new stage in the history of teaching was beginning.

Religious and military emphases of general education

Education of the laity in the 9th and 10th centuries. The clergy who dominated society thought it necessary to give laymen some directives about life comparable to those offered in monastic rules and thus issued what were called *miroirs* ("mirrors"), setting forth the duties of a good sovereign and exalting the Christian struggle. Already the image of the courtly and Christian knight was beginning to take shape. It was not a question of governing a state well but, rather, of governing oneself. The layman must struggle against vice and practice virtue; he must emphasize his religious heritage. Alcuin became indignant when he heard it said that the reading of the Gospel was the duty of the clergy and not that of the layman. Huoda, wife of Bernard, duke of Septimania, addressed a manual to her 16-year-old son, stressing the reading and praying that a young man should do. In the libraries of the laity, the volumes of the Old and New Testaments took first place, along with prayer books, a kind of breviary designed for day-to-day use.

If a minority of aristocrats could receive a suitable moral and religious education, the masses remained illiterate and preferred a military apprenticeship to study. "He who has remained in school up to twelve years without mounting a horse is no longer good for anything but the priesthood," wrote a German poet. Writers of hagiographic texts were fond of contrasting the mother of the future saint, anxious to give education to her son, and the father, who wanted to harden his son at an early age to the chase or to war. The Carolingian tradition, however, was not totally forgotten by princes and others in high places. In Germany, Otto I and his successors, who wished to recreate the Carolingian Empire, encouraged studies at the court; Wipo, the preceptor of Henry III, set out a program of education for the laity in his *Proverbia*. Rediscovering the ancient moralists, he praised moderation as opposed to warlike brutality or even the ascetic strength of the monks. The same tendency is found in other writings. The rediscovery of the ancient moralists Cicero and Seneca inevitably made itself felt in the program of education that the clergy of the 11th century began to offer the laity.

THE MEDIEVAL RENAISSANCE

The era that has been called the "renaissance of the 12th century" corresponds to a rediscovery of studies originating in the 11th century in a West in the process of transformation. The church cast off the tutelage of lay power, and there was general acceptance of the authority

of the church in matters of belief, conduct, and education; the papacy took over the direction of Christianity and organized the Crusades to the East; the monarchies regrouped the political and economic forces of feudal society; the cities were reanimated and were organized into communes; the merchants traced out the great European trade routes and, before long, the Mediterranean ones. Soon contact with the East, by trade and in the Crusades, and with the highly cultivated Moors in Spain further stimulated intellectual life. Arabic renderings of some of the works of Aristotle, together with commentaries, were translated into Latin, exercising a profound influence on the trend of culture. It was inevitable that the world of education would take on a new appearance.

Changes in the early schools. In the first place, the monastic reformers made the decision to close their schools to those who did not intend to enter upon a cloistered life. According to their idea of solitude and sanctity, recalling the words of St. Jerome, "the monk was not made to teach but to mortify himself." Divine works were to be the only object of study and meditation, and Pierre de Celle asserted that "divine science ought to mould rather than question, to nourish conscience rather than knowledge."

The scholarly monks completed their studies before being admitted to the monastery—the age of entrance, for instance, being fixed at 15 years at Cîteaux and 20 years at Cluny. If there were admitted a few oblates (laymen living in monasteries under modified rules), they were given an ascetic and moral education and were taught to read the Holy Writ and, what was still more desirable, to "relish" it. In the Carthusian monastery the four steps of spiritual exercise were reading, meditation, prayer, and contemplation. Thus, there existed a monastic culture, but there were no truly monastic studies such as existed in the 9th and 10th centuries. The rich libraries of the monasteries served only a few scholarly abbots, while the monks searched for God through prayer and asceticism.

In the cities, on the contrary, the schools offered to all the clergy who so desired the means of satisfying their intellectual appetite. More and more of them attended these schools, for the studies were a good means of social advancement or material profit. The development of royal and municipal administrations offered the clergy new occupations. Hence the success of the schools for notaries and the schools of law and rhetoric. These schools were organized under the protection of the collegiate churches and the cathedrals. The schools for secular subjects were directed by an archdeacon, chancellor, cantor, or cleric who had received the title of *scholasticus*, *caput scholae*, or *magister scholarum* and who was assisted by one or more auxiliary masters. The success of the urban schools was such that it was necessary, in the middle of the 12th century, to define the teaching function. Only those could teach who were provided with the *licencia docendi* conferred by the bishop or, more often, by the *scholasticus*. Those who were licensed taught within the limits of the city or the diocese, whose clerical leaders supervised this monopoly and intervened if a cleric set himself up as master without having the right. The popes were sufficiently concerned about licensing that the Lateran Council of 1179 gave this institution universal application.

Study of the liberal arts and philosophy

The pupils who attended these urban schools learned in them their future occupation as clerics; they learned Latin, learned to sing the service, and were initiated into Holy Writ. The more gifted ones extended their studies further and applied for admission to the liberal arts (the trivium, made up of grammar, rhetoric, and logic; and the quadrivium, including geometry, arithmetic, music, and astronomy) and, upon completion of the liberal arts, to philosophy. Philosophy had four branches: theoretical, practical, logical, and mechanical. The theoretical was divided into theology, physics, and mathematics; the practical consisted of morals or ethics (personal, economic, political). The logical, which concerned discourse, consisted of the three arts of the trivium. Finally, the mechanical included the work of processing wool, of navigation, of agriculture, of medicine, and so on. This was an ambitious humanistic program. In fact, the students became specialized in the study of one art or another according to their tastes or the presence of a renowned master, such as Guillaume de Champeaux at Paris and St. Victor for rhetoric and theology; Peter Abelard at Paris for dialectic and theology; Bernard de Chartres for grammar; William of Conches at Chartres for grammar, ethics, and medicine; Thierry de Chartres for rhetoric. In particular teachers of the "literary" arts, grammar and rhetoric, always had great success in a period of enthusiasm for the ancient authors. It may be noted that Bernard de Chartres organized his literary teaching in this fashion: grammatical explanations (*declinatio*), studies of authors, and each morning the correction of the exercises given the day before.

The third art of the trivium, logic (or dialectics), was nevertheless a strong competitor of the other two, grammar and rhetoric. Since the 11th century, Aristotle's *Posterior Analytics*, translated centuries earlier by Boethius, had developed the taste for reasoning, and, by the time that Abelard arrived in Paris around 1100, interest in dialectics was flourishing. The written words of the Scriptures and of the Fathers of the Church were to be subjected to the scrutiny of human reason; a healthy skepticism was to be the stepping-stone to knowledge, aided by an understanding of critical logic. While dialectic—or logic—reigned in Paris, the masters at Chartres offered a study of the whole of the quadrivium—arithmetic, music, geometry, and astronomy. This interest in the sciences, which had been manifest at Chartres since the early 11th century, had been favoured by the stimulus of Greco-Arabic translations. The works of Euclid, Ptolemy, Hippocrates, Galen, and other Hellenic and Hellenistic scholars, as preserved in the Arabic manuscripts, were translated in south Italy, Sicily, and Spain and were gradually transmitted north. The scientific revival allowed the Chartrians to Christianize Greek cosmology, to explain Genesis according to physics, and to rediscover nature. Another discovery was that of law. The conflicts in the second half of the 12th century between the church and the lay powers encouraged on both sides a new activity in the juridical field. The princes found in the Corpus Juris Civilis, the 6th-century Roman code of the emperor Justinian, the means of legitimizing their politics, and the papacy likewise used Roman sources to promote its claims.

The development of the universities. At the end of the 12th century, the multiplicity of students and masters, their rivalries, and the conflicts in which they opposed the religious and civil authorities obliged the world of education to reorganize. To understand the reorganization, one must review the various stages of development in the coming together of students and masters. The first stage, already alluded to, occurred when the chancellor of a cathedral or some other authority began to accord to other masters permission to open other schools than the episcopal school in the neighbourhood of his church. A further stage was reached when a license to teach—granted only after a formal examination—empowered a master to carry on his vocation at any similar centre.

The *studia generalia* and the *universitas*

A further development came when it began to be recognized that, without a license from pope, emperor, or king, no *studium generale* could be formed possessing the right of conferring degrees, which originally meant nothing more than licenses to teach.

Students and teachers, as *clerici* ("clerks," or members of the clergy), enjoyed certain privileges and immunities, but, as the numbers travelling to the *studia generalia* increased, they needed additional protection. In 1158 Emperor Frederick I Barbarossa of the Holy Roman Empire granted them privileges such as protection against unjust arrest, trial before their peers, and permission to "dwell in security." These privileges were subsequently extended and included protection against extortion in financial dealings and the *cessatio*, or the right to strike, discontinue lectures, and even to secede to protest against grievances or interference with established rights.

In the north of Europe licenses to teach were granted

by the chancellor, *scholasticus*, or some other officer of a cathedral church; in the south it is probable that the guilds of masters (when these came to be formed) were at first free to grant their own licenses, without any ecclesiastical or other supervision. Gradually, however, toward the end of the 12th century, a few great schools claimed, from the excellence of their teaching, to be of more than merely local importance. In practice, a doctor of Paris or Bologna would be allowed to teach anywhere; and those great schools began to be known as *studia generalia;* that is, places resorted to by scholars from all parts. Eventually the term came to have a more definite and technical significance. The emperor Frederick II in 1225 set the example of attempting to confer upon his new school at Naples, by an authoritative bull, the prestige that the earlier *studia* had acquired by reputation and general consent. Pope Gregory IX did the same for Toulouse in 1229, and he added to its original privileges in 1233 a bull by which anyone who had been admitted to the doctorate or mastership in that university should have the right to teach anywhere without further examination. Other *studia generalia* were subsequently founded by papal or imperial bulls, and in 1292 even the oldest universities, Paris and Bologna, found it desirable to obtain similar bulls from Pope Nicholas IV. From this time the notion began to prevail that the essence of the *studium generale* was the privilege of conferring a universally valid teaching license and that no new *studium* could acquire that position without a papal or imperial bull. There were, however, a few *studia generalia* (such as Oxford) the position of which was too well established to be seriously questioned, although they had never obtained such a bull; these were held to be *studia generalia* by repute. A few Spanish universities founded by royal charter were held to be *studia generalia* for the kingdom.

The word *universitas* originally applied only to the scholastic guild (or guilds)—that is, the corporation of students and masters—within the *studium*, and it was always modified, as *universitas magistrorum*, or *universitas scholarium*, or *universitas magistrorum et scholarium*. In the course of time, however, probably toward the latter part of the 14th century, the term began to be used by itself, with the exclusive meaning of a community of teachers and scholars whose corporate existence had been recognized and sanctioned by civil or ecclesiastical authority.

The Italian universities. The earliest *studia* arose out of efforts to provide instruction beyond the range of the cathedral and monastic schools for the education of priests and monks. Salerno, the first great *studium*, became known as a school of medicine as early as the 9th century, and, under the teaching of Constantine the African (died 1087), its fame spread throughout Europe. In 1231 it was licensed by Frederick II as the only school of medicine in the kingdom of Naples. It remained a medical school only.

The Bologna prototype of universities

The great revival of legal studies that took place at Bologna about the year 1000 had been preceded by a corresponding activity at Pavia and Ravenna. In Bologna a certain Pepo was lecturing on parts of the Corpus Juris Civilis about the year 1076. The secular character of this new study and its close connection with the claims and prerogatives of the Western emperor aroused papal suspicion, and for a time Bologna and its students were regarded by the church with distrust. The students found their first real protector in the emperor Frederick I Barbarossa. The immunities and privileges he conferred eventually extended to all the other universities of Italy.

The first university of Bologna was not constituted until the close of the 11th century—the "universities" there being student guilds, formed to obtain by combination that protection and those rights that they could not claim as citizens. As the number of students increased, the number of *universitates*, or societies of scholars, increased, each representing the national origin of its members (France, England, Provence, Spain, Italy). The practice at Bologna was adopted as other *studia generalia* arose.

These confederations were presided over by a common head, the *rector scholarium*, and the different nations were represented by their *consiliarii*, a deliberative assembly with which the rector habitually took counsel. The students at Bologna were mostly of mature years. As the civil law and the canon law were, at first, the only branches of study, the class they attracted was often composed of men already filling office in some department of the church or state—archdeacons, heads of schools, canons of cathedrals, and like functionaries.

About 1200 the two faculties of medicine and philosophy were formed. The former was developed by a succession of able teachers, among whom Thaddeus Alderottus was especially eminent. The faculty of arts, down to the 14th century, scarcely attained equal eminence.

The term college at Bologna long had a different meaning from the ordinary modern one. The masters formed themselves into *collegia* (that is, organizations), chiefly for the conferment of degrees. Places of residence for students existed at Bologna at a very early date, but it was not until the 14th century that they possessed any organization; the humble *domus*, as it was termed, was at first designed solely for necessitous students who were not natives of Bologna; a separate house, with a fund for the maintenance of a specified number of scholars, was all that was originally contemplated.

From the 13th to the 15th century a number of universities in Italy originated from migrations of students; others were established by papal or other charters. Almost all the schools taught civil or canon law or both. Of these institutions the most important were Padua, Piacenza, Pavia, Rome, Perugia, Pisa, Florence, Siena, and Turin.

The Paris prototype of universities

The French universities. The history of the University of Paris well illustrates the fact that the universities arose in response to new needs. The schools out of which the university arose were those attached to the cathedral on the Île de la Cité and presided over by its chancellor. Although, in the second decade of the 13th century, some masters placed themselves under the jurisdiction of the abbot of the monastery of Sainte-Geneviève on the Left Bank of the Seine, it was around the bestowal of the license by the chancellor of Notre Dame that the university grew up. It is in this license that the whole significance of the master of arts degree was contained; for admission to that degree was the receiving of the chancellor's permission to "incept"; and by "inception" was implied the master's formal entrance upon the functions of a duly licensed teacher and his recognition as such by his brethren in the profession. The stage of bachelordom had been one of apprenticeship for the mastership; and his emancipation from this state was symbolized by the placing of the magisterial cap (biretta) upon his head. The new master gave a formal inaugural lecture, and he was then welcomed into the society of his professional brethren with set speeches and took his seat in his master's chair.

Some time between 1150 and 1170 the University of Paris came formally into being. Its first written statutes were not, however, compiled until about 1208, and it was not until long after that date that it possessed a "rector." Its earliest recognition as a legal corporation belongs to about the year 1211, when a brief of Innocent III empowered it to elect a proctor to be its representative at the papal court. With papal support Paris became the great trans-Alpine centre of orthodox theological teaching. Successive pontiffs, down to the Great Schism of 1378, cultivated friendly relations with the university and systematically discouraged the formation of theological faculties at other centres. In 1231 Gregory IX, in the bull *Parens Scientiarum* ("Mother of Learning"), gave full recognition to the right of the several faculties to regulate and modify the constitution of the university. The fully developed university was divided into four faculties: three superior, those of theology, canon law, and medicine; and one inferior, that of arts, which was divided into four nations (French, Picard, Norman, and English), which included both professors and scholars from the respective countries. The head of each faculty

was the dean; of each nation, the proctor. The rector, in the first instance head of the faculty of arts, eventually became the head of the collective university.

After the close of the Middle Ages, Paris came to be virtually reduced to a federation of colleges, though at Paris the colleges were less independent of university authority than was often the case elsewhere. Other major French universities of the Middle Ages were Montpellier, Toulouse, Orléans, Angers, Avignon, Cahors, Grenoble, Orange, and Perpignan.

The English offshoots of Paris: Oxford and Cambridge

The English universities. The University of Paris became the model for French universities north of the Loire and for those of central Europe and England; Oxford would appear to have been the earliest. Certain schools, opened early in the 12th century within the precincts of the dissolved nunnery of St. Frideswide and of Oseney Abbey, are supposed to have been the nucleus around which it grew. But the beginning may have been a migration of English students from Paris about 1167 or 1168. Immediately after 1168, allusions to Oxford as a *studium* and a *studium generale* begin to multiply. In the 13th century, mention first occurs of university "chests," which were benefactions designed for the assistance of poor students. Halls, or places of licensed residence for students, also began to be established. Against periodic vicissitudes such as student dispersions and plagues, the foundation of colleges proved the most effectual remedy. The earliest colleges were University College, founded in 1249, Balliol College, founded about 1263, and Merton College, founded in 1264.

The University of Cambridge, although it came into existence somewhat later than Oxford, may reasonably be held to have had its origin in the same century. In 1112 the canons of St. Giles crossed the River Cam and took up their residence in the new priory in Barnwell, and their work of instruction acquired additional importance. In 1209 a body of students migrated there from Oxford. Then about 1224 the Franciscans established themselves in the town and, somewhat less than half a century later, were followed by the Dominicans. At both the English universities, as at Paris, the mendicants and other religious orders were admitted to degrees, a privilege that, until the year 1337, was extended to them at no other university. Their interest in and influence at these three centres were consequently proportionately great.

In 1231 and 1233 royal and papal letters afford satisfactory proof that the University of Cambridge was already an organized body, with a chancellor at its head.

Although both Oxford and Cambridge were modelled on Paris, their higher faculties never developed the same distinct organization; and, while the two proctors at Cambridge originally represented north and south, the nations are scarcely to be discerned. An important step was made, however, in 1276, when an ordinance was passed requiring that everyone who claimed to be recognized as a scholar should have a fixed master within 15 days after his entry into the university. The traditional constitution of the English universities was, in its origin, an imitation of the Parisian, modified by the absence of the cathedral chancellor. But the feature that most served to give permanence and cohesion to the entire community at Cambridge was, as at Oxford, the institution of colleges. The earliest of these was Peterhouse, in 1284. All the early colleges were expressly designed for the benefit of the secular clergy.

Universities elsewhere in Europe. From the 13th to the 15th centuries, *studia generalia* or universities proliferated in central and northern Europe and were usually modelled on the University of Paris. Although the earliest was Prague, which existed as a *studium* in the 13th century and was chartered by Pope Clement VI in 1348, perhaps no medieval university achieved a more rapid and permanent success than Heidelberg. The University of Heidelberg, the oldest in the German realm, received its charter in 1386 from Pope Urban VI as a *studium generale* and contained all the recognized faculties—theology, canon law, medicine, and the arts, as well as civil law. In the subsequent 100 years, universities were founded at Cologne, Erfurt, Leipzig, Rostock, Freiburg, Tübingen, Ofen (Budapest), Basel, Uppsala, and Copenhagen.

Higher education in Spain

Spain was also an important scene of developments in higher education. Valladolid received its charter in 1346 and attained great celebrity after it obtained the rank of *studium generale* and a *universitas theologiae* by a decree of Pope Martin V in 1418. Salamanca was founded in 1243 by Ferdinand III of Castile with faculties of arts, medicine, and jurisprudence, to which theology was added through the efforts of Martin V. The College of St. Bartholomew, the earliest founded at Salamanca, was noted for its ancient library and valuable collection of manuscripts. Other important early Spanish and Portuguese schools were Seville, Alcalá, and Lisbon.

General characteristics of medieval universities. Generally speaking, the medieval universities were conservative. Alexander Hegius and Rudolf Agricola carried on their work as reformers at places such as Deventer, in the Netherlands, remote from university influences. A considerable amount of mental activity went on in the universities; but it was mostly of the kind that, while giving rise to endless controversy, turned upon questions in connection with which the implied postulates and the terminology employed rendered all scientific investigation hopeless. At almost every university the Realists and Nominalists represented two great parties occupied with an internecine struggle (see EPISTEMOLOGY).

In Italian universities such controversies were considered endless and their effects pernicious. It was resolved, accordingly, to expel logic and allow its place to be filled by rhetoric, thereby effecting that important revolution in academic studies that constituted a new era in university learning and largely helped to pave the way for the Renaissance. The professorial body in the great Italian universities attained an almost unrivalled reputation throughout Europe. For each subject of importance there were always two, and sometimes three, rival chairs. While other universities became sectarian and local, those of Italy continued to be universal, and foreigners of all nations could be found among the professors.

Student life and studies

The material life of the students was difficult. In order to aid the poorest, some colleges founded by clerical or lay benefactors offered board and lodging to a number of foundationers. Courses, too, could occasionally be difficult. The courses in theology were particularly long —eight years at the minimum (one could not be a teacher of theology in Paris before the age of 35). Many students preferred the more rapid and more lucrative paths of law and medicine. Others led the life of perpetual students, of vagabond clerics, disputatious goliards, the objects of repeated but ineffectual condemnation.

The methods of teaching are particularly well-known in the case of Paris. The university year was divided into two terms: from St. Remi (October 1) to Lent and from Easter to St. Pierre (June 29). The courses consisted of lectures (*collatio*), but more often of explications of texts (*lectio*). There were also discussions and question periods. Examinations were given at the end of each term. The student could receive three degrees: the *determinatio*, or baccalaureate, gave him the right to teach under the supervision of a master; the *licencia docendi* was literally the "license to teach" and could be obtained at 21 years of age; then there was the doctorate, which marked his entrance into mastership and which involved a public examination.

Lay education and the lower schools. The founding of universities was naturally accompanied by a corresponding increase in schools of various kinds. In most parts of western Europe, there were soon grammar schools of some type available for boys. Not only were there grammar schools at cathedrals and collegiate churches, but many others were founded in connection with chantries and craft and merchant guilds and a few in connection with hospitals. It has been estimated, for example, that, toward the close of the Middle Ages, there were in England and Wales, for a population of about 2,500,000, approximately 400 grammar schools, rather better provision than in Victorian days of the 19th century. Knowl-

Early grammar schools

edge of the teaching provided in the grammar schools at this period is too slight to justify an attempt at a description. No doubt the curriculum varied, but religion was all-important, with Latin as a written and spoken language the other major element in the timetable. There might have been instruction in reading and writing in the vernacular, but, in addition to the grammar schools, there were writing and song schools and other schools of an elementary type. Elementary teaching was given in many churches and priests' houses, and children who did not receive formal scholastic instruction were given oral teaching by parish priests in the doctrines and duties of the faith. The evidence of accounts, bills, inventories, and the like suggests that there was some careful teaching of writing and of an arithmetic that covered the practical calculations required in ordinary life.

Girls were sometimes taught in nunneries, but usually in the home, and those of the upper classes, at least, generally learned to read, write, and keep accounts, to perform household duties, and to obtain such elementary medical knowledge as might be helpful when called on to treat minor accidents or ailments. For young and grown-up alike, there was much that was educative in medieval society, and the influence of the community life of church, guild, and village was an important factor. Medieval education had many shortcomings, and its benefits were too often confined to a few; but on the whole the mass of the people were by no means sunk in brutish ignorance. The number of people who could read the vernacular, as evidenced by the demand for books in the vulgar tongue as soon as printing made them available, is proof that the latter part of the Middle Ages was certainly not a time of general illiteracy.

In fulfillment of its responsibility for education, the church from the 11th century onward made the establishment of an effective education system a central feature of ecclesiastical policy. During the papacy of Gregory VII (1073–85), all bishops had been asked to see that the art of grammar was taught in their churches, and a Lateran Council in 1215 decreed that grammar school masters should be appointed not only in the cathedral church but also in others that could afford it. Solicitude at the centre for the advancement of education did not, however, result in centralized administration. It was the duty of bishops to carry out approved policy, but it was left to them to administer it, and they in turn allowed schools a large measure of autonomy. Such freedom as medieval schools enjoyed was, however, always subject to the absolute authority of the church, and the right to teach, as earlier noted, was restricted to those who held a bishop's license. This device was used to ensure that all teachers were loyal to the doctrines of the church.

Training for feudalism

In medieval society there was an entirely different training for boys of high rank, and this created a cultural cleavage. Instead of attending the grammar school and proceeding to a university, these boys served as pages and then as squires in the halls and castles of the nobility, there receiving prolonged instruction in chivalry. The training was designed to fit the noble youth to become a worthy knight, a just and prudent master, and a sensible manager of an estate. Much of this knowledge was gained from daily experience in the household, but, in addition, the page received direct instruction in reading and writing, courtly pastimes such as chess and playing the lute, singing and making verses, the rules and usages of courtesy, and the knightly conception of duty. As a squire he practiced more assiduously the knightly exercises of war and peace and acquired useful experience in leadership by managing large and small bodies of men. But this was a type of education that could flourish only in a feudal society; and, though some of its ideals survived, it was outmoded when feudalism was undermined by the growth of national feeling. (P.R./Ed.)

V. Education in Asian civilizations: c. 700 to the eve of Western influence

INDIA

During its medieval period, India was ruled by dynasties of Muslim culture and religion. Muslims from Arabia first appeared in the country in the 8th century, but the foundation of their rule was laid much later by Muḥammad Ghūri, who established his power at Delhi in 1192. The original Muslim rule was replaced successively by that of the Muslim Pashtuns and Mughals.

The foundations of Muslim education. Muslim educational institutions were of two types—a *maktab*, or elementary school, and a *madrasah*, or institution of higher learning. The content of education imparted in these schools was not the same throughout the country. It was, however, necessary for every Muslim boy at least to attend a *maktab* and to learn the necessary portions of the Qur'ān required for daily prayers. The curriculum in the *madrasah* comprised Ḥadīth (the study of Muslim traditions), jurisprudence, literature, logic and philosophy, and prosody. Later on, the scope of the curriculum was widened, and such subjects as history, economics, mathematics, astronomy, and even medicine and agriculture were added. Generally, all the subjects were not taught in every institution. Selected *madrasas* imparted postgraduate instruction, and a number of towns—Āgra, Badaun, Bīdar, Delhi, Jaunpur, and a few others—developed into university centres to which students flocked from far and wide for study under renowned scholars. The sultans and *amīrs* of Delhi and the Muslim rulers and nobles in the provinces also extended patronage to Persian scholars who came to their courts from other parts of Asia under the pressure of Mongol inroads. Delhi vied with Baghdad and Cordova as an important centre of Islāmic culture. Indian languages also received some attention. The Muslim rulers of Bengal, for example, engaged scholars to translate the Hindu classics, the *Rāmāyaṇa* and the *Mahābhārata*, into Bengali.

Developments under the Pathans

Under the Pathan Lodis, a dynasty of Afghan foreigners (1451–1526), the education of the Hindus was not only neglected but was often adversely affected in newly conquered territories. The rulers generally tolerated Sanskrit and vernacular schools already in existence but did not help the existing ones with money or build new ones. At early stages, the *maktabs* and *madrasas* were attended by Muslims only. Later, when Hindus were allowed into high administrative positions, Hindu children began to receive Persian education in Muslim schools.

The Mughal period. The credit for organizing education on a systematic basis goes to Akbar the Great (lived 1542–1605), a contemporary of Queen Elizabeth I of England and undoubtedly the greatest of Mughal emperors. He treated all his subjects alike and opened a large number of schools and colleges for Muslims as well as for Hindus throughout his empire. He also introduced a few curricular changes, based on students' individual needs and the practical necessities of life. The advanced curriculum included ethics, arithmetic, astronomy, geometry, agriculture, economics, public administration, natural philosophy, abstract mathematics, divinity, and history. The scope of the curriculum was so widened as to enable every student to receive education according to his religion and views of life. The adoption of Persian as the court language gave further encouragement to the Hindus and the Muslims to study Persian.

Akbar's policy was continued by his successors Jahāngīr and Shāh Jahān. But his great-grandson Aurangzeb (1618–1707) changed his policy with regard to the education of the Hindus. In April 1669, for instance, he ordered the provincial governors to destroy Hindu schools and temples within their jurisdiction; and, at the same time, he supported Muslim education with a certain religious fanaticism. After his death, the glory of the Mughal Empire began gradually to vanish, and the whole country was overrun by warlords.

During the Mughal period, girls received their education at home or in the house of some teacher living in close proximity. There were special arrangements for the education of the ladies of the royal household, and some of the princesses were distinguished scholars. Vocational education was imparted through a system of apprenticeship either in the house of *ustāds* (teachers) or in *kārkhānahs* (manufacturing centres).

Muslim rulers of India were also great patrons of litera-

ture and gave considerable impetus to its development. Akbar ordered various Hindu classics and histories translated into Persian. In addition, a number of Greek and Arabic works were translated into Persian. Literary activities did not entirely cease even in the troubled days of later rulers. Men of letters were patronized by such emperors as Bahādur Shāh and Muḥammad Shāh and by various regional officials and landlords.

Such is the history of Muslim education in India. It resembles ancient Indian education to a great extent: instruction was free; the relation between the teachers and the taught was cordial; there were great centres of learning; the monitorial system was used; and people were preoccupied with theology and the conduct of life.

Educational accomplishments of the Muslim period

There were, however, several distinctive features of Muslim education. First, education was democratized. As in mosques, so in a *maktab* or *madrasah*, all were equal, and the principle was established that the poor should also be educated. Second, Muslim rule influenced the system of elementary education of the Hindus, which had to accommodate itself to changed circumstances by adopting a new method of teaching and by using textbooks full of Persian terms and references to Muslim usages. Third, the Muslim period brought in many cultural influences from abroad. The courses of studies were both widened and brought under a humanistic influence. Finally, Muslim rule produced a cross-cultural influence in the country through the establishment of an educational system in which Hindus and Muslims could study side by side and in which there would be compulsory education in Persian, cultivation of Sanskrit and Hindi, and translation of great classics of literature into different languages. Ultimately, it led to the development of a common medium of expression, Urdu.

Education in the Muslim era was not a concerted and planned activity but a voluntary and spontaneous growth. There was no separate administration of education, and state aid was sporadic and unsteady. Education was supported by charitable endowments and by lavish provision for the students in a *madrasah* or in a monastery.

The Muslim system, however, proved ultimately harmful. In the early stages genuine love of learning attracted students to the cultural centres, but later on "the bees that flocked there were pre-eminently drones." The whole system became stagnant and stereotyped as soon as cultural communication was cut off from the outside world because of political disturbances and internecine wars. The Indian teachers were reduced to dependence on their own resources, and a hardening tradition that became increasingly unreceptive to new ideas reduced the whole process to mere routine. (S.N.M.)

CHINA

The T'ang dynasty (AD 618–907). The T'ang was one of China's greatest dynasties, marked by military power, political stability, economic prosperity, and advance in art, literature, and education. It was an age in which Buddhist scholarship won recognition and respect for its originality and high intellectual quality, in which the rise of new sects marked the final integration of Buddhism into Chinese life, and in which China superseded India as the land from which Buddhism was to spread to other countries in East Asia.

The T'ang was known for its literature and art and has been called the Golden Age of Chinese poetry. There were thousands of poets of note who left a cultural legacy unsurpassed in subsequent periods and even in other lands. There also flourished prose writers, whose style was studied by young students all the way down to the 20th century, and artists whose paintings reflected the influences of Buddhism and Taoism.

One of the greatest gifts of China to the world was the invention of printing. Block printing was invented in the 8th century and movable type in the 11th century. The first book printed from blocks was a Buddhist *sūtra*, or set of precepts, in 868. Printing met the demand created by the increase in the output of literature and by the regularized civil-service-examination system. It also met the popular demand for Buddhist and Taoist prayers and charms. One historian (Kenneth Scott Latourette) noted that "as late as the close of the eighteenth century the [Chinese] Empire possibly contained more printed books than all the rest of the world put together."

Education in the T'ang dynasty was under the dominant influence of Confucianism, notwithstanding the fact that Buddhism and Taoism both received imperial favours. An academic-examination system was firmly established, and officials were selected on the basis of civil-service examinations. But Confucianism did not dominate to the extent of excluding other schools of thought and scholarship. Renowned scholars were known to spurn public office because they were not satisfied with the identification of public service with a narrow interpretation of Confucianism. Artists and poets were, in general, rebellious against traditional Confucianism.

An emperor in the 5th century ordered the establishment of a "School of Occult Studies" along with the more commonly accepted schools of Confucian learning. It was devoted to the study of Buddhism and Taoism and occult subjects that transcended the practical affairs of government and society. Such schools were often carried on by the private effort of scholars who served as tutors for interested followers.

School structure in the T'ang era

The schools of T'ang were well organized and systematized. There were schools under the central government, others under local management, and private schools of different kinds. Public schools were maintained in each prefecture, district, town, and village. In the capital were "colleges" of mathematics, law, and calligraphy, as well as those for classical study. There was also a medical school.

Semiprivate schools formed by famous scholars gave lectures and tutelage to students numbering in the hundreds and continued to supplement the public schools. Students from Korea and Japan came to study in China and took back the lunar calendar and the Buddhist sects, as well as the examination system and the Confucian theories of government and social life. Chinese culture also penetrated Indochina.

The examination system was at this time given the form that remained essentially unchanged until the 20th century. Examinations were held on different levels, and for each a corresponding academic degree was specified. Interestingly enough, there was provision for three degrees, not unlike the bachelor's, master's, and doctor's degrees of modern times. The first degree was the *hsiu ts'ai* ("cultivated talent"), the second the *ming ching* ("understanding the classics"), and the third the *chin-shih* ("advanced scholar"). The name of the second degree was in later periods changed to *chü jen* ("recommended man"). An academy of scholars later known as the Hanlin Academy was established for select scholars whom the emperor could call upon for advice and expert opinion on various subjects. Membership in this institution became the highest honour that could be conferred upon those who passed the *chin-shih* degree with distinction. To be appointed a Hanlin scholar was to be recognized as one of the top scholars of the land. Among the services that they rendered were the administration and supervision of examinations and the explanation of difficult texts in literature, classics, and philosophy.

Examinations were given for students of medicine and for military degrees. The study of medicine included acupuncture, massage, and exorcism, as well as the treatment of general diseases of the body and those of eye, ear, throat, and teeth.

The Sung (960–1279). The Sung was another dynasty of cultural brilliance. Landscape painting approached perfection, and cultural achievement was stimulated by the invention of movable type (first made of earthenware, then of wood and metal). This advance from the older method of block printing led to the multiplication of books; the printing of a complete set of the classics was a boon to literary studies in schools.

The rulers of Sung were receptive to new ideas and innovative policies. The outstanding innovator of the dynasty was Wang An-shih, prime minister from 1068 to 1076. He introduced a comprehensive program of re-

form that included important changes in education; more emphasis was subsequently placed on the study of current problems and political economy.

Educational controversy in the Sung era

Wang's reforms met with opposition from conservatives. The controversy was only a phase of a deeper and more far-reaching intellectual debate that made the philosophical contributions of the Sung scholars as significant as those of the Hundred Schools in the Chou dynasty over a millennium earlier. It involved the interpretation of the classics and a re-examination of China's traditional thought. Confucianism and the dominant mode of Chinese thinking had been subject to the challenge of ideas from Legalism, Taoism, and Buddhism, and, despite the resistance of conservatives, the traditional views had to be modified. Outstanding Confucian scholars of conservative bent argued vigorously with aggressive proponents of new concepts of man, of knowledge, and of the universe. The result was Neo-Confucianism, or what some prefer to call rational philosophy. It comprised a reinterpretation of the past, a new formulation of thought, and new directions in scholarship in response to new contacts, fresh ideas, and a bold presentation of opposing views and proposals. The most eminent Neo-Confucianist was Chu Hsi, a Confucian scholar who had studied Taoism and Buddhism. His genius lay in his ability to synthesize ideas from a fresh point of view. Sung scholars distinguished themselves in other fields, too. Ssuma Kuang's *Tzu-chih t'ung-chien* ("Comprehensive Mirror for Aid in Government") was a history of China from the 5th century BC to the 10th century AD. The result of 20 years of painstaking research, it consisted of 1,000 chapters prepared under imperial direction. A volume on architecture was produced that is still used today as a basic reference work, and a treatise on botany contained the most ancient record of varieties of citrus fruits then known in China. No less worthy of mention is an encyclopaedia titled *T'ai-ping yü lan*.

The general pattern of the school system remained essentially the same, with provision for lower schools, higher schools, and technical schools. There was an increase in nonliterary studies and a consequent broadening of the curriculum. A noteworthy development was the rise of a semiprivate institution known as the *shu-yüan*, or academy. With financial support coming from both state grants and private contributions, these academies were managed by noted scholars of the day and attracted many students and lecturers who discoursed on the new ideas of rational philosophy and on subjects not taught in the state schools. Often located in mountain retreats or in the woods, they symbolized the influence of Taoism and Buddhism and a desire to pursue quiet study far away from possible government interference.

The Mongol period (1279–1368). The Mongols were ferocious fighters but inept administrators. Distrustful of the Chinese, they enlisted the services of many nationalities and employed non-Chinese aliens in order to avoid too much dependence on the Chinese. To facilitate the employment of non-Chinese aliens, the civil-service examinations were suspended for a number of years. Later, when a modified form of examinations was in effect, there were special examinations for Mongol candidates to make sure of their admission into high offices.

The Mongols despised the Chinese and placed many limitations on them. Consequently, an aftermath of Mongol rule was a strong antiforeign reaction on the part of the Chinese. The antiforeign reaction was accompanied by an overanxious desire to preserve the Chinese heritage, and the long-range result was an increasing formalism and conservatism that contrasted sharply with the creativity of the Han, the T'ang, and the Sung dynasties.

Despite the setback in Chinese culture under Mongol rule, the period was not devoid of positive cultural development. The increase in foreign contacts as a result of travel to and from China brought new ideas and new knowledge of other lands and other peoples. Mathematics and medicine were further influenced by new ideas from abroad. The classics were translated into the Mongol language, and the Mongol language was taught in schools.

Private schools and the academies of the Sung dynasty became more popular. As a result of a decrease in opportunities for government appointment, scholars were no longer concentrated in the capital city and withdrew into the provinces for study and tutoring. Relieved of the pressure of preparing for the examinations, they applied their talents to the less formal but more popular arts and literary forms, including the drama and the novel. Instead of the classical form, they used the vernacular, or the spoken, language. The significance of this development was not evident until the 20th century, when a "literary revolution" popularized the vernacular tongue.

The Ming period (1368–1644). The Ming dynasty restored Chinese rule. Ming was famous for its ceramics and architecture. There were excellent painters, too, but they were at best the disciples of the T'ang and Sung masters. The outstanding intellectual contribution of the period was the novel. Ming novels continued to be written in the vernacular language and are today recognized as masterpieces of popular vernacular literature. Also of note was the compilation of *Pen-ts'ao kang-mu* ("Great Pharmacopoeia"), a valuable volume on herbs and medicine which was the fruit of 26 years of labour.

The *Yung-lo* encyclopaedia

Of considerable scholarly and educational importance was the *Yung-lo ta-tien* encyclopaedia, which marked a high point in the Chinese encyclopaedic movement. It was a gigantic work resulting from the painstaking efforts of 2,000 scholars over a period of five years. It ran into more than 11,000 volumes, too costly to print, and only two extra copies were made.

The examination system remained basically the same. In the early period of the dynasty, the schools were systematized and regularized. In the latter part of the dynasty, however, the increasing importance of the examination system relegated the schools to a secondary position. The decline of the state-supported schools stimulated the further growth of private education.

The Manchu period (1644–1911). Except for two capable emperors, who ruled for a span of 135 years at the beginning, the Manchu dynasty was weak and undistinguished. Under emperors K'ang-hsi and Ch'ien-lung, learning flourished, but there was little originality. The alien Manchu rulers were so eager to promote Chinese learning that they concentrated on the preservation of what seemed best for stability and the maintenance of the status quo. They ordered new editions of classical and literary works and the preparation of new encyclopaedias. The encyclopaedias, concordances, and dictionaries were the fruits of painstaking labour but were not creative contributions to scholarship.

Distrust of the Chinese by the Manchus and a feeling of insecurity caused the conquerors to erect barriers between themselves and the Chinese. The discriminatory policy was expressed in the administration of the examinations. To assure the appointment of Manchus to government posts, equal quotas were set aside for the Manchus and the Chinese, although the former constituted only about 3 percent of the population. The Chinese thus faced the keenest competition in the examinations, and those who passed tended to be brilliant intellects, whereas the Manchus could be assured of success without great effort.

Schools were encouraged and regulated during the early period of the dynasty. The public school system consisted of schools for nobles, national schools, and provincial schools. Separate schools were maintained for the Manchus, and, for their benefit, Chinese books were translated into the Manchu language. Village and charitable schools were supported by public funds, but they were neglected in later years, so that, by the end of the dynasty, private schools and tutoring had overshadowed them.

At the threshold of the modern era, China had sunk into political weakness and intellectual stagnation. The creativity and originality that had brightened previous periods of history were now absent. Examinations dominated the educational scene, and the content of the examinations was largely literary and classical. Taoism and Buddhism had lost their intellectual vigour, and Confucianism became the unchallenged model of scholarship.

Influence of the examination system

Much could be said for the Chinese examination system at its best. It was instrumental in establishing an intellectual aristocracy whereby the nation could be sure of a cultural unity by entrusting government to scholars reared in a common tradition, nurtured in a common cultural heritage, and dedicated to common ideals of political and social life. It established a tradition of government by civilians and by scholars. It made the scholars the most highly esteemed people of the land. The examinations provided an open road to fame and position. Chinese society was not without classes, but there was a high degree of social mobility, and education provided the opportunity for raising one's position and status. There were no rigid prerequisites and no age limits for taking the examinations. Selection was rigorous, but the examinations were, on the whole, administered with fairness. The names of the candidates did not appear on the examination papers, and the candidates were not permitted to have any outside contacts while writing them.

Nevertheless, the system had serious drawbacks. The content of the examinations became more and more limited in scope. The Confucianist classics constituted the core, and a narrow and rigid interpretation prevailed. In early times Chinese education was broad and liberal, but, by the 19th century, literary ability and knowledge of the classics had become practically the sole concern of the examinations and of education. Art, music, and science had been dropped on the wayside; even arithmetic was not accorded the same importance as reading and writing. Modern science and technology were completely neglected.

Time was when higher criticism was practiced by eminent scholars, but after alien rule by the Mongols the Chinese were so obsessed with the restoration of their heritage that they bent over backward to preserve the past and to avoid deviating from established forms and views. This conservatism was accentuated under Manchu rule and resulted in sterility and stagnation. The creativity and original spirit of classical education was lost. From the standpoint of the new needs of the 19th century, the narrow curriculum was far removed from the pressing problems of changing times. (T.H.C.)

JAPAN

The ancient period to the 12th century. The Japanese nation seems to have formed a unified ancient state in the 4th century AD. Society at that time was composed of *shizoku*, or "clans," each of which served the *chōtei* ("the Imperial court") with its specialized skill or vocation. People sustained themselves by engaging in agriculture, hunting, and fishing, and the chief problem of education was how to convey the knowledge of these activities and provide instruction in the skills useful for these occupations.

Influence of Chinese and Indian civilization

The influence in Japan of the civilizations of China and India had a profound effect on both the spiritual life and the education of the Japanese. Toward the 6th century the assimilation of Chinese civilization became more and more rapid, particularly as a result of the spread of Confucianism. Buddhism was also an important intellectual and spiritual influence. Originating in India and then spreading to China, Buddhism was transmitted to Japan through the Korean peninsula in the mid-6th century.

A monarchic state system with an emperor as its head was established following a coup d'etat in 645. The subsequent Taika (Great Reform) era saw the beginning of many new institutions, most of which were primarily imitations of institutions of the T'ang dynasty of China. In the field of education, a *daigakuryō*, or college house, was established in the capital, and *kokugaku*, or provincial schools, were built in the provinces. The chief aim, however, was to train government officials. The early curriculum was almost identical to that of the T'ang dynasty of China but by the 8th and 9th centuries had been modified considerably to meet internal conditions, particularly as regards the educational needs of the nobility.

Through the Nara and the Heian eras (8th to 12th centuries), the nobility (*kuge*) constituted the ruling class, and learning and culture were the concern primarily of the *kuge* and the Buddhist monks. The nobility lived an artistic life, so that the emphasis of education came to be placed on poetry, music, and calligraphy. Teaching in the *daigakuryō* gradually shifted in emphasis from Confucianism to literature, since the *kuge* set a higher value on artistic refinement than on more spiritual endeavours. Apart from the *daigakuryō*, other institutions were established in which families of influential clans lodged and developed their intellectual lives.

The feudal period (1192-1867). *Education of the warriors.* Toward the mid-12th century political power passed from the nobility to the *buke*, or warrior, class. The ensuing feudal period in Japan dates from the year 1192 (the establishment of the Kamakura shogunate) to 1867 (the decline of the Tokugawa shogunate).

The warrior's way of life was quite unlike that of the nobility, and the aims and content of education in the warrior's society inevitably differed. The warrior had constantly to practice military arts, hardening his body and training his will. Education was based on military training, and a culture characteristic of warriors began to flourish.

Some emphasis, though, was placed on spiritual instruction. The warrior society, founded on firm master–servant relations and centring on the philosophy of Japanese family structure, set the highest value on family reputation and on genealogies. The military arts also proved insufficient to enable warriors to grasp political power and thereby maintain their ruling position. There thus arose a philosophy of *bumbu-kembi*, which asserted the desirability of being proficient in both literary and military arts. The children of warriors attended temples and rigorously trained their minds and wills. Reading and writing were the main subjects.

Temples were the centres of culture and learning and can be said to have been equivalent to universities, in that they provided a meeting place for scholars and students.

Education in the temple, originally aimed at instructing novitiates, gradually changed its character, eventually providing education for children not destined to be monks. Thus, the temples functioned as institutions of primary education.

Education in the Tokugawa era. In 1603 a shogunate was established by a warrior, Tokugawa Ieyasu, in the city of Edo (present Tokyo). The period thence to the year 1867, the Tokugawa, or Edo, era, constitutes the later feudal period in Japan. This era, though also dominated by warriors, differed from former ones in that internal disturbances finally ended, and long-enduring peace ensued. There emerged a merchant class that developed a flourishing commoner's culture. Schools for commoners thus were established.

Temple schools of the Tokugawa period

Representative of such schools were the *terakoya* (temple schools), deriving from the earlier education in the temple. As time passed, some *terakoya* used parts of the houses of commoners as classrooms. As private-run schools designed to provide elementary education, the *terakoya* developed rapidly after the middle years of the Tokugawa era. At the end of the period, such schools flourished not only in the major cities but also in every town and village throughout the country. An increasing number of schools came to teach arithmetic as well as reading and writing and assumed the characteristics of the modern primary school. Pupils counted on a soroban, or abacus, in the arithmetic lesson.

The shogunate supported Confucianism as the highest learning and established shogunate-administered schools. Learning was encouraged among shogunal retainers. *Han*, or feudal clans, following the same policy, built schools in their castle towns for the education of their own retainers.

The warriors' schools were at the apex of the educational system in the Tokugawa era. One of them, the Confucian Academy, was administered directly by the shogunate, becoming a model that the feudal clans throughout Japan followed in establishing their *hankō*, or clan schools. It also functioned as the teachers' training school for *hankō* and survived, until the decline of the shogunate, as the highest seat of learning in the nation.

Feudal clan schools

The heads of the feudal clans invited Confucianists and strategists to their courts, encouraged learning among retainers, and established schools in their castle towns. The *hankō* were directly controlled by the clans and, though few in number at the beginning, gradually spread after about 1750, so that by the end of the era they numbered over 200.

The curriculum in the *hankō* consisted chiefly of *kangaku* (the study of books written in Chinese) and, above all, of Confucianism. Classics of Confucianism, historical works, and anthologies of Chinese poems were used as textbooks. Brush writing, *kokugaku* (study of thought originating in Japan), and medicine were also included. Later, in the last days of the shogunate, *yōgaku* or Western studies and Western medicine were added in several institutions.

Both *hankō* for warriors and *terakoya* for commoners were the typical schools after the middle of the Tokugawa era. Also to be found, however, were *gōgaku*, or provincial schools. They were founded at places of importance in the domain of every clan. Some *gōgaku* were the schools for warriors, but the others were for commoners.

Effect of early Western contacts. The Europeans who first arrived in Japan were the Portuguese, in 1543. In 1549 the Jesuit Francis Xavier visited Japan, and, for the first time, the propagation of Christianity began. Many missionaries began to arrive, Christian schools were built, and European civilization was actively introduced.

In 1633 the shogunate, in apprehension of further Christian infiltration of Japan, banned foreign travel and prohibited the return of overseas Japanese. Further, in 1639, the shogunate banned visits by Europeans. This was the so-called *sakoku*, or period of national isolation. From that time on Christianity was strictly forbidden, and international trade was conducted only with the Chinese and the Dutch.

The *sakoku* policy restricted contact with Europeans to the Dutch only, and, accordingly, Western studies developed as *rangaku*, or learning through the Dutch language.

It is noteworthy that the Tokugawa period laid the foundation of modern Japanese learning. As a result of the development of *hanko* and *terakoya*, Japanese culture and education had developed to such an extent that Japan was able to absorb Western influences and attain modernization at a remarkably rapid pace after the Meiji Restoration of 1868. (A.Na.)

VI. European Renaissance and Reformation

THE CHANNELS OF DEVELOPMENT IN RENAISSANCE EDUCATION

The Arabic influence. The civilization of the Arabs, which flourished from the 7th to the 15th centuries, had a great influence on European Humanism. Early on they had translated works of science and philosophy from Greek, Syriac, ancient Persian, and Hindi. Astronomy came to them from the Greco-Egyptian tradition and mathematics from the Indians, but they then made original contributions to these fields, as well as to medicine, in which their work had far-reaching effects.

In 1056 Constantine the African came from the Muslim city of Carthage in North Africa to Monte Cassino near Rome, where he organized a centre for the translation from Arabic into Latin of significant works in philosophy and the sciences, but particularly in medicine. These texts were then used by the recently established medical school in Salerno, which in turn stimulated research in other European centres, principally in medicine but also in other sciences, thus breaking the scientific monopoly that the Arabs had had for some centuries and paving the way for the new outlook on the world that was later to have its full expression in the Humanistic movement and in the Renaissance.

Humanism

The secular influence. The word humanism comes from *studia humanitatis* ("studies of humanity"). Toward the end of the Middle Ages there was a renewed interest in those studies that stressed the importance of man, his faculties, affairs, worldly aspirations, and well-being. The primacy of theology and otherworldliness was over; the *reductio artium ad theologiam* (freely, "reducing everything to theological argument") was rejected since it no longer expressed the reality of the new situation that was developing in Europe, particularly in Italy. Society had been profoundly transformed, commerce had expanded, and life in the cities had evolved. Economic and political power, previously in the hands of the ecclesiastical hierarchy and the feudal lords, was beginning to be taken over by the city burghers. Use of the vernacular languages was becoming widespread. The new society needed another kind of education and different educational structures; the burghers required new instruments with which to express themselves and found the old medieval universities inadequate.

Humanistic thought did not suddenly develop but was anticipated in the 14th century by such writers as Petrarch and Boccaccio. Similarly, the educational institutions of Humanism had their origin in the schools set up in the free cities at the end of the 13th and the 14th centuries—schools designed to answer to the needs of the new urban population that was beginning to have greater economic importance in society. The pedagogical thought of the Humanists took these transformations of society into account and worked out new theories that often went back to the classical Greek and Latin traditions; it was not, however, a servile imitation of the pedagogical thought and institutions of the classical world.

The Renaissance of the classical world and the educational movements it gave rise to were variously expressed in different parts of Europe and at various times from the 14th to the 17th centuries; there was a connecting thread, but there were also many differences. What the citizens of the Florentine Republic needed was different from what was required by princes in the Renaissance courts of Italy or in other parts of Europe. Common to both, however, was the rejection of the medieval tradition that did not belong in the new society they were creating. Yet the search for a new methodology and a new relation with the ancient world was bitterly opposed by the traditionalists, who did not want renewal that would bring about a profound transformation of society; and, in fact, the educational revolution did not completely abolish existing traditions. The Humanists, for example, were not concerned with extending education to the masses but turned their attention to the sons of princes and rich burghers.

The Humanists had the important and original conception that education was neither completed at school nor limited to the years of one's youth but that it was a continuous process making use of varied instruments: companionship, games, and pleasure were part of education. Rather than suggesting new themes, they wanted to discover the method by which the ancient texts should be studied. For them knowledge of the classical languages meant the possibility of penetrating the thought of the past; grammar and rhetoric were being transformed into philological studies not for the sake of pedantic research but in order to acquire a new historical and critical consciousness. They reconstructed the past in order better to understand themselves and their own time.

THE HUMANISTIC TRADITION IN ITALY

Early influences. One of the most influential of early Humanists was Manuel Chrysoloras, who came to Florence from Constantinople in 1396. He introduced the study of Greek and, among other things, translated Plato's *Republic* into Latin, which were important steps in the development of the Humanistic movement.

Inspired by the ancient Athenian schools, the Platonic Academy established in Florence in the second half of the 15th century became a centre of learning and diffusion of Christian Platonism, a philosophy that conceived of all forms as the creative thoughts of God and that inspired considerable artistic innovation and creativity. Marsilio Ficino and Pico della Mirandola were perhaps the most original of the scholars who taught there. Florence was the first city to have such a centre, but Rome and Naples soon had similar academies, and Padua and Venice also became centres of culture.

A famous early Humanist and professor of rhetoric at Padua was Pietro Paolo Vergerio (1370–1444). He wrote the first significant exclusively pedagogical treatise, *De ingenuis moribus et liberalibus studiis* ("On the Manners of a Gentleman and on Liberal Studies"), which, though not presenting any new techniques, did set out the fundamental principles by which education should be guided. He gave pedagogical expression to the ideal of harmony, or equilibrium, found in all aspects of Humanism, and underlined the importance of the education of the body as well as of the spirit. The liberal arts were emphasized ("liberal" because of the liberation they reputedly brought), but the program outlined by Vergerio included mathematics, astronomy, and natural sciences as well as medicine, law, metaphysics, and theology. This did not mean going into each one of these subjects in depth; Humanism was by its nature against encyclopaedism, but it brought out the relations between the disciplines and enabled a man to know many subjects before making a decision as to which one he should dedicate himself to. Learning was not to be exclusively from books, and emphasis was placed on the advantages of preparing for social life by study and discussion in common. Vergerio felt that education should not be used as a means of entering the lucrative professions; medicine and law, in spite of being considered important fields of study, were looked on with suspicion if one's aim in studying them was that of gaining material advantages.

Emphasis on the liberal arts

Humanistic boarding schools. The theory of Humanistic education, written about in many treatises, was given practical expression in a few boarding schools founded and directed by outstanding Humanists. These schools offered a general nonprofessional education and were attended by young men before going to a university. Among the most famous were those of Gasparino Barzizza, Guarino Veronese, and Vittorino da Feltre.

Gasparino Barzizza lived in Padua from 1408 to 1421, and his school was considered a model by many who came after him. The novelty was not so much in its organization as in the high calibre of the Humanists who taught there. The school had a hard struggle, however, because of resistance to the new methods, particularly at the universities.

Barzizza was followed by Guarino Veronese (1374–1460), who opened first a boarding school at Verona and subsequently another one at Ferrara, having been invited by the lord of Ferrara, Nicolò d'Este, to take charge of the education of his son. Guarino wrote no treatises, but something may be learned about his work from his large correspondence and from *De ordine docendi et studendi* (1485; "On the Order for Teaching and Studying"), written by his son Battista. The courses were organized into three stages: the elementary level, at which reading and pronunciation were primarily taught, followed by the grammatical level, and finally the highest level, concentrating on rhetoric. The education given in his schools was perhaps the best example of the Humanistic ideals, since it underlined the importance of literary studies together with a harmonious development of body and spirit, to the exclusion of any utilitarian purpose.

Humanist de-emphasis of "useful" education

Vittorino Rambaldoni da Feltre was a disciple of both Barzizza and Guarino. He started boarding schools at Padua and Venice and, most importantly, in 1423 one at Mantua, where he had been invited by the reigning lord, Gianfrancesco Gonzaga. This last school, known as La Giocosa (literally, the "jocose" or "humorous"), soon became famous. At La Giocosa only those who had both talent and a modest disposition were accepted; wealth was neither necessary nor sufficient to gain admission; in fact, the school was one of the few efforts made during this period to extend education to a wider public. The program of study at La Giocosa was perhaps closer to the medieval tradition than that of the other boarding schools, but, in any case, the spirit was different. Studies were stimulating; mathematics was taught pleasantly—Vittorino going back to very ancient traditions of practicing mathematics with games. After having studied the seven arts of the trivium (grammar, rhetoric, and logic) and the quadrivium (geometry, arithmetic, music, and astronomy), students completed the cycle by a study of philosophy and then, having mastered this discipline, could go on to higher studies leading to such professions as medicine, law, philosophy, and theology. Italian was completely ignored at Vittorino's school; all instruction was given in Latin, the study of which, together with Greek, reached a high level of excellence. Great importance was given to recreation and physical education; his concern for the health of his students did not come to an end with the scholastic year, for during the summers, when the cities became unhealthy, he would arrange for his students to go to Lake Garda or to the hills outside Verona.

Vittorino's educational philosophy was inspired by a profound religious faith and moral integrity, which contrasted with the general relaxation of standards within the church itself; but, if he was severe with himself, he was very open and tolerant with his pupils. The school continued only for a while after his death because, more than in the case of the other schools, La Giocosa was identified with the personality of the founder.

Nonscholastic traditions. Leon Battista Alberti, one of the most intelligent and original architects of the 15th century, also dedicated a treatise, *Della famiglia* (1435–44; "On the Family"), to methods of education. Alberti felt that the natural place for education was the home and not scholastic institutions. The language in which he wrote was Italian, education being in his view so important in social life that he felt that discussion of it should not be limited to scholars. He stressed the importance of the father in the educational process.

Baldassare Castiglione expressed the transition of Humanism from the city to the Renaissance court. He himself was in the service of some of the most splendid princes, the Gonzagas at Mantua and the Montefeltros at Urbino. Just as in the 15th century the Humanists had been concerned with the education of the city burgher, so in the 16th century they turned their attention to the education of the prince and of those who surrounded him. *Il cortegiano* ("The Courtier") was published in 1528, and within a few years it had been translated into Latin and all the major European languages. The courtier was to be the faithful collaborator of the prince. He had to be beautiful, strong, and agile; he had to know how to fight, play, dance, and make love. But this was not all, since great importance was also attached to the study of the classics and the practice of poetry and oratory; the courtier had to be able to write in rhyme and in prose and have perfect command of the vernacular, which was becoming important in political affairs; but above all he had to have skill at arms.

Education of the courtier

The courtier described by Castiglione, though in the service of necessarily devious princes, had to know how to keep his dignity and his virtue. Castiglione's moral standards, reflecting the spiritual climate at Urbino, completely disappeared, however, in Giovanni della Casa's work, *Galateo* (1551–54), in which considerations of etiquette were placed above all others; the values of Humanism no longer existed, and all that was left was ceremonial.

THE HUMANISTIC TRADITION OF NORTHERN AND WESTERN EUROPE

The economic and social conditions behind the intellectual and cultural revolution of Humanism in Italy were also present, though in different forms, in other parts of Europe. In some states, such as England, France, and Spain, Humanism and educational reforms developed around the courts, where political power was being concentrated; in others, such as the Netherlands, they were brought about by the city burghers, whose power, both economic and political, was increasing. The educational reforms that the Humanists brought about in northern and western Europe developed slowly, but on the whole they were lasting, since they affected a greater number of people than was the case in Italy, where they tended to be restricted to a narrow circle of families. There were close relations between Italian and other European educational Humanists, as there were among English, Dutch,

Courtly and bourgeois forms of Humanism

French, and German Humanists, and, thus, national differences were not so significant.

Dutch Humanism. In the Netherlands the ground for educational reform had already been prepared in the 14th century by the Brethren of the Common Life, a group founded by Gerhard Groote to bring together laymen and religious men. Although their work was not originally in the field of education, education started when they set up hostels for students and exercised some moral direction over these students; this work was extended, and the Brethren eventually set up schools, first at Deventer, then in other cities. Some of the most important Humanists of the Netherlands and Germany attended their schools—among others, Erasmus.

The school at Deventer came to have great prestige under Alexander Hegius, rector from 1465 to 1498 and author of a polemic treatise, *De utilitate Graeci* ("On the Usefulness of Greek"), underlining the importance of studying Greek, and of *De scientia* ("On Knowledge") and *De moribus* ("On Manners"). Hegius had great talent as an organizer and succeeded not only in attracting some of the best scholars of the time but also in giving the school an efficient structure that became a model for many schools in the north.

Desiderius Erasmus was a great educator, and his influence was felt all over Europe. His strong personality earned him the respect and sympathy of Humanists who saw in him, as in few others, the symbol of their ideals and values. Unfortunately, his proposals for reform and greater tolerance were not always accepted in the tortured Europe of the 16th century.

Erasmus was a prolific writer, and part of his work was concerned with education: *De ratione studii* (1511; "On the Right Method of Study"), *De civilitate morum puerilium* (1526; "On the Politeness of Children's Manners"), *Ciceronianus* (1528), *De pueris statim ac liberaliter instituendis* (1529; "On the Liberal Education of Boys from the Beginning"). His educational program was original in many ways but in no sense democratic. The masses could not partake in higher education, since their aim was that of gaining skill in an occupation. He felt that religious instruction should be made available to all but that classical literary studies—the most important of all studies—were for a minority.

The classical and elitist tradition in Humanism

Study of ancient languages and intelligent comprehension of texts formed the basis of Erasmus' system of education; he took a stand against the formalism and dogmatism that were already creeping into the Humanist movement. Erasmus was in favour of acquiring a good general liberal-arts education until the age of 18, being convinced that this would be a preparation for any form of further study. His great love for the classical languages, however, made him neglect the vernacular; he was not interested in local traditions; and he attributed very little importance to science, which he did not think necessary for a cultured man. He was against instruction being imposed without the participation of the student. His optimism about the nature of man and the possibilities of molding him made Erasmus feel that, if adequately educated, any man could learn any discipline. He further sought renewal of the schools and better training for teachers, which he felt should be a public obligation, certainly no less important than military defense. Many of Erasmus' themes were elaborated a century later by Comenius and form the basis of modern education, in particular the effort to understand the child psychologically and to consider education as a process that starts before the school experience and continues beyond it.

Juan Luis Vives. Strongly influenced by Erasmus was Juan Luis Vives, who, though of Spanish origin, spent his life in various parts of Europe—Paris, Louvain, Oxford, London, Bruges. His most significant writings were *De institutione foeminae Christianae* (1523; "On the Education of a Christian Woman"), *De ratione studii puerilis* ("On the Right Method of Instruction for Children"), *De subventione pauperum* (1526; "On Aid for the Poor"), and *De tradendis disciplinis* (1531; "On the Subjects of Study").

Not only was his vision of the organic unity of pedagogy new, but he was the first of the Humanists to emphasize the importance of popular education. He felt that it was the responsibility of the city to provide instruction for the poor and that the craft and merchant guilds had an important contribution to make to education. Unlike other Humanists, moreover, he did not despise the utilitarian aspects of education but on the contrary suggested that his pupils should visit shops and workshops and go out into the country to learn something of real life.

The new social and utilitarian traditions

Just as he felt that education should not be limited to a single social class, so he felt that there should be no exclusion of women, though perhaps they required a different kind of education because of their different functions in life.

Vives worked out a plan to take account of both educational structures and teacher training. In emphasizing the social function of education, he was against schools being run for profit and believed that teachers should be prepared not only in their specific fields but also in psychology so as to understand the child. He also suggested that teachers should meet four times a year to examine together the intellectual capacities of each one of their pupils so that suitable programs of study could be arranged for them. Vives considered that, in teaching, games had psychological value. He favoured use of the mother tongue as being simple for the boys to learn; nevertheless, as a Humanist, he had a passion for Latin and felt that there was no substitute for Latin as a universal language. Classical studies were to be completed by investigation of the modern world, in particular its geography, the horizons having been greatly enlarged by recent discoveries. Vives's method was an inductive one, based not on metaphysical theories but on experiment and exercise.

The early English Humanists. At the end of the 15th century there was a flowering in England of both Humanistic studies and educational institutions, enabling a rapid transition from the medieval tradition to the Renaissance. The English Humanists prepared excellent texts for studying the classical languages, and they started a new type of grammar school, long to be a model. Most important were John Colet and Thomas More. Thomas Linacre, author of *De emendata structura latini sermonis libri sex* ("Six Books on the Flawless Structure of the Latin Language"), should also be remembered, as well as William Lily, author of a Latin syntax, *Absolutissimus de octo orationis partium constructione libellus* (1515; "Comprehensive Study of the Construction of the Eight Parts of Speech"), and director of St. Paul's School in London from 1512 to 1522.

The English grammar schools

John Colet has an important place in English education. As dean of St. Paul's Cathedral he founded St. Paul's School, thus favouring the introduction of Humanism in England and the transformation of the old ecclesiastical medieval schools. He had travelled a great deal in France and Italy and wanted to bring to his country the Humanistic culture that had so fascinated him. In 1510 he started a "grammar school," open to about 150 scholars who had an aptitude for study and had completed elementary school. Colet's personality and energy made his school a lively centre of English Humanism.

Thomas More was both a distinguished Humanist and a statesman. He was interested in pedagogy, to which he dedicated part of his work *De optimo reipublicae statu deque nova insula Utopia* (1516; "On the Highest State of a Republic and on the New Island Utopia"). In his Utopia, More saw the connection between educational, social, and political problems and the influence that society therefore has on education. English Humanists such as More were engaged in a bitter battle because medieval tradition was deeply rooted; they were fierce opponents of a group called the Trojans, who opposed the Greek language and all that the new instruction of that language represented.

EDUCATION IN THE REFORMATION AND COUNTER-REFORMATION

New political and social systems developed in those European countries that, for various reasons and at dif-

ferent times, broke away from the Church of Rome in the 16th century. The religious reforms brought about by Luther, Calvin, Zwingli, and the ruling family of England were both cause and effect of these transformations. Characteristic of all these countries was the importance of the state in the organization of the educational system.

Humanism and the Reformation

The Reformation and European Humanism influenced one another. There were analogies between the flowering of the classical world in the European courts and the reawakening of religious interests; there were similarities in the critical position adopted toward Aristotelianism and in the interest shown toward the study of classical languages, such as Greek and Hebrew. The presuppositions behind the two movements—Humanism and Reformation—were different, however, and sooner or later a clash was inevitable. The most spectacular of these clashes was between Erasmus and Luther, despite the fact that for a long time they had respected each other. It was important for Erasmus and for the Humanists to encourage the development of a world of writers and artists who, free from material preoccupations, could devote their time to literary and artistic pursuits. For the Reformers the situation was different: they did not aim to educate a small minority; unlike Erasmus, Luther had to keep the popular masses in mind, for they had contributed to the success of the religious reforms.

Martin Luther and the German Reformation. Martin Luther specifically wished his humble social origins to be considered a title of nobility. He wanted to create educational institutions that would be open to the sons of peasants and miners, though this did not mean giving them political representation. (The German princes were glad to promote the Reformation on condition that it would not diminish but would, on the contrary, increase their political power.) Luther realized that an educational system open to the masses would have to be public and financed by citizens' councils. His educational programs are set out in *An die Radsherrn aller Stedte deütsches Lands: Das sie christliche Schulen affrichten und hallten sollen* (1524; "Letter to the Mayors and Aldermen of All the Cities in Behalf of Christian Schools"), in *Dass man Kinder zur Schulen halten solle* (1530; "Discourse on the Duty of Sending Children to School"), and in various letters to German princes.

Lutheran emphasis on public schools for all

Pre-Reformation schools in Germany had been influenced by the Humanistic movement and had been restricted to rather a narrow circle. As a social reformer, Luther suggested that sons of those lacking means and for whom work was a necessity should spend one or two hours a day at school and the rest of the time at home learning a trade. Luther was thus in favour of limited democratic reforms of the educational system: even though public schools would be open only a few hours, they would be open to all, girls and boys, without reference to the financial situation of the family.

Humanistic schools, whose upkeep was the responsibility of the princes and the cities, were soon organized—on the premise that a new class of cultivated men must be developed to substitute for the dispossessed monks and priests. In 1543 Maurice of Saxony founded three schools open to the public, supported by estates from the dissolved monasteries. It was more difficult to set up the popular schools, for which there was no tradition. In towns and villages of north Germany Johannes Bugenhagen (1485–1558) set up the earliest schools to teach religion and reading and writing in German, but it was not until 1559 that the public ordinances of Württemberg made explicit reference to German schools in the villages. This example was shortly followed in Saxony.

Whereas Luther combined his interest in education with his work as a religious reformer and politician, another Reformer, Philipp Melanchthon (1497–1560), concentrated almost entirely on education, creating a new educational system and, in particular, setting up a secondary school system. He taught for many years at the University of Wittenberg, which became one of the centres of theological studies in Reformation Germany; and his experience there enabled him to reorganize the old universities and set up new ones, such as Marburg, Königsberg, and Jena. His ideas about secondary education were put into practice in the schools he founded at Eisleben. Scholastic work was divided into three stages, access to each successive stage depending on the ability of the student to master the previous course work; this was a new concept (foretelling the later "grading system"), unknown in the traditional scholastic system. He was convinced that too many subjects should not be imposed on the student. He felt that Latin was important, but not German, Greek, or Hebrew, as had been taught in the Humanistic schools; such variety, he felt, was exhausting and possibly harmful. This opened the door to a new type of formalism, however, a danger that in other spheres the educational reformers had tried to fight.

Growing formalism in German schools

The work of Johannes Sturm (1507–89) illustrates this danger. He founded a grammar school in Strassburg that became a model for German schools. Sturm believed that methods of instruction in elementary schools and, to some degree, in secondary schools should be different from those in the institutes of higher education. Not much autonomy was to be allowed the child, who started learning Latin at the age of six by memorizing. Sturm's love of Latin was even greater than that of his friend Erasmus, who never wanted it to become a mechanical exercise. As a consequence, German was neglected, as was physical instruction, and too much importance was given to form and expression for its own sake.

The work of Valentin Friedland, known as Trotzendorf (1490–1556), was interesting in a different way. He founded a grammar school at Goldberg, where he tried to put into practice Luther's idea that school should be enjoyable. His school did not limit itself to instruction but was run like an autonomous society.

The English Reformation. The separation of the Church of England from the Church of Rome in the 16th century under Henry VIII did not have quite the repercussions in the scholastic field that were experienced by the continental Reformations. The secondary school system in England had been strongly influenced by the Renaissance in the period preceding the reform, and about 300 grammar schools were already in existence. Nevertheless, the situation became precarious, for political reasons, under a succession of sovereigns.

Henry VIII included the schools in his policy of concentration and consolidation of power in the hands of the state. In 1548, under Henry's son Edward VI, the Chantries Act was passed, confiscating the estates of the church expressly for use in education; but the turmoil of the times, under the boy Edward and then his Catholic sister Mary I, allowed the funds allocated to education to be diverted elsewhere. Many primary schools and grammar schools disappeared or retrenched their operations for lack of funds. Elizabeth I, however, succeeding to the throne in 1558, revived Henry VIII's scholastic policy; considerable sums were appropriated for education, even though it was not always possible to enforce the new provisions because of local opposition and some lack of concern on the part of the Anglican clergy.

The growth of a rich and prosperous mercantile class and the spread of Calvinist reforms through the Puritans in England and the Presbyterians in Scotland were also factors in the transformation of English education in the 16th and 17th centuries. Scholastic programs reflected changes in society: importance was given to English, to science, to modern languages (in particular French and Italian), and to sports, as is still the case in England today. The Puritan contribution was thus considerable, though often hindered by the traditional forces of the Anglican Church and the old nobility.

The work of Sir Thomas Elyot and Roger Ascham

Sir Thomas Elyot, in *The Boke Named the Governour* (1531), wrote the first treatise in English that dealt specifically with education. He was interested in those who would have the future economic and political power in their hands. Though their education was to include the classics, it was to be supplemented by the needs of the new mercantile class—the national English language, manual arts, drawing, music, and all forms of sport. Elyot was obviously influenced by Erasmus.

Roger Ascham was close in thought to many of the English Humanists. In *The Scholemaster* (1570) he underlined the importance of the English language (in spite of his being a professor of Greek) and proposed that it should be used in teaching the classical languages. He also believed that physical exercise and sport were important, not only for the nobility and the leisured classes but also for students and teachers. He was aware of the social changes in the country; and, observing with sadness the corruption of the new wealth, he was particularly chagrined to see students going to university not to gain culture but to prepare themselves for high offices of state.

Richard Mulcaster had 30 years of experience as an educator at St. Paul's School and at the Merchant Taylors School, a Latin secondary school maintained by the tailors' guild in London—and most famous of all the "guild schools." Mulcaster was in favour of efficient teacher training and of teachers being adequately paid. In agreement with some of the Lutheran educational reforms, he felt that schools should be open to all, including women, who should moreover have access to higher education. He is particularly remembered for his opposition to Italianate trends: "I love Rome, but London better. I favour Italy, but England more. I know the Latin, but worship the English."

Sir Francis Bacon was interested in education though it was not his main concern—his main concern being the championship of the scientific method and "sense" realism, in opposition to traditional Aristotelianism and Scholasticism. He was opposed to private tutors and felt that boys and youths were better off in schools and that their education should be geared to their social status and future activity. Schooling should aim at preparing statesmen and men of action as well as scholars and thus should include history, modern languages, and politics. Bacon himself had a passion for study not only for its utilitarian purposes but because of its being for him a true source of delight.

The French Reformation. François Rabelais was a great and original interpreter of Humanistic ideals, and his views on education reflected this. He himself studied in various fields, from medicine to letters, and was passionately interested in all of them. His controversy with the Sorbonne, a remaining stronghold of medievalism and Scholasticism, was bitter and satirical. In *Gargantua* the Sorbonistes, or Sorbonagres, had filled Gargantua's head with useless notions, and it took a purge to liberate him from such indigestible knowledge.

Reformers opposed to medieval Aristotelianism and authority

Rabelais's educational philosophy was entirely different from that of the medievalists—his being based on liberty of the pupil, in whom he had maximum faith. In his novel, this cult of liberty was celebrated in the utopian Abbey of Thélème, where all could live according to their own pleasure but where the love of learning was so great that everyone was dedicated to it, getting much better results than those obtained at the medieval universities. And yet in the education of Gargantua and Pantagruel, there were limits placed on liberty: Gargantua's day started at 4 in the morning; he studied all subjects, both literary and scientific; and this was alternated with play and pleasing diversions. The heavy program, however, was not a constriction because of Gargantua's delight in learning. The culture that Rabelais wanted for his two heroes was directly connected with the world in which they lived.

Gargantua and *Pantagruel* were perhaps among the first texts by a Humanist in which not only the quadrivium but scientific studies were enthusiastically proposed. There was nothing arid or abstract in Rabelais's approach to nature, and in this context the classics also had a new flavour: ancient literature, no longer limited to Latin, Greek, and Hebrew but expanded to include Arabic and Chaldaic, could bring to light valuable knowledge that had been accumulated by the classical world.

Petrus Ramus, one of the most bitter critics of French medieval Aristotelianism, was an intelligent reformer of educational methods. His best known treatises are *Aristotelicae animadversiones* ("Animadversions on Aristotle") and *Dialecticae partitiones* ("Divisions of Dialectic"), both condemned by royal decree; he also wrote two discourses on philosophy, *Oratio de studiis philosophiae et eloquentiae conjungendis* (1546; "Speech on Joining the Study of Philosophy with the Art of Speaking") and *Pro philosophica Parisiensis accademiae disciplina oratio* (1551; "Speech in Defense of the Philosophical Discipline of the Parisian Academy"), as well as *Ciceronianus*, published posthumously. In these works his criticism of traditional ways and of the degeneration of Humanistic thought made him hated by all Roman Catholics, though not much better understood by Protestants; he died a Protestant victim of the massacre of St. Bartholomew. His program of study was fairly close to the traditional one, but his method was original, for he was concerned that the teacher should not suffocate the child with too many lessons and considered the child's autonomous activity important. He especially resented any pedagogy that relied on a blind appeal to authority; learning had to be utilitarian and issue from practice.

Michel de Montaigne (1533–92) was much influenced by his personal experience as a student. Though often critical of Humanism, especially when it was misinterpreted and transformed into pedantic studies, he had great admiration for the classics and lacked the scientific interests of Rabelais or Ramus. Montaigne wrote specifically about education in two essays on the upbringing of children and on pedantry. Culture, he felt, had become imitation, often with no trace of originality left, whereas it should be a delight—not something a student is forced to assimilate but something to draw the student's participation. He was in favour of instruction by tutors capable of giving the student individual attention —the ideal tutor being one with a good mind rather than one filled with pedantic notions. He also believed in the importance of physical education and in a boy's being hardened to nature and to danger.

For Montaigne it was important not only to travel to foreign countries but also to stay there for a while, to learn languages but, even more, to learn about foreign customs and thus break out of the narrow limits of one's own province. There were many differences between Montaigne and Erasmus, but both were convinced that for the wise man there could be no geographical boundaries, for, through cultural diffusion, barriers would be broken down.

The Calvinist Reformation. The Protestant Reformer John Calvin was of French origin, but he settled in Geneva and made this Swiss city one of the most prominent centres of the Reformation. Unlike Luther, whose reforms were backed by princes hoping to gain greater political independence, Calvin was supported by the new mercantile class, which needed political and administrative changes for the purposes of its own expansion.

Though he considered popular education important, Calvin concentrated on higher education. The theological academy he founded in Geneva in 1559 became distinguished under the directorship of Theodore Beza, an intelligent Reformer but unfortunately a very intolerant one, at least in theological matters. Calvin's influence on higher education was felt in many of the European universities, even as far as England, where, in spite of Anglican opposition, the Puritans had gained a foothold.

Calvinist emphasis on universal literacy

Calvin was in favour of universal education (the cost to be in large part borne by the community), but "universal" did not mean "democratic." Even if some form of instruction was to be given to everyone (so that everyone might in some measure read the Scriptures for himself, in good Calvinist tradition), very few individuals reached secondary or higher education, and of these only a minute percentage came from the working classes. Documents of the period show the steps taken to achieve the aim of universal education. In the Netherlands, the Calvinist Synod of The Hague in 1586 made provision for setting up schools in the cities, and the Synod of Dort in 1618 decreed that free public schools should be set up in all villages. In Scotland in 1560 John Knox, a disciple of Calvin and the leader of the Scottish Presbyterians, aimed at setting up schools in every community, but the

nobility prevented this from actually being carried out. The major educational contributions of Calvinism were its diffusion to a larger number of people and the development of Protestant education at the university level. Not only Geneva was significant but also the universities of Leiden (1575), Amsterdam (1632), and Utrecht (1636) in the Netherlands and the University of Edinburgh (1582) in Scotland. The Puritan, or English Calvinist, movement was responsible for the founding of Emmanuel College at the University of Cambridge (1584).

The Roman Catholic Counter-Reformation. The religious upheaval, so important in northern Europe, also affected, though less violently, the Latin countries of southern Europe. If the new ferment in the Roman Catholic Church was mainly directed at answering the Protestants, at times it also had something original to suggest. At the Council of Trent (1545–63) the Roman Catholic Church tried to come to terms with the new political and economic realities in Europe.

The growth of seminaries

Education was foremost in the minds of the leaders of the Counter-Reformation. The faithful were to be educated. For this, capable priests were needed, and, thus, seminaries multiplied to prepare the clergy for a more austere life in the service of the church. There was a flowering of utopian ideas, which should be remembered when trying to understand unofficial Catholic thought of the period. Various writings, such as *La città del sole* ("The City of the Sun"), by Campanella, *Repubblica immaginaria* ("The Imaginary Republic"), by Agostini, and *Repubblica di Evandria* ("Evander's Republic"), by Zuccolo, are examples of this new vision of the church and of the duties of Christians. But if in the minds of the utopians this education was to be universal, it was in fact almost entirely directed at the ruling classes.

The Society of Jesus, founded in 1534 by Ignatius Loyola, was not specifically a teaching order, but it was nevertheless very important in this field. The first Jesuit college was opened in Messina, Sicily, in 1548; by 1615 the Jesuits had 372 colleges, and by 1755, just 18 years before the suppression of the order, the number had risen to 728. (The Society was not re-established until 1814.) In *Ratio studiorum*, an elaborate plan of studies issued by the Jesuits in 1599, there is laid out an organization of these institutions down to the smallest details; an authoritarian uniformity was thus the rule in their colleges, and individual initiative was discouraged. The complete course of study took 13 years, divided into three periods: six years that included grammar and rhetoric, three years of philosophy, and four of theology. The teacher was thought of not only as an instructor but also as an educator and often a controller, for he was at the centre of a vast network of controls, in which those students considered promising also took part. Emulation was encouraged in the class, which was often divided into two groups to stimulate competition. These new techniques, as well as the Jesuits' efficient training of teachers, had good results, proof of this being the rapid increase in their colleges, which found greater favour than others started in the same period.

The legacy of the Reformation. The effects on education of a movement as complex and widespread as the Reformation were far-reaching. Perhaps its most original contribution was the extension of education at the elementary level. As a result, the vernacular language took on a new importance, and also the new pedagogy had to take account of the realities of the situation—namely, that the children brought into the new school network could not spend as much time on "useless" books, so that schoolwork had to be combined with learning a practical trade, which had not previously been considered a part of education. (E.Ge.)

VII. European education in the 17th and 18th centuries

THE SOCIAL AND HISTORICAL SETTING

The Renaissance had been the beginning of a new era in history, which culminated in the 17th and 18th centuries in the development of the absolutist state everywhere but in England and Holland (and even in these states the issue was for some time in doubt). France, the Habsburg Empire, England, and Russia became the leading powers in Europe. The absolutist state extended its control beyond the political and into the religious (with the creation of the established church) and into almost all other aspects of human life. Although the High and later Middle Ages had witnessed the growth of middle class forces, the pattern of society still clearly bore the stamp of court life. The concentration of power determined this life, and the citizen and his possessions were more and more at the disposal of the aristocracy. The citizen was subject.

Influence of absolutism on education

Even in an absolutist state, however, education cannot be the sole privilege of the rich or the ruling classes, because an efficient absolutist state requires capable subjects, albeit bound to their social position. Elementary education for the middle classes thus developed in the 17th and 18th centuries, and more and more the state saw as its task the responsibility for establishing and maintaining schools. This tendency toward general education did not stem only from considerations of political expediency; it stemmed also from the desire to improve the world through education—making all areas of life orderly and subordinate to rational leadership. There was not only an inclination toward encyclopaedism and systemization of the sciences but also, in similar fashion, a tendency to set education aright by extensive school regulations.

The 18th century is especially marked as a century for education. Essentially, there were three leading reforms: teaching in the mother language grew in importance, rivalling Latin; the exact sciences were brought into the curriculum; and the correct methods of teaching became a pedagogic question.

If a distinction can be made between the 17th and the 18th centuries, it was this: in the 17th century the aim of education was conceived as a religious and rationalistic one, whereas in the 18th century the ideal of the secular, pragmatic, "enlightened" gentleman prevailed more and more.

The new scientism and rationalism. These social and pedagogic changes were bound up with new tendencies in philosophy. Sir Francis Bacon of England was one who criticized the teachers of his day, saying that they offered nothing but words and that their schools were narrow in thought. He believed that the use of inductive and empirical methods would bring the knowledge that would give man strength and make possible a reorganization of society. Therefore, he demanded that schools should be scientific workplaces in the service of life and that they should put the exact sciences before logic and rhetoric.

Another 17th-century critic of medievalism was René Descartes, but he did not proceed from empirical experience, as did Bacon; for him the only permanence and certainty lay in human reason or thinking (*cogito ergo sum*, "I think; therefore, I am"). The ability to think makes doubt and critical evaluation of the environment possible. A science based only on empiricism fails to achieve any vital, natural explanations but only mathematical, mechanistic ones of doubtful living use. Only what reason (*ratio*) recognizes can be called truth. Thus, education must be concerned with the development of critical rationality and the teaching of any practical discipline that makes a man master and lord of nature.

Knowledge conceived as thinking

Like Descartes, Benedict de Spinoza and Gottfried Wilhelm Leibniz also outlined rationalistic philosophic systems. Decisive for educational theory was their statement that knowledge and experience originate in thinking (not in sense impressions) and that formal thinking categories should form the substance of education. Here the overthrow of encyclopaedism is already hinted at: education is guaranteed not by limitless widening of assimilated facts but by the mastery of thinking and judgmental categories.

The Protestant demand for universal elementary education. The schools that were actually developed fell short of these philosophically based demands. This is especially true of elementary education. In the Middle

Ages, the grammar schools (especially for the education of the clergy) had developed, and the Humanism of the Renaissance had strengthened this tendency; only those who knew Latin and Greek could be considered educated. For basic, popular education there were meagre arrangements. Although schools for basic writing and arithmetic had been established as early as the 13th and 14th centuries, they were almost exclusively in the towns; the rural population had to be content with religious instruction within the framework of the church. An improvement came as a result of Protestantism. John Wycliffe had demanded that everyone become a theologian, and Martin Luther, by translating the Holy Scriptures, made the reading of original works possible. Everyone, he asserted, should have access to the source of belief, and all children should go to school. So it happened that church regulations of the 16th and 17th centuries began to contain items governing schools and the instruction of young people (mainly in reading and religion). The Protestant "bell ringer" schools acquired great importance alongside the town schools. At first, such schools were directed and supported almost entirely by the church. Not until the 18th century, following the general tendency toward secularization, did the state take over the responsibility of supporting the schools.

EDUCATION IN 17TH-CENTURY EUROPE

Central European theories and practices. It was while Europe was being shaken by religious wars and was disintegrating into countless small states that such writers as Tommaso Campanella and Sir Francis Bacon dreamed their utopias (*La Città del sole* and the *New Atlantis*, respectively), where peace and unity would be had through logical and realistic means. To even attempt realizing this dream, however, man needed suitable education.

Realism in education

Both leading representatives of so-called pedagogic realism, Wolfgang Ratke and John Amos Comenius, were motivated by this ideal of world improvement through a comprehensive reform of the school system. Despite this common starting point, however, both were highly distinct personalities and, moreover, had divergent influences on the development of education and schools.

The pedagogy of Wolfgang Ratke. Wolfgang Ratke (1571–1635), a native of Holstein in Germany, journeyed to England, Holland, and through the whole of Germany and to Sweden expounding his ideas to the political authorities and finding considerable support. His plans for progressive reform failed for several reasons. First, political conditions during the Thirty Years' War were understandably not favourable for any kind of planning or reform of schools. Moreover, even when Ratke had opportunities, he demonstrated scant administrative or practical ability in trying to put his plans into execution. Several of his attempts collapsed because of this. Finally, Ratke's ideas were not free of exaggerations and presumption. He promised, for example, to be able to teach ten languages in five years, each language in six months.

His thoughts about the art of teaching are of greater importance for the theory and practice of education. First, he believed that everything must be studied through induction and experiment (as Bacon has espoused). Knowledge is to be gained by experience in dealing with specific problems: only then can the problem be discussed and a rule or "law" be reached regarding it.

Second, everything must follow the order and course of what may be called human nature. In modern terms, one would say that a lesson should be designed with psychological conditions taken into consideration.

Third, he asserted that everything should be taught first in the mother language, the mother language being the natural and practical language for a child and the one that allows him to concentrate wholly on the business at hand. Only when the mother language is fully commanded should the child attempt a foreign language; then special attention should be paid to speaking it and not merely reading it.

Fourth, Ratke emphasized what might now be called a kind of programmed learning. One piece of work should be fully completed before progress is made to the next piece, and there should be constant repetition and practice. The teacher's methods and the textbook program should agree and coincide.

Ratke's teacher-centred education

Fifth, there should be no compulsion. A teacher should not be a taskmaster. To strike a pupil was contrary to nature and did not help him learn. A pupil should be brought to love his teacher, not hate him. On the other hand, all work was the teacher's responsibility. The pupil should listen and sit still. More generally, all children, without exception, should go to school, and no lessons should be cancelled for any reason. There is, of course, a certain paradox in Ratke's views here—at least in modern terms. There was to be no compulsion, and yet pupils were to remain utterly disciplined. The emphasis on order, uniformity, and strictness was common to the times, however, and Ratke was not alone in failing to see the possibility of a pupil working independently.

As for curricula, Ratke suggested reading and writing in the native tongue, singing, basic mathematics, grammar, and, in the higher classes, Latin and Greek. The sciences had not yet appeared in his timetable. His demand that, above all, young people should be given instruction in the affairs of God is typical of the combination of rationalistic and religious education in the 17th century.

The pedagogy of Comenius. John Amos Comenius (1592–1670) was, even more than Ratke, a leading intellect of European educational theory in the 17th century. Born in Moravia, he was forced by the circumstances of the Thirty Years' War to wander constantly from place to place—Germany, Poland, England, Sweden, Hungary, Transylvania, and Holland—and was deprived of his wife, children, and property. He himself said, "My life was one long journey. I never had a homeland."

As a onetime bishop of the Bohemian Brethren, he sought to live according to their motto, "Away from the world towards Heaven"—yet while combining a religious and realistic outlook. Preparation for the hereafter, he felt, comes not through disregarding this world but through *recte vivere*, or "living rightly"—that is, living one's life according to correct factual and moral principles and seeking "learned piety" (*pietas litterata*). Whether his realism was truly realistic or not, Comenius could certainly be said to have had a philosophy that was humanitarian, inspired at least partly by the turmoil of his times. It encompassed three levels: (1) peace on earth exists only when religious factions cease fighting and unite toward realizing God's will; (2) such understanding and cooperation can best be achieved through "pansophia," universal knowledge among all men and all nations, achieved by means of (3) widespread educational reforms in methods and principles of teaching, including a universal language and universal coeducation.

The curriculum of Comenius

An all-embracing school system would serve these ends. During infancy (up to six years of age), the child in his "mother school," or family grouping, would develop his basic physical faculties. During the following period (seven to 12), the child would go to the "vernacular school," which was divided into six classes according to age and could be found in every town. The prime aim of these schools would be to develop the children's imagination and memory through such subjects as religion, ethics, diction, reading, writing, basic mathematics, music, domestic economy, civics, history, geography, and handicraft. This vernacular school formed the final stage of education for technical vocations. After this school would come the grammar school (or Latin school), which the pupils would attend during their youth (13–18) and which would exist in every town of every district. Through progressive courses in language and the exact sciences, the young people would be brought to a deeper understanding of things. Finally, the university (19–24) would be a continuation of this school. Every province ought to have one such university, whose central task would be the formation of willpower and powers of judgment and categorization. Over and above this four-tier school system Comenius also envisaged a "college of light," a kind of academy of the sciences for the centralized pooling of all learning. It is important to note, in this

regard, that it was Comenius' stay in England (1641–42) that initiated discussions leading to the founding of the Royal Society (incorporated 1662). Furthermore, the German philosopher Leibniz, influenced by Comenius, founded the Berlin Academy, and similar societies sprouted elsewhere.

With regard to methodology, Comenius believed that, like nature, education must take care to get the right timing and the right sequence. The lesson must begin with clear, practical facts and enable pupils to engage in independent and self-regulated activity and to have time for revision and practice. Most important, everything should be presented to the child's senses—and to as many senses as possible simultaneously, using pictures, models, workshops, music, and other "objective" means. On the upper age levels, he recommended that language study and other studies be integrated, and indeed he employed this scheme in his *Gate of Languages Unlocked* (1631), a book of Latin and sciences arranged by subjects, which revolutionized Latin teaching and was translated into 16 languages. *Orbis Sensualium Pictus* (1658; "Picture of the Sensual World"), which remained popular in Europe for two centuries, attempted to dramatize Latin through pictures illustrating Latin sentences, accompanied by one or two vernacular translations. His major theories were developed in *The Great Didactic* (1657) and in *Pampädia* (discovered in 1935).

The schools of Gotha. The zeal for reform on the part of such educators as Ratke and Comenius, on the one hand, and the interests of the ruling classes, on the other, led in the years after about 1650 to the publication of school regulations, free of church regulations. The circumstances in the central German principality of Gotha were typical. The duke, Ernst the Pious, commissioned the rector Andreas Reyher to compile a system of school regulations, which appeared in 1642 and is known historically as the *Gothaer Schulmethodus.* This was the first independent civil system of school regulations in Germany and was strongly influenced by Ratke. The most important points of these regulations were compulsory schooling from the age of five; division of the school into lower, middle, and higher classes; extension of the usual subjects (reading, writing, basic arithmetic, singing, and religion) to various other fields (natural history, local history, civics, and domestic economy); the introduction of textbooks (for reading and basic arithmetic), notably the first textbook of exact sciences for elementary schools, Reyher's own *Kurzer Unterricht von natürlichen Dingen* (1657; "Short Course on Natural Things"); and methodical instruction that, above all, emphasized the clarity of the lesson and the activity of the pupils.

Systematizing education

The system of elementary schools in Gotha was an example for many other parts of Germany. The Duke also took an interest in the education and examination of teachers and tried to raise their status. The other German lands for the most part did not keep pace with this latter development.

French theories and practices. In the second half of the 17th century, Germany suffered from the aftereffects of the Thirty Years' War, whereas France under Louis XIV reached the zenith of political and military power. France's leadership was also demonstrated in the cultural field—including education. Some of the most important developments in France included the promotion of courtly education and the involvement of religious orders and congregations in the education of the poor. One of the most important educational theorists of the late 17th century was a French cleric—Fénelon, archbishop of Cambrai.

Views of Montaigne

Courtly education. The rationalistic ideal of French courtly education can be seen foreshadowed in Michel de Montaigne's *Essais* (1580), in which the ideal man was described as having a natural, sensible way of life not deeply affected by the perplexities of the time but admitting of pleasure. He had a "correct" attitude toward the world and people, a certain spiritual freedom, and an independent judgment—all of which, in Montaigne's view, were more important than being steeped in knowledge. "As lamps are extinguished from too much oil, so is the mind from too much studying." Montaigne came from a merchant family that aspired to nobility, and thus there is a certain fashionable elitism in his views; he held, among other things, that courtly education succeeds best when the pupil studies under a private tutor.

This ideal, rather unlike the ideal of the learned and humanistic Renaissance man, became important in 17th-century France, especially after midcentury and the rise of the court of Louis XIV. The education of the would-be versatile and worldly-wise gentleman was furthered not only by the continuation of the institution of private tutoring but also by the establishment of schools and academies for chevaliers and nobles, in which the emphasis was on such subjects as deportment, modern languages, fencing, and riding. It was most emphatically an example of class education, designed for the nobility and higher military and not for any commoners.

The teaching congregations. In the countries, such as France, that remained Catholic, the Roman Church retained control of education, and indeed, as monarchy became more absolute, so largely did the authority of the church in matters of education. In France, practically all schools and universities were controlled by so-called teaching congregations or societies, the most famous and powerful of which during the first half of the 17th century was the Society of Jesus. By midcentury the Jesuits had 14,000 pupils under instruction in Paris alone; and their colleges (not including universities) all over the land numbered 612.

Jesuit education

It was their successful teaching and comparatively mild discipline that caused the Jesuit schools to attract thousands of pupils. "They are so good," said Francis Bacon of the Jesuit teachers in his *Advancement of Learning,* "that I wish they were on our side." The curriculum was purely classical, but importance was attached to spacious, well-adapted buildings and amenities designed to make school life interesting. In general, however, the religious and international conflicts did great harm to education, which suffered much because those kings and religious factions that gained power in France (as elsewhere) used the schools to propagate their cause, discarding teachers not of the approved persuasion. Moreover, the schools continued largely to ignore the new directions of men's minds; in the universities staffed by Jesuit fathers, medieval Scholasticism, though purged of the formalistic excesses that had degraded it, was fully restored. Schools and universities declined for the most part to contemplate any enlargement of the frontiers of knowledge and were too often deeply involved in the religious conflicts of the time. The University of Paris in particular remained distracted throughout the 17th century by theological dissensions—in at least one instance as a result of the rivalry that ensued after the Jesuits had effected a footing at the Collège de Clermont.

Aside from the Jesuits, the most important teaching congregations in France were the Bérullian Oratory, or Oratorians, and the Jansenists of Port Royal. The former, founded in 1611 and soon to open a number of schools and seminaries for young nobles, was composed of priests—but priests more liberal and rationalist than was common for the times. They offered instruction not only in the humanities but also in history, mathematics, the natural sciences, and such genteel accomplishments as dancing and music and, though continuing to use Latin in instruction, promoted also the use of the vernacular French in the initial years of their curriculum. They tended indeed to be drawn to the ideas of Descartes, to a faith based on reason. When in 1764 the Jesuits were banned from France, their teaching positions were largely assumed by Oratorians.

The Jansenists

More famous than the schools of the Oratorians, though enjoying a briefer career, were the Little Schools of Port Royal. Their founder was Jean Duvergier de Haurame, better known as the Abbot of Saint Cyran, who was one of France's chief advocates of Jansenism, a movement opposed to Jesuitry and Scholasticism and favouring bold reforms of the church and a turn to a certain Pietism. About 1635 Saint Cyran, with the help of some wealthy,

influential Parisians, succeeded in gaining control of the convent of Port Royal, near Versailles. There the Jansenist group began about 1637 to educate a few boys, and by 1646 it had established the Little Schools of Port Royal in Paris itself. Their curriculum was similar to that of the Oratorians, though excluding dancing, and was celebrated for its excellence in French language and logic and in foreign languages. The theory of learning adopted was that things should begin with what is familiar to the child: thus, a phonetic system of teaching reading was used; all instruction was in French, not Latin; student compositions were directed toward topics drawing on one's own experiences or toward subjects in one's current reading. Involved in political struggles with the Jesuits, who were still influential at court, the Jansenists were fated to have all their schools closed down by 1660, but their theories and practices were widely adopted and became extremely influential.

Female education. During the century, the education of girls was not entirely neglected, and France was notable for its efforts. Mme de Maintenon, for instance, had been a pupil of the Ursuline nuns in Paris and then a governess at the court of Louis XIV, before she was wedded to the King in 1684. From her royal vantage point, she took upon herself the founding of a school in 1686 at Saint-Cyr near Versailles—a higher school principally for orphan girls descended of noble families. Besides such basic subjects as reading and writing, the girls were prepared for their future lives as wives and mothers or as members of genteel professions. In 1692 this school was taken over by the Augustinian nuns. Another important worker in the field of female education was St. Jane Frances de Chantal, who, together with her father confessor, St. Francis de Sales, founded in 1610 the order of the Visitandines, a group dedicated to charitable work and the religious education of women.

Views of Fénelon

François de Salignac de la Mothe Fénelon, archbishop of Cambrai and noted theologian and writer, is especially known for his views on the education of girls. In his "Traité de l'éducation des filles" (1687), he remarked on the importance of women in improving the morals of society and went on to express his thoughts about girls' education. Because girls, he believed, are meant to fulfill roles as housewives and mothers, they should pursue religious and moral education rather than scholarly learning. They should learn reading and writing, basic mathematics, history, music, needlework, Latin (because it is the church language), but no modern languages, since they tend to moral corruption. Education, he maintained, should make the lady of the house both Christian and accomplished, neither ignorant nor *précieuse*.

English theories and practices. The 17th century in England (up to the Glorious Revolution of 1688–89) was one of argument over religious and political settlements bequeathed by Queen Elizabeth; the period was one characterized by the confrontation of two different world views—on one side the royalist Cavaliers and on the other side the Puritans. The division was reflected in education.

The Puritan reformers. In the Anglo-American world the Reformation came about in the form of Calvinism—"Puritan" being the derisory name for strict Calvinists. Their ideals were sober, practical behaviour, careful management, thrift, asceticism, and the rejection of hedonistic pleasures of life. Many of the educationists who sought this Puritan ideal were followers of the reform plans of Comenius. Samuel Hartlib, a Polish merchant residing in England who was friend, publisher, and patron of Comenius, tried to interest Parliament in the idea of popular education; his tractate entitled "London's Charity Enlarged" (1650) proposed that a grant be made for the education of poor children, all in the interest of general social betterment. The Committee for Advancement of Learning, which he founded in 1653, was the impulse and model for later educational associations. In general, his ideas for reform included the introduction of agricultural schools, the state organization of the educational system, as well as the establishment of general elementary education. The name of John Dury stands close to those of Comenius and Hartlib. In 1651 appeared his book *The Reformed School*, in which he proposed teaching societies in England much like the teaching congregations in France. Indeed, he was particularly insistent that control of education be in the hands not of a regimentizing state but of free educational organizations. He was also concerned about teaching youth the useful arts and sciences so that they might "become profitable instruments of the Commonwealth." From him, too, stemmed the draft of a nursery school; thus, he can be regarded as the first representative of infant teaching in England.

Sir William Petty, the noted economist, carried the idea of education in the useful arts even further. He wanted to turn ordinary schools into trade or handicraft schools and proposed a *gymnasium mechanicum* or "Colledge of Tradesmen of the Advancement of all Mechanical Arts and Manufactures."

The Humanism of John Milton

The most renowned of the Puritan intellectuals, John Milton, was more concerned with the education of "our nobler and our gentler youth" than with the education of common boys. "Of Education" (1644), written at the request of Hartlib, was one of the last in the long line of European expositions of Renaissance Humanism. Milton's aim was the traditional aim, the molding of boys into enlightened, cultivated, responsible citizens and leaders. His proposed academy, which would take the place of both secondary school and college, was to concentrate on instruction in the ancient classics, with due subordination to the Bible and Christian teaching. The traditional role of physical and martial exercise was perhaps heightened by Milton's anxiety over the English Civil War in progress. Interestingly, he also gave a large place to all kinds of science.

Royalist education. Frequently opposed to Puritanism on educational as well as political grounds were the royalists and supporters of the nobility. In education, their views went back to Thomas Elyot and Roger Ascham in the 16th century, who had written so persuasively about the education of gentlemen in the tradition of the so-called courtesy books. Influenced by these few English forerunners and also by Montaigne were James Cleland (*The Institution of a Young Nobleman*, 1607) and Henry Peacham (*The Compleat Gentlemen*, 1622). In the view of the latter, an extreme royalist, "Fashioning him [the pupil] absolute in the most necessary and commendable Qualities concerning Minde and Body to country's glory" was the overriding aim of education; the table of contents of *The Compleat Gentlemen* exhibits the variety of interests of an ideal gentleman or noble—cosmography, geometry, poetry, music, sculpture, drawing, painting, heraldry, and so on. John Gailhard (*The Compleat Gentleman*, 1678), another writer in the same tradition, can be said to have anticipated John Locke's empiricism (see below) when he wrote that "the nature of Youth is like Wax by fire, or a smooth table upon which anything can be written."

The academies. The beginning of academies for the promotion of philosophy, arts, or sciences can be traced to the early Renaissance, particularly in Italy and France. The Platonic Academy in Florence, cited earlier in this article, was one of the most noted of speculative societies. The first scientific academies belong to the 16th century: in 1560, for instance, the Academia Secretorum Naturae was founded in Naples; in 1575 Philip II of Spain founded in Madrid the Academia de Ciencias Matemáticas. Then, in 1617, the first German academy, Fruchtbringende Gesellschaft, was founded at Weimar for the purification of the language and the cultivation of literature. A number of other academies were founded throughout Europe.

Royal Society and Académie des Sciences

It was in the 17th century that the two pre-eminent scientific academies were founded. Both the English Royal Society and the French Académie des Sciences began as informal gatherings of famous men. The "invisible college" of London and Oxford had its first meetings in 1645; it was incorporated as the Royal Society in 1662. In Paris, a group of men including the philosophers Descartes and Pascal started private meetings almost at the same time. In 1666 they were invited by the economic

minister Colbert to meet in the royal library. In 1699 the society was transferred to the Louvre under the name of the Académie des Sciences. The Académie Française also started as a private society of men of letters some five years before its incorporation in 1635 under the patronage of Cardinal de Richelieu. In the 18th century, the fame and achievements of these English and French academies became internationally recognized, and many other European countries started to found their own national academies.

EDUCATION IN 18TH-CENTURY EUROPE

General condition of education during the Enlightenment. In the 18th century the theories and systems of education were influenced by various philosophical and social trends. Among these were realism, which had its origins in Ratke and Comenius, among others, and also Pietism, which derived principally from Philipp Jakob Spener and August Hermann Francke in the late 17th and early 18th centuries (see below). Another trend was the far-reaching spiritual and humanitarian movement of the Enlightenment, best seen in the pedagogical views of John Locke and in the upsurge of philanthropy. Also important was naturalism, of which Rousseau can be regarded as the main representative. Ultimately, the Enlightenment was the most important of these trends, mainly because it most affected the political scene.

Locke's theory of knowledge

John Locke and the ideas of the Enlightenment. For 18th-century education, the late-17th-century philosopher John Locke is significant both for his general theory of knowledge and for his ideas on the education of youth. Philosophically, he was a thorough empiricist; that is, he was suspicious of the view that a thinker could work out in his study by pure reason alone the truth about the universe. Much as he admired Descartes, he was annoyed by this speculative spirit in him, and he despised it in the Scholastic and Jesuitical philosophers. In this sense he rejected metaphysics. Knowledge of the world around one could be gained only through sense perception or experience and by rational reflection on experience. It did not begin in innate knowledge of maxims or general principles.

For education this meant that Locke and like-minded men of the 18th century would emphasize the principles of practice and conditioning. By example, by habituation and practice, through encouragement, respect, and discredit, a child's good habits and intellect could be developed. Experience would be the watchword. "Children," he wrote,

> are not to be taught by rules which will be always slipping out of their memories. What you think necessary for them to do, settle in them by an indispensable practice as often as the occasion returns.

Some Thoughts Concerning Education (1693), in which these words appeared, was actually a compilation of replies written earlier to a friend and country squire who had requested advice about the education of his son. Thus, the work is somewhat random, written to no particular didactic end, though full of commonsense advice on the rearing of a squire's son, who was to be physically, mentally, socially, and morally prepared for life. Moral training was especially emphasized; character development should come first before learning; the educator's aim is to instill virtue, wisdom, and good breeding into the minds of the young. This does not mean ironhandedness, however; young children should be allowed to give vent to their feelings and should be restrained rarely; "the chief art is to make all that they have to do sport and play too." Locke sounds remarkably modern in this; and his writings in any case were enormously influential during the 18th-century Enlightenment.

The condition of the schools and universities. The school system became more and more in the 18th century an ordered concern of the state. Exponents of enlightened absolutism, as well as parliamentarians, recognized that the subject was of more use to the state if he had a school education. Ideally, there was to be compulsory schooling everywhere, but of course in practice the ideal was scarcely reached anywhere. The state also recognized that worthwhile school instruction depended on the standard of education of teachers: thus, the first teachers' colleges were established. But admittedly the standard of education of teachers was fairly poor. The teaching profession still did not provide a living wage, for which reason can be read from a regulation of 1736:

> If the teacher is a workman he can already support himself; if he is not, then he is hereby allowed to go to work for daily wages for 6 weeks at harvest-time (*Principia regulativa,* clause 10).

Ever since the 16th century, the universities had suffered a decline, mainly as a result of religious wars. Progress in the exact sciences was accomplished under government support in the academies of science, not in the universities, which became more and more training institutions for higher civil servants. There was, however, a notable change for the better, at least in Germany.

Halle, the first modern university

The year 1694 saw the foundation of the University of Halle, which has been described as the first real modern university. It originated in a *Ritterschule,* or "knight's school," imitative of the schools for chevaliers in France, and in 1694 the Holy Roman emperor Leopold I granted it a charter. The primary object in founding a university in Halle was to create a centre for the Lutheran party; but its character, under the influence of its two most notable teachers, the philosophers Christian Thomasius and August Hermann Francke, soon expanded beyond the limits of this conception. Thomasius was the first to set the example—soon after followed by all the universities of Germany—of lecturing in the vernacular instead of the customary Latin; this was a declaration of war against Scholasticism. Francke, as the founder of the Pietistic school, exercised great influence. Throughout the whole of the 18th century, Halle was the leader of academic thought and advanced theology in Protestant Germany, although sharing that leadership, after the middle of the century, with the University of Göttingen (founded 1737). With Göttingen, another important contribution was made by the revival of classical studies and the creation of a faculty of philosophy distinct from that of theology. This was designed not only to advance scholarship but also to train teachers. Halle itself established the first chair of educational theory.

The background and influence of Pietism. The dispute over the correct religious dogma, fought for almost 200 years with the utmost strength, controversy, and academic subtlety and reaching its terrible culmination in the Thirty Years' War, led to a certain ill feeling against dogmatically sanctioned religious revelation. There was a widespread trend toward secularization. Everywhere, there was a clear tendency to free belief from dogmatic quarrels. The search for a new belief took generally two different paths. One wanted to base belief in man's reason; the other wanted a godliness of the heart. For one line of thought, belief was a postulate of omnipotent human reason; for the other, man, corrupted by original sin, was to be saved only by simple belief in God's grace. The one path turned to the religious understanding of the Enlightenment; the other followed the subjective, mystical, zealous devoutness of Pietism. Such a movement away from the institutionalized church, away from the established church, and toward an intensified faith was evident in France within Catholicism in the form of Jansenism and Quietism. In England it was clearly evident in certain forms of Puritanism and in Independent movements and Quakerism. In Germany it was evident in Pietism.

Rationalistic versus devotional experience

Pietism was a Protestant movement of renewed faith that became popular from about 1675 to 1740, though it remained residually influential even into the 19th century. Its spiritual centres were in Württemberg, among the Moravian Brethren, and above all in Halle. Pietism was principally opposed to dogmatic Protestant orthodoxy, which usually included impatience and polemics against other beliefs. Pietism, on the contrary, stood for the renewal of importance of the individual prayer and for humility. The experiences of belief were to be based less in the acceptance of fixed conditions of belief and more in a mystical, personal submersion in feelings. Ac-

cording to standard Protestant theory, salvation could be hoped for only by the suppression of the corrupted individuality and by waiting for the grace of God to show one the way. From this came the Pietists' inclination to turn away from the world with its temptations (*e.g.*, the theatre, dancing, games, and other enjoyments). The uneasiness that they felt toward church institutionalization led to their splitting into numerous separatist groups; their subjective certainty about their belief led to a certain arrogance; and finally their seclusion led often to a joyless and moralizing way of life.

Although the founder of German Pietism is considered to be Philipp Jakob Spener, who established several private devotional gatherings (*collegia pietatis*) for Bible study in Frankfurt am Main and elsewhere, he was important for education only in the sense that he fashioned a spirit or concept in which education could be conducted—a concept that would subordinate all education to a simple Christian faith. This concept was realized mainly by his follower August Hermann Francke.

August Hermann Francke. Francke, after service as a grammar school teacher and priest in Leipzig, Lübeck, Hamburg, and Erfurt, was, through Spener's recommendation, given a post at the University of Halle in 1691, at the same time assuming the post of parish priest nearby. Motivated by the sad conditions of neglect in his parish, he quickly devoted himself to practical pastoral duties. In 1695 he instituted a vernacular school for the poor, popularly called the "ragged school," whose purpose was that the children should be led to a living knowledge of God and Christ and to a rightly accomplished Christianity. Through his activity and eloquence Francke quickly won several charitable patrons for his school, and the institution quickly expanded. After the school for the poor came the establishment of an elementary school for children of fee-paying burghers, then an orphanage, and lastly a *Pädagogium*, or boarding school, for the sons of nobility. Because Francke felt a lack of suitable teachers for his schools, he subsequently established two teachers' seminaries, *seminarium praeceptorum* and *seminarium selectum* (for teachers in higher schools). In 1697 there followed a Latin grammar school and in 1698, even if short-lived, a *gynaeceum*, a school for the daughters of nobility. To the whole complex of Halle's institutions (known collectively as the Halle Foundation) there also belonged a book shop with a publishing house and press, a very profitable chemistry laboratory, as well as four agricultural properties, a Bible institution, and an office for sending evangelical missions abroad. These institutions flourished, and about 1750 they were more and more brought under the control of the state. (In 1946 they were incorporated into the Martin Luther-Universität Halle-Wittenberg.)

The schools of Halle

Francke's main concern was ministerial work in the spirit of Pietism and not systematic educational theorizing. His educational aims were religious and at the same time practical. He himself paraphrased it as "true godliness and Christian wisdom"—true godliness meaning a pious, moral, devout life, and Christian wisdom referring to an ability to work hard according to the Protestant ethic. Francke's style of education went along with this aim: the corrupted willfulness of man must be broken; that does not happen through severe punishment but through "loving reproaches," a close supervision of the pupils, and a schooled and regimented care of the spirit. Games and childlike exuberance have no place in the system; thus, education had a joyless and moralizing effect and made heavy demands on the children, perhaps too heavy.

Strictness and realism in Pietistic schools

The harsh demands and regimentation are shown, for instance, in the daily timetable and the syllabus. The children arose at 5:00 AM; there was almost continuous instruction with frequent Bible reading and religious lessons until 7:00 in the evening. The grammar school had lessons in reading, writing, basic mathematics, catechism, the Holy Scriptures, Latin, Greek, Hebrew, optionally another Oriental language, geography, history, mathematics (including astronomy and geometry), botany, zoology, mineralogy, anatomy, and theology, as well as lathework, glass polishing, field trips to observe trades, factory work, horticulture, and so on. These latter subjects were counted as "recreation." The pansophic idea of Comenius was being followed here, in the sense that there was to be an all-encompassing education. It is worth noting that Francke was actually trying to inject realism into education—promoting, as he did, scientific subjects, lessons in manual skills, planned field trips, and even the reading of newspapers in the classroom.

Johann Julius Hecker. Julius Hecker came to Halle shortly before Francke's death in 1727 and became a teacher in the *Pädagogium*. In 1739 he was summoned by Frederick I of Prussia to Berlin, where he established a six-year *Realschule*, or "realist school," designed to prepare youth for the Pietistic and Calvinistic ideal of hard work and, especially, for the new technical and industrial age that was already dawning in countries such as England and France. Godliness was to be combined with a realistic and practical way of life. As early as 1699 Francke had conceived the idea of a school for children who were not meant for scholarship but who could serve usefully in commercial pursuits or administration; and in 1739 one of his teachers, Christoph Semler, published a pamphlet proposing such a "mathematical and mechanical *Realschule*." It was Hecker's fortune to put these plans into realization. His school included, among other things, classes for architecture, building, manufacturing, commerce, and trade. Both the exact sciences and manual skills were in the curriculum. A room for natural-history specimens, geographical maps, and realia was set aside for the illustration of lessons. Schools like Hecker's were gradually opened in other cities. In the 19th century the courses were extended to nine years, and such an institution was renamed *Oberrealschule*, or "higher realist school"; henceforth it was one of the main types of German secondary education.

Realschule, or "realist school"

Hecker is significant for two other, more minor contributions. He worked on a uniform program of education for teachers, *Kurmärkisches Landschullehrerseminar* (1753; "Seminary for Bell Ringers and Schoolmasters"). He was also entrusted by the King with the compilation of the general school regulations (1763), which fashioned the main outlines of the Prussian school system.

The background and influence of naturalism. Pietists emphasized Christian devotion and diligence as paths to the good life; Enlightenment thinkers focussed on reason and clear thinking as the sensible way to happiness. In Jean-Jacques Rousseau one finds a decisive change in the history of ideas; he gave a third answer. Only by reverting back to nature can the real, happy man come into being. For the naturalists of the Rousseau variety, "nature" is not a primitive or raw condition that man must conquer through culture. Nature is itself a governing principle, which should correct the unnatural development of mankind. Human reason can never fully take in the laws of "wise" nature; if man wants to see the play of nature, he must feel it.

Jean-Jacques Rousseau. Of those who thought and wrote about education in the 18th century no one has had so great an influence as Rousseau, whose *Émile* (1762) has often been called the charter of childhood. "The first thing," he wrote in his preface, "is to study your pupils more, for it is very certain that you do not know them." By stressing the importance of helping children to grow and develop naturally Rousseau started a revolution in educational theory that in time completely changed the relationship of teacher and pupil. His insistence that child nature is wholly good helped to destroy the harsh systems of discipline widely prevalent in his day, but it should be noted that it is a view at variance with Christian doctrine and with the findings of modern psychoanalysis. His version of education, so different from the artificial, conventional, formal teaching then usual, inspired generations to come.

The main ideas of Rousseau's education were these: attention to naturalness; development of independent judgment, harmony of needs, and abilities; and the founding of a general humanity and not a training of people to fill

Rousseau's educational ideas in *Émile*

set roles. The child was to be educated to be a man, not to be a priest, civil servant, or soldier. The first book of the educational novel *Émile* describes the period from birth to learning to speak. The most important thing for the healthy and natural development of the child at this age is that he learn to use his physical powers, especially the sense organs. The teacher must pay special attention to distinguishing between the real needs of the child and his whims and fancies. The second book takes in the time from the child's learning to speak to the age of 12. Games and other forms of amusement should be allowed at this age, and the child should by no means be overtaxed by scholarly instruction at too early an age. The child Émile is to learn through experience, not through words; he is to bow not to the commands of man but to necessities. The third book is devoted to the ages from 12 to 15. This is the time of learning, not from books of course but from the "book of the world." Émile must gain knowledge independently without long-winded studying, in concrete situations, which, if necessary, his tutor may provide. In this learning are included practical subjects (a trade, among other things). Not until the age of 15, described in the fourth book, does Émile learn of the world of morals, ethics, and religion. Here for the first time he comes face to face with history, comes into contact with other people, and finally goes to Paris to look for a wife. He is unable to find one, of course, since everything there is corrupt. He finds his Sophia in the country, in simple surroundings.

In Rousseau's view, the education of girls was to be similar with regard to naturalness, but it differed because of sexual differences. A girl cannot be educated as a man. She is more the centre of the family, a housewife, and a mother and should strive to please her husband, concern herself more than he with having a good reputation, and be satisfied with a simple religion of the emotions, since her intellectual education is not of the essence. "Her studies must all be on the practical side."

Even though Rousseau himself never had any success as a practical teacher, his theories certainly had a lasting influence. With his criticism of culture he opposed a naïve optimistic feeling of progress, which equated growth of knowledge with moral growth. By showing the child's right to a natural development relevant to his age he placed the teacher in the role of an adviser, and he also freed the child from the compulsion of having to be a miniature grown-up.

The Sensationists. A group of French writers contemporary with Rousseau and paralleling in some ways the thought of both Rousseau and Locke are known as the Sensationists, or, sometimes, the Sensationist psychologists. One of them was Étienne Bonnot de Condillac, who, along with Voltaire, may be said to have introduced Locke's philosophy to France and established it there.

Views of Condillac

The most important of Condillac's works is the *Traité des sensations* (1754), in which he imagined a statue organized inwardly like a man, animated by a soul that had never received an idea, into which no sense impression had ever penetrated. He then unlocked its senses one by one, beginning with smell. At its first experience of smell the consciousness of the statue was entirely occupied by it; and this occupancy of consciousness was attention. The statue's smell experience would produce pleasure or pain; and pleasure and pain would thereafter be the master principle determining all the interests and operations of the mind. The next stage was memory, which was the lingering impression of the smell experience upon the attention. From memory sprang comparison and from comparison judgment, giving rise to the powerful principle of the association of ideas. From comparison of past and present experiences in respect of their pleasure-giving quality arose desire; it was desire that determined the operation of man's faculties, stimulated the memory and imagination, and gave rise to the passions. Throughout the *Traité* Condillac examined all the senses and their combinations and came to the conclusion that man was nothing but what he had acquired; all notions of innate faculties and ideas were to be rejected. The important point for education is that, in Condillac's view, the teacher was to concentrate on training the child's sense observations and comparative understanding and to do so in a properly graded or progressive fashion. He had also to take cognizance of the pleasure–pain principle involved in experience.

Claude-Adrien Helvétius, a countryman of Condillac's professing much the same philosophy, was perhaps even more insistent that all men lacked any intellectual endowment at birth and, though of differing physical constitution, had the potential for identical passions and ideas. What made men different in later life were differing experiences. Hypothetically, two men brought up with the same chance experiences and education would be exactly the same. From this it followed, in education, that the teacher must attempt to control the environment of the child and guide his instruction step by step. Helvétius also contended that the only effective motivation was self-interest, founded on the love of pleasure and the fear of pain, and teachers should keep this in mind.

The Rousseauists. Rousseau left behind no disciples in the sense of a definite academic community, but hardly a single theorist of the late 18th century or afterward could avoid the influence of his ideas. One of those influenced was the German Johann Bernhard Basedow, who agreed with Rousseau's enthusiasm for nature, with his emphasis on manual and practical skills, and with his demand for practical experience rather than empty verbalism. The teacher, in Basedow's view, should take pains over the clearness of the lesson and make use of the enjoyment of games: "It is possible to arrange nearly all playing of children in an instructive way. . . ." In another respect, however, the contrast between Rousseau and Basedow could not be sharper; Basedow tended to force premature learning and overload a child's capabilities. A foreign language, for instance, was to be learned in six months. He promoted, in general, a pedagogic hothouse atmosphere. Basedow, however, was perhaps influenced by his seven-year-old daughter, who was put forward as a wonder child with extraordinary knowledge. He established an experimental school called a *Philanthropinum*, in Dessau, which lasted from 1774 to 1793.

Kant on pedagogy

The philosopher Immanuel Kant referred to Rousseau's influence on him. Kant dealt specifically with pedagogy only within a lecture he gave as holder of the chair of philosophy in Königsberg; the main features of the lecture were collected in a short work, *Über Pädagogik* (1803). In it he asserted, "A man can only become a man through education. He is nothing more than what education makes him." Education should discipline man and make him cultured and moral; its aim is ultimately the creation of a happier mankind. In general, it may be said that Kant agreed with Rousseau's education according to nature; but, from his ethical posture, he insisted that restraints be put on the child's passionate impulses and that the child even be taught specific maxims of conduct. The child must learn to rule himself and come to terms with the twin necessities of liberty and constraint, the product of which is true freedom.

> Children should be educated, not with reference to the present conditions of things, but rather with regard to a possibly improved state of the human race—that is, according to the ideal of humanity and its entire destiny. (From "On Pedagogy.")

The influence of nationalism. The Enlightenment was cosmopolitan in its effort to spread the light of reason, but from the very beginning of the age there were nationalistic tendencies to be seen in varying shades. Although Rousseau himself was generally concerned with universal man in such works as the *Social Contract* and *Émile*, his *Considérations sur le gouvernement de Pologne* ("Considerations on the Government of Poland") did lay out a proposal for an education with a national basis, and generally his ideas influenced the nationalistic generation of the French Revolution of 1789.

National views of the Philosophes

France. The real starting point generally of national pedagogic movements was in France. It perhaps began with the Philosophes, the rationalists and liberals such as Voltaire and Diderot, who emphasized the development of the individual through state education, not as

a means, of course, of adjusting to the state and its current government but as a means of creating critical, detached, responsible citizens. The Marquis de Condorcet was closely connected with this line of thought. For him man was by nature good and capable of never-ending perfection, and the goal of education should be the "general, gradually increasing perfection of man." He drafted a democratic and liberal but at the same time somewhat Socialist concept of school policy: there should be a uniform structure of public education and equal chances for all; ability and attainment should be the only standards for selection and careers; and private interests should be prevented from having influence in the educational system. An educational concept so rationalistic in its aims and with such a democratic and liberal structure cannot be narrowly nationalistic; it is cosmopolitan. But Condorcet was nationalistic insofar as he wanted "to show the world at last a nation in which freedom and equality for all was an actuality." He was, in fact, a strong supporter of the Revolution.

Many of the Rousseauists were nationalistic in a somewhat different way. They believed in a kind of "moral patriotism." They distrusted state-controlled nationalism and favoured instead a virtuous, patriotic citizen who experienced spontaneous feelings for his nation. Proper development in the family setting and in school would lead to the mastery of everyday situations and would naturally lay the foundations for this true nationalism.

Some of the French revolutionists, particularly Jacobins such as Robespierre and Saint-Just who were associated with the period of the Terror (1793–94), were concerned with an education for the revolutionary state, an education marked by an enmity toward scholarly knowledge, by state control, collectivism, the stressing of absolute equality, and the complete integration of all. What is good is decided by the collective "people." Thus, it could be said that the Jacobins favoured a complete politicalization of educational practice and theory. Connected with this was their support for private and boarding-school education on Spartan lines.

Benevolent despotism and education

National education under enlightened rulers. The absolutism of the 18th century has often been called "benevolent despotism," referring to the rule of such monarchs as Frederick II the Great, of Prussia, Peter I the Great and Catherine II the Great, of Russia, Maria Theresa and Joseph II of Austria, and lesser figures who were presumably sufficiently touched by the ideas of the Enlightenment to pursue social reforms. Their reforms were limited, however, and usually did not include anything likely to upset their sovereignty. Thus, they were often willing to improve education for middle class persons useful in civil service and other areas of state administration, but they were often chary of educating the poor. That risked upsetting the social order.

Frederick the Great, for example, was opposed to general education for all. For reasons of state, though, his minister Freiherr von Zedlitz founded a chair of pedagogy at Halle (1779) and generally planned for the improved education of teachers; he supported the founding of new schools and the centralization of school administration under an *Oberschulkollegium*, or national board of education (1787); and one of his colleagues, Friedrich Gedike, was instrumental in introducing the school-leaving examination for university entrance, the *Abitur*, which still exists. Zedlitz even acknowledged the work of philanthropists in education.

The guarded though increasingly liberal attempt by benevolent despots to nationalize and expand education is well illustrated by the events in Russia. Until the 18th century, schools in Russia were founded by ecclesiastical organizations (monasteries), the clergy (priests, deacons, readers), and private persons (boyars, or lower level aristocrats). Boys were taught reading, writing, arithmetic, singing, and religion. A system of state-owned schools was started by Peter the Great as a state organization for purposes of administration in peace and war and for the development of mining and industry. Peter did not intend to promote the Orthodox faith or formal classical learning, whether Greek, Latin, or Slavonic, or universal education. He created mathematical, navigation, artillery, and engineering schools for utilitarian purposes. In 1725 an Academy of Sciences with a university and a *gimnaziya* (secondary school) was founded at St. Petersburg. These utilitarian, secular, and scientific characteristics of Peter's schools became the dominant features of the Russian system, but, as a result of the many changes of policy of his successors after his death in 1725, they did not develop into a national system of education. A second attempt at building up a national system of schools was made by Catherine II. After many abortive schemes, Catherine issued in 1786 a statute for schools, which can be considered the first Russian education act for the whole country. According to this act, a two-year course in minor schools was to be started in every district town and a five-year course in major schools in every provincial town. Catherinian schools were also to be utilitarian, scientific, and secular. At the end of the 18th century, 254 towns had the new schools, but 250 smaller towns and the rural districts had no schools whatever. The third nationalizing attempt in Russia was made by Alexander I and was influenced by the disintegration of the serf system, by the development of industry and commerce, and by the ideas of the French Revolution. The new statutes (1803 and 1804) maintained the principles of utility and secular scientific instruction. The parochial schools (*prikhodskiye uchilishcha*) in the rural areas were to instruct the peasantry in reading, writing, arithmetic, and elements of agriculture; the district schools of urban areas (*uyezdniye uchilishcha*) and the provincial schools (*gimnazii*) were to give instruction in subjects necessary for civil servants—law, political economy, technology, and commerce. The system was state controlled and free and formed a continuous ladder to the universities. Later conservative reactions, however, tended to blunt or reverse these reforms.

The education act of Catherine II

England. In England the development of a "national" education took a completely different course. It was influenced not by a political but by an industrial revolution. It is true that theorists such as Adam Smith, Thomas Paine, and Thomas Robert Malthus proposed state organization of elementary schooling, but even they wanted to see limited state influence; the state could pay the musicians but not call the tune. Not until 1802 did Parliament intervene in the development of education, when the Health and Morals of Apprentices Act required employers to educate apprentices in basic mathematics, writing, and reading. For the most part this remained only a demand, since the employers were not interested in such education.

The reluctance on the part of the state induced several philanthropists to form educational societies, principally for the education of the poor. In 1796, for example, was founded the Society for Bettering the Conditions of the Poor. A further impulse for elementary education stemmed from the Sunday schools, the first of which was founded in 1780 in Gloucester; by 1785 their numbers had so increased that the Sunday School Society was founded. The lessons in such schools, however, were mainly those of Bible reading.

The monitorial, or Lancasterian, system

Educators Andrew Bell and Joseph Lancaster played a major role in progress toward an elementary school system. They realized that the root of the problem lay in the lack of teachers and in the lack of money to hire assistants. Therefore, first Bell developed, then Lancaster modified, the so-called monitorial system (also called the Lancasterian system), whereby a teacher used his pupils to teach each other. The use of children to teach other children was not new, but Bell and especially Lancaster took the approach and developed it into a systematic plan of education. From 200 to 1,000 children were gathered in one room and seated in rows, usually of ten pupils each. An adult teacher taught the monitors, and then each monitor taught his row of pupils the lesson in reading, writing, arithmetic, spelling, or higher subjects. Besides monitors who taught, there were, in Lancaster's system, monitors to take attendance, give examinations, issue supplies, and so on; school activity was to be directed with military precision; the emphasis was on drill and memori-

zation. The system and the publicity connected with it expanded the efforts toward mass education, even though, pedagogically, the whole process was so routinized and formalized that opportunities for creative thinking or initiative scarcely existed. Also Lancaster's statement that "Any boy who can read can teach" proved to be false. The only valid, long-range answer to teacher shortages would be the expanded training of teachers. (H.-J.I.)

EUROPEAN OFFSHOOTS IN THE NEW WORLD

Spanish and Portuguese America. With the Spanish conquerors of the New World, the conquistadores, came friars and priests who immediately settled down to educate the Indians and convert them. Because no concept of education as a governmental responsibility existed, the Roman Catholic Church assumed complete control of elementary education, and the early Franciscan and Dominican friars were followed by Augustinians, Jesuits, and Mercedarians.

Church control of colonial education

The first elementary school in the New World was organized in Mexico by the Franciscan Pedro de Gante in 1523 in Texcoco, followed in 1525 by a similar school in San Francisco. Because such schools in Mexico were designed for Indian children, the monks learned the native languages and taught reading, writing, simple arithmetic, singing, and the catechism. The schools of the *hospicio* of the bishop Vasco de Quiroga in Michoacán added agriculture, trades, and crafts to their curriculum.

Mestizo children, the issue of Spanish and Indian parents, were often abandoned; thus, special institutions appeared to collect and educate them—for example, the Colegio de Niñas and the Colegio de San Juan de Letrán, founded by Viceroy Mendoza in New Spain, and the Bethlehemite schools of Guatemala and Mexico.

In the beginning, children of Spaniards born in the colonies, called Creoles, had tutors. Eventually, schools promoted by municipal authorities (*cabildos*) emerged, especially in Chile and Argentina (*escuelas del rey*).

During the 18th century the Enlightenment came to Latin America, and with it a more secular and widespread education. Among famous projects were those of Viceroy Vertiz y Salcedo in Argentina and two model schools, free for children of the poor, by Archbishop Francos y Monroy in Guatemala. In New Spain the Colegio de las Vizcaines (1767) became the first all-girl lay institution.

Because of the social structure, riches and administrative privilege were held by an elite, the Creoles. Secondary education was scarce and originally existed only in the monasteries, where the grammar and Latin colleges prepared the clergy and some lay Creoles who wanted to enter the universities. There also existed a few special colleges or secondary institutions for the Indian nobility, the first outstanding one being Santa Cruz de Tlaltelolco (1535–95) in Mexico, which produced teachers of native languages and liberal arts. Similar colleges existed in Bogotá, Quito, Cuzco, Charcas, Santiago, and Chillán. Though the Dominicans had been pioneers in all such education, the Jesuits became the most important teachers. They offered an efficient education, molded to contemporary requirements, in boarding schools, where the elite of the Spaniards born in the Americas studied. When their order was expelled in 1767, education was dealt a severe blow. In Portuguese Brazil, where the expulsion edict had been issued eight years earlier and where they had been the only educators, the royal chancellor was forced to make feeble attempts toward organizing a secular education. The Spanish king, Charles III, also took advantage of the occasion and founded some new institutions—the Academy of San Carlos, the School of Mining in Mexico, the Royal College of San Carlos in Buenos Aires—and modernized others.

The Latin American universities

Traditionally, Spanish universities had been organized on the model either of Paris or of Bologna. The former was a *universitas magistrorum*, governed by professors organized in faculties, whereas the latter, as a *universitas scholarium*, received its corporate authority from the student body organized into "nations" that elected leaders to whom even the professors were subject. In 1551 the Council of the Indies authorized the founding of the first American universities, one in Mexico and one in Lima; academic government was placed in the hands of a *claustro*, or faculty, composed of the rector, the teachers, and the professors. Dedicated to general studies, the universities required a papal as well as a royal authorization.

The Real y Pontificia Universidad de Mexico was the first to open its doors, in 1553. In the Spanish colonies eventually ten major and 15 minor universities came into existence. The latter were actually colleges or secondary institutions—nine Jesuit, four Dominican, one Franciscan, and one Augustinian—which, because they were located far from the closest university (minimally 200 miles), were given special authorization to grant higher degrees. In Brazil no university existed, and Portuguese born in the colony had to go to Portugal for study.

Though in Spain itself law reigned supreme, in the Americas theology became the principal chair. Teaching was in scholastic mode: it began with the reading of a classical text; then the professor explained the thesis or proposition and offered arguments pro and contra so that a conclusion in accord with Catholic dogma would result. (J.V.de K.)

French Québec. Soon after the founding of the Québec colony in 1608, the first organized educational activity began with missionary work among the Indians, carried on mainly by members of the Récollet and Jesuit orders and, from 1639, by Ursuline nuns. The first mission "school" recorded was that of Brother Pacifique du Plessis, established in 1616 in Trois-Rivières (Three Rivers).

Christian efforts among the Indians were only an environmental dimension of the religious purposes that framed educational activity in Old World France. Roman Catholic social philosophy allowed no compromise in the spiritual direction of education, and both in informal socialization patterns and in what formal provisions existed the doctrine and aim of religion coincided with that of education. At the general level, education was intended to produce religious conformation in thought and behaviour; at the higher level, education was to produce a progeny of clerical leadership. The paternalistic authority of church and monarch was carried from the Old to the New World, where it perhaps became even more pervasive, due to the initial absence of alternative institutional developments. In education, the exclusive role of the state (though not insignificant) was confined to financial subsidization. Authority for the institution of education was vested in the bishop.

Most of the nonreligious functions now associated with formal education were, in the 17th and 18th centuries, carried in other institutional sectors: the family, the community, the vocation. Just as there was no sharp break between church and school in formal learning, there was an easy transition between the information and behaviour necessary for work and life as transmitted in the course of various socialization experiences. Thus, the self-sustaining and isolated life of the farmers, the wild and solitary ways of the *coureurs de bois* (the fur traders), the miniature of European manners and customs established in the cities by the gentry—all contained within their own cycle the educative procedures for life in that society. Education as a separate institution was understandably associated with learning not related to the business of life.

The schools of New France

Institutional forms found in French colonial Québec included parish schools, girls' schools, secondary schools, and vocational schools; and literacy records indicate that the provision for education was in sum comparable to that in the Old World. Parish or common schools were irregularly provided to afford the rudiments of literacy and religion. Because of the relative sparseness of educational resources, social classes were frequently mixed in these schools. Girls' schools were established by the Ursulines from 1642 and by the Sisters of the Congrégation de Notre Dame from 1659, with a rudimentary curriculum but including a characteristic "finishing" of social graces appropriate to the French-Canadian girl. Vocational training was probably of least concern in this early period, but specific attempts to institutionalize this educa-

tional area were begun as early as 1668 with the establishment of L'École des Arts et Metiers in Saint Joachim, for instruction in agriculture and certain trades.

Secondary education was offered by the Jesuits from 1636. The Jesuit college, offering early training for eventual entrance into the priesthood, was conducted along characteristically Jesuit lines: militaristic discipline in conduct, unequivocal authority in method, classical curriculum in content. The classical curriculum pattern, comprising basically Latin, Greek, mathematics, philosophy, and theology, was to be essentially preserved in the French-Canadian development of *collèges classiques* for secondary education.

In 1663, Bishop Laval established in the city of Québec the *grande seminaire* as the apex of the educational "system," as the first French-Canadian "university." Shortly thereafter, he also established the preparatory *petit seminaire*.

Following the cession of Québec to Britain in 1763, education fell prey to political and cultural disruption. Although the British military and colonial government attempted to preserve the structure of French civil and religious institutions, the cultural integrity of the system was inevitably broken. Financial grants from France for education discontinued and were not replaced by the British government; recruitment to religious orders was restricted; and educational development was obstructed by the continual association of educational plans with cultural–religious controversies. The end of the 18th century saw French-Canadian education fall backward into neglect. (R.F.L.)

British America. *New England.* The year 1630, chronicled in New England annals as the beginning of the Great Migration, witnessed the founding there of Puritanism as the established religion. Rejecting democracy and toleration as unscriptural, the Puritans put their trust in a theocracy of the elect that brooked no divergence from Puritan orthodoxy. So close was the relation between state and church that an offense against the one was an offense against the other and, in either case, "treason to the Lord Jesus." The early Puritans also put their confidence in centralized church governance; however, geographic reality forced them to settle for a localized, congregational administration, for impossible roads made land travel over any distance onerous and even dangerous, and thus the focal point of social and political life had to be the village. Small and constricted, a place where the vital necessities, sacred and profane, were within walking range of all and where one's conduct was exposed to constant public watch, the New England village was the prime mover of communal life.

Puritan education in New England

In Puritan moral theology the young, like the old, were sinners doomed by almost insurmountable odds to perdition. Not even infants were spared. To God, indeed, they were depraved, unregenerate, and damned. Hence, the sooner the young learned the ground rules of the good society, as revealed in the Bible, the better. The task of teaching them first befell the parents. Later, when they were old enough, the burden was conferred upon the school. And schools were not long in coming. The first was probably at Boston, which, in 1635, sought the services of a schoolmaster. The year following, Charlestown undertook to pay a teacher out of the town purse. Three years thereafter, Dorchester made fiscal provision to maintain a permanent town school. What these towns inaugurated others imitated, so that by the 1640s the idea of town-supported schooling had lost its novelty.

If towns braved the first steps in education, then the Commonwealth of Massachusetts did not trail far behind. In 1642 it ordered parents and masters of apprentices to see to it that their charges were instructed in reading, religion, and the colony's principal laws. Five years later, the General Court reinforced this enactment with yet another. Aimed, as it explained, at the "old deluder Satan," it undertook to thwart him from keeping "men from a knowledge of the Scriptures," by requiring every township of 50 households to commission someone to teach reading and writing. In addition, the law directed towns of 100 families to furnish instruction in Latin grammar so that youth might be "fitted for the university." Finally, the measure required teachers to be paid by "parents or masters . . . or by the inhabitants in general." Nevertheless, the measure was given only a pallid obedience, and directly and indirectly numerous towns evaded its requirements. More pertinent, doubtless, to subsequent times, is its underlying assumption that the state may compel the schooling of its young and that in order to support education it may impose taxes.

The school founded in Boston in 1635 was the Boston Latin School. The first secondary school in colonial America, Boston Latin was modelled on the grammar schools of England, which is to say that it put an overwhelming emphasis on the ancient languages and "humane learning and good literature." Taking its novices at an age of seven, when they could read rudimentary English, the school belaboured them with Latin grammar. Once they were its master, they were put upon reading the salient Latin literati. After six years of such industry they proceeded similarly with Greek. Sometimes, when circumstances were propitious, a bright lad was set to work on Hebrew. The legatee of the classical humanistic tradition but rescored to attune it to the Reformation, the Boston Latin School was the most famous of its kind in New England. But there were several others of high merit, among them Cambridge, Dorchester, and Roxbury, all of which, like Boston, are still in practice.

The founding of Harvard College

The first colonists had scarcely settled when, in 1636, the General Court appropriated £400 "towards a school or college." When, two years later, John Harvard died and left the institution his library and some £800, the grateful founders honoured their school with his name. Designed to train youth for important Puritan places, particularly in the ministry, the college accepted only those who could read, write, and speak Latin in prose and verse, besides knowing Greek nouns and verbs familiarly. Once admitted, the student was lodged at the college, pledged to a blameless behaviour, and put upon a prescribed four-year course of grammar, rhetoric, logic, arithmetic, geometry, astronomy, ethics, ancient history, Greek, and Hebrew. If he weathered these hazards, he was made a bachelor of arts (B.A.), and, if ambition still rowelled him, he could enroll for another three years to become a master of arts (M.A.).

So things sat until the century's passing. Then, swayed by the intellectual breezes of Europe's Enlightenment, Harvard College ventured some earnest renovation. Its texts, cobwebbed with Aristotelianism, were replaced with newer ones by Locke and Newton. In 1718 it added mathematics and sciences to its offerings, and 20 years later it enriched itself with a professorship of mathematics and natural philosophy. There were the usual grumblings from conservatives. In truth, in 1701 a number of Congregational parsons, all Harvard sons, distressed by their alma mater's dalliance in newfangled ideas, inaugurated a grove of their own, the collegiate school of Connecticut, now Yale University. Harvard, however, remained unchastened.

The new academies. Disdainful of the challenging intellectual values, the Latin schools continued in their classical tracks. By the 18th century, however, their tradition was playing out, especially among the rising nabobs of the marketplace. When the old schools failed to respond to their demands for an education calculated to prepare their sons for everyday living, they resorted to private schooling. From such endeavour emerged the academy. The first school of strictly native provenance, it made its advent in 1751 in Philadelphia (the Philadelphia Academy), the work in the main of Benjamin Franklin. What differentiated it from its classical antecedent was its hearty promotion of "useful learning," to wit, the vernacular, modern languages, history, geography, chronology, navigation, mathematics, natural and applied science, and the like.

The first academies addressed themselves solely to boys, but time saw them vouchsafe instruction to girls in a "female department," which in turn gave way to the "female academy." Private ventures always, academies generally were not loath to solicit outside assistance—some, in-

deed, as in New York, enjoyed a public subsidy. Whatever their special character, to their very end they maintained their original purpose of bringing education into closer consonance with "the great and the real business of living," as Phillips Academy of Andover, Massachusetts, phrased it when, in 1778, it held its first sessions. To this purpose they taught anything for which there was a sufficient call, from the subjects proffered by the original Philadelphia Academy to several dozen more.

Diversity of the middle colonies

The middle colonies. The religious uniformity that marked the Puritan theocracy was missing in the middle colonies. From New York through Delaware there flourished a host of sects whose scriptural interpretations were diverse—often, in fact, in collision. Nor was there even the tie of a common language, for the settlers came from many lands. Divergent in religion and language, the bedrock in those times of elementary schooling, the middle colonists could not accommodate themselves, as did the Puritans, to a single school teaching reading and religion to all the children of the neighbourhood. Instead, they depended on parish or parochial schools, each of them free to teach by its own denominational lights. True, for a time New Netherland, with its established Dutch Reformed Church, maintained some town schools, but, after the English seized the colony (renaming it New York), such endeavours ceased. Pennsylvania, linguistically and denominationally the most heterogeneous of the colonies, began its educational history by ordering the erection of public schools and the instruction of children. But the ordinance fell prey to powerful sectarian antagonisms, and in 1701 the colony essayed to make peace by sanctioning the establishment of parochial schools.

Like the New Englanders, the middle colonists aspired to establish colleges, but, with no friendly lawmakers to sustain them, they found their task heavily hobbled, and the mid-1700s were upon them before their hopes materialized with the advent, in 1746, of the College of New Jersey (Princeton). There followed King's College (Columbia) in 1754; the College and Academy of Philadelphia (Pennsylvania) in 1755; and Queen's College (Rutgers) in 1766. Common to these schools was their stress on the ancient languages, metaphysics, and divine science. At the same time, however, one discerns signs of a new liberalism. Both Rutgers and Columbia announced their interdenominationalism. Pennsylvania offered courses in physics, and in 1765 it became the first colonial college to sponsor systematic instruction in medicine.

Effects of plantation life on Southern education

The Southern colonies. Unlike New Englanders, Southerners resided not in villages but on widely scattered plantations. For years, town life was impossible and so, per consequence, were town schools. But even had their establishment been feasible, the odds against them were staggering, since the ruling classes, like their analogues overseas in England, were averse to schooling the young under governmental direction. Instead, they regarded education as a personal concern, the affair of parent and church rather than the state. Left thus to their own devices, Southerners schooled their young to suit their taste, the rich resorting to tutors and private schools and the rest scratching out an education as best they could. Time saw the appearance of a number of free schools serving those who were neither rich nor poor. For the offspring of the low-down and unregarded folk, Virginia enacted its law of 1642. An echo of England's Poor Law, it provided for the "relief of such parents whose poverty extends not to give them [the children] breeding." For this purpose it ordered the creation of a "workhouse school" at James City to which each county was to commit two children of an age of six or over. There, besides being reared as Anglicans, they were to be "instructed in honest and profitable trades and manufactures as also to avoid sloth and idleness." Amended several times, the statute became the model for similar legislation throughout the South.

If Southerners dawdled in schooling the multitude, in the higher learning they moved more quickly. As early as 1619 the Virginia Company reserved £1,500 and several thousand acres of land to found a university at Henrico, but a massacre of nearly all the inhabitants shattered the plan. Several other attempts followed, but not until 1693 did the South obtain a college. Named for its royal sponsors, William and Mary College was chartered to propagate the "Liberal Arts and the Christian Faith," with particular stress on preparing young men for the Anglican pulpit. To accomplish this, it offered preparatory courses in ancient languages, followed by the conventional collegiate curriculum of rhetoric, logic, ethics, mathematics, physics, and metaphysics, besides sacred and moral science, including "the commonplaces of divinity and the controversies with heretics." As the 18th century swept on, the secular interest that had invaded Harvard appeared in Virginia, and there ensued a waning of the earlier religious motivation. In 1779, led by Thomas Jefferson, the college trustees refurbished the school with chairs in medicine, mathematics, physics, moral philosophy, economics, law, and politics. Concurrently, it discontinued the chair in divinity as "incompatible with freedom in a republic." (A.E.M.)

Newfoundland and the Maritime Provinces. Newfoundland was, during most of this period, under British control, and, though there were settlers even before the 17th century, the island was not considered a settlement colony. Other than for naval training and fishing advantages, the British government had no concern for Newfoundland. Thus, policies were constructed with regard to the rights and advantages of English seamen, while, implicitly as well as in overt regulations, settlement was obstructed and restricted. Destruction from the running French–English military conflicts further discouraged development. These conditions of economic and political diminution of the settlement from outside were aggravated by the usurious conduct of merchants and the corruption of officials and by the national and religious divisions among the inhabitants themselves.

With such substantial problems of mere survival in Newfoundland, it is not surprising that the luxury of formal education was almost absent during this period. Some accounts verify that informal, unorganized efforts were made on an occasional basis to convey minimum schooling to settlers' children, but the only organized effort was that of the Society for the Propagation of the Gospel in Foreign Parts (SPGFP). The SPGFP founded or aided a school in Bonavista in 1722 and in St. John's in 1744 and sponsored schools in more than 20 settlements between 1766 and 1824. Religion was undoubtedly more important than education as such to the society, but its provision of reading materials as well as the mere act of establishing some kind of school filled a notable void in the Newfoundland settlement. Other charitable societies, such as the Society for Improving the Condition of the Poor in St. John's, the Benevolent Irish Society, the Newfoundland School Society (later the Colonial and Continental Church Society), the Wesleyan Society, the Sisters of the Presentation, the Sisters of Mercy, and the Irish Christian Brothers, carried the charity-school work into the 19th century and maintained a thread of education through the colonial "dark ages."

Society for the Propagation of the Gospel in Foreign Parts

For a time after 1763, the Maritimes were all one colony—Nova Scotia—but Prince Edward Island was separated in 1769 and New Brunswick in 1784. This area comprised a heterogeneous population of French Acadians, English Protestants and others from Europe, Highland Scots, and loyalists from the United States. Each of these groups carried attitudes more or less favourable to education, and the regionalization of these attitudes, together with other conditions, influenced the differential development of education in the area. At the end of the 18th century, for example, New Brunswick, with a high loyalist population promoting political and educational development, probably ranked highest among the Maritime colonies in educational interest.

The first relatively organized attempt at common schooling in the Maritimes was made by the SPGFP, closely connected to the Church of England. The society opened both weekday and Sunday schools, and it might be said that it fostered teacher training in stipulating qualifications for its teachers. Other than SPGFP schools, education in the Maritime colonies was carried on by itin-

erant teachers and in scattered private-venture schools. Schools for separate ethnic or religious groups were discouraged by the Anglicans, but consistent pressure for such schools did succeed, at least temporarily; for example, in Lunenburg, Nova Scotia, and in Sydney, on Cape Breton Island. An interesting note is the establishment of a school for blacks in Halifax in 1788.

Upper schools were established only toward the end of the 18th century in the Maritimes. As they were established singularly and recruited from a social class rather than from a lower school, there is no clear line of demarcation among the various types as there would be later in an integrated system. Basically, they were Anglican and classical, although the private schools, advertising to as wide a clientele as possible, often included some breadth, extending into practical studies. Probably the most influential of the early attempts were the two Latin grammar schools founded in 1788 and 1789 at Windsor and Halifax, Nova Scotia. The former became associated with King's College, established in Windsor at the same time. Thomas McCulloch's Academy at Pictou, Nova Scotia, and the College of New Brunswick at Fredericton, both founded around the turn of the century, should also be mentioned as early exemplars of higher education.

(R.F.L.)

VIII. Western education in the 19th century

THE SOCIAL AND HISTORICAL SETTING

From the mid-17th century to the closing years of the 18th century, new social, economic, and intellectual forces steadily quickened—forces that in the late 18th and the 19th centuries would weaken and, in many cases, end the old aristocratic absolutism. The European expansion to new worlds overseas had stimulated commercial rivalry. The new trade had increased national wealths and encouraged a sharp rise in the numbers and influence of the middle classes. These social and economic transformations, joined with technological changes involving the steam engine and the factory system, together produced industrialism, urbanization, and the beginnings of mass labour. At the same time, intellectuals and philosophers were assaulting outworn economic abuses, old unjust privileges, misgovernment, and intolerance. Their ideas, which carried a new emphasis on the worth of the individual—the citizen rather than the subject—helped not only to inspire political revolutions, sometimes successful, sometimes unsuccessful, but, more important, to make it impossible for any government, even the most reactionary, to disregard for long the welfare of the common man. Finally, there was a widespread psychological change: man's confidence in his power to use resources, master nature, and structure his own future was heightened beyond anything known before; and this confidence on a national scale—in the form of nationalism—moved all groups to struggle for the freedom to direct their own affairs.

Education as the responsibility of the state

All these trends influenced the progress of education. One of the most significant results was the gradual acceptance of the view that education ought to be the responsibility of the state. Some countries, such as France and Germany, were inspired by a mixture of national aspiration and ideology to begin the establishment of public educational systems early in the 19th century. Others, such as Great Britain and the United States, under the spell of laissez-faire, hesitated longer before allowing the government to intervene in educational affairs. The school reformers in these countries had to combat the prevailing notion that "free schools" were to be provided only for pauper children, if at all; and they had to convince society that general taxation upon the whole community was the only adequate way to provide education for all the children of all the people.

The new social and economic changes also called upon the schools, public and private, to broaden their aims and curricula. Schools were expected not only to promote literacy, mental discipline, and good moral character but also to help prepare children for citizenship, for jobs, and for individual development and success. Although teaching methods remained dominantly oriented toward textbook memorizing and strict discipline, a more sympathetic attitude toward children began to appear. As the numbers of pupils expanded rapidly, individual methods of "hearing recitations" by children began to give way to group methods. The monitorial, or Lancasterian, system became popular because, in the effort to overcome the shortage of teachers during the quick expansion of education, it enabled one teacher to use older children to act as monitors in teaching specific lessons to younger children in groups. Similarly, the practice of dividing children into grades or classes according to their ages—a practice that began in 18th-century Germany—was to spread everywhere as schools grew larger.

THE EARLY REFORM MOVEMENT: THE NEW EDUCATIONAL PHILOSOPHERS

Influence of Rousseau

The late 18th and 19th centuries represent a period of great activity in reformulating educational principles, and there was a ferment of new ideas, some of which in time wrought a transformation in school and classroom. Of those who thought and wrote about education, no one was to have so great an influence as Rousseau (discussed in the preceding section), who, by stressing the importance of helping children to grow and develop naturally, started a revolution in educational theory that in time largely changed the relationship between teacher and pupil. His version of education, so different from the artificial, conventional, formal teaching then usual, inspired others to continue the revolution that he initiated. Among those influenced in the 19th century were Johann Pestalozzi, Friedrich Froebel, and Johann Friedrich Herbart.

Pestalozzianism. The theories of the Swiss reformer Johann Heinrich Pestalozzi laid much of the foundation of modern elementary education. Beginning as a champion of the underprivileged, he established near Zürich in 1774 an orphanage in which he attempted to teach neglected children the rudiments of agriculture and simple trades in order that they might lead productive, self-reliant lives. A few years later the enterprise failed, and Pestalozzi turned to writing, producing his chief work on method, *How Gertrude Teaches Her Children*, in 1801, and then began teaching again. Finally in 1805 he founded at Yverdon his famous boarding school, which flourished for 20 years, was attended by students from every country in Europe, and was visited by many of the most important figures of the time, including the philosopher J.G. Fichte, the educators Friedrich Froebel and Johann Friedrich Herbart, and the geographer Carl Ritter.

The pedagogy of Pestalozzi. In spite of the quantity of his writings, it cannot be said that Pestalozzi ever wrote a complete and systematic account of his principles and methods; an outline of his theories must be deduced from his various writings and his work. The foundation of his doctrine was that education should be organic, meaning that intellectual, moral, and physical education (or, in his words, development of "head, heart, and body") should be integrated and that education should draw upon the faculties or "self-power" inherent in the human being. Education should be literally a drawing out of this self-power, a development of abilities through activity—in the physical field by encouraging manual work and exercises, in the moral field by stimulating the habit of moral actions, and in the intellectual field by eliciting the correct use of the senses in observing concrete things accurately and making judgments upon them. Words, ideas, practices, and morals have meaning only when related to concrete things.

Child-centred education

From these overarching principles there followed certain practical rules of educational method. First, experience must precede symbolism. There must be an emphasis on object lessons that acquaint the child with the realities of life; and the effort to relate experience and abstract thought (and language) must be gradual and progressive. A person gets knowledge by his "own investigation, not by endless talk about the results of art and science." A person "is much more truly educated through that which he does than through that which he

learns" secondhand. Next, the program should be child centred. There must be an allowance for individual differences (whenever possible, grouping children according to ability), and there must be freedom to learn. The teacher's task is to offer "continual benevolent superintendence—giving a helping hand to the instinctive efforts" of the child. "The nature of the child must determine all the details of his education." This also means that the stages of education must be related to the stages of child development. "Each child should be taught that which he has to learn at the time his nature calls for it, for this is proof that his sensibility and power are ready for it." Finally, education should be correlated and well rounded. Intellectual, moral, and physical activities should be as one. All these ideas, which may sound commonplace to today's reader, were extraordinarily innovative for the times.

Self-help for the poor

Much of Pestalozzi's pedagogy, it should be noted, was influenced by the fact that his main work was with children of the poor. Thus, there was a strong emphasis on education in the home. There was a strong emphasis on the development of skills. (The philosopher Fichte accused Pestalozzi of trying to make children learn reading and writing too early but, as an admirer of Pestalozzi, acknowledged that the man was swayed by the need to fit the children for making their own living as soon as possible.) Pestalozzi also placed heavy emphasis on manual training, integrating it with other activities. In effect, whereas the reformers of the Enlightenment and the French Revolution had stressed, and were stressing, the "emancipation" of the lower classes, men like Pestalozzi, in a realistic vein, aimed at helping poor people to help themselves, helping them to get rid of a sense of failing and develop a spirit of enterprise. This was social reform, not social revolution. Indeed, Pestalozzi viewed revolutionaries as "shipwrecked women, [who] saw every straw as a mast by which the republic could reach the shore."

The influence of Pestalozzi. "The art of education," Pestalozzi claimed, "must be significantly raised in all its facets to become a science that is to be built on and proceeds from the deepest knowledge of human nature." By his own efforts in this direction, he stimulated pedagogic theory and practice to an enormous degree in many parts of the Western world. By his philanthropic efforts in behalf of the poor, he inspired new movements toward the reform of philanthropic educational institutions and the pedagogy applied to such institutions; he created a new methodology for elementary education that was introduced not only into schools but also into programs of teacher education in Europe and America; and by his own example he gave teachers a high professional ethos. Against these achievements his weaknesses pale into insignificance: his lack of organizing ability in trying to realize his ideas; some formalistic exaggerations in method. Pestalozzi was a restless, passionate person, self-critical to the point of being self-tormenting, who, like few others at any time, recognized and sincerely tried to alter the misery existing in the world. If the Enlightenment saw its pedagogic mission as the spreading of the light of reason, then Pestalozzi showed that it was not reason alone but above all love that would show a way out of the "mire of the world."

Pestalozzi's influence abroad

It is hardly possible to name all of Pestalozzi's disciples —the Pestalozzians—for almost all the pedagogic figures of his time literally or figuratively went to his school. His influence was most profound in Germany, especially in Prussia and Saxony. Generally speaking, in the first half of the 19th century the English school system was completely under the influence of the disciplinarian monitorial systems of Bell and Lancaster (see preceding section). Pestalozzi for most Englishmen was "a distressing type of the German" and "an idealistic dreamer," as some critics put it. Nevertheless, he exercised some influence in England through James Pierrepont Greaves and the London Infant School Society and through Charles and Elizabeth Mayo and the Home and Colonial School Society. In the United States, Pestalozzianism was introduced by a Philadelphia scientist and philanthropist, William Maclure, one of the sponsors of the utopian colony at New Harmony, Indiana. The movement became extremely popular, extending from New England and New York to St. Louis.

In Switzerland itself, in Hofwil near Bern, Philipp Emanuel von Fellenberg founded an institution for the education of the poor. He tried to build up a kind of pedagogic province or miniature state, in which work was the means of self-help and in which the pedagogic program was the joint responsibility of teachers and pupils. His educational aim was "the harmonious development and education of all the combined talents and abilities in human nature with which God has entrusted each person."

Froebel and the kindergarten movement. Next to Pestalozzi, perhaps the most gifted of early 19th-century educators was Friedrich Froebel, the founder of the kindergarten movement and a theorist on the importance of constructive play and self-activity in early childhood. He was an intensely religious man who tended toward pantheism and has been called a nature mystic. Throughout his life he achieved very little literary fame, partly because of the style of his prose and philosophy, which is so romantically obscurantist as to be difficult to read and sometimes scarcely comprehensible.

In early life, Froebel tried various kinds of employment until in 1805 he met Anton Gruner, a disciple of Pestalozzi and director of the normal school at Frankfurt am Main, who persuaded him to become a teacher. After two years with Gruner, he visited Pestalozzi at Yverdon, studied at Göttingen and Berlin, and eventually determined upon establishing his own school, founded on what he considered to be psychological bases. The result in 1816 was the Universal German Educational Institute at Griesheim, transferred the following year to Keilhau, which constituted a kind of educational community for Froebel, his friends, and their wives and children. To this period belongs *The Education of Man* (1826), his most important treatise, though typical of his obscurantism. In 1831 he was again in Switzerland, where he opened a school, an orphanage, and a teacher-training course. Finally, in 1837, upon returning to Keilhau, he opened his first *Kindergarten*, or "garden of children," in nearby Bad Blankenburg. The experiment attracted wide interest, and other kindergartens were started and flourished, despite some political opposition.

The first kindergarten

The pedagogy of Froebel. Froebel's pedagogic ideas have a mystical and metaphysical context. He viewed man as a child of God, of nature, and of humanity who must learn to understand his own unity, diversity, and individuality, corresponding to this threefold aspect of his being. On the other hand, man must understand the unity of all things (the pantheistic element).

> Education consists of leading man, as a thinking, intelligent being, growing into self-consciousness, to a pure and unsullied, conscious and free representation of the inner law of Divine Unity, and in teaching him ways and means thereto.

Education had two aspects: the teacher was to remove hindrances to the self-development or "self-activity" of the child, but he was also to correct deviations from what man's experience has taught is right and best. Education is thus both "dictating and giving way." This means that ordinarily a teacher should not intervene and impose mandatory education, but when a child, particularly a child of kindergarten age, is restless, tearful, or willful, the teacher must seek the underlying reason and try to eradicate the uncovered hindrance to the child's creative development. Most important, the teacher's dictating and giving way should not flow from the mood and caprices of the teacher. Behaviour should be measured according to a "third force" between teacher and child, a Christian idea of goodness and truth.

School, for Froebel, was not an "establishment for the acquisition of a greater or lesser variety of external knowledge"; actually, he thought children were instructed in things they do not need. School instead should be the place to which the pupil comes to know the "inner relationship of things," "things" meaning God, man, nature, and their unity. The subjects followed from this: religion, language and art, natural history, and the knowl-

edge of form. In all these subjects the lessons should appeal to the pupil's interests. It is clear that, in Froebel's view, the school is to concern itself not primarily with the transmission of knowledge but with the development of character and the provision of the right motivation to learn.

Froebel's emphasis on play

Froebel put great emphasis on play in child education. Just like work and lessons, games or play should serve to realize the child's inner destiny. Games are not idle time wasting; they are "the most important step in the development of a child," and they are to be watched by the teachers as clues to how the child is developing. Froebel was especially interested in the development of toys for children—what he called "gifts," devised to stimulate learning through well-directed play. These gifts, or playthings, included balls, globes, dice, cylinders, collapsible dice, shapes of wood to be put together, paper to be folded, strips of paper, rods, beads, and buttons. The aim was to develop elemental judgment distinguishing form, colour, separation and association, grouping, matching, and so on. The important point is that the children were to play with these things not as they wished but as organized or subtly guided by the teacher. "The child must feel some relationship to you in his activity, as you feel to God in everything you do." This high evaluation of the personal relationship in education is also clear in Froebel's concept of the kindergarten.

The kindergarten movement. The kindergarten was unique for its time. Whereas the first institutions for small children that earlier appeared in Holland, Germany, and England had been welfare nursery schools or day-care centres intended merely for looking after children while parents worked, Froebel stood for the socializing or educational idea of providing, as he put it in founding his kindergarten, "a school for the psychological training of little children by means of play and occupations." The school, that is, was to have a purpose for the children, not the adults. The curriculum consisted chiefly of three types of activities: (1) playing with the "gifts," or toys, and engaging in other occupations designed to familiarize children with inanimate things: (2) playing games and singing songs for the purpose not only of exercising the limbs and voice but also of instilling a spirit of humanity and nature; and (3) gardening and caring for animals in order to induce sympathy for plants and animals. All this was to be systematic activity.

The kindergarten plan to meet the educational needs of children between the ages of four and six or seven through the agency of play thereafter gained widespread acceptance. During the 25 years after Froebel's death in 1852, kindergartens were established in leading cities of Austria, Belgium, Canada, Germany, Great Britain, Holland, Hungary, Japan, Switzerland, and the United States. In Great Britain the term infant school was retained for the kindergarten plan, and in some other countries the term *crèche* has been used (see also PRESCHOOL EDUCATION).

Widespread acceptance of kindergartens

Herbartianism. Johann Friedrich Herbart was a contemporary of Froebel and other German Romanticists, but he can hardly be put into the ranks of such pedagogues. During his lifetime his sober, systematic "philosophical realism" found little approval; and only posthumously, during the latter half of the 19th century, did his work achieve great importance. He is regarded as one of the founders of theoretical pedagogy, injecting both metaphysics and psychology into the study of how people learn.

The psychology and pedagogy of Herbart. As a young man of 18, Herbart had studied at the University of Jena under the Idealist philosopher Fichte. It was a long while before he broke from the spell of Fichte's teachings, which denied the existence of things independent of the consciousness, and turned to philosophical Realism, which asserts that underlying the world of appearances there is a plurality of things or "reals" that have existence apart from the operations of the mind. Change consists simply in the alteration in the relations between these reals, which resist the changed relationships as a matter of self-preservation.

Ideas, as things, likewise always exist and always resist change and seek self-preservation. It is true that some ideas may be driven below the threshold of consciousness; but the excluded ideas continue to exist in an unconscious form and tend, on the removal of obstacles (as through education), to return spontaneously to consciousness. In the consciousness there are ideas attracting other ideas so as to form complex systems. These idea masses correspond to the many "interests" of the individual (such as his home and his hobbies) and to broader philosophical and religious concepts and values. In the course of mental development certain constellations of ideas acquire a permanent dominance that exercises a powerful selective facilitating influence upon the ideas struggling to enter or re-enter the consciousness.

In his systematic account of the nature of education, Herbart conceived the process as beginning with the idea masses that the child has previously acquired from experience and from social intercourse. The teacher creates knowledge from the former and sympathy from the latter. The ultimate objective is the formation of character by the development of an enlightened will, capable of making judgments on right and wrong. Moral judgments (like reals) are absolute, springing from contemplation, incapable of proof and not requiring proof. Ethics, in other words, is the ultimate focus of pedagogy.

In the classroom, it is the aim of the lessons to introduce new conceptions, to bind them together, and to order them. Herbart speaks of "articulation." First the student becomes involved in a particular problem; then he considers its context. Each of these two stages has a phase of rest and of progress, and thus there are four stages of articulation: (1) clarification, or the static contemplation of particular conceptions; (2) association, or the dynamic linking of new conceptions with old ones; (3) systematization, or the static ordering and modification of what in the conceptions are deemed of value; and (4) methodization, or the dynamic application and recognition of what has been learned. Herbart phrased this system of instruction only in very general terms, but his successors tended to turn this framework into a rigid schedule that had to be applied to every lesson. Herbart himself warned:

"Articulation," or the systematization of lessons

> We must be familiar with them [the methods], try them out according to circumstances, alter, find new ones, and extemporize; only we must not be swallowed up in them nor seek the salvation of education there.

Herbart's ethics and psychology are today considered old-fashioned. The tendency toward a schematic, rigid type of instruction, as adopted and simplified by his disciples and widely practiced for decades, was strongly criticised by reformers at the beginning of the 20th century. Indeed, criticism of Herbart sometimes became too negative and overlooked his merits: the establishment of pedagogy as an autonomous science; the discovery of interest and spontaneity as part of the educational process; and the attempt to give instruction a psychologically based rationale.

Herbartians. Herbart's followers, who practiced in the latter half of the 19th century, were mainly concerned with applying the master's thoughts to school practices and teacher training. Among the followers were Tuiskon Ziller in Leipzig (who was the founder of the Association for Scientific Pedagogy, or Verein für wissenschaftliche Pädagogik), Wilhelm Rein in Jena, and Friedrich Wilhelm Dörpfeld in Barmen. Ziller's ideas are representative. He insisted that all parts of the curriculum be closely integrated and unified—history and religion forming the core subjects on which everything else was hinged. The sequence of instruction was to be adjusted to the psychological development of the individual, which was seen as corresponding to the cultural evolution of mankind in stages from primitive savagery to civilization. His main aim in education, like the aim of most Herbartians, was promoting character building, not simply knowledge accumulation.

Other German theorists. In the history of pedagogy there is no period of such fruitfulness as the 19th century in Germany. In addition to Herbart, Froebel, Pestalozzi

(in German Switzerland), and their followers, there were scores of the most important writers, philosophers, and theologians contributing their ideas on education—including Friedrich Schiller, Johann Wolfgang von Goethe, G.W.F. Hegel, Friedrich Ludwig Jahn, Johann Paul Friedrich Richter, Ernst Moritz Arndt, Friedrich Nietzsche, and Julius Langbehn. To list the many ideas and contributions of these figures and others is impossible here, but it is worthwhile to suggest briefly the work of three men—Johann Gottlieb Fichte, Friedrich Schleiermacher, and Wilhelm von Humboldt—representing three divergent views.

When the great heterodox University of Berlin was founded in 1809, Fichte became one of its foremost professors and a year later its second rector, having already achieved fame throughout Germany as an Idealist philosopher and fervent nationalist. At a time when Napoleon had humbled Prussia, Fichte in Berlin delivered the powerful *Addresses to the German Nation* (1807–08), full of practical views on national recovery and glory, including suggestions on the complete reorganization of the German schools along Pestalozzian lines. All children would be educated—and would be educated by the state. Boys and girls would be taught together, receiving virtually the same education. There would be manual training in agriculture and the industrial arts, physical training, and mental training, the aim of which would be not simply the transmission of measures of knowledge but rather the instillation of intellectual curiosity and love and charity toward all men. Unlike Pestalozzi, however, Fichte was wary of the influence of parents and preferred educating children in a "separate and independent community," at least until a new generation of parents had arisen, educated in the new ideas and ideals. Here was an apparent revival of Plato's idea of a strictly ordered, authoritarian state.

Fichte's ordered education

Another of the founders of the University of Berlin (teaching there from 1810 to 1834) was the Protestant theologian Friedrich Schleiermacher, who sounded a very modern note by offering a social interpretation of education. Education, in his view, was an effort on the part of the older generation to "deliver" the younger generation into the four spheres of life—church, state, social life, and science. Education, however, not only assumes its organization in terms of these four areas of life but also serves to develop and influence these areas.

Perhaps more than any other individual, the philologist and diplomat Wilhelm von Humboldt was responsible for the founding of the University of Berlin. Supported by the king of Prussia, Frederick William III, he adopted for it principles that raised it to a foremost place among the universities of the world—the most important principle being that no teacher or student need adhere to any particular creed or school of thought. This academic freedom survived in Germany despite its temporary suspension and Humboldt's dismissal by a reactionary Prussian government in 1819. Philosophically and pedagogically, Humboldt was himself a Humanist—a part of a wave of what were called New Humanists—who reasserted the importance of studying the classical achievements of humanity in language, literature, philosophy, and history. The aim of education in these terms was not the service of society or the state but rather the cultivation of the individual. Though generally commendable, this view sometimes tended toward a certain egoistic detachment from society, a measure of disdain for the work-a-day world, an occasional overemphasis on style of utterance, and a kind of aestheticizing of education.

Humboldt's Humanism

French theorists. At this time there were two men in France who were making their names through the introduction of new methods—Jean-Joseph Jacotot and Édouard Séguin. Jacotot was a high school teacher, politician, and pedagogue, whose main educational interests focussed on the teaching of foreign languages. "You learn a foreign language," he said, "as you learn your mother-language." The pupil is confronted with a foreign language; he learns a text in the language almost by heart, compares it with a text in his own native language, and then tries gradually to free himself from the comparison of texts and to construct new combinations of words. The teacher controls this learning by asking questions. "My method is to learn one book and relate all the others to it." The learning of grammar came later.

Jacotot's method was successful. Its fundamentals are partly old—first the practical side and then the rule, constant repetition, and self-activity on the part of the pupils. His method is also partly questionable. This is especially true of Jacotot's two basic theses: (1) that everyone has the same intelligence, differences in learning success being only a case of differences in industry and stamina; and (2) that everything is in everything: "Tout est dans tout," which suggests that any subject or book is analogous to any other. Jacotot's efforts to extend his method into other subjects were also doubtful.

The doctor and psychologist Édouard Séguin developed a pedagogy for pupils of below-average intelligence. Historically, scientific attempts to educate mentally retarded children had begun with the efforts of a French doctor, Jean-Marc-Gaspard Itard, during the latter part of the 18th century. In his classic book, *The Wild Boy of Aveyron* (1801), Itard related his five-year effort to train and educate a boy found, at about the age of 11, running naked and wild in the woods of Aveyron. Later, Séguin, a student of Itard, devised an educational method using physical and sensory activities to develop mental processes. Limbs and the senses were, in his view, a part of the whole personality, and their development was a part of the whole human education. In his book *Idiocy* he wrote,

Education of the mentally retarded

> From the distinction between a circle and a square up to that between right and wrong, we have followed a continuous path, beginning where the function awakes to the perception of simple notions, finishing where the faculties refuse to soar higher in the atmosphere of idealism.

Séguin's published works influenced Maria Montessori (see the next section on the 20th century), an Italian pediatrician who became an educator and developed methods of training young mentally retarded children in Rome in the 1890s. Her methods, like Séguin's, were based on sensorimotor training. (H.-J.I.)

DEVELOPMENT OF NATIONAL SYSTEMS OF EDUCATION

The great changes in Europe in the 19th century included, among other things, the further consolidation of national states, the spread of modern technology and industrialization, and increasing secularization. These changes had consequences for the design of school systems. National school systems had to be conceived and organized. Alongside the older schools, including elementary schools, Latin, or grammar, secondary schools, and universities, there developed so-called modern schools that stressed the exact sciences and modern languages, reflecting the new technological and commercial age. Vocational schools also appeared in greater numbers. The influence of the church was increasingly repressed, and the influence of the state on the school system correspondingly grew stronger. The ideal of universal education—education for all—became more and more a reality.

Germany. Martin Luther's pronouncements on the educational responsibilities of the individual had no doubt helped create that healthy public opinion that rendered the principle of compulsory school attendance acceptable in Prussia at a much earlier date than elsewhere. State intervention in education was almost coincident with the rise of the Prussian state. In 1717 Frederick William I ordered all children to attend school if schools were available to them. This was followed in 1736 by edicts for the establishment of schools in certain provinces and in 1763 by Frederick II the Great's regulation asserting the principle of compulsory school attendance.

Humboldt's reforms. The schools, however, had established a traditional classical curriculum that ignored the changing needs of life and fields of knowledge. No effective reorganization of the educational system was carried out until after the disaster of the Battle of Jena (1806), during the Napoleonic Wars, which brought about the virtual collapse of Prussia and at the same

Reforms inspired by the Napoleonic disasters

time introduced a period of reform in the government as a whole. One of the first acts of the prime minister Freiherr Karl von Stein in 1807 was to abolish certain semiecclesiastical schools and to place education under the Ministry of the Interior, with Wilhelm von Humboldt at the head of a special section. Humboldt's policy in secondary education was a compromise between the narrow philological pedantry of the old Latin schools and the large demands of the new Humanism that he espoused. The measure introduced by Humboldt in 1810 for the state examination and certification of teachers checked the then-common practice of permitting unqualified theological students to teach in the schools and raised the teaching profession to a high level of dignity and efficiency, placing Prussia in the forefront of educational progress. It was also a result of the initiative of Humboldt that the methods of Pestalozzi were introduced into the teachers' seminaries. To this period also belong the revival, in 1812, of the *Abiturientenexamen* ("the school-leaving examination"), which had fallen into abeyance. About the same time, the local administrations, called *Schulvorstände* for the country and *Schuldeputationen* for the towns, were instituted.

Developments after 1815. The period that succeeded the peace of 1815 was one of political reaction, and not until the 1830s were there further significant reforms. In 1834, for example, an important step was taken in regard to secondary education by making it necessary for candidates for the learned professions, as well as for the civil service and for university studies, to pass the leaving examination of the *Gymnasien*, the classical secondary schools. Thus, through the leaving examination, the state held the key to the liberal careers and was thereby able to impose its own standards upon all secondary schools.

In connection with the so-called Kulturkampf, or struggle between the state and the Roman Catholic Church, the school law of 1872 reasserted the absolute right of the state alone to the supervision of the schools. Nevertheless, the Prussian system remained both for Catholics and for Protestants essentially denominational. On the elementary level, in particular, the mixed school was established only when the creeds were so intermingled that a confessional school was impracticable. In all cases the teachers were appointed with reference to religious faith; religious instruction was given in school hours and was inspected by the clergy.

Types of German secondary schools

The official classification, or grading according to the type of curriculum, of secondary schools in Prussia (and throughout Germany) was very precise. The following were the officially recognized types: (1) the classical nine-year *Gymnasium*, with a curriculum that included Latin, Greek, and a modern language; (2) the semiclassical nine-year *Realgymnasium*, with a more modern curriculum that included, in addition to Latin and modern languages, the natural sciences and mathematics; and (3) the modern six-year *Realschule* or nine-year *Oberrealschule*, with a curriculum of sciences and mathematics. (There were also some variations on these basic types, modifying the length of the courses.)

The differentiation between the types was the result of a natural educational development corresponding to the economic changes that transformed Prussia from an agricultural to an industrial state. The classical schools long retained their social prestige and a definite educational advantage in that only their pupils were admissible to the universities. From the foundation of the German Empire in 1871 the history of secondary education was largely concerned with a struggle for a wider recognition of the work of the newer schools. The movement received a considerable impetus by the action of Emperor William II, who summoned a school conference in 1890 at which he set the keynote: "It is our duty to educate young men to become young Germans and not young Greeks or Romans." New schedules were framed in which the hours devoted to Latin were considerably reduced, and no pupil could obtain a leaving certificate without a satisfactory mark in the mother tongue. The reform lasted only a single school generation. In 1900 equality of privileges was granted to three types of schools, subject to certain reservations: the theological faculties continued to admit only students from classical schools, and the pupils of the *Oberrealschule* were excluded by their lack of Latin from the medical faculties; but insofar as Latin was required for other studies, such as law or history, it could be acquired at the university itself.

Although the official curricula were binding on the schools, their rigidity was not absolute; experiments were possible, but they were carefully supervised. The chief innovation was the postponement of the beginning of Latin to the fourth year and the introduction of French as the first foreign language. This enabled parents to defer their decision as to the form of their son's education until he was about 12 years of age.

A further instance of the willingness of the authorities to sanction reasonable changes was seen in the permission accorded to certain schools to vary the course of study in the top classes, as a preparation for the freedom of choice of the university.

Girls' schools. In Prussia, as elsewhere, the higher education of girls lagged far behind that of boys and received little attention from the state or municipality, except insofar as the services of women teachers were needed in the elementary schools. Thus it came about that in Prussia secondary schools for girls were dealt with administratively as part of the elementary school system. After the establishment of the German Empire in 1871, a conference of directors and teachers of these schools was held at Weimar and put forth a reasoned plea for better organization and improved status. The advocates of reform, however, were not at unity in their aims; some wished to lay stress on ethical, literary, and aesthetic training; others stressed intellectual development and claimed an equal share in all the culture of the age. But even in the schools the women fought an unequal battle, for all the heads and a large part of the staff were men, usually academically trained. The women continually demanded a larger share of the work, and this was secured by the establishment of a new higher examination for women teachers. University study, though not prescribed, was in fact essential, and yet women had not the right of access to the university in Germany. They were allowed to take the leaving examination, for which private institutions prepared them, but their admission to the university rested with the professor. Not until the 20th century were desired changes achieved.

The new German universities. Unquestionably one of the greatest worldwide influences exercised by German education in the 19th century was through its universities, to which students came from all over the world and from which every land drew ideas for the reformation of higher education. To understand this, one must be aware of the state of higher education in most countries in the 19th century. Although the century witnessed a steady expansion of scientific knowledge, the curriculum of the established universities went virtually untouched. Higher education followed a single dimension. This was the century of the scientists Michael Faraday, Hermann von Helmholtz, James Prescott Joule, Charles Darwin, Joseph Lister, Wilhelm Wundt, Louis Pasteur, and Robert Koch. Yet, until the end of the century, most of the significant research was done outside the walls of higher educational institutions. In Great Britain, for instance, it was the Royal Society and other such societies that fostered advanced studies and encouraged research. The basic curriculum of colleges and universities remained nontechnical and nonprofessional. The English cardinal John Henry Newman, lecturing in Dublin on *The Idea of a University* in 1852, stated that the task of the university was broadly to prepare young men "to fill any post with credit, and to master any subject with facility." The university ought not to attempt professional and technical education.

Condition of 18th- and 19th-century higher education

While Newman's words epitomized the views held in most colleges and universities in Europe and America, some of the new universities in Germany were moving toward the expansion of the educational enterprise. In 1807 Fichte had drawn up a plan for the new University

of Berlin, which Humboldt two years later was able to realize in its founding. The school was dedicated to the scientific approach to knowledge, to the combination of research and teaching, and to the proliferation of academic pursuits; and its ideal was adopted in the founding or reconstitution of other universities—Breslau (1811), Bonn (1818), Munich (1826). By the third quarter of the 19th century the influence of German *Lernfreiheit* (freedom of the student to choose his own program) and *Lehrfreiheit* (freedom of the professor to develop the subject and to engage in research) was felt throughout the academic world. The unity of the universities, for better or worse, was more and more dissolved by the fragmentation of subjects into different branches. Some critics would eventually condemn what they considered to be the excesses of the free elective system and the extreme departmentalization of research and curricula. Much of the debate, however, would centre on the general education of undergraduates. The conviction, fathered in Germany, that investigation and research were a main function and responsibility of institutions of higher education seemed secure.

Lernfreiheit and *Lehrfreiheit*

France. In France the Jesuit schools and the schools of other teaching orders created at the time of the Renaissance had reconciled the teaching of the new Humanism with the established doctrines of the Roman Catholic Church and flourished with special brilliance. But, despite the changes brought about by the Renaissance and the attention given to the sciences in the 17th and 18th centuries, it was not until the advent of the French Revolution that the universal right to education was proclaimed (1791).

Unfortunately, the Revolution had little opportunity to put these principles into effect before Napoleon restored the old system, with his own concession—a provision for the study of mathematics. He did, however, reorganize the structure of secondary and higher education in a unified state system, with secondary schools maintained by the *communes*, and with state lycées, universities, and special institutions of higher education. Within this structure the rector of a university headed a teaching body, recruited by the state and supervised by an inspectorate, ranging through various grades up to the university council. Grades of proficiency in studies, from simple certificates to the degrees of *baccalauréat*, *licence*, and doctorate were awarded on the result of examinations, and these tests were made a necessary condition of entry into such professions as medicine, law, and teaching. This structure, despite many modifications, has survived until modern times.

Napoleonic system of education

Development of state education. French educational history in the 19th century is essentially the story of the struggle for the freedom of education, of the introduction at the secondary level of the modern and scientific branches of learning, and, under the Third Republic, of the establishment of primary education, at once secular and compulsory, between the ages of six and 12. There were also a middle education between the ages of 13 and 16 and, finally, a professional and technical education.

Under the restoration of the monarchy in 1814, education fell inevitably under the control of the church; but, during the bourgeois monarchy of Louis Philippe, a law was passed in 1833 that laid the foundations of modern primary instruction, obliging the *communes* to maintain schools and pay the teachers. The higher primary schools that were founded were suppressed by Roman Catholic conservatives in 1850 (their restoration later constituted one of the great positive services rendered by the Third Republic to the cause of popular education). The 1850 law restored the "liberty of teaching" that, in effect, meant free scope for priestly schools, but it also made provision for separate communal schools for girls, for adult classes, and for the technical instruction of apprentices. In 1854 France was divided for purposes of educational administration into 16 (now 17) districts called *académies*, each administered by a rector and each with a university at the apex of the educational structure. The rector not only was made the chief administrator of the university but also was responsible for secondary and higher education within his *académie;* he nominated candidates for administrative positions in his area, appointed examination committees, supervised examination content and procedures, and presided over a personal cabinet, called an academic council. Unlike the political division in some other countries, the *académies* were given little power or authority of their own; rather, they were administrative arms of the national ministry of education. They represented a devolution rather than a delegation of power from the central government.

Centralization of French education

After the Franco-Prussian War, the Third Republic addressed itself to the organization of primary instruction as "compulsory, free, and secular." The law of 1878 imposed on *communes* the duty of providing school buildings and provided grants-in-aid. The national government also henceforth paid salaries throughout the public sector of education. In 1879 a law was passed compelling every department to maintain training colleges for male and female teachers. The law of 1881 abolished fees in all primary schools and training colleges; the law of 1882 established compulsory attendance; and, finally, the law of 1886 enacted that none but lay persons should teach in the public schools and abolished in those schools all distinctively religious teaching.

Secondary education. In European systems of higher education, secondary education was pre-eminently a preparation for the university, with aims and ideals of general culture that differentiated it radically and at the very outset from education of the elementary type. Down to the beginning of the 20th century, the French system could be regarded as a typical and extreme example of the European theory.

The characteristic European organization has been called the "dual plan": elementary and secondary education were distinct types, and only a minority of the elementary school pupils passed on to the secondary schools, generally only if they were bright and could win scholarships through a competitive examination. The secondary schools drew their clientele from private preparatory schools, called the lycées in France. Furthermore, the courses in the lycées were definite and were limited to the study of French language and literature, foreign languages (ancient or modern), mathematics and science, history and geography, some art, music, and physical training. Pupils who did not complete the full course generally entered civil-service or other white-collar occupations. With the development of commerce and industry in the 19th century, France instituted the *écoles primaires supérieures*, or "higher primary schools," for those who did not go on to universities but who needed a better education than the primary schools could give. The curricula of these schools were somewhat more advanced than those of the primary schools; pupils remained longer (up to the age of 16) and were prepared for employment in business as white-collar workers, but generally at a lower level than pupils who came from the lycées. In effect, the different types of schools tended to maintain class cleavages since students of the secondary schools enjoyed higher social and occupational prestige than those of the upper primary schools.

European "dual plan"

The foundation of secondary schools for girls was in its way one of the most notable achievements of the Third Republic. It was inaugurated by the law of December 22, 1880, called after its author the Loi Camille Sée. Until World War II, the curricula were different from those of the boys' schools, and the course of study was only five years. There were no ancient languages, and mathematics was not carried to so high a level as in the boys' lycées.

England. Influenced by doctrines of laissez-faire, England hesitated a long time before allowing the state to intervene in educational affairs. At the beginning of the 19th century, education was regarded as entirely the concern of voluntary or private enterprise, and there was much unsystematic philanthropy. Attempts were made to canalize and concentrate it, and many hoped that the Church of England and the dissenting churches would join in a concerted effort to provide a national system of elementary education on a voluntary basis. But discor-

Laissez-faire and English voluntary education

dant views prevented such cooperation, and two voluntary societies were founded, one representative of the Church of England and the other of dissent. In 1829 the Catholics were emancipated by law from disabilities they had long suffered, and so they also were able to provide voluntary schools. Other religious bodies joined in the effort to meet the growing need for elementary schools, but it was soon evident that voluntary finance would not be equal to this formidable task. In 1833 the government made a small building grant to these societies, and in this modest way state intervention began. Six years later a committee of the Privy Council was established to administer the state grants, now made annually, and to arrange for the inspection of voluntary schools aided from public funds. The work involved led to the establishment of a small central education department, which was the beginning of the ministry of education.

Elementary Education Act. England prolonged its reliance on voluntary initiative for year after year as population increased, and, with the growing industrialization, people crowded into the new towns. At last in 1870 Parliament, after long, acrimonious debates, passed an Elementary Education Act, the foundation upon which the English educational system has been built. Religious teaching and worship were the crucial issues in the debates, and the essentials of the settlement agreed upon were (1) a dual system of voluntary and local-authority schools and (2) careful safeguards to ensure as far as possible that no child would receive religious teaching at variance with his parent's wishes. It was left to the school boards—as these first local education authorities were called—to decide whether to make elementary education compulsory in their districts. In 1880, however, it was made compulsory throughout England and Wales, and in 1891 fees were abolished in all but a few elementary schools.

Secondary and higher education. Secondary education, however, was still left to voluntary and private enterprise. Attention was focussed on the "public" schools (independent secondary schools such as Eton and Harrow, usually for boarders from upper and well-to-do middle class homes), which under the leadership of outstanding headmasters such as Thomas Arnold were thoroughly reformed. Several new universities were founded during the 19th century, and the latter half of it saw the founding of a number of girls' high schools and boarding schools offering an education comparable to that in boys' public schools and grammar schools. Several training colleges for teachers were established by voluntary agencies, and universities and university colleges toward the end of the century undertook the training of postgraduates as teachers in departments of education created for this purpose.

Russia. Influenced by the disintegration of the serf system, the development of industry and commerce, and the ideas of the French Revolution, Tsar Alexander I at the beginning of the 19th century tried to institute new educational reforms. The statutes of 1803 and 1804 maintained the principles of utility and secular scientific instruction fostered by Peter I the Great and Catherine II the Great in the 18th century. The parochial schools (*prikhodskiye uchilishcha*) in the rural areas were to instruct the peasantry in reading, writing, arithmetic, and elements of agriculture; the district schools of urban areas (*uyezdnye uchilishcha*) and the provincial schools (*gimnazii*) were to give instruction in subjects necessary for civil servants (law, political economy, technology, and commerce). The system was state controlled and free, and it formed a continuous ladder leading to the universities. During Alexander's reign the old Catherinian schools were remodelled and new schools founded.

Russian reform and reaction

Nicholas I, coming to the throne in 1825, considered this democratic trend harmful and decreed that

> It is necessary that in every school the subjects of instruction and the very methods of teaching should be in accordance with the future destination of pupils, that nobody should aim to rise above that position in which it is his lot to remain.

A new statute of 1828 decreed that parochial schools were intended for the peasants, the district schools for merchants and other townspeople, and *gimnazii* for children of the gentry and civil servants. Instruction in the *gimnazii* in Latin and Greek was increased. Although the legislation of Nicholas I established a class system, one way for the gentry and another for the rest, the utilitarian character of the whole system remained.

The Russian radical intelligentsia was fiercely opposed to the privileged schools for the gentry and demanded the re-establishment of a democratic system with a more modern curriculum in secondary schools. This was coupled with the demand for the emancipation of the serfs and the equality of women in education. The new tsar in 1855, Alexander II, inaugurated a period of liberal reforms. The serfs were emancipated in 1861, and thus all social restrictions were removed. A new system of local government in rural areas (*zemstvo*) was enacted with a right to found schools for the peasantry, now free. Combined efforts of the government, *zemstva*, and peasant communities produced a growth of schools in the rural areas. The utilitarian trend was evident in the establishment of technical schools with vocational differentiation. The education of women was promoted, and the first higher courses for women were founded in main cities.

The reign of Alexander II, which was later marked by reactionary measures and political oppression, ended in his assassination in 1881 by the terrorist branch of the Narodniki revolutionary organization. A period of reaction followed under his successor, Alexander III. All reforms were suspended, and the growth of educational institutions was interrupted. The chief procurator of the Holy Synod attempted to build up a rival system of parochial schools under the control of the orthodox clergy; and the Minister of Public Instruction tried to return to the class system of Nicholas I. These reactionary measures set back the growth of education. Four-fifths of all children were deprived of education. The result was that at the turn of the century nearly 70 percent of Russia's male population and 90 percent of its female population were illiterate (1897 census.) The aboriginal dwellers of Russia's national outskirts (more than one-half of the country's population) were almost totally illiterate. (Ed.)

The United States. Administered locally everywhere, schooling of the United States's masses in the republic's younger days was immensely diverse. In New England, primary schooling enjoyed public support. In the South, apart from supplying a meagre learning to pauper children, the states abstained from educational responsibility. In the middle states elementary schools were sometimes public; more often they were parochial or philanthropic. Only beyond the Alleghenies in the huge national domain was there any federal provision for education. There, under the Articles of Confederation, the Ordinance of 1787 reserved a plot of land in every prospective township for the support of education. The measure not only laid the groundwork for education in the states of the Ohio Valley and the Great Lakes; it also became a precedent for national educational aid. Thus, in 1862 the Morrill Act granted every state establishing a public agricultural college 30,000 acres (12,000 hectares) of public land for each of its lawmakers in Congress. Since then some 12,000,000 acres (5,000,000 hectares) have been distributed, on which some 70 of the so-called land-grant colleges currently flourish.

American land-grant colleges

Several of the Founding Fathers expressed belief in the necessity of public education, but only Thomas Jefferson undertook to translate his conviction into actuality. Convinced that democracy can be effective only in the hands of an enlightened people, he offered Virginia's lawgivers a plan in 1779 to educate school children at public cost for three years and a few gifted boys beyond that. The proposal elicited some support but encountered resistance not only from the ruling classes, who insisted that education was a private responsibility, but also from the clergy, who regarded instruction of the common child as an ecclesiastical prerogative. Hence, Jefferson's plan was rejected. Some 40 years later he submitted another proposal for public schools, but again the legislators voted it down. Only one of Jefferson's dreams fructified

—the University of Virginia. When it opened in 1825, it was the most up-to-date institution of its sort, the first frankly secular university in America and the closest to a modern-day conception of a state university.

The educational awakening. When Jefferson died in 1826, the nation stood on the threshold of a stupendous transformation. During the ensuing quarter century it expanded enormously in space and population. Old cities grew larger and new ones more numerous. The era saw the coming of the steamboat and the railroad. Commerce flourished, and so did agriculture. The age witnessed the rise of the common man with the right to vote and hold office. It was a time of overflowing optimism, of dreams of perpetual progress, moral uplift, and social betterment.

The common school

Such was the climate that engendered the common school. Open freely to every child and upheld by public funds, it was to be a lay institution under the sovereignty of the state, the archfather, in short, of the present-day American public school. Bringing the common school into being was not easy. Against it bulked the doctrine that elementary school was essentially for pious ends and that any education that excluded religious instruction—as all state-maintained schools were legally compelled to do—was godless. Nor had there been any great recession of the contention that education was not a proper governmental function, and for a state to engage therein was an intrusion into parental privilege. Still more distasteful was the fact that public schooling would occasion a rise in taxes.

Yet the common school also mustered some formidable support, and finally, in 1837, liberal Massachusetts lawmakers successfully carried through a campaign for a state board of education. It is especially to Horace Mann, the board's first secretary, that Massachusetts credits its educational regeneration. Something of a dreamer, but a hardened pragmatist withal, Mann combined a lucrative legal practice with the labours of a legislator in the Massachusetts senate. There he supported a host of liberal causes, from more humane jails to religious freedom and better schools. To gather data on educational conditions in Massachusetts, Mann roved the entire commonwealth. He lectured and wrote reports, depicting his dire findings with unsparing candour. There were outcries against him, but when Mann resigned, after 12 years, he could take pride in an extraordinary achievement. During his incumbency, school appropriations almost doubled. Teachers were awarded larger wages; in return they were to render better service. To help them Massachusetts established three state normal schools, the first in America. Supervision was made professional. The school year was extended. Public high schools were augmented. Finally, the common school, under the authority of the state, though still beset by difficulties, slowly became the rule.

What Mann accomplished in Massachusetts, Henry Barnard (1811–1900) achieved in Connecticut and Rhode Island. More reserved than his Massachusetts counterpart, Barnard has come down the ages as the "scholar of the educational awakening." He is seen in this capacity as a founder of the Association for the Advancement of Education. He became its first president and editor of its *American Journal of Education*, in whose 30 volumes he discussed virtually every important pedagogical idea of the 19th century.

Although New England led the field in the drive to modernize education, similar campaigns were under way in other states. Though the pattern of reform was similar, there were differences nonetheless. In Pennsylvania the assault centred on the pauper school; in New York it was against sectarianism. Aggravating the contest everywhere, however, was the controversy over the state's right to assume educational authority, and especially its power to levy school taxes.

Rise of the United States high school

Secondary education. The soil that rooted the common school became the seedbed for the high school. Some of its essence is discernible in the 18th-century academy with its accent on modern and useful learning. But the academy catered to a paying clientele and was thus offensive to connoisseurs of democracy. Once the common school was solidly entrenched, the scant opportunity afforded the lower classes for more than a rudimentary education fell under increasing challenge. If it was right to order children to learn reading, writing, and arithmetic and to offer them free tax-supported schooling, some reasoned, then it was also right to accommodate those desiring advanced instruction. Needless to say, the idea ran into opposition; yet it persisted. Before long, indeed, a few common schools, yielding to parental insistence, introduced courses beyond the elementary level. Such was the germ of the high school in the U.S.

The United States's first high school opened in Boston in 1821 as the English Classical School, a designation that soon was changed to English High School. Designed for the sons of the "mercantile and mechanic classes," it provided three years of free instruction in English, mathematics, surveying, navigation, geography, history, logic, ethics, and civics. Shortly after, high schools appeared in Portland, Maine, and Worcester, Massachusetts. In 1825 New York City inaugurated the first high school outside New England. The next year Boston braved free secondary education for girls, judiciously diluted and restricted to 130. When the number of applicants vastly exceeded this figure, the city fathers abandoned the project.

The high school movement was spurred less by these diffuse developments than by legislation by Massachusetts in 1827 that ordered towns of 500 families to furnish public instruction in American history, algebra, geometry, and bookkeeping, in addition to the common primary subjects. Furthermore, towns of 4,000 were to offer courses in history, logic, rhetoric, Latin, and Greek. Unhappily, the measure lacked public backing, and a generation passed before its boons became an actuality. Nevertheless, it set the guideposts for similar legislation elsewhere. Although high schools steadily increased, the contention that government had no right to finance them remained an issue until the 1870s, when Michigan's supreme court, finding for the city of Kalamazoo in litigation brought by a taxpayer, declared the high school to be a necessary part of the state's system of public instruction.

Education for females. Though the common school vouchsafed instruction to girls, their chances to attend high school—not to say college—were slight. For daughters of the wealthy there were "female academies," but they were not numerous, and often they were finishing schools rather than cultivators of the intellect. The truth is that as late as the 1840s, when the lowliest man could vote and hold office, women were haltered by taboos of every sort. But as America advanced industrially, and more and more women flocked to the mill and the office, their yearning for a fuller life ignited, and with it their desire for greater educational opportunity. As in the struggle for the common school, the cause of women's education bred leaders, many of whom founded schools in the Northeast. Not till 1861, however, when Vassar was founded, could women point to a truly first-rate college. Meanwhile, in 1833, Oberlin College in Ohio had hazarded coeducation, and 20 years later Antioch College, also in Ohio, followed suit. Beyond the Mississippi every state university, except that of Missouri, was coeducational from its beginning. The East moved more warily; Cornell University was the first Eastern school to become coeducational, in 1872.

Co-education

Higher education. While women were crusading for a more spacious educational opportunity, the college itself was undergoing alteration. It had begun as a cradle of divinity, but, as the 18th century waned, it was displaying a mounting secularity, with chairs in science, mathematics, law, and politics. In the course of the 19th century, not only did colleges surge in number, but some of the more enterprising of them undertook to reshape their purpose. Some (for instance, William and Mary), though still calling themselves colleges, engaged in university work. Soon after its opening in 1885, Bryn Mawr College in Pennsylvania announced courses for the master's and doctor's degrees. Inspired by the scholarly accomplishments of German universities, Johns Hopkins Uni-

versity in Baltimore, founded in 1867, put its weight on research. Twenty years later Clark University in Massachusetts opened as a purely graduate school. Two years later Catholic University of America in Washington, D.C., did the same. Soon the graduate trend invaded some of the older schools, such as Harvard University.

The early normal schools, or teacher-training schools, were primitive; often they were merely higher elementary schools, rehearsing their students for a year in basic reading and arithmetic, rectitude and piety, some history, mathematics, and physiology, and, if they survived, a rudimentary pedagogy. It was not until the 1860s, under the spell of Pestalozzi and later on, Froebel and Herbart, that teacher training in America began to gather power and momentum. (A.E.M.)

The British dominions. *Canada.* Canadian educational developments in the 19th century can be divided into early, middle, and late periods—in the east running to about 1840, 1870, and 1900, respectively. In the west, parallel developments began later, so that the second and third periods telescope into the early decades of the 20th century. These developments culminated in educational systems similar to those of the present.

In the early period of the 19th century, schooling was much the same as it was in England; it was provided through the efforts of religious and philanthropic organizations and dominated by the Church of England. Although there was overlap among types of schools (identified historically), there are records of parish schools, charity schools, Sunday schools, and monitorial schools for the common people. The instructional fare was a rudimentary combination of religious instruction and literacy skills, perhaps supplemented by some practical work.

More advanced education was limited to the upper social classes and was given in Latin grammar schools or in private schools with various curricular extensions on the classical base. Academies, largely supported by the middle class of nonconformist groups, presented a broad curriculum of liberal arts that spanned the secondary and higher levels of education. In general, instruction relied on a simple chain concept of "transmission–absorption–mental storage," which was kept going by direct application of reward or punishment.

In the middle period, public systems of education emerged, accommodating religious interests in a state framework. Public support was won for the common school, leading toward universal elementary education. Secondary and higher education began to assume a public character. The principle of local responsibility under central provincial authority was elaborated in the respective provinces.

Church and state relations in Canada

Of central importance in the development of Canadian education is the kind of agreement reached on church–state relations in education during this period. At one extreme is the arrangement made in Newfoundland from 1836 to accommodate all numerically represented denominations separately within a loose system (not until 1920 was a unified system of education developed, which still works through five denominational subsystems); at the other extreme are the arrangements made in British Columbia, which became decisive when it entered the Canadian Confederation, to establish and maintain a free, unified, centralized nonsectarian system. Other provinces eventually developed patterns that represented compromises. The Nova Scotia–New Brunswick pattern, for instance, provided a unified system that in principle was nonsectarian but that allowed the grouping of Roman Catholic children for education, thus legalizing sectarian schools within the system. Ontario placed separate Catholic schools within a unified school system. And Québec provided separate administrative machinery for Protestant and Roman Catholic schools and a complete dual system of schools, from common school to university.

The British North America Act of 1867, Canada's constitution, lodged authority for education in the provinces, at the same time guaranteeing denominational rights (in the "minority-school protective clause") if such rights existed at the time of entry into confederation. These two provisions established the pluralistic nature of Canadian education, and the union of the provinces and the entrance of western provinces gave Canada, by 1880, a national base on which to build the Canadian institution of education.

The final years of the 19th century were years of structural formalization of the educational foundations developed in the productive middle period. In this, Ontario's leadership was evident, especially as it affected the model of education evolving in the western territories. Although the North West Territories Act of 1875 established a principle of duality in the west, the Territorial Ordinance of 1892 changed the pattern to that of Ontario, a unified system with minority rights in education. After Alberta and Saskatchewan were admitted as provinces in 1905, some divergence from Ontario took place: notably, both provinces required that Roman Catholic taxes go to separate Catholic schools (the decision in Ontario was based on free choice), and Alberta allowed separate school privileges through the secondary level.

Toward the end of the 19th century, elementary schooling, by then established, was becoming compulsory. The cost of secondary education was diminishing, and the distinction in level and curriculum between the secondary and the elementary school was sharpened in order to define the structural parts and connections in a system of public schools. Communities were responsible for maintaining schools through a combination of local taxes and provincial grants, while provincial departments standardized the conduct of schooling through inspections, examinations, and prescription of course content and materials.

Changes in instructional theory, taking place during the latter part of the 19th century throughout the Western world, revolutionized the classroom. One major shift was from the imposition of knowledge on the mind of the learner to an emphasis on the learner's activity of perception and comprehension of knowledge. The impact of science on the higher school curriculum was matched by its impact on educational theory and, consequently, on teacher training. Both scientific disciplines (such as educational psychology) and scientific methods of teaching became necessary to the training of teachers who were to operate in a new setting of teacher–pupil and subject-matter relations.

Australia. The development of Australian education through the 19th century was affected by a pervasive British influence, by a continuous economic struggle against harsh environmental conditions, and by the tendency for population to be concentrated in centres that accrued and extended political authority over the region. The particular historical thread around which educational developments took place was the question of denominational schools.

Church and state relations in Australia

From the first immigrant landing in 1788 through the early decades of the 19th century, education was provided on an occasional and rather haphazard basis, by the most expedient means available. In general, the assumption and the practice was that schooling would be provided by the church or by church organizations, such as the Society for the Propagation of the Gospel in Foreign Parts, and colonial governments made small grants to aid such provision. It was also assumed that the Church of England would dominate the religious-educational scene, and a Church and School Corporation was set up in 1826 to administer endowments for Church of England efforts. Even at this early stage, however, the resistance of Nonconformists, especially Presbyterians and Roman Catholics, shortly defeated the attempt to "establish" Church of England institutions. The only early organized attempt at mass education was through monitorial systems.

In 1833 the governor of New South Wales asserted government responsibility for education by proposing the introduction of a nondenominational system that would reduce religion in schools to reading commonly approved scriptures and to providing release time for sectarian in-

struction by clergymen. The importance of the proposal lay in its spirit of religious compromise and its initiation of state responsibility for education, both of which were predictive of future development.

Because of sectarian resistance, mainly from Anglican and Catholic groups, so-called national schools were introduced alongside denominational schools in 1848 as a dual system, administered by two corresponding boards. Through the middle period of the century, similar sectarian compromises were found in other Australian colonies—such as Van Diemen's Land (Tasmania), Western Australia, and South Australia—leading to the establishment of state systems. Educational efforts were, however, seriously impeded by the extremity of the struggle for survival in hostile geographic conditions.

The trend toward sectarian and church–state compromise continued with a series of education acts passed between 1850 and 1871. In New South Wales there was a vigorous campaign for a unified state system of schools. With the support of one Anglican wing and of the other Protestant groups, a Public Schools Bill was passed in 1866, creating a single Council of Education. State aid to denominational schools was continued, but now under conditions stipulated by the state.

Victoria became a separate colony in 1850 and was initially fraught with particular problems occasioned by the arrival of a migrant gold-rush population. Little was accomplished in education, other than increased assistance to religious denominations, until 1856. After that the move for a state system gained impetus, and a Common Schools Bill was passed in 1862, establishing a system similar to that accepted in New South Wales. Soon after separation, Queensland's Primary Education Bill was passed in 1860, subordinating denominational schools and reinforcing the principle of common-school development in Australia. South Australia held to a continuous development of a general system based on common Christianity, but Western Australia's Elementary Education Bill of 1871 returned to dual support for both government and voluntary schools.

The support for state educational systems increased during the 1860s and 1870s as an alternative to interdenominational conflict was sought. In this development the Protestants, gradually and sometimes reluctantly, acquiesced. Catholic resistance was never overcome, and the consequent evolution of a separate Roman Catholic school system did not diminish Catholic dissatisfaction with the movement to state schools. The dilemma of Catholic citizens with regard to nonsectarian public education was universal: as citizens they were financially obligated for the public schools; as Roman Catholics they were committed to education in schools of their own faith.

Education in the later 19th century also took other directions. The intention to educate all children and to raise the quality of instruction in common schools required governmental actions that could transform voluntary, exclusive, uneven provisions into uniform public standards. In Australia, particular motivating factors were the dramatic increases in population and economic growth and the recognized inadequacy of existing schools. Although the full move to secular, free, compulsory public education was not completed until the 20th century, the establishment of secular public school systems under central government control was made unequivocal through the passage of legislation between 1872 and 1895 (Victoria, 1872; Queensland, 1875; South Australia, 1875; New South Wales, 1880; Tasmania, 1885; Western Australia, 1893 and 1895). These bills did not abolish general Christian instruction, nor did they generally refuse release time for sectarian instruction. They did disallow sectarian claims for financial support and for a place in public education. The decision was for the operation of schools for all children, undertaken by the one agency that could act on behalf of the whole society, the central government.

New Zealand. In New Zealand's early colonial period, between 1840 and 1852, certain provisions were made for endowments for religious and educational purposes, but education was considered, in accordance with prevailing views in England, a private or voluntary matter. Corresponding to general social distinctions, academic education was relegated to denominational, fee-charging schools, and common education was provided as a charitable service. Religious preference was avoided as much as possible, with the aim of minimizing sectarian conflict.

Church and state relations in New Zealand

Secular opposition to religious bias, even on a pluralistic basis, was, however, already evident. In 1852 New Zealand was granted self-government under the Constitution Act, and responsibility for education was placed in the councils of the six provinces. Although each province acted independently and somewhat according to the traditions of the dominant cultural group, the general sentiment moved in the next 20 years toward the establishment of public school systems.

The province of Nelson, from a highly mixed and Nonconformist popular base, led the way in establishing nondenominational schools, administered by a board, supported through tax levies, and reaching relatively high attendance proportions. Otago, under Scottish Presbyterian influence, set up well-organized administrative procedures and a complete array of school types, though resisting the equalizing tendency of free schools. Canterbury, an Anglican preserve, held to denominational grants initially, but by 1863 this support was channelled through a public board of education, and thereafter the development of a primary system proceeded rapidly, becoming secular and free by 1873. Wellington's Common School Act of 1855 set a legal basis for public schools. There was little alteration to private initiative and school fees until 1871, however, when the Education Act established a secular basis and started the province toward free, compulsory schooling. In Auckland the denominational principle was retained until 1869; between then and 1872, provisions of the Nelson system were adopted, and primary education was made secular, free, and compulsory. By 1876, then, when the provincial governments were abolished, the people of New Zealand, through varying regional decisions, had accepted governmental responsibility for education, had opted for nonsectarian schools, and had started on the path to free, compulsory common schooling.

The basic national legislation was passed in 1877. The Education Act provided for public elementary education that would be secular, free to age 15, and compulsory to age 13. Because of enforcement difficulties and legal exceptions, the compulsory clause was rather loose, but it instituted the rule. It was strengthened between 1885 and 1898, and bold steps in 1901 and 1910 led to steadily increasing high school enrollments after 1911. The act of 1877 also revised the administrative structure under a central (national) ministerial Department of Education. Initially, the central department was little more than a funding source, while critical control was vested in regional boards elected by local school committees. The power of the new boards was enhanced by their coincidence to the old provincial boards, but the central principle had been accepted, and increasing recognition of regional inequalities led to augmentation of the department's role before the end of the century. In the competitive struggle between the department and the regional boards that waxed and waned well into the 20th century, neither gained the exclusive dominance sometimes sought. The primary position of the central authority in educational administration was confirmed in the reform period between 1899 and 1914, however, when control of inspectors, effective control of primary teacher appointment and promotion, and stipulative control in fund granting went to the Department of Education. These developments, together with curriculum and examination reforms, marked a new beginning in New Zealand education. (R.F.L.)

SPREAD OF WESTERN EDUCATIONAL PRACTICES TO ASIAN COUNTRIES

India. Originally the British came to India as tradesmen, but gradually they became the rulers of the coun-

try. On December 31, 1600, the East India Company was established, and, like all commercial bodies, its main objective was trade. Gradually during the 18th century the pendulum swung from commerce to administration; the deterioration of Mughal power in India, the final expulsion of French rivals in the Seven Years' War, and the virtual appropriation of Bengal and Bihār in a treaty of 1765 had all made the Company a ruling power. In spite of this, the Company did not recognize the promotion of education among the natives of India as a part of its duty or obligation. For a long time the British at home were greatly opposed to any system of public instruction for the Indians, as they were for their own people.

Education under the East India Company

The feelings of the public authorities in England were first tested in the year 1793, when William Wilberforce, the famous British philanthropist, proposed to add two clauses to the company's charter act of that year for sending out schoolmasters to India. This encountered the greatest opposition in the council of directors, and it was found necessary to withdraw the clauses. For 20 years thereafter, the ruling authorities in England refused to accept responsibility for the education of Indian people. It was only in 1813, when the company's charter was renewed, that a clause was inserted requiring the governor general to devote not less than 100,000 rupees annually to the education of Indians.

Some organization was required in order to disburse the educational grant. A General Committee of Public Instruction, constituted in Calcutta in 1823, started its work with an Orientalist policy, rather than a Western-oriented one, since the majority of the members were Orientalists. The money available was spent mainly on the teaching of Sanskrit and Arabic and on the translation of English works into these languages. Some encouragement was also given to the production of books in English.

Missionary education and the "semirationalist" movement

Meanwhile, a new impetus was given to education from two sources of different character. One was from the Christian missionaries and the other from a "semirationalist" movement. The Christian missionaries had started their educational activities as early as 1542, upon the arrival of St. Francis Xavier. Afterward the movement spread throughout the land and exercised a lasting influence on Indian education. It gave a new direction to elementary education through the introduction of instruction at regular and fixed hours, a broad curriculum, and a clear-cut class system. By printing books in different vernaculars, the missionaries gave a great fillip to the development of Indian languages. But hand in hand with the study of the vernaculars went the teaching of Western subjects through the medium of English, called in India "English education."

Besides the missionaries, there were men in Bengal who, though admitting the value of Oriental learning for the advancement of civilization, thought that better things could be achieved through a knowledge of English. In 1817 these semirationalists, led by Rammohan Roy, the celebrated Indian reformer, founded the Hindu College in Calcutta, the alumni of which established large numbers of English schools all over Bengal. The demand for English education in Bengal thus preceded by 20 years any government action in that direction.

In the meantime the influence of the Orientalists was waning in the General Committee, as younger members with more radical views joined it. They challenged the policy of patronizing Oriental learning and advocated the need for spreading Western knowledge through the medium of English. Thus arose the controversy as to whether educational grants should be used to promote Oriental learning or Western knowledge. The controversy between the Orientalists and the Anglicists was decided in favour of the latter by the famous Minute on Education of 1835 submitted by Thomas Babington Macaulay, the then legal member of the governor general's executive council. His recommendations were accepted by Lord William Bentinck, the governor general. The decision was announced on March 7, 1835, in a brief resolution that determined the character of Indian education for the ensuing century. Although the schools for Oriental learning were maintained for some years, the translation of English books into Sanskrit and Arabic was immediately discontinued. Thus the system of "English education" was adopted by the government. It should be noted, though, that primary education did not attract any attention at all.

Orientalists versus Anglicists

Bentinck's resolution was followed by some more enactments accelerating the growth of English education in India. The first was the Freedom of Press Act (1835), which encouraged the printing and publication of books and made English books available to the people at low cost. Two years later, Persian was abolished as the language of record and the courts (to the dismay of the Muslims) and was replaced by English and Indian languages in higher and lower courts, respectively. Finally, Lord Hardinge, as governor general, issued a resolution on October 10, 1844, declaring that for all government appointments preference would be given to the knowledge of English. These measures strengthened the position of English in India, and the lingering prejudices against learning English vanished forever.

It may be noted, however, that, although English education held its ground in Bengal, it was found that in Bombay, Madras, and the North-Western Provinces there was as yet little effective demand for English, and the tendency was to lay the main stress on Indian languages. Bombay adopted the policy of encouraging primary education and spreading Western science and knowledge through the mother tongue. This was done under the able guidance of Mountstuart Elphinstone, then the governor, even though the government also conducted an English school in almost every district in the province. Between 1845 and 1848 a bitter controversy arose regarding the medium of instruction, but the issue was between the mother tongue and English, and not between a classical language and English as it was in Bengal. The controversy gathered strength every day; and, in those days of centralization, the matter had to be referred to the Bengal government, which advised the Bombay government to concentrate its attention on English education alone, thus throttling the growth of education through the mother tongue in Bombay. Meanwhile, the Madras government was biding its time, leaving the field of positive effort open to Christian missionaries; as a result of this missionary initiative, English education in the Madras presidency was more extensively imparted than in Bombay. The Bengal government, however, did not neglect vernacular education altogether; in 1844 it established 101 vernacular schools for the main centres of population throughout the province.

A laudable experiment in the field of vernacular education was tried by a famous lieutenant governor, James Thomason, in the North-Western Provinces. He obtained government permission to set up one well-equipped and well-staffed school in every *tahsil*, or local division, as a model for other schools in the neighbourhood, but, although the scheme was based on a good principle, it did not make much headway. He tried another scheme to bring primary education within easy reach of the common people—a scheme known as the *ḥalqabandī* system. In each *ḥalqah* (circuit) of villages, a school was established in the most central village so that all the villagers within a radius of two miles might avail themselves of it. For the maintenance of these schools the village landholders agreed to contribute at the rate of 1 percent of their land income. The experiment proved successful, and in ten years Thomason opened 897 schools and provided elementary education for 23,688 children.

Ḥalqabandī system

The next step in the history of Indian education is marked by Sir Charles Wood's epoch-making Dispatch of 1854, which led to (1) the creation of a separate department for the administration of education in each province, (2) the founding of the universities of Calcutta, Bombay, and Madras in 1857, and (3) the introduction of a system of grants-in-aid. Even when the administration of India passed from the East India Company into the hands of the British crown in 1858, Britain's secretary

of state for India confirmed the educational policy of Wood's Dispatch.

It may be noted that the newly established universities did not initially undertake any teaching responsibilities but were merely examining bodies. Their expenses were confined to administration and could be met from the fees paid by the candidates for their degrees and certificates. Although the establishment of the universities did result in a rapid expansion of college education and although the products of the new learning displayed keen scholarship, the value of learning nevertheless soon decayed. In such circumstances it was ironical for the Indian Education Commission of 1882 to declare, "The university degree has become an accepted object of ambition, a passport to distinction in public services and in the learned professions." Another undesirable practice was the domination of the universities over secondary education through their entrance examinations. University policies regarding curricula, examination systems, mediums of instruction, and other vital problems began to be chalked out by university teachers who had very little experience in schoolteaching and who kept the administrative needs and requirements of colleges in the forefront. Thus, secondary schools began to aim at college education and did not prepare their students for life.

Excessive emphasis on higher education

The new system also became top-heavy. It must be stated that the Commission of 1882 made a very valuable recommendation that the "elementary education of the masses, its provision, extension and improvement requires strenuous efforts of the state in a still larger measure than heretofore." It also desired to check the wild race for academic distinction and "to divert some part of the rapidly swelling stream of students into channels of a more practical character." Despite this warning, however, alternative courses in commerce, agriculture, and technical subjects that were offered in a number of selected schools did not prove popular. The educated classes could not be diverted from their conventional path. The press and the public did demand more and wider facilities for technical education at the higher level, but the government proved indifferent.

In a general view of education during the last two decades of the 19th century, drift was more apparent than government resolve. Elementary education was starved and undernourished, and secondary education was suffering from want of proper supervision. There was an unplanned growth of high schools and colleges since the Education Commission had given a free charter to private enterprise. Many of these private institutions were "coaching institutions rather than places of learning." The universities had no control over them, and state control was negligible because the government had adopted a laissez-faire policy.

The second half of the 19th century is, nonetheless, of great significance to the country because modern India may indeed be said to be a creation of this period. It brought about a renaissance by breaking down geographical barriers and bringing different regions and long-separated Indian communities into close contact with one another. The blind admiration for Western culture was gradually passing away, and a new vision and reorientation in thought were coming about. A feeling of dissatisfaction also developed toward the existing governmental and missionary institutions. It was felt by some of the Indian patriots that the character of Indian youths could be built by Indians themselves. This led to the establishment of a few notable institutions aiming at imparting sound education to Indian youth on national lines—institutions such as the Anglo-Mohammedan Oriental College in Alīgarh (1875), the D.A.V. College in Lahore (1886), and the Central Hindu College in Banares (1898). The politically minded classes of the country had also come to regard education as a national need. They were critical of the government's educational policy and resented any innovation that might restrain the pace of educational advance or diminish liberty. (S.N.M.)

Japan. *The Meiji Restoration and the assimilation of Western civilization.* In the early 19th century, Japan still lived under a feudal system headed by the Tokugawa (Edo) shogunate, a dynasty of military rulers who held the real power while the emperors remained mere figureheads. It was not until 1868 that the shogunate was overthrown, the feudal system abolished, and the Imperial authority of the Meiji dynasty restored, leading to drastic reforms of the social system. This process has been called the Meiji Restoration.

The Tokugawa heritage

In the following generation Japan quickly adopted Western industry and culture and developed rapidly as a modern state. But the rapid modernization of Japan could not be accounted for without the long-enduring peace and cultural achievements of the Tokugawa era. It had boasted a high level of Oriental civilization, especially centring on Confucianism, Shintōism, and Buddhism. The ruling samurai, or warriors, had studied literature and Confucianism at their *hankō* (clan schools); the commoners had learned reading, writing, and arithmetic at numerous *terakoya* (temple schools). This cultural heritage helped equip Japan with a formidable potential for rapid westernization. Indeed, some elements of Western civilization had been gradually introduced into Japan even during the Tokugawa era. The shogunate, notwithstanding its isolationist policy, permitted trade with the Dutch, who conveyed modern Western sciences and arts to Japan. Only after 1853, however, did Japan open its door equally to Western countries, as a result of pressures exerted by the United States Navy under Adm. Matthew C. Perry. Thenceforth Japan was forced to cope with all kinds of Western information and communications, spoken and written in English, German, French, and other languages.

Western studies (yōgaku), especially English-language studies, became increasingly popular after the Meiji Restoration; Western culture flooded into Japan. The Meiji government dispatched study commissions and students to Europe and to the United States, and the so-called westernizers defeated the conservatives who tried in vain to maintain allegiance to traditional learning.

Establishment of a national system of education. In September 1871 Japan's first true Ministry of Education was established. It assigned commissioners, many of whom were *yōgakusha* (students of Western learning), to design the school system, and in September 1872 the *gakusei*, or government order of education, was promulgated. It decreed that all youth, regardless of class or sex, should receive education. The country was initially divided into eight university districts, which were further divided into 32 middle school districts and 210 primary school districts. Each respective district would have one university (*daigaku*), one middle school (*chūgakkō*), and one primary school (*shōgakkō*). Whereas Tokugawa education had separated warriors and commoners, *gakusei* envisioned a unified, classless system of modern national education, designed on a ladder plan. Although the district system was said to have been borrowed from France, the new Japanese education was not merely imitative of a single model; it was based on the study of Western education and assimilated the essences of education in all advanced countries. Curricula and methods of education, for instance, were drawn primarily from the United States.

Gakusei, or government order of education

At the time, however, Japan was not sufficiently prepared to carry out completely the plans of *gakusei*. Districts were marked, and primary schools were opened, but the real conditions were far short of the ideal. No university was erected at all. Soon after the promulgation of *gakusei*, the government, adapting itself to the need for speedy westernization, established professional schools and foreign-language schools, in which foreigners taught in foreign tongues. Thus, the school system of Japan split into dual lines: one consisted of the primary schools for commoners, and the other consisted of the professional schools for leading classes.

Under the *gakusei* system of education, the Ministry of Education, together with local officials, managed with difficulty to set up primary schools and to make children attend them. The number of primary schools amounted to 24,000 in 1875, with 45,000 teachers and 1,928,000 pupils. The ratio of school attendance reached 35 per-

cent of all who could attend (ages six to 14); even those children who commenced schooling tended to drop out after a year or so. In 1873 an educator from the United States, David Murray, was invited to Japan as an adviser to the Ministry of Education; another, M.M. Scott, assumed direction of teachers' training and introduced modern methods and curricula at the *shihangakkō* (normal school), established under the direct control of the ministry. The *shihangakkō* designed curricula for the primary schools, modelled after those of the United States, and compiled primary textbooks involving new teaching methods. These methods and curricula, radically different from that of *terakoya*, or temple schools, of the Tokugawa era, spread gradually into the elementary schools of almost all regions.

Work of educators and teachers from abroad

Many teachers from abroad were engaged at large salaries in professional schools and foreign-language schools. Foreign missionaries built their own institutions. Private foreign-language schools (mainly English) also helped introduce Western culture. In 1877 the University of Tokyo—Japan's first university in a modern sense—was founded, and it too employed many European and American instructors.

The conservative reaction. Japan's education experienced a turning point with the Satsuma Rebellion in 1877. Following this last and greatest of the samurai uprisings, the nation again forged ahead toward political unity, but there was an increasing trend of antigovernment protest from below, which has usually been called the Free People's Rights Movement. Because of the Satsuma rebellion, the government was in heavy financial difficulties. Also, with the people's inclination toward Western ideas fading away, a conservative reaction began to emerge, emphasizing the forgotten traditions closely associated with Confucian and Shintō ideology and favouring a return to local control of education.

There had been mounting discontent among the rural people against the old law of 1872, mainly because it had imposed upon them the financial burdens of establishing schools and yet had not lived up to expectations. Tanaka Fujimaro, an executive of the Ministry of Education, just returning from an inspection tour in the United States, thought that the government should transfer its authority over education to the local governments, as in the United States. In September 1879 the government nullified the former *gakusei* and put into force the *kyoiku-rei* (Education Law), which made for rather less centralization. Not only did the new law abolish the district system that had divided the country into districts for *daigaku*s, *chūgakkō*s, and *shōgakkō*s, but also it reduced central control over school administration, including the power to establish schools and regulate the duration of attendance. The law was intended to encourage the initiatives of towns and villages. Such a drastic educational reform, however, led to a decline in the efficiency of education in some regions, and criticism arose among those prefectural governors who had been striving to enforce *gakusei* in their regions.

As a countermeasure, the government then again changed the law in 1880, revising the rights of prefectures. Thereafter, the prefectural government would provide regulations within the limits of criteria set by the Ministry of Education; some measure of educational unity was thus reached on the prefectural level, and the school system received some needed adjustment. Yet, because of economic stagnation, the attendance ratio remained low.

Re-emphasis on Confucian and Shintōist values

Reacting to the increasing conservative trend, the Ministry of Education reintroduced Confucian and Shintōist values. In the primary schools, *shūshin* (ethics) was made the most important core of the curricula, and the ministry compiled a textbook with overtones of Confucian morality.

Establishment of nationalistic education systems. With the installation of the cabinet system in 1885, the government made further efforts to pave the way for a modern state. The promulgation of the Meiji constitution, the constitution of the Empire of Japan, in 1889 established a balance of Imperial power and parliamentary forms. The new minister of education, Mori Arinori, acted as a central figure in enforcing a nationalistic educational policy and worked out a vast revision of the school system, and this set a foundation for the nationalistic educational system that developed during the following period in Japan. Japanese education thereafter, in the Prussian manner, tended to be autocratic. Later, in 1903, the Ministry of Education was even confirmed in its power to alter, add, or delete information in national textbooks to accord with political currents.

Based on policies advocated by the educational minister, a series of new acts and orders were published one after another. The first was the Imperial University Order of 1886, which changed the name of the University of Tokyo to Tokyo Imperial University (*Tokyo Teikoku Daigaku*), thus, as the name indicates, rendering the university a servant of the state, to train high officials and elites in various fields. The ministry also carried out sweeping revisions of the normal school, which adopted militaristic education and trained teachers to obey strictly the order of their seniors.

Together with these reforms, the Imperial Rescript on Education (*kyoiku-chokugo*) of 1890 played a major role in affirming the nationalistic system. By re-emphasizing the traditional Confucian and Shintō values and redefining the courses in ethics (*shūshin*), it was to place morality and education on a foundation of Imperial authority. It would provide the guiding principle for Japan's education until the end of World War II.

Promotion of industrial education. Ever since the Meiji Restoration in 1868, the national target had been *fukoku-kyōhei* ("wealth accumulation and military strength") and industrialization. From the outset the Meiji government had been busy introducing science and technology from Europe and America but nevertheless had difficulties in realizing such goals.

Inoue Kowashi, who became minister of education in 1893, was convinced that modern industries would be the most vital element in the future development of Japan and thus gave priority to industrial and vocational education. In 1894 the Subsidy Act for Technical Education was published, followed by the Technical Teachers' Training Regulations and the Apprentice School Regulations. The system of industrial education was in general consolidated and integrated. These measures contributed to the training of many of the human resources required for the subsequent development of modern industry in Japan. (A.Na.)

IX. Education in the 20th century

SOCIAL AND HISTORICAL BACKGROUND

International wars, together with an intensification of internal stresses and conflicts among social, racial, and ideological groups, are characteristic of the 20th century and have had profound effects on education. Rapidly spreading prosperity and affluence, immense increases in population, an explosion of knowledge, the establishment of many new professions, the growth of large-scale science-based industry, the enormous influence of mass media such as television, the increasing power of organized labour, a trend toward Socialism, and widespread skepticism about all accepted values, including those supported by religion, are other factors that have also had far-reaching effects.

The two world wars weakened the military and political might of the larger European powers and thus helped to liquidate colonialism. In Africa and Asia, almost every nation became independent, one consequence of which has been a great increase in the quantity of education provided. Attempts, not always successful, have been made to eradicate illiteracy. Colleges and schools have been built everywhere, and the growth in the number of pupils and students has been astonishing.

The establishment, after revolution and civil strife, of Communist and Socialist governments in many parts of the world has resulted in the promotion and expansion of education by governments that have seen education as a key to industrial development. The growing affluence of masses of the population in high-income areas in North

America and Europe has brought about, particularly since World War II, a tremendous demand for secondary and higher education. Most children stay at school till 16, 17, or even 18 years of age, and a substantial fraction spend two, three, or four years at college. The number of universities in many countries has doubled or trebled, and the number of students has increased four times between 1950 and 1970. This explosive growth is sustained by the fact that many more workers need to study in lecture room and laboratory after their school years are completed, if they are to use skillfully the instruments, materials, and methods put at their disposal by modern scientific technology.

Demands of industry for technical and continuing education

Employers and managers, as well as governments, realize very clearly that modern industry has a built-in obsolescence. New methods, processes, and machines are continually introduced. Old skills become irrelevant; new industries spring up. In addition, the amount of scientific, as distinct from merely technical, knowledge grows continually. More and more research workers, design specialists, and high-level professionals are called for. The reaction has been to encourage the establishment of technical and technological colleges; to promote adult education at all levels; to turn attention to part-time and evening courses; and to provide more training and education within the industrial enterprises themselves.

The adoption of modern methods of food production has diminished the need for agricultural workers, who have headed for the cities. Urbanization, however, brings problems: city centres decay, and there is a trend toward violence. The poorest remain in these centres, and it becomes difficult to provide adequate education.

SUMMARY OF MAJOR TRENDS AND PROBLEMS

In general, the chief trends in education since 1900 may be summarized thus: (1) There has everywhere been a very great increase in the number of pupils and students, at all levels. Secondary education is being universalized. (2) The tertiary level—higher education—has become more important. Universities are changing from selective to mass institutions. (3) The relation between education and material well-being has become clearer. In consequence, increasing attention is paid to technical and technological training. (4) The development of new science-based industries, the decay of old industries, and the very rapid obsolescence of modes of production have convinced administrators, managers, and workers that facilities for retraining workers and for in-service education must be provided. This draws attention to the importance of adult education and of permanent, lifelong, continuing education. A major difficulty here is that no one knows what the future for which people are being prepared will be like. All that is certain is that it will be very different from the present. Hence, there is a stress on adaptability, on the readiness to accept and welcome change and novelty. (5) There is a general acceptance of the notion that equality of educational opportunity is an ideal that must be accepted. In consequence there is everywhere a growing acceptance of the "common" or "community" or "comprehensive" school and college. Elitism and selectivity are being abandoned, even rejected, almost everywhere.

Problems of all kinds arise as a consequence of these trends. Among them the following are important: (1) Education is expensive, requiring vast resources in materials and manpower. How can these be best mobilized? (2) Mass systems, replacing selective systems, call for new modes of organization and administration. How should the secondary and tertiary levels be structured? What kinds of schools and colleges are needed? (3) What should be taught at each level of education and how? How should the problem of curriculum and method be approached? What are the relative claims of general and vocational education? (4) What are the best ways of selecting pupils for the various levels? How should students be allocated at the third level among the different professional paths available? (5) Is it possible to use modern methods of planning to make education more productive and less costly? (6) Can new inventions such as television, colour photography, tape recorders, and computers be used to teach students more cheaply and more efficiently? (7) How can systems of permanent, lifelong education be established and how should they be organized?

The above are no more than examples of the kind of problems being studied in the last third of the 20th century. The way in which the discussions proceed is influenced, as should be expected, by the intellectual and cultural climate of the times. There is widespread skepticism about the real value of intuitive and contemplative philosophy. Science has enormous prestige. Mathematics and statistics are revered, as are all quantitative and measurable considerations. The result is that growing importance is accorded to the findings of the social sciences, such as economics and sociology, and less to the arguments and proposals of philosophers, historians, and humanists in general. Positivism, pragmatism, and social, cultural, and moral relativism are dominant, even triumphant.

MAJOR INTELLECTUAL MOVEMENTS

Influence of psychology on education. The attempt to apply scientific method to the study of education dates back to the German philosopher Johann Friedrich Herbart, who called for the application of psychology to the art of teaching. But not until the end of the 19th century, when the German psychologist Wilhelm Max Wundt established the first psychological laboratory at the University of Leipzig in 1879, were serious efforts made to separate psychology from philosophy. From Wundt's monumental *Grundzüge der physiologischen Psychologie* ("Fundamentals of Physiological Psychology") flowed the various movements that had significant effects on education in the 20th century.

Influence of William James

Among Wundt's pupils was the American psychologist and philosopher William James, often considered the father of American psychology of education. In 1878 he established the first course in psychology in the United States and in 1890 published the famous *Principles of Psychology*, in which he argued that man should be thought of as a living organism with instinctive tendencies to react with his environment. A child's mind, therefore, is that aspect of his being that enables him to adapt to the world, and the purpose of education is to organize the child's powers of conduct so as to fit him to his social and physical environment. Interests must be awakened and broadened as the natural starting points of instruction. James's *Principles* and *Talks to Teachers on Psychology* cast aside the older notions of psychology in favour of an essentially behaviourist outlook; they asked the teacher to help educate heroic individuals who would project daring visions of the future and work courageously to realize them.

Both William James and the American philosopher John Dewey are often thought of as defending "functionalism," a body of psychological theory that has had great influence on education during the 20th century. The functionalists viewed man as a living organism, a product of both heredity and environment, and were interested not merely in what the phenomena of consciousness are but also in what they do. They helped to clear away many of the fantastic notions once held about the successive steps involved in the development of mental functions from birth to maturity. Their methodology yielded valuable clues to the understanding of the psychology of learning, and they were the first to call attention to the part played by motivation and goal seeking.

Influence of Freudianism

Freudianism was one of the intellectual mainstreams that influenced educational theory in the 1920s. Freudians began to apply Freudian doctrines to education soon after World War I, but they made a direct impact upon only a limited circle of educators. The powerful and pervasive influence of Freudianism came indirectly through gradual public acceptance of the psychoanalytical image of the child. It accelerated changes in the emotional climate and in the authority pattern of the classroom.

The new psychology that developed during the early decades of the 20th century represented a scientific and

experimental approach to the biological growth of the human animal and to the learning process. Each school of psychology added more to the knowledge of human behaviour, and each had its effect on education. Schools and educators could not return to the concepts of education that had predominated at the turn of the century.

Traditional movements. *Essentialist education.* The name essentialist is derived from the obvious stress on "essentials," by which is meant those human experiences past and present that—so some believe—are indispensable to people living today or at any time. They hold that it is the main function of organized education to transmit these essentials to the young. The leading exponent of the essentialist doctrine was the American educationist William Chandler Bagley. Bagley published *Education and Emergent Man* (1934), a powerful refutation of pragmatism. He believed that it is possible to accept a thoroughgoing evolutionary theory that links mankind with the entire range of life and yet recognize in mankind a potential nobility, all this without bringing in a metaphysical element.

The essentialists saw in the progressive movement the abandonment of standards of scholastic achievement, the neglect of system and sequence, indiscriminate use of activity, overemphasis on social studies, irresponsibility in curriculum revision, and an attempt to use elementary schools to establish a new social order. Bagley spoke for many when he wrote,

> It is true that the world of today is a different world from the world of 1913 and from the world of 1929 . . . but this does not mean that everything has changed. . . . The winds that blow still follow the laws of storms; *Huckleberry Finn* and *Treasure Island* still delight youth; and the Sistine Madonna is just as beautiful as of yore. (From *Education and Emergent Man*, 1934.)

The movement culminated in the formation of The Essentialist Committee for the Advancement of American Education, which aimed at combatting falling standards of achievement in American schools. The essentialists demanded a return "to the exact and exciting studies." They favoured the "mental disciplines" and gave their blessing to Latin, algebra, and geometry. In the matter of method and content, Essentialists put effort above interest, subjects above activities, collective experience above that of the individual, logical organization above the psychological, and the teacher's initiative above that of the learner.

Humanistic, or liberal, education. The chief proponents of "humanistic," or "liberal," education were Robert M. Hutchins, formerly chancellor of the University of Chicago, and Mortimer J. Adler, professor of the philosophy of law at the same institution. Adler argued for the restoration of an Aristotelian viewpoint in education. Maintaining that there are unchanging verities, he sought a return to education fixed in content and aim. He claimed to prove by philosophical inquiry that

The work of Adler and Hutchins

> education is the process by which those powers (abilities, capacities) of men that are susceptible to habituation, are perfected by good habits, through means artistically contrived, and employed by any man to help another or himself achieve the end in view (*i.e.*, good habits). (From National Society for the Study of Education, *41st Yearbook*, Part 1, p. 246, 1942.)

Hutchins denounced American higher education for its vocationalism and "anti-intellectualism," as well as for its delight in minute and isolated specialization. Anti-intellectualism in American education, Hutchins argued, leads to sentimentalism. Suspicion of the intellect leads to the emphasis on knowing what one wants rather than why one wants it. Thus, "unlimited acquisition" becomes the human law, and "success" becomes the measurement of education.

Hutchins and his colleagues urged a return to the cultivation of the intellect. Everyone between the ages of 16 and 20, except the obviously unfit, should be given the same education. The first steps in the training of the intellect would be through grammar, rhetoric, and logic. Through these the learner can cultivate the arts of reading, writing, and speaking correctly. He would be required to study theoretical mathematics, which "exemplifies reasoning in its clearest and most precise form."

Religious and classical education. Opposed to the fundamental tenets of pragmatism is the philosophy that underlies all Catholic education. Theocentric in its viewpoint, Catholic scholasticism has God as its unchanging basis of action. It insists that without such a basis there can be no real aim to any type of living, and hence there can be no real purpose in any system of education. It teaches that man is a personal creation of God; that he is body (material) and soul (spiritual); and that this dual elemental composition functions as an integrated unity. The supernatural is the essence of the Catholic system. It pervades its theology, its ethics, its practice, its view of life, and its education. The church's

The aim of Catholic education

> whole educational aim is to restore the sons of Adam to their high position as children of God. [It insists that] education must prepare man for what he should do here below in order to attain the sublime end for which he was created . . . The true Christian does not renounce the activities of this life, he does not stunt his natural faculties; but he develops and perfects them, by coordinating them with the supernatural. He thus enables what is merely natural in life and secures for it new strength in the material and temporal order, no less than in the spiritual and eternal. (From Pius XI, encyclical on the "Christian Education of Youth," December 31, 1929.)

Such is the ultimate end of Catholic education, and to it every Catholic educational institution, from infant school to the graduate school, must address itself. Everything in education—content, method, discipline—must lead in the direction of man's supernatural destiny. Every agency playing a part in education—the school, the family, and the state—must heed this ultimate end.

> It is necessary not only that religious instruction be given to the young at certain fixed times, but also that every other subject taught be permeated with Christian piety. (From Leo XIII, encyclical "Militantes Ecclesiae," August 1, 1897.)

Experimental movements. *Child-centred education.* Proponents of the child-centred approach to education have typically argued that the school should be fitted to the needs of the child, and not the child to the school. One of the forerunners, called the father of progressive education by John Dewey, was the American educationist Francis W. Parker. In his view, what mattered in a school was not the learning of subject matter, neatly and logically arranged, but the child's own development. Parker became superintendent of schools at Quincy, Massachusetts, in 1875, where he introduced his ideas and practices. The old-fashioned, stiff, unnatural order was banned. An activity program was introduced, and subjects were interrelated around a central core instead of being taught for their own sake. In 1883 he moved to Cook County Normal School, Chicago, surrounding himself with excellent teachers. There he continued along the path he had started at Quincy. He assailed the mechanical, assembly-line methods of traditional schools. He stressed "quality teaching," by which he meant such things as activity, creative self-expression, excursions, understanding the individual, and the development of personality. Parker stressed the child's need for art, music, craft training, science, and physical training. Through the "Quincy method" and the Cook County Normal School, the first steps were taken toward more modern educational methods.

A different approach to child-centred education arose as a result of the study and care of the physically and mentally handicapped. Teachers had to invent their own methods and special apparatus to meet the needs of such children, because the ordinary schools did not and could not supply them. When these methods proved successful with handicapped children, the question arose whether they might not yield even better results with ordinary children. During the first decade of the 20th century, the educationists Maria Montessori of Rome and Ovide Decroly of Brussels both went on to apply their educational inventions in schools for ordinary boys and girls.

The Montessori method

The Montessori method's underlying assumption was the child's need to escape from the domination of parent and teacher. According to Maria Montessori, there is per-

manent conflict between adult and child. Children are the unhappy victims of adult suppression, who have been compelled to adopt defensive measures foreign to their real nature in the struggle to hold their own. The first move toward the reform of education, thought Maria Montessori, should be directed toward the adult educator: to enlighten his conscience, to remove his perception of superiority, and to make him humble and passive in his attitudes toward the young. The next move should be to provide a new environment in which the child has a chance to live a life of his own, free from frustrations. In the Montessori method, the special senses are separately trained by means of apparatus calculated to enlist spontaneous interest at the successive stages of mental growth. By similar self-educative devices, the child is led to individual mastery of the basic skills of everyday life, and then to schoolwork in arithmetic and grammar. There are no teachers but only kindly directors whose function it is to see that things go according to a master plan.

The Decroly method's essential feature was a program of work based on centres of interest and the individualism of learning by means of educative games. The basic feature was the workshop-classroom, at once a workshop, a study, a museum, a zoo, a library, in which children could go freely about their own occupations, planning, talking, looking on, cooperating as the occasion might require. Behind the complex of individual activities there was a carefully organized scheme of work based on an analysis of the fundamental needs of the child. The teachers were required to follow an orderly method in guiding the children. The principle of giving priority to wholes rather than to parts was emphasized in teaching children to read, write, and count, and care was taken to reach a comprehensive view of the experiences of life.

The Montessori method, promoted by the Association Montessori Internationale, and the Decroly method have gradually spread throughout the world, and their success has done much to stimulate the development of other aspects of modern education. Partly as a result of a renewed emphasis on individual learning, educators—often not aware of the source of their ideas—have begun once more to look for better methods of teaching classes that give more consideration to individual difference in the needs and abilities of pupils.

Pragmatist and progressive education. The progressive education movement was part and parcel of a broader social and political reform called the Progressive movement, which dates to the last decades of the 19th century and the early decades of the 20th. Elementary education had spread throughout the Western world, largely doing away with illiteracy and raising the level of social understanding. Yet, despite this progress, the schools had failed to keep pace with the tremendous social changes that had been going on. The increasing mechanization of life and work gradually reduced the need and opportunity for the exercise of personal skills and activities, and in the schools the children were expected to sit immobile, absorbing passively.

Experimental schools were established during the last decade of the 19th century and in the early 20th century by several educational reformers who wished to put their ideas into practice. The development of a new philosophy of education and of new methods was a natural outgrowth of such schools. They comprised three groups: the country boarding schools, the American experimental group, and experimental schools of the Montessori type. There were also other educational reformers who did not establish experimental schools but contributed by their writings.

Some early experimental schools

What is considered to be the first modern experimental school, Abbotsholme, Derbyshire, was founded by the English educator Cecil Reddie in 1889. Reddie's aim was to develop personality through freedom, his motto being "liberty is obedience through law." The aim of instruction was not only to impart knowledge but also to develop character and encourage reason and judgment. The methods of teaching varied, but a favourite one was group discussion. One of the innovations was a system of self-government by the pupils. John Haden Badley, an associate of Reddie at Abbotsholme, founded Bedales School, in Hampshire, in 1893. Essentially the same as Abbotsholme, there was one great difference: Bedales was coeducational and thus highly unconventional. The country boarding school was soon introduced in Germany, France, and Switzerland.

The principal experimental schools in America until 1914 were the Laboratory Schools of the University of Chicago, founded in 1896 and directed by John Dewey; the Francis W. Parker School, founded in 1901 in Chicago; the School of Organic Education at Fairhope, Alabama, founded by Marietta Johnson in 1907; and the experimental elementary school at the University of Missouri (Columbia), founded in 1904 by Professor Junius L. Meriam. The common goal of all was to eliminate the school's traditional stiffness and to break down hard and fast subject-matter lines. Each school adopted an activity program. Each operated on the assumption that education was something that should not be imposed from without but should draw forth the latent possibilities from within the child. And each believed in the democratic concept of individual worth.

Dewey, whose writings and lectures influenced educators throughout the world, laid the foundations of a new philosophy that affected and continues to affect the whole structure of education, particularly at the elementary level. His theories were expounded in *School and Society* (1899), *The Child and the Curriculum* (1902), and *Democracy and Education* (1916).

The views of John Dewey

For Dewey, philosophy and education render service to each other. The one indicates what social values are desirable; the other seeks to promote them. Education becomes the laboratory of philosophy. Society should be interpreted to the child through his daily living in the classroom, which acts as a miniature society. Education leads to no final end; it is something continuous, "a reconstruction of accumulated experience," which must be directed toward social efficiency. Education *is* life and not merely a preparation for life.

The influence of progressive education advanced slowly during the first decades of the 20th century. The experimental schools touched only a small part of the population, and World War I interrupted their increase. A number of progressive schools, however, were established, such as the Play School and the Walden School in New York City, the Shady Hill School in Cambridge, Massachusetts, the Elementary School of the University of Iowa, and the Oak Lane Day School in Philadelphia.

Experimental schools sponsored by universities found few imitators, but the idea of a democratic education through individual activities, which was a fundamental principle in their experimentation, led progressive-minded teachers to try out new ways of their own in their schools. Dewey had given them a philosophy of education for general guidance, but for the most part their approach was not doctrinaire. They wanted a freer, more individual kind of schooling. It was for them to find out by practical trial how to achieve this result under ordinary conditions.

The spread of progressive education was more rapid in the third decade of the 20th century. The movement was not confined to any particular country. In the United States the progressives felt that it was necessary to band together, with the result that the Progressive Education Association (PEA) was formed in 1919. The PEA did much to further the cause of progressive education until it ended, as an organization, in 1955. As in the United States, Europe's leading progressives found it desirable to band together, and in 1921 the New Education Fellowship was formed. During World War II the activities of the New Education Fellowship were curtailed, but it managed to keep going and eventually acquired national sections in 25 countries under the new name of the World Education Fellowship.

Although the name progressive education has fallen somewhat into disrepute since the 1950s, the notions it expressed have had deep influence on public school systems everywhere. Activity programs, imaginative writ-

ing, projects, trips, movable desks, and space in every classroom for dramatics and informal activities are found in almost all school systems. The grading system has been done away with in many schools, and the results of individual research are often pooled and reported to the class. Children are given more responsibility for the social life of their school and so are practiced in citizenship as they never were before. And these developments are common, in varying degree, all over the world.

Scientific-realist education. The scientific-realist education movement began with an appeal by the ladies who had been put in charge of special schools opened for backward and abnormal children in Geneva, Switzerland (1900). Their appeal was made to a young doctor, Édouard Claparède, then an assistant in the Psychological Laboratory of the University of Geneva. He responded to their appeal, and this experience brought him to realize some of the defects of ordinary schools. In a lecture to the Medical Society of Geneva, he suggested the need for *l'école sur mesure* ("the school made to measure"). Not as much thought is given, he argued, to the minds of children as to their feet. Their shoes are of different sizes and shapes, made to fit their feet. When shall we have schools to measure? The psychological principles needed to adapt education to individual children were expounded in his *Psychologie de l'enfant et pédagogie experimentale* (1909). Later Claparède took a leading part in the creation of the Institut J.-J. Rousseau in Geneva, a school of educational sciences to which came students from all over the world.

Jean Piaget's studies of child development

Theorists such as Claparède hoped to provide a scientific basis for the whole of the educational enterprise, an aim that was furthered by the Swiss psychologist Jean Piaget, who studied in a philosophical and psychological manner the intellectual development of children. Piaget argued, on the basis of his observations, that development of intelligence exhibits four chief stages and that the sequence is everywhere the same, although the ages in the stages of development may vary from culture to culture. He starts by defining thinking as an action, a sort of manipulation. It begins as an operation upon actual and material things and objects—upon water, or air, or a ball. These operations are then interiorized. They become part of the living organism itself, mind as well as body, and they are gradually generalized and formalized.

The first stage in the development takes place at the infant stage, when the child, even before he learns to speak, puts objects together (addition), then separates them (subtraction). He perceives them as collections, rings, networks, groups. By the age of two or three, a basis has been laid. Kinetic muscular intelligence has developed to some degree—the infant thinks with his fingers, his hands, his body. Aided by language, the capacity for symbolic thinking slowly develops. This constitutes the second stage. Up to the age of seven or eight, some of the fundamental categories of adult thinking are still absent: there is seldom any notion, for instance, of cause and effect relationships.

The third stage is that of concrete operation. The child has begun to know how to deal with mental symbols and acquires abstract notions such as "responsibility." But he operates only when in the presence of concrete objects that can be manipulated; he still needs the crutch of experience. Pure abstract thinking is still too difficult for him. Nevertheless, notions of classification, series, one-to-one correspondence, whole numbers, fractions, space, speed, time, and chance gradually become clear—clear but always limited and bounded. At this stage the teaching must be exceedingly concrete and active; purely verbal teaching is out of place.

Only after about 12 years of age, with the onset of adolescence, does the power develop to deal with formal mental operations not immediately attached to objects. Only then do theories begin to acquire real significance, and only then can purely verbal teaching be used.

The child's *total* development, particularly his emotional and social growth, also concerned educational reformers. They pointed out that it is wrong to assume that incentives to mental effort that are effective with adults are equally effective with the young. The English philosopher Alfred N. Whitehead, in his doctrine of the "Cycle of Interests," put forward a theory very much in line with the ideas of the reformers. Romance, precision, and generalization, said Whitehead, are the stages through which, rhythmically, mental growth proceeds.

> Education should consist in a continual repetition of such cycles. Each lesson in a minor way should form an eddy cycle issuing in its own subordinate process.

Whitehead believed that any scheme of education must be judged by the extent to which it stimulates a child to think. His warning to teachers is:

> In training a child to activity of thought, above all things we must beware of what I will call 'inert ideas,'—that is to say, ideas that are merely received into the mind without being utilised, or tested, or thrown into fresh combinations.

From the beginning of his education, the child should experience the joy of discovery. The discovery he has to make is that general ideas give an understanding of the stream of events that shape his life.

Social-reconstructionist education. Social-reconstructionist education is based on the theory that society can be changed and reconstructed through the complete control of education. The objective is to change society to conform to the basic ideals of the political party or government in power or to create a utopian society through education. This movement has progressed from the experimental stage to a system of education that controls a large fraction of the world's population.

Communist education, a variety of social-reconstructionism, is based upon the philosophy propounded by Karl Marx, Friedrich Engels, and Lenin. M.I. Kalinin, formerly president of the U.S.S.R., expressed the general aims of Communist education in a short book, *On Communist Education* (1950), as follows:

The aims of the Soviet education system

> Communist principles, taken in their elementary form, are the principles of highly educated, honest, advanced people; they are love for one's socialist motherland, friendship, comradeship, humanity, honesty, love for socialist labour and a great many other universally understood lofty qualities. The nurturing, the cultivation of these attributes, of these lofty qualities, is the most important component part of communist education.

Side by side with his general and technical education, the Communist pupil is constantly reminded of Marxist principles and their applications.

> To learn Marxism means to know after mastering the Marxist method how to approach all other problems connected with your work. If, let us say, the sphere of your future work is agriculture, will it be of advantage to employ the Marxist method? Of course it will. But to employ the Marxist method, you have to study agriculture, too, you have to be an agricultural expert. Otherwise nothing will come of your attempt to apply Marxism in agriculture. This should not be forgotten if you wish to apply Marxism in practice, if you wish to be men of action, and not textmongers of Marxism. But what does being a Marxist mean? It means being able to adopt the correct line. But to be able to adopt the correct, Marxist line, you also need to be a first-rate expert in your particular sphere of activity. (*Ibid.*, p. 16.)

Communist education is strictly controlled as to both curricula and methods. No religious instruction is permitted. From the 1950s onward, much attention has been paid to the ideal of "polytechnization." Man, so the argument runs, is not simply *Homo sapiens* but rather *Homo faber*, the constructor and builder. He attains full mental, moral, and spiritual development through entering into social relations with others, particularly in cooperative efforts to produce material, artistic, and spiritual goods and achievements. The school should prepare pupils for such productive activities—for instance, by studying and, if possible, sharing in the work done in field, farm, or factory. Stress should be laid in the curriculum on science, which is the theory of production, and on mathematics, which is the language of science. The pursuit of these polytechnical aims has led to interesting and valuable experiments and has undoubtedly contributed to rapid industrialization.

Educational aims of the Nazis

The Nazi social-reconstructionist education system in Germany (1933–45) was an attempt to insure that the totalitarian government had complete control over the populace. Even before the National Socialists came to power, Hitler in *Mein Kampf* hinted at far-reaching educational changes. The Ministry of Public Enlightenment and Propaganda exercised control over virtually every form of expression—radio, theatre, cinema, the fine arts, the press, churches, and schools. The control of the schools began in March 1933 with the issuing of the first educational decree, which held that "German culture must be treated thoroughly."

The Nazi government reorganized the school curriculum in accordance with Nazi beliefs. *Rassenkunde* ("race science") was given first place in the school curriculum. A major part of biology became race science, and health education and physical training did not escape the racial stress. Geography became geopolitics, the study of the fatherland being fundamental. Physical training was made compulsory for all: the body came first, character next, and the intellect last.

The Nazi education system was designed to control completely the education of the young, from the primary schools through the universities, and in their everyday life. The secondary schools were run as National Socialist *Erziehungsstatten* (places of education), and youth labour service was made compulsory. An integral part of the Nazi education were the Hitler Youth organizations, in which the program of indoctrination so relentlessly carried out in the school was supplemented along military and political lines.

Reconstructionist education in Israel

Another social-reconstructionist movement, and a very different one, is that of the kibbutzim (collective farms) of Israel. The most striking feature of kibbutz education is that the parents forgo their natural desire to rear and educate their offspring and instead hand them over to the "Children's House" to be educated by professionals (specially appointed nurses and educators). What makes this more astonishing is the fact that children are usually withdrawn from the care of their parents at a very early age and, in some kibbutzim, immediately after birth.

The kibbutzim type of education developed for both practical and economic reasons. It released mothers from the exacting duty of looking after and rearing their own children, thus making it possible for them to work side by side with the men. The labour force was thus augmented, since only a small staff is required to look after the children. It also enabled the members of the group to offer their children conditions of material comfort, which they as individuals could not afford to give them. With the development and consolidation of the kibbutz, the economic motive behind collective education gradually receded, and ideological and educational considerations gained prominence. These were: (1) that the kibbutz way of life makes for complete equality of the sexes; (2) that the education of children in special children's houses is the best way of perpetuating the kibbutz way of life; (3) that collective education is more "scientific" than education within the family, inasmuch as children are reared and trained by experts (*i.e.*, qualified nurses, kindergarten teachers, and other educators), in an atmosphere free of the tensions engendered by family relationships; and (4) that collective education is more democratic than the traditional education within the family, and more in keeping with the spirit of cooperative living. It is, indeed, the practical realization of the ideal of educational equality, which is in turn the corollary of social and economic equality.

The system of education adopted in the kibbutzim tended to be influenced by the ideas of Sigmund Freud. The literature produced by the ideologists and teachers in the schools shows that they accept the Freudian conception of the main task of education: the problems of child management and discipline, the legitimate use of reward and punishment, the educator's attitude to the child's impulses and bodily desires and the attempt to sublimate them—all of these figure quite prominently. The problems are dealt with in the light of Freud's warning that an outright authoritarian approach on the part of the educator may be harmful to the child. The kibbutz teacher and educator constantly strive for new methods to replace the authoritarian approach of the traditional educator.

Kibbutz education has, at least in theory, been on the whole permissive and opposed to unmotivated prohibitions. It does not inculcate a consciousness of sin, nor does it promote taboos. It does not regard any instinctive behaviour as intrinsically evil or wicked and rejects corporal punishment as morally wrong and harmful to the child. Kibbutz educators view punishment of any sort as undesirable.

In the beginning the kibbutz was exclusively an agricultural unit, but now it is often mixed: industrial as well as agricultural. The former prejudice against academic studies is decreasing. This change is evident in the variety of subjects studied by young people. It is understood that at the completion of his studies the student will return to the kibbutz, which is essentially a democratic institution, the educational policy of which will always be influenced by the wishes of the parents.

WESTERN PATTERNS OF EDUCATION

United Kingdom. *Early 19th to early 20th centuries.* English education has been less consciously nationalist than that of continental European countries, but it has been deeply influenced by social class structure. Traditionally, the English have held that the activity of the government should be restricted to essential matters such as the defense of property and should not interfere in education, which was the concern of family and church. The growth of a national education system throughout the 19th century continued without a clear plan or a national decision. The cornerstone of the modern system was laid by the Elementary Education Act of 1870, which accepted the principle that the establishment of a system of elementary schools should be the responsibility of the state. The act divided the country into districts. Where voluntary schools were insufficient, school boards were elected to levy taxes, maintain elementary schools, and pay the fees of needy children. The act of 1870 did not eliminate the traditional prominence of voluntary agencies in the sphere of English education. Nor did it provide for secondary education, which was conducted largely by voluntary fee-charging grammar schools and "public" schools. These public schools were usually boarding schools charging rather high fees. Their tradition was aristocratic, exclusive, formal, and classical. Only a small proportion of the population was served by them. Their main goal was to develop "leaders" for service in public life. In 1900, one child in 70 could expect to enter a secondary school of some kind. The grammar schools copied the curriculum of the public schools, so that only the intellectual and social elite were able to attend.

The Elementary Education Act of 1870

In 1899 an advance was made toward the development of a national system encompassing both elementary and secondary education by creating a Board of Education as the central authority for education. The next step was the passing of the Education Act of 1902, known, after its sponsor, as the Balfour Act. This established a comprehensive system of local government for both secondary and elementary education. It created new local education authorities and empowered them to provide secondary schools and develop technical education. Under the act the county and county-borough councils became the Local Education Authority. School boards were abolished. All councils under the act were required to appoint an education committee with a proportion of co-opted members with experience of education, of whom some were to be women. Local education authorities were "to supply or aid the supply of education other than elementary." Taking advantage of this, local education authorities provided many new secondary schools that were mainly of one type. In regulations issued in 1904, Sir Robert Morant, the first secretary of the Board of Education, disregarding the opportunities offered by the wide terms of the act, set a pattern for their development based on the academic tradition of grammar and public schools.

It was the voluntary-school issue that made the act one of the most fiercely contested measures of the 20th century, especially the decision to give voluntary schools the benefits of rate (local-tax) aid. Voluntary schools (former board schools) were also brought under the general control of the new local education authorities. But the managers of voluntary schools retained the power of appointing teachers, subject to the consent of the local authority, which could not be withheld, except on educational grounds. The managing body was to consist of four foundation managers and two local-authority representatives, and the religious teaching was to be in accordance with the "trust deed" of the school. As a result, the dual system agreed upon in 1870 was not only confirmed but strengthened, while at the same time unified administration of all elementary schools under the new local education authority opened the way to general advance in this important branch of education.

Provisions of the act of 1918

The Education Act of 1918 (The Fisher Act), re-enacted with surviving earlier legislation in consolidated form in the Education Act of 1921, aimed at the establishment of a "national system of public education available for all persons capable of profiting thereby." Local authorities were called upon to prepare plans for the orderly and progressive development of education. The school-leaving age was raised to 14, and power was given to local authorities to extend it to 15.

Education Act of 1944. The Education Act of 1944 involved a thorough recasting of the educational system. The Board of Education, with its president empowered only to superintend, was replaced by a minister who was to direct and control the local education authorities. He could overrule local authorities, governors, and managers if they appeared to him to be acting unreasonably. Vested with such authority, a minister could do much to assure a more even standard of educational opportunity throughout England and Wales and could determine priorities and take the lead in planning. The act provided two promising planning devices. First, every local education authority was required to submit for the minister's approval a development plan for primary and secondary education and a plan for further education in its area. Second, two central advisory councils were constituted, one for England, another for Wales. Unlike the former consultative committee, they had power, in addition to dealing with problems set by the minister, to tender advice on their own initiative. The total number of education authorities in England and Wales was reduced from 315 to 146. To enable county education committees to keep in touch with local circumstances, provision was made for a considerable delegation of power to divisional executives, who with the various bodies of school governors and managers do much to ensure local interest and initiative.

The complexity of the education system in England and Wales arises in part from the pioneer work done in the past by voluntary bodies and a desire to retain the voluntary element in the state system. The act of 1944 continued the religious compromise expressed in the acts of 1870 and 1902 but elaborated and modified it after much consultation with the parties concerned. The act required that, in every state-aided primary and secondary school, the day should begin with collective worship on the part of all pupils and that religious instruction should be given in every such school. As in earlier legislation there was, however, a conscience clause and another to ensure that no teacher should suffer because of his religious convictions.

Structural changes under the 1944 act

Two fundamental reforms in the act were the requirement of secondary education for all, a requirement that meant that no school fees could be charged in any school maintained by public authority; and replacement of the former distinction between elementary and higher education by a new classification of "three progressive stages to be known as primary education, secondary education, and further education." Thus, the primary stage, compulsory from age five, covers the period from two years old to 11–12 years old; the secondary stage, compulsory to 15, covers from 11–12 years of age to 18–19, while further education is officially described as the "post-secondary stage of education, comprising all vocational and non-vocational provision made for young people who have left school, or for adults." Further education thus embraces the vast range of university, technical, commercial, and art education and the wide field of adult education and also, in the words of the act, facilities for

> leisure-time occupation, in such organized cultural training and recreative activities as are suited to their requirements, for any persons over compulsory school age who are able and willing to profit by the facilities provided for that purpose.

The Ministry of Education's interpretation of the type of secondary education to be provided under the act was the touchstone applied to every local development plan submitted. On this interpretation, to provide an adequate secondary education in accordance with "age, ability, and aptitude," it was necessary to establish separate schools with different programs, to which children were recruited at 11 by means of selection tests. If, in exceptional circumstances, such provisions were made in a single school, then the school must be large enough to comprise the three separate schools under one roof.

The tripartite system of grammar, technical, and secondary modern schools did not, in fact, flourish. The ministry had never been specific about the proportion of "technically minded" children in the population, but, in terms of school places provided in practice, it was about 5 percent. Since, on the average, grammar school places were available to 20 percent, this left 75 percent of the child population to be directed to the secondary modern schools for which the ministry advocated ad hoc courses not designed to lead to any form of qualification.

The comprehensive movement. Selection procedures at the age of 11 proved to be the Achilles' heel of the grammar school–secondary modern system. Stress was laid on the fact that there was no longer a "competitive examination" but only an "objective process of allocation." "Intelligence" tests were generally described as scientific measures of a child's inherent powers, so exact as to permit an accurate forecast of what he would achieve in later school life and indeed life itself. Various developments, however, contributed to the downfall of selection at 11: first, the examination successes of the secondary modern schoolchildren; second, the failure of a significant proportion of the children so carefully selected for grammar schools; third, the report of a committee appointed by the British Psychological Society to examine the validity of "intelligence" tests. This report supported arguments that education itself promotes intellectual development and that "intelligence" tests do not in fact measure genetic endowment but rather educational achievement. The National Foundation for Educational Research in 1957 issued a report in which it was estimated that some 12 percent of children were allocated to the wrong schools at the age of 11 and that not even the most stringent methods of allocation could reduce the error to below 10 percent. In the light of such findings, the bipartite structure of secondary education began to be modified, especially in its selective aspects, but with many local variations.

The main issue in the 1950s and 1960s was whether or not the grammar schools should be retained with selection at 11 plus. One of the main arguments used was that the right of "parental choice" must be upheld. Another was that it was in the "English tradition" to retain a selective system. But gradually the number of comprehensive (nonselective) schools increased until, by 1970, nearly half the children were being taught in one or another variant of such schools. There was widespread agreement either that selection should be abandoned altogether or, at least, that the age at which selection operated should be raised to 13 or 14.

Policies of Labour and Conservative governments

The Labour Party during the election of 1964 promised to promote the establishment of the comprehensive school and to abolish selection at 11 plus. Indeed, one of the first acts of the Labour government on taking office was to present plans for reorganizing secondary education. But, instead of legislating, it issued a circular in

the belief that this would enlist local support and encourage local initiative. The result was conflict between national policy and local policy in areas in which the education committees had a temporary majority to vote down the national policy. Although many local authorities (in 1970, 26 out of 162) completely abandoned selection at 11 plus and 104 declared their intention to do likewise, the course that secondary education will take in the future has not been settled. The Conservative government elected in 1970 has declared its intention of leaving decisions about reorganization to the local authorities. Some would prefer to maintain both grammar and comprehensive schools. Others think that the coexistence of both is not possible.

The future course of the public schools (fee-paying private schools), with their attendant private preparatory schools, has yet to be determined. It is far from clear whether they can, in fact, be fully integrated into the national system.

Further education. It is in this sector of education, which is concerned with education beyond the normal school-leaving ages of 15, 16, or 18, that the most complex problems have arisen, particularly since the end of World War II. Many of them are the outcome of the astonishing growth in the number of students, this growth itself being the result of the growth of population and the growth of aspirations. In addition, the explosion of knowledge and the creation of many new professions raise difficulties about the content and structure of courses and the requirements for certificates, diplomas, and degrees.

Many new postschool technical colleges were founded in the early years of the century. The Fisher Act of 1918 empowered the local authorities to levy a rate (tax) to finance such colleges. The universities, on the other hand, received funds from the central government through the University Grants Committee, established in 1911 and reorganized in 1920, after World War I. It was empowered to inquire into the financial needs of university education and to advise the government as to the application of any grants that might be made by the government. Student numbers rose between the war years to more than 50,000 but dropped below 40,000 during World War II. By 1970 the number had risen to well over 300,000.

Organization of higher education

Higher education in Britain is divided into two main branches: technical and university. Technical education operates under a system in which technical colleges are divided into four groups—local, area, regional, and colleges of advanced technology—depending on the level of the courses they offer. The colleges of advanced technology were granted the right to issue a new graduate equivalent award, the Diploma in Technology, and a supplementary postgraduate qualification: membership of the College of Technologists.

In the 19th century the dominance of Oxford and Cambridge was challenged by the rise of the civic universities, such as London, Manchester, and Birmingham. Following the lead of the 18th-century German universities and responding to a public demand for increased opportunity for higher education, Britain's new civic universities quickly acquired recognition—not only in technological fields but also in the fine and liberal arts.

The financing of higher education in the universities is through the University Grants Committee, which provided two-thirds of the income for the universities in 1947. During the 1960s many new universities were founded: their number increased from 23 to 44. Several of them have a strong scientific and technological bias.

A new type of technical college was established in the 1960s—the polytechnic, which provides mainly technological courses of university level as well as courses of a general kind in the arts and sciences. Polytechnics will be chartered to award degrees awarded by a Council for National Academic Awards.

Scotland and Northern Ireland. The educational systems of Scotland and Northern Ireland are separate and distinct from that of England and Wales, although there are close links between them. The essential features of the Education Act of 1944 of England and Wales were reproduced in the Education Act of 1945 in Scotland and in the Education Act of 1947 in Northern Ireland. There were such adaptations in each country as were required by local traditions and environment. In both countries compulsory attendance is from five to 15 and will ultimately be 16. The system in each consists of primary schools from five to 11 years, compulsory secondary education for all to 15 and to 18 on a voluntary basis, and further education from 15 to 18. In Scotland the schools that provide further education are called junior colleges. Secondary education in both countries must be appropriate to the abilities and aptitudes of pupils and is given either in the same school or, as in Scotland, in separate schools. By the 1970s approximately 40 percent of the Scottish schools had become comprehensive. In Northern Ireland secondary education is given in intermediate schools, technical intermediate schools, and grammar schools. As in England and Wales, the local education authorities have been requested to prepare reorganization schemes on comprehensive lines for submission to the secretary of state in Scotland and to the minister of education in Northern Ireland.

Religious instruction is made a regular part of the school curriculum, and in Northern Ireland a period of collective worship each week is required by the Education Bill, rights of conscience being safeguarded.

Germany. *Imperial Germany.* The formation of the German Empire in 1871 saw the beginning of centralized political control over the whole country. What was desired was a system of education that would make the great bulk of the population not only literate but also pious and moral, vocationally and economically efficient, and above all obedient and disciplined. A special type of education was reserved for the minority of citizens in the upper social and economic strata. By separating and differentiating the education of the masses from that of the upper class, the state assured itself, on the one hand, of a vast number of trained and subservient followers and, on the other hand, of a small elite corps equipped to fill the higher positions in the *Reich*.

The German school structure

The education system was structured to accomplish this goal. During the last decade of the 19th century, it was re-examined and overhauled, but the changes did not remove class privileges. Fees, for example, continued to be charged in secondary schools, and no ladder of opportunity was provided to make possible upward mobility.

The *Volksschule* was universal, free, and compulsory. The fundamental subjects were taught along with gymnastics and religion, which held important places in the curriculum. Girls and boys were taught in separate schools except when it was uneconomical to do so. Boys usually received training in manual work, and girls were introduced to domestic science. Graduates of the *Volksschule* found it almost impossible to enter the secondary school, as they graduated at 14 and the entry age to the secondary school was nine. The young graduates of the *Volksschule* had no other destiny than work and continuation school. The *Vorschule* was a private elementary school that charged fees for its three-year program and prepared its pupils for the secondary schools. This was the school attended by the children of the well-to-do.

The secondary schools, which were designed for the intellectual and social elite, were of several kinds. For boys there was the *Gymnasium*, which stressed Latin and Greek. The *Realgymnasium* offered a curriculum that was a compromise between the humanities and modern subjects. It required Latin but not Greek. The *Oberrealschule* stressed modern subjects, particularly sciences and mathematics, and, instead of Latin and Greek, modern languages were taught. A boy about to enter secondary school at the age of nine thus had to decide on one of the three types of curricula.

Although Kaiser William II threw his influence on the side of the modernists in 1890, the *Gymnasium* continued to overshadow the other two schools.

The education of girls was not strongly encouraged. Secondary schools for them were recognized by Prussia in 1872 and were extended and improved in 1894 and

again in 1908. These schools were fee paying and were thus available chiefly to the upper social and economic strata. The course of instruction lasted ten years, from six to 16. This ten-year school was called the *Lyzeum*, the first three years being preparatory. Beyond it was the *Oberlyzeum*, which was divided into two courses: the *Frauenschule*, which offered a two-year general course; and the *Lehrerinnenseminar*, which offered a four-year course for prospective elementary school teachers. Girls who wanted a secondary school education similar to that of the boys transferred at the age of 13 to the *Studienanstalt*.

The continuation school (*Fortbildungsschule*) made rapid strides during the early decades of the 20th century. It was a form of trade school for the graduates of the *Volksschule*.

Weimar Republic. In no sphere of public activity did the establishment of the Weimar Republic after 1919 cause more far-reaching changes than in that of education. The elementary school, which under the old regime was a class school, became a national institution. The concept of the *Einheitsschule* (common school) became an accomplished fact through the establishment of the four-year *Grundschule*, which was free and compulsory for all children. The *Vorschule* was abolished.

The *Grundschule* provided basic training. Besides the elementary subjects and religion, the child was instructed in drawing, singing, physical training, and manual work. The *Oberstufe*, the four upper classes of the elementary school, combined with the *Grundschule*, formed a complete whole. Most elementary schools thus provided an eight-year course of study.

Intermediate schools (*Mittelschulen*) were established for children who wished a longer and more advanced elementary school course and were able to pay modest fees. There were also Latin schools, or *Rektoralschulen*, which were lower secondary fee-paying schools maintained in the smaller localities. The first three years were common to all, but the last three years offered differentiated programs. Some intermediate schools were designed to lead to secondary schools and included a second foreign language in their curricula. The Weimar Constitution preserved the religious tradition, which had been an essential part of the school curriculum in Germany since the Reformation. No pupil, however, could be compelled to study religion, and no teacher could be forced to teach it. Communities were accorded the right to establish schools in accordance with the particular religious beliefs of the pupils.

Secondary schools in the Weimar period

As regards secondary education, the Weimar Republic kept the prewar division of *Gymnasium*, *Realgymnasium*, and *Oberrealschule*. In addition, there was established the *Aufbauschule*, which was a six-year school following completion of the seventh year of the elementary school, and the *Deutsche Oberschule*, a nine-year school that required two modern foreign languages. True to its name, it stressed German culture.

There were several types of secondary schools for girls. The school comparable to the *Gymnasium* was the *Gymnasiale Studienanstalt*. The *Oberlyzeum* gave more attention to the modern languages. The school comparable to the *Oberrealschule* was the *Oberlyzeum der Oberrealschulrichtung*, which focussed on the sciences (for an account of educational policies during the Nazi period, see above *Social-reconstructionist education*).

Changes after World War II. The basic law of the Federal Republic of Germany (West Germany) of May 1949 granted local autonomy in educational matters, and the 11 *Länder* (provinces) and city-states passed their own laws. In 1949 the Standing Conference of Ministers of Education was established to discuss problems common to all; it is advised by a federal educational council created in 1953.

Education was made compulsory from the ages of six to 18 years. Of this period eight or nine years are spent in a full-time school of general education. The pupil leaving it at the age of 14 or 15 must spend three more years in a part-time vocational school. Tuition fees and supplies are free in all the systems. Full-time attendance to the age of 15 was made compulsory in Berlin, Bremen, Hamburg, Hesse, Lower Saxony (now Niedersachsen), Saarland, and Schleswig-Holstein. In Baden-Württemberg it is compulsory up to that age only in some of the larger communities and districts. The other *Länder* have proposed the introduction of a ninth compulsory year as soon as possible. There are only privately supported preschools and kindergartens. There is a four-year *Grundschule* course in the *Länder* and a six-year course in the city-states. This is followed by four years in the upper division of the elementary school or by three, four, or five years in an intermediate school (*Mittelschule*) or six, eight, or nine years in an academic, technical, or general secondary school leading to the university. In the city-states the *Einheitsschule* (common-school) plan—combined elementary and secondary—has been introduced. It has a uniform basic grade and an upper grade consisting of practical, technical, and economic branches. The transition from the elementary school to secondary education in the *Länder* is still selective, in that admission requires the passing of an entrance examination.

In order to provide able young people, already at work, with an opportunity of preparing for the maturity (matriculation) examination in full-time secondary courses, the *Kolleg* (institute preparing for the maturity examination) has been established. The *Kolleg* usually covers three years and gives access to higher education.

France. *The Third Republic.* The establishment of the Third Republic (1870) brought about the overhaul and renovation of the French schools, in the process of which education became a national enterprise. In 1882 primary education was made compulsory for all children between the ages of six and 13. In 1886 members of the clergy were forbidden to teach in the schools, and in 1904 the teaching congregations were suppressed. France had thus established a national free, compulsory, and secularized system of elementary schooling.

The secondary schools charged fees. Their purpose was to bestow a liberal education and to select an elite for administration and leadership. Two types of secondary schools existed—the *écoles secondaires communales* and the *lycées*. Classical studies were emphasized, and, although this tradition was heavily criticized, very few modifications were made. One of the first attempts was a reform of 1902 that promoted the study of modern languages and of science.

Centralized administration in French education

The administration of education in France is highly centralized and is concerned with every phase of national education. At the head of the system is the minister of national education, a member of the Cabinet and usually a member of the legislature. The minister is advised and assisted in the execution of his duties by a hierarchy of administrators, inspectors, and other officials. France is divided into about 40 administrative areas, each known as an "academy." The chief education officer is the rector, the minister's most important representative, who administers the laws and regulations. The largest and most important body is the Higher Council for National Education, which reports to the minister on questions of administration, studies, textbooks, and discipline.

Changes after World War II. In 1947 a commission established to examine the educational system recommended a thorough overhauling of the entire school system. Education was to be compulsory from the ages of six to 18. Schooling was to be divided into three successive stages: (1) six to 11, aimed at mastery of the basic skills and knowledge that enable the child to understand and to be understood; (2) 11 to 15, a period of guidance to discover aptitudes; (3) 15 to 18, a stage during which education was to be diversified and specialized.

Preschool education is given in the *école maternelle*, in which attendance is voluntary from the age of two to six years. Schools are restricted to 150 students. The curriculum is varied, consisting of physical and breathing exercises, games and movement with songs, manual work, and drawing. There are also exercises in observation; exercises for the development of moral habits; language and recitation; and introduction to reading,

writing, and arithmetic. French educationists are justly proud of the quality of their preschool education.

Education is compulsory between six and 16 years of age and is free. In every community of over 500, separate schools for boys and girls must be maintained, unless special permission is given to operate a mixed school. The program is the same for all children between the ages of six and ten. Reading and writing, arithmetic and metric system, history and geography, civic education, first notions of natural science and other scientific subjects, drawing, singing, manual work, and physical training are taught.

Secondary schools (*lycées*) provide either four-year or seven-year courses and tend to specialize in either academic or technical studies. It is usual to speak of a first cycle (11–15) and a second cycle (15–18). The first cycle (11–15) provides general education and is the same in all schools. During this cycle the student is observed by the teacher and a guidance council and, at the age of 15, enters into the second cycle. In the second cycle (15–18), the student is given a choice between occupational training or academic training, depending on his preferences and ability. The occupational training is divided into three courses. The first course involves full-time training over a two-year span, which is given in colleges of secondary education. The curriculum is not specialized and prepares pupils for industrial, commercial, or administrative occupations. At the end the students sit for the diploma of professional studies (*brevet d'études professionnelles*—B.E.P.). The second option consists of two years of either direct apprenticeship or training courses with a narrower form of specialization. Students sit for the certificate of professional aptitude (*certificat d'aptitude professionnelle*—C.A.P.) at the end of the second year. The third possibility is full-time training over a one-year period. This is designed for students who go to work without training, once compulsory schooling is over at age 16. It leads to the certificate of professional training (*certificat de formation professionnelle*—C.F.P.).

Those choosing academic training enter one of four streams: classical, economic, scientific, or technical. In the second year a third foreign language may be offered. Students study for the *baccalauréat*, which gives admission to the university. Students whose marks are not sufficient to obtain the *baccalauréat* may qualify for the certificate of completion of secondary studies.

Higher education is offered in universities, in institutes attached to a university, and in the *grandes écoles*. Students attend for two to five years and sit either for a diploma or, in certain establishments, for university degrees or for a competitive examination such as the *agrégation*.

Reform in the French universities

The existing universities are being decentralized by the creation of colleges, institutes, or schools, each with much autonomy. The entire university system is being drastically reformed, allowing for a measure of student participation in the running of universities, encouraging diversification of courses, and diminishing the importance of examinations. Undergraduate courses last for three or four years, depending on whether the B.A. or M.A. degree is sought.

The higher doctorates are considerably more difficult to obtain and represent solid research or scholarly achievement. They are essential to the award of a full professorship.

Other European countries. *Italy.* Education in Italy up to 1923 was governed by the Casati Law, passed in 1859, when the country was being unified. The Casati Law organized the school system on the French plan of centralized control. School attendance was compulsory only for the years six to nine. Religious education was abolished in the schools by the Coppino Act of 1877, which also extended compulsory school attendance to four years. The Orlando Law of 1904 extended compulsory education, at least in the larger communities, to the age of 12.

In 1923 the entire national school system was reformed. The principle of state supremacy was reinforced by introducing at the end of each main course of studies a state examination to be taken by pupils both from public and private schools. In 1935 Cesare de Vecchi, a violent Fascist leader, became minister of education. He dissolved consultative educational bodies and vested all power in the minister himself. Confusion and chaos followed, and reforms were commenced in 1939. They were accompanied by a reorganization of the youth movements (started in 1937), which played an important role in all schools.

Since World War II, attendance at an elementary school for five years has been compulsory. Elementary schools educate pupils from the ages of six to 11. Infant schools, which are not compulsory, take children between the ages of three and five. These include nursery schools, kindergartens, and similar institutions.

Nonstate schools are those whose operation is only in part or not at all the responsibility of the state, and they are divided into officially recognized schools (*scuole parificate*), private schools (*scuole private*), and subsidized schools (*scuole sussidiate*).

From 11 to 14, young people also compulsorily attend secondary school (*scuola media*). The *scuola media* opens the way to art institutes, professional institutes, and technical schools (which are not obligatory) and offers courses of varying duration, leading to a diploma. Because this diploma does not allow the pupil to continue his studies, these schools have gradually declined in importance.

The *scuola media* also leads to schools that in turn give entry to the universities. These schools—technical institutes and grammar schools (*licei*)—offer courses lasting five years, except for those of the teacher-training institutes (*istituto magistrale*) and art schools (*liceo artistico*), which last only four years. Technical institutes can specialize in agriculture, crafts and commerce, tourism, surveying, industry, and nautical studies. There are also technical schools for girls only. There are also two types of *licei*, one tending to specialize in classics and the other in science. The technical institutes, the *licei*, and the teacher-training institutes open the way to university education.

Italian university education

In Italy there are many state universities and some independent ones. Italian universities are made up of a varied number of faculties, each of which can award one or more degrees. One characteristic of the university in Italy is the large number of *fuori corso* (students who have not managed to complete their studies in the normal period of time, which ranges from four to six years, depending on the faculty). University studies require the passing of a variable number of examinations, at the end of which the students sit for a degree (*laurea*), which gives them the title of *dottore*. To be able to exercise any profession, such as that of lawyer, doctor, or business consultant, one must take a state examination.

Netherlands. The first modern school law in the Netherlands was passed in 1801, when the government laid down the principle that each parish had the right to open and maintain schools. A debate between the proponents of denominational and nondenominational schools went on during the 19th century. The controversy was closed by a law of 1920, which declared that denominational schools were fully equal with state schools, both types being eligible for public funds. The resultant decentralization is unique in western Europe. The private school, in return for public funds, must provide a curriculum equivalent to that offered by the public schools.

The Ministry of Education and Science supervises the quality of education, while the local authorities in the provinces administer it. Under the minister is the secretary general for education, who acts as the permanent chief of the ministry. The Education Council advises the ministry on all important general questions that are of direct concern to the ministry.

Education is compulsory from the age of seven to 15, although most children start at age six. Elementary education is from six to eight years in duration. Higher elementary schools offer an additional two years of work in practical subjects for those students who do not go

to secondary school. Secondary education consists of the *hoogere burgerschool*, a three- to four-year school leading to lower administrative posts or to the university, the *gymnasium*, which leads to the university, the *lyceum*, which combines the above two, the commercial school, and the girls' high school. There are technical schools at the primary and secondary level and institutions for the training of teachers.

Switzerland. The Swiss constitution of 1874 provided that each canton or semicanton must organize and maintain free and compulsory elementary schools. The federal government exercises no educational function below the university level, except to help finance the municipal and cantonal schools. The federal government administers only the Federal Institute of Technology in Zürich.

The Swiss school system thus consists of 25 cantonal systems, each having its own department of education, which sets up its own school regulations. Private schools for children under the age of compulsory attendance are controlled by the local school authorities. Compulsory school starts at six or seven years of age and continues until 14, 15, or 16, according to the canton. Preschool, from four to six years, is followed by a primary school attendance of six to nine years' duration. Secondary education includes schools of various types, which prepare students for university, higher commercial schools, and secondary technical schools. Subjects taught are diversified, and the pupil's future professional life is a decisive factor in the selection of courses. In addition to the routine courses, there are classes in carpentry, cooking, sewing, wood carving, and other manual skills. Physical education is also part of the curriculum. Vocational training is compulsory for boys and girls during apprenticeship and serves to maintain the skill and high quality of Swiss workmanship.

Agricultural schools, schools of applied arts, technical schools with specialized courses in watchmaking, fine mechanics, ceramics, metalwork, carpentry, silk weaving and the various skills of the hotel and tourist trade are found in Swiss cities. There are seven universities, all under the control of the cantons. A serious attempt is being made to achieve some educational unity out of the great diversity of the Swiss education system.

(J.A.L./R.L.Sw.)

United States. As the United States entered the 20th century, the principles that underlie its present educational enterprise were already set. Educational sovereignty rested in the states. Education was free, compulsory, universal, and articulated from kindergarten to university, though the amount of free schooling varied from state to state, as did the age of required school attendance. Although a state could order parents to put their children to their books, however, it could not compel them to send them to a public school. Parents with sectarian persuasions could send their offspring to religious schools. In principle there was to be equal educational opportunity; unhappily, the practice even now lags behind the precept.

American principle of equal educational opportunity

Expansion of American education. Though such principles have remained the basis of America's educational endeavour, yet that endeavour, like America, has undergone a vast evolution. As the century began, American youth attended an eight-year elementary school, whereupon those who continued went to a four-year high school. Known as the "eight–four system," this organization wholly prevailed till about 1910, when the "six–three–three system" made a modest beginning. Under the rearrangement, the pupil studied six years in the elementary and three in the junior and senior high schools, respectively. In 1900 only a handful of the lower school's alumni—some 500,000—advanced into the high school. Fifty years later, the process had swollen tenfold. Of those who took their high school diploma during the earlier period, some three out of every four entered college. Today, though more than ever throng the college, the ratio is almost reversed, and, for every four disgorged by the high school, only one makes tracks for the higher learning.

There are several reasons for these developments. To begin with, America's secondary school, reflecting the nation's expanding utilitarianism, has attuned itself more and more to preparing the young for everyday living. Consequently, though it still serves prospective collegians the time-honoured academic fare, it has gone to great lengths to accommodate the generality of young America with such useful and practical enlightenment as automobile driving, home nursing, cookery, carpentry, plumbing, writing, acting, and the like. Doubtless, too, national prosperity and, even more, the inarguable cash value that a secondary diploma bestows upon its owner have enhanced the high school's present flourishing state. Finally, there stands the fact that several states now require their young to attend school until their 16th, and sometimes even their 17th, birthday—which makes their attendance at high school almost unavoidable.

Federal involvement in local education

Although the U.S. Constitution has delegated educational authority to the states, this does not mean a lack of federal concern or, more critically, of federal counsel and assistance. Actually, national educational aid is older than the Constitution, having been initiated in 1787 in the form of land grants. Seventy-five years later the Morrill Act disbursed many thousands of acres to enable the states to promote a "liberal and practical education." Soon thereafter, the government created the federal Department of Education under the Department of the Interior. Now the Office of Education in the Department of Health, Education, and Welfare, this agency gathers educational information and broadcasts it in a variety of publications. At the request of state and local governments, it has assisted in several nationwide educational surveys.

Since the passage of the Morrill Act in 1862, the flow of federal aid has steadily increased. Beginning with the Smith–Lever Act of 1914, Congress has legislated measure upon measure to develop vocational education in schools below the college plane. A new trail was opened in 1944, when the lawgivers financed the first "GI Bill of Rights" to enable veterans to continue their education in school or college. At length, in 1965, under the Elementary and Secondary Education Act, the legislature appropriated $775,000,000 to subsidize various worthy projects. Among the law's beneficiaries was the nursery school, a rarity at the dawn of the century but serving some 300,000 pupils by the 1970s. The nursery school is a prekindergarten school. Taking its protégés soon after they can walk, it instructs and entertains them to their sixth birthday. Much of their time is given to play. But they are also introduced to some of life's sober affairs, such as learning to live together, keeping themselves clean and tidy, and the like. Under supervision, they occasionally fare forth into shops, cinemas, zoos, and similar landmarks of civilized life.

Programs of special education

Although, patently, not all men are created equal, yet in the American democracy everyone, regardless of condition, is expected to have his fair chance. Such is the tenet that underlay the establishment of the free, tax-supported common school and high school. As science pointed the way, the effort to bridge the gulf between the haves and have-nots presently extended to those with physical and mental handicaps—the blind, the deaf, the dumb, the crippled, and the mentally defective. Of modest proportion at the century's beginning, teaching the handicapped has since become part of the American way. The federal government, for example, subsidizes the publication of books in Braille for use in state schools. Most states and many cities have long since undertaken programs to teach the handicapped, though financially the going has been difficult. Finally, in 1958, Congress appropriated $1,000,000 to help prepare teachers of mentally retarded children. Thenceforward, federal aid for the handicapped has steadily increased.

If the handicapped child has been an object of educational concern, then the gifted child has generally been neglected. The truth is that, until psychologists and sociologists started to apply their science to the superior child, apart from being occasionally viewed as somewhat freakish, he was not suspected of entertaining any particular problems. Eventually, however, augmented

with federal, state, and sometimes foundation money, one city after another embarked on educational programs for the bright child. The upshot was that, by the mid-1960s, some three out of every four municipalities were reported in one way or another to be thus engaged.

Experiments in education. Besides the development of education for exceptional children, there developed numerous "experiments" or "plans" to bring newer learning theories into practice. Among them there was the Dalton Plan, introduced in 1920 at Dalton, Massachusetts, by Helen Parkhurst. Designed to enable a learner to study at his own pace, it discarded the traditional recitation and instead put the pupil upon a mimeographed monthly assignment, or "contract," including readings, questions, written work, and so forth. He distributed his time to suit his need, labouring more intensely on his weak subjects and easing up on his stronger ones. He might dispose of them at an even daily gait; or he might gallop through them in a few days and then do as he chose. Though the Parkhurst system has disappeared, its shift from short, daily assignments to the study of broad topics over a period of time—nowadays spoken of as "units"—has lingered.

Another attempt to individualize learning was the Winnetka Plan. Introduced in 1919 by Carleton Washburne at Winnetka, Illinois, it, too, banished the recitation. Instead of being held to day-by-day achievements, the Winnetka pupil was to achieve certain planned "goals." Guided by simple directions, he was free to proceed as he pleased. When the task was done, he underwent a self-administered test, and, if he fared well, he was allowed to grapple with the next task, and so on from year to year until he secured his diploma. Because the plan sought to adjust the child's capacity to his rate of learning, and because it viewed learning as a continuous rather than a segmented process, failure to be promoted was nonexistent.

Different from the Dalton and Winnetka schemes was the Gary Plan. Instituted in 1908 by William Wirt at Gary, Indiana, it put its stress on stretching the taxpayer's dollars to effect an exemplary all-round education embracing work, study, and play. To this end Wirt conjured up a "complete school," comprising "playground, garden, workshop, social center, and traditional school under one management," and frequented by children from kindergarten through high school. Something of an efficiency wizard, Wirt grouped the students into several "platoons," striving thereby to effect a maximum use of the school's varied facilities, day and night, 12 months a year.

Progressive education

Besides Dalton and other pedagogic innovations, the 20th century saw the development of "progressive education," some of the principles of which were first proclaimed by the 18th-century French philosopher Jean-Jacques Rousseau and elaborated upon by the 19th-century figures J.H. Pestalozzi and Friedrich Froebel. What is currently called progressive education is essentially of American provenance, largely the pioneering work of Francis W. Parker and John Dewey. Parker laid its groundwork, first at Quincy, Massachusetts, then at Chicago, especially in the Cook County Normal School. Dewey, through his work in the Laboratory School of the University of Chicago, but more through his writing and teaching at Columbia University, prepared the philosophic seedbed from which much of the progressive movement sprouted and grew. In any case, the progressive believes, with Rousseau, that the heart of education is the child; that he has a nature all his own that demands respect and understanding; that interest is the motive of successful learning and without it learning is sterile; that young and old learn what they *live* or experience and translate what they learn into their behaviour; that the school should be a "place of good living" providing the interests and activities that the child's nature requires; and, finally, that the school should be a living society helping the child to participate effectively within a social group. Progressivism reached its apogee in the 1920s. Its support came chiefly from the elementary school and from theory-and-practice departments of teachers' colleges. Nevertheless, it never lacked opposition. It was censured especially for its "soft pedagogy" and the alleged downward slide of academic standards. Such charges were never proved, however, and meticulous studies have tended to discredit them.

Changes in higher education. The pedagogic experimentalism that marked America's elementary learning during the century's first quarter was less robust in the high school and feebler still in the college. The first venture of any consequence into collegiate progressivism was undertaken in 1921 at Antioch College, in Ohio, under its president, Arthur E. Morgan. Seeking to fuse a liberal college education, vocational training, and "apprenticeship for life," Antioch required a student to divide his time between his study of the traditional subjects and the extramural world, for which, every five weeks or so, he forsook the classroom to work at a full-time job. Not intended as vocational preparation or even a device to aid the student economically, the Antioch plan sought to amalgamate its liberal learning with "actual living in actual society."

Experiments at Antioch, Bennington, Chicago, and Harvard

While Antioch took the midpath between tradition and innovation, in 1932 Bennington College for women, in Vermont, strode boldly toward progressive ends. Putting a high value on student freedom, self-expression, and creative work, and less on intellectualism, Bennington essayed to weld its curricular and extracurricular segments into an undifferentiated entity. To this purpose it staffed its faculty largely with successful artists, writers, musicians, and other creative persons, rather than Ph.D.'s. And to the same purpose it granted students a large say in making the rules under which they lived.

Such developments in America's higher learning incited gusty blasts from Robert M. Hutchins, president and then chancellor of the University of Chicago from 1929 to 1951. He excoriated Bennington for its vocationalism and anti-intellectualism, its debasement of pure learning with courses in Ping-Pong teaching, cafeteria management, and the like. To arrest such deterioration, Hutchins recommended a mandatory study of grammar, rhetoric, logic, mathematics, and Aristotelian metaphysics. One consummation of the Hutchins prescription is the study of some 100 "great books," wherein reside the unalterable first principles that Hutchins insists are the same for all men always and everywhere. In the groves of higher learning, the Hutchins proposal bore no lasting fruit—save at Saint Johns College at Annapolis, Maryland. There, all courses are required, and for four years all students are made to ponder the First Principles in the Great Books.

The vocationalism that Hutchins deplored was taken to task by several others, but with quite different results—notably by Harvard in its report on *General Education in a Free Society* (1945). Declaring against the high school's heavy vocational leaning, it urged the adoption of a general curriculum in English, science, mathematics, and social science. At Harvard, moreover, the brakes were put on all specialization until the student had completed a two-year selection of courses in the humanities, natural science, and social science. Rather than offer a single "core" course, however, the faculty gave the student a choice among four or five offerings in each of these fields, each prepared by outstanding scholars especially for the instruction of nonspecialists. Optional advanced courses also were offered under the same program. In this way, it was felt, all students would gain a common appreciation of the Western heritage.

The junior college

The desire to enable a greater number of youth to savour learning beyond the high school propagated the junior college (sometimes called the community college). Conceived early in the century by William Rainey Harper, president of the University of Chicago, it proposed to separate the four-year college into an upper and lower half, the one designated as the "university college" and the other as the "academic college." The junior college is a two-year school, sometimes private but commonly public. In the latter event, its tuition toll is slight—often, indeed, it is almost nil. As a dispenser of higher learning, the junior college offers first- and second-year

college work, sometimes with vocational extras. In other cases it may be simply an advanced secondary school. Graduates from the former may continue as juniors in a four-year college or university.

Professional organizations. Americans, as is well-known, like to organize, and in this respect educators have been no different from the generality. They were indulging their proclivity as early as 1743, when the American Philosophical Society was founded, and they have been at it increasingly ever since. Not a few of their organizations, such as the American Historical Association, the Modern Language Association of America, and the American Home Economics Association, are for the advancement of some specialty. Others are more concerned with the interests of the general educational practitioner. Of these the National Education Association (NEA) is the oldest. Founded in 1857, it undertook "to elevate the character and advance the interest of the teaching profession." Despite its high mission, it threw off no sparks, and it was not until after 1870 that it began to grow and prosper. With headquarters in Washington, D.C., the NEA conducts its enormous enterprise through a brigade of commissions and councils, some of them quite large, as witness the Educational Policies Commission, the Legislative Commission for the Defense of Democracy through Education, the National Commission on Safety Education, the National Commission on Teacher Education and Professional Standards, the National Council of Education, and the National Council on Teacher Retirement.

A youngster by comparison, but growing rapidly, is the American Federation of Teachers, an affiliate of the AFL-CIO. Formed in 1916, the federation concerns itself with bettering the teacher's lot. Through collective bargaining and teachers' strikes, it has worked successfully for better wages, pensions, sick leaves, academic freedom, and other benefits.

Although teaching in America is spoken of as a profession, it is only in the recent past that some of its practitioners, like the doctors and lawyers, have undertaken to bring order and dignity to their occupation. Toward such an achievement such bodies as the American Association of Colleges for Teacher Education, the American Association of University Professors, and particularly the National Commission on Teacher Education and Professional Standards (TEPS) and the National Council for Accreditation of Teacher Education (NCATE) have laboured industriously and even with a fair success. (A.E.M.)

Elder members of the British Commonwealth. *Canada.* Although a Canadian nation had been formed by the end of the 19th century, separate political, economic, and geographic influences continued through the 20th century to restrain unified educational development. The historical principle of maintaining minority rights resulted in a truly pluralistic cultural concept, recognized to some extent in religious and linguistic concessions in schools. Each provincial system developed unilaterally, thus producing separately centralized educational units; and, even within a province, the evolving principle of local responsibility and the sparseness of settlement in many areas of Canada challenged the effectiveness of simple control principles. Different production emphases and differential advantages of territorial acquisition after confederation in 1867 had the effect of dividing Canada into "rich" and "poor" provinces, which can support schools accordingly. Finally, the European basis of education was never reconciled philosophically with that evolving out of the North American environment, with the consequence that educational actions were often taken without regard for their integration in a Canadian foundation.

These divisions are characteristic of Canadian education in the 20th century. It is nevertheless possible, because of a common national experience and because of the communication stimulated by national development, to describe education in national terms. Educational movements afoot in the early 20th century and associated with "progressive education" (such as child study, kindergarten development, and curriculum integration) had a relatively mild impact on traditional practices and forms. Instruction in the Canadian school remained essentially teacher centred, with a strong emphasis on obedience and conformity, and based on an educational version of philosophical Realism. Only changes that corresponded to established Canadian convictions, such as the acceptance of some activity principle in methods, were incorporated into the conduct of education, and the antagonistic reaction to such changes was disproportionate to the moderation with which reform was approached.

Traditional versus progressive education

The major change in school structure occurring during the 20th century was at the secondary level. The standard eight-year elementary program was first extended by continuation classes or schools alongside exclusive secondary schools, producing an uneven, overlapping postelementary structure. In the 1930s, an expanded school population, reaching into the secondary grades, led to decisive action on compulsory attendance and to standardization of high school provisions. Junior high schools were introduced in some provinces as a transitional level between elementary and secondary schooling, while some provinces simply developed junior and senior stages of a total secondary program. The two extremes in secondary development were probably represented by Québec and the west. In the French-speaking schools of Québec, the secondary system consisted of private classical colleges leading to a *baccalauréat* on the one side and terminal courses in special schools or institutes on the other. Only after 1956 were public high schools with a variety of courses established, and only from 1964 has there been a move to unify the entire provincial system. In the western provinces, large regional schools and composite high schools have been developed extensively, Alberta having proceeded apace in this direction. British Columbia, following the Chant Commission Report in 1960, reorganized its secondary program to include five core streams, only one of which is academic–technical.

From the attempt to broaden the curriculum in response to the requirements of an expanded school population in the second quarter of the century, regular revisions have been made in curricula and methods issued in Canadian schools. Most revision efforts have originated with developments in the United States, though they have taken a particular form in Canadian education. Present trends are common in North America and include providing flexibility in teaching assignment (for instance, team teaching), in school plant (such as "open area" schools), and in program (such as "continuous progress" principles). Both the attempt to reconcile individual educational requirements with the demands of mass systems and the current emphasis on the essential structure of subject matter lead to a search for new techniques of selecting and transmitting knowledge in schools.

Changes in the elementary program have been largely in the area of teaching methods, and this applies generally to the secondary schools also, although the secondary curriculum has been modified by some additions, by expanding the catalog of optional subjects, and by reorganizing to include new courses of study. Although the basic division remains one between the university-preparation course and a general terminal course, more alternatives are beginning to appear.

Regional pattern of Canadian universities

A new dimension in higher education was added with the establishment of provincial universities in the west (1901–08). This completed a set of regional patterns for university development that have continued to this day. Canadian universities have, within these patterns, drawn their criteria from French, British, or American models. From the 1950s, a boom in Canadian higher education has led to increasingly independent considerations on the role of universities in Canadian development, possibly the most visible result being the attention now given to the rationalization of higher education within the provincial system.

The administration of public education is the exclusive responsibility of the provinces, which have worked out schemes of local authority under provincial oversight. Although the specific structure of the departments of edu-

cation varies among the provinces, they conform to a basic structure. Each is headed by a politically appointed minister of education, who may be advised by a council. The main functions of educational supervision are now usually carried out through specific directorates for such areas as curriculum, examinations, vocational education, teacher training and certification, and adult education. Three developments, however, have strengthened local autonomy in educational administration. Throughout the second quarter of the 20th century, consolidation of rural schools and administrative units took place in the west, thus resulting in stronger educational units more competent to act independently. More recently, especially in Ontario, Québec, and New Brunswick, moves toward regional decentralization produced rather independent subprovincial units, synthesizing the advantages of local and central control. Finally, rapid urban development in Canada has led to relatively autonomous city school operations.

Federal influences in Canadian education

Canada's federal government has no constitutional authority in education and therefore maintains no general office dealing directly with educational matters. Federal activities in education are nevertheless carried out under other areas of responsibility, and certain functions of an office of education are subsumed under the secretary of state. Under its responsibility for native peoples and its jurisdiction over extraprovincial territories, the federal government, through the Department of Indian Affairs and Northern Development, finances and supervises the education of Indians and Eskimo. In the Yukon, schools are administered by the territorial government, though largely financed from Ottawa.

Through agricultural and technical assistance acts in 1913 and 1919, the federal government began to promote vocational education, and this principle was extended through emergency programs in the depression years of the 1930s and during World War II. More recently, vocational programs of wide scope have been introduced on a principle of federal support and provincial operation. The Technical and Vocational Assistance Act of 1960 was followed by a great surge in vocational education, including the construction of new schools and school additions, special institutes, and the preparation of vocational teachers. Program definitions in this area have become ever broader, and new federal policy is likely to be aimed at a broad base of support at the postsecondary level.

The federal government has maintained and supported the education of armed-forces personnel, including the Royal Military College of Canada and cadet or regular officer's training programs in schools and universities, educational aid to postwar veterans, and the operation of schools for children of overseas personnel. Research and development in higher education are promoted directly through grants and through the offices of the National Research Council and the Canada Council. Of service to educational research is the Education Division of the Dominion Bureau of Statistics, which disseminates organized statistical information on Canadian schools. Perhaps less direct but of great importance are national agencies operating in the area of mass communications media, such as the National Advisory Council on School Broadcasting and the National Film Board. Together, the activities of the federal government not only support but also strongly influence certain areas of education and complete a picture of local–provincial–federal involvement in Canadian education.

Australia. The 20th-century development of Australian education continued to be influenced by British models and to be characterized by the exercise of strong central authority in the states. Yet, because Australian national development has taken place entirely in this century, increasing attention has been given to the role of education in nation building.

Educational systems were built through the establishment of primary schools by the end of the 19th century, the extension of these through continuation programs, and the development of state secondary schools in the early part of the 20th century. The independent secondary schools that offered the bulk of secondary education before 1900 continued to be influential, either as components of the separate Roman Catholic system or as "elite" private schools of denominational or nondenominational character, but the growth of state systems carried the state high schools into numerical prominence.

The early development of educational systems before and around the turn of the century was a crude beginning, the minimal provisions being accentuated by poor teacher preparation, administrative thrift schemes, and excess in the exercise of administrative authority. Improvement of these conditions and systematic positive development can be dated from the Fink Report of 1898 in Victoria and similar reform appeals in other states between 1902 and 1909. The steady pace of progress from that time was broken by a surge of growth and innovation in Australian institutions after World War II.

Education in small, isolated communities throughout the vast Australian area has required special attention. Two particular means of reaching isolated children and adults have been used successfully. Correspondence education was begun in 1914 in Victoria, and other states followed after 1922. The procedures have been gradually refined and the levels extended. The correspondence system embraces primary, secondary, technical, and university courses and is supplemented by extensive educational broadcasting by radio. The other, more formal means of reaching rural children has been through efforts devoted to the establishment of schools in the outback.

Early efforts included provisional schools, itinerant teachers, and central schools. The small one-teacher bush schools became typical after federation in 1901 and still make up a large proportion of Australian state primary schools. Much attention has been given to methods of teaching in the one-room school, earning Australia international recognition for expertise in this area. Progress toward rural school consolidation began in Tasmania in 1936. The Tasmanian model has combined special features of school independence, pupil freedom, involvement in agricultural projects, and parental cooperation with the "area school" movement.

State and federal powers in Australia

Education is a state, rather than a federal, responsibility in Australia. Authority is concentrated in a state department of education, and control is exercised through the standard of department policy and through prerogatives distributed in a hierarchical organization of educational experts. Some decentralization has been accomplished in New South Wales and Queensland, but the administrative areas so established are coordinated with the central department rather than with other local units, thus preserving the central principle. The political head is the minister of education, and the permanent official in charge is the director or director general of education. The main divisions of the department are normally those for primary, secondary, and technical education, each directed by a senior official; additional divisions, such as special education, guidance, and in-service training, are particular to the states.

Since World War II, with the financial assets of exclusive income-taxing power, the commonwealth (federal) government has played an increasing role in educational development, particularly at the tertiary level. Through the States Grants Act in 1951, the Murray Report in 1957, the Martin Report in 1964, and the establishment of the Australian Universities Commission, the Commonwealth Scholarships Board, and the Commonwealth Advisory Committee on Advanced Education, the federal government has moved into the planning as well as the funding of postsecondary education concurrently with the states. The Commonwealth Office of Education, established in 1945, advises on financial assistance to the states and on educational matters generally, acts as a liaison agent among the states and between Australia and other countries, undertakes some educational research, and provides educational information and statistics.

About three-quarters of Australian schools are public. The remainder are made up of Roman Catholic schools (which constitute more than 80 percent of the nonpublic schools) and other private schools, many of which have

considerable influence in the leadership of Australian society. The curriculum and syllabus for each program or course in the state schools is prescribed by the Department of Education, and nonpublic schools generally follow this standard.

Primary schools are normally of six years' duration, to about age 12, though some schools retain the seventh, and even eighth year of the old pattern. Within primary schools, pupils are organized in grades and advance by annual promotion. By selection or choice, pupils in the past have proceeded to academic high schools or to an alternative form (mainly technical) of secondary education. The trend now, however, is to comprehensive schools—schools offering academic, commercial, and technical programs, either separately tracked or somehow unified with gradual differentiation from lower to the highel levels.

New Zealand. The religious and regional issues that have fettered educational development in other countries of the British Commonwealth were basically settled in New Zealand when the decisions were made in the last quarter of the 19th century to provide wholly secular primary schools and administrative centralization. The major issue in the 20th century has been the achievement of equal educational opportunity. Although New Zealand has accepted the responsibility to educate each child—without racial, social, or narrowly intellectual restriction—to the limits of his ability, the unification of the total system to this end has proved quite difficult.

New Zealand's goal of equal educational opportunity

The Education Act of 1914 consolidated the changes that had taken place since 1877. In subsequent reform periods, especially during the '30s and after World War II, barriers to pupil progress through the system were removed or modified. In 1934, the school-leaving certificate examination was established on a broader basis than the university entrance examination, and, in 1936, the proficiency examination governing secondary entrance was abolished. In 1944–45, the school-leaving age was raised to 15; a common core of early secondary studies, including English, social studies, general science, mathematics, physical education, and a craft or fine-arts subject, was established; and universities agreed to accept accredited-school courses without further examination for university entrance. These actions illustrate a gradual but steady facilitation of access through an increasingly coordinated system. This direction is carried into the third 20th-century reform period of the 1960s in the recommendations of the Currie Commission (1962) and the provisions of the Education Act of 1964.

Since 1877, the administration of education has been conducted by a central Department of Education and by elected regional boards of education. Virtually all funds come from the central source, and education is free until the age of 19 for qualified pupils. University tuition is also paid for successful students. The Department of Education is headed politically by a minister and permanently by a director general. The inspectorate is divided into primary and secondary units. In addition to these two basic divisions, the department contains offices for child welfare, technical education, higher education, Maori education, and education in the island territories.

New Zealand children generally start school at the age of five years and spend eight years in primary school. The secondary system has developed through the growth of three separate kinds of school: (1) the district high school, which represented more or less a secondary "top" on a primary school; (2) the independent, academic, one-sex secondary school proper; and (3) the technical school, which took shape between 1900 and 1908. These three types have remained, but some of their uniqueness has been lost through certain refinements. The isolated position of the fee-charging secondary schools of the 19th century was compromised by free-place legislation in 1903, and, by 1914, they were brought into the state system, though retaining a good deal of their independent status. The district high schools remained in the primary system, but their incorporation in the secondary inspection scheme and in secondary teacher classification placed them clearly within that sector of school operation. The technical high school evolved into a general high school with technical bias. Through common departmental inspection, curriculum, and examination standards, and through the effect of the movement for more general postprimary provisions after 1945, the secondary schools have increasingly approximated a single pattern.

Private and native schools

Although an extensive Roman Catholic private school system grew up after the secularization of state education, these schools are also integrated into the general system through adherence to state standards, verified by government inspection. Rural and native education have also been given careful attention in New Zealand. Pains are taken to ensure that rural schools are provided with adequate facilities and teachers. Where possible, consolidated schools have been constructed, served by an extensive school transportation system. Isolated districts are reached through the Department of Education correspondence school and through radio instruction. Maori education has been a responsibility of the Department of Education since 1879. Both Maori and European children attend the general public schools, but Maori schools, stressing oral English and Maori culture, are also present in the villages. The government has, however, been reexamining Maori education since the Currie Report in 1962, giving attention to particular areas of inadequacy in the existing provision of schooling. (R.F.L.)

REVOLUTIONARY PATTERNS OF EDUCATION

Russia: from tsarism to Communism. *Before 1917.* At the turn of the 20th century, the Russian Empire was in some respects educationally backward. According to the census of 1897, only 24 percent of the population above the age of nine were literate; by 1914 the rate had risen to approximately 40 percent. The large quota of illiteracy reflected the fact that, by this time, only about half the children between eight and 12 attended school. The elementary schools were maintained by the *zemstvo* (local government agencies), the Orthodox Church, or the state, the secondary schools mainly by the Ministry of Education.

After the Revolution of 1905 the Duma (parliament) made considerable efforts to introduce compulsory elementary schooling; it was hoped to accomplish this by 1922. At the upper stages of the educational system, progress was significant, too; nevertheless, the secondary schools (*gimnazii, realnyye uchilishcha*) were only to a small degree attended by students of the lower classes, and the higher institutions even less. Preschool education as well as adult education was left to the private initiative of the educationally minded intelligentsia, who were opposed to the authoritarian character of state education in the schools. In 1915–16 the minister of education, Count P.N. Ignatev, started serious reforms to modernize the secondary schools and to establish a system of vocational and technical education, which he regarded as most important for the industrialization of Russia. During the Provisional government (February to October 1917, old style), the universities were granted autonomy, and the non-Russian nationalities received the right of instruction in their native languages. The education system envisaged by the liberal-democratic and moderate Socialist parties was a state common school for all children based on local control and the direct participation of society.

Reform before the Revolution

1917–30. After the October Revolution of 1917, the Bolshevik Party proclaimed a radical transformation of education. Guided by the principles of Marx and influenced by the contemporary movement of progressive education in the West as well as in Russia itself, the party and its educational leaders, N.K. Krupskaya and A.V. Lunacharsky, tried to realize the following revolutionary measures as laid down in the party's program of 1919: (1) the introduction of free and compulsory general and polytechnical education up to the age of 17 within the Unified Labour School (Yedinaya Trudovaya Shkola), (2) the establishment of a system of preschool education to assist in the emancipation of women, (3) the opening of the universities and other higher institutions to the working people, (4) the expansion of professional education for persons from the age of 17, and (5) the creation of a

Revolutionary experimentalism

system of mass adult education combined with the propaganda of Communist ideas. In 1918 the Soviet government had ordered by decree the separation of church and school—that is, the abolition of religious instruction in favour of atheistic indoctrination, the coeducation of both sexes in all schools, the self-government of students in schools and universities, the abolition of marks and examinations, and the introduction of productive labour. In 1919 special workers' faculties (*rabfaki*) were created at higher institutions and universities for the development of a new intelligentsia of proletarian descent.

Lenin paid special attention to the campaign against illiteracy and to a widespread technical education; both seemed to him to be prerequisites for the establishment of an industrial Communist society in Russia. During the period of the New Economic Policy (1921–27), when there was a partial return to capitalistic methods, the revolutionary spirit somewhat diminished, and the educational policy of party and state concentrated on the practical problems of elementary schooling, the struggle against juvenile delinquency, and the schooling of adult illiterates. When the policy of five-year plans began in 1928 under the slogan of "offensive on the cultural front" and with the help of the Komsomol (the Communist youth league), the campaign against illiteracy and for compulsory elementary schooling reached its climax. At the same time the revolutionary experimental spirit regained its strength; men such as P.P. Blonsky, S.T. Shatsky, V.N. Shulgin, and A.P. Pinkevich, who can be regarded as representatives of the first period of Soviet education, attempted to establish a new Marxist educational science. It was a kind of combination of biology and sociology from a materialistic point of view, which tried to maintain the rights of the individual child within the Socialist community. This idea found its expression in the creation of a special branch of educational science, pedology (*pedologiya*), which continued to exist until 1936, when it was banned by a special party decree.

The Stalinist years, 1931–53. In connection with the policy of rapid industrialization and collectivization of farmers and with the concentration of political power in the hands of Stalin, the Soviet educational policy in the 1930s experienced remarkable changes. Starting with the decree of 1931, the structure and the contents of school education underwent in the next few years the following process of "stabilization": (1) four years was laid down as the compulsory minimum of schooling for the rural districts, and seven years for the cities; (2) the new system of general education embraced the grades one to four (*nachalnaya shkola*), the grades five to seven, which continued the elementary stage on the lower secondary level (*nepolnaya srednyaya shkola*), and the grades eight to ten, which provided a full secondary education (*polnaya srednyaya shkola*); (3) the new curriculum was to provide the students with a firm knowledge of the basic academic subjects and was to be controlled by a system of marks and examinations; (4) the decisive role of the teacher within the educational process was re-established, while the Pioneers and Komsomol organizations (for youth aged ten to 15 years and 14 to 26 years, respectively) were above all to instill a sense of discipline and an eagerness for learning; (5) manual work disappeared from the school curriculum as well as from the teacher-training institutions. These changes, carried out under A. Bubnov, the new people's commissar for education (1929–37), were accompanied by the rejection of the ideas of progressive education and the beginning of the cultivation of older Russian traditions. During World War II, furthermore, the idea of Soviet patriotism emerged fully, penetrating the theory and practice of education. The principles of the outstanding educator A.S. Makarenko, with their emphasis on collectivism, gained ground upon the former influence of Western educational thought.

Return to authoritarianism and traditionalism

The institutions of higher learning were reshaped in the 1930s, too. The number of students in institutions providing secondary specialized education, usually called *tekhnikumy*, rapidly grew from 1,000,000 in 1927–28 to 3,800,000 in 1940–41. The number of students in institutions of higher education (*vyssheye uchebnoye zavedeniye*) grew from 168,554 to 811,700 in the same period. In 1932 a central committee for technical higher education was created, and in 1936 its functions were extended to the universities and other institutions. The main characteristics of higher education that developed in this period remained unchanged for the next decades: the paramount task of higher learning was to provide specialized professional education within the framework of manpower policy and economic plans; strict control of the student's program was to be imposed by the central authorities; and the system of evening and correspondence instruction on the level of higher and secondary specialized education (*vecherneye i zaochnoye obrazovaniye*) was to parallel full-time studies.

A rather unexpected result of the rise of academic standards in higher education was the decline in the percentage of students from the working class and the peasantry. Between 1940 and 1956, students in the upper grades of secondary schools and in higher and secondary specialized establishments were required to pay tuition fees, though, as before, a great many received government stipends.

During the 1940s, "labour reserve" trade schools and factory schools for skilled and semiskilled labour were filled by drafting youth between the ages of 14 and 17. In the period 1940 to 1958, an average of 570,000 persons were annually subjected to such recruitment. The draft first affected those students who were unsuccessful academically in regular secondary schools and could not achieve even the seventh grade. For youngsters of this kind and for people who could not continue general secondary education, schools for the working youth (*shkoly rabochey molodyozhi*) and schools for rural youth (*shkoly selskoy molodyozhi*) were established in 1943–44 as part-time institutions. The main features of education policy, developed in the late 1930s, remained in force after the war: the orientation of all kinds of schooling and training to the paramount necessities of the economic system; the inculcation of Communist discipline and Soviet patriotic attitudes; and finally a rigid control of the whole educational system by party and state administration.

Post-Stalin era. Since the death of Stalin in 1953, it has been possible to observe a few changes in official policy that have affected both education and science. The 20th Party Congress in 1956 paved the way for a period of reforms inaugurated by N.S. Khrushchev. The central idea was formulated as "strengthening ties between school and life" at all levels of the educational system. The basic documents of the educational reform were the theses of the Central Committee of the Communist Party and the Soviet Government (November 1958) and the All-Union Law of December 24, 1958, followed by separate laws in each of the 15 union republics in 1959. The educational reform in the Soviet Union influenced to a high degree similar reforms in the eastern European countries.

Practicalism and polytechnization

The key issue of the reform debate in 1958 that preceded the decrees was the question of labour training in the secondary schools and of the best way to achieve it. The old idea of polytechnical education has been revived, but mainly in the sense of preparing secondary school students for specialized vocational work in industry or agriculture. Since the early 1950s there has been a growing imbalance between the output of secondary school graduates desiring higher education and the economic demands of skilled manpower at different levels. The educational reforms of 1958 pursued the aim of combining general and polytechnical education with vocational training in a way that directed the bulk of young people after the age of 15 straight into "production."

The new structure of the school system after 1958 developed as follows: (1) the basic school with compulsory education is the eight-year general and polytechnical labour school, for ages seven to 15 (*vosmiletnyaya shkola*); (2) secondary education beyond the eight-year school is provided alternatively by secondary general and polytechnical labour schools with production training (*sred-*

nyaya obshcheobrazovatelnaya trudovaya politekhnicheskaya shkola s proizvodstvennym obucheniem) or by evening or alternating-shift secondary general education schools (*vechernyaya smennaya srednyaya obshcheobrazovatelnaya shkola*), the former school for working or rural youth. Both types were three-year schools, embracing grades nine to 11. The duration of schooling until the final secondary examination was thus prolonged for one year, one-third of the curriculum being used for productive labour and vocational training.

For a transition period the admission to institutions of higher education was to be made dependent on two years of practical experience after the former ten-year secondary school had been completed. Between 1960 and 1962, however, only about 60 percent of those admitted to full-time higher education had actually had any such practice. The connection of study and productive work was to be continued during the course of higher education. Great emphasis was laid upon the further expansion of evening and correspondence education on both levels—at the level of secondary specialized education and at the level of the universities and other higher institutes. In the academic year 1967–68, 56.3 percent of all Soviet students in higher education (of the total number of 4,311,000) carried out their studies in this way. The establishment of five higher technical education institutes in factories (*zavody-vtuzy*) in 1960 was intended to train technological engineers on the actual premises of large industrial enterprises.

In the system of vocational-technical education, the reform of 1958 brought a transformation of the former labour-reserve schools into urban vocational–technical schools or rural schools of the same type (*gorodskiye i selskye professionalnyye tekhnicheskiye uchilishcha*). As a rule they require the completion of the eight-year school, but in fact there are many pupils with lower achievements; the length of training is from one to three years, depending upon the type of career.

Besides introducing polytechnical education and productive labour, the Khrushchev reforms emphasized the idea of collective education from early childhood. Preschool education for the age group up to seven years was to be rapidly developed within the newly organized unified crèches and nursery schools (*yasli i detskiye sady*); and, as a new type of education, boarding schools (*shkoly-internaty*) had been created in 1956 that embraced grades one to eight or one to 11. Some party circles wanted this kind of boarding education for the majority of all young people, but development lagged behind planning, and the idea of full boarding education has since been abandoned. Nevertheless, there were schools and groups with an "extended" school day (*shkoly i gruppy prodlennogo dnya*), and these and the boarding schools accounted for the education of some 4,500,000 children in 1969.

Qualitative reforms

The polytechnization of the Soviet school system as it took shape during the Khrushchev period turned out, in the course of its realization, to be a failure. A revision of the school reform was carried out between August 1964 and November 1966 that brought about several important results: (1) the grade 11 of the secondary school (except for the evening school) was abolished; general education returned to the ten-year program; (2) vocational training in the upper grades was retained only in a small number of well-equipped secondary schools; (3) a new curriculum and new syllabi for all subjects were elaborated. In 1966 a central Ministry of Education was established in Moscow to coordinate and guide the activities of the administrative bodies in each of the republics (see EDUCATION, SYSTEMS OF). The aim of educational policy as outlined at the 23rd Party Congress in 1966 is to achieve universal full-time education of at least ten years in the early 1970s. About 75 percent should receive it within the normal secondary school, the remainder either in specialized secondary schools or in three- or four-year establishments that combine vocational training and academic instruction (decree of April 1969). In accordance with the needs of technical modernization of the Soviet economy, the main task of education and training on the secondary level is to provide a firm knowledge in the basic subjects and to equip the pupils with motivation for further learning. Since 1958 some hundreds of secondary schools for gifted pupils in mathematics, science, or foreign languages have been developed, besides the well-known special schools for music and arts.

The educational sciences are mainly concentrated in the Academy of Pedagogical Sciences in Moscow (established in 1943). The academy maintains 12 research institutes and takes part in educational policy making. In each republic there is a special research institute of education. In the field of higher education the new statute of 1969 extended to some degree the responsibility of the individual institution and the academic staff in economic affairs and the planning of curricula. After the period of numerical expansion of higher education that made the Soviet Union rank second only to the United States, the improvement of quality in teaching and organization has top priority. The ideal of Soviet education is a learned society within the framework of Communism and in connection with the historical traditions of Russia. (O.A.)

China: from Confucianism to Communism. *The modernization movement.* The political and cultural decline of the Manchu dynasty was already evident before the 19th century, when mounting popular discontent crystallized into open revolts; and the dynasty's weakness was starkly exposed by its inability to cope with the aggressive Western powers during the 19th century. At the time when Western nations were closing in on China, the Manchus were harassed by a series of internal rebellions, the best known of which was the Taiping Rebellion (1850–64). After the military defeats administered by the Western powers, even Chinese leaders who were not in favour of overthrowing the Manchus became convinced that change and reform were necessary.

Most of the proposals for reform provided for changes in the educational system. New schools began to appear. Missionary schools led the way in the introduction of the "new learning," teaching foreign languages and knowledge about foreign countries. New schools established by the government fell under two categories: foreign-language schools to produce interpreters and translators and schools for military defense. Notable among the latter were the Foochow Navy Yard School to teach shipbuilding and navigation and a number of academies to teach naval and military sciences and tactics.

China's defeat by Japan in 1894–95 gave impetus to the reform movement. A young progressive-minded emperor, Kuang-Hsü, who was accessible to liberal reformers, decided upon a fairly comprehensive program of reform, including reorganizing the army and navy, broadening the civil-service examinations, replacing the rigid form of the old style of writing with essays on current affairs, establishing an Imperial University in the national capital and modern schools in the provinces, creating a translation bureau, and so on. The imperial edicts in the summer of 1898 spelled out a program that historians have called the Hundred Days of Reform. Unfortunately for China and for the Manchu dynasty, it met with strong opposition from the conservatives, who appealed to the empress dowager Tz'u-hsi for support. The ultraconservative Empress Dowager took prompt and peremptory action, putting the young Emperor in detention and assuming full imperial power herself to stop the reform movement. The edicts of the summer were reversed and the reforms nullified. Frustration and disappointment in the country led in 1900 to the emotional outburst of the Boxer Rebellion.

Hundred Days of Reform and the aftermath

After the Boxer settlement, which exposed China's complete helplessness before foreign powers, even the Empress Dowager saw no way out but to accept the necessity of change. Belatedly, she now ordered the very changes that she had opposed during the Hundred Days of Reform. Modern schools were to be established on all levels, teaching modern subjects such as Western history, politics, science, and technology, along with Chinese classics. The civil-service examinations were to be broadened to include Western subjects. A definite plan was ordered to send students abroad for study and recruit them for

government service upon return from abroad. But these ameliorative measures were not enough to meet the pressing demands now being presented with increasing forcefulness. Finally, an edict in 1905 abolished the examination system that had dominated Chinese education for centuries. The way was now cleared for the establishment of a modern school system.

Changing forms of the modern Chinese school system

The first modern school system was adopted in 1903. The system followed the pattern of the Japanese schools, which in turn had borrowed from Germany. Later, however, after establishment of the republic, Chinese leaders felt that the Prussian-style Japanese education could no longer satisfy the aspirations of the republican era, and they turned to American schools for a model. A new system adopted in 1911 was similar to what was then in vogue in the United States. It provided for an eight-year elementary school, a four-year secondary school, and a four-year college. Another revision was made in 1922, which again reflected American influence. Elementary education was reduced to six years, and secondary education was divided into two levels. A three-year junior middle school was in line with the junior high school movement then gaining acceptance in the United States. This six–three–three–four system continued until recent years.

Education in the republic. The first decade of the republic, up to the 1920s, was marked by high hopes and lofty aspirations that remained unfulfilled in the inclement climate of political weakness, uncertainty, and turmoil. The change from a monarchy to a republic was too radical and too sudden for a nation unschooled in political participation. The young republic was torn by political intrigue, by unscrupulous power seekers, and by internecine warfare among self-styled military chieftains known as warlords. There was no stable government, no effective leadership to make plans for the nation.

A school system was in existence, but it received scant attention or support from those responsible for government. School buildings were in disrepair, libraries and laboratory equipment were neglected, and teachers' salaries were pitifully low and usually in arrears.

New intellectual movements during the republic

It was, nevertheless, a period of intellectual ferment. The intellectual energies were channelled into a few movements of great significance. The first was the New Culture Movement, or what some Western writers have called the Chinese Renaissance. It was at once a cordial reception to new ideas from abroad and a bold attempt to reappraise China's cultural heritage in the light of modern knowledge and modern scholarship. China's intellectuals opened their minds and hearts to ideas and systems of thought from all parts of the world. Translated works of Western educators, philosophers, and literary writers were eagerly read by students and educated people. There was a mushroom growth of journals, school publications, literary magazines, and periodicals expounding new ideas. It was at this time that Marxism was introduced into China.

Another movement of great significance was the Literary Revolution. Its most important aspect was a rebellion against the classical style of writing and the advocacy of a vernacular written language. The classics, textbooks, and other respectable writings had been in the classical written language, which, though using the same written characters, was so different from the spoken language that a pupil could learn to read without understanding the meaning of the words. Now, progressive scholars rejected the heretofore respected classical writing and declared their determination to write as they spoke. The new vernacular writing, known as *pai-hua* ("plain speech"), won immediate popularity and facilitated the expression of ideas and views in a form of writing readily understandable to the many, rather than merely to the scholarly few. Breaking away from the limitations of stilted language and belaboured forms, the *pai-hua* movement was a big boon to the freedom and creativity released by the New Thought Movement and produced a new literature attuned to the realities of contemporary life.

A third movement growing out of the intellectual freedom of this period was the Chinese Student Movement, or what is known as the May Fourth Movement. The name of the movement rose from nationwide student demonstrations on May 4, 1919, in protest against the decision of the Paris Peace Conference to accede to the Japanese demand for territorial and economic advantages in China. So forceful were the student protests and such overwhelming support did they get from the public that the weak and inept government was emboldened to take a stand and refused to sign the Versailles Treaty. The students thus had a direct hand in changing the course of history at a crucial time. The May Fourth Movement was in effect the culmination of a growing political and social awakening of Chinese students as a result of the new freedom and new vistas brought within their reach by the New Thought Movement and its offshoots. Chinese youth was rebelling against the kind of education that concerned itself with books and academic knowledge detached from the challenging problems of contemporary life. For better or for worse, the old concept of the scholar was now shattered, and from now on Chinese students constituted an active force on the political and social scene.

Education under the Nationalist government. Nationalist China rose in the mid-'20s amid a resurgence of nationalism and national consciousness stimulated by post-World War I developments. It was led by the Kuomintang, the political party originally organized by Sun Yat-sen, the founder of the republic. Cognizant of the popular appeal of nationalism, the Kuomintang set up a Nationalist government pledged to achieve national unity at home and national independence from foreign control as prerequisites to a program of modernization and national reconstruction. In education, it set out to systematize and stabilize a shaky and ill-supported school system and use it as a means of national regeneration. Schools were assured of financial support, however inadequate, and placed under strict supervision and firm control by public authorities.

State control and centralization of education

State control of education by means of centralized administration was instituted. Measures were adopted to correct the abuses and chaos that had resulted from the laissez-faire educational policy of the warlords. Decrees and regulations issued by the Nationalist Ministry of Education were strictly enforced, with the aid of a centrally administered system of inspection and accreditation. Detailed regulations covered the curricula of all types of schools on all levels, minimum standards of achievement, teaching procedures, teachers' qualifications, and specifications for school buildings, libraries, laboratories, and the like. Private education was permitted, even encouraged, by means of supporting grants from public funds, but private schools were subject to government control as much as public schools and were required to follow the same prescriptions with regard to curriculum and all other details.

A uniform system of schools was in effect throughout the country. Elementary education was provided in the four-year primary school, followed by the two-year higher elementary. In areas where there were not enough funds to support longer courses, there were abbreviated schools having only one or two grades. Theoretically, the government was committed to the goal of four-year compulsory education, but financial problems prevented an early realization of this goal. Adult education was given much attention in adult schools, in mass education projects, and in different forms of "social education." The latter term encompassed a variety of educational agencies outside the schools, such as libraries, museums, public reading rooms, recreational centres, music, sports, radio broadcasting, and films. Reduction of illiteracy was a major objective.

There were three parallel types of secondary education: the academic middle school, the normal school, and the vocational school. To counteract the traditional preference for the academic type of education, the government restricted the growth of the academic middle school. At the same time, vocational schools were encouraged as an alternative type of secondary education.

Nationalist promotion of "practical studies"

A major objective of government policy was to promote "practical studies." In secondary education, "practical studies" meant the development of vocational and technical schools and more attention to science and laboratory experience in middle schools. In higher education, measures were taken to steer students away from liberal arts, law, education, and commerce to the "practical courses" of science, engineering, technology, agriculture, and medicine. Government grants for private as well as public colleges were usually designated for the science program. As a result of this policy, the years prior to World War II saw a steady increase of enrollment in the "practical courses" of study and a corresponding decline of enrollment in the arts–law–education–commerce courses. The increase of interest in science was also evident in the secondary schools.

It may be said that the thrust of educational policy in Nationalist China was to rectify the imbalance of the past, especially the nonvocational literary tradition of premodern days and the laissez-faire policy of the warlord's regime. In the attempt to counteract past tendencies, however, it was possible that the pendulum might be swinging too far to the other extreme. Some educators expressed the fear that the promotion of "practical studies" might lead to a narrow, utilitarian concept of education and a neglect of the humanities and social sciences. Others were uneasy over the danger of regimentation through centralized administration. Nevertheless, education under the Nationalist government did succeed in establishing an effective national system of education, promoting science and technical studies, and correcting the abuses and irregularities of the earlier period. Thanks to dependable financial support, state schools and universities gained in prestige and academic performance until they were recognized as among the outstanding educational institutions of the country.

Among other accomplishments of this period may be mentioned the growth of postgraduate education and research, the general acceptance of coeducation in elementary and higher education, and the teaching of the Kuo yü (National Tongue) as an effective means of unifying the spoken language and thus overcoming the difficulties of local dialects.

Education under Communism. The Communist revolution is a total revolution, demanding no less than the establishing of a new society radically different from what it calls the feudal society of traditional China and from the bourgeois society of the West. This new society calls for people with a new outlook on life, new loyalties and new motivations, and new concepts of individual and group life. The new society cannot be established without new people, and the creation of the "new Socialist man" (Maoist style) must be a task of the highest priority. It is the task of education.

Education of the new Socialist man

The People's Republic of China makes no distinction between education and propaganda or indoctrination. All three share the common task of changing man. The agencies of education, indoctrination, and propaganda are legion—newspapers, posters, and propaganda leaflets, radio broadcasting, the drama, neighbourhood gatherings for the study of current events, as well as political rallies, parades, demonstrations, and many forms of "mass campaigns" under careful direction. It is evident that the schools constitute only a small part of the educational program. During the Cultural Revolution of 1966–69, schools and universities were closed, but the Communists could well argue that those were the years when an intensive educational program was carried on to combat bourgeois and revisionist tendencies and to hasten the appearance of the "new Maoist man."

When the Communists came to power in 1949, they took up three educational tasks of major importance: (1) teaching many illiterate people to read and write; (2) producing the trained personnel needed to carry on the work of political organization, agricultural and industrial production, and economic reform; and (3) remolding the behaviour, emotions, attitudes, and outlook of the people. The literacy campaign makes use of the radio and special classes organized in factories and other production enterprises, as well as adult schools of various types. The training of farm managers, factory foremen, bookkeepers for communes and cooperatives, technicians, and cadres of all kinds is done by short-term courses, institutes, or special classes in schools or elsewhere.

The process of remolding goes on everywhere, in schools and outside. Factories, government offices, industrial organizations all require their personnel to engage in regular "study," which is the term used for political and ideological indoctrination. Besides these "study" sessions, there are numerous group meetings in which individuals are supposed to help one another in "thought reform"; in such meetings each person is expected to lay bare his thoughts and feelings to be examined by his peers under the guidance and supervision of authorized representatives of the state and Communist Party. The technique of "thought reform" by means of "criticism and self-criticism" is well planned and carefully executed and constitutes an important phase of the remolding process.

Emphasis on short-term education

Millions of cadres have been given intensive training to carry out specific programs; there are cadres for the enforcement of the agrarian law, the marriage law, the electoral law; some are trained for industry or agriculture, others for the schools, and so on. Each group is trained to perform a specific function. The training may take a few weeks or a few months. This method of short-term ad hoc training is characteristic of Communist education in general. The needs are urgent and specific, and education must meet them. There is no time for lengthened courses of study, no room for frills or trimmings, no concern for what "bourgeois" education would value as breadth or depth of understanding.

The Communists reject the concepts of "bourgeois education" and its emphasis on scholarship or academic standards. Knowledge without application is useless; Mao speaks derisively of bourgeois scholars immersed in book knowledge and aloof from politics and production. The product of education is described as the "red expert." An expert is one who has special skills and ability to contribute to production, and he must be "red" by a thorough immersion in Communist ideology. From literacy classes and short-term training programs to the schools and universities, the central aim of education is to produce zealous supporters of the proletarian revolution led by the Chinese Communist Party.

There are three types of schools: the full-time school, the work–study school, and the spare-time school. Students in the work–study school spend a part of their time in productive labour; they work on farms, in factories, or in other forms of productive enterprises. Theoretically, study is organized to help solve concrete problems of production, thus bridging the gap between knowledge and action; at no time is the student removed from actual experience on the production front. The spare-time school is designed for adults who attend after their work hours; workers do so after the day's work, and peasants attend "winter schools" in the lax agricultural season. Thus, there is no interruption of production. Spare-time schools or classes have become an important vehicle of adult education.

Prescribed courses of definite length and content belong to the era of bourgeois education, which the Cultural Revolution of 1966–69 made a renewed effort to stamp out. There is no stable system of schools. Primary schools consist of any length from one or two years to five. Secondary education has been reduced to four years, and higher education to one or two or more years, according to the nature of the course. Spare-time education claims to be able to qualify an illiterate for "secondary education" by a few years of part-time study and for "higher education" in another short period. It is obvious that the terms elementary, secondary, and higher are merely relative terms and have no specific reference to commonly understood standards in terms of curriculum content. Prerequisites for further study are so flexible that they are practically nonexistent. Colleges and universities admit workers and peasants of "advanced production experience" and cadres of high political fervour and ide-

ological orthodoxy, even though their academic qualifications are inadequate by Western standards. Those who have proved to be politically "red" and to have some degree of expertise in production are judged to be more worthy of higher education than "bookworms" erudite in book knowledge but unable to serve the revolution adequately.

Directions after the Cultural Revolution. Since the Cultural Revolution, education has moved in a different direction. Premium is put on work experience; continued study is not important and is even discouraged except for a select few. All schools and universities were closed in 1966 for reorganization and for planning to move in new directions. The schools were ordered to reopen in 1967, but compliance was slow and hesitant, and the colleges and universities did not admit regular new classes until September 1970.

Emphasis on work experience

Enrollment in higher education has been greatly curtailed. Higher education will concentrate largely on engineering and science. Professional training will be given in shortened courses. Medical colleges are proposing to shorten their courses to two or three years; "barefoot doctors," trained to treat common diseases and perform simple surgery, are produced in a few months with no academic prerequisites beyond some form of general education. This is in line with the trend of practical training in the quickest possible time, with little concern for theoretical study that does not have immediately practical value.

Two developments since 1968 deserve mention. To reduce the number of students seeking advanced study, and to implement the intensified emphasis on production and labour, Mao issued a directive to send millions of young people, students, and "intelligentsia" to the rural areas for long-term settlement and to engage in agricultural and industrial production. Even students who qualify for higher education are now required to join the production front, and their production experience is a prerequisite for admission into universities. After higher study, they are supposed to return to the production front. The intelligentsia, including teachers, are to live and work in rural areas to be "re-educated" by the workers and peasants. Political "study" or ideological indoctrination is an essential part of this re-education. Only by such experience and identification with the labouring masses can the intelligentsia hope to overcome the harmful effects of bourgeois-dominated education.

Emphasis on proletarian leadership

A second measure designed also to terminate "the domination of education by bourgeois intellectuals" is to put education under firm proletarian leadership. Backed by the army, teams of workers (in city schools) and peasants (in rural schools) were in 1968 dispatched into the schools and universities to take over the management of the institutions and to play a "leadership" role in the political education of students and teachers. Known as the Mao Tse-tung Thought Propaganda Teams, these selected workers, peasants, and soldiers, under the guidance of the Communist Party, are today the governing cadres in schools and universities, and their chief mission is to make sure that Mao's thought and directives are faithfully and literally carried out. Most members of the teams have had little schooling, and some are barely literate, but they have had experience in labour and production, and they are sufficiently versed in quotations from Chairman Mao to be able to lecture to teachers and students on the correct political line that must guide all educational effort. They constitute the new "proletarian leadership" in medical schools, hospitals, technical universities, as well as other types of higher education and all lower schools.

These are startling innovations. They serve to emphasize the rejection of what the Communists condemn as bourgeois education. It would be irrelevant to raise such questions as academic standards, freedom of thought, systematic knowledge, educational stability or continuity, or the articulation of schools of different levels. Education is designed to serve the proletarian revolution and is subject to constant change in response to the needs of the revolution. There is as yet no firmly established system, but a new pattern is emerging, and the innovations here briefly described are some aspects of this pattern.

(T.H.C.)

MODERNIZING AFRO-ASIAN PATTERNS OF EDUCATION

Japan. *Education at the beginning of the century.* Between 1894 and 1905 Japan experienced two conflicts, the Sino-Japanese and Russo-Japanese wars, which increased nationalistic feelings; and it also experienced accelerated modernization and industrialization. In accord with the government's new nationalism and efforts to modernize the country, educational reform was sought. The Japanese education system took as its model the western European educational systems, especially that of Germany. But the basic idea of education was expressed in the Imperial Rescript on Education (Kyōiku-chokugo), which stressed the need for traditional education.

Effect of Japan's nationalism and economic growth

In 1900 the length of the ordinary primary school (*jinjyō-shōgakkō*) was made four years, and it was made compulsory for all children. At the same time, the cost of compulsory education was subsidized from the national treasury. In 1907 the length of compulsory education was further extended from four to six years. As the educational system gradually improved and as modernization progressed and the standard of living increased, school enrollments soared. Whereas in 1890 only 48.93 percent of the primary-age children were in school, in 1910 the percentage had reached 98.14.

In those days, boys and girls in primary school studied under the same roof, though in separate classrooms. In secondary education, however, there were entirely separate schools for boys and girls—the *chūgakkō*, or middle school, for boys and the *jogakkō*, or girls' high school, both aiming at providing a general education. Other than these, there was the *jitsugyōgakkō*, or vocational school, which was designed to afford vocational or industrial education for both boys and girls. All these secondary schools were for students who had completed the six- or four-year course of primary education. Thus, secondary education was organized into the three parallel systems—a higher general education for boys, a higher general education for girls, and a technical and vocational education.

As for the primary and secondary curriculum, the Imperial Rescript on Education in 1890 provided the ideological basis for the system, making it clear that traditional Confucian and Shintō values were to serve as the basis of moral education. This emphasis was implemented by courses on "ethics" (*shūshin*), which served as the core of the curriculum. In 1903 a system of national textbooks was enacted, giving the educational ministry the capacity to alter, add, or delete indoctrination in accordance with political currents.

To accomplish an expansion of education there was obviously also a need for teachers, and thus a system of *shihangakkō*, or normal schools for training primary school teachers, was established in 1886 and subsequently developed under the strong control of the government. At first there was only one school in every prefecture, but after 1897 the government admitted more. Normal schools for girls were established independently. All the normal schools, in any event, were run by the prefectures, and none was private. At first only the graduates of the higher primary schools were qualified for the normal school, but in 1907 a new course was introduced for graduates of the middle schools and the girls' high schools.

For training secondary school teachers, there was after 1886 the *kōtō Shihangakkō*, or higher normal school, and the *joshi kōtō shihangakkō*, or higher normal school for women. Additionally, "temporary teachers' training institutes" were established after 1902. These were all state run. There were also state-run institutes for training vocational school teachers.

In the Tokugawa era there had been academies on the Chinese model for the study of Confucianism, but not until 1877, after the Meiji Restoration, did there appear in Japan a university, or *daigakkō*, of the European variety. In that year Tokyo University was founded, with

Japan's Imperial universities

four faculties—law, physical sciences, literature, and medicine. In the early years, research and education were dominated by foreigners: most programs were taught in the English language by English and American teachers or, in the medical faculty, in the German language by German instructors. In 1886 Tokyo University was renamed the Imperial University, or Teikoku Daigaku, by imperial order and, as a state institution, was assigned to engage exclusively in research and instruction of such sciences and technology as were considered useful to the state. Modern Western sciences formed the core of this research and instruction, though some traditional Japanese learning was revived; and the university borrowed much of the style and mode of the German universities.

In one important respect it differed from the European tradition: as an Imperial university it added to the four established faculties two others, first engineering and then agricultural science. This indicated the government's intention to make the Imperial University the highest seat of learning in all important fields and to concentrate in it all the functions relating to the training of leaders of all kinds. All these reforms heightened not only the importance of higher education but also the demand for it. Thus, in 1897 Kyōto Imperial University was established, followed by Tōhoku Imperial University in 1907, Kyūshū Imperial University in 1910, and Hokkaidō Imperial University in 1918. These universities were modelled after the imperial university in Tokyo—renamed the Tokyo Imperial University—and inherited its tradition. The higher middle schools established in 1886 were remodelled into the *kōtō-gakkō*, or higher schools, in 1894. In the 20th century the higher schools developed as preparatory schools for universities.

Higher education was advanced in another area by the College Order of 1903, which enabled certain upper level private schools to be approved as *semmongakkō*, or colleges, and to receive the same treatment as state-run universities. Until then the private colleges had not clearly been given a legal status and had been treated as rather inferior.

Efforts at reform

Education to 1940. The events of World War I and its aftermath tremendously influenced Japanese society. In the postwar days, Japan experienced the panic and social confusion that was sweeping many nations of the world. Moreover, the intensified leftist movement and the terrible Kantō earthquake of 1923 caused uncertainty and confusion among the Japanese. Nevertheless, the period was one that earned the name of the "*Taishō* democracy" era, which featured the dissemination of democratic and liberal ideas. And it was also a period that marked Japan's real advancement on the world scene and the expansion of its capitalistic economy, all conducive to the flourishing of nationalism. It was quite natural that these varied currents of the times should greatly influence education.

Educational reform was carried out through the debates and recommendations of the Extraordinary Education Council established in 1917. The reform placed an emphasis on higher education, though secondary education also experienced remarkable growth. As for primary education, the target of the reform was to improve the content and methods of education and to establish the financial foundation of compulsory education.

In 1907, as noted earlier, the period of compulsory education had been extended to six years, and the ordinary primary school course had become six years. The central problem afterward was how to revise the content of education. After World War I, the new educational movements generally called progressive in the West were introduced into Japan and came to thrive there. Many private schools advocating this "new education" were established, and the curricula of many state and public schools were also refashioned. The method of new education was gradually introduced into the state textbooks. Preschool education was also encouraged; a state-run kindergarten attached to Tokyo Girls' Normal School had been first established in 1876, and later many public and private kindergartens emerged, particularly after issuance of the Kindergarten Order in 1926.

Governmental aid for compulsory education was gradually put forward, and by 1940 this developed into a system whereby the government financed half the teachers' salaries and the prefectural governments the other half. Primary education thus further expanded. Between 1910 and 1940 the number of primary teachers and pupils almost doubled. In the latter year there were 287,000 teachers and 12,335,000 pupils.

Secondary education continued to be provided by the middle schools for boys, the girls' high schools, and the vocational schools. These schools increased remarkably both in numbers of institutions and in enrollments after World War I, reflecting the social demand. As a result, the secondary schools assumed more of a popular and less of an elitist character than they had evidenced in the Meiji Era. In 1931 two courses were provided for the middle school system; one was for those who advanced on to higher schools, and the other course was for those who went directly on to a vocation. Enrollments of all kinds leaped: whereas in 1910 the enrollments in middle schools, girls' high schools, and vocational schools had been 122,000 pupils, 56,200 pupils, and 64,700 pupils, respectively, the respective figures in 1940 were 432,000 pupils, 555,000 pupils, and 624,000 pupils.

Increases in enrollments, 1910–40

Meanwhile, the *jitsugyō hoshūgakkō*, or supplementary vocational schools, which had been built after 1893 as part-time educational institutions for working students, reached enrollments exceeding 1,000,000 by 1922. In 1935 *seinengakkō*, or youth schools, were newly established, uniting these supplementary vocational schools with the *seinen kunrenjo*, or youth-training centres, that had earlier been set up to provide military training for youth.

A drastic reform of higher education was instituted in 1918, when the University Order and the Higher School Order were issued on the recommendation of the Extraordinary Education Council. Before that, there had been only the imperial universities, which were state run. The order approved the founding of private universities and colleges. As a consequence, the old influential private colleges, or *semmongakkō*, rich in tradition, were approved as formal universities or colleges, resulting eventually in such famous universities as Keiō Gijuku and Waseda. National colleges of commerce, manufacturing, medicine, and so on were also opened. In general, universities and colleges multiplied, numbering in 1930 as many as 46 (17 state, five public, and 24 private). College-preparatory education concurrently enlarged through the establishment of public and private higher schools under the Higher School Order. The higher schools were remodelled after the German *Gymnasium* and the French lycée and offered a seven-year course.

Japan's examination system

It is also important to understand the examination system that pervaded Japanese education (not unlike the dual plans of Europe). From the beginning of the Meiji era, when the modern education system was established, elementary pupils passed on to secondary schools only if they passed a competitive, selective examination. In the 20th century, as graduates from the primary schools increased and as applicants to the secondary schools also sharply increased, the competition became ever more severe. Its ill effects were widely discussed, and the Ministry of Education eventually revised the examination system, abolishing the written achievement test. Henceforth, selection was to be based on a report of the principals of the primary schools, personal interviews, and physical tests. This new system, in turn, was abandoned for a while in favour of the old written achievement test, but in 1939 the new system was re-established on the same principle as before, with only slight modifications.

The examinations admitting secondary school graduates to higher schools or colleges were decidedly more competitive than those on the lower level; indeed, in extreme cases, the number of applicants was ten or more times the number admitted. The severity of the entrance examinations is only partly attributable to the fact that applicants outnumbered the total number of seats being offered; more important, most students were competing for the relatively few places in certain elite schools. There

had developed a deep social consciousness in Japan, which respected and gave priority to the graduates of specific elite universities—a consciousness born in the process of the rapid modernization of Japan. Although the Ministry of Education did at times try to carry out reforms, placing more emphasis on school records than on selection tests, the efforts were unavailing.

Education changes during World War II. The Manchurian Incident in 1931 escalated into the Sino-Japanese War of 1937, and national life became more and more militaristic. Education acquired an intensely nationalistic character. With the outbreak of war in the Pacific in 1941, the education system underwent emergency "reforms." Elementary schools were renamed *kokumingakkō*, or national schools, under the National School Order issued in 1941. The order proclaimed the idea of a national polity or spirit peculiar to Japan; the content and the methods of education were revised to reflect this nationalism. Moreover, the period of compulsory education was officially extended to eight years, though it actually remained six years because of the worsening war situation.

Militarism and nationalism

Secondary education was similarly made "national." In 1943 the Secondary School Order was issued in an attempt to unify all the secondary schools, but it also, because of the war, shortened secondary education to four years. Military education was especially strengthened. As the war worsened, students above the secondary schools were mobilized as temporary workers in military industries and at agricultural districts in order to increase production, and a great number of students were sent to the battlefields. As a result, classes were virtually closed at schools higher than secondary toward the end of World War II.

Education after World War II. After its surrender in 1945, Japan was placed under Allied occupation and was forcibly "demilitarized" and "democratized." Drastic reforms swept over education. They were a product not only of occupation policy but also of the reflection and criticism of the Japanese themselves regarding their prewar and their wartime education.

The Japanese lost much of their ethical foundation as a result of the defeat, the first in their history. The conventional educational principles espousing Imperial supremacy received a heavy blow, and the educational world of Japan fell into spiritual chaos and vacancy. Owing to the exhaustion of war, the basic conditions for education were fairly destroyed, as reflected in the lack of food and houses, as well as in the economic confusion. Education in Japan after the war was thus confounded for a time but arose with democratic ideas as its reviving energy.

From September to December 1945, the general headquarters of the supreme commander for the Allied powers (GHQ) issued four significant directives concerning educational administration in Japan, largely aimed at eliminating militarism and ultranationalism from the sphere of education. Many wartime teachers were banished from public office; church and state were separated in that Shintō education was removed from the curricula. These directives were issued with the aim of establishing a democratic educational system.

In 1946, American experts on educational affairs arrived in Japan and issued the "Report of the United States Education Mission to Japan," which provided the basis for the directives that GHQ issued to the Japanese Ministry of Education, the actual agency effectuating all reforms. The Fundamental Law of Education and the School Education Law, both enacted in 1947, and the Boards of Education Law of 1948 set the tone and outlines of the new education and the new democratic ideas.

The new Japanese school system

The conventional European dual system was replaced by a democratic ladder system, in which school programs were unified and simplified and the period of attendance was settled in six, three, three, and four years, respectively, for *shōgakkō*, or primary schools, *chūgakkō*, or lower secondary schools, *kōtōgakkō*, or upper secondary schools, and *daigaku*, or universities. This system was an obvious reflection of the American elementary schools, junior and senior high schools, and universities. The period of compulsory attendance was extended to nine years; coeducation was introduced; and provisions were made for education for the physically handicapped and other special education.

The reform of the content of education proceeded from a reduction of the strong state control of former days and the encouragement of teachers' initiative. State textbooks were abolished in favour of textbooks produced by private enterprise, and schools were controlled locally by elective boards of education. Ethics disappeared from the curricula and was replaced by new subjects, such as *shakaika*, or social studies, designed to prepare children for life in a democratic society. All the schools showed a rapid growth. Kindergartens developed considerably as the standard of living in Japan began rising. Compulsory nine-year education was so successful that the rate of attendance in lower secondary schools exceeded 99 percent from the outset and from 1953 on maintained 99.9 percent. Because of the democratic character of the postwar school system, the number that went on to high schools increased rapidly. The percentages of those passing from lower secondary into upper secondary schools increased from 42.5 percent in 1950 to 70.6 percent in 1965.

Changes after the end of Allied occupation

The peace treaty of 1952 not only liberated Japan from the restraints of occupation but also allowed education there to be adjusted to native conditions. Central direction of the schools was increased; controls on textbook certification were strengthened; the political indoctrination of the leftist Japan Teachers' Union was hindered; and efficiency ratings for teachers were instituted. A certain reactionary trend had thus revived. On the whole, however, the postwar educational reforms were retained and advanced, and their subsequent elaboration helped match Japan's rapid economic growth.

The educational reform after World War II also altered the character of the universities, which, in democratic fashion, were opened more widely to all the people. The former institutions—universities, colleges, and various schools for teachers' training—were reorganized into four-year universities and colleges, with a less Imperial or nationalistic tone and a more professional and practical outlook. Facilities and students increased rapidly in number. The 245 universities and colleges in 1960 had increased to 382 in 1970. The number of students rose from 630,000 to 1,400,000 in the same period. Two-year courses for a master's degree and three-year courses for a doctorate (four years for medical and dental students) were established in the new system of universities. Even junior colleges, or *tanki daigaku*, were born, as institutions giving shorter, more "practical" courses in higher education. By the 1970s the total number of students attending universities, colleges, and junior colleges had reached as high as 20 percent of the youth population. This fact eloquently suggests the transformation of universities in Japan after World War II. (A.Na.)

India. *Preindependence period.* Amid the rising nationalism of the latter part of the 19th century, Indians became more and more critical of the domination of Western learning as imposed by the British rulers and demanded instead more attention to Indian languages and culture. The Indian National Congress, several Muslim associations, and other groups raised their voices against the British system of education. Nor were British authorities altogether blind to the needs of the country. When Baron Curzon of Kedleston arrived as viceroy in 1898, his determination to improve education was immediately translated into an order for a close survey of the entire field of education. It revealed: "Four out of five villages are without a school. Three boys out of four grow up without any education and only one girl out of forty attends any kind of school." Education had advanced, but had not penetrated the country as the British had earlier expected.

Political conflicts involved in education in India

Curzon applied himself to the task of putting matters in order. He disapproved of the doctrine of state withdrawal from direct educational enterprise; rather, he considered it necessary for the government to maintain a few institutions of every type as models for private enterprise to imitate. He also abandoned the existing policy of educa-

tional laissez-faire and introduced a stricter control over private schools through a vigilant policy of inspection and control. Such a policy aroused bitter feelings among some educated Indians, since it was believed that Lord Curzon was bent on bringing the entire system of education under government control.

The main battle, however, was fought over the universities. With Eton and Balliol in mind, Baron Curzon set up the Indian Universities Commission of 1902 to bring about a better order in higher education. The commission made a number of important recommendations—namely, to limit the size of the university senates; to entrust teaching powers to universities in addition to examining; to insist on a high educational standard from affiliated colleges; to grant additional state aids to universities; to improve courses of studies; to abolish second-grade colleges; and to fix a minimum rate of fees in the affiliated colleges. The report was severely criticized, and the last two recommendations had to be dropped. Legislation in regard to the other proposals was passed despite bitter opposition in the legislature and the press.

The conflict resulted less from educational differences than from political feeling for or against centralization. In one part of the country, violent agitation had already started on the question of the partition of Bengal. In another part, the patriot Bal Gangadhar Tilak declared: "Swaraj [self-rule] is our birth-right." Thus, Baron Curzon's educational reforms were considered sinister in their intentions, and his alleged bureaucratic attitude was resented. Thus, after five years of resolute efforts, Curzon failed to inspire general confidence, and he left "education a battle field."

Swadeshi movement

The administrative policy of Baron Curzon also gave rise to the first organized movement for national education. A body known as the National Council of Education, in Calcutta, established a national college and a technical institution (the present Jadavpur University) in Calcutta and 51 national schools in Bengal. These schools sought to teach a trade in addition to ordinary subjects of the matriculation syllabus. The movement received a great impetus, because the Calcutta Congress (1906) resolved that the time had arrived for organizing a national system of education. With the slackening of the Swadeshi Movement, however, most of the national schools eventually closed. The effect of the movement was nevertheless noticeable elsewhere: Rabindranath Tagore started his famous school in West Bengal near Bolpur in 1901; the Arya Pratinidhi Sabha established *gurukulas* at Vrindāban and Hardwār; the Indian National Congress and the All-India Muslim League at their sessions in Allahābād and Nāgpur, respectively, passed resolutions in favour of free and compulsory primary education.

In 1905 Baron Curzon left India. In order to pacify the general public, his successors modified his policy to some extent, but the main program was resolutely enforced. Although Indian public opinion continued its opposition, the reforms of Baron Curzon brought order into education. Universities were reconstituted and organized, and they undertook teaching (initially, Indian universities had been simply institutions conducting examinations for degrees). Colleges were no longer left to their own devices but were regularly visited by inspectors appointed by the universities. The government also became vigilant and introduced a better system for inspecting and granting recognition to private schools; the slipshod system of elementary education was also improved. The number of colleges and secondary schools continued to increase as the demand for higher education developed.

In 1917 the government appointed the Sadler Commission to inquire into the "conditions and prospects of the University of Calcutta," an inquiry that was in reality nationwide in scope. Covering a wide field, the commission recommended the formation of a Board of Secondary and Intermediate Education with full powers to control secondary and intermediate education, the institution of intermediate colleges with two-year courses, the provision of a three-year degree course after the intermediate stage, the institution of teaching and unitary universities, the organization of postgraduate studies and honours courses, and a greater emphasis on the study of sciences, on tutorial systems, and on research work. The government of India issued a resolution in January 1920, summarizing the report of the commission. Since then, all legislation of any importance on higher education in any part of India has embodied some of the recommendations of the commission, which can be regarded as the greatest single factor in the history of university education in India.

Meanwhile, World War I had ended, and the new Indian constitution in 1921 made education a "transferred" subject (that is, transferred from British to Indian control), entrusting it almost entirely to the care of the provinces. In each province, educational policy and administration passed into the hands of a minister of education, responsible to the provincial legislature and ultimately to the people. Although European-style education was still maintained as a "reserved" subject and was not placed under the control of the Indian minister of education, this anomaly was corrected by the Government of India Act of 1935, which removed the distinction between transferred and reserved subjects and introduced a complete provincial autonomy over education.

Generally, the new constitution of 1921 was considered inadequate by the Indian National Congress. In protest, Mahatma Gandhi launched the Non-cooperation Movement, the campaign to boycott English institutions and products. Educational reconstruction was kept in the forefront: national schools were established throughout the country, and *vidyapeeths* ("national universities") were set up at selected centres. The courses of study in these institutions did not differ much from those in recognized schools, but Hindi was studied as an all-India language in place of English, and the mother tongue was used as the medium of instruction. Teaching the use of *charkha* ("spinning wheel") was intended as a symbolic preliminary step toward the complete economic independence of India from the West. These institutions, however, functioned for a short time only and disappeared with the suppression of the Non-cooperation Movement. The Congress' struggle for self-rule, however, became more vigorous, and with it spread the national movement toward education to suit national needs. The Government of India Act of 1935 further strengthened the position of the provincial ministers of education, since the Congress was in power in major provinces. The developmental program of provincial governments included the spread of primary education, the introduction of adult education, a stress on vocational education, and an emphasis on the education of girls and underprivileged people. The importance of English was reduced, and Indian languages, both as subjects of study and as mediums of instruction, began to receive greater attention.

Non-cooperation Movement

General educational trends, 1921–47

On this general background, educational developments from the inauguration of reforms in 1921 until independence in 1947 can be viewed. In the field of elementary education, the most important event was the passing of compulsory-education acts by provincial governments—acts empowering local authorities to make primary education free and compulsory in the areas under their jurisdiction. Another noteworthy feature was the introduction of Gandhi's "basic education," which was designed to rescue education from its bookish and almost purely verbal content by emphasizing the teaching of all school subjects in correlation with some manual productive craft. Considerable expansion took place in the field of secondary education. During 1946–47, there were 5,298 high schools, with an enrollment of 2,199,000 pupils. (The corresponding figures for 1916–17 had been 1,507 and 57,200.) A general demand for secondary education developed with the political awakening among the masses. Schools in rural, semi-urban, and less advanced communities were established, as well as schools for girls. Some provision was made for alternative or vocational courses when the provincial governments started technical, commercial, and agricultural high schools and gave larger grants to private schools providing nonliterary courses. But the expected results were not achieved be-

cause of a lack of funds and of trained teachers. Secondary schools still concentrated on preparing students for admission to colleges of arts and sciences.

The period is also marked by a diminishing of the prejudices against the education of women. The impetus came from the national movement launched by Mahatma Gandhi, whose appeal to Indian mothers for the country's cause encouraged a spirit of nationalism. Thousands of ladies came out of the purdah and suffered the same hardships as men for the cause of national emancipation. It was also realized that the education of the girl was the education of the mother and through her of her children. Between 1921–22 and 1946–47, the number of educational institutions for girls was nearly doubled.

In the field of university education, outstanding developments included (1) the establishment of 14 new universities, unitary as well as affiliating; (2) the democratization of the administrative bodies of older universities by a substantial increase in the number of elected members; (3) the expansion of academic activities through the opening of several new faculties, courses of studies, and research; (4) a substantial increase in the number of colleges and student enrollments; (5) the provision of military training and greater attention to physical education and recreational activities of students; and (6) the constitution of the Inter-University Board and the development of intercollegiate and interuniversity activities. With these improvements, however, the educational system of the country had become top-heavy.

Postindependence period. India and Pakistan were partitioned and given independence in 1947, and one of India's first acts was to give itself a new constitution. Although this document did not change the overall administrative policy of the country (education continued to be the prime responsibility of the state or provincial governments), the union government did assume responsibility for the coordination of educational facilities and the maintenance of appropriate standards in higher education and research and in scientific and technical education.

Five-year plans

In order to raise the standard of living, the national government developed successive five-year plans—1951–56, 1956–61, 1961–66, and 1969–1974. Under this program, the majority of educational plans are not centrally controlled but rather are formulated and implemented by state governments, with limited assistance from the government of India. In the first 20 years of independence, the enrollment in recognized educational institutions rose from 18,000,000 to 70,000,000. In 1946–47, 14,000,000 children attended primary schools, representing 35 percent of the age group six to 11. In 1968–69 this had risen to 56,000,000, or 78 percent of the same age group. A comparable increase was achieved in the age group of 11 to 14: in 1946–47 the enrollment was 2,000,000, or 9 percent of the total number; in 1968–69, it rose to 12,700,000, or 33.5 percent. In the field of secondary education, the enrollment rose from 870,000 in 1946–47 (3.8 percent of the age group 14–17) to 6,590,000 (19.4 percent). The increase in enrollment in higher education has been even more rapid. There were 19 universities in 1947. Their number in 1970 was 74. There were also in 1970 some 3,200 affiliated colleges and a number of advanced technological and research institutes conferring their own degrees. Enrollments in these various institutions of higher learning rose from about 218,600 in 1946–47 to over 2,000,000 in 1970. These enrollment figures do not represent a large part of the population of the country (over 500,000,000), but, in comparison with the enrollment in the preindependence period, the expansion was significant.

The education commissions and their recommendations

Since 1947 the government of India also appointed three important commissions for suggesting educational reforms. The University Education Commission of 1949 made valuable recommendations regarding the reorganization of the courses, techniques of evaluation, media of instruction, student services, and the recruitment of teachers. Then came the appointment of the Secondary Education Commission in 1952. The recommendations of these two commissions led to some changes in school and college courses, such as the conversion of the ten-year school into one of 11 years and the establishment of multipurpose schools with diversified courses. But the general dissatisfaction with the existing condition of education continued to grow. It could not satisfy the aspirations of the people, either the educated or the illiterate. Ultimately, an Education Commission was set up in 1964. Whereas the previous two commissions had each examined only one level of education, the new one embraced education at all levels, as it was required to advise the government on a national pattern and development of education. The commission submitted its report in June 1966 with far-reaching suggestions, dealing with seven major points—a national enrollment policy, the structure and pattern of the various stages of education, a new outlook in the school curriculum, the improvement of higher education, the vitalization of educational administration and finance, a stress on professional preparation, and the status of teachers. The commission's report led to a resolution on a national policy for education, formally issued by the government of India in July 1968.

The country has planned to spend 6 percent of its gross national income on education. Even at this higher rate of outlay, India's per capita expenditure on education is small in comparison with Western standards. A century ago the first task was the education of the higher classes; today it is that of the masses. India has failed to carry out the constitutional directive of providing universal education for children in the age group of six to 14; the girls are still lagging behind boys in educational facilities; and the number of adult illiterates is daily mounting. Money is essential for solving these difficult problems.

Of late, public attention has been increasingly concentrated on the growing disparity between the number of educated persons and the opportunities of congenial and profitable employment open to them. The remedy may lie not in extending and improving facilities for higher education but in diversifying them and in changing attitudes toward industry and labour. (S.N.M.)

South Africa. From the time of the first white settlements in South Africa, the Protestant emphasis on home Bible reading ensured that basic literacy would be achieved in the family. Throughout the development from itinerant teachers to schools and school systems, the family foundation of Christian education remained, though it was gradually extended to embrace an ethnic–linguistic "family."

Early efforts to establish education in South Africa

Despite some major 19th-century legislation on the administration of education (1874 in the Transvaal and the Orange Free State, 1865 in the Cape of Good Hope, 1873–77 in Natal) and some early efforts to establish free schools, political and linguistic problems impeded the development of public education before 1900. Natal had gone furthest in affirming government responsibility for education and setting up administrative machinery to implement this responsibility, but, by and large, provision for schooling remained voluntary and piecemeal until the beginning of the 20th century.

The Boer, or South African, War (1899–1902) suspended educational development entirely and confirmed the resolve of each white South African group to protect its own cultural prerogatives. When the Union of South Africa was created in 1910, it was a bilingual state, and, in education, English-speaking and Afrikaans-speaking schools were established for white Europeans. Furthermore, a political tightness and separateness increased among the Afrikaners after the war and strengthened their tendency to exclude nonwhites from the cultural and political life of the dominant society. The trend toward separate schools for linguistic and racial groups became a rather rigid practice in most of South Africa after union.

The preliterate tribal education of African natives in the South African colonies was replaced by church mission schools. Established from 1789, they were dedicated to converting the natives to Christianity and generally inculcating an attitude of service and subservience to white men. These schools spread from 1823 to 1842, and colonial governments began making occasional grants to

them from 1854. Some mission schools included a mixture of races, but, by and large, segregation was established by custom. There were exemplary schools—such as the Lovedale Missionary Institution—that followed rather liberal social and curricular policies, but most schools held to narrowly religious content. The African mission schools were virtually brought into the state system through government subsidies and through provincial supervision, inspection, and control of teaching, curriculum, and examination standards. Schooling, in any event, has never been made compulsory for Bantu children and only in certain areas for Coloured children (racially mixed and other nonwhites).

The union and school systems

By the time the union was formed, the new provinces had each established school systems, structured mainly for European children but including provisions for other groups. Specific arrangements varied, but basically the systems were headed by a department of education under a director and controlled through an inspectorate. Three of the provinces had school boards that localized the department administration. Provision was made for public, primary, and secondary education and for teacher training (though public secondary schooling had barely begun and continued to be provided in private schools, with or without state aid). Compulsory-attendance regulations were being effected for European children, while separate school developments were under way for other groups. The language of instruction had been established provincially, with both Afrikaans and English in use.

The South Africa Act of 1910 left the control of primary and secondary education with the provinces, while reserving higher education to the union government. The Union Department of Education, Arts, and Science became the central educational authority and expanded its responsibilities through the 20th century by accepting control of special sectors such as vocational, technical, and artistic education. Including other central departments with educational responsibilities, such as the Department of Social Welfare, Department of Agriculture, and Department of Defense, the South African government exercises wide educational powers. In 1935 an Interprovincial Consultative Committee was established to coordinate educational matters among the provinces and between the provinces and the central government. In 1962 a National Advisory Education Council was appointed. By recent legislation, the central government's general responsibility for educational policy has been affirmed, while provincial areas of administrative competence have been extended.

Primary and secondary schooling, once articulated, were organized as eight- and four-year units, respectively, and have since been reorganized on a seven–five basis. Vocational high schools, now within the general secondary provisions of the provinces, offer technical, commercial, and domestic-science courses. The general high schools have been predominantly academic institutions but have come to offer a choice of subjects that differentiate pupil programs according to ability and future career intention. Private schools, both independent and aided, are found mainly in Transvaal and Cape Province, but over 90 percent of South African white children are in state schools. With exceptions, public education is free through the tenth year and is compulsory for European children to age 16 (or until the completion of the eighth year in the Cape and Natal).

English and Afrikaans and the division of education

The language of instruction does not greatly affect the curriculum or organization of schools, but it does present a basic educational division in South Africa. Both English and Afrikaans are official languages of the republic. About 60 percent of the white population speak Afrikaans and about 40 percent English, and the two languages are used almost proportionately in schools. By law, instruction is given in the mother tongue, the other language being introduced as a second language. Coloured and Asiatic pupils are taught in the official language common to their area of residence, and under recent apartheid legislation Bantu pupils are assigned to use their own tribal language.

In 1922, when the Phelps–Stokes Commission on education in Africa offered its report, South Africa's example in the development of liberal and adaptable educational provisions for Africans, particularly in Natal and the Cape, was held up for emulation. The passing of the tribal system was noted and efforts toward interracial cooperation complimented. It was obvious at that time, however, that little of particular value to Africans was being done in the European-model schools and that noteworthy educational efforts were associated with special institutions, such as Lovedale School and University College of Fort Hare in the Cape.

Concern over Bantu education in the 1940s, led to the creation of the Eiselen Commission, whose report in 1951 accorded with the separatist views of the nationalist government coming to power in 1948 and presented a basis for apartheid legislation in education. The Bantu Education Act of 1953 resulted.

Apartheid and Bantu education

The policy of apartheid, or "separate development," has been controversial, both within South Africa and throughout the world. Fundamentally, the government position rests on three assumptions: (1) that each cultural group should be encouraged to retain its identity and develop from its present stage according to its unique characteristics; (2) that, with a population of diverse racial–social groups, the way to ensure peaceful coexistence and general progress is through legal and institutional separation; and (3) that the only agency capable of exercising overall responsibility for this development is the central government. Implementation of apartheid policy has been carried out through the 1950s and 1960s and has led to a virtually total separation of educational facilities for white, Bantu, Coloured, and Asiatic populations.

Since 1953, state funds have been withdrawn from denominational native schools, and control of Bantu education has been removed from the provinces and placed within a central Department of Bantu Education. A state secretary is in charge, with assistants for administrative and for professional matters. Regional offices are under regional directors, who supervise European inspectors and Bantu subinspectors of native schools. In the consequent organizational revisions, most attention has been given to the lower primary course (first four years). The Bantu primary course is eight years in length, with a screening examination after standard two (or lower primary) and after standard six (or upper primary). Although there has been a substantial increase in Bantu school attendance over the past decade, few nonwhite South African students enter vocational or general high schools, and those who do rarely go beyond the three-year junior certificate. In 1956 the central government assumed responsibility for Bantu teacher training on a regional basis. In 1959 the racial separation of educational programs was made complete through the Extension of University Education Act. From this date, nonwhites were barred from entrance to the established universities, and separate university colleges were set up to provide higher education to nonwhites on an ethnic–linguistic basis—(1) Zulu, (2) Xosa, (3) Sotho, Tsonga, Venda, Tswana, (4) Coloured, (5) Asiatic. Syllabuses and examinations for all nonwhite colleges are prepared by the University of South Africa in Pretoria.

There is no doubt that the separate schools in South Africa offer unequal educational provisions. Such inequalities are meaningful, however, only in terms of one of two basic educational criteria: the effectiveness of education for socioeconomic progress and the adequacy of education for human development. Both criteria are problematic in South African education today. (R.F.L.)

EDUCATION IN COLONIES AND NEWLY EMERGING NATIONS

Patterns of African education. Despite the diversity of ethnic and linguistic groups and of religious beliefs and practices throughout the different geographic and climatic zones of black Africa and despite the different kinds of social organization and levels of political, economic, and social development in precolonial African societies, there are numerous common traits among them. Thus, it is possible to speak of a traditional African education—one, namely, that took place almost entirely

within the framework of family and limited social groupings, such as peer age groups and village gatherings. Chiefly, it may be said that traditional African education had the following characteristics: (1) it was collective or communalistic and deeply democratic; (2) it was intimately tied to the practical tasks of day-to-day living and it also involved learning social relations and spiritual concerns; (3) its methodology included peer-group game playing, observation of adults, and then incremental assumption of adult activities, with more and more autonomy; (4) it was lifelong, the crowning achievement being the title of sage given to the elderly; and (5) its content was often esoteric, involving, as it did, the transmission of certain secrets of one's family or secret society—secrets such as craft techniques or the preparation of medicines or poisons. The major exception to this pattern of precolonial education was the Qur'ānic school. Islām expanded south into eastern Africa in the 9th and 10th centuries and into western Africa in the 11th century. As it was assimilated into precolonial African societies, it provided them with a script (the Arabic), and, because of the central attention given to the Qur'ān, it imposed a certain bookishness on the first formal African schools. In some areas, moreover, there developed a cultural flowering, involving an indigenous literature in Arabic transcription. Significantly, Muslim instruction in black Africa borrowed freely from the practices of traditional education—instituting "bush" schools, recruiting by age groups, arranging group gatherings for reading of the Qur'ān, and adopting practices suggestive of initiation ceremonies. The influence of the Qur'ānic school, however, was marginal even among Muslimized populations; it offered the means of learning the Qur'ānic verses essential to prayer, and it trained the marabouts, but it left most aspects of traditional education intact.

Traditional African education

Although some precolonial African societies may be credited with great accomplishments, generally to the end of the 19th century there was economic, social, and technological stagnation in Africa. This stagnation is partly attributable to the defects of traditional African education—its insufficient use of literature, its iron respect for authority, its excessive reliance on empirical knowledge and techniques, and its lack of a framework or support appropriate for further progress.

General influences and policies of the colonial powers. During the colonial period, the first direct "educational" influences from outside came from religious missionaries, first Portuguese (from the 15th century) and then French, Dutch, English, and German (from the 15th to the 19th centuries). Starting from coastal bases, they undertook to penetrate into the interior and begin campaigns to convert the black populations. The missions were the first to open schools and to develop the disciplined study of African languages, in order to translate sacred texts or to conduct religious instruction in the native tongues.

Early mission and lay schools

The partition of Africa by the colonial powers in the 19th and early 20th centuries led first to the establishment of mission schools and then to the establishment of "lay" or "public" or "official" schools. The importance of either the lay or the religious system depended on the political doctrines of the mother country, its institutions (a firmly secular state or one with a state religion), and the status of the colony and its history. Whatever the system or administrative attitude, however, the fundamental purpose of colonial instruction was the training of indigenous subaltern cadres—clerks, interpreters, teachers, nurses, medical assistants, workers, and so forth—all indispensable to colonial administration, businesses, and other undertakings. Though inspired by the system in the mother country, no colonial system compared to its prototype: local examinations and diplomas, for instance, were not equivalent to those in the mother country. From the beginnings of colonialism to the end of World War II, the larger intention was not to "educate" the subject peoples but rather to extend the language and administrative policies of the colonizer.

Such a generalization, though, is subject to a slight qualification with reference to the religious missions. Both the missions and the political administrations viewed African populations and cultures with condescension, and both wished to model the African man in accordance with their own needs and objectives. The religious missions, however, became involved in the cultures of the Africans through continual contact with them in the daily ministrations; they used African languages in instruction wherever the colonial administration permitted it. Moreover, for a long while, religious establishments were alone in offering vocational education, some secondary education, and even some higher education to Africans—frequently in the face of the fears or opposition of the colonial authorities.

German educational policy in Africa. Well before Chancellor Otto von Bismarck had granted a charter to the German Colonial Society in 1885, German missionaries, both Protestant and Catholic, were operating in various regions of West, Central, and East Africa—from 1840 in Mombasa (now in Kenya), from 1845 in Cameroon, from 1847 in Peki Blengo (Togo), and from 1876 in Mpwapwa, Buganda (Uganda), and Tanga (Tanzania). English and American missionaries also operated in German areas. Instruction was everywhere conducted in the local languages, which were objects of study by numerous missionaries and by eminent scholars.

After 1900, with the organization of colonial administrations, the central governments and local authorities added lay schools to the existing mission schools. By 1903 there were, in Tanganyika, 15 mission schools and 20 lay schools. In 1911 the missions had 30,000 primary pupils and the lay schools 3,500 pupils; some 2,500 students were receiving vocational or higher education. In Togo the missionaries were subsidized, and thus by 1912 there were 181 Catholic mission schools, 156 Protestant mission schools, and only three official lay schools. Alongside these general schools in such places as Togo and Cameroon there were a few normal schools, schools of agriculture, seminaries, and apprenticeship centres.

With the creation of the Ministry of Colonies in 1907, the coastal regions were divided into zones of influence relating to the various religious missions—Catholic, Protestant, and Methodist. In these coastal areas, education received rather favourable development (the interior Muslim areas were almost untouched by the Europeans). Because primary instruction was always conducted in the local languages—German being reserved for postprimary schools—the most lasting effect of German policy was to make education in the African languages a tradition that would be difficult to undo even after the departure of the Germans. From 1898 to 1914 in German East Africa some half dozen publications appeared in Swahili—newspapers and brochures in printings of more than 10,000 copies. German colonization in black Africa thus had some permanent results.

German emphasis on African languages

Education in British colonies and former colonies. In the British colonies, as elsewhere, religious missions were instrumental in introducing European-type education. The Society for the Propagation of the Gospel in Foreign Parts, the Moravian Mission, the Mission of Bremen, the Methodists, and Roman Catholic missionaries all established themselves on the Gold Coast (Ghana) between 1820 and 1881, opening elementary schools for boys and girls, a seminary, and eventually a secondary school (in 1909). In Nigeria, Protestant missions were opened at Badagri, Abeokuta, Lagos, and Bony from 1860 to 1899, and the Roman Catholic missions entered afterward and opened the first catechism schools, primary schools, secondary schools, and normal schools. In Uganda and Kenya, the Church Missionary Society, the Universities Mission to Central Africa, the White Fathers, and the London Missionary Society opened the first mission schools between 1840 and 1900.

The first official lay schools came later and for a long time constituted a weak minority. In 1899 in Nigeria, for instance, only 33 of the 8,154 primary schools were government run and only nine of the 136 secondary schools and 13 of the 97 normal schools. Similarly in the Gold Coast in 1914 the government was responsible for only 8 percent of the schools. In Kenya and Uganda, all schools were conducted by missions. Not until 1922 did

the British government assume some responsibility for education in Uganda by opening the first government technical school at Makerere (the future Makerere University College); its purpose was to develop craftsmen such as carpenters and mechanics, as well as civil servants, business clerks, and industrial labourers. Only in territories seized from the Germans in World War I did the British take over the administration of existing government schools (previously set up by the Germans). Generally the British preferred to leave education to missions, which were given variable financial aid, usually from local and inadequate sources.

British efforts at reform in the 1920s and 1930s

Following the publication of critical reports in 1922 and 1925, when there was growing uneasiness among the Africans, the missions, the governors, and the administrators, the necessity of a precise policy on education was imposed on the British authorities. In 1925 an Advisory Committee on Education in the Colonies, created in 1924 and presided over by W. Ormsby-Gore, published an important report. The ideas, principles, and methods formulated in this document covered the matters involved in defining a policy; namely, the encouragement and control of private educational institutions, the cooperation by the governmental authorities with these institutions, and the adaptation of education to the mentality, aptitudes, occupations, and traditions of the African peoples. Special importance was attached to religious and moral instruction, to the organization and status of education services, to subsidies to private schools, to instruction in the African languages and the publication of manuals, to the training of native teachers, to the inspection of schools and the upgrading of teachers, to professional training and technique, and to the education of young girls and women. The structure of an educational system, at the most advanced stage, was to consist of an elementary education (generally six years), diversified middle and secondary education (four to six years), technical and professional schools, specialized schools of higher education, and adult education.

In practice, subsequent British policy in black Africa was far from the recommendations of the Ormsby-Gore committee. The subsidies to mission schools were subject to regulations that varied from one colony to another and paid insufficient attention to the character of the education. The development of instruction, especially secondary, was generally curbed, and various local associations and numerous organizations therefore arose to promote the expansion of education. The colonial governments exerted real effort only on behalf of schools that trained subaltern cadres for administration and commerce (mostly schools for the children of chiefs and prominent persons and the colleges at Makerere and Achimota). Government-sponsored secondary education got started only after 1930 in the Gold Coast, only in a conditional manner in 1933 at Makerere College in East Africa, and only after 1935 in Nigeria. In Uganda no complete secondary school existed until 1945.

The Advisory Committee reports published in 1935 and 1944 raised the same questions and the same fundamental themes, indicating that the government still was playing an insufficient role in education. Development was primarily a result of the efforts of missions, of various private local or foreign institutions, and of local indigenous authorities. The efforts of certain individual administrators, such as Sir Philip Mitchell in Uganda and Sir Donald Cameron in Tanganyika, were also effective. Only the political consequences of World War II brought the appointment of commissions and officials to study more deeply the problems of education in the English colonies of black Africa. After the war, the different sectors of education were developed with the growing participation of Africans, who were gaining more autonomy. Secondary education expanded. Institutions of higher learning were improved and increased in number: university colleges were established at Accra and Ibadan in 1948, at Makerere in 1949, and at Khartoum in 1951; a College of Technology (later, University of Science and Technology) was founded in Kumasi in 1951; and the Royal Technical College of East Africa (later, University College) was founded in Nairobi in 1954. Beginning in 1950, development plans for the various colonies—Ghana (the Gold Coast), Nigeria, Sierra Leone, Kenya, Uganda, and Tanganyika—contributed to educational progress.

Post-World War II reforms

Upon achieving home rule and then independence, the new African states born of the old British colonies were inheritors of an educational system that, though better than that of the other African states, was still a cause for concern. In most states (Ghana, Kenya, and Malawi being the only exceptions) less than 40 percent of the population had a primary education. Secondary education was even less widespread, Ghana being the only country in which it exceeded 10 percent. Higher education existed in urban centres but still in an embryonic state. Other serious obstacles to the ultimate development of education for all the people included the diversity of organizations and institutions responsible for education, the necessity for students to pay fees, and the complexity of the legislation in force.

Educational improvements after independence

Every one of the various countries set upon to improve education. They offered subsidies to private schools, extended supervision over them, and regulated their tuition. They increased the number of primary and secondary schools offering free or partly free instruction and created numerous institutions of higher learning, such as the universities of Cape Coast in Ghana, of Lagos, of Ifé, and of Ahmadu Bello in Nigeria, and various branches of the University of East Africa in Kenya, Uganda, and Tanzania. The educational systems inherited from colonial rule (six to eight years of primary instruction, two to four years of higher primary instruction, and five to six years of secondary education) were subjected to "Africanization" or adaptation to local conditions. Reform, in short, was widespread and profound. Taking into account the generally high rate of population growth, however, the rate of educational growth is not spectacular. Moreover, the place made for African languages in primary education seems everywhere to have been eclipsed by English, the official language—in spite of the widespread use of African languages in magazines, newspapers, radio, television, and motion pictures.

Education in French colonies and former colonies. As elsewhere in Africa, mission schools were the first to be established in French colonies. Although public or official schools appeared in Senegal between 1847 and 1895, the first such schools in Upper Senegal, Niger, Guinea, the Ivory Coast, and Dahomey were begun only from 1896 on. In 1900 there were about 70 schools and 2,500 students throughout French West Africa.

Only after 1900, with the organization of the federated colonies of French West Africa and French Equatorial Africa, was there a French colonial policy on education. By decree in 1903, education in French West Africa was organized into a system of primary schools, upper primary schools, professional schools, and a normal school. Two further reorganizations followed decrees in 1912 and 1918, and important schools were established—the St. Louis Normal School in 1907 (transferred to Gorée in 1913), the School for Student Marine Mechanics of Dakar in 1912, and the School of Medicine of Dakar in 1916. The educational organization that remained in force in French West Africa from 1924 until 1947 included a system consisting of primary instruction for six years (regional urban schools), of intermediate–higher primary education given in upper primary schools and in professional schools (generally one for each colony), and at the top the federal schools—two normal schools, a school of medicine and pharmacy, a veterinary school, a school for marine mechanics, and a technical school. The two schools for secondary education, both in Senegal (the Faidherbe State Secondary School of St. Louis and Van Vollenhoven State Secondary School, at Dakar), were reserved for Europeans and those rare Africans having French status.

Total enrollment in French West African schools rose from 15,500 in 1914 to 94,400 in 1945. The number of students in the higher primary schools grew in the same period only from 400 to 800 or 900. (The area's total population in 1945 was almost 16,000,000.)

Educational policy was stated frankly in the official statements of governors general:

> Above all else, education proposes to expand the influence of the French language, in order to establish the [French] nationality or culture in Africa (*Bulletin de l'Enseignement en AOF*, No. 45, 1921); Colonial duty and political necessity impose a double task on our education work: on the one hand it is a matter of training an indigenous staff destined to become our assistants throughout the domains, and to assure the ascension of a carefully chosen elite, and on the other hand it is a matter of educating the masses, to bring them nearer to us and to change their way of life. (From *Bulletin de l'Enseignement en AOF*, No. 74, 1931.)

After World War II, all inhabitants of the newly established "French Union" became citizens in common who were represented in the French Parliament. This political policy carried over into education, which became even more assimilationist: the old higher primary schools, for instance, became classical and modern secondary schools on the French model. An Investment Fund for Economic and Social Development provided financial and developmental aid to education—to the extent that primary enrollments rose to 156,000 in 1950 and to 356,800 in 1957, and higher primary enrollments rose to 5,800 in 1950 and to 14,100 in 1957. Technical and professional education also expanded, from 2,200 students in 1951 to 6,900 in 1957. Scholarships, awarded by the central government, the colonies, and local groups, enabled an increasing number of African youth to pursue higher education in France. In Senegal in 1950 the first French West African university was established, the Institute for Higher Studies, later called the University of Dakar, followed by those of Abidjan and Brazzaville.

In 1957 and 1958, when the colonies achieved autonomy and then a kind of commonwealth status within the new French Community established by the Gaullist constitution, education began a more intensive development, at least quantitatively. More primary schools were opened; larger staffs and more schools were created on the secondary level; teacher training was accentuated; and more scholarship students went to France. Within three years, after the French African countries had achieved full independence, this upgrading of education accelerated. Curricular reforms, however, have been slow. Although such countries as Guinea, Mali, and the Congo (Brazzaville) introduced such reforms as the Africanization of history and geography, generally the traditional French system persists, and courses are taught in French. The so-called ruralization of primary education—that is, the spread of education out beyond the towns—proceeds under the aegis of the governments and French educational officials.

The rise in the number of primary students has been spectacular: between 1955 and 1967, for instance, the number of primary graduates increased in Guinea from under 34,000 to over 164,000, in Senegal from about 62,000 to almost 219,000, and in Chad from about 21,000 to almost 140,000. Admittedly, such progress depended on recourse to unqualified teaching personnel, thus putting in doubt the qualifications of all the graduates. Also, in the former French areas, the number of students attaining a higher education has remained among the lowest in Africa.

Education in Belgian colonies and former colonies. As elsewhere and perhaps more than elsewhere, the Catholic and Protestant missions played the prime role in the development of education in the Belgian Congo (today Zaire) and in Ruanda-Urundi (the present states of Rwanda and Burundi). In the period before 1908, when the Belgian king Leopold II treated the Congo as virtually his private preserve, the missions had assumed an unofficial responsibility for education. After 1908, when the Belgian parliament assumed control of the Congo, the Catholic mission schools were given a privileged official status, with government subsidies, while the Protestant schools, though financially unassisted, were also officially authorized to operate. Throughout the colonial period the overwhelming majority of schools were missionary, and until 1948 the systems were limited to two-year primary schools, three-year middle schools, and a sprinkling of technical schools for training indigenous cadres for administration, health, teaching, and mechanical labour. In 1948 the Belgian government issued a new plan entitled "Organization of Free Subsidized Instruction for the Indigenous with the Assistance of Christian Missionary Societies," which promised more diversification in primary education (both vocational and secondary–preparatory), the institution of a six-year secondary-education program, and the future creation of institutes of higher learning. In practice, the fullest emphasis was subsequently given to the so-called general two-year primary education, which was oriented toward rural crafts, technical training, and a "democratic" distribution of education. (Education was of course still designed in the interests of colonialism.) It is in this context that the great number of persons with a primary education in Zaire must be appreciated: 909,500 students in 1950 (compared with 370,000 in 1935 or with 2,066,800 in 1965).

Catholic missionary schools in Belgian areas

In 1962 the government of the newly independent Congo proceeded with a reform of the old educational system: the first primary degree was standardized and its length extended from two or four years to six years; and pupils were to take a common primary course prior to their orientation toward general, normal, or technical secondary education or toward professional education. Numerous specialized schools of higher education were created: the National Institute of Public Works and Construction, the School of Civil Engineers, the National Institute of Mines, the Higher Pedagogical Institute, the Higher Institute of Architecture, and the National School of Administration. To the already existing Lovanium University of Kinshasa (founded in 1954) and the Official University of the Congo (founded in 1955 in Lubumbashi) there was added the Free University of the Congo (founded in 1963 in Kinshasa). The result is that the Congo is among the African countries enjoying the best school and university infrastructure, despite the long historical delay. Although less pronounced, an analogous evolution has characterized Burundi and Rwanda.

Education in other colonies or former colonies. Except for Equatorial Guinea, which became independent of Spain in 1968, the African territories administered by Spain and Portugal are the only ones still retaining the status of colonies; in all of them there are nationalist movements seeking independence and carrying on armed struggles. Quiescent or suppressed movements also exist in South Africa, South West Africa, and Rhodesia.

Generally, the ruling policy in these countries is to perpetuate colonial control within the framework of racial discrimination, or apartheid. In the Spanish and Portuguese colonies, education is designed to assimilate a thin stratum of mulattos for the propagation of the Spanish and Portuguese languages and the Catholic religion; hence the importance of mission schools. The educational system imitates that of the mother countries and includes four years of primary instruction and seven of secondary. The per capita rate of registration for primary and secondary education, however, is among the lowest in Africa—in Angola, for example, only 2 percent in 1951 and only 16 percent in 1964. Higher education is nonexistent, and only those who are "assimilated" receive it—in Spain or Portugal itself. Any improvement of the system results from the political pressures of independent African nations and of nationalist movements.

Education in Spanish and Portuguese areas

Ethiopia was less influenced by Italy, which ruled it briefly (from 1935 to 1942), than by Great Britain, which traditionally held sway in East Africa. Its educational system therefore has remained very close to that in the English former colonies. Although Amharic has become the language for primary education, English is used in secondary and higher education. School registration remain among the lowest in Africa: 8 percent in 1965.

Problems and tasks of education in contemporary Africa. The independent African states face numerous problems in implementing an educational policy that will encourage economic and social development. Pedagogical problems and economic and political problems all intermix. The difficulties confronting most governments,

however, are basically political: they are usually oriented toward maintaining political, economic, and cultural ties with the old colonial power, and they therefore maintain the old educational programs and policies—expanded, perhaps, but usually revised, if at all, very conservatively. There is a pronounced distrust of anything that deviates from the traditional path of colonial education or the colonial powers' educational system.

Thus, numerical increases in school enrollments, though occasionally spectacular, fail to correspond to the legitimate aspirations of the people or even, more modestly, to the initial objectives fixed by the governments themselves. The Conference of Nairobi in July 1968 viewed as rather alarming the lack of progress in education and literacy in the context of growing populations. There has also been concern about the financial difficulties of the different states, the unsuitability of current educational systems to local needs, the waste and duplications in primary and secondary education, and the insufficient liaison between educational policy makers and the planners of economic and social development. In short, an educational crisis has developed and ripened in black Africa. (A.M.)

Patterns of education in the Arab world. The countries comprising the modern Arab world form a vast territory stretching from the Atlantic Ocean eastward to the Persian Gulf, with over 106,000,000 Arabic-speaking people, predominantly of the Muslim faith. Arab education was shaped in the postmedieval centuries largely by two significant developments. One was the rise and fall of the Ottoman Empire, which began with the fall of Constantinople and the end of the Byzantine Empire in 1453, reached its peak of territorial growth and power under Süleyman the Magnificent in 1520–66, and then gradually declined until it was all but liquidated in the Treaty of Sèvres in 1920. What remained was reconstructed by the Treaty of Lausanne (1923) as the modern Turkish republic under Mustafa Kemal Atatürk. The other influential development was the far-reaching territorial and educational control of Arab states by European powers, chiefly France and Great Britain, gradually replacing the steadily declining Ottoman Empire. During this long period, education in the Arab world was governed to a large extent by Ottoman educational policies, French influence in areas of French control, British influence in areas of British control, and Italian influence in Libya, and finally, largely after World War I, the development of national systems of education in modern times in independent Arab states.

Historical background of modern Arab education

In efforts to break away from Ottoman and European political, economic, and educational domination, the Arab nations have tried to create among themselves unity of purpose, educational improvements, economic cooperation, cultural interchange, and military defense. Among the important means used to this end have been such movements as Pan-Islāmism, which began in the late 1800s; Pan-Arabism, which was initiated during World War II; and the Arab League, which was founded in 1945 to promote closer cultural, economic, political, and military ties among the pact members. Member nations in the Arab League include Saudi Arabia, Lebanon, Syria, Jordan, Egypt, Yemen, Libya, The Sudan, Morocco, and Tunisia.

Since their independence, almost all Arab states have made sweeping advances in the development of national systems of education. Education in the modern Arab nations draws upon not only recent European and American ideas and practices but also upon, certain traditional concepts and practices rooted in medieval and postmedieval Muslim education and surviving in scattered centres of Arab society to the present day.

Educational background and modern development in some Arab states. The impact of this historical background upon Arab education can best be illustrated by historical sketches of a few Arab states: Algeria, Egypt, Iraq, Lebanon, Morocco, and Syria.

Algerian education

Algeria was under the Ottomans at least nominally until 1848 and under French colonial rule from about 1830–48 until 1962. Only Qur'ānic schools existed before 1830, teaching religion and some reading, writing, and grammar, rarely beyond the primary level. These schools underwent a period of decline following the advent of French colonial rule and were mostly replaced with French schools for French children but open also to Muslim pupils. The legal provisions of France's free, compulsory public-school system were extended to Algeria in 1833, leading to the establishment of a complete French public educational system by 1909 and a provision for compulsory education for ages six to 14 by 1936. The University of Algiers, which combined existing schools of medicine, law, science, and letters, was established in 1879 and reorganized in 1909.

Until it was abolished in 1949 there existed a dual school system, European and Muslim, but all elementary schools established by the French government concentrated on teaching the French language. Moreover, private schools received financial support from the government only if they offered instruction in French. Without financial support, the large majority of Muslims were thus left without any education of their own. In 1951 the French government did begin a few experimental secondary schools (*lycées d'enseignement franco-Musulman*) that offered a seven-year program to French and Muslim pupils completing a five-year elementary school and, more significantly, combined elements of both Arabic and French cultures in their curricula. The aim, nevertheless, was to prepare students for the examinations of the French baccalaureate.

As early as 1931 a native group, the Association of the Learned Men, dissatisfied with the traditional Qur'ānic schools, established modern Arabic primary schools, which added such subjects as North African geography and arithmetic to the traditional religious subjects; 193 such schools were operating in 1955. A few madrasahs offered advanced training in Arabic, but they were closed in 1957, except for three, which were converted to normal schools for training teachers in Arabic culture. The best was the Institut Benbadis in Constantine, with a four-year Arabic secondary program. This was closed along with many other Muslim schools in the 1962 revolution, initiating the present educational system.

Although a dual system of elementary and secondary education continued immediately after independence, steps were taken between 1962 and 1964 to transform Algerian education into a national system under the Ministry of National Education. The aim was to introduce compulsory teaching of Arabic at all levels, to train Arabic-speaking teachers, and to Algerianize the curricula of elementary, secondary, and higher education. Classical and modern high schools were needed, as well as technical colleges, teacher-training colleges, vocational schools, and universities. Education, in short, was to be democratized to make it available to all Algerian students at all levels. Professional training was needed for teachers and for education counselors, and programs of adult education were planned. It was necessary to construct schools and supply equipment sufficient to these needs, to prepare thousands of Arabic texts, and to arrange educational relations and exchanges with other countries.

Egyptian education

Of all the Arab countries in the Middle East, the Arab Republic of Egypt has the longest educational history. Its higher education (religious) dates back over 1,000 years, as represented by the al-Azhar University. Whereas other Arab nations broke away from the educational program of the Ottoman Empire, Egypt has retained in part the Ottoman system that dates back for centuries. With such a long history, Egypt has developed a comparatively complex educational system, continually modified by laws initiating new types of educational organization and programs based on new ideas and needs. Because of this historical background, the system today is at once modern and ancient, with some practices dating back to medieval times and others based on modern Western policies, programs, and practices.

The Egyptian Ministry of Education, founded in 1836–37, has continued (except for a short interval under Sa'īd Pasha) to exist to the present day. It was influenced first

by French methods of education and later, after British occupation, by British influence until 1922; during this period, both French and English languages and cultures continued to influence, if not shape, Egyptian education. When Egypt received its independence in 1922 and the Ministry of Education went to Egyptian hands in 1923, it began dramatic progress under central control.

As early as the 1820s, Egypt had been sending technical missions to Italy and France for new ideas on the development of a modern school system and a modern press. But the plans for a modern education were not realized until after independence and, particularly, not until after the 1952 revolution under Gamal Abdel Nasser. A ten-year educational plan was launched in 1952 to build 400 schools annually. The present educational enterprise thus includes a steadily increasing enrollment, not only in primary and secondary schools but also in preparatory and technical schools, including industrial, commercial, and agricultural education. In higher education, there are the Universities of Cairo, Alexandria, al-Azhar, 'Ain Shams, Asyūt, and others, and there are also higher institutes and vocational-training centres.

Iraqi and Lebanese education

In the golden age of Islāmic education from 800 to 1100, Mesopotamia (modern Iraq) was one of the great centres of learning in eastern Islām. It fell under the Ottoman rule from the middle of the 16th century to World War I. During this long period the Turkish language was the medium of instruction in almost all schools, and, because of the linguistic barriers, the large majority of Iraqi children were deprived of any kind of education. Instruction in religion and classical learning dominated education until 1850: elementary schools emphasized reading, writing, and memorization of selections from the Qur'ān and other religious literature; the little higher education that existed dealt largely with Muslim theology and the study of Arabic classics. Iraq did share some of the Ottoman educational reforms that established a secular system of public education throughout the Ottoman Empire in the mid-19th century, but the new school system did not replace the traditional *kuttābs*, or religious schools.

Since World War II, steady modernization of education has taken place at all levels in Iraq. Efforts have been exerted toward establishing kindergartens; primary education is both free and compulsory by law but awaits new schools and facilities for fuller implementation; and secondary education has been growing at a slow pace.

Prior to 1926, Lebanon was an integral part of Syria, which after the fall of the Ottoman Empire in 1918 was mandated to France in 1922. In 1943 Lebanon gained independent sovereignty. By that time, however, it had already had an organized system of education dating back about 200 years. With a Christian majority, the country has historically attracted the establishment of many sectarian schools, such as 'Ayn Waraqah in 1789, which boasted of teaching four languages—Arabic, Syrian, Italian, and Latin—in addition to all courses usually taught in the elementary and secondary schools of Europe, including theology, philosophy, and law. The school became a model for the developing national schools in Lebanon, concurrently with the establishment of many other sectarian schools. The American missionary schools were first established during the first quarter of the 19th century; and British–Syrian mission schools were set up during the third quarter of the 20th century. All these schools contrasted with the Latin types represented by French and Italian schools and with the schools representing Greeks, Danes, Germans, and Russians.

Because only one Ottoman public school existed prior to World War I, the French easily took over and initiated their own public school system, including an upper elementary level. Nevertheless, at the time of independence (1943), private schools in Lebanon assumed by far the largest share of formal education (953 private compared with 252 public schools). Independent Lebanon soon decreased the ratio by establishing a complete public school system. Thus by 1964 there were 1,273 public elementary and secondary schools and 1,456 private schools at both levels. In 1966 enrollments in primary schools numbered 360,000; in secondary schools 82,000; and in higher education 23,400. The system also includes vocational and technical schools and teacher education. Lebanon enjoys today the highest rate of literacy, 87 percent, of all the nations of the Middle East.

Moroccan and Syrian education

Before independence in 1956, Morocco was under Spanish and French protectorates and was an international zone for 44 years. The French government maintained an exclusive educational system for French students, open to only a few Moroccans. Except for the traditional Qur'ānic reading and memorization schools, the establishment of modern schools in Morocco awaited independence, after which began a continuous program of educational expansion in number and types of schools as well as in a variety of curricula to meet diversified needs. As far as possible, subjects in primary schools are being taught in the Arabic language. Primary education is preparatory for secondary schools, which lead to higher education in al-Qurawīyīn University, the oldest university in Morocco, and the modern Muhammad V University at Rabat, with faculties of law, humanities, science, sociology, medicine, engineering, and theology.

Syria achieved independence in 1941 after 19 years of French mandate. In 1958 Syria joined Egypt in forming the United Arab Republic but dissolved the union, along with Yemen, in 1961 and has since been known as the Syrian Arab Republic. In the last two decades the republic has made great educational advances, having, next to Lebanon, the highest literacy rate in the Arab world.

The educational system of the Syrian Republic provides, under the Ministry of Education, elementary, general-preparatory (junior-high-school), general-secondary (senior-high), technical, and higher education, including college and university. There are also separate teacher-training institutes to meet the needs of elementary and secondary schools; lower technical schools, including industrial, commercial, agricultural, and feminine arts; and higher technical institutes, including commercial, agricultural, fine arts, and industrial training. University education, as that in Aleppo, includes faculties of medicine, dentistry, nursing, pharmacy, law, arts, sciences, commerce, engineering, education, and Islāmic law.

Arab education: prospects and problems. Independence caught the Arab nations unprepared for the demands and advantages of the postwar technological world. To make the adjustment swiftly, they are undergoing a revolution through education. In 1965 out of a population of 105,000,000 they have enrolled 12,500,000 students in their schools at all educational levels—9,700,000 in primary schools, ages six to 12; 1,840,000 in secondary schools. Similar advances have been made in the 26 universities and in a number of colleges and institutes; their enrollment totalled 248,000 in 1963–64.

Although elementary and secondary education is tuition-free in all Arab states and higher education in some, the unprecedented increases in population—at the rate of 3 percent a year, one of the highest rates in the world (from 92,000,000 in 1960 to 105,000,000 in 1965)—and a lack of funds and facilities are still making the advantages of education inaccessible to many Arab students. Almost one-half of the Arab population is still illiterate. Remarkable advances have been made, however, in the status and education of girls in most Arab states, at all levels, including higher education.

In the area of knowledge and skills there have been notable advances in scientific research, social sciences, and the arts, with relatively insufficient development in scientific and technological studies, at both the secondary and the university levels. Although every segment of the educational enterprise is under continuous revision, the greatest need in Arab education today is sweeping advances in applied sciences preparing trained individuals to manage a developing industrial society. There is a danger that many university graduates, who specialize in large numbers in humanities, arts, and social sciences, may find themselves unemployable in a society with a pressing need of technologists.

Education in Israel. Geographically in the midst of the Arab world but ideologically and politically in conflict with it is Israel, a relatively new homeland for a

people who have traditionally placed great importance on education and scholarship.

Although the new Israeli government in 1949 expediently reaffirmed the status of the various educational systems inherited from British rule, the State Education Law of 1953 reformed them by setting up a national school system of two parts. There is the Hinukh Mamlakhti, or State Education System, which offers general and vocational education; and the Hinukh Mamlakhti Dati, or Religious State Education System, having a vocational, religious, and Zionist background. Each system has its own teachers and administrators, but both are supervised by the Ministry of Education and Culture. In addition, there is a third and private system, the Aguyat Yisrael, of religious but non-Zionist cast, which receives government subsidies so long as its basic curriculum meets state requirements. For Arab minorities there are separate schools conducted by local Arab authorities.

According to the 1953 law, the aim of Israeli education for Jews is

> to base elementary education on the values of Jewish culture and the achievements of science, on love of the homeland and loyalty to the State and the Jewish people, on practice in agricultural work and handicraft, on *ḥalutzic* [pioneer] training, and on striving for a society built on freedom, equality, tolerance, mutual assistance and love of mankind. (From *Israel Government Yearbook, 1968–1969.*)

Israeli emphasis on Jewishness

The emphasis on Jewishness is continued on the secondary level, at which study of Hebrew language and literature, the Bible, and the Talmud are stressed along with more conventional sciences and humanities.

Institutions of higher education in Israel are generally self-governing but are advised by a national Council of Higher Education. The chief institutions are the Hebrew University of Jerusalem, Tel Aviv University, Technion (or the Israel Institute of Technology) in Haifa, and the Bar-Ilan University in Ramat Gan. (M.K.N.)

Patterns of education in Latin America. The term Latin America is a facile concept hiding complex cultural diversity. This abstraction covers a conglomerate of areas, distinguished by differences not only in the Indian and Negro population base but also in the superimposed nonindigenous patterns—Spanish, Portuguese, French, Dutch, and Anglo-Saxon. In this brief survey, generalizations will be limited to the major Spanish and Portuguese patterns, which account for 95.7 percent of the population and 98.3 percent of the area.

The heritage of independence. At the beginning of the 19th century, the Spanish colonies enjoyed a prosperity that led to optimism, thoughts of independence, and republican rule. In the prolonged struggle for independence, they were all but ruined, and the change from absolute monarchy to popular democracy was far from easy. The revolutionaries had a blind faith that a separation of the branches of government and a written constitution would miraculously change overnight a reality three centuries in the making. Thus novel customs clashed with those of the past; governmental practice did not follow political theory; and the legal equality of the citizens hardly corresponded to economic and educational realities. An abyss separated the educated, rich Spaniards born in America from the rest of the population, and the majority of the population lacked the education to benefit from its new rights. Although a small group of poor criollos and mestizos who had served in minor administrative posts during colonial times sought to bring about changes, they themselves and the rich, in positions of advantage, split into liberal groups and conservative groups. The struggles among them would lead to almost a century of anarchy. In this respect at least, Brazil was more fortunate, for it obtained its independence peacefully, passing from colony to empire and then to a republic.

Catholicism and education in Latin America

When educational ideologies began to be defined, the Roman Catholic Church became a source of controversy. The conservatives wanted to follow established educational patterns and considered Catholicism a part of the national character. The liberals thought it a major obstacle to progress. To uproot the church's privileges, governments in many countries made education both secular in character and a state monopoly. In others, as in Colombia, by way of a concordat with the Holy See, religious education became the official one.

Everyone was aware of the need to educate in order to create a new national consciousness, and the task was begun by importing the Lancaster method of "mutual" instruction (so named from its developer, the English educator Joseph Lancaster), which in monitorial fashion employed brighter or more proficient children to teach other children under the direction of an adult master or teacher. Its obvious advantage was that it could accomplish an expansion of education rather quickly and cheaply. Beginning in 1818 it was introduced in Argentina; 1821 in Chile and Colombia; 1822 in Peru and Mexico; and 1823 in Brazil. In 1824 Simón Bolívar personally invited Lancaster to visit his Greater Colombia. Until well into the second half of the 19th century, it was to be the most widely used system.

Almost all the heroes of independence tried to establish schools and other educational institutions. José de San Martín founded the National Library and the Normal Lancasteriana, a teacher-training school, in Lima; Bolívar established elementary schools in convents and monasteries and founded the Ginecco (1825), known afterward as the Normal Lancasterian School for Women. Bernardino Rivadavia, the first president of Argentina, also stimulated educational development, including the establishment of the University of Buenos Aires. In midcentury, Benito Juárez in Mexico also championed education as the only bulwark against chaos and tyranny.

By the 1870s the liberals had won the day almost everywhere throughout Latin America. Education was declared to be compulsory and free, the lack of teachers and teacher colleges notwithstanding. A program to remedy this situation was launched. Chile paid for educator Domingo Faustino Sarmiento's travels to the United States and Europe and enabled him to found, on his return in 1842, the Normal School for Teachers. This was the first non-Lancasterian teachers college and was to be followed in 1850 by the Central Normal School in Lima and in 1853 by the Normal School for Women in Santiago. Countries with more acute educational problems, such as Ecuador, simply imported the Brothers and Sisters of the Sacred Heart and put them in charge of organizing their educational system. During the 1870s and 1880s, foreign teachers began to be imported, while at the same time students were sent abroad. Sarmiento had already called in North American teachers to open his normal schools in the 1860s, and Chile invited Germans for its Pedagogical Institute (1889). Germans and Swiss came to Mexico and Colombia; a number of distinguished Mexican educators were trained by Germans in the Model School in Orizaba. With the foreign professors came new pedagogical ideas—especially those of Friedrich Froebel and Johann Friedrich Herbart—and also new ideologies, foremost among them positivism, which flourished in Argentina, Brazil, Chile, and Mexico.

Administration. With independence, the task of overseeing public instruction fell to the state and local authorities. Fiscal poverty and a lack of trained personnel soon proved them unequal to the task. Furthermore, since most existing schools were confessional and private, the need for intervention by the central authorities to enforce unity became obvious. In 1827 the Venezuelan government established a Subdirectory of Public Instruction, which in 1838 became a directory. Mexico established a General Directory of Primary Instruction in 1833. Soon, some countries decided to assume responsibility for centralization through a ministry for public instruction—Chile and Peru in 1837, Guatemala in 1876, and Venezuela in 1881. Other governments abstained from accepting total responsibility. In Mexico, no ministry was created till 1905 and then only with jurisdiction over the Federal District and territories; even that became a victim of the revolution of 1910. In 1922 a Mexican ministry was re-established, now in charge of the whole republic and taking up the functions that the states could not fulfill. In Argentina the Lainez Law, decreed in

Efforts to centralize educational administration

1905, authorized the National Council of Education to maintain, if need be, schools in the provinces.

Today, in all countries the control over education is in the hands of a ministry of public education or a similar government unit. Its functions include planning, building, and administering schools, authorizing curricula and textbooks for public elementary and secondary schools, and supervising private ones. In some countries, the states sustain their own educational systems, which the federal government then supplements, but, because of the disparity between city and countryside, these federal governments often have had to shoulder almost the total burden of rural elementary education.

Primary education and literacy. At the time of independence, elementary education consisted of teaching reading and writing, the religious and civil catechisms, and rudiments of arithmetic and geometry. By the second half of the century, it became differentiated between "elementary primary" and "superior primary" education, and the curriculum was enlarged to include the teaching of national language, history, geography, rudimentary natural sciences, hygiene, civics, drawing, physical education, and crafts for boys and needlework for girls. The elementary primary school was increased to five or six years, and the superior primary was to become the secondary school of the 20th century. These educational levels absorbed the greatest part of the governmental efforts and became a means to do away with illiteracy and also to create a concept of citizenship.

Primary instruction was improved by special programs and teacher training, and both benefitted from educational influences coming from abroad but also from improvements resulting from the study of national problems. Today, primary school teachers are trained in teachers colleges having the status of secondary schools.

Problems of rural and native education

Thanks to solid foundations laid during the 19th century, public education in Argentina and Chile reached a high level of competence. In other countries, because of such factors as a more heterogeneous population, a higher level of demographic growth, and greater geographical barriers, the results of great efforts have been less than impressive, Although all countries have declared primary instruction to be free and compulsory, the situation in reality is rather complex. Whereas, in towns, many children have gone from kindergarten to secondary schools since the beginning of the century, in the rural areas, even today, many schools have only one teacher to handle students of all levels. Furthermore, because many Indian citizens do not understand Spanish, special instruction is required. In the 20th century, governments have established special institutions for Indians, such as the "departments of native instruction," "native institutes," "special normal schools," and "cultural missions." The first cultural mission was created by the Mexican secretary of education, José Vasconcelos, in 1923. The idea was to send an elementary school teacher, an expert in trades and crafts, a nurse, and a physical-education teacher to underdeveloped communities, in which, during a limited period, the population would be provided with some general education. The United Nations Educational, Scientific and Cultural Organization (UNESCO) has helped in the training of teachers for these special areas through two regional centres of fundamental education for Latin America (CREFAL), one in Mexico and the other in Venezuela. Many countries have tried to master the dropout problem by offering at least one free meal a day to those who continue their schooling.

Uruguay, Argentina, and Chile have been able to multiply their schools and thus to provide facilities for their entire population of school age. In other countries, the efforts may be gauged by comparing statistics. In Peru, only 29,900 children went to school in 1845; but there were 59,000 in 1890; 1,075,000 in 1955; and 2,054,000 in 1965. In Brazil, there were 115,000 pupils in 1869; 300,000 in 1889; 4,878,000 in 1955; and 9,923,000 in 1965. In Mexico, there were 349,000 in 1874; 800,000 in 1895; 3,349,000 in 1955; and 7,813,000 in 1969. Unfortunately, the high population-growth rate (2.9 percent) makes it difficult to keep up with the ever-increasing needs.

Fight against illiteracy

Illiteracy has been fought by various means in accordance with the political and socioeconomic situation. Until the middle of the 19th century, illiteracy in Latin America was in excess of 90 percent. Of Brazil's population, only 1.5 percent were literate in 1823. Around the beginning of the 20th century, illiteracy had decreased to 39 percent in Argentina (1908), 50.4 percent in Uruguay (1908), and 68.2 percent in Chile (1895); in other countries it fluctuated between 80 and 98 percent. By 1960 illiteracy was down to 8.6 percent in Argentina, 9.7 percent in Uruguay, 16.4 percent in Chile, 37.8 percent in Mexico, 38.9 percent in Peru, and 39.4 percent in Brazil. Nations with the greatest illiteracy were Guatemala, with 62 percent; Bolivia, with 68.9 percent; and Haiti, with 89.3 percent.

Secondary education. During the 19th century, many countries established new secondary schools on the basis of colonial institutions. Thus, in 1821 Argentina converted its College of San Carlos into its College of Moral Sciences. Mexico attempted a total reform in 1833 but would not complete it until 1867 with the founding of the National Preparatory School, which involved reforming the whole system on the basis of Positivist philosophy. In Brazil in 1837 the Pedro II College was founded as a model secondary school, but secondary instruction did not prosper till the return of the Jesuits in 1845 and was to be supplemented later by *gimnasios*—that is, *Gymnasien* on the German model. Peru and Venezuela established national colleges, and Chile and Argentina created *liceos* (modelled on the French lycées) and, later, national colleges. (The term college in all cases here is used in the continental European sense to refer to secondary institutions, not institutions of higher education.)

Secondary emphasis on university preparation

In all countries (except perhaps Chile), secondary instruction has been considered a preparation for the university. All attempts to make it more formative and practical have failed, in spite of the fact that the government has taken charge. The secondary-preparatory course lasts from five to six years, with a degree of bachelor (*bachillerato*) usually given upon its completion. Its teachers come from the humanities departments of the universities and the superior normal schools (which have existed since 1869 in Argentina, since 1889 in Chile, and in the 20th century in the other countries).

Polytechnical education—industrial, commercial, and agricultural—had been a concern of liberal governments since the end of the 19th century but has developed only recently. Traditional prejudices against practical instruction were overcome only after industrialization began. It has been emphasized only in Argentina, Venezuela, Chile, and Mexico.

Higher education. Imbued with a revolutionary spirit in which education was a vital element, Latin Americans founded ten universities between 1821 and 1833, among them the University of Buenos Aires (1821). Bolívar himself established two in Peru—Trujillo (1824) and Arequipa (1828). With independence, practically all theological faculties had disappeared, and their position of pre-eminence was taken over by faculties of law.

Four universities were founded in the 1840s, Chile's among them, and ten more in the second half of the 19th century. In Mexico the new institutions called themselves institutes of arts and sciences, because the University of Mexico (founded in 1551) was associated with colonialism and had become a favourite target of the liberals. The University of Mexico was suppressed in 1865, after several earlier attempts, not to be reopened until 1910, the year of the revolution. Argentine liberals solved their problem by passing the Avellaneda Law (1885), which allowed only national universities, prohibiting private universities (until the reform of 1955).

In Brazil, the republican constitution of 1891 decreed that all secondary and higher education would be a federal or state function. Several higher schools were established, but the country's first university, at Rio de Janeiro, was not founded until 1920.

Almost all higher education in Latin America came to be secular and state operated. The fact that Latin American governments, themselves unstable, generally took

Emphasis on state universities

charge of higher education, however, explains in part its uncertain existence.

Some colonial religious institutions nevertheless survived. During part of the 19th century, for instance, the University of the Republic in Montevideo maintained its ties with the church. In 1855 the University of San Carlos in Guatemala, through a concordat with Rome, reverted to pontifical status. But, with the exception of the Universidad Católica in Chile, founded in 1888, and the Pontificia Universidad Católica del Peru, founded in 1917, all religious universities are recent creations. Indeed, today the majority of private institutions are religious or confessional, with the significant exception of some recently established technological institutes (Monterrey, in Mexico; Buenos Aires). The need for technical education was also recognized by the Mexican government when it founded, in 1936, the National Polytechnical Institute as its second national institution of higher learning, with several branches in the country (regional technological institutes) to serve the particular needs of each region.

Until the 20th century, universities were mainly professional schools. Often, they also supervised primary and secondary education (Uruguay 1833–37; Chile 1842–47; Mexico 1917–21). Today, they also conduct research and try to encourage regional developments. Unofficially, they have sometimes played a role in political life. Since the reform movement for student representation at the University of Córdoba, in Argentina, in 1918, they have become involved in political controversies. The Mexican government tried to extricate the National University from political strife by giving it autonomy in 1929. Student demonstrations by the late 1960s, however, proved this measure to lack effectiveness.

Higher education has proved to be the best means of furthering social mobility. In spite of this, institutions of higher learning in Latin America have suffered from several handicaps. Foremost is the lack of sufficient funds, which usually results in poor research facilities. Second, both students and professors are generally engaged only half time. This increases the dropout rate and decreases performance. Thus, most highly qualified professionals are trained abroad. At the same time, both the political situation and economic pressures have induced an exodus of the most highly educated Latin Americans to the United States.

In 1960 there existed 148 institutions of higher learning in Latin America. Four countries had the highest number of university students, in absolute terms: Argentina, 195,000; Brazil, 95,600; Mexico, 95,500; and Colombia, 45,000. But, on the basis of the number of students per 10,000 population, the four highest places were taken by Argentina, 93; Uruguay, 48; Cuba, 38; and Chile, 35. Colombia had only 32, Mexico 27, and Brazil 14.

(J.V.de K.)

Historical background of modern Southeast Asian education

Patterns of education in Southeast Asia. The history of education in the countries in Southeast Asia (namely, Bangladesh, Burma, Cambodia, Sri Lanka [former Ceylon], Indonesia, Laos, Malaysia, Pakistan, the Philippines, Singapore, and North and South Vietnam) bears the imprint of the distinctive cultural heritage of each of these countries—a product of its geographical, ethnic, linguistic, religious, economic, and political background. The course of educational development in these countries, however, seems to fall into a general pattern with three notable phases.

The first phase represents the earliest period, steeped in legend and history. Education during this period centred on the social and cultural values of the religions that prevailed in some of the greatest civilizations of the time—namely, the Indic, the Chinese, the Buddhist, and the Islāmic. The second phase marked the process of westernization of education through contact with Western countries. The aim was primarily to educate an elite group on Western lines in the furtherance of the interest of the ruling power. The third phase came in the wake of the resurgence of the people in this region after World War II. The most striking feature of this period was the attempts at planned development—to expand education rapidly, to improve its quality, and above all to correct the old imbalance by shifting the emphasis from the traditional liberal, general education to scientific and technical education. The gap between resources and needs is the chief constraint on faster progress.

All countries in this region are committed to the objective of universal primary education of at least seven years' duration. But about half the children of school-going age in the region are still out of school, and the dropout rate was as high as 53 percent in 1960. The majority of the adult population is still illiterate (though Sri Lanka, Indonesia, Malaysia, the Philippines, and Thailand are exceptions in this regard). Education of girls lags far behind that of boys. The proportion of girls enrolled as compared with boys, though rising gradually, was only 38 percent in 1967 (an exception is the Philippines).

By and large, the rate of growth in higher education has been faster than in any other levels. A development of far-reaching social consequence is the movement to extend the use of national languages in all fields of higher education. Although English remains the most important foreign language in the region, in such countries as Indonesia and Thailand, the national languages are in use as mediums of education at all levels, with English as the second language. Other trends include increasing attention to research and the development of services for academic counselling and career guidance.

Education in all these countries is organized in three levels—primary, secondary, and higher. The duration of primary education varies from five to seven years (in a few cases divided into two stages), the commencing age being five to seven years. Secondary education with two to three stages also has a duration of five to seven years, ending about age 17 to 19, the commencing age for higher education. The responsibility for the administration of education is shared between the national and the provincial or local governments in varying measure in the region. In Pakistan, for example, it rests predominantly with the provincial governments, but it is largely with the national governments in Indonesia, Thailand, and the Philippines. In all countries, the national governments are responsible for overall planning and coordination of education.

During the 20th century the indigenous system of education continued in all of these countries in some form, along with the new system evolved on Western lines. Western models with modifications to meet the needs of the changing society became the mainstream in each country. In spite of the local changes, it retained its resemblance to the educational system of the country on which it was patterned. By and large, the British pattern is found in Bangladesh, Burma, Sri Lanka, Malaysia, and Pakistan; the Dutch in Indonesia; the American in the Philippines; and the French in Cambodia, Laos, and North and South Vietnam.

Bangladesh. Comprising what was formerly the eastern wing of Pakistan, Bangladesh emerged in December 1971 as an independent sovereign state with a population of over 75,000,000, the eighth-largest in the world. It has a fine educational and cultural tradition. According to an early-19th-century survey, 100,000 schools were already in existence in Bengal when the beginnings of Western education for an elite group were laid in 1835 under British rule. An extremely valued educational asset of the country is its rich national language, Bengali.

Notable among the earliest educational institutions established on Western lines were Dacca College (1841), Rajshahi College (1872), and the University of Dacca (1921). In 1969–70, there were six universities and 286 colleges, with an enrollment of over 270,000; 5,200 secondary schools, with an enrollment of 1,400,000; and over 29,000 primary schools, with an enrollment of 6,300,000. Post-secondary technical and vocational institutions of various types numbered 57, with an enrollment of 13,000, indicating a wide leeway to be made up in this critical area of education. Major reforms are under way to orient the educational system to a new social order inspired by the ideals of "nationalism, democracy, socialism, and secularism" on which the new nation is founded.

Burma. The indigenous system of education in Burma

Buddhist and Socialist influence in Burma

consisted mainly of Buddhist monastic schools imparting education at both primary and higher levels. They were based on (1) the moral code of Buddhism, (2) the divine authority of the kings, (3) the institution of *myothugyi* (township headmen), and (4) widespread male literacy. The Western system of education was established after the British occupation of the country in 1886. The new system recognized women's right to formal education in public schools, and women began to play an increasingly important role as teachers. The Government College at Rangoon and the Judson College established in the 19th century were incorporated as the University of Rangoon under the University Act of 1920.

Ever since independence in 1948, Burma has passed through significant political changes. A unified system of state schools with Burmese as the language of instruction was introduced in 1950. The major objective was indicated in the proclamation on the "Burmese way of socialism" made by the Revolutionary Council: "An educational system equated with livelihood and based on socialistic moral values will be brought about. Science will be given precedence in education." As a result, the curriculum has been redesigned to achieve a balance among academic subjects, civic education, and practical arts. The teacher-education program is oriented to the needs of rural schools and to local economic growth and social development. As a result of various measures, enrollments increased between 1946–47 and 1962–63 nearly fourfold in the primary, 14-fold in the secondary, and sevenfold in the higher stage of education.

Buddhist, Muslim, and Western influences in Ceylon

Sri Lanka. Following the advent of Buddhism in the 3rd century BC, the monastic system of education centring on the teaching of Buddha became the principal system in Ceylon (now Sri Lanka). With the beginning of the Muslim settlements in the 7th century AD, schools for Muslim children were established. Western education was introduced by missionary workers arriving in the wake of the Portuguese, Dutch, and British occupations of the island between 1543 and 1802. The first schools established by the British were English schools at central stations. It was, however, the reforms introduced during the administration of Sir Hercules Robinson in the 1860s that provided the system instrumental in building the modern Sri Lanka.

Various legislative measures extended elementary education and eventually raised the compulsory school age to 14 years in 1917. Further reforms introduced during 1931–46 paved the path of educational progress. With the literacy rate rising from 56.3 percent of males and 21.2 percent of females in 1921 to 70.1 percent of males and 43.8 percent of females in 1946, Ceylon established an early lead in literacy in the region. Until 1947 education beyond the primary level was practically confined to the middle class. The movement to put the entire educational system within a national orientation, which gained strength with the introduction of universal franchise in 1931 and of parliamentary government in 1947, found official acceptance after independence in 1948.

A milestone in the growth of higher education was the establishment of the University of Ceylon in 1942. A separate university was formed from the Colombo campus of the University of Ceylon in 1967. Within the indigenous classical system of education, two universities, Vidyodaya and Vidyalankara, were established in 1959 for the promotion of Sinhala and Buddhist culture.

Malay, Chinese, and English heritage in Malaysia

Malaysia and Singapore. The origin of the educational system of Malaysia can be traced to the Qur'ānic schools, which after the advent of the British rule became secularized and developed into government schools with Malay as the medium of instruction. In 1916 these schools were remodelled according to the recommendations in the Winstedt Report. There were also three other streams of schools using either Chinese, Tamil, or English as the language of instruction. The first major development in higher education was the establishment of the Malay College at Kuala Kangsar in 1905 "to prepare the highborn Malays" for administrative service. Among other institutions of higher education are the University of Malaya established at Singapore in 1949 and a division of this university established at Kuala Lumpur in 1959; this division became the National University of the Federation of Malaya in 1961; the division at Singapore is called the University of Malaya. The second university in Singapore, Nanyang University, sponsored by a group of wealthy Chinese businessmen in 1953 and incorporated in 1958, is predominantly Chinese in character.

The Ordinance of 1957 as amended by the Education Act of 1960 provides the legal framework of the present structure of education in Malaysia. It is based on the concept of a single national school system, a unified teaching service, and a federal inspectorate, with local authorities for primary and vocational education. Under the first Malaysia Plan, 1966–70, there were striking gains: enrollment in primary schools exceeded 90 percent of the age group; enrollment in secondary schools rose by 70 percent and, in the university stage, by 200 percent.

Muslim and British influences in Pakistan

Pakistan. The educational system that grew up in the subcontinent during 2,000 years before the advent of the British was in turn Brahminic, Buddhist, and Islāmic in character. The Muslim educational system became the mainstream of education from the 11th to the 18th century. Although British rule was established in 1757 over parts of the subcontinent, no significant step in education was taken by the new government until 1835, when a few schools teaching in English were set up in the principal towns. The first universities, purely affiliating in character and modelled on London University, were established in 1857. The period between World War I and the end of World War II marked a steady but unplanned growth in education and intensification of the struggle for independence. On August 14, 1947, Pakistan emerged as a national sovereign state.

For the new state the initial years proved to be a period essentially of consolidation and exploration. The constitution of Pakistan adopted in 1956 recognized the obligation of the state to provide education among other basic necessities of life, and education was an important element of Pakistan's three five-year plans covering the period 1955–70. As recommended by the Commission on National Education in 1960, the educational system was redesigned in both structure and content. Under the new education policy adopted in March 1970, further reforms were launched to make the educational system more responsive to the goals of national development. Notable among them were measures for a faster growth of scientific, technical, and vocational education and greater autonomy for the institutions of higher education as a fillip to research and creative work. An index to the progress of education during the postindependence period was the rapid rise in enrollment at all levels between 1947–48 and 1969–70, threefold in primary, fivefold in secondary, and nearly 15-fold in higher education.

Muslim and Dutch influences in Indonesia

Indonesia. The educational system in Indonesia was profoundly influenced by the Hindu and Buddhist religions from AD 100 to 1500 and by Islām from 1400 to 1600. The first schools on Western lines were established during the Portuguese and Spanish period (1500–1600). In 1848 the Dutch government for the first time officially assumed responsibility for the provision of education for the native population. The educational policy issued through the Royal Decree of 1892 divided the native primary schools into first- and second-class schools, the former for the Indonesian upper classes and the latter for the masses. The impact of the growth of liberal ideas in Europe could be seen with the advent of the 20th century in the provision for teaching Western science and culture to the native children.

After final independence of the country from the Dutch in 1949, the educational system was substantially remodelled. Article 3 of the provisional constitution of the Republic of Indonesia recognized the right of every Indonesian citizen to education according to his free choice. The Ministry of Education and Culture had carried out a ten-year program of development in education during 1950–60 and issued seven major objectives (*sapta usaha tama*) for educational development in schools and universities, followed in October 1960 by "five principles of Indonesian education" (*pantja wardhena*). The first

Five-Year Plan (1969–70 to 1973–74), adopted in 1968, aimed at linking education to "the needs and possibilities of economic and social development." Notable gains were made between 1950–51 and 1962–63, as indicated by the substantial increase in enrollments—twofold in primary, more than eightfold in secondary, and over tenfold in higher education.

Philippines. The pre-Spanish Philippines possessed a system of writing similar to Arabic, and it was not uncommon for adults to know how to read and write. Inculcation of reverence for the god Bathala, obedience to authority, loyalty to the family or clan, and respect for truth and righteousness were the chief aims of education.

Spanish and American influences in the Philippines

After the Spanish conquest, apart from parochial schools run by missionaries, the first educational institutions to be established on Western lines were in higher education. The Santo Tomás College, established in 1611 and raised to the status of a university in 1644–45, served for centuries as a centre of intellectual strength to the Filipino people. Educational growth, however, was slow, mainly because of lack of government support.

With the advent of the American rule, the stress laid on universal primary education in the policy announced by U.S. Pres. William McKinley on April 7, 1900, led to a rapid growth in primary education. A number of institutions of higher education were also established between 1907 and 1941, including the University of the Philippines (1908). Private institutions of higher education, however, far outnumbered the state institutions, thus indicating a trend that remains a characteristic feature of the system of higher education in the Philippines.

The new Republic of the Philippines emerging after World War II launched a national plan for reconstruction and development of education followed by the five-year socioeconomic program in 1963. The Four-Year National Plan (1971–74) and the recommendations of the Presidential Commission to Survey Philippine Education (1970) envisaged far-reaching reforms to make education "responsive to the challenge of modernization and the goals of national development." During 1950–65 the country made impressive progress in education. The number of technical and vocational schools doubled from 112 to 224 during 1959–69, and 102,070 students were enrolled under the Bureau of Vocational Education programs in 1969–70.

Thailand. The traditional system of education in Thailand was inspired by the Thai philosophy of life

The Thai philosophy

based on (1) dedication to Theravāda Buddhism, with its emphasis on moral excellence, generosity, and moderation, (2) veneration for the king, and (3) loyalty to the family. The beginning of the present system of education can be traced to 1887, when King Chulalongkorn set up a department of education with foreign advisers, mostly English educationists. Gradually, temple schools were established. The process of westernization of education was strengthened with the establishment of a Medical School in 1888, a Law School in 1897, and a Royal Pages' School in 1902 for the general education of "the sons of the nobility." It was converted into the Civil Service College in 1910.

The abolition of the absolute monarchy after the 1932 revolution led to the broadening of higher education with cadres of high-level specialists in various fields. By 1953 the following state institutions of higher education had come into existence: Chulalongkorn University, Thammasat University (of Moral and Political Sciences), the University of Medical Sciences, Kasetsart University for Agriculture and Veterinary Sciences, Silpakorn University for Fine Arts, and the College of Education.

Thai is the medium of education at all levels, but English is taught as a second language from grade five. The educational system is organized by the state, and all registered institutions are under its supervision. Compulsory primary education for four years—introduced by law in 1921 and since raised to seven years—has progressed well, with 5,700,000 children (84 percent of the age group) enrolled in 1969.

Cambodia. For nearly four centuries before the advent of the French in 1863, the educational system in Cambodia grew up around Theravāda Buddhism, which became the established religion toward the end of 1430 under the Thai influence. In 1887 Cambodia became a part of the French Indochina Union and did not achieve complete independence until 1954. Pagoda schools, imparting education at the primary level, were remodelled and integrated into the primary school system administered by the Ministry of Education.

Indochinese education under colonialism and war

Modern higher education is a fairly recent development, dating from 1946, when a school for health officers was established. A number of other institutions of higher education came into being between 1949 and 1958. The Royal Khmer University was inaugurated in 1960, incorporating some of the existing institutions of higher education. A striking feature of later plans had been the increase of expenditures on both higher education and vocational education (in relation to primary education), though plans were frustrated by civil war.

Laos. The pagoda school was the main unit of the traditional educational system in Laos. Efforts toward modernization came in the wake of the country's becoming a French protectorate in 1893 and finally after its inclusion in 1904 within the French Indochina Union. The medium of education was changed to French when the French Education Service was created.

After independence, education developed rapidly, as indicated by the rise in enrollment between 1956 and 1963 from 75,000 to 133,000 in the primary and from 1,500 to 4,000 in the secondary stage. This improvement was made in spite of the loss of schools in the territory controlled by the antigovernment Pathet Lao in the civil war. The rural areas have been served mainly by pagoda schools, village primary schools, and Rural Community Centres (one for every five villages in 1963–64). Primary schools with a full six-year course are for the most part in towns and townships. Plans were made to treble enrollments by 1980.

Vietnam. Long Chinese domination over the emperors of Vietnam resulted in strong Confucian and Taoist influences on the Vietnamese educational system, though it centred on Buddhism. The establishment of French rule, commencing with the occupation of Saigon in 1859, led to the gradual growth of a pattern of education similar to that of the rest of the former Indochina Union. Vietnamese attempts to develop education were thwarted by the continued fighting from World War II onward and, after the partition of the country in 1954, by fighting between the South Vietnamese government forces and the Vietcong. The plans for national development have been tentative in view of the uncertainty created by the war. A notable reform in the educational systems in both North and South Vietnam, however, was the diversification of education and provision of technical and vocational education in secondary and higher levels.

(M.S.H.)

BIBLIOGRAPHY. A very large number of general histories of education have appeared since World War II, and publication of such works seems always to be increasing. A few are regularly reviewed in the *History of Education Quarterly* (1961– ; formerly the *History of Education Journal*, 1949–60), which, however, concentrates mostly on items of interest to Americans. All the general histories seem concerned with the educational history of either one country or the West. Even books in English entitled *A History of Education* tend to centre on Western education; non-Western developments, if treated at all, are usually treated in the initial chapters on ancient civilization or in the very last chapters in terms of the Westernizing of such countries as Japan and India; non-Western events between these extremes are usually left unnoticed. Medieval Muslim education is frequently treated because of its impact upon Western developments.

Given these limitations, the best general histories of education are WILLIAM BOYD and EDMUND J. KING, *The History of Western Education*, 8th ed. (1966); R. FREEMAN BUTTS, *A Cultural History of Western Education*, 2nd ed. (1955); S.E. FROST, *Historical and Philosophical Foundations of Western Education* (1966); HARRY G. GOOD and JAMES D. TELLER, *A History of Western Education*, 3rd ed. (1969); ADOLPH E. MEYER, *An Educational History of the Western World* (1965); JAMES MULHERN, *A History of Education: A Social Interpretation*, 2nd ed. (1959); MEHDI NAKOSTEEN,

The History and Philosophy of Education (1965); I.N. THUT, *The Story of Education: Philosophical and Historical Foundations* (1957); ROBERT ULICH, *The Education of Nations: A Comparison in Historical Perspective*, rev. ed. (1967), and *The History of Educational Thought*, rev. ed. (1968); and JOHN E. WISE, *The History of Education* (1964).

Despite its age, the five-volume *Cyclopedia of Education*, ed. by the American educator PAUL MONROE (1911–13, reprinted 1968), remains one of the most comprehensive and best sources of information on many individual historical topics. Its excellence was early recognized; when the English educator FOSTER WATSON developed his four-volume *Encyclopaedia and Dictionary of Education* (1921–22), he acknowledged the influence of Monroe's opus; Foster's work, incidentally, though largely written by Britishers, had many foreign contributors, including John Dewey and Benedetto Croce. There have since appeared many other national encyclopaedias of historical interest in education. The Japanese educational encyclopaedia *Kyokkugaku Jiten*, 6 vol. (1957–59), gives especially great attention to both Japanese and foreign educational history; regrettably there is no English version.

For historical surveys of individual countries, the following are a few of the useful works: W.H.G. ARMYTAGE, *Four Hundred Years of English Education*, 2nd ed. (1970); S.J. CURTIS, *History of Education in Great Britain*, 5th ed. (1963); CHARLES FOURRIER, *L'Enseignement français*, vol. 1, *De l'antiquité à la révolution* (1964) and vol. 2, *De 1789 à 1945* (1965); NICHOLAS HANS, *History of Russian Educational Policy, 1701–1917* (1931, reprinted 1964); WILLIAM H.E. JOHNSON, *Russia's Educational Heritage* (1950, reprinted 1969); ADOLPH E. MEYER, *An Educational History of the American People*, 2nd ed. (1967); R. FREEMAN BUTTS and LAWRENCE A. CREMIN, *A History of Education in American Culture* (1953); CHARLES E. PHILLIPS, *The Development of Education in Canada* (1957); F. HENRY JOHNSON, *A Brief History of Canadian Education* (1968); TOKIOMI KAIGO, *Japanese Education: Its Past and Present*, 2nd ed. (1968); T.N. SIQUEIRA, *The Education of India*, 4th ed. (1952); and PING WEN KUO, *The Chinese System of Public Education* (1915).

Education in primitive and early civilized cultures: Monographs dealing solely with education in primitive or primordial civilizations are not common; information is to be found chiefly in works treating larger subjects. The best for primitive education are YEHUDI A. COHEN, *The Transition from Childhood to Adolescence* (1964); MARGARET MEAD, *Continuities in Cultural Evolution* (1964); and GEORGE D. SPINDLER (ed.), *Education and Culture: Anthropological Approaches* (1963). An elaborate illustration of primitive education is provided in JOHN W.M. WHITING, *Becoming a Kwoma* (1941). Relatively rich descriptions and interpretations of Egyptian and Mesopotamian education are offered in JAMES MULHERN, *A History of Education: A Social Interpretation*, 2nd ed. (1959); and THOMAS WOODY, *Life and Education in Early Societies* (1949, reprinted 1970). TOM B. JONES, *Ancient Civilization*, rev. ed. (1964), sheds light upon the development of several ancient civilizations, including those of the Near East and Egypt. HOWARD S. GALT, *A History of Chinese Educational Institutions*, vol. 1 (1951); and KWANG-CHIH CHANG, *The Archaeology of Ancient China*, rev. ed. (1971), illuminate the historical background for North China. The important sources for New World civilizations are ABRAHAM ARIAS-LARRETA, *Literaturas aborígenes: Azteca, incaica, maya–quiche* (1951; Eng. trans., *Pre-Columbian Literatures: Aztec, Incan, Maya–Quiché*, 1964); MIGUEL LEON-PORTILLA, *Las literaturas precolombinas de México* (1964; Eng. trans., *Pre-Columbian Literatures of Mexico*, 1969); SYLVANUS GRISWOLD MORLEY, *The Ancient Maya*, 3rd ed. (1956); THEODORE A. WILLARD, *The Lost Empires of the Itzaes and Mayas* (1933); J. ERIC S. THOMPSON, *The Rise and Fall of Maya Civilization* (1954); LOUIS BAUDIN, *La Vie quotidienne au temps des derniers Incas* (1955; Eng. trans., *Daily Life in Peru Under the Last Incas*, 1961); and A. HYATT VERRILL, *Old Civilizations of the New World*, new ed. (1938).

Education in classical cultures: Only a limited number of works deal solely with ancient Asian education. A short, broad survey of events from the dawn of Indian civilization is contained in T.N. SIQUEIRA (*op. cit.*). More specifically for ancient India, D.G. APTE, *Our Educational Heritage: The Schools of Background of Hindu Education* (1961), is a brief, elementary account; and R.K. MOOKERJI, *Ancient Indian Education, or; Brahmanical and Buddhist*, 4th ed. (1969), is a somewhat more sophisticated account for advanced students who are already acquainted with the broad outlines. FRANK E. KEAY, *Indian Education in Ancient and Later Times*, new ed. (1938), surveys education from the Vedic period (on up to the advent of British rule). A detailed description of ancient Chinese education from the earliest times to the 10th century AD is given in HOWARD S. GALT (*op. cit.*); the further development of this scholarly work was cut short by the author's death. PING WEN KUO (*op. cit.*), is a succinct but well-organized account of Chinese education from ancient times (on up to the beginning of the 20th century). Some excellent accounts of education among the ancient Hebrews and Jews are NATHAN DRAZIN, *History of Jewish Education from 515 B.C.E. to 220 C.E.* (1940); ELIEZER EBNER, *Elementary Education in Ancient Israel During the Tannaitic Period (10–20 C.E.)* (1956); and NATHAN MORRIS, *The Jewish School: An Introduction to the History of Jewish Education* (1937). For the ancient West, HENRI I. MARROU, *A History of Education in Antiquity* (Eng. trans. 1956), provides a general survey of Greek and Roman education, but to be preferred to this inadequate English translation of the 1st French edition is the 6th enlarged French edition, *Histoire de l'éducation dans l'antiquité* (1965). Other important general surveys of the West include EDGAR B. CASTLE, *Ancient Education and Today* (1961); JOHN F. DOBSON, *Ancient Education and Its Meaning to Us* (1932); FRANK P. GRAVES, *A History of Education Before the Middle Ages* (1909); S.S. LAURIE, *Historical Survey of Pre-Christian Education*, 2nd ed. rev. (1900, reprinted 1970); and WILLIAM A. SMITH, *Ancient Education* (1955). On special but important topics there are JOHN P. MAHAFFY, *The Progress of Hellenism in Alexander's Empire* (1905); MARTIN P. NILSSON, *Die hellenistische Schule* (1955); OSCAR W. REINMUTH, *The Ephebic Inscriptions of the Fourth Century B.C.* (1971); and MARTIN L. CLARKE, *Higher Education in the Ancient World* (1971). Specifically on Roman schools there are AUBREY O. GWYNN, *Roman Education from Cicero to Quintilian* (1926, reprinted 1966); and THEODORE J. HAARHOFF, *Schools of Gaul: A Study of Pagan and Christian Education in the Last Century of the Western Empire* (1920).

Education in Persian, Byzantine, early Russian, and Islāmic civilizations: One of the best detailed studies of ancient Persian culture and education is MANECKJI N. DHALLA, *Zoroastrian Civilization* (1922). JAMES DARMESTETER (trans.), *The Zend-Avesta*, 2 vol., 2nd ed. of vol. 1 (1895), is excellent for the Zoroastrian foundation of ancient Persian civilization, while A.V.W. JACKSON, *Zoroaster, the Prophet of Ancient Iran* (1899), is a briefer, though still scholarly, survey of Zoroastrianism. One of the best summaries of Byzantine education is GEORGINA BUCKLER, "Byzantine Education," in NORMAN H. BAYNES and HENRY ST. L.B. MOSS (eds.), *Byzantium: An Introduction to East Roman Civilization* (1948). Brief treatments of Byzantine education are also contained in GERVASE MATHEW, *Byzantine Aesthetics* (1963); DEAN A. MILLER, *The Byzantine Tradition* (1966); CHARLES DIEHL, *Byzance, grandeur et décadence* (1919; Eng. trans., *Byzantium: Greatness and Decline*, 1957); and ROBERT BYRON, *The Byzantine Achievement: An Historical Perspective, A.D. 330–1453* (1929, reprinted 1964). A good brief account of early Russian education may be found in THOMAS DARLINGTON, *Education in Russia* (1909). Kievan culture and education are treated in BORIS D. GREKOV, *The Culture of Kiev Rūs* (1947; orig. pub. in Russian, 1944); early Ukrainian education is sketched in MICHAEL S. HRUSHEVSKY, *A History of the Ukraine* (1941; orig. pub. in Russian, 1918). MEHDI NAKOSTEEN, *The History of Islamic Origins of Western Education, A.D. 800–1350* (1964), is an extensive introductory, documented survey of medieval Muslim education and its impact upon Western education. BAYARD DODGE, *Muslim Education in Medieval Times* (1962), is an excellent brief survey, as are B.S. KHUDA, "The Educational System of the Muslims in the Middle Ages," *Islamic Culture*, 1:442–472 (1927); and AHMAD SHALABI, *History of Muslim Education* (1954). Two other significant works are DE LACY E. O'LEARY, *How Greek Science Passed to the Arabs* (1949) and *Arabic Thought and Its Place in History*, rev. ed. (1939, reprinted 1963).

The European Middle Ages: Some of the best surveys of medieval European education are contained in the general histories of education listed at the beginning of this bibliography. On the earlier periods, some useful works are THEODORE J. HAARHOFF, *The Schools of Gaul: A Study of Pagan and Christian Education in the Last Century of the Western Empire*, 2nd ed. (1958); HUGH GRAHAM, *The Early Irish Monastic Schools* (1923); W.G. HANSON, *The Early Monastic Schools of Ireland, Their Missionaries, Saints and Scholars* (1927); and JAMES B. MULLINGER, *The Schools of Charles the Great and the Restoration of Education in the Ninth Century* (1877). For later periods there are two significant works in French: EMILE LESNE, *Les Écoles de la fin du VIII^e siècle à la fin du XII^e siècle* (1940); and PHILIPPE DELHAYE, "L'Organisation scholaire au XII^e siècle," *Traditio*, 5:211–268 (1947). On significant special topics there are SIR JOHN EDWIN SANDYS, *A History of Classical Scholarship from the Sixth Century B.C. to the End of the Middle Ages*, 3rd ed. (1921); REGINALD L. POOLE, *Illustrations of the History of*

Medieval Thought and Learning, 2nd ed. rev. (1920); JAMES W. THOMPSON, *The Medieval Library* (1939); JAMES A. CORBETT (ed.), *The De Instructione Puerorum of William of Tournai* (1955); A.L. GABRIEL, *The Educational Ideas of Vincent of Beauvais* (1956); and CLARA PATRICIA MCMAHON, *Education in Fifteenth-Century England* (1947, reprinted 1968). There are many studies of medieval universities, a few of the most important being HASTINGS RASHDALL, *The Universities of Europe in the Middle Ages*, new ed., 3 vol. (1936); ROBERT S. RAIT, *Life in the Medieval University* (1912, reprinted 1969); CHARLES H. HASKINS, *The Rise of Universities* (1923; paperback ed., 1957); and A.L. GABRIEL, *Garlandia: Studies in the History of the Medieval University* (1969).

Education in Asian civilizations, c. 700 to the eve of Western influence: India's medieval, or Muslim, period is well covered in three works: S.M. JAFFAR, *Education in Muslim India* (1936), is a vivid account based on contemporary chronicles and other documents; N.N. LAW, *Promotion of Learning in India During Muhammadan Rule* (1916), surveys the efforts of Muslim rulers to promote learning in India and contains very useful illustrations; MANSOORUDDIN QURAISHI, *A Survey of Muslim Education in the Middle Ages* (1956), in focussing on the advent of the Muslims in India and on their dissemination of Islāmic teaching, relates how this Muslim education acquired an Indian character. For education in China, EDWARD A. KRACKE, *Civil Service in Early Sung China, 960–1067* (1953), may be added to the books of HOWARD S. GALT (*op. cit.*), for the period up to the 10th century; and PING WEN KUO (*op. cit.*). For general surveys of the history of Japanese education, the chief works in English are TOKIOMI KAIGO, *Japanese Education: Its Past and Present*, 2nd ed. (1968); and the MINISTRY OF EDUCATION (JAPAN), *An Outline History of Japanese Education, Literature and Arts* (1876). RONALD P. DORE, *Education in Tokugawa, Japan* (1965), provides good coverage of the period immediately prior to the modern.

European Renaissance and Reformation: Three works in English by WILLIAM HARRISON WOODWARD are useful introductions to Renaissance education: *Studies in Education During the Age of the Renaissance, 1400–1600* (1906, reprinted 1965), *Vittorino da Feltre and Other Humanist Educators* (1897, reprinted 1964), and *Desiderius Erasmus Concerning the Aim and Method of Education* (1904, reprinted 1964). HANS BARON, *The Crisis of the Early Italian Renaissance*, 2 vol. (1955; rev. ed., 1 vol., 1966); STANFORD E. LEHMBERG, *Sir Thomas Elyot: Tudor Humanist* (1960); and FOSTER WATSON, *Vives on Education: A Translation of the De tradendis disciplinis* (1913), are other important treatments of the Renaissance. In Italian, two excellent works by EUGENIO GARIN are *L'Educazione in Europa, 1400–1600* (1957), which covers the Humanistic movement, the Renaissance, and the Reformation and Counter-Reformation in Europe generally, and *L'Educazione Umanistica in Italia* (1949), an earlier work covering the effects of the Humanistic movement on education in Italy, where the movement started. JOHN LAWSON, *Mediaeval Education and the Reformation* (1967), contains an analysis of the transformation of the schools and universities as a result of the Reformation, especially in terms of the new curricula. Other important works on the Reformation and Counter-Reformation are FREDERICK EBY (ed.), *Early Protestant Educators: The Educational Writings of Martin Luther, John Calvin, and Other Leaders of Protestant Thought* (1931, reprinted 1971); F.V.N. PAINTER, *Luther on Education* (1889, reprinted 1965); ALLAN P. FARRELL, *The Jesuit Code of Liberal Education: Development and Scope of the Ratio Studiorum* (1938); EDWARD A. FITZPATRICK (ed.), *St. Ignatius and the Ratio Studiorum* (1933); and HOWARD C. BARNARD, *The Port-Royalists on Education* (1918).

European education in the 17th and 18th centuries: The general histories of education cited at the beginning of this bibliography offer good accounts of the 17th, 18th, and 19th centuries, when educational theory flourished as it never had before and when educational institutions proliferated. For the 17th century, an additional useful work is JOHN WILLIAM ADAMSON, *Pioneers of Modern Education, 1600–1700* (1905). Some major theories are also covered in MATTHEW SPINKA, *John Amos Comenius, That Incomparable Moravian* (1943); WILL S. MONROE, *Comenius and the Beginnings of Educational Reform* (1900, reprinted 1971); and JOHN WILLIAM ADAMSON (ed.), *The Educational Writings of John Locke* (1912). HOWARD C. BARNARD, *The French Tradition in Education, Ramus to Mme. Necker de Saussure* (1922, reprinted 1970), covers France down to the 18th century. For the 18th century itself, useful introductions are NICHOLAS A. HANS, *New Trends in Education in the Eighteenth Century* (1951); DAVID SALMON, *The Education of the Poor in the Eighteenth Century* (1908); FRANCOIS DE LA FONTAINERIE (ed. and trans.), *French Liberalism and Education in the Eighteenth Century* (1932); and HERBERT MCLACHLAN, *English Education Under the Test Acts; Being the History of the Nonconformist Academies, 1662–1820* (1931). For information on the major theorists there are AUGUSTE PINLOCHE, *La Réforme de l'éducation en Allemagne au dix-huitième siècle: Basedow et le philanthropinisme* (1889); WILLIAM BOYD, *The Educational Theory of Jean Jacques Rousseau* (1911, reprinted 1963), and *The Minor Educational Writings of Jean Jacques Rousseau* (1911, reprinted 1962); and RICHARD L. ARCHER (ed.), *Rousseau on Education* (1912). The best studies available on colonial Latin America are JOSE LUIS BECERRA LOPEZ, *La organización de los estudios en la Nueva España* (1963); and JOHN T. LANNING, *Academic Culture in the Spanish Colonies* (1940, reprinted 1971).

Western education in the 19th century: As already noted, the general works listed at the beginning of this bibliography treat the 19th century in excellent fashion. There are useful specialized works, however. The best works on the theorists are KATE SILBER, *Pestalozzi: The Man and His Work*, 2nd ed. (1965); WILLIAM H. KILPATRICK, *Froebel's Kindergarten Principles Critically Examined* (1916); CHRISTIAN UFER, *Vorschule der Pädagogik Herbarts*, 5th ed. (1894; Eng. trans., *Introduction to the Pedagogy of Herbart*, 1901); FRANK H. HAYWARD, *The Meaning of Education As Interpreted by Herbart* (1907); and E.I.F. WILLIAMS, *Horace Mann, Educational Statesman* (1937). In this century of German pre-eminence in education, it is worthwhile to consult WILHELM H. LEXIS, *A General View of the History and Organisation of Public Education in the German Empire* (1904); WILLY MOOG, *Geschichte der Pädagogik*, vol. 3, *Die Pädagogik der Neuzeit vom 18. Jahrhundert bis zur Gegenwart* (1933); and FRIEDRICH PAULSEN, *Das deutsche Bildungswesen in seiner geschichtlichen Entwicklung* (1906; Eng. trans., *German Education, Past and Present*, 1908), this last being a classic analysis. For England there are JOHN W. ADAMSON, *English Education, 1789–1902* (1930); and R.L. ARCHER, *Secondary Education in the Nineteenth Century* (1921). For 19th- and early-20th-century Russia, there is PATRICK L. ALSTON, *Education and the State in Tsarist Russia* (1969). Two interesting specialized works are A.G. AUSTIN, *Australian Education, 1788–1900* (1961); and ARTHUR G. BUTCHERS, *Young New Zealand* (1929). For India during the era of British rule, there are SYED NURULLAH and J.P. NAIK, *A History of Education in India During the British Period*, 2nd ed. rev. (1951); S.N. MUKERJI, *History of Education in India: Modern Period*, 5th ed. (1966); and B.D. SRIVASTAVA, *The Development of Modern Indian Education*, 2nd rev. ed. (1964). The works of TOKIOMI KAIGO and the MINISTRY OF EDUCATION (JAPAN), already cited for Japanese education, are useful here.

Education in the 20th century: All the works listed at the beginning of this bibliography contain surveys of 20th-century practices and theories. ADOLPH E. MEYER, *The Development of Education in the 20th Century*, 2nd ed. (1949), treats the development of education in a generalized story form and is one of the better books on the history of education in the 20th century. Good descriptions of the various contemporary philosophies of education may be found in JOHN PAUL STRAIN (comp.), *Modern Philosophies of Education* (1971); THEODORE B.H. BRAMELD, *Patterns of Educational Philosophy* (1971); and JOHN S. BRUBACHER, *Modern Philosophies of Education*, 4th ed. (1969). Although otherwise wholly oriented toward American institutions and practices, LEE C. DEIGHTON (ed.), *The Encyclopedia of Education*, 10 vol. (1971), does contain individual articles on the nations of the world and, in these articles, offers a measure of recent history. More detailed surveys, often with a sociological slant, are being offered in the series of small volumes being issued by the Commonwealth and International Library—each, though separately authored, with the title *Society, Schools, and Progress in*, followed by the name of the country or region (*e.g.*, *Society, Schools, and Progress in Australia; Society, Schools, and Progress in Eastern Europe*); over a dozen volumes have appeared so far on systems, for example, in Australia, Canada, China, eastern Europe, England, France, India, Israel, Nigeria, Peru, Scandinavia, Tanzania, the U.S., and the West Indies. An excellent cross-national comparison is to be found also in JOHN F. CRAMER and GEORGE S. BROWNE, *Contemporary Education: A Comparative Study of National Systems*, 2nd ed. (1965).

Works on individual countries and most regions are legion; only a sample can be cited here. For Europe there are EDMUND J. KING, *Other Schools and Ours*, 3rd ed. (1967), and *Education and Development in Western Europe* (1969); URSULA K. SPRINGER, *Recent Curriculum Developments in France, West Germany, and Italy: A Study of Trends at the Middle Level of Education* (1969); RAYMOND POIGNANT, *L'Enseignement dans les pays du Marché commun, étude comparative sur l'organisation et l'état de développement de l'enseignement dans les pays du Marché commun, aux États-Unis, en Grande-Bretagne et en U.R.S.S.* (1965; Eng. trans., *Education and Development in Western Europe, the United States, and the*

U.S.S.R.: A Comparative Study, 1969); WILLIAM O. LESTER SMITH, *Education in Great Britain*, 5th ed. (1967); JEAN CAPELLE, *L'École de demain reste à faire* (1966; Eng. trans., *Tomorrow's Education: The French Experience*, 1967); JOACHIM H. KNOLL, *The German Educational System* (1967); and HERMAN RUGE, *Educational Systems in Scandinavia* (1962). For the United States there are LAWRENCE A. CREMIN, *The Transformation of the School: Progressivism in American Education, 1876–1957* (1961); WILLIAM E. DRAKE, *The American School in Transition* (1955); NEWTON EDWARDS and HERMAN G. RICHEY, *The School in the American Social Order*, 2nd ed. (1963); and S. ALEXANDER RIPPA, *Education in a Free Society*, 2nd ed. (1971). For elder members of the British Commonwealth, there are, for Canada, FRANK MacKINNON, *The Politics of Education* (1960); and FREEMAN K. STEWART, *Interprovincial Co-operation in Education* (1957); for Australia, UNESCO, *Compulsory Education in Australia* (1962); and for New Zealand, ARTHUR G. BUTCHERS, *Education in New Zealand* (1930); and WILLIAM B. SUTCH, *The Quest for Security in New Zealand, 1840 to 1966* (1966). For education under Communism, two general treatments are WASYL SHIMONIAK, *Communist Education: Its History, Philosophy, and Politics* (1970); and EDMUND J. KING (ed.), *Communist Education* (1963). For the Soviet Union, two important analyses in German have been written by OSKAR ANWEILER: *Geschichte der Schule und Pädagogik in Russland, vom Ende des Zarenreiches bis zum Beginn der Stalin-Ära* (1964), which covers the 20th century up to the early 1930s, and *Die Sowjetpadägogik in der Welt von heute* (1968), which focusses largely on the 1950s and 1960s. Other important works, in English, are JAAN PENNAR, IVAN I. BAKALO, and GEORGE Z.F. BEREDAY, *Modernization and Diversity in Soviet Education, with Special Reference to Nationality Groups* (1971); GEORGE Z.F. BEREDAY, WILLIAM W. BRICKMAN, and GERALD H. READ (eds.), *The Changing Soviet School* (1960); GEORGE Z.F. BEREDAY and JAAN PENNAR (eds.), *The Politics of Soviet Education* (1960); and NIGEL GRANT, *Soviet Education* (1964). For education in 20th-century China prior to Communist rule, the most useful works are KNIGHT BIGGERSTAFF, *The Earliest Modern Government Schools in China* (1961); WOLFGANG FRANKE, *The Reform and Abolition of the Traditional Chinese Examination System* (1960); and THEODORE E. HSIAO, *The History of Modern Education in China* (1932). Post-1949 education in mainland China is well covered in R.F. PRICE, *Education in Communist China* (1970); and THEODORE H.E. CHEN, *The Thought Reform of the Chinese Intellectuals* (1960). Three works on Japanese education, which largely relate it to socio-economic development, are the MINISTRY OF EDUCATION (*op. cit.*), the JAPANESE NATIONAL COMMISSION FOR UNESCO, *The Role of Education in the Social and Economic Development of Japan* (1966); and HERBERT PASSIN, *Society and Education in Japan* (1965). For India two works by S.N. MUKERJI are especially useful: *Education in India, Today and Tomorrow*, 6th ed. (1969), which focusses on current problems and policies, and *History of Education in India: Modern Period*, 5th ed. (1966), which treats mostly of the British period. To these may be added B.D. SRIVASTAVA, *The Development of Modern Indian Education*, rev. ed. (1963). Racial and linguistic divisions in South African education are treated in S. PIENAAR and ANTHONY SAMPSON, *South Africa: Two Views of Separate Development* (1960). Nation building in Africa has elicited several works on education and development in Africa, past and present; the most significant recent works are ABDOU MOUMOUNI, *L'Éducation en Afrique* (1964; Eng. trans., 1968), which largely concentrates on former French colonies; JOHN CAMERON, *The Development of Education in East Africa* (1970), which is concerned with former British colonies; K.A. BUSIA, *Purposeful Education for Africa* (1964); JOHN W. HANSON, *Imagination and Hallucination in African Education* (1965); and L. GRAY COWAN, JAMES O'CONNELL, and DAVID G. SCANLON (eds.), *Education and Nation-Building in Africa* (1965). The best surveys of the Arab countries are RODERIC D. MATTHEWS and MATTA AKRAWI, *Education in Arab Countries of the Near East* (1949); ABDEL AZIZ EL-SAYED, "Education in the Arab World," *Mid East*, vol. 7 (1967); and FAHIM I. QUBAIN, *Education and Science in the Arab World* (1966). Historical surveys of education in Latin America are relatively poor, except for those dealing with certain countries, such as Mexico. The most useful works are ROBERT J. HAVIGHURST, *La sociedad y la educación en América Latina* (1962); HAROLD R.W. BENJAMIN, *Higher Education in the American Republics* (1965); JOSEFINA VAZQUEZ DE KNAUTH, *Nacionalismo y educación en México* (1970); and ROBERT J. HAVIGHURST and JOAO ROBERTO MOREIRA, *Society and Education in Brazil* (1965). Surveys of education in Southeast Asia are even scarcer, the best studies being MUHAMMAD SHAMSUL HUQ, *Education and Development Strategy in South and Southeast Asia* (1965), which analyzes planned educational development in Southeast Asia with special reference to Pakistan, India, Indonesia, and the Philippines; and UNESCO and the INTERNATIONAL ASSOCIATION OF UNIVERSITIES, *Higher Education and Development in Southeast Asia*, 3 vol. (1967), which contains useful background materials in the form of country profiles.

Education, Philosophy of

Philosophy of education is a field of inquiry, speculation, and application in which philosophical methods are applied to the study of a problem, topic, or issue in education. Characteristic of these methods is the attempt to think as accurately, clearly, coherently, and systematically as possible. Analytical philosophers would say that philosophy of education should end with the attempt to clarify and justify educational statements and arguments. In practice, however, the field includes much more than that. It considers as relevant material much that has been written on education by influential philosophers of the past. There is, therefore, much overlap with the field of history of education, and ultimately no clear demarcation can be drawn between the two fields, which nourish and illuminate each other in their interconnectedness (see EDUCATION, HISTORY OF). Many philosophers of education also go beyond analysis in being concerned with establishing a commitment to value judgments and substantive positions. They take pains to attempt to clarify and justify those judgments and positions on the grounds that clear and substantiated judgments have greater probability of being sound.

Different conceptions of the philosophy of education

The philosophy of education has a special concern with the *applications* of knowledge and theories. Thus, many philosophers of education are especially interested in the relationship between theory and practice. Moreover, they are often concerned with the ways in which philosophy relates to other fields of study in the attempt to shed light on educational problems and issues. This gives them a wide-angled approach to education, which some philosophers have called "educational theory" to distinguish it from a more narrowly analytical form of philosophy of education.

With regard to the term "education," there is a similar spectrum of views ranging from the narrow view of education as that which goes on in schools and universities to a definition of education as all those experiences that affect the growth and development of a person throughout life. The former view has tended to give way, with increased recognition of the crucially important part that informal experiences and relationships play in determining what and how an individual learns.

COMMON ASSUMPTIONS ABOUT HUMAN LEARNING

Symbolization. First, it is to be noted that human learning is largely dominated by symbolic processes. Much of the learning that man acquires during his lifetime is gained through his growing ability to understand and manipulate symbols—verbal, mathematical, artistic, musical, and so on. This symbolic emphasis gives human learning much of its power. It brings power because symbols enable man to deal abstractly and at a high level of generality with words, data, and ideas. Thus, he can learn to think rapidly, to link varied items in fruitful ways, and to create shortcuts to new knowledge.

Dangers of abstraction

The symbolic emphasis also brings dangers. It can trap man into circling around at a high level of generality without ever feeling the need to tie his abstractions to concrete applications. Schooling thus can become an apparently self-justifying cycle, which in fact fails to pay off in terms of improving men's lives. Moreover, since learners assimilate and master these symbolic processes at different rates, it is tempting for educators to identify all education with symbol manipulation, to classify those who take longer to master the process as inferior, and to reserve the privileges of higher schooling for those who master this particular process rapidly. This is to mistake a part for the whole and leads to enormous losses of human power and development.

Human motivation. Motivations to learning are more variable in man than in subhuman species. In other animals learning patterns develop largely through instinctual

motivations. This means that lower animals need less training than humans before they are independent and self-reliant. Human beings are the most dependent of creatures when young, and they take longest to educate for independent activity. It is precisely this long period of dependence and education that constitutes man's superiority over lower animals, for it is in this period that the growing human being absorbs much of his culture and develops the skills and knowledge that enable him to build on the work of his predecessors. His lower degree of reliance on innate mechanisms also means that man is more flexible in his responses and is capable of adjusting those responses in the light of previous experiences. Thus, he is not condemned to repeat previous patterns of living and thinking but can create change, both in himself and in his culture.

Educators have often acted as if man were a lower animal, for schooling has often resembled training, with emphasis upon imitation, obedience, repetition, drill, and control, more than it has resembled education, with emphasis upon initiative, creativity, choice, decision making, and freedom. As a result, schooling has been more successful in improving man's skill in mechanical and repetitive activities at the lower end of his capacity scale than in developing higher qualities of intellect, feeling, and will that constitute his peculiar humanness.

Human capacity to learn. So far there have been discovered no limits to man's capacity to learn. From earliest times, however, men in positions of power or influence have suggested that the learning capacity of certain individuals or groups is severely limited and that they should not be expected to profit greatly, if at all, from education. These "ineducable" individuals have usually been members of minority or disadvantaged groups. But, repeatedly, when their cultural disadvantages have been removed, these groups have shown that their previous failure to learn has been due not to incapacity but to lack of fully realized opportunity.

Categorizing learners

These findings have led educators to be much more modest and less hasty in their labelling and classifying procedures. It has been realized that labels affixed to children tend to become self-fulfilling prophecies, that those who are expected to learn usually do so, and those who are expected to fail to learn also usually do so. Hence, when educators resort to classifying children at all, they increasingly tend to use their labels as temporary rather than permanent, as saying something only about a quality of the child rather than about his person, and as something to be abandoned as soon as the child's performance proves the label wrong.

Similarly, no one has been able to confirm any certain limits to the speed with which man can learn. Schools and universities have usually been organized as if to suggest that all students learn at about the same rather plodding and regular speed. But, whenever the actual rates at which different people learn have been tested, nothing has been found to justify such an organization. Not only do individuals learn at vastly different speeds and in different ways, but man seems capable of astonishing feats of rapid learning when the attendant circumstances are favourable. It seems that, in customary educational settings, one habitually uses only a tiny fraction of one's learning capacities.

Complexity of human learning. Human learning is complex rather than simple. Learners are apt to learn more than one thing at a time. Sometimes this process is conscious, as when one simultaneously or rapidly assimilates many specific items of a whole. More often, the process is entirely or partly unconscious, as when the student learns some "content" consciously but at the same time absorbs unwittingly a great deal more from interrelationships, tones of voice, and so on.

Correlative learning

Educators are therefore becoming increasingly concerned with these concomitant learnings. They are aware that the long-term significance of the arithmetical skill that the student consciously learns may be nugatory compared with the importance of what he learns about himself as a learner, about his capacities and limits, about his relationship with his teacher, about power and authority, about his relationships with his fellow students, about equality, collaboration, competition, and friendship. As educators become more knowledgeable about the importance of learning climates, they are impelled to abandon simplified techniques of teaching in favour of a more complex approach that views learning in the context of a matrix of relationships and forces that act upon the student, the teacher, the school, and the community.

Intellectual–emotional–physical–volitional integrity of learning. Human learning concerns the whole person. The intellect is not the only agent of learning. This activity is shared by the body, the emotions, and the will. Moreover, the process cannot be limited to any one of these domains without affecting the others. Educators are most conscious of intellectual learnings, which tend to play the largest part in their plans and intentions. But there is increasing evidence that makes clear the folly of attempting to confine education to the training of intellects. If the teacher does so, he is destined to fare badly, for the child who is emotionally frozen or whose stomach is empty or who is determined to thwart the teacher will not perform intellectually as the teacher intends.

Educators are also becoming more aware of the other side of this coin—that is, that the learner's powers are vastly enhanced when not only is his intellect stimulated but also his feelings are respected, his body is nurtured, and his will to learn is strengthened. Effective education, therefore, is found when the learner is regarded as a person to be respected, nurtured, strengthened, and stimulated, rather than as an intellect to be trained.

DIFFFERING CONCEPTIONS OF EDUCATION

Model theories of the educated person. In different historical eras and in different cultures a variety of conceptions has been put forward concerning the nature of mind, of truth, of knowledge, of moral goodness, of aesthetic beauty, and of the purposes of life. These views carry implications for the purpose and nature of the educational process, the ends toward which one should educate, the means by which one can best achieve those ends, the degree of consistency between the ends and the means, and the model, if any, of the ideally educated person that one has in mind when engaging in the educational process. These relate to some of the perennial questions that concern the philosopher of education. The following represent some of the most influential models that have been presented of the educated person.

Platonic view. The first great attempt to create a philosophically coherent model of the educated person was that of Plato. Reacting against the turbulence and chaos of his own times, Plato envisaged in *The Republic* and the *Laws* a permanent, stable, hierarchical society in which those most adept at education would rule, those moderately adept would become warriors and carry out the orders of the rulers or guardians, and those least adept at education would fill the lowliest worker functions in society. The education that would thus order and segregate the different groups in society would be based upon the ability to understand the perennial, ideal Forms that, Plato maintained, underlie the transient, concrete manifestations of those Forms in everyday life. Since, supposedly, not all people could surmount the difficulties of such an intellectually demanding program of study, it would be justifiable to select, classify, segregate, and reject students at the various stages of the educational process.

Intellectually segregated education

The Platonic scheme has been enormously influential, especially in the Western world, during the last 25 centuries. Most educational programs in the West have consistently reflected this hierarchical pattern. Schooling has usually been a process of selection and rejection, with great effort and ingenuity expended on testing, measuring, classifying, and segregating in accordance with the best available knowledge. Similarly, Plato's concept of mind has exerted lasting influence on Western education. Patterns of schooling have reflected the greater prestige accorded to the study of ideas and abstractions and the lower prestige given to practical studies and manual

work. There has persisted a dichotomy between the so-called liberal arts, which have been considered suitable educational fare for potential leaders of society, and so-called vocational studies, which have been considered more suitable for potential followers. This pattern has lasted to the present day, not only in Europe and North America, but also in those parts of Asia, Africa, and Latin America greatly influenced by European culture. Thus, one finds in many former colonial societies that students often strongly prefer to follow "liberal" studies, even though the choice may condemn them to genteel unemployment in a society whose economy cries out for people with technological, practical, and manual skills.

Thomist view. In the 13th century, St. Thomas Aquinas made a monumental attempt to reconcile the two great streams of the Western tradition. In his teaching at the University of Paris and in his writings—particularly the *Summa theologiae* and the *Summa contra gentiles*—Aquinas tried to synthesize reason and faith, philosophy and theology, university and monastery, activity and contemplation. In his writings, however, faith and theology ultimately took precedence over reason and philosophy because the former were presumed to give access to truths that were not available through rational inquiry. Hence, Aquinas started with assumptions based on divine revelation and went on to a philosophical explication of man and nature. The model of the educated man that emerged from this process was the Scholastic, a man whose rational intelligence had been vigorously disciplined for the pursuit of moral excellence and whose highest happiness was found in contemplation of the Christian God.

This Scholastic model has greatly affected the development of Western education, especially in fostering the notion of intellectual discipline. Aquinas' theological–philosophical doctrine has been a powerful intellectual force throughout the West and has constituted the official basis of Catholic theology since 1879. Although Aquinas made an important place in his hierarchy of values for the practical uses of reason, later Thomists have often been more exclusively intellectual in their educational emphasis. For Aquinas, the primary agent of education was the learner, and his model was, thus, a person capable of self-education. Intellectually autonomous, he should be able to conduct his own process of research and discovery. The Roman Catholic Church, however, has usually put the learner firmly under the authoritative superordination of the teacher.

Lockean view. John Locke, the 17th-century English philosopher, has been credited with formulating the classical liberal defense of individual freedom against the authorities of state and church. Opposed both to what he deemed the stagnation of unreflective tradition and the perils of enthusiastic radicalism, Locke saw science, reason, and experience as the best safeguards against these dangers. Responding to the rise of the new bourgeoisie and the new science, he became the principal spokesman for the increasingly powerful middle class, who were predominantly skeptical and practical in their intellectual temper. The model of the gentleman had traditionally been the English ideal of the educated person. Locke's achievement was to take this ideal and modify it to a form acceptable to the new bourgeoisie. Originally an aristocratic model, the gentleman ideal became infused, under Locke's influence, with democratic, Puritan, and practical characteristics.

Education of the practical gentleman

Locke's notion of the mind at birth as a *tabula rasa*, a "blank tablet" devoid of innate ideas, gave enormous importance to the role of experience and sense perception in the educational process. In *Some Thoughts Concerning Education* (1693) and the *Conduct of the Understanding* (1706), Locke outlined the heavily experiential education that would be appropriate for a gentleman. His four cardinal aims of education, in order of importance, were virtue, wisdom, breeding, and learning. Some critics have insisted that the order has remained important to the present day in English education, that learning must always be lightly worn and never ostentatious. Not only was Locke's thinking influential in shaping the subsequent development of English educational thought, but his Puritan individualism also had a considerable effect on the growth of American educational ideals. Locke's failure to recognize the possibilities of the uses of institutional power and legislation for interventions that would enhance rather than restrict freedom was an omission that has often bedevilled American educational thinking.

Naturalistic view. Most movements in philosophy and education have seemed to engender their own opposition. Hence, the rationalism and scientific objectivity of the Enlightenment found a reaction in the subjectivity and emotional spontaneity of romantic naturalism, the principal spokesman of which was Jean-Jacques Rousseau. In particular, Rousseau reacted against the excessive formalism and rationalism of 18th-century France. Out of this reaction there came a model of the educated person as the natural man, a figure presented in contrast to what Rousseau saw as the pathetic products of contemporary civilization. Against civilized values like rationalism, conscious reflection, control, complexity, and objectivity, Rousseau offered his own values of romanticism, intuitive spontaneity, freedom, simplicity, and subjectivity.

In *Émile* (1762), one of the most influential books on education ever written, Rousseau argued that one should protect the child from the corruptions of civilization and carefully nurture his natural, spontaneous impulses, which were always healthy. It was important, he maintained, to avoid premature intellectualization of emotion so that the child's intellectual powers could develop without distortion. Feeling should precede thinking, and the child should be controlled only by things, not by adults' wills. In these ideas lay some of the germs of progressive education, which spread throughout the world during the 19th and 20th centuries. Constantly in tension with the classical demands of reason, discipline, authority, and scholarship, the romantic naturalism of the progressive-education movement has continued to remind educators that their ultimate concern should be the growth of the unique, ultimately unfathomable child.

Subjectivity and spontaneity in learning

Marxist view. Probably the most influential writer of recent times was Karl Marx, whose writings, mostly in collaboration with Friedrich Engels, altered the course of history and continue to affect the lives of millions of people in all parts of the world. A central concern of Marx and Engels was to cure the alienation and dehumanization of man caused by what they saw as the exploitative forces of capitalism. In Marx's writings, the material dimension of history appeared as primary. Economic production was deemed the basis of life, and the prevailing ideas (religious, educational, and political) of a society were seen as being determined by its economic structure. The dominant ideas of an epoch or society were considered to be the ideas of its ruling class—that is, the class that controlled the means of material production. In order to find the hidden interest behind an idea, Marx argued, one had to examine its social function rather than its intellectual content. Marx saw the need for a proletarian revolution in order to bring about Communism. Under Communism, he argued, the opposition between the individual and the group would disappear; each man's interests would be seen to be identical with the interests of all, and alienation would be banished.

In Marx's view, what was needed for man's growth toward maturity was genuine community; that is, the voluntary drawing together of autonomous and socially responsible persons. The model of the educated person that Marx put forward was not the irresponsible individualist nor the coerced collectivist but the accountable communal man, who attained his freedom not by fleeing from social relationship but *through* social relationships. Individual freedom required social authority.

Marxist emphasis on social education

Marx's and Engels' writings, particularly *Das Kapital* (1867–94), *The German Ideology* (London ed., 1938) and *The Communist Manifesto* (1848), have reshaped the world. Millions have been inspired by their vision of unalienated work and education. Unfortunately, like many influential ideas, they have been abused and distorted.

Several states have tried to bring about a Communist utopia through collectivist coercion and social manipulation in a distortion of Marx's arguments. There is a need for state intervention to remove gross inequalities and to expand opportunities, in Marx's view, but ultimately human regeneration is a task for each individual.

Pragmatist view. Out of the America that was created by immigration, urbanization, and industrialization in the second half of the 19th century came the philosophy of Pragmatism. Associated with such thinkers as C.S. Peirce, William James, and John Dewey, Pragmatism, as the dominant American philosophy, exerted a strong influence on the shape of education in the United States, and affected educational ideas and practices in Europe and Japan. In the hands of Dewey, Pragmatism evolved into a philosophy that saw man as formed through interaction with his natural and social environment. The educated person was always viewed by Dewey in a social context. Neither the individual nor society had any meaning without the other. Dewey created a model of the educated person as the reflective man, one who was critical of the authority of custom and tradition as the determinant of belief and action and who preferred the method of science, of "organized intelligence" as the best way to solve his problems.

Progressive emphasis on blending individual and social needs

In *My Pedagogic Creed* (1897), *How We Think* (1910), *Democracy and Education* (1916), *Human Nature and Conduct* (1922), and a stream of other philosophical and pedagogic writings, Dewey formulated a viewpoint that constituted a rigorous intellectual core of the progressive-education movement, although he criticized many of the manifestations of progressive pedagogy in practice. For example, he viewed the child's interests as vitally important and to be neither repressed nor humoured. To repress them was to commit the fault of much traditional education by ignoring the child's unique bent. But to humour them was to commit the fault of some progressive education by failing to discover the underlying power below the passing whim. Subject matter, Dewey argued, should consist of activities that enabled the child to reflect upon his social experiences. When subject matter preceded or was unrelated to the child's experiences, it was largely meaningless. It gained meaning through being made the medium for continued reflection upon, and reconstruction of, experience.

Behaviourist view. In the 20th century, the use of science has been extended to the study of virtually all aspects of human affairs. The possibilities of scientific control of men and events have brought profound changes in philosophy and education. By studying only the behavioral aspects of man, science has been able to predict and control in ways that have powerful and sometimes frightening implications. The behaviourist view has been most notably represented by the American psychologist B.F. Skinner. In his writings, including the utopian novel, *Walden Two* (1948), *Science and Human Behavior* (1953), and *Beyond Freedom and Dignity* (1971), he has firmly rejected the conventional model of man as a free agent who acts in accordance with the decisions of an inner self that is neither fully explicable nor fully controllable by scientific means. Instead, Skinner envisages the use of scientific knowledge about the control of human behaviour to create a planned man, one who will be conditioned to behave in the way best calculated to achieve society's goals. Behavioral engineering will have removed all of his antisocial tendencies, and he will want only what is good for himself and his society.

Programmed learning and behavioral development

Behaviourism in general and Skinner in particular have exerted considerable influence on Western, and especially American, education through developments that range from the invention of programmed instruction (or the so-called "teaching machine") to the widespread emphasis on behavioral objectives in educational programs. The philosophy of Behaviourism compels one to examine carefully the issue of control in education. Skinner wants to use scientific control to bring about a society in which it will be easy to be good and to bring about an educational process through which it will be easy to be excellent. There is no alternative to control, in his view. It is simply a matter of *who* is to control. One does not grant the child "freedom" merely by leaving him alone. To refuse to use scientific control to shape human behaviour is, for the Behaviourist, a failure in responsibility.

Existentialist view. The application of science to ever more aspects of the study of man has been particularly marked in the West; but, in reaction to this trend, there has developed some criticism of the scientific way of viewing man as an object to be categorized, studied objectively, or subsumed under a generalization. Prominent in this reaction have been Existentialist philosophers, among whom the Jewish philosopher, Martin Buber, played an outstanding role in deepening contemporary understanding of man and education. In such books as *I and Thou* (1923) and *Between Man and Man* (1947), Buber's model of the educated person appeared as one whose life was shaped by existential decision making. Such a person did not determine choices in advance of existential situations. He used principles and traditions only as checks or reminders, not as infallible guides. His values were created in the concrete here and now and were manifested as he related to other men. Thus, each man was seen as a unique person rather than as a member of a category.

Dialogue between learning and life

A vital concept for Buber was responsibility, viewed in terms of one's response to another. Thus, the dialogue became a central focus in his educational philosophy. The educated person was one who could listen as well as talk. And since genuine dialogue depended upon authenticity, upon *being* rather than *seeming*, one needed the courage to be oneself in relationships. Buber also urged the recognition of a continuity between learning and life, rather than the encouragement of knowledge for its own sake. He insisted that learning be related to consequent action. Thus, for Buber, the educated person was not one who merely had had his cognitive faculties trained but one whose inmost spirit had been infused by what he had learned.

Areas of disagreement among educational theorists. *Conceptions of what constitutes knowledge.* Although there is wide agreement that the assimilation of knowledge by the learner is a principal goal of education, this agreement is more apparent than real, because there is much disagreement about what constitutes knowledge. Clearly, if one person identifies knowledge with information, his pedagogic approach is likely to differ from that of one who identifies knowledge with a process of thinking. Some philosophers have attempted to clarify a distinction between "knowing that" (something is true or false) and "knowing how" (to do or learn to discover something). The former emphasis is common in educational programs that focus on the product—that is, on the information that the learner has amassed and can reproduce at the end of his program. The latter emphasis is common in programs that focus on the process—that is, on the skills and attitudes that the learner has adopted that enable him to learn more.

Apprenticeship, teaching, and dialogue

Conceptions of how knowledge should be communicated. Throughout history, the commonest way for knowledge to be communicated has been through what can be loosely called apprenticeship. The one who does not know (the apprentice) watches the one who does (the master); he imitates the master, probably fails, watches again, tries again, and so on until he knows what the master knows. This is primarily the way young people learn role identity, for example—what it means to be a husband or wife, a father or mother, a male or female. It is not an effective method for stimulating the growth of new knowledge. A second method, one that has been time-honoured in institutions of formal schooling, is telling. The one who knows (the teacher) tells the one who does not (the student). The student listens, tries to remember, and is usually required to reproduce his memorizations at some stage so that the teacher can judge whether or not the knowledge has been assimilated. This method is a much less effective way of communicating knowledge than would be guessed from its prevalence as an educational practice. Other methods try to

remove the difficulties of human relationships from the act of communication by removing one party from the scene. For example, the apprentice can watch the master on film or videotape. Or the teacher can write his lectures in a book, which the student can then read. Another method is that of the dialogue. Unlike the previous methods, which imply superiority–inferiority relationships, this method implies equality between the members of the dialogue. All may at different moments be teachers or learners. The method assumes that all have some knowledge to give and that all need to learn.

Conceptions of the purpose of education. One of the commonest areas of disagreement among educational theorists concerns what education should be for. Two broad divisions of opinion can be identified. They are, first, that education should serve the needs of the individual and second, that it should serve the needs of society. In industrialized nations it is common for both of these goals to be held but for different classes of the population. For the elite, the needs of the individual tend to prevail, and thus upper-class schooling often tolerates diversity and encourages idiosyncrasy. For the masses, the needs of society tend to dominate, and schooling usually serves to prepare children to become obedient, well-drilled, uncomplaining workers in industry and agriculture. In addition to this dichotomy, there are many national and cultural variations. In France and Germany, for example, there is a strong tendency to see the primary purpose of education as some form of intellectual development, with the French *lycée* and the German *Gymnasium* serving as characteristic institutions. In England, education has usually been seen as primarily serving the purpose of character building. The English public school is sometimes taken as an epitome of this emphasis. In Roman Catholic and Communist countries, moral or religious training is usually the primary purpose of education. Hence, every subject is imbued with religious (or, if it is Marxism–Leninism, quasi-religious) content, and there is a constant attempt to draw moral lessons from educational material. In the United States, where large-scale immigration once brought the fear of social disintegration, preparation for citizenship and development of national consciousness have tended to be emphasized. Even today, nationalistic rituals such as displaying flags and reciting the "Pledge of Allegiance" in classrooms distinguish American schools from those in most other countries.

Needs of the individual and of society

Conceptions of uniform versus differential grouping. One of the controversies that most consistently divides educational theorists is whether students should be clustered together with similar students for instruction or whether instructional groups should be made deliberately diverse. The criteria that are employed for differentiating students are manifold. They include chronological age, mental age, IQ, skin colour, sex, social class, geographical location, parental income, performance ability on various tests, and so on. Some of these criteria, such as skin colour, are used "officially" in some countries, such as South Africa, and "unofficially" in others, such as the United States. Other criteria, such as parental income, are used overtly in some schools (expensive, private schools) and covertly in others (public schools located in expensive suburbs). Some criteria, such as mental age, IQ, and performance ability, often have the effect of separating rich from poor or elites from cultural minorities because of the cultural content of the tests used. The customary arguments used in favour of homogeneous grouping tend to emphasize speed and efficiency in instruction and learning. Arguments in favour of heterogeneous grouping tend to emphasize social outcomes, such as an enhanced understanding of others and tolerance of diversity.

Means of segregating students

Conceptions of control and discipline. When education is viewed as a transaction between superior (the teacher) and inferior (the student), questions of control invariably arise; *i.e.*, can students be relied upon to do what is best if they are not controlled by teachers? Answers to this question refer back to assumptions about the nature of man as learner. Those theorists who tend to see man as basically untrustworthy will tend to find justification for a regimen of strict control over students, in order to prevent their natural impulses from harming themselves and others. Theorists who view man as basically trustworthy will tend to justify more lenient, loose, and permissive systems of control. Most theorists would agree that an important goal of discipline would be for the student to develop self-discipline. But disagreement arises over whether one best learns self-discipline through practice in obeying others or through practice in commanding oneself.

Conceptions of the need for competition and collaboration. In most cultures of the world, children from an early age seek to compete against and to surpass their fellows. Whether this competitive spirit is innate or whether it is acquired through the culture is at present unverifiable. The question that divides education theorists, however, is whether these existing competitive strivings should be encouraged or reduced. Some argue that, since competition is endemic in the culture and since schooling should assimilate the child to the culture, the school should encourage individual competition and help children to develop the strengths necessary to compete successfully. On the other hand, others argue that competitiveness in the culture is pernicious and that schooling should not serve to adjust children to harmful aspects of the culture but should foster cultural progress. Usually, the school is in conflict over these two attitudes and gives mixed messages to students. As a result, the students often suffer the double strain of trying to compete successfully but to do so without appearing to compete.

Conflict of aims in school

Conceptions of the boundaries of formal education. Considerable disagreement exists over what should legitimately be studied in formal institutions of learning. Usually some topics or subjects are considered taboo. These taboos may come about through interpretations of the law, as in the case of the exclusion of religious teaching from public schools in the United States. Or they may come about as a result of pressure from interest groups, as in the attempts to exclude sex education, teaching about Communism, and sensitivity training from American schools. The major considerations are that young children are not well equipped to resist heavy bias in teaching and that they are usually compelled by law to attend school and thus constitute a captive audience. It is sometimes argued, therefore, that they should be protected against religious and political propaganda and against material or experiences that require greater maturity to be handled creatively. On the other side, the danger in such arguments is that they can be used to keep all controversy out of schools and to render them places characterized by dull uniformity of thought.

BIBLIOGRAPHY. For an excellent example of the analytical approach to philosophy of education, see ISRAEL SCHEFFLER (ed.), *Philosophy and Education*, 2nd ed. (1966). A representative British example is P.H. HIRST and R.S. PETERS, *The Logic of Education* (1970). Several scholars have attempted to group philosophies of education into schools of thought. The best collections are JOHN PAUL STRAIN (comp.), *Modern Philosophies of Education* (1971); and THEODORE B.H. BRAMELD, *Patterns of Educational Philosophy: Divergence and Convergence in Culturological Perspective* (1971). For examples of attempts to focus on a single problem or issue and to combine clarity and commitment, see PAUL NASH, *Authority and Freedom in Education: An Introduction to the Philosophy of Education* (1966); KENNETH D. BENNE, *Education in the Quest for Identity and Community* (1962); and ROBERT ULICH, *The Human Career: A Philosophy of Self-Transcendence* (1955). A good collection of Existentialist statements on education may be found in MAXINE GREENE (comp.), *Existential Encounters for Teachers* (1967). For selections from the classics on conceptions of the educated person, see PAUL NASH (ed.), *Models of Man: Explorations in the Western Educational Tradition* (1968); and ROBERT ULICH (ed.), *Three Thousand Years of Educational Wisdom*, 2nd ed. enl. (1954). Original essays on all of these major figures may be found in PAUL NASH, ANDREAS M. KAZAMIAS, and HENRY J. PERKINSON (eds.), *The Educated Man: Studies in the History of Educational Thought* (1965).

Education, Social Aspects of

Education is a form of human interaction. It is a social act that is made possible through a network of human relationships. It is this network, and the individual relations and roles of people within it, that really determines the nature of education in a particular society.

The social aspect of education is illustrated by considering the dependence of individuals upon one another for learning. The nonhuman animal, bird, or insect can live out its life guided largely by biological inheritance, a genetic "program" for the behaviour of the organism. Inborn patterns teach it to raise its young, find food, and protect its territory. What it needs to know is transmitted largely through the genes.

Most of what human beings need to know, on the other hand, is not genetically programmed. Very early in life a child must start to learn a vast, intricate, and often confusing way of life. That way of life—the culture—cannot be biologically inherited; it must be learned anew by each person.

Schools, as formal institutions for learning, impose a particular set of conditions on education. As a result, school learning is quite different from that which takes place in the family, in peer groups, or in the community. "Education," in its widest sense, may be thought of as the socialization process through which a person learns his way of life. It is a continuing process from birth to death.

This article discusses four social dimensions of education: important social functions performed by the kind of education that takes place in schools; the social factors within the community that influence school education; the school's own bureaucratic organization, which influences school practices; and the social system of the school and its influence on teaching and learning.

THE SOCIAL FUNCTIONS OF EDUCATION

The transmission of culture. Schools are, first of all, agents of cultural transmission. Without some means of inheriting, as well as extending, the culture each new generation would have to start afresh. Culture depends upon continuity, and schools help to provide it by transmitting accumulated knowledge and skills and values and beliefs.

In primitive societies informal education was adequate for transmitting knowledge and skills. A child required no special preparation to learn the things he needed to know. He learned from his father and other adults the arts of hunting and food gathering. In somewhat later societies he learned to cultivate, plant, and harvest. Tasks were unspecialized and were easily transmitted to the child. The learning process was spontaneous, with parent and child largely unaware that it was happening.

The transmission of skills. Endowed with a capacity to learn, even very primitive man started to control his environment for his own purposes. He developed fire to keep himself warm, clothing to shield himself from the wind and cold, baskets and kettles to carry more than his hands could, and finally the wheel, to which he transferred burdens from his back. Some men were better at certain skills than others; they became artisans, making copper pots, weaving baskets, making wheels. Young men came to watch and to learn. They became apprentices, helping and learning at the same time. The first formal schools probably sprang up around such artisans, arising from clearly definable social and economic needs that were in turn a result of man's increasingly complex way of living.

These new agencies on the social scene separated children from their families for periods of time and put them in schools. Schools became institutions for learning; teaching became a profession, and learning a recognized pursuit of the young. Schools, in a cultural sense, are institutions created by society to transmit important knowledge and skills to the young.

The transmission of values and beliefs. Schools also transmit values and beliefs. Such qualities as honesty, thrift, and industriousness are, of course, encouraged by teachers in schools the world over. In some countries, Great Britain being an example, a certain amount of instruction in the established faith is required by law, whereas in many others, the United States and France being examples, instruction in the state schools is resolutely secular.

Education and indoctrination

But even in those countries in which education is secular, political and ideological beliefs may be inculcated to varying degrees. Such is the case in all Communist countries, in which Marxism–Leninism is taught in the manner of an official faith. In non-Communist states, governments may resort to transmitting propaganda through state controlled schools in an attempt to secure the future commitment of youth to the regime. An extreme example of this occurred in Ghana during Kwame Nkrumah's rule.

In Western countries political and ideological values are transmitted not by means of a program of overt indoctrination but through the fostering of patriotic ideals. The extent to which attempts are made to influence the political and social ideas of youth varies considerably from country to country and even from school to school. Most school curricula, however, provide for instruction in the history and practice of parliamentary democracy, and students are encouraged to participate in open decision making, as, for example, in debating societies and in the election of student officials.

In the United States the political content or slant of education has at certain periods and in certain local educational jurisdictions gone beyond this. Local education boards, made up of opinion leaders in the community, have in some cases allowed political attitudes to influence such matters as the selection and dismissal of teachers and the political content of school textbooks. The latter have sometimes reflected the hostile attitudes of local community and opinion leaders to foreign countries such as the Soviet Union and to domestic United States policies regarded as Socialistic.

Preparation for working life. Another social function that schools perform is to allocate youth to particular work roles. Modern society has an infinite variety of tasks to be performed, which, in terms of the education required to perform them, vary widely. Some may be performed with an elementary school education, and some require sophisticated higher education. The number of tasks that can still be performed by those with only an elementary education is diminishing rapidly in modern technological society; but occupations necessitating education at higher levels are increasing rapidly.

The process of channelling students toward a particular type of career begins in the elementary schools, in which grading is based typically on the level of capacity for achievement. The level of achievement in elementary school is usually an important factor in determining the type of education a child will receive at the secondary level. In the secondary school the basis for selection shifts to the *type* of achievement and the kind of job to which the education is likely to lead the student as an adult. The differentiation is therefore on the type rather than the level of capacity. The period since World War II has witnessed an increasing vocational emphasis in secondary education. This is a consequence of the desire of governments to secure an economic return from burgeoning education budgets, of the urgent need to prepare youth (a steadily expanding age group in the total work force) for gainful employment, and of the demands of industry for increasing numbers of skilled workers.

Vocational emphasis of secondary education

Such practical requirements have led to a typical tripartite division of secondary education: academic, technical, and general. In some secondary education systems —that of the United States for example—all three types of curriculum may be offered within the same school. In other systems—such as those of Great Britain, France, Germany, and the Soviet Union—separate schools are maintained for each type of ability and aptitude. In any case, the school thus puts its imprint on youth, certifying the tasks that they are presumably capable of performing in society.

Schools allocate youth in yet other ways. A school certificate is now almost a requirement for any kind of em-

ployment in all industrialized countries. A university degree carries its own status. And beyond the general values of certificates and degrees there is the hierarchy of values attached to the status of the institution from which they were taken. An "academic" secondary school, a "polytechnical" school, a "vocational school," and a "community college" all carry perceived images in society that are related to the likely performance of their graduates. At a still more elite level certain prestigious institutions, such as Oxford and Cambridge, the French *écoles nationales*, and the American "Ivy League" colleges imprint upon the individual an image of quality and high expectation.

The caretaking of youth. A further social function of education is the caretaking of youth. This function is seldom listed among the stated objectives of education. Some sense of the importance of this function in an industrialized society may be gained by looking at the relatively easy way in which youth enter an unindustrialized one. In a society that is composed of small farmers, herdsmen, artisans, shopkeepers, and servants, children tend to step quite directly into their father's or mother's occupations. Indeed, it is frequently necessary for economic reasons that they do so. In industrialized societies, on the other hand, few youths have an intimate knowledge of their father's work. Except in rural areas, few have the opportunity even to see their fathers at work, let alone gain an understanding of that work. The chances are that the father works away from home in an environment unknown to the child. The parents' work is also likely to be such that it is almost impossible for children to be apprenticed in it. Often the work is specialized, technical, and beyond the reach of children.

State nurseries

In some countries schools are expressly assigned a caretaking function, the purpose being to free parents to enter the labour force. The state nurseries of the Soviet Union and the kibbutzim of Israel are examples. In the kibbutzim, nursery-age children are cared for while parents are in the fields or factories. Thus parents are relieved of some of the day-to-day concerns involved in raising children, and the mother is free to take her place in the labour force.

Other schools serve a caretaking function simply as a social convenience, a place for socially minded mothers to "park" their children while they engage in other pursuits. This purpose is especially apparent in those affluent societies in which leisure time is abundant and in which sufficient money is available to permit mothers to engage in noneconomic pursuits.

Promotion of peer-group relations. The promotion of peer-group relations is a further important social function performed by education. All individuals have a basic need to relate to one another. The fear of being alone, of being cut off from meaningful human contact, of being a "nobody," runs deep within society. Social needs are among the most persistent and demanding.

Adolescent peer groups serve very real functions in society. They provide a way in which children can learn to become independent of family authority. In modern society maturity is equated with independence, with the ability to formulate one's own judgments, and with the capacity to take independent action and live by the consequences of that action. Peer groups provide children with experience of egalitarian relationships not possible in the family. Through peer groups the child is exposed to the values and experiences of dozens of other families, many of which may be greatly different from his own. Through these contacts the child's horizons are broadened, his perceptions widened.

In order for peer groups to serve these important functions the child must get outside of the family and interact freely with children of his own age. The school is ideal for this purpose. Its corridors and classrooms, clubs and activities provide a natural and convenient setting for the young to socialize. In addition, schools provide an environment in which boy–girl relationships and understanding may develop. This mixing of the sexes in youth performs a valuable function in Western society, in which the selection of mates is based largely on personal choice. Adolescence is a time for testing relationships and forming standards of selection.

ENVIRONMENTAL FACTORS AFFECTING SCHOOLS

There are various ways in which social and cultural factors in the community affect the school and its practices. It is possible, for purposes of discussion, to group schools in various ways according to the dominant cultural characteristics that they share with their communities. It should be realized, of course, that such categories are arbitrary and that all schools will not fit neatly into the types selected for convenience of study. One useful typology is that which places schools in broad demographic categories, which may then be compared in respect to such matters as political and social beliefs, economic wealth, social class, and ethnic composition. In this manner schools may be typed as village, town, suburban, and depressed-neighbourhood.

Demographic classification of schools

Village schools. Village schools play a particularly important role in the educational systems of underdeveloped countries. They are found in the bush and on the veld of Africa and throughout Asia and are spread across the length and breadth of South America. They symbolize the interest of people everywhere in providing formal education for their children.

Small village schools continue to exist in Europe and North America, but they belong to a vanishing era. This is not the case in other parts of the world, where the spread of education is symbolized by an open plot of ground in some remote area where parents have gathered after a hard day in the fields to build a school for their children, often on land they have purchased.

Village schools have an organic unity with the community. They impose no new ideals, open no strange vistas, and are rarely concerned about the future and preparing for it. The student's future is known, determined within the expectations of the village and the family. He is to take no sharp departures from the family's occupation, learn no disturbing new ideologies, perform no acts that lack time-worn precedents. Thus the student is held close to his past, fixing in him its value, motivating him to follow its precepts. His schooling sanctions what is already regarded to be of value. It looks to the past rather than the future, rating stability over change.

The town school. The town school has a cultural style with distinctive characteristics of its own. The student body of the town school is more mixed than that of the village school. In it are both "town" and "country" children who represent more than one social and economic class. Social class differences are usually not great, however, and children do not always divide themselves rigidly along social class lines.

The cultural and political style of the town is reflected in the elected school board. On it are the "solid" members of the community who represent the upper and middle classes. There is little disagreement among the social classes of the town regarding the functions of the school. Although there is not in the town the organic link with the school that one finds in the village, there tends to be general agreement about what the school ought to do.

The smallness of the town contributes to the school's cultural style. The small number of students provides an important deterrent to social class bias, for school activities must include almost everybody. If the school were larger it would likely be more selective. Like the community, the school requires the participation of all of its members. Children with a variety of backgrounds are in this way accepted in the school and begin to adjust early to the realities of human differences.

The town school thus socializes the young in terms of town values. It selects and sorts students to some degree but is relaxed about the process. It does not pressure students to go in directions in which they do not seem inclined to go. Because its broad scale of values permits a kind of natural selection to take place, the town school is not expected to force the child upward. In this regard the town school's cultural style is in sharp contrast to that of the suburban school, in which the dominant value is achievement for the future.

The suburban school. Social stratification takes place among and between suburbs. Some suburbs spring up in areas favourable to high status residential development —around golf courses, lakes, and along scenic rivers, for example. Other suburbs develop in less favourable locations. The city dweller who seeks a home in the suburbs soon discovers that the amount of money he can pay will largely determine the desirability of the neighbourhood in which he can afford to live and also the type of school his children will attend. Because of economic and social stratification in middle class neighbourhoods, the social composition of student bodies in the schools tends also to be stratified along social class lines.

Mobility is an important feature of upper middle class suburban culture. People who are upwardly mobile are likely to be transferred by their employers, to take new positions in other cities, or simply to move further out to other suburbs. Change rather than stability is the dominant feature. The future rather than the past or the present is the dominant direction.

Competitive ethos of the suburban school

The emphasis in suburban schools is typically on achievement in university entrance examinations. Counsellors help students secure college admission, and academic subjects are stressed.

The culture style of the suburban school is reflected in its teachers. A large number of the teachers are often strangers in the community, seeing parents in only a professional capacity. They rarely own property within the suburb and are not otherwise involved in its problems. The student is profoundly influenced by the professional role of the teacher in the suburban school. He sees the teacher only as "teacher," rather than as also a community leader, or for that matter, simply as a "human being." Thus the teacher's partial view of the child is matched by the child's partial view of the teacher. This relationship, however, is probably congenial to the main business of the suburban school—academic preparation. The teacher's narrowly defined professional role sharpens the focus on the academic business at hand. The broad values of the village and town teacher tend to be screened out by the drive for good grades and other symbols of academic achievement. The cultural style of the suburban school thus mirrors the values of the mobile elite of society. In this school the selection and sorting process tends to become feverish: the school transmits values connected with achievement, and socialization revolves around the acquisition of academic and social status.

The depressed-neighbourhood school. The cultural pattern of the depressed-neighbourhood school contrasts sharply with that of village, town, and upper middle class suburb. Located usually in a crowded quarter of the city, it has an asphalt pavement for a playground and high brick walls for landscape.

Most of the students are from lower working class or poor families. It is in depressed-neighbourhood schools that one is most likely to encounter extremely hostile relations between student and teacher and high rates of juvenile delinquency. Students generally leave school as soon as they are legally able to do so, and a high proportion of the teacher's time and energy is devoted to maintaining discipline and attempting to ensure at least functional literacy.

The uncongenial nature of the depressed-neighbourhood school serving the slums is not conducive to the fulfillment of any of the school's educational and socializing functions. Student attitudes, often reinforced by negative, alienated, and antisocial norms in the surrounding community, result frequently in hostile responses to attempts to introduce middle class values and aspirations.

Even in those cases in which students do aspire to break away from the depressed neighbourhood, its schools, and the concomitant lack of opportunities, upward mobility is particularly difficult. Students with a deficient educational background are likely to experience difficulty in finding employment when they enter the job market. A partial solution to this problem in several European countries and in the United States has been to provide more opportunity for further education beyond the minimum school-leaving age. Institutions providing this type of education, on a full- or part-time basis, have minimal entrance requirements and concentrate on remedying deficiencies in basic education and on providing elementary industrial and technical skills.

ORGANIZATIONAL AND SOCIAL FACTORS INFLUENCING SCHOOL PRACTICES

School organization. The bureaucratic view of school organization holds that teachers are employees in an organization in which superior–subordinate relationships should be clearly drawn and standards of business efficiency applied. The bureaucratic model places power at the top, supported underneath by line and staff relationships. Bureaucratic organizations such as this usually exhibit three characteristics. They are *standardized;* the stress is on uniformity among personnel and their interchangeability. Standardization calls for uniform rules and work procedures. Bureaucratic organizations are *centralized* in decision making and, thus, diminish the responsibility of employees. Centralization demands that the primary responsibility of the employees be to the organization. A bureaucratic organization is *specialized;* it stresses efficiency and technique.

Characteristics of bureaucratic organization

A professional organization, in contrast, stresses quite opposite conditions: the uniqueness of personnel and their skills; diffuse and flexible rules; the responsibility of professionals, rather than of administrators, for making policy decisions; primary loyalty to clients and colleagues rather than to the organization; and aiding students rather than applying efficiency and techniques. In a school that is organized along professional lines, teachers, as trained specialists, have more control over both the conditions of their work and over standards, and they are usually judged by peers rather than by outsiders.

Persons holding the bureaucratic and professional views take quite different positions on how conflicts should be resolved. Those taking the bureaucratic view argue that conflict should be resolved through meliorative processes of discussion and persuasion. Professional teacher groups, on the other hand, tend to hold the view that conflict is to be resolved by adversary processes, such as collective bargaining, in which parties bargain as equals. The melioristic approach is based on the assumption that educational conflict is amenable to resolution through good faith and serious communication. The adversary approach to conflict resolution assumes that conflict exists and will continue to exist in schools in which groups have different self-interests.

Formal and informal relationships. Each school has two types of social system, formal and informal. The formal social system is based on official positions, such as "teacher," "administrator," and "student," on the status relationships among them, and on the interactions of the people who occupy them. The status relationships of the formal social system may be observed in the administrative organization chart of the school. Such a chart diagrammatically describes the school's social hierarchy, with administrators assigned to boxes at the top, with teachers and students near the bottom, and supervisory personnel and "middle management" between. Lines connecting the boxes describe status relationships. A person's position in this hierarchy is usually determined by his authority and responsibility.

Whereas the formal social structure is diagrammatically neat, the informal social system is a scramble of relationships that tie people together within and across many boxes and lines. It represents the ability of people to humanize cold bureaucratic structures. The informal social system also represents a way for people to defend themselves against other persons of formal power and to develop power of their own. For the informal social system does have power. Teachers who do not like a program that they feel the administration has imposed on them can quietly agree among themselves to subvert it. Students who do not like a school policy can take measures to force a change. In these cases the struggle becomes one between the "establishment" and the informal social structure.

The informal social system of students has considerable

influence on academic achievement. Research suggests that the students' informal social system may apply sanctions to support athletics and social activities and discourage scholastic achievement. In the informal system the status of the brilliant student may thus not be valued, even though it is valued in the formal system.

Teacher–administration relationships. Perhaps the most crucial teacher–administrator relationship is that between the teacher and the school administrator. Of particular relevance is the question of whether the leadership efforts of the administrator have, or can have, a significant effect on instruction.

Importance of administrative leadership

Some research indicates that the school administrator's leadership does indeed have a positive impact on teacher morale and performance. One study of the leadership of elementary school principals in the United States found a positive relationship between leadership and teacher morale and performance. The research indicated, for instance, that the principal's leadership score was related to the classroom performance of the teachers. The higher the leadership score of the principal the more likely were the teachers to "do everything possible to motivate students," "plan classes so that different types of students can benefit from them," "provide opportunities to go beyond the minimum demands of assigned work," "try new teaching methods in their classroom," and "take a strong interest in the social and emotional problems of their students" and the less likely were teachers to "do textbook teaching only." These findings suggest that principals who provide a high degree of professional leadership are more likely to have teachers who are more productive and enjoy higher morale.

Parent–teacher relationships. Most parent–teacher interaction focusses on the child's school performance. In this respect the teacher is the judge of the performance, not the parent. In this most crucial matter, it is the teacher who is the dominant figure in the interaction. This focus of the relationship becomes even more crucial when it is remembered that most parents attach great importance to school achievement as a means to finding employment or gaining university admission. Middle class parents are convinced that their child's present school performance will determine his future life chances.

The achievement of the child compared to other children is of key importance in teacher–parent relations. To achieve scholastically the child must compete successfully against others, yet parents often disavow interest in how well their child is doing competitively. Teachers also attempt to play down the competitive emphasis and accentuate individual talents and abilities. The teacher attempts to reconcile conflicting values and expectations. The community values success as expressed in school performance. Yet children, being different, do not and cannot all achieve scholastic success in the same measure. The grading system, by definition, grades. The teacher's attempt to stress other values represents a sensible reconciliation in an area in which the school is a battleground of conflicting values.

Peer-group relations. One of the social functions of schools is to provide for peer-group activity under the supervision of adults. Peer groups serve important functions in society, and the school provides an ideal place for these functions to be performed.

Particularly noticeable are the changing positions of peer groups, with respect to adults, as children move from one age group to another. These changing positions may be described as a circle on which peers and parents begin at the same point. A small child tends to accept parental values uncritically. As he grows, however, the child gradually moves away from parental influence and toward peer influence, until as an adolescent he stands almost on the opposite side of the circle from that of his parents. Adolescence creates within youth an earnest effort to become independent, to reject the symbols of dependence, and to free themselves of authority and control. The peer group becomes supreme during this period, and it frequently wields more control than the family or any other group. By the time the youth reach the secondary school, adult values seem irrelevant or at least remote. What adults teach in the secondary school seems to have no vital relation to the peers' immediate personal and social concerns, which are intense and all absorbing.

Yet it is during this period that maximum pressure is exerted by the school and society for academic achievement. For those students who have university ambitions this is the critical period of decision. The record that determines future opportunities for advancement is being compiled. Peers are caught in the cross fire of pressures. From their fellows comes the urgent call of allegiance to the group and to peer solidarity and for a strong show of independence. From the adult world come pressures to achieve in matters not seemingly relevant at the present but supposedly necessary for the future. The student must reconcile these apparently irreconcilable appeals.

From this point on the circle a youth starts his journey back toward identification with adult values. If he enters a university, the need for the group begins to wane. He starts to feel independent, able now to focus more on his future. The need to prepare for a vocation and for marriage and a home comes more sharply into view. As he proceeds through the undergraduate course and possibly through graduate school, or out into marriage and a job, he thinks and behaves more and more like an adult.

The peer group and individual aspirations

In the peer group the students' informal social structure can be seen, a structure distinct from the formal program of classes, courses, and teaching. The formal and informal systems exist side by side and apparently converge at one critical point: the adolescent's level of educational aspiration, which is positively related to his peer-group membership. If the child's peer group values education, his desire for an education is reinforced. The opposite is also true.

Teacher–student relationships. In school, teachers perform a variety of social roles related to students, and these roles help to define the nature of teacher–student relationships. The teacher is, for example, a mediator of learning. Standing between students and the subject matter to be learned, the teacher seeks to bring the two together. This role is the one for which teachers are professionally trained and the one in which they tend to feel the most comfortable with students. As an examiner the teacher evaluates the work and progress of students in terms of stated or implied standards and objectives. The teacher is also a disciplinarian who is expected to promote conduct that is acceptable within the norms of the school. Sometimes the teacher is a confidante to students, sharing their trust and perhaps performing the functions of a parent counsellor. The teacher is expected to be a surrogate of middle class morality, representing the community in the classroom in upholding moral values and norms. Traditionally, the teacher was expected to be a parent substitute who acted with "reasonable care" in respect to the student's safety and general welfare. This role continues with respect to small children but is disappearing with respect to adolescents and young adults on university campuses. Finally, the teacher is an academic adviser who assists students in planning programs and in solving problems associated with learning.

The teacher's relationship with the student is sometimes described as a "client" relationship, like that of a doctor with his patient or a lawyer with his client. The analogy is only partly accurate. The relationship is indeed a professional one in that the roles of teacher and student are defined by law and convention. The teacher, however, is not granted the same freedom that a doctor enjoys with his patient or a lawyer with his client. Further, the teacher cannot select his client, as can the doctor or lawyer. Nor does the student client usually have the freedom to choose his teacher. For the teacher, the parent of the student is the indirect client, monitoring, as it were, the professional work of the teacher with the child.

Education, Systems of

The term system of education refers to a society's total pattern of formal institutions, agencies, and organizations that transmit knowledge and the cultural heritage and that influence the social and intellectual growth of the individual. Although it would be possible to analyze a metropolitan, state, or provincial system of education, this article deals with national education systems.

A point to be emphasized when viewing systems comparatively is that no educational system is fixed or static but is always in a process of change, even if the change is not always clearly identifiable or perceptible. Since education is concerned with human beings—and they are changing—it is reasonable to infer that man's institutions and activities are also subject to modification. As one authority on comparative education, I.L. Kandel, put it in *The New Era in Education* (1955), no national educational system "has reached a stage of equilibrium; all are in a state of becoming." Also helpful in understanding such systems is the awareness that any system is affected by social, cultural, spiritual, economic, and political tendencies and forces, some of which originated centuries ago. Moreover, the educational ideas, practices, and structure derive frequently, in whole or in part, from countries other than the one being considered. It is clear, therefore, that the study of educational systems is a complex procedure combining description with analysis. Each individual system or issue must be understood fully and in terms of its various historical and contemporary contexts.

The article is divided into the following sections:

I. General characteristics of educational systems
  Varieties of administrative structure and control

III. Trends and prospects

I. General characteristics of educational systems

VARIETIES OF ADMINISTRATIVE STRUCTURE AND CONTROL

Types of systems. For purposes of classification it is useful and convenient to consider educational systems with reference to administrative structures and controls. In a large majority of countries, there is a centralized governmental agency, usually called the ministry of education or the ministry of education and culture, which organizes, administers, finances, and controls the formal and cultural aspects of education in all regions and localities. The laws, curricula, personnel, and materials and methods of instruction are in large measure determined in the central office, with variations in specific situations as occasion demands. However, even in a classic example of centralization—France—there is *in practice or action* no perfect centralization.

Centralization and decentralization

In some countries, such as Switzerland, education is carried on under the jurisdiction of the constituent states —the 22 cantons and 3 half-cantons. Though this situation is described as decentralized, there may be centralizing tendencies of a nonformal educational nature or common elements in the educational programs of the various units.

As a general rule, centralization often is taken to imply uniformity and conformity, if not indeed a monolithic or totalitarian situation, whereas decentralization is often equated with democracy and diversity. In point of actual fact, the line of demarcation is seldom that sharp. It is possible to have local linguistic differences in education, as in the Soviet Union, but centralized ideological control. On the other hand, in a country like Denmark, which has a centralized educational system, there exists considerable freedom of thought and opinion. One must be careful, therefore, to look under the surface of the classification in each particular instance.

Still another type of educational system is one in which administration and control are shared by national and local authorities. Perhaps the best example of this system is in England, where the educational laws originate in the Parliament but the actual administration is in the hands of the local governments. The Department of Education and Science (formerly the Ministry of Education), on the national level, issues reports, disburses funds, and offers guidelines, but it does not control the schools.

Nonpublic or private schools and other educational facilities may be controlled but not financed by the central authority in some cases. In others they may receive full or partial subsidies with varying degrees of autonomy. When the schools are related to a church or religious movement, they are frequently under the authority of a centralized agency, even though they may not be controlled by the government. In the worldwide perspective, there is a variety of patterns of educational systems.

FACTORS IN THE FORMATION OF A SYSTEM

Ethnic and linguistic factors. All systems of education are rooted in the past and are compounds of a variety of constituent factors influencing educational institutions and their functions. Racial and ethnic attitudes, for example, have played an important role in the formation of educational policy and in the administration of education in several countries. Historically, the attitude of the dominant white majority toward the blacks in the United States has resulted in discriminatory practices and segregated school facilities, a situation that has been undergoing change in recent decades. In England the recent influx of Indians, Pakistanis, and West Indians has provoked issues of curriculum, language, and equality of opportunity. The South African government's official policy of segregating various racial groups—white, black, coloured, and Asian—has brought about a quadripartite racial system of education. The caste system of India has continued to exert an influence on education, as newspaper reports periodically testify, in spite of the fact that discrimination against the untouchables is no longer legal. Also pertinent is the widespread Japanese effort to exclude the Eta (historically, an "untouchable" caste of uncertain origin) from any relationship, educational or

Racial considerations

otherwise, with the majority of the population, so that the Eta continue to have the lowest educational, social, and economic standard in the country.

Language is another significant factor affecting education in many countries. In some, such as South Africa, Belgium, and the Province of Quebec in Canada, the problem of bilingualism must be taken into account in administration, physical plant, curriculum planning, teacher preparation and selection, textbooks, and the like. Switzerland has been faced by the need of teaching in three, actually four, official languages. In the Soviet Union each constituent republic has a language of its own, and an Uzbek national living in Tadzhikistan has to learn the Tadzhik, Russian, and Uzbek languages if he is to participate and profit fully from his residence in the republic. The educational system of Israel, apart from maintaining schools in the Hebrew and Arabic languages, must also take into consideration the problem of teaching Hebrew to the new immigrants who arrive with multifarious linguistic backgrounds. Countries like Peru and Ecuador, with a large Indian population speaking many tongues, are endeavouring to solve the problem of teaching the national language. North and South Chinese can communicate with each other only via the written script or through such a neutral medium as pidgin English. After more than two decades of independence, India still is involved in the issue of national versus local languages, with English and Hindi dominating at the present time. Finally, recent social and economic trends resulting from migration have brought about changes in societies in which a single language has long been dominant. In certain parts of the United States, as in New York City, the influx of Puerto Ricans has necessitated the addition of Spanish-speaking teachers and other changes in the urban school system. The arrival of immigrants from Asia has brought about pressures in some of the cities of England with regard to teaching Tamil, Hindi, and other Asiatic languages in the schools.

Political ideology

Political factors. The political development of a country historically is a potent influence on the educational system. A totalitarian government will naturally organize a totalitarian educational system. In Nazi Germany, the objectives of Aryan or Nordic supremacy were applied in such a way as to deprive Jews and other non-Aryans of access to higher education, as well as to persecute them in countless ways. The authorities of Fascist Italy imposed their political credo—"Believe, obey, fight!" and "Mussolini is always right!"—upon all pupils and students and monopolized all media of public expression. The rules of the U.S.S.R. prohibit the teaching of religion, non-Marxian economics, and other doctrines deemed to be inconsistent with Communist ideology. Nations officially committed to the principles of democratic government and life tend to reveal a more pluralistic attitude toward other viewpoints and peoples. Though there may be discrepancies and contradictions in educational systems founded on the democratic philosophy, there is usually at least an *effort* to attain the professed aims of democratic education for the greater good of the nation and the individual.

Among the political ideologies and attitudes, account must also be taken of Socialist countries such as Sweden, which endeavour to organize their educational systems in such a way as to achieve maximum equalization of opportunity for all. Although this is also an objective of other democratic countries, in a dominantly socialist milieu it is likely to be accompanied, for example, by the elimination of all methods of selecting students that might lead to an elitist society in any form. Thus, in the years following World War II, when Sweden's Labour Party came to power, a concerted campaign was made to substitute the *comprehensive* secondary school (a school offering both academic and vocational curricula) for the dual types (separate schools for academic and vocational curricula), as well as to reduce the influence of the traditional private or independent school.

Religious and other factors. Until recently, many school systems derived their educational objectives and some of their content from religious ideologies. In many diverse countries, including West Germany, England, Denmark, and Norway, the study of religion is a regular part of the curriculum. As a general rule, religious instruction has tended to persist in Roman Catholic countries, such as Spain and Italy. Secularization of schools was undertaken in France in the late 19th century, with the result that religion is no longer taught in the public schools there. In the Soviet Union, by constitutional prohibition, religion may not be taught in schools, although, interestingly, another Communist country, Poland, permits the teaching of religion. In some countries, such as the United States, there exists a dual system of education, one with a secular orientation that is publicly supported and one that is composed of a private, often church-supported series of networks, both of them contributing to the culture and economy of the country. The United States, in line with the doctrine of separation of church and state implied in the First Amendment to the Constitution, does not support religion in education, but some states do allow some benefits to children attending church-administered schools, and some provide such schools with funds obtained from taxes.

A thorough analysis of an educational system would comprise, in addition to the miscellaneous factors already enumerated, the educational history of the country, together with foreign influences; the aims and ideals of education; the organization of the preschool, elementary, secondary, vocational, higher, adult, and professional levels; the provisions for the handicapped and other forms of special education; the varieties of administration, supervision, finance, and control; the types of curricula, methodology, and materials of instruction; the means of psychological and achievement testing; the types of youth groups and agencies; the measure of scholarly, educational, and professional organizations and publications; the influences of the mass media; and those problems and issues peculiar to the country, as well as those common to other countries. (W.W.B.)

II. Types of educational systems and their characteristics

CENTRALIZED SYSTEMS

France. The modern tradition of education in France can be traced to the Revolution of 1789, when the firm hold of the Roman Catholic Church was broken for the first time. The constitution of 1791 provided for the creation of a system of free, public, universal education. Centralization came with the Napoleonic period, especially with the establishment in 1806 of the "University of France," a rather abstract term that covered the entire educational system at elementary, secondary, and higher levels. During most of the 19th century, private and parochial schools were allowed, but, with the advent of the Third Republic in 1871, secularist trends again dominated. The laws of 1881–86 made French education free, compulsory, and secular, with teachers in state schools required to be laymen. The universities, which had been discontinued in 1808 in favour of a system of faculties of science and letters (see HIGHER EDUCATION), were reconstituted by the law of 1896. To maintain centralization, the national government assumed the sole right to grant certificates and degrees, even for students in private schools. There is now one significant exception: although the government confers the major doctorate, the *doctorat d'état*, each university is authorized to grant the *doctorat d'université*, a lesser degree, often to foreign students.

The French system as the classic example of centralization

Because the French system is the classic example of centralized administration, it will be worthwhile to detail its structure. The country is divided into political-educational units decreasing in size from *académies* to *départements* to *communes*. Each of 23 *académies* is headed by a university. The chief administrator of both the university and the *académie* is called a rector, who is appointed from the ranks of university professors by the president of France on recommendation of the national minister of education. He is responsible primarily for

secondary and higher education within his *académie;* he nominates candidates for administrative positions in his area, appoints examination committees, supervises examination content and procedures, and presides over a sort of personal cabinet called an academic council. Unlike political divisions in such countries as Australia, Canada, the United States, and West Germany, the *académies* have little power or authority of their own; rather, they are administrative arms of the Ministry of National Education; they represent a devolution rather than a delegation of power from the central government. (Since the law of 1968 the universities themselves, however, have been controlled by elected faculty-student councils.) The *départements* (from two to eight in each *académie*) are likewise administrative units governed by prefects who are appointed in Paris. The prefect heads the elementary school system, acting in a manner similar to the rector. The prefect, too, has an advisory council, appointive in nature, and by no means equivalent to local boards of education in such countries as the United States and Canada. *Départements* are empowered to levy subsidiary school taxes as approved by the national government; in the early 1960s about half the cost of *département* schooling was met by local taxation. *Départements* are also permitted to provide further school services, on approval of higher authorities, including additional emoluments for teachers. There are about 38,000 *communes,* varying in size from the smallest community to the city of Paris itself. The chief officer of the *commune* is the mayor, who is also the president of the *commune* school board. Again, these school boards are largely advisory in nature; they also see to it that national and *département* educational procedures and policies are carried out in their particular area; they have only minor administrative responsibilities and can initiate very few regulations or practices. Actually, the *département* prefect assumes much of the control over education in the *commune,* as such control is derived from higher authorities.

The French educational system is characterized by a pyramid of bureaus that reach their apex in the Ministry of National Education in Paris. As in all national systems, even including Great Britain, the minister of education is a political appointee of the prime minister and, as such, usually falls whenever his government falls. Practical control is exercised by a powerful and permanent civil service, which remains relatively unaffected by political changes. A corps of inspectors general, appointed by the Ministry of National Education, reports on progress and needs in all areas. Increasingly, control is being transferred to local governments, especially in matters involving purely internal conduct, but final responsibility still lies heavily with the central ministry.

Types of French schools

The French system of education is free, secular, and compulsory for children from age 6 to 16. Although most schools are public, there are a substantial number of private schools, most of them under Roman Catholic auspices. The state offers subsidies to private schools and exercises some control over their instruction and school sanitation. The school system as a whole consists of the following levels. For preschool children aged two to six there are the *école maternelle,* the *jardin d'enfants,* and the *classes enfantines* of the elementary schools. For children aged 6 to 11 there is the *école primaire élémentaire.* On the intermediate level, adolescents aged 11 to 15 go to either the *collège d'enseignement secondaire* or the university-bound *lycée.* On the higher secondary level adolescents aged 15 to 18 continue on one of three courses: the college of general and technical secondary education, the *lycée,* or the elementary normal (teacher-training) school. Finally, there are the universities (which admit those passing the *baccalauréat* examination) and the *grandes écoles*—such higher professional institutions as the École Polytechnique, the Conservatoire National Supérieur de Musique, and the École Normale Supérieure. The system also includes a variety of agricultural, vocational, and technical schools, as well as special schools for the handicapped.

French education, in general, aims at the cultivation of reason and the intellect—the objective being, in terms of content, to impart a general education (*culture générale*) stressing literary, historical, scientific, and technological phases more equally than before. (W.W.B./G.F.K.)

Italy. Italian education today is founded upon the constitution of January 1, 1948, which provides for a free, compulsory, eight-year elementary education and further secondary and higher education for students having means or meriting scholarships or other allowances. Beginning in the mid-19th century increasing laicization eventually diminished the control of the Roman Catholic Church and ended the teaching of theology in the state universities; nevertheless religious instruction has remained compulsory in the elementary schools (though pupils may be individually exempted on parental request) and voluntary in the secondary schools.

The minister of public instruction is the central director and supervisor for all forms of education, from preschool through university, and for artistic and cultural activities. The curriculum of all schools, including private schools desiring official recognition, must conform to that prescribed by the ministry. This central authority is represented in each provincial capital by a *provveditore agli studi,* or superintendent of education, who oversees all elementary and secondary schools within his area, both public and private, and who lends a certain note of "decentralization" to the system by being permitted to exercise some local discretion in implementing programs. Each province is itself divided into school districts (each headed by an inspector of schools), which are further subdivided into teaching groups or "circles" (*circoli didattici*), headed by a director and consisting of 60 to 100 teachers. Universities and higher institutes are supervised directly by the central ministry's directorate-general for higher education. An important consultative body in the ministry is the Higher Council of Public Education (Consiglio Superiore della Pubblica Istruzione), composed of 60 members chosen by teachers and professors, chaired by the minister, and authorized to offer advice, thus providing the central authority with an awareness of public and professional opinion.

Decentralizing elements in Italy's centralized system

In structure, Italian education begins with the preschool (*scuola materna*) for children aged three to six and the five-year elementary school (*scuola elementare*). There are two types of intermediate school—the *scuola media inferiore* leading to secondary education and the *scuola di avviamento professionale* which might be called "prevocational." There follows either the two- to five-year vocational school (*istituto professionale*) or various forms of secondary education for students aged 14 to 19, including the classical school or *ginnasio-liceo,* the *liceo-scientifico* or four-year institute for elementary school teachers and art students, and various five-year technical institutes. In higher education the state and private universities and higher institutes offer almost identical curricula leading to the *laurea di dottore* (doctor's degree). Except for the course in medicine and surgery, however, the Italian *laurea* is not regarded internationally as the equivalent of the Ph.D. as granted in the United States and some other countries. Unlike England and the United States, Italy has offered few opportunities for postgraduate study. The new law of 1969 on university reform may, however, change the status of higher education. The authorities hope that the new research doctorate (*dottorato di ricerca*) will win international recognition for the products of the higher educational system of Italy.

The aim of the Italian school system is to give a basic education to all, including religious and linguistic minorities, and to aid those lacking means to pursue secondary and higher studies. Apart from preparing skilled workers and professionals, the school attempts to educate citizens for living in a democratic society.

Scandinavian countries. Historically, Scandinavian education has been strongly influenced by Lutheran doctrines. Supervisory and administrative activities by the clergy were not discontinued until 1933 in Denmark and until 1958 in Sweden. The survival of some church influence in Norwegian education is evident from the ex-

istence of the Royal Department of Church and Education. Even though the administrative role of religion has been fading in recent decades, Lutheran religious instruction is still required in the public schools, with provisions made for abstention on the basis of conscience.

Lutheran influences in Scandinavian systems

Since the mid-19th century there have taken place several significant developments in education. The Danish movement in adult education, centring on the "folk high school" (*folkehøjskoler*) was founded in 1844 and became the model for similar efforts in other European countries, particularly Great Britain, and in North America. The Swedish *grundskola*, a nine-year comprehensive elementary school, introduced by stages since 1949, has encouraged other countries to try similar educational reforms combining classical, modern, and technical studies. Also gaining international notice has been the Swedish program of sex education in the schools.

In every Scandinavian country the educational ministry is the central and supreme authority and issues regulations and plans binding on local boards and councils. The local authorities are, however, granted extensive autonomy in educational matters. In Denmark the Ministry of Education (Undervisningsministeriet) shares decision making and financing with the municipal councils (such as the Municipal Council of Copenhagen) and, in rural parishes, with county school directorates. In all areas there are teachers councils entitled to be consulted on all important educational questions. The Ministry of Education also exercises supervisory relations with the various state institutions of higher learning, such as the University of Copenhagen. In Norway, the Department of Church and Education (Kirke- og Undervisningsdepartementet) exercises overall control of schools and direct supervision of teacher training and higher education, but local authorities have considerable latitude of action with regard to equipment, appointments, and finance. In Sweden the school system is under the authority of the ministerial Department of Education (Undervisningsdepartementet), but effective operational direction is exercised by the Royal Board of Education (Kungliga Skolöverstyrelsen) for elementary and nonvocational secondary schools and by the Royal Board of Vocational Education (Kungliga Överstyrelsen för Yrkesutbildning) for vocational and technical schools. Local school authorities share in the administration of elementary and secondary education; county school boards are concerned with supervision of elementary schools, teacher appointments, and the disbursement of state funds to the schools. In Scandinavia generally, the trend in recent years has been toward an increase in shared educational responsibility among the various levels of government, even if ultimate control and direction (especially with regard to curriculum) remains in the hands of the central ministry.

Like other school systems in Europe, the Scandinavian school systems have traditionally been dual-tracked: at the secondary or intermediate level the majority of students were channelled into vocational schools and students of merit or means were channelled into academic and pre-university schools. The Danish "academic" channel consists of a three- or four-year preschool (*børnehave*), a seven-year elementary school (*hovedskole*), a three-year course of lower secondary education (*realafdeling*) leading to the academic three-year secondary school (*gymnasieskole*), and then an institution of higher education. The Norwegian system consists of a four-year preschool, a seven-year compulsory elementary school (*barneskole*), a three-year general lower secondary school (*ungdomsskole*), a three-year lower academic secondary school (*realskole*), and a three-year higher academic secondary school (*gymnas*). Sweden has tended to de-emphasize the old dual plan and introduce comprehensive schools; it has a four-year preschool (*förskola*), a comprehensive nine-year elementary school (*grundskola*), and a three-year academic secondary school (*gymnasium*). In each country the transition from secondary to higher education is by way of an examination (*studentereksamen* in Denmark, *examen artium* in Norway, *studentexamen* in Sweden). Each country provides for vocational and technical training on various levels.

The aim of education in Denmark, as expressed in the Elementary Education Act of 1958 and other documents, is not only the dissemination of knowledge but also the development of character in line with Christian principles and of friendly attitudes toward other nations. According to the Norwegian law of 1959, education is a cooperative process between school and home for the attainment of civic virtue, Christian character, basic knowledge, and respect for other peoples, so that the individual can function as a useful human being. These aims are also shared by the Swedish educational system. (W.W.B.)

Latin American countries. Education in most Latin American nations is based on Spanish—or, in Brazil, on Portuguese—traditions as modified by later French, German, and American influences. As a rule, education is under the control of a national ministry of education of varying designation—such as the Ministry of Education and Justice (Argentina), the Ministry of Education and Culture (Brazil), the Ministry of Culture (El Salvador), or the Ministry of Education and Religion (Paraguay). The degree of centralization may be greatest in Cuba, which follows Marxist political principles, but educational authority is generally everywhere vested in a national ministry.

Uruguay's unique system of centralization

Uruguay, however, provides an interesting example of a different type of centralized control. Although nominally the highest administrative agency is the Ministry of Public Education and Social Welfare, the ministry actually concerns itself primarily with welfare services. Educational administration falls within the province of four national autonomous educational councils: the National Council for Primary and Teacher Education (Consejo Nacional de Enseñanza Primaria y Normal); the National Council for Secondary Education (Consejo Nacional de Enseñanza Secundaria); the Central University Council (Consejo Central Universitario); and the National Council for Industrial Education (Consejo de la Universidad del Trabajo), which occupies itself with agricultural, vocational, and industrial schools of all types, but which is divorced from the political and ideological overtones that characterize labour educational administration in such a country as Mexico. The coexistence of these four councils illustrates a form of decentralization; since the councils operate on a national basis, however, and since their functions interlock, the resulting organization might be conceived as a type of pluralistic centralized control. As for curricula, the policy regarding the teaching of religion varies—for example, in Brazil it is optional, whereas in Mexico it is forbidden in public schools. Among educational problems common to the Latin American nations are the instruction of the indigenous Indian population, the reduction of illiteracy, the changes resulting from unstable political conditions in some countries, the need for properly prepared teachers, the inequality between rural and urban schools, the education of vast numbers of poor people, and the perennial unrest among students in secondary schools and higher educational institutions.

Other centralized systems. National systems of education prevail in Belgium, the Netherlands, Greece, and other countries where centralized controls are geographically practical and strategic—such as the Middle East (Turkey, Iraq, Syria, Egypt, etc.)—and other political systems not federal in nature. In most traditionally centralized systems, however, local control over educational administration has increased since World War II.

(W.W.B./G.F.K.)

DECENTRALIZED SYSTEMS

Included in decentralized systems are state, provincial, county, and community types of school administration. Local emphases in administration are to be found in countries where public schooling originated in grass roots or separatist movements, or where political unity was achieved out of a confederation of sovereign states; though in some instances of federalization (Italy), a

central ministry has been granted administrative as well as advisory power. As a rule, however, cultural and political units have jealously guarded their control over education. Characteristics of local control may be generalized thus: (1) weak central ministries or bureaus of education, which are largely advisory in character; (2) financial support for education locally derived, aid from central authorities being mostly in the form of supplementary or emergency funds accepted with a minimum amount of control; and (3) administrative power lodged in local boards of education, sometimes appointed, sometimes elected. In such countries as Canada, West Germany, and Australia, where the separate states are sovereign, state ministers of education are appointed and state systems of inspection prevail. In the United States the state executive officer of education becomes either a commissioner of education (if appointed) or a state superintendent of schools, each with less power than his counterpart abroad.

United States. The United States is perhaps the outstanding example of local control on state, county, and community levels. The decentralization of education characteristic of U.S. schooling is a source of bewilderment to observers from other countries who seek to understand not only the many different types of state-controlled education but yet another system in the District of Columbia, administered by the federal government.

The whole is complicated by a myriad of local county, township, or community units of education, by types of schooling directly supported and controlled by the federal government, and by the great variation among the states as regards internal administration and relations with local organizations. Some states, like Delaware, tend toward centralization. Massachusetts is an example of decentralization. Even in the support of education, the amount of funds provided can vary from the practice in a state such as Nebraska, where in the 1960s, for example, over 75 percent of expenditures were underwritten by local authorities, to those like New Mexico, where state rather than local revenues paid for most public schooling. In addition to the various state public-school systems, there exist, outside these systems, parochial schools that are administered by church groups (especially Roman Catholics) and a large variety of privately supported schools.

Federal influence in the U.S.

Although no mention is made of education in the U.S. Constitution, the federal government has been mindful of the need to support formal schooling, exemplified in the Land Ordinance of 1785 and the Northwest Ordinance of 1787, by which part of the national domain was set aside for school purposes, and in the numerous federal statutes that have supported types of education (technical, military, agricultural, etc.) necessary to national welfare. The earliest federal statutes, enacted in accordance with traditional educational practices, gave control of lands and resources to local townships; but by 1804, with the Ohio Territory Act, the states accepted custodianship and assumed control of federal school support.

Education in the different colonies was variously conceived as a family, church, state, or charity matter. In Massachusetts, compulsory school attendance laws were enacted, but responsibility for education still lay with parents. In Virginia, voluntary charity groups were active. Later, however, the federal government, acting by authority of the "general welfare clause" of the Constitution (section 8, article i), required of all states joining the union that satisfactory provision for public education be stipulated in the state's constitution. By a series of Supreme Court decisions the federal government settled local educational disputes and in part guided the course of education in its national implications. The federal government has also supervised the educational welfare of territories, trusts, and dependencies and assumed the responsibility for educational agencies supplying the federal government with the kind of personnel and services it requires. Included in this category are the various academies and institutes that train officers and specialists for such areas as national defense, diplomacy, internal security, and technology. The federal government has also supported educational relief programs, such as the National Youth Administration and the Civilian Conservation Corps in the 1930s, the work-study and other educational programs set up under the Economic Opportunity ("War on Poverty") Act of 1964 and the school-aid bill of 1965.

The U.S. Office of Education was established by Congress in 1867. In 1939 it was transferred from the Department of the Interior to the Federal Security Agency. It became a branch of the Department of Health, Education, and Welfare when that department was established in 1953. It is not an administrative agency in essence, although it has assumed control over some projects supported by the federal government, such as certain programs of vocational education, exchange of students and teachers with other countries, certain aspects of land-grant-college administration, and the general promotion of educational thought and practice throughout the country. Specifically, its functions involve the collection, interpretation, publication, and dissemination of factual information on education, not only in the U.S. but abroad. Its specialists may be drawn upon for counsel by any educational group in the country. (Similar agencies exist in India, Canada, Australia, West Germany, and other nations where federated governments and local controls determine educational administration.)

State influence and responsibility in the U.S.

Responsibility for education in the United States rests with the individual states. The states delegate this responsibility to the local communities, not simply as a devolution of power, as in France and other centralized systems, but as a matter of self-determination under fairly liberal state school codes. It is commonly claimed that the three levels of educational organization and administration in the U.S.—federal, state, and local—are actually interdependent rather than hierarchic. Hence, a system of checks and balances is said to prevail in educational as well as other governmental matters. In practice, however, administration rests heavily on the shoulders of local communities and operates in accordance with local decisions, as long as such decisions accord with federal and state statutes.

On the state level, educational administration generally is headed by a state board of education, sometimes appointed by the governor or the state legislature, sometimes elected. As a rule, state boards of education are less powerful than state ministries of education in other countries, largely because local communities in the United States assume much more administrative responsibility. By way of exception, however, the board of education of the state of New York exercises powerful control over educational standards through a system of statewide examinations. The extensive ramifications of its operations are seen in the fact that its staff consists of over 500 full-time professionals. State boards range in size from 3 to 19. They are largely composed of laymen, but in some instances professional educators may become members.

Again, the duties of these state boards vary from state to state, but in general they all concern themselves with the distribution of state or federal funds (allotted to the states), the enforcement of educational statutes, the determination of basic courses of study, the adoption or recommendation of textbooks, the certification of teachers, the approval of building and maintenance standards, the provision of library services, and the operation of teachers' colleges. State boards likewise interest themselves in the improvement of education as a function of government, the equalization of educational opportunity, the provision of educational leadership, and the improvement of local operations. The inspection of local schools and school systems by inspectors responsible to state boards or other authorities is found in many states but is not as highly developed as in most other countries. School and classroom supervision is provided by local systems through specialists who do not function as inspectors but rather as "helping teachers." In one state they are officially so designated. The genius, but also the weakness, of the U.S. educational system lies in its more

Authority of local school districts in the U.S.

than 30,000 school districts, each exercising an amount of autonomy unequalled in any other country. Administrative authority is assumed by a local board of education, which in about 90 percent of cases is elected by the people. Boards of education are usually independent of other agencies of local government; in fact, school funds voted by boards of education are for the most part not subject to rejection by other bodies. In cases of dispute over budgets between boards of education and boards of finance, the courts have ruled almost exclusively in favour of the former. In most communities, school taxes have first priority and usually are independent of other sources of revenue.

The duties of a local board of education are limited to community needs. It selects the superintendent of schools, who in turn recommends personnel for appointment by the board. In nearly all cases, boards of education have the power directly to appoint nonteaching employees and to determine educational policy for the district, acting usually on professional advice, secured by way of the superintendent of schools and in accordance with the wishes of the community at large. The board assists the superintendent in the preparation of the budget, approval of which obligates the local board to see that tax funds are provided.

Because of the administrative decentralization, there is no uniform school organization or curriculum. Preschool education consists of nursery schools and kindergartens, although the latter in recent years have become more integrated with—usually a part of—the elementary schools. The elementary-secondary sequence overall is 12 years in length (not counting a one- or two-year kindergarten), but the subdivisions of these years are various: eight-four or six-six (elementary school and high school), six-three-three (elementary school, junior high school, and senior high school), and four-four-four (primary school, middle school, and high school), and some modifications of these basic patterns. In many states and local communities, there are also 2-year "junior" or "community" colleges, which provide terminal education (usually vocational or semiprofessional) for many students and the first two years of undergraduate college study for others, who customarily then transfer to full colleges or universities. Admission to a state college or university requires only a high-school diploma in many state institutions, but in other state colleges and universities, the requirements are either a superior high-school record or a satisfactory score on a national test administered by a group such as the College Entrance Examination Board, a nongovernmental organization, or both. Thus, the process of admission is less selective and more flexible than that of most other countries (see below *Sectarian systems*). (G.F.K.)

Federal Republic of Germany. During the 19th century and until the advent of Adolf Hitler and his Nazi dictatorship in 1933, Germany enjoyed an excellent reputation in education all over the world. After the debacle of World War II, Germany was split into four zones of occupation by the victorious powers, so that four systems of education resulted. With the establishment of the Federal Republic (West Germany) and the Democratic Republic (East Germany), in 1949, the organization of education in the West began to come under German direction. East Germany, too, controlled its own educational system, but it drew more inspiration from Soviet education than West Germany did from the English, French, and American systems.

According to Article Seven of the Basic Law (constitution) of 1949 of the German Federal Republic, education is a function of the 11 states (*Länder*), including West Berlin. In each state, the ministry of education exercises fairly complete control over all schools and close supervision of all major activities, although the local authorities (*Schulträger*) have responsibility for school buildings, equipment, and student health and welfare. Financing of schools is generally a function shared by the provincial and the local authorities. External university administration, including certain financial, academic, examination and other aspects, is exercised by the division of higher education of the state ministry of education, though the universities enjoy a large amount of autonomy.

Elements of centralization in West Germany's federal system

Even if West Germany does not have a centralized administration, it has been making some efforts, since 1948, to secure some sort of uniformity through the Permanent Conference of Ministers of Education (Kultusministerkonferenz). The periodic discussions of problems common to the various states has led to the adoption of agreements as to educational policy and content. Such decisions lack a legal status, however, unless they are adopted by the legislatures of the separate states. By way of example, the Hamburg Agreement of 1964 concerned such questions as examinations and grades, the period of compulsory attendance, the beginning of the school year, holidays, and terminology relating to schools.

The school systems of West Germany start with a three-year nursery school and kindergarten. Full-time compulsory attendance extends from age 6 to age 14 or 15, depending on the state; some education is compulsory until 18. The four-year elementary school (*Grundschule*) is the basis of the school system (in Hamburg, Bremen, and Berlin, elementary education lasts six years). Completion of the *Grundschule* leads to the five-year upper elementary school (*Hauptschule*) or to the six-year secondary school (*Realschule*) or to the nine-year academic secondary school (*Gymnasium*) preparatory to the university. In recent years it has become increasingly possible for pupils to demonstrate their ability at various stages and thus be enabled to transfer from one type of school to another. The passing of the *Abitur*, or school-leaving, examination gives the student access to higher education. Recently, through the "second chance" (*Zweiter Bildungsweg*), young adults may qualify for the university by attending a special preparatory school (*Kolleg*) or by passing special examinations. The university or professional college (*Hochschule*) confers a diploma or degree of *Doktor*, which requires a thesis. Formerly, for teaching in a higher educational institution, the presentation and defense of an advanced dissertation was necessary; the successful candidate received the degree of *Habilitation*. This degree, however, is no longer required for assuming a professorial post in a university.

The West German educational authorities are addressing themselves to various problems on the provincial and local levels. One problem concerns the facilitation of the transition between the terminal *Realschule* and the academic *Gymnasium*. Another issue is that of the provision of technical secondary schools parallel to the *Gymnasium*, so as to raise the level of vocational training. Also pertinent is the matter of educational television courses as supplements to instruction and as preparation for higher studies. A perennial question relates to how to teach the German child and adolescent the history of his country during the 20th century, with particular reference to World War I, the Weimar era, the Nazi era, World War II and its aftermath, the relations between West and East Germany, the importance of democratic government and society for the future of Germany, and other significant developments. Much has been done through conferences, teachers' publications, and new textbooks for pupils. (W.W.B.)

Ancient Indian and modern English influences in Indian education

India. In ancient and later times, India served as the educational inspiration for countries in Central and Southeast Asia. With respect to Europe, there was Indian influence, mainly through the Arabs, in the areas of grammar, literature, and mathematics. From the late 18th century to the mid-20th, Indian education came under the influence of the English educational tradition. The ideas of Mohandas K. Gandhi, Rabindranath Tagore, Jawaharlal Nehru, and other national intellectual leaders helped form the foundation of the school system of India, independent since 1947.

India may be taken as an example of local control strongly exercised by the various regional states under state ministries of education. Unlike the United States Constitution, the Indian constitution of 1947 asserts that

the federal government will endeavour to provide free, compulsory education for all children until they reach the age of 14. Partly because the central government did not have sufficient funds to implement this ideal and partly because of the natural diversity of India's population, considerable responsibility for education has been delegated to the states. The National Ministry of Education has advisory functions approximating those of the U.S. Office of Education, but whereas the U.S. commissioner of education is appointed by the president, the Indian minister of education is elected by Parliament and is directly responsible to that body.

Each state ministry of education is headed by an elected minister and has five divisions: (1) administration and cultural relations, (2) bureau of development, (3) general education, (4) technical education, and (5) scholarships. Delegation of authority by the states to the local communities is restricted to elementary education, as is the case in most countries, while secondary education is subject to state control. Indian state governments are responsible for educational policy, the local units being conceived largely as administrative and taxation units. Control over education is exercised through an inspection system.

Advising each state minister of education is the director of public education, who is a permanent executive head of the state ministry. He controls the inspectorial staff, the teachers, and the government-recognized private schools and is responsible for executing the policies of the Ministry of Education, principal among which is the inculcation of basic education through productive activity and local crafts to all children between the ages of 6 and 14. In the curricular system, the pupil may begin an eight-year elementary school at the age of six and possibly move on to a three-year secondary school and a three-year college, which comprise the higher scholastic organization. Other variations of the elementary school offer four- or six-year programs followed by a three-year junior secondary or middle school and a three-year secondary school.

Problems facing Indian education

There are great inequalities of educational opportunity in India, where population distribution, linguistic diversity, and the heritage of the caste system aggravate an already difficult educational situation. The Indian national government has confessed its inability to assist adequately in fostering school development, not for want of desire but from sheer financial inability. It has confined its efforts to supporting higher and technical education, research in the interest of national welfare, experiments in educational methods, the production of suitable literature, the training of specialized personnel, and the translation of important works into Indian languages. The administrative problem in India is therefore not one of where control ideally may be located but of securing the kind of educational organization and administration that will best serve a country that is as yet economically undeveloped, and where the many religions and sects insist upon tying public education to their particular beliefs.

Widespread, endemic poverty often prevents individuals from utilizing their full potential in acquiring an education or, if already educated, from using what they had learned. The problem of basic education, or the teaching of literacy, crafts, and skills, remains a pressing one, inasmuch as India still has some 300,000,000 illiterates.

Apart from the problems of literacy and the untouchables, the most publicized issue has been that of language. With some 12 major regional languages and about 200 other languages, it is clear that a significant barrier exists to effective communication. It is also obvious that a fully educated individual must know Hindi, the "official language of the Union," English as the international and common cultural language, and a regional language. In addition, some may have to acquire written knowledge of another language—their native tongue. The central government is endeavouring to have Hindi accepted as the national language. With political and other factors involved in the campaign, the future of linguistic education in India seems clouded.

Canada. With a population of native Indians and Eskimos and with immigrants from France, Britain, and the American colonies, Canada already had a complexion of cultures by the time the British North America Act of 1867 created the confederation of provinces. During the following century, Canada was to experience an influx of persons from Europe, Latin America, and Asia and thus became, like the United States, a product of many cultures. Under the terms of section 93 of the 1867 act, each of the ten Canadian provinces was given authority to direct educational activities within its own borders. However, the provincial legislatures were denied the right of enacting any law that "shall prejudicially affect any Right or Privilege with respect to Denominational Schools which any Class of Persons have by Law in the Province at the Union." In this way, the religious educational traditions existing at the time, particularly those of the Roman Catholics and the Protestants, were safeguarded (see below *Sectarian education* for further description of Canada's Catholic and Protestant school systems). Other religious denominations were also able to protect their own private schools according to this provision of the act.

In Canada there is neither a central ministry of education, as in all European countries, including England, nor an office of education, as in the United States. Instead, the Education Division of the Dominion Bureau of Statistics publishes an *Annual Survey of Education in Canada;* the Canadian Education Association collects and publishes research studies and disseminates information on procedures and practices in the various provinces; and a national research council assists materially in advanced research and investigation at the university level. The dominion government is not without authority, however, in educational matters. For one thing, it is empowered to overrule any act of a provincial government. It protects the educational rights of minorities; it has provided crown lands for the support of education; it is responsible for the operation of schools in the Yukon and Northwest Territories and for Indians and Eskimos; it grants a limited amount of aid for vocational and higher education; it supports research and other types of educational investigation; it provides special grants to increase staff salaries in universities; it supports school broadcasts. (Pressures upon the dominion government to support education at the federal level are similar to those in the United States.)

The structure of Canadian provincial education

Each provincial department of education is headed by a minister of education, who is a member of the provincial legislature and hence of the party in power and who is responsible to the legislature in matters involving broad educational policy. The deputy minister of education is the chief permanent officer of the provincial department of education. Educational administration within each province is a joint function of this provincial department of education and the local school districts. The functions of the province include curriculum, textbook selection, supervision, and finance, while the school district is concerned with teacher appointments, school maintenance, administration of funds, and general school policy. Some effort has been made, over the years, to achieve some federal coordination by such nongovernmental bodies as the Canadian Education Association, the Canadian Teachers' Federation, and other groups. Moreover, since 1968, the Council of Ministers of Education, which is made up of the educational directors of the ten provinces, has been meeting in order to further interprovincial cooperation. The most persistent administration problem in Canada is how to find the means of providing larger and more efficient units of organization and administration, at the same time preserving local control of schooling in a sparsely settled, widely diversified, heterogeneous nation (see below *Sectarian systems*).

Because of the decentralized nature of Canadian education, there are problems in the description of the school system. Preschool education consists of a two-year nursery school and a one-year kindergarten, but these are not attended everywhere. The elementary school, depending upon the province, may be eight, seven, or six years in

length. Secondary education is generally made up of a junior level, grades seven to nine, and the senior level, grades 10 to 12 or 13. Admission to colleges and universities is gained on the basis of a high school diploma, although an entrance examination may be required by some institutions in certain instances. The higher educational sequence offers programs leading to bachelor's, master's, and doctor's degrees in the humanities, social sciences, sciences, and various professional fields.

Australia. The underlying tradition of Australian education, as one would expect from the composition of its population, has been British. During the 20th century, as a consequence of various connections with foreign countries, other influences, especially American, have been added. As its history developed, Australia turned increasingly toward state involvement in education, equality of opportunity, and secularization. According to the constitution of the Commonwealth of Australia, promulgated in 1900, education was to be a function of the six states rather than that of the federal government. However, without the necessity of any constitutional change, there has taken place an increasing federal participation, mainly financial, in educational affairs.

Anglo-American influences in Australian education

The educational system of each state is centrally administered by a department of education operating under a minister of education. The director of the department, together with his staff and the inspectorate, deal with the elementary and secondary schools and with the teachers' colleges. Denominational and other independent schools, though they do not as a rule receive state aid, are subject to some state inspection and control. Since 1968 the Department of Education and Science of the Commonwealth of Australia undertook to administer education in the Australian Capital Territory and in the Northwest Territory, with teachers supplied by New South Wales and South Australia respectively.

Compulsory attendance begins at the age of 6 and extends to 15 in five states and to 16 in Tasmania. As a general rule, elementary and secondary education last six years each.

Australia may be taken as an example of a system in which administration may be decentralized in the states, but in which, nevertheless, there is a high degree of conformity. Many foreign observers and domestic specialists have been critical of what has been termed excessive centralization and authoritarianism in the administration of education in the states. The uniformity in the various schools within each state is praised by some as contributing to the equality of standards but criticized by others as lacking in creativity and in the opportunity for teachers and administrators to exercise initiative and to participate in the process of decision making. There is a likelihood of change as the tendency of parents to take part in school affairs increases. Laymen have hitherto not had any role of significance in Australian education. The formation of lay groups with a concern for educational issues is another signpost toward possible change in the future.

Financing of education remains a problem in Australia as in many other countries. Associated with it is the suspicion that the federal government would interfere in state school affairs if it gave financial aid. The issue of governmental contributions to denominational schools has been the subject of considerable debate; the arguments—double taxation on the one hand and the weakening of the public school system on the other—have been raised in much the same way as in the United States. The question of selectivity of students for higher education, together with difficulty of transfer from one kind of secondary school to another, has also been aired in conference and in print.

JOINT NATIONAL AND LOCAL SYSTEMS

Examples of national and local systems working cooperatively or in partnership are to be found in Great Britain and, to some extent, Japan.

England. The basic point about education in the United Kingdom is that the Department of Education and Science directs education in England and Wales only. The administration of education in Scotland is under the direction of the Scottish Education Department, which functions under the secretary of state for Scotland. In Northern Ireland, the school system is administered by the Ministry of Education in Belfast. The Department of Education and Science in London is also responsible for all the universities of Great Britain. Although Welsh schools are directed by the Education Office for Wales, located in Cardiff, this is a regional unit of the Department of Education and Science in London.

English education has been formed out of a long tradition going back to the Middle Ages and from a series of laws beginning with the Education Act of 1870, which established compulsory, government-financed elementary schools. Government-supported secondary schools date from the Education Act of 1902, which also set up a national system of education in cooperation with local school administration.

Britain's Local Education Authorities and Department of Education and Science

Present-day educational administration in England was fixed by the Education Act of 1944, which lodged final authority in the central Department of Education and Science (then called the Ministry of Education) but which placed immediate administrative responsibility upon Local Educational Authorities (LEAs). The Education Act of 1944 sets the structure of administration and control but allows local authorities to interpret policies in accordance with local need, preference, and internal school conditions. Central authority is vested in three bodies: the department, the Central Advisory Councils, and the civil service, representing the political, the advisory, and the professional elements of education respectively. The minister of education, appointed by the prime minister, is responsible for broad educational policy and practice within the framework of existing legislation as approved by Parliament. The two Central Advisory Councils (for England and Wales) advise the minister on internal matters of administration. The civil service is responsible for the communication and interpretation of broad policy at the local level. The permanent education secretary guarantees continuity of policy and operations. The "eyes and ears" of the ministry are Her Majesty's Inspectors, better known as HMIs, who are members of the civil service. The HMIs have four major duties: (1) to ensure that government appropriations are being spent wisely, (2) to see that educational legislation is being complied with, (3) to act as missionaries disseminating enlightened educational thought, and (4) to keep the ministry informed on what is being done at the grass roots of education.

The LEAs are not elected directly by popular vote but are appointed by county and borough councils, which are in turn elected directly by the people. Actual supervision is, however, delegated to education committees, which are appointed by the LEAs out of their own membership plus a minority of non-LEA members who are interested in education. One of the committee's functions, like that of a local board in the United States, is to appoint a chief education officer, usually called a director of education. The director of education enjoys less power and independence of action than the U.S. superintendent of schools, his chief function being to present proposals to his committee for decision and action, to record decisions and to carry them out. On the other hand, the headmaster of an English school, especially on the secondary level, is a more powerful and influential person than his U.S. colleague; he is given wide latitude in the formulation and execution of internal policy. As the power of the headmaster increases, it is natural that the power of the director of education decreases. Nevertheless, with the aid of a corps of local inspectors and advisers, the director of education commands a post of considerable weight, which takes on added importance in view of the director's responsibility to the national Department of Education and Science, as well as to his local education committee. Moreover, the national offices exercise additional influence through the distribution of official syllabi and teaching handbooks (though headmasters and

teachers are not constrained to follow them) and the distribution of examinations for the General Certificate of Education and the Certificate of Secondary Education. In general, it may be said that in contrast with other leading nations, England presents an educational administrative system that not only operates cooperatively on both local and national levels but also unites with private endeavours and voluntary organizations to spread the responsibility for control throughout the entire political and social structure of the nation.

Compulsory attendance in England begins at 5 and continues to age 15. The school system makes provisions for nursery schools for children aged two to five. Formal school attendance begins with age five, when the child enters the two-year infant school or department. Between seven and nine, the pupil attends the junior school. The seven-year secondary school may be the comprehensive type with three courses—general (modern), technical, and grammar (academic)—or bilateral with two of these courses. This school has been increasingly replacing the three separate secondary schools, into which children were firmly distributed upon taking a selective examination at the age of 11 (the 11-Plus examinations). Of the 146 local education authorities of England and Wales in 1968, 107 had reorganized or approved the reorganization of secondary education on the comprehensive pattern, while 24 others submitted plans for the approval of the Department of Education and Science. There is a strong likelihood that secondary education will be completely comprehensive in due time.

Admission to a university depends on the results on the Advanced Level of the General Certificate of Education, although Oxford and Cambridge insist on special entrance examinations.

Many of the problems of British education revolved about the determination of the government to extend educational opportunity as widely as possible. This policy not only involved finance but also opposition on the part of those who believe in a high degree of selectivity. Also related to this issue was the campaign to alter the complexion of the traditional, independent (public) schools by securing the enrollment of children from the less affluent elements of society. The status of the colleges of education remains a controversial question in higher educational circles. The growing population of Asiatic, African, and West Indian origins added a new dimension—the racial and ethnic—to the problems of British education. Local areas, such as Birmingham, experienced difficulties with newcomers who made unprecedented demands for special consideration of language, dress, and religion in the educational process.

Japan. The modern Japanese educational system dates from the beginning of the Meiji era in 1868 with the adoption of the policy that "knowledge shall be sought for all over the world and thus shall be strengthened the foundations of the Imperial polity." This was translated into a twofold campaign of importing foreign scholars and professional men to instruct the Japanese and of sending selected young men to study in European and American universities. The outcome was the radical transformation of Japan into a modern, technologically competent society that, in time, excelled the developed countries in several respects. However, the traditional Japanese morality, of Confucian origin, was not only retained but also made the ideological cornerstone of the educational system. The collapse of Japan in World War II brought about the introduction of Western, specifically American, educational ideas and organization. With the passing of the military occupation, however, many of these were modified or discarded and once again the question of moral instruction came to the fore.

Multiple influences on modern Japanese education

After World War II in Japan, educational administration tended to follow directives issued by the United States as the occupying power. Organization was established on three levels: national, prefectural, and local community. The central Ministry of Education, though stripped of much of its power, is still, as in England, the chief administrative authority. The ministry has a secretariat and five divisions: elementary and secondary education, higher education and science, social education, research, and administration. Advice on general policy is afforded by 18 councils on education, including a central council for education. The national Ministry of Education is entitled to draft laws in the interest of national educational standards, but its power to instruct local boards is limited by the Diet, Japan's parliament. Since the ministry allots much financial aid to local systems, especially for school buildings, considerable indirect control is added to that which may be exercised directly. In consideration also of the weakness of local boards, due in part to educational tradition in Japan and in part to insufficient funds for vigorous programs at the local level, the ideal of a weak central Ministry of Education advocated by the United States educational mission failed to materialize. Concrete evidence is seen in such developments as the assumption by the central ministry of responsibility for the nine years of compulsory schooling and the security of teachers' salaries and emoluments. Also, the recommended transfer of university control to local authorities has failed, so that since 1954 universities have fallen within the province of the national educational administration.

Unlike England, the roots of local self-determination, especially in educational matters, are not deep in Japan, so that local controls are in a stage of growth rather difficult to delineate. Local boards of education are legally responsible for the establishment and maintenance of elementary and lower secondary schools; while the prefectural board of education administers upper secondary and special schools, the certification of teachers, certain aspects of private schools, and the choice of textbooks. Originally, too, these boards were supposed to be elected, but because educated Japanese people did not wish to run for the office (or could not afford campaign expenses), and because the Japanese themselves did not feel a strong affinity for the elective process, board members became appointive. Another difficulty with implementing the ideal of local controls in Japan has been the traditional method of collecting taxes. It has not been possible to establish a system of special school taxes, so that local boards must depend upon general local revenues supplemented by allotments from the central ministry. Although the trend may be back to a centralized administration in Japan, local authorities still exercise far more control than before the war, so that a modified type of partnership in educational administration may therefore be said to prevail in Japan, in principle if not always in practice.

Problems of local control in Japan

The contemporary Japanese school system consists of a three-year kindergarten, a six-year elementary school, a three-year lower secondary school, and a three-year upper secondary school.

On the higher educational level, there are two- and three-year junior colleges in addition to universities and professional schools. Compulsory attendance is required from ages 6 to 15.

The educational objectives of the Allied occupation of Japan were to discredit and eliminate militarism and chauvinism and to modernize and democratize the school system. The Japanese constitution of 1946 was a step in this direction and was followed more specifically by the Fundamental Law of Education passed in 1947. It is clear, however, that the present system still makes it difficult for young Japanese who are less than brilliant to obtain opportunities for advancement in education and society; many Japanese educational leaders have felt that the democratic principles that had been pushed by the Americans must be supplemented by the inculcation of the ideals of Japanese morality and love of native land. Many Japanese are convinced that education is incomplete without courses in morals. This view, however, has been increasingly opposed by the teachers' organization (Nikkyoso) and by the Federation of Student Self-Government Associations (Zengakuren), which has frequently demonstrated in behalf of Marxist principles and causes.

SYSTEMS CONTROLLED BY POLITICAL PARTIES

The Soviet Union, the People's Republic of China, and Spain are among the prime examples of educational administration as controlled by a single political party or ideological group.

U.S.S.R. The right of all citizens to education is guaranteed by the constitution (article 121, revised), which provides for universal, compulsory education from ages 7 to 15 and for extensive development of secondary education. All forms of education, both secondary and higher, are free of charge; there is a system of state stipends payable to students who have distinguished themselves in higher schools; education in the schools is in the students' native language; and free technical, industrial, and cultural training for the working people is organized at plants, state farms, machine tractor stations, and collective farms.

The Soviet Union resembles India and China in its multiplicity of cultural, national, and linguistic groups. There are nearly 200 such groups incorporated into the union; more than 100 different languages are spoken. Within the Russian Soviet Federated Socialist Republic, by far the largest union republic, are no less than 100 cultural and linguistic groups. Under such circumstances, the U.S.S.R. could not help but organize as a federal state; indeed, one secret of Soviet success may be traced to the willingness of the central government to cater in part to national and cultural differences, including instruction in vernacular languages at primary and secondary levels, with Russian compulsory.

The administration of Soviet education

Until 1966 the Soviet Union had no central ministry for elementary and secondary education, relying instead upon the 15 separate ministries of education in the constituent republics to unify their activities in accordance with educational directives emanating from Communist Party headquarters and the central government in Moscow. In 1966 the Ministry of Education was set up to direct elementary and general secondary education with the same measure of authority carried by the already existing Ministry of Higher and Specialized Secondary Education, which controls all the universities, the vocational and technical secondary schools (*tekhnikums*), and most of the teachers institutes. Each of the republics now has dual ministries subordinate to these two in Moscow. In addition, there are urban, territorial (*kray*), regional (*oblast*), and district (*rayon*) levels of administration that direct educational work in accordance with the rules and regulations of the respective ministries. The underlying administrative principle is that of "democratic centralism," a hierarchical system whereby authority is exercised downward and information is sent upward through the various echelons. Policies may originate locally, but they have to be submitted up the line for approval. The philosophy underlying all policy and practice is that of the Communist Party, and party principles are the same for the entire nation.

Policy deliberations and decisions on all significant educational issues are made by the Central Committee of the Communist Party of the U.S.S.R. and the Council of Ministers of the U.S.S.R., with statements generally issued under joint auspices. The national legislature, the Supreme Soviet of the U.S.S.R., then enacts these decisions into law, which becomes the model for laws promulgated by the Supreme Soviets of the separate republics. The coordination of educational and economic planning is accomplished by the higher educational ministries together with the State Planning Committee (Gosplan) of the U.S.S.R. and of the republics. The outcome of such planning is the establishment of the number of persons to be trained in specific categories in the higher institutions and the specialized secondary schools of the entire country. The centralization of Soviet education is also illustrated by the existence of the Academy of Pedagogical Sciences of the U.S.S.R., which conducts research programs, prepares courses of study and textbooks, and develops methods of instruction.

Influence of the Communist party

The Communist Party not only sets policy but also determines who may be appointed or elected to educational office and exerts controls in a number of complex ways. Local school boards, for instance, are appointed by executive committees of the local soviet concerned. The local director of education is likewise appointed by the executive committee of the council. School principals are, however, named by local school boards; and principals in turn select the teachers, subject to approval of the school board. The school principal is also in charge of school purchases; but he must buy all supplies from government houses. The internal duties of local school boards resemble those of most countries, but they must look to higher authorities for the determination of overall policy and practice and have no authority to levy taxes. Each school is guided by a council consisting of parents, teachers, Communist Party members, and others connected with school life, including clerks and janitors. These councils occupy themselves vigorously with the ongoing activities of the school, uniting with parent-teacher associations in physical (as well as ideational) projects, such as cleaning and redecorating classrooms and providing benefits and perquisites not forthcoming from governmental sources.

In addition, there is an inspectorial system (under the control of each republic ministry), which interests itself in the improvement of teaching and classroom management. Although inspectors must see that party policies are carried out, in practice, they interest themselves primarily in modern pedagogical methods and in supervision; they also teach demonstration classes. Inspectors cooperate closely with school principals; they do not "rate" teachers, except to recommend awards or special honours for particular tasks well done.

The Soviet school system begins with a nursery or crêche (*yasli*) for children between the ages of three months and three years. The kindergarten (*detsky sad*) provides additional preschool education to children between three and seven. Then follows an eight-year school (*vosmiletnyaya shkola*), which covers the compulsory attendance period of 7 to 15. The first four years are considered elementary (*nachalnaya shkola*), whereas the remaining years constitute the first stage of the secondary school (*srednayaya shkola*), which is two years in length. Beginning with the fall of 1969, a new change in elementary education, first in Moscow and eventually through the Soviet Union, makes the elementary school three years long and the secondary school seven years and available to all. Admission to a higher educational institution is achieved after the completion of the ten-year school with a certificate of maturity (*attestat zrelosti*) and the passing of a highly competitive entrance examination. The possession of recommendations from officials testifying to service in the Communist Party of Komsomol, the trade unions, agriculture, industry, or the armed forces is a vital aid to acceptance to higher education, enabling the applicant to enter on the basis of a less rigorous selective process.

Finally, Communist education naturally has the task of preparing future leaders, for whom special party schools are established. In all schools the party exerts its influence in the organization of pupils in various types of political youth leagues, with Pioneer groups for ages between 10 and 15 and the Komsomol, or Young Communist's league, for youth over 14. Members of these groups are chosen for their loyalty to party principles and their actual or potential capacity for leadership. In sum, administrative policies in the U.S.S.R. may sometimes originate in local areas, but, even then, to become effective they must be approved at the top. Approved policy then sifts down through the various levels, and its enactment is overseen by party members or affiliates, who penetrate every phase of public and educational life.

People's Republic of China. Practices similar to those in the Soviet Union prevail in China, despite the present ideological split. Following World War II Chinese schools were reorganized under the aegis of Russian counsellors and modelled after the educational ideals of the Soviet Union. Articles 41 through 47 of chapter 5 of the Common Program contain the core of Chinese ed-

Centralization in Communist Chinese education

ucational policy. Education, according to this program, shall be "national, scientific, and cultural." It shall promote the five "loves": fatherland, people, labour, science, and public property. Education and politics become inseparable, so that educational leaders are either members of the Communist Party or pledged to support its principles. The entire nation is organized under such centralized ministries as finance, trade, labour, heavy industry, fuel industry, textiles, foods, light industries, railways, communications, agriculture, conservation, forestry, and land reclamation. The listing of these ministries is not merely a verbal duty; it reveals the nature of Communist China; and the school system is charged with providing trained personnel for all these ministries.

As in the Soviet Union, the administration is highly centralized under a Ministry of Education and a Ministry of Higher Education in Peking. The former has jurisdiction over the nursery, kindergarten, elementary, middle, part-time, and teacher-training schools; the latter, over the universities, colleges, higher technical schools, and research institutes. It is worthy of note that there was a single ministry controlling all education in 1949, two in 1951, one again in 1954, and two once more in 1964. As in the Soviet Union, private schools and colleges are not permitted to exist, thus assuring complete educational centralization.

The administrative structure in Chinese education is similar, in terms of hierarchy, to that of other countries: apart from the national ministry, there are educational authorities on the provincial (*sheng*) and the county (*hsien*) levels. School administration is said to be "democratized" by the organization of educational councils, in which teachers, students, and workmen enjoy equal voting status. The democratic way is also said to be practiced in all kinds of meetings and discussion groups, findings of which are transferred for action to higher authorities on the basis of "discussion by the many but decisions by the few." Heading these educational discussions, or influential in their operation, however, are members of the party. When one compares two such highly nationalized systems as China and France, political preference is readily discerned as perhaps the chief agent for ordering educational ends, even though the means of administration are similar.

School organization in Communist China does not differ substantially in structure from that of China prior to 1949 or from that of Taiwan. The major differences are in the underlying philosophy, the content and method of instruction, and the administrative control. The nursery is for children up to the age of four, while the kindergarten is for those aged four to seven. Formal elementary education extends for six years, but attendance is not compulsory by law, inasmuch as schooling, which is regarded as a privilege, is virtually universal. Two three-year middle schools provide general secondary education. Of special significance are the half-work and half-study schools, which seek to bring about the synthesis of the labourer and the intellectual. As in the Soviet Union, the children and the young people obtain political education from the Young Pioneers and the Communist Youth League. Students who are not admitted to either branch of the middle school may enroll in a vocational, technical, or normal school, or go directly to work. Admission to the university is on the basis of the national need of specific specialized personnel, an entrance examination, political status, and social (*i.e.*, proletarian) origin.

The aim of Communist Chinese education comprises the development of the new Chinese man who will be imbued with the Marxist-Leninist principles and who will use his knowledge and ability for the cultural advancement of the country and for the perpetuation of Communism. The Chinese authorities themselves often speak of education as aiming at the achievement of the status of "both red and expert," meaning one who is simultaneously a dedicated Communist and an accomplished specialist.

Spain. In recent decades Spain has attracted less notice in educational affairs, in part because of the powerful control exercised by the regime of Francisco Franco and by the conservative Spanish wing of the Roman Catholic Church. Recognizing that in an increasingly technological world persistent illiteracy, unequal educational opportunity, and other practices handicap the country, Spain's legislature, the Cortes, adopted in 1970 a new law to reform Spanish education. The tempo of educational change, evidently, is increasing: as recently as 1964 compulsory attendance was raised to age 14 (in law if not always in practice), and the Technical Education Act provided for advanced study of technical subjects.

Like the classic French system, Spain is divided into educational districts—12 of them—each with a university as a centre. All districts are subordinate to the central Ministry of Education and Science (Ministerio de Educación y Ciencia) in Madrid and liable to periodic or ad hoc inspection by its representatives. This central control applies to private as well as public schools. There are not only a hierarchy of inspectors—such as *inspectores generales* and provincial *inspectores centrales* and area *inspectores*—but also a complex of "technical advisers" who share in guiding teachers in the performance of their work. Although universities are outside the system of state inspectorates and in theory are autonomous, the rectors of all the universities are called to Madrid for regular meetings with the minister of education and science in order to arrive at important decisions.

The Spanish "academic" school system consists of a two-year nursery school (*escuela maternal*), a two-year kindergarten (*escuela de párvulos*), a four-year elementary school (*escuela primaria*), and a seven-year secondary school (the public *instituto* or the private *colegio*). Admission to an academic secondary school, which is not free, is possible after four years of elementary education if the pupil obtains a certificate (*certificado de estudios primarios*) after an examination. Secondary education is divided into three cycles: a four-year course leading to the diploma of *bachillerato general elemental;* a two-year course ending with the *bachillerato general superior;* and a one-year *curso preuniversitario*, the successful completion of which entitles the student to enter any faculty in a higher educational institution. In addition to the academic schools, Spain has a network of many vocational, trade, industrial, technical, commercial, and art schools on the different levels of instruction. Elementary school teachers are prepared in a secondary-level institution (*escuela de magisterio*) with a three-year program. Secondary school teachers must hold the university degree.

Political and religious influences in Spanish education

The fundamental aim of education in Spain, the development of a literate citizenry, is similar to that of modern nations generally. Special attention, however, is given to the formation of loyalty to the political ideology of the government and to the principles of religion as taught by the Roman Catholic Church. The Spanish state guarantees the teaching of the Catholic religion as a regular and compulsory subject in all educational institutions, whether state controlled or not, and no matter what their level and purpose. Any publication at all may be suppressed if it is contrary to Catholic dogma and morals. Also, in tests for the selection of teachers, for example, examining boards are composed of five members, three of whom, including the chairman, must be church officers. It must be said, however, that religious minorities have been receiving increased privileges in recent years with regard to education. In the early 1970s, moreover, the Spanish bishops had decided to separate themselves from politics and concentrate more on religious matters.

(W.W.B./G.F.K.)

SECTARIAN SYSTEMS

Religious and denominational influences control school administration in various nations and regions of the world—including Spain (as noted above), Ireland, certain provinces of Canada, and such Muslim countries as Pakistan. In some other countries, such as the United States, ecclesiastical and other religious bodies maintain elementary and secondary school systems separate from the public school systems.

Ireland. The aim of Irish education, as expressed in the republic's constitution of 1937, echoes the principles propounded by Pope Pius XI in the encyclical *Divini Illius Magistri* (1929), on the "Christian Education of Youth." Fundamentally, the government recognizes the natural right of parents to direct the education of their children either at home or in state schools. While the Roman Catholics, who comprise 97 percent of the population, are accorded a "special position," the state also recognizes the existing Protestant sects, the Jewish denominations, and the other religious groups. This recognition occurs not only in the freedom of religious instruction but also in the form of financial subsidies for the schools of minority religions. Religion is a component part of all curricula, including vocational education, of all institutions without regard to religious group, since there are no neutral or secular schools in Ireland. However, in line with article 44 of the constitution of 1937, the right to be absent from religious instruction is guaranteed.

Roman Catholic involvement in Irish education

Educational administration is centralized in the Ministry of Education, which issues a manual, *Rules and Regulations for National Schools*, and courses of study. The national inspectors, with the authority of the Ministry of Education, perform a critical and an instructive function in the effort to ensure compliance with the educational directives in the national or state-supported schools.

Compulsory school attendance extends between the ages of 6 and 14. After the preschool, the child enters the six-year elementary school, where he obtains the basic learning—Irish, English, arithmetic, and other subjects required for later education. Then follows the secondary educational sequence of four to six years, depending on the academic or vocational nature of the program. Entrance into a secondary school, until recently, depended on the possession of a Primary School Certificate or the passing of a special examination; now a school principal's report card is generally sufficient. Those pupils who do not go on to the secondary school complete their compulsory education requirement by attending extended primary classes, the "Secondary Top," and may even continue with secondary courses to the age of 18, at which time they may apply for the state examinations leading to the Leaving Certificate and admission to higher education. The secondary schools, many of them operated by Roman Catholic religious orders, though free, are under private control. (W.W.B.)

Canada: Quebec and Newfoundland. As noted in the discussion of Canada under *Decentralized systems* above, the British North America Act of 1867 delegated jurisdiction over education to the provinces. In the provinces of Quebec and Newfoundland, administration is sectarian in nature, though the schools are otherwise "public." Education is free and compulsory, but children must attend the school of their denomination, unless an "outsiders' fee" is paid. Quebec developed with two distinct groups: the Protestant English and the Roman Catholic French, each demanding the right to educate its members. There was no minister of education in Quebec until 1964 when such a ministry was established; the dual Catholic-Protestant system was retained. School districts may be organized by minorities in any community, if there are a sufficient number of pupils to justify the procedure and a sufficient number of taxpayers capable of assuming the responsibility. This principle of "dissent" is guaranteed by law. Individual taxpayers may also designate the school system to which their taxes must be paid. The French-speaking school districts in Quebec are generally coterminous with the Roman Catholic parishes; otherwise, it is obvious that political districts and school districts are not necessarily identical.

Denominational schools in Quebec and Newfoundland

In Newfoundland, where early settlement took place along denominational lines, nearly every local community has a majority of one or another of the various denominations. This situation has produced a sectarian system of education, whereby the churches of the various groups have built and in large part control their own schools. Directors of education are nevertheless responsible to the provincial ministry of education. Increasingly the schools of Newfoundland are becoming consolidated, however, especially at the secondary level, reflecting a national trend. (G.F.K.)

Pakistan. An Islāmic system of education can be exemplified by Pakistan, which, in its constitution of 1949, proclaimed that sovereignty and authority were derived from Allāh. Initially, a dominion in the British Commonwealth of Nations, Pakistan became an Islāmic republic in 1956.

Islamic influences in Pakistan

Education in Pakistan is dedicated to the perpetuation of the ideas and values of Muslim religion and society, a tradition dating from the rise of the Muslim faith in the 7th century. With over 88 percent of the population adherents of Islām, it is understandable that considerable attention is paid in the schools to the teachings of the Qur'ān and the Ḥadīth (oral tradition), which are the basis of orthodoxy (*sunnah*). At the same time, as a developing nation desiring to modernize itself as rapidly as possible, Pakistan has organized schools and higher education that would prepare personnel to help achieve this aim.

The responsibility for education is vested in the central Ministry of Education, which sets and proclaims policies and coordinates the activities of subordinate bodies. When Pakistan was divided into two provinces, East and West Pakistan, separated by more than 1,000 miles of Indian territory, it was necessary to set up two distinct provincial departments, each headed by a secretary of education. When the eastern province broke away and became the new state of Bangladesh, there remained only the single secretary in Karachi. Thus, Pakistan now has six regional directorates of education, which report to the director of public instruction in the provincial department. To some extent, the local school authorities share some of the educational power.

There are three forms of educational facilities in Pakistan: public schools and colleges, fully financed by the central or provincial authorities; public schools, supported jointly by central, provincial, and local governments; and private schools, which may be independently endowed or which may receive government aid for buildings and maintenance. The traditional schools, *maktab* (or primary school), *madrasah* (or general school), and *dār al-ʿulum* (or "house of sciences") did stress Islāmic religion and culture and did not favour the standard subjects of the humanities, mathematics, and the like, but even they are becoming more secularized. The secular component of Pakistani education consists largely of the various subjects taught in modern school systems, even though due recognition is still also given to the moral and spiritual values of Islām. The structure of the secular system is made up of a five-year elementary school for children aged five or six, a three-year middle school, a two-year high school, and a two-year intermediate college. Limited preschool education exists mainly in the larger cities. Pakistan has not yet passed a compulsory school attendance law.

Education in Pakistan underwent a crisis as a result of the exchange of populations with India during the establishment of the country. Among the pressing contemporary problems is that of illiteracy. As of 1961, 84.1 percent of the total population were illiterate. The highest rate of illiteracy was 96.6 percent in the Lasbela district of West Pakistan. Even with a reduction of illiteracy during the 1960s, the problem was far from being solved. Alongside this is the issue of the uncertainty of a national language, with implications of difficulties for education. The elementary school curriculum is composed of reading and writing a national mother tongue: this is usually Urdu; English is optional. (W.W.B.)

United States: parochial education. Many church parishes and other religious bodies in the United States maintain elementary and secondary schools that provide education based on sectarian principles and are separate from the public, or common, school system. Such schools for the children of members of a parish or congregation are supported principally by the voluntary offerings of the parishioners, augmented occasionally by modest fees; they are distinguished from public schools operated un-

der the direction of school boards made up of local citizens and supported by public taxes and from private schools maintained by private individuals or groups and supported principally by tuition fees. These parochial systems or schools exist for the three major religious divisions in the United States: the Roman Catholics, the Protestants, and the Jews.

Roman Catholic parochial schools. These schools in the United States are organized on a diocesan basis and are financed by the parish. In some areas they may serve the children of several parishes or a district defined by the bishop. Such schools are called diocesan schools and are financed by the several parishes involved and sometimes by diocesan funds. The administration of the schools of a diocese is the direct responsibility of the bishop. This work is usually delegated to a priest appointed by the bishop, who is given the title of superintendent of schools or secretary for education. His functions closely parallel those of the chief school officer in the public school system. He is responsible for the organization and supervision of the schools of the diocese, selection of textbooks, preparation of courses of study, policies and practices of all the schools, and enforcement of diocesan and state regulations. His office and authority are defined by the bishop.

Roman Catholic schools in the U.S.

Most dioceses have a school board made up of members appointed by the bishop. Usually this board has no administrative power but acts in an advisory capacity to the bishop and his chief school officer.

The Roman Catholic schools teach the same subjects as the public schools, but two important differences should be noted. In the Catholic school, a course in Christian doctrine is included that presents the truths of faith and morals that are the teachings of the Roman Catholic Church. Other courses, particularly in such areas as the social studies and humanities, are often given a Catholic orientation.

Oftentimes diocesan systems organize on a statewide or regional basis in order to share certain educational advantages and to exchange ideas and programs for the betterment of their teachers and schools. All diocesan systems are members of the National Catholic Educational Association, a nationwide organization established for the mutual benefit of all schools and teachers. The common interests of the Catholic bishops of the United States in education are represented by the department of education in the National Catholic Welfare Conference.

Protestant parochial schools. Among Protestant groups that maintain parochial school systems in the United States, the Lutheran bodies are by far the most active, with around 190,000 children in Lutheran schools. Smaller school systems are sponsored by the Seventh-day Adventists, the National Union of Christian Schools, the Protestant Episcopal Church, the National Association of Christian Schools (evangelical), and the Quakers, Mennonites, Baptists, Methodists, and Presbyterians.

Protestant schools in the U.S.

The administration of most Protestant schools is in the hands of a board of education elected by the sponsoring group—either individual congregation, association of congregations, or association of individuals. This board selects a principal and in cooperation with him develops the policies that control the school program. The clergy of the sponsoring groups have been active participants in all aspects of such school programs.

The teachers in Protestant schools are drawn from denominational teachers colleges and liberal arts colleges. In addition to meeting the general requirements set for teachers at the elementary and secondary levels, teachers in Protestant schools need training in Bible and doctrine to achieve the objectives of Christian education.

Protestant elementary and secondary schools strive to meet or exceed the educational requirements of the several states. While the course of study for each grade is substantially the same as given in the public schools, Christianity is made a unifying and integrating factor in the educational program.

Jewish parochial schools. The Jewish day school or "complete" school (*i.e.*, the Jewish parochial school) in the United States is an educational institution in which a combined program of Jewish and general studies is offered. There are four types of institutions that provide intensive Jewish religious education as well as a complete course of study in general subject matter. These are the Talmudic day school, the modern day school, the integrated day school, and the Hebrew-English private school.

Jewish day schools and private schools in the U.S.

The Talmudic day school makes provision for the study of the Hebrew texts of the Pentateuch, major portions of the Prophets and Scriptures, including the Masoretic commentaries, and places great stress on teaching of the Talmud. The secular studies meet the requirements of the city and state authorities. The school day ranges from eight to ten hours. Hebrew studies are given in the morning hours and the English in the afternoon.

The modern day school stresses the study of Hebrew language, the Bible, Jewish history, prayers, and selected portions from the Talmud. All instruction is in the Hebrew language. The secular subjects generally are given equal attention and equal time.

The integrated day school aims to achieve a blending of instruction in Judaism and secular subjects. To attain this end "both curricula are offered departmentally throughout the school day." The pupil may begin the school day with the study of the Bible, go next to a lesson in arithmetic, then proceed to the reading of a Hebrew text, then to geography, and so on.

The Hebrew-English private school emphasizes the study of general subjects and provides opportunities for Jewish learning for only five hours a week. Its aim is to be a modern and progressive school that satisfies those parents who seek private instruction of a high calibre and who are eager to solve the problem of a two-school system. A number of day schools are also sponsored by Yiddish culture groups. The program of these schools differs from the modern day school in that Yiddish language and literature are included as basic subjects of instruction.

The majority of day schools (85 percent) are sponsored by Orthodox groups. Some that fall in the category of modern day schools are conducted by Conservative and other groups. By the 1960s enrollment in the United States and Canada had increased to more than 50,000 pupils in about 300 schools, almost one-half of which were in New York City. The number of children in the day school constituted 8.5 percent of the total Jewish religious school enrollment. The overwhelming majority of Jewish children attend the public schools, and for them Jewish education is supplementary to their general education. Most day schools conduct classes on the elementary level; only a few operate high school departments. Torah Umesorah (National Society for Hebrew Day Schools) and the National Council for Torah Education help to establish day schools, place teachers and administrators, conduct seminars and workshops for educational personnel, and publish Hebrew text materials.

(Ed.)

III. Trends and prospects

Worldwide, many educational trends and changes are clearly evident, even though there remains a confusion of policies. Of particular international concern is the modernization and growth of the developing nations. The interest in, and responsibility for, the development of these countries has been manifested by the industrialized nations, by intergovernmental bodies, nongovernmental groups, and higher educational institutions. The newer countries are beset by problems that cannot be solved by any form of instantaneous action. One such problem is the "brain drain," whereby young students and professionals of underdeveloped countries trained in advanced countries find socioeconomic conditions there so much more favourable to their growth that they fail to return and help their own people to attain their national objectives. It is clear that the underdeveloped countries cannot rapidly become developed under such circumstances. In a number of instances, however, the changes under way hold out promise for the better utilization of native talent

Developing nations

educated abroad. The growth of indigenous universities, together with the multiplication of suitable employment opportunities and the recognition of the academic and professional attainments of natives, may operate, in the years to come, in favour of the development of new countries so that they will be decreasingly dependent on the industrialized nations.

Science and humanism

The emphasis from the 1950s to the 1970s on science and technology in government and society had its repercussions on all levels of education from the primary through the postgraduate. The spectacular advancements in the various branches of theoretical and applied science contributed to the growth of interest in such studies. At the same time, some observers in different countries began to call attention to the relative neglect of and lack of interest in the areas of the humanities and the social sciences. Concern was expressed in many quarters at the decline of values and morals among young and old; the rise of violence on local, national, and international scales; and the growing prevalence of pollution of the environment, with the resultant dangers to man everywhere. Some have questioned the governmental policies whereby large shares of the budget were allocated to science and technology, while insignificant sums were granted for culture and general education. The malaise that seemed to have gripped the economically advanced nations also appeared to have engulfed the developing countries, which desired to take a giant step forward and enjoy very quickly what they conceived to be the benefits of modernized living. It was obvious to critics of the contemporary scene that some reassessment would have to take place. Just as the scientific and technological revolution took place as a reaction to a rather fixed society and order of things, it seemed desirable, perhaps inevitable, that there would be a resurgence of the humanistic values in life and education. Many hoped for and looked to a better balance of what C.P. Snow called the two cultures, both in the older and in the newer nations.

Early childhood education

One of the noteworthy trends in recent years has been the increase of attention to, and of facilities for, preschool education, especially prior to the kindergarten period. Some countries, such as the Soviet Union, have placed considerable weight, for social and economic as well as educational reasons, on the years of early childhood. Although the idea was not really new—one thinks of the experiments in nursery education in Britain and elsewhere in the 1920s—it is only relatively recently that a trend along these lines has developed on a wider geographical scale. To some extent, this is a response to the socioeconomic conditions that require the entrance of women into the labour force. But one cannot overlook the cumulative effect of the research findings and public statements by educators and child-development specialists—psychologists, psychoanalysts, psychiatrists, sociologists, and social workers. It is fair to speculate that, in spite of the added cost to all countries, the nursery school will be increasingly recognized as a basic component of national educational systems in various parts of the world. There may be some opposition on the part of parents and professionals who feel that the family is the fundamental educational institution, and such a view cannot be discounted. However, it is possible that the values of a socialized educational experience for every child, for part of the day at least, will find favour among all types among the population (see also PRESCHOOL EDUCATION).

The new media

The development of mass communications through new media has made more people than ever aware of the educational potentialities of radio, television, and devices for rapid reproduction of printed and visual materials. Some advantage has already been taken of the newer mass media for the wider circulation of information and ideas. Workers in the field of adult education in many countries have made use of them in the teaching of literacy, liberal arts, cultural experiences, and vocational work. In schools, even in developing countries, one can nowadays find records, tapes, projectors, screens, films, and various other devices that serve as aids in teaching the sciences, social studies, and other areas of knowledge. In many countries, teaching machines and computers have made their appearance. It is easy to understand that the new devices demand an increased expenditure, a factor that might inhibit adoption in the more impoverished areas. There are some educators and others who look upon the mass media as something less than an unmixed blessing, especially since these methods might facilitate the dissemination of untruth as well as truth, misunderstanding along with understanding. The likelihood, in general, is that the newer mass media will persist as helps to the educational process, just as the book and the blackboard became recognized as fixtures in the schools of the past.

Some note has already been taken of the increasing impact of science and technology on the mind and world of modern man. The advent of automation in industry and in other aspects of contemporary life has also given rise to reflection in many circles all over the world. There is little doubt that large numbers of persons are enjoying what they regard as benefits of living, travelling, and consuming brought about by the introduction of automation in industry and society. The reduction of the amount of time spent at work by the average man in advanced countries has resulted in an increasing awareness of the importance of the wise use of leisure, as well as of the freeing of the mind and soul of man from the uniformity and mechanization of life. Many educators and others who followed this development with concern gave more thought to the importance of adult education and free-time activities. The availability of time, due to a shorter work day, an outcome of labour-union activity, industrial automation, and other factors, made possible the planning of constructive and meaningful recreational activities and educational programs. Such a situation was conceivable, as a rule, in an economically advanced country, rather than in one which was still undergoing development. Yet, in the developed countries, there did not seem to develop a mass movement toward the maximum utilization of time released from labour for benevolent recreation, cultural development, and educational growth. In far too many cases, in different parts of the world, leisure time was employed in an aimless, monotonous pursuit of nonconstructive and superficial activity. The process of reorienting the general public toward a voluntary acceptance and appreciation of the value of applying the spare time, or part of it at least, toward enhancing one's educational and cultural level will remain an arduous one.

The uses of leisure

In view of the fact that automation will doubtless continue and even develop further, there is a definite obligation for a greater expenditure of effort on the part of educators and others concerned with a stable society to convince men and women of the necessity of the wise and constructive use of leisure time.

(W.W.B.)

Education of the Exceptional

In the context of education, the term exceptional children refers to children who deviate socially, mentally or physically from the average to such an extent that they require major modifications of usual school practices in order to develop to their full capacity. Approximately 10 to 15 percent of all school children are considered exceptional in these terms.

Special education

To promote their maximum development or to lessen their dependence on society, handicapped and gifted children are often provided with programs of "special education." Special education involves adaptations of the curriculum, the teaching techniques, or the organizational program, rather than a necessarily totally different program. It refers only to those aspects of education that are unique or are added to the regular program. The amount and kind of adaptation needed depend upon many factors, including the degree of deviation and the type of deviation.

TYPES OF VARIATION AND HANDICAP

The gifted. Children who are superior in intellectual ability often function two or more years ahead of the grade level in which they are normally placed. It is not unusual to find a gifted child of 10 who is reading at the level of age 14 and who is interested in science and history well beyond his age level.

The gifted have been variously defined as those having IQ's on an individually administered intelligence test above 125, 130, or 140, but since the IQ definition alone is not usually considered to be conclusive, other criteria are used.

The mentally retarded. Among intellectual deviates are children variously called mentally retarded, intellectually limited, or subnormal. (The older terms feebleminded and mentally deficient are not generally used in education.) These children appear to be substantially below the average child in learning ability and find it difficult to cope with the program of the regular grade levels.

The mentally retarded are generally classified according to the degree of mental subnormality they exhibit and their potential for learning and adjustment. For educational purposes the majority are grouped in school in classes for either the "educable" or the "trainable" mentally retarded. The classification "educable mentally retarded" covers those children whose IQ's are roughly between 50 and 75 and who can be educated (1) academically, to the level of an average child of 9 to 11 years of age; (2) socially, in adjustment to the home and community; and (3) occupationally, in being able to support themselves totally or partially at the adult level. The classification "trainable mentally retarded" covers those children whose IQ's are roughly between 25 and 50, but who can be trained to learn (1) self-care skills such as dressing, feeding, and toiletting; (2) social adjustment in the home or immediate neighbourhood; and (3) some degree of economic usefulness in the home and neighbourhood or at routine tasks in a sheltered environment under supervision. The "totally dependent" retarded child (IQ below 25) is generally under health or nursing care auspices.

Educable and trainable retarded

Sensory handicaps. The two sensory handicaps most affecting children's education are impaired vision and impaired hearing.

The visually impaired. A person is defined as "blind" if his vision (after correction) is 20/200 in his better eye. This degree of visual acuity is in general inadequate for education through the eyes, and special techniques have been devised to make possible education through tactual and auditory channels. A person is defined as being "partially sighted" if the vision in his better eye (after correction) is less than 20/70 but better than 20/200. Such children need special equipment and are often taught in special classes or resource rooms that provide special methods and materials. In many cases they can be educated in a regular class if special materials and equipment are provided.

Children with impaired hearing. Like children with impaired vision, the deaf and the hard of hearing fall into separate categories. Those designated as "deaf" are so impaired in hearing that they have to be educated exclusively through other senses. The "hard of hearing," on the other hand, have sufficient hearing to be educated through the auditory channel though amplification devices such as hearing aids are needed.

Orthopedic and neurological handicaps. *Orthopedic and special health problems.* Children who are crippled or orthopedically handicapped and those with special health problems include many categories. The crippled child is one who has an orthopedic impairment interfering with the normal functions of the bones, joints, or muscles to such an extent that special arrangements must be made by the school to transport him and to adapt him to a school environment. Included in the category of the crippled are children born with such handicaps as dislocated hips or joints, club feet, and spina bifida and children born normal who acquire a crippling condition through accidents or through such infections as poliomyelitis, osteomyelitis, and tuberculosis of bones or joints.

Some children have special health problems that do not result in motor handicaps. These include cardiac conditions, tuberculosis, delicate constitution, and chronic illnesses that may nonetheless require special adjustment of school programs.

The neurologically impaired. Neurological impairment probably affects more children than any other cause

of exceptionality. It occurs in many forms and in many degrees of involvement. Not a disease, it is a condition affecting the nervous system. It may involve intelligence, the neuro-motor functions, perceptual abilities, the senses, bodily balance, or any combination of neurological involvements. Cerebral palsy, the most commonly diagnosed neurological impairment, results in a disturbance in the development of neuromotor functions and is sometimes associated with deficiencies in vision, hearing, and speech. Intelligence is also affected in half these children. Usually they are either spastic or suffering from extremely jerky movements of the limbs (athetoids).

Cerebral palsy

Epilepsy is a specific form of neurological impairment resulting in recurring motor, sensory, or psychic malfunctioning of varying frequency and varying degrees of intensity. It has been stated that 50 percent of all epileptics can be kept free of convulsions with the proper administration of drugs and that 80 percent can lead normal lives and even engage in competitive work. The control of epilepsy by drugs has, of course, resulted in a decrease in the number of schools for epileptics, since most of these can be educated in regular grades and school situations.

Epilepsy

Communication disorders. *Speech defects.* Speech is considered defective when it deviates from the average enough to draw unfavourable attention to the speaker, whether through unpleasant sound, lack of intelligibility, or unappropriateness to the age level of the speaker. Such defects include disorders of articulation, disorders of voice, delayed speech, stuttering, and speech disorders resulting from cleft palate, cerebral palsy, or hearing loss. A large percentage of speech problems respond to therapy, and many may be completely corrected.

Learning disability. Learning disability as an educational term refers to a disorder or delayed development in the processes of communication or academic achievement and has been defined by the National Advisory Committee for Handicapped Children as follows:

> Children with special learning disabilities exhibit a disorder in one or more of the basic psychological processes involved in understanding or in using spoken or written language. These may be manifested in disorders of listening, thinking, talking, reading, writing, spelling, or arithmetic. They include conditions which have been referred to as perceptual handicaps, brain injury, minimal brain dysfunction, dyslexia, developmental aphasia, etc. They do not include learning problems which are due primarily to visual, hearing, or motor handicaps, mental retardation, emotional disturbances, or to environmental disadvantage.

Social and emotional disorders. Some children are either unable or unwilling to conform to accepted norms of behaviour, and if these deviations are serious or extreme or persistent, they are considered behavioural disorders. Basically, such problems fall into two categories: (1) emotional maladjustment, in which the child shows inner tensions, anxiety, neuroticism, or psychotic behaviour, and (2) social maladjustment, in which the child shows defiance and disregard for constituted authority and general antisocial behaviour. Although there is sometimes an overlap between the emotionally disturbed and the socially maladjusted, emotional disturbance basically refers to the psychological characteristics of the child, whereas social maladjustment refers to the relations of the child to society as a whole. In many instances a child may be well adjusted, conforming to his peer group or gang but quite maladjusted with regard to the larger society.

PATTERNS OF SPECIAL EDUCATION

Historical background. Although some attention was given to the care and protection of handicapped children shortly after the beginning of the Christian era, special education in Western society did not truly begin until the 16th century. Pedro Ponce de León (1520?–84) successfully taught some deaf pupils in Spain to speak, read, and write; and it is assumed that his methods were followed by Juan Pablo Bonet, who, in 1620, published the first book on the subject. This gave rise to a wider interest in the education of the deaf in Europe. In England John Bulwer (fl. 1654) wrote on teaching the deaf to speak and read the lips, and in France, similar work was later carried on by Charles-Michel, abbé de l'Epée (1712–89), who made a most profound contribution in developing the natural sign language of the deaf into a systematic and conventional language to be used as a medium of instruction. His work was developed by the abbé Sicard (1742–1822) and gave rise to the manual system or silent method of teaching the deaf. In Germany Samuel Heinicke (1727–90) educated deaf children orally, and later Friedrich Moritz Hill (1805–74), perhaps one of the greatest educators of the deaf, developed this method in relation to the concept that education must relate to the "here and now" of the child—known as the natural method. Thus arose the oral method of instruction that continued to influence the teaching of the deaf and in time became an accepted practice throughout the world.

No real attempt was made to educate or train the blind until the close of the 18th century. Valentin Haüy (1745–1822), the man to whom the title "father and apostle of the blind" afterward was given, opened the Institution Nationale des Jeunes Aveugles in Paris in 1784, with 12 blind children as his first pupils. News of Haüy's success in teaching these children to read soon spread to other countries. Schools for the blind were opened in Liverpool (1791), London (1799), Vienna (1805), Berlin (1806), Amsterdam and Stockholm (1808), Zürich (1809), and Boston and New York (1832).

Scientific attempts to educate mentally retarded children began with the efforts of Jean-Marc-Gaspard Itard (1775–1838), a French physician and otologist connected with an institution for the deaf. In his classic book, *The Wild Boy of Aveyron* (1801), he related his five-year effort to train and educate an 11-year-old boy found running naked and wild in the woods of Aveyron. Later Edouard Séguin (1812–80), a student of Itard's who emigrated to the United States in 1848, devised an educational method using physical and sensory activities to develop mental processes. Séguin's published works influenced Maria Montessori (1870–1952), an Italian pediatrician who became an educator and the innovator of a unique method of training young mentally retarded and culturally deprived children in Rome in the 1890s and early 1900s. Self-education through the use of specially designed "didactic materials" for sensorimotor training was the keynote of the system.

In advanced countries today, special education of the handicapped has become relatively universal; and, in the process, two concepts of individual differences have evolved: (1) the concept of "interindividual differences," which compares one child with another, and (2) the concept of "intraindividual differences," which is concerned with how the child's abilities in one area compare with his abilities in other areas. The grouping of children in special classes rests on the concept of *inter*individual differences, but the instructional procedures for each child are determined by *intra*individual differences—that is, by his abilities and disabilities.

Concepts of individual differences

Modern patterns of organizing educational programs. *Diagnostic patterns.* Because children with a particular kind of handicap do not form a homogeneous group, diagnosis must go beyond merely classifying the children according to their major deviation. A child suffering from cerebral palsy, for example, has a motor handicap, but in intelligence he may be superior or average or mentally retarded. Hence children with certain labels of cerebral palsy or deafness or blindness must be carefully assessed before placement in a particular group.

For the gifted and the mentally retarded, the primary criterion of identification is an individually administered intelligence test. If the child is high (for the gifted, generally above 125 IQ) or low (for the mentally retarded, below 75), he is considered for the special program. The determination is made by psychologists who in most cases must certify the child for eligibility for special programs. In making their assessment, psychologists also take into account other criteria such as school achieve-

ment, personality, and an evaluation of the adjustment of the child in the regular grades.

For children with sensory handicaps the evaluation of the problem is made by medical personnel. Orthopedically and neurologically impaired children are assigned to special programs upon the results of orthopedic or neurological examination by physicians, with supplementary assessment by psychological and educational diagnosticians. Children with learning disabilities are assessed primarily by psycho-educational diagnosticians, who through educational and psychological diagnostic tests determine the child's potential for learning and his level of achievement. Ancillary diagnoses by medical, psychological, and other personnel are considered in the determination of eligibility for special programs and in the kind of programs required. Socially and emotionally maladjusted children are generally referred by parents or by regular teachers when they find it difficult to manage the child at home or in school. Psychiatrists and clinical psychologists, together with social workers and educational personnel, determine eligibility for assignment to special programs.

Patterns of instructional adaptation. The goals of special education are similar to the goals for ordinary children, only the techniques for attaining them are different. An effort is made, for example, to teach all exceptional children (except those unable to profit at all from school experience) to read. Most gifted children have little difficulty in learning to read, many of them having learned to read at home before entering the first grade. The mentally retarded, on the other hand, obviously require prolonged periods of more intensive and more individualized instruction, which includes more techniques to maintain interest, more active participation, and much repetition of similar material in varied form. Children with severe sensory handicaps (the deaf and the blind) must learn to read through other sense modalities. The deaf learn to read through a visual method not involving the sense of hearing. The blind learn to read Braille through the tactile and kinesthetic sense.

Techniques for teaching the deaf and the blind

The most specialized teaching techniques are required for deaf children who, because of their hearing loss and their inability to develop auditory language, are inhibited in the ability to speak and to learn to read. The inability to read well inhibits other educational endeavours. Special techniques involve learning to speak by kinesthetic and visual methods, learning to "hear" others through lip reading, and learning to read by special visual techniques to compensate for their deficiency in oral language. General information is sometimes obtained by the deaf through manual language and finger spelling. For several centuries, the major controversy in the education of the deaf has been whether to use manual or oral methods to educate the deaf. There are thus some schools that teach primarily by the oral method (speech and speech reading) without the use of manual language and some that educate by a combination of oral and manual methods.

There is no major controversy about the education of the hard-of-hearing. These children are generally educated in regular classes with ordinary children but receive special instruction from visiting teachers in auditory training and the use of hearing aids, speech correction, and speech reading.

The blind are educated through the sense of hearing and the use of the tactile sense. Books are prepared in Braille, a code of embossed dots over which the blind person runs his fingers and translates the sequences of dots into meaning—much in the same manner as the average person translates sequences of seen letters into meaning. Many textbooks, much literary material, and quantities of information are also transcribed onto tapes and records for the blind. Mobility training has been developed and is being widely used to help the blind move about comfortably in their environment by using senses other than vision.

Partially seeing children, on the other hand, are educated primarily through the visual, auditory, and haptic senses, using magnification of their limited sight, training of visual perception, and utilization of large-type print.

For children with motor handicaps, required academic adjustments are minimal. Unless the child has other problems such as learning disabilities, mental retardation, or speech problems (which are often found among the cerebral palsied), crippled children learn like other children and can follow the same classroom materials. Special techniques are necessary, however, to help such children to adapt to their environment and to adapt the environment to their disability. Wheel chairs, modified desks, and other apparatus aid the child in mobility and the manipulation of classroom materials. One of the most important aspects of the education of the orthopedically handicapped is attitudinal—that is, preparing the child for adapting to the world outside the classroom and facing his handicap in such a way as to permit him to lead a relatively normal life.

Children with learning disabilities and those with speech defects require highly specialized techniques, usually on an individual basis.

For children with social and emotional problems, special therapeutic and clinical services may be provided. Psychotherapy and behaviour therapy by clinical psychologists, social workers, and psychiatrists are generally a part of the educational program. Academic teachers in these classes stress personality development, social adjustment, habits of interpersonal relations. With this group of children, these factors are prerequisite to academic achievement. Academic work is, however, sometimes therapeutic in itself and is promoted as much as possible.

Grouping patterns. The various types of organization by which exceptional children are grouped for educational purposes are determined by the extent of the exceptionality as well as by the type of exceptionality.

Special classes

The most common organization for the majority of handicapped children has been the self-contained "special class" in either state or privately operated school systems. Special classes for the gifted, the mentally retarded, the deaf and the hard of hearing, the blind and the partially sighted, and for other handicapped children are found in school systems throughout the world. This type of organization allows the child to live at home and often to attend a neighbourhood school that has organized a special class.

Within the regular school, children with speech problems, learning disabilities, and special handicaps are often given tutoring by specially trained personnel. Such children attend regular classes but receive special help for short periods each day or several times a week to help correct their special disability. Children who are homebound and cannot attend school are taught at home by special teachers.

The "resource room" is a specially equipped room with a specially trained teacher who serves children sent to her for part of the day. Children assigned to a resource room attend regular classes with ordinary children but go to the resource room for special help such as tutoring or remedial work.

Less common than these programs are special "day schools" organized for some particular kind of handicapped child. These differ from special classes or rooms in that the whole school serves crippled children or mentally retarded or emotionally disturbed, the deaf, or the blind. Children attending these schools also live at home but very often are transported to and from school by bus.

"Residential schools" enroll handicapped children for 24 hours a day and are usually attended by children who cannot obtain services in their community for any one of various reasons. Sometimes the services are simply not available; sometimes the severity of the handicap makes it difficult to adjust in a day school or special class; sometimes the children are dependent, or the parents find that keeping the child at home creates problems for the rest of the family, or the environment does not provide sufficient help for the child himself. State and private residential schools for the deaf and for the blind, and for the severely mentally retarded are the most common. In some

European countries such as France and the Soviet Union, areas outside the large cities are preferred as sites for boarding schools or residential schools for the educable mentally retarded.

Children confined to hospitals for varying lengths of time are frequently offered educational services individually or in small groups while they are in the hospital. The goal is to assist them in keeping up with their education so that they will not be retarded educationally when they return to their home and school.

PROBLEMS OF THE PERSONAL ADJUSTMENT OF EXCEPTIONAL CHILDREN

Research on the personal adjustment of gifted and handicapped children (other than the socially or emotionally disturbed) has not shown the probability of maladjustment to be as great as "common sense" would indicate. It was once assumed, for example, that a gifted child would show exceptional talent in some area but would be abnormal in social relations. This myth has long been discarded; studies over a period of years have shown that the extremely gifted (children with IQ's of 140 and above) were better adjusted than the average, personally and socially, in school and in later life.

Personal adjustment of the handicapped is contingent upon many factors, among which is excessive frustration of the child in his growing years when there is a discrepancy between his ability to perform and the requirements of the environment. During the preschool years the handicapped child is a major concern of his parents. Their anxiety leads them to seek diagnosis and cures from many sources. How well the parents learn to accept the handicap and to assist the child in developing without undue pressure, rejection, or overprotection determines to a large extent the child's personal adjustment.

In his early school years the handicapped child meets obstacles to development when in competition with the average child. Studies have shown that when mentally retarded or crippled children are assigned to regular grades without special provisions being made for them, they tend to be isolated and rejected by their normal classmates. Special classes and other special provisions have been organized to avoid these problems and to decrease the discrepancies between the requirements of the environment and the ability of the child to perform.

The adolescent level is difficult for handicapped children, as it is for all children. At this age level more personal and social problems appear. Special provisions are less common than in schools for younger children. Because many handicapped children (the mentally retarded, the cerebral palsied, the deaf, and the blind) are unable to cope with the more abstract and academic requirements of the school at this age level, special provisions must be made for them.

Prevocational training and instruction in the practical tasks of life in a nonacademic way assist exceptional children in adjusting to their school, their peers, and their families. Vocational rehabilitation programs in European countries and the United States have been instrumental in educating handicapped adolescents and youth in vocations in which they have a possibility of becoming self-sufficient and independent at the adult level.

One of the major goals of special education (beyond developing skills and imparting information) is the ultimate adjustment of the handicapped to the society of nonhandicapped individuals. This goal has created a problem in the organization of special classes and schools. One criticism of special education programs is that they tend to segregate children with their own kind. Currently, efforts are being made to organize programs that integrate the deviant child with average children. For the gifted, special programs of enrichment and acceleration are increasingly preferred to special classes. Resource rooms for those impaired in sight or hearing make it possible to retain the child in the regular grades for part of the day. The older educable mentally retarded can be assigned to regular workshops, physical education classes, home economics classes, and other nonacademic classes for part of the day. Similar adjustments in programs are used for other handicapped children. The goal is to adjust these children to the larger society of nonhandicapped before they leave school.

BIBLIOGRAPHY. One of the first authoritative textbooks to be published on handicapped children and their education, including research findings to 1924, was J.E.W. WALLIN, *The Education of Handicapped Children* (1924). More recent textbooks include; W.M. CRUICKSHANK and G.O. JOHNSON (eds.), *Education of Exceptional Children and Youth*, 2nd ed. (1967), prepared by specialists in each area of exceptionality, with emphasis on educational progress; L.M. DUNN (ed.), *Exceptional Children in the Schools* (1963), includes research findings on the characteristics and general educational adaptations for various types of exceptionality; and S.A. KIRK, *Educating Exceptional Children* (1962), utilizes the concept of intra-individual differences as the central theme and discusses special educational techniques. Another work that discusses special methods of instruction used by teachers is N.G. HARING and R.L. SCHIEFELBUSCH (eds.), *Methods in Special Education* (1967).

(S.A.K.)

Edward I of England

King of England from 1272 to 1307, Edward I presided over a period of rising national consciousness within the country. During his reign, the English Parliament began to develop its distinctive character, and the monarchy extended its effective control over Wales. His attempt to extend English suzerainty over Scotland initiated two and a half centuries of sanguinary warfare between the two countries. His reign is particularly noted for administrative efficiency and legal reform. He introduced a series of statutes that did much to strengthen the crown in the feudal hierarchy. His definition and emendation of English common law has earned him the name of the "English Justinian."

Edward I, watercolour, 15th century. In the British Museum (Cotton MS. Julius E. IV).

Early life. Edward was born at Westminster on June 17, 1239, the eldest son of King Henry III and Eleanor of Provence. In 1254 he was given the duchy of Gascony, the French Oléron, the Channel Islands, Ireland, Henry's lands in Wales, and the earldom of Chester, as well as several castles. Henry negotiated Edward's marriage with Eleanor, half sister of Alfonso X of León and Castile. He married Eleanor at Las Huelgas in Spain (October 1254) and then travelled to Bordeaux to organize his scattered appanage. He now had his own household and officials,

chancery and seal, with an exchequer (treasury) at Bristol Castle; though nominally governing all his lands, in Gascony and Ireland he merely enjoyed the revenues. He returned to England in November 1255 and attacked Llewelyn ap Gruffydd, prince of Gwynedd, to whom his Welsh subjects had appealed for support when Edward attempted to introduce English administrative units in his Welsh lands. Edward, receiving no help from either Henry or the marcher lords, was defeated ignominiously. His arrogant lawlessness and his close association with his greedy Poitevin uncles, who had accompanied his mother from France, increased Edward's unpopularity among the English. But after the Poitevins were expelled, Edward fell under the influence of Simon de Montfort, his uncle by marriage, with whom he made a formal pact. Montfort was the leader of a baronial clique that was attempting to curb the misgovernment of Henry.

Role in barons' revolt

Edward reluctantly accepted the Provisions of Oxford (1258), which gave effective government to the barons at the expense of the king. On the other hand, he intervened dramatically to support the radical Provisions of Westminster (October 1259), which ordered the barons to accept reforms demanded by their tenants. In the dangerous crisis early in 1260 he supported Montfort and the extremists, though finally he deserted Montfort and was forgiven by Henry (May 1260). He was sent to Gascony in October 1260 but returned early in 1263. Civil war had now broken out between Henry and the barons, who were supported by London. Edward's violent behaviour and his quarrel with the Londoners harmed Henry's cause. At the Battle of Lewes (May 14, 1264) his vengeful pursuit of the Londoners early in the battle contributed to Henry's defeat. Edward surrendered and became a hostage in Montfort's hands. He escaped at Hereford in May 1265 and took charge of the royalist forces, penned Montfort behind the River Severn, and, by lightning strategy, destroyed a large relieving army at Kenilworth (August 1). On August 4 he trapped and slew Montfort at Evesham and rescued Henry. Shattered and enfeebled, Henry allowed Edward effective control of government, and his extreme policy of vengeance, especially against the Londoners, revived and prolonged rebel resistance. Finally, the papal legate Ottobuono, Edward's uncle Richard, earl of Cornwall, and other moderates persuaded Henry to the milder policy of the Dictum of Kenilworth (October 31, 1266), and after some delay the rebels surrendered. Edward took the cross (1268), intending to join the French king Louis IX on a crusade to the Holy Land, but was delayed by lack of money until August 1270. Louis died before Edward's arrival; and Edward, after wintering in Sicily, went to Acre, where he stayed from May 1271 to September 1272, winning fame by his energy and courage and narrowly escaping death by assassination but achieving no useful results. On his way home he learned in Sicily of Henry III's death on November 16, 1272.

Crusading activity

Accession and character. Edward had nominated Walter Giffard, archbishop of York, Philip Basset, Roger Mortimer, and his trusted clerk Robert Burnell to safeguard his interests during his absence. After Henry's funeral, the English barons all swore fealty to Edward (November 20, 1272). His succession by hereditary right and the will of his magnates was proclaimed, and England welcomed the new reign peacefully, Burnell taking charge of the administration with his colleagues' support. The quiet succession demonstrated England's unity only five years after a bitter civil war. Edward could journey homeward slowly, halting in Paris to do homage to his cousin Philip III for his French lands (July 26, 1273), staying several months in Gascony and reaching Dover on August 2, 1274, for his coronation at Westminster on August 19. Now 35 years old, Edward had redeemed a bad start. He had been arrogant, lawless, violent, treacherous, revengeful, and cruel; his Angevin rages matched those of Henry II. Loving his own way and intolerant of opposition, he had still proved susceptible to influence by strong-minded associates. He had shown intense family affection, loyalty to friends, courage, brilliant military capacity, and a gift for leadership; handsome, tall, powerful, and tough, he had the qualities men admired. He loved efficient, strong government, enjoyed power, and had learned to admire justice, though in his own affairs it was often the letter, not the spirit of the law that he observed. Having mastered his anger, he had shown himself capable of patient negotiation, generosity, and even idealism; and he preferred the society and advice of strong counsellors with good minds. As long as Burnell and Queen Eleanor lived, the better side of Edward triumphed, and the years until about 1294 were years of great achievement. Thereafter, his character deteriorated for lack of domestic comfort and independent advice. He allowed his autocratic temper full rein and devoted his failing energies to prosecution of the wars in France and against Scotland.

Parliament and statutes. Shrewdly realistic, Edward understood the value of the "parliaments," which since 1254 had distinguished English government and which Montfort had deliberately employed to publicize government policy and to enlist widespread, active support by summoning representatives of shires and boroughs to the council to decide important matters. Edward developed this practice swiftly, not to share royal power with his subjects but to strengthen royal authority with the support of rising national consciousness. From 1275 to 1307 he summoned knights and burgesses to his parliaments in varying manners. The Parliament of 1295, which included representatives of shires, boroughs, and the lesser clergy, is usually styled the Model Parliament, but the pattern varied from assembly to assembly, as Edward decided. By 1307, Parliament, thus broadly constituted, had become the distinctive feature of English politics, though its powers were still undefined and its organization embryonic.

The Model Parliament

Edward used these parliaments and other councils to enact measures of consolidation and reform in legal, procedural, and administrative matters of many kinds. The great statutes promulgated between 1275 and 1290 are the glory of his reign. Conservative and definitory rather than original, they owed much to Burnell, Edward's chancellor. With the vast developments and reorganization of the administrative machine that Burnell coordinated, they created a new era in English government. The quo warranto inquiry, begun in 1275, the statutes of Gloucester (1278) and of Quo Warranto (1290) sought with much success to bring existing franchises under control and to prevent the unauthorized assumption of new ones. Tenants were required to show "by what warrant" or right they held their franchises. Edward strove, unsuccessfully, to restore the feudal army and strengthen local government institutions by compelling minor landowners to assume the duties of knighthood. His land legislation, especially the clause *de donis conditionalibus* in the miscellaneous Second Statute of Westminster (1285) and the statute Quia Emptores (Third Statute of Westminster, 1290), eventually helped to undermine feudalism, quite contrary to his purpose. By the Statute of Mortmain (1279) the crown gained control of the acquisition of land by ecclesiastical bodies. The Statute of Winchester (1285) codified and strengthened the police system for preserving public order. The Statute of Acton Burnell (1283) and the Statute of Merchants (1285) showed practical concern for trade and merchants. These are but the most famous of many statutes aimed at efficiency and sound administration.

Decline of feudalism

Wars. Meanwhile, Edward destroyed the autonomous principality of Wales, which, under Llewelyn ap Gruffydd, had expanded to include all Welsh lordships and much territory recovered from the marcher lords. Domestic difficulties had compelled Henry III to recognize Llewelyn's gains by the Treaty of Shrewsbury (1267), but Edward was determined to reduce Llewelyn and used Llewelyn's persistent evasion of his duty to perform homage as a pretext for attack. He invaded Wales by three coordinated advances with naval support (1277), blockaded Llewelyn in Snowdonia, starved him into submission, and stripped him of all his conquests since 1247. He then erected a tremendous ring of powerful castles encircling Gwynedd and reorganized the conquered dis-

tricts as shires and hundreds. When English rule provoked rebellion, he methodically reconquered the principality, killing both Llewelyn (1282) and his brother David (1283). By the Statute of Wales (1284) he completed the reorganization of the principality on English lines, leaving the Welsh marchers unaffected. A further Welsh rising in 1294–95 was ruthlessly crushed, and Wales remained supine for more than 100 years.

After 1294, matters deteriorated. Queen Eleanor had died in 1290, Burnell in 1292, and Edward never thereafter found such good advisers. The conquest and fortification of Wales had badly strained his finances; now endless wars with Scotland and France bankrupted him. He quarrelled bitterly with both clergy and barons, behaving as a rash and obstinate autocrat who refused to recognize his limitations. Philip III and Philip IV of France had both cheated him of the contingent benefits promised by the Treaty of Paris (1259). By constant intervention on pretext of suzerainty they had nibbled at his Gascon borders and undermined the authority of his administration there. After doing homage to Philip IV in 1286, Edward visited Gascony to reorganize the administration and restore authority. On returning to England in 1289 he had to dismiss many judges and officials for corruption and oppression during his absence. In 1290, having systematically stripped the Jews of their remaining wealth, he expelled them from England. French intervention in Gascony was now intensified; affrays between English and French sailors inflamed feelings; and in 1293 Philip IV tricked Edward's brother Edmund, earl of Lancaster, who was conducting negotiations, into ordering a supposedly formal and temporary surrender of the duchy, which Philip then refused to restore. The Welsh rising and Scottish troubles prevented Edward from taking action, and when at last, in 1297, he sailed to attack France from Flanders, his barons refused to invade Gascony, and Wallace's rising forced him to return. He made peace with Philip (1299), and by Boniface VIII's persuasion, married Philip's sister Margaret, and eventually recovered an attenuated Gascon duchy.

Renewal of quarrels with Scotland

For more than 100 years relations between England and Scotland had been amicable, and the border had been remarkably peaceful. Edward inaugurated 250 years of bitter hatred, savage warfare, and bloody border forays. The deaths of Alexander III of Scotland (1286) and his granddaughter Margaret, the Maid of Norway (1290), whom Edward planned to marry to his heir, Edward of Caernarvon (afterward Edward II), ended the line of succession. Many dubious claimants arose, and the Scottish magnates requested Edward's arbitration. Edward compelled the nobles and the claimants to recognize his suzerainty, and only then adjudged John de Balliol king (1292). Balliol did homage and was crowned, but Edward's insistence on effective jurisdiction, as suzerain, in Scottish cases eventually provoked the Scottish nobles to force Balliol to repudiate Edward's claims and to ally with France (1295). Edward invaded and conquered Scotland (1296), removing to Westminster the coronation stone of Scone. William Wallace led a revolt in 1297, and Edward, though brilliantly victorious at Falkirk (July 22, 1298), could not subdue the rebellion despite prolonged campaigning (1298–1303).

Last years. The strain of these years provoked heavy collisions between Edward and his magnates. He had quarrelled violently with his archbishops of Canterbury, John Peckham (1279–92) and Robert Winchelsey (1293–1313), over ecclesiastical liberties and jurisdiction. In 1297 Winchelsey, obeying Pope Boniface VIII's bull *Clericis Laicos* (1296), rejected Edward's demands for taxes from the clergy, whereupon Edward outlawed the clergy. His barons now defied his orders to invade Gascony and, when Edward went to Flanders, compelled the regents to confirm the charters of liberties, with important additions forbidding arbitrary taxation (1297), thereby forcing Edward to abandon the campaign and eventually to make peace with France. Although Pope Clement V, more pliant than Boniface, allowed Edward to exile Winchelsey and intimidate the clergy (1306), the barons had exacted further concessions (1301) before reconciliation. Edward renewed the conquest of Scotland in 1303, captured Stirling in 1304, and executed Wallace as a traitor in 1305; but when Scotland seemed finally subjected, Robert I the Bruce revived rebellion and was crowned in 1306. On his way to reconquer Scotland, Edward died at Burgh by Sands, near Carlisle, on July 7, 1307.

BIBLIOGRAPHY. E.M. BARRON, *The Scottish War of Independence*, 2nd ed. (1934), although not wholly objective, is a clear and readable account of the wars. J.E. MORRIS, *The Welsh Wars of Edward I* (1901, reprinted 1968), makes clear the impact of these wars on Edward's military organization and technique as well as on constitutional development in England. D. PASQUET, *Essai sur les origines de la Chambre des Communes* (1914; Eng. trans., *An Essay on the Origins of the House of Commons*, 1925), takes the view that the English Parliament owes more to the initiative and needs of the King than to any sense of community among his subjects. There is a vast body of more recent literature on parliamentary origins. This is summarized and selections from it are presented in *Historical Studies of the English Parliament*, ed. by E.B. FRYDE and EDWARD MILLER, 2 vol. (1970). T.F.T. PLUCKNETT, *Legislation of Edward I* (1949), is an analysis of Edward I's statutes, showing that, far from being antifeudal, Edward's measures were intended to support his own position within the feudal hierarchy. F.M. POWICKE's two works on the 13th century, *King Henry III and the Lord Edward*, 2 vol. (1947), and *The Thirteenth Century, 1216–1307* (1953), present the reign in terms of social forces at work in politics, particularly those springing from the baronage. G. TEMPLEMAN, "Edward I and the Historians," in the *Cambridge Historical Journal*, 10:16–35 (1950), summarizes the changing views of Edward I from Polydore Vergil to Powicke and Plucknett. T.F. TOUT, *Chapters in the Administrative History of Mediaeval England*, vol. 2 (1920, reprinted 1967), demonstrates Edward's aims with regard to administrative efficiency and royal control. Tout's *Edward the First* (1893) is still the best biography of the King; L.F. SALZMAN, *Edward I* (1968), adds nothing substantially new to our understanding of the King or the man.

(R.F.Tr.)

Edward III of England

King of England from 1327 to 1377, Edward III led England into the Hundred Years' War with France. His victories of Crécy, Sluis, and Calais were much celebrated by the 14th-century historian Jean Froissart, but their long-term significance is debatable. The eldest son of Edward II and Isabella of France, Edward III was born at Windsor on November 13, 1312. He was summoned to Parliament as earl of Chester (1320) and was made duke of Aquitaine (1325), but, contrary to tradition, he never received the title of prince of Wales.

Edward III grew up amid struggles between his father and a number of barons who were attempting to limit the king's power and to strengthen their own role in governing England. His mother, repelled by her husband's treatment of the nobles and disaffected by the confiscation of her English estates by his supporters, played an important role in this conflict. In 1325 she left England to return to France to intervene in the dispute between her brother, Charles IV of France, and her husband over the latter's French possessions, Guyenne, Gascony, and Ponthieu. She was successful; the land was secured for England on condition that the English king pay homage to Charles. This was performed on the King's behalf by his young son.

The heir apparent was secure at his mother's side. With Roger Mortimer, an influential baron who had escaped to France in 1323 and had become her lover, Isabella now began preparations to invade England to depose her husband. To raise funds for this enterprise, Edward III was betrothed to Philippa, daughter of William, count of Hainaut and Holland.

Within five months of their invasion of England, the Queen and the nobles, who had much popular support, overpowered the king's forces. Edward II, charged with incompetence and breaking his coronation oath, was forced to resign, and on January 29, 1327, Edward III, aged 15, was crowned king of England.

Regency

During the next four years Isabella and Mortimer governed in his name, though nominally his guardian was Henry, earl of Lancaster. In the summer of 1327 he took

part in an abortive campaign against the Scots, which resulted in the Treaty of Northampton (1328), making Scotland an independent realm. Edward was deeply troubled by the settlement and signed it only after much persuasion by Isabella and Mortimer. He married Philippa at York on January 24, 1328. Soon afterward, Edward made a successful effort to throw off his degrading dependence on his mother and Mortimer. While a council was being held at Nottingham, he entered the castle by night, through a subterranean passage, took Mortimer prisoner, and had him executed (November 1330). Edward had discreetly ignored his mother's liaison with Mortimer and treated her with every respect, but her political influence was at an end.

Edward III now began to rule as well as to reign. Young, ardent, and active, he sought to remake England into the powerful nation it had been under Edward I. He still resented the concession of independence made to Scotland by the Treaty of Northampton; and the death of Robert I, the Bruce, king of Scotland, in 1329 gave him a chance of retrieving his position. The new king of Scots, his brother-in-law, David II, was a mere boy, and Edward took advantage of his weakness to aid the Scottish barons who had been exiled by Bruce to place their leader, Edward Balliol, on the Scottish throne. David II fled to France, but Balliol was despised as a puppet of the English king, and David returned in 1341.

Hundred Years' War. During the 1330s England gradually drifted into a state of hostility with France, for which the most obvious reason was the dispute over English rule in Gascony. Contributory causes were France's new King Philip VI's support of the Scots, Edward's alliance with the Flemish cities—then on bad terms with their French overlord—and the revival, in 1337, of Edward's claim, first made in 1328, to the French crown. Edward twice attempted to invade France from the north (1339, 1340) but the only result of his campaigns was to reduce him to bankruptcy. In January 1340 he assumed the title of king of France. At first he may have done this to gratify the Flemings, whose scruples in fighting the French king disappeared when they persuaded themselves that Edward was the rightful king of France. But his pretensions to the French crown gradually became more important, and the persistence with which he and his successors urged them made stable peace impossible for more than a century. This was the struggle famous in history as the Hundred Years' War. Until 1801 every English king also called himself king of France.

Battle of Sluis

Edward was present in person at the great naval battle off the Flemish city of Sluis in June 1340, in which he all but destroyed the French navy. Despite this victory his resources were exhausted by his land campaign, and he was forced to make a truce (which was broken two years later) and return to England. During the years after 1342 he spent much time and money in rebuilding Windsor Castle and instituting the Order of the Garter, which became Britain's highest order of knighthood. A new phase of the French war began when Edward landed in Normandy in July 1346, accompanied by his eldest son, Prince Edward, later known as the Black Prince (born 1330). At first the king showed some lack of strategic purpose, engaging in little more than a large-scale plundering raid to the gates of Paris. The campaign was made memorable by his decisive victory over the French at Crécy in Ponthieu (August 26), where he scattered the army with which Philip VI sought to cut off his retreat to the northeast. Edward laid siege to the French port of Calais in September 1346 and received its surrender in August 1347. Other victories in Gascony and Brittany, and the defeat and capture of David II at Neville's Cross near Durham (October 1346), gave further proof of Edward's power, but Calais was to be his only lasting conquest. He ejected most of its French inhabitants, colonizing the town with Englishmen and establishing there a base from which to conduct further invasions of France. Nevertheless, in the midst of his successes, want of money forced him to make a new truce in September 1347.

Years in England

Edward returned to England in October 1347. He celebrated his triumph by a series of splendid tournaments. In 1348 he rejected an offer to become Holy Roman emperor. In the same year the bubonic plague known as the Black Death first appeared in England and raged until the end of 1349. Its horrors hardly checked the magnificent revels of Edward's court, and neither the plague nor the truce stayed the slow course of the French war, though the fighting was indecisive and on a small scale. Edward's martial exploits during the next years were those of a gallant knight rather than of a responsible general. Although the English House of Commons was now weary of the war, efforts to make peace came to nothing and large-scale operations began again in 1355 when Edward led an unsuccessful raid out of Calais. He harried the Lothians, part of southeast Scotland, in the expedition famous as the Burned Candlemas (January and February 1356), and in the same year he received a formal surrender of the Kingdom of Scotland from Balliol. His exploits were, however, eclipsed by those of his son, Edward, whose victory at Poitiers (September 19, 1356), resulting in the capture of the French king John II (who had succeeded Philip VI in 1350), forced the French to accept a new truce. Edward entertained his captive magnificently, but forced him by the Treaty of London (1359) to surrender so much territory that the agreement was repudiated in France. In an effort to compel acceptance, Edward landed at Calais (October 28) and besieged Reims, where he planned to be crowned king of France. The strenuous resistance of the citizens frustrated this scheme and Edward marched into Burgundy, eventually returning toward Paris. After this unsuccessful campaign he was glad to conclude preliminaries of peace at Brittany (May 8, 1360). This treaty, less onerous to France than that of London, took its final form in the Treaty of Calais, ratified by both kings (October 1360). By it, Edward renounced his claim to the French crown in return for the whole of Aquitaine, a rich area in southwest France.

Capture of the French king

The years of decline: 1360–77. The Treaty of Calais did not bring rest or prosperity to either England or France. Fresh visitations of the Black Death in England in 1361 and 1369 intensified social and economic disturbances, and desperate but not very successful efforts were made to enforce the Statute of Labourers (1351), which was intended to maintain prices and wages as they had been before the pestilence. Other famous laws enacted during the 1350s had been the Statutes of Provisors (1351) and Praemunire (1353), which reflected popular hostility against foreign clergy. These measures were fre-

quently re-enacted, and Edward formally repudiated (1366) the feudal supremacy over England still claimed by the papacy.

Resumption of fighting

When the French king Charles V, son of John II, repudiated the treaty of Calais, Edward resumed the title of king of France, but he showed little of his former vigour in meeting this new trouble, leaving most of the fighting and the administration of his foreign territories to his sons Edward and John of Gaunt, duke of Lancaster. While they were struggling with little success against the rising tide of French national feeling, Edward's want of money made him a willing participant in the attack on the wealth and privileges of the church. Meanwhile, Aquitaine was gradually lost, Prince Edward returned to England in broken health (1371), and John of Gaunt's march through France from Calais to Bordeaux (1373) achieved nothing. Edward's final attempt to lead an army abroad himself (1372) was frustrated when contrary winds prevented his landing his troops in France. In 1375 he was glad to make a truce, which lasted until his death. By it, the only important possessions remaining in English hands were Calais, Bordeaux, Bayonne, and Brest.

Edward was now sinking into his dotage. After the death of Queen Philippa in 1369 he fell entirely under the influence of his greedy mistress, Alice Perrers, while Prince Edward and John of Gaunt became the leaders of sharply divided parties in the royal court and council. John of Gaunt returned to England in April 1374 and with the help of Alice Perrers obtained the chief influence with his father, but his administration was neither honourable nor successful. At the famous so-called Good Parliament of 1376 popular indignation against John of Gaunt's ruling party came at last to a head. Alice Perrers was removed and some of Gaunt's followers were impeached. Before the Parliament had concluded its business, however, the death of the Prince Edward (June 8, 1376) robbed the Commons of its strongest support. John of Gaunt regained power, and the acts of the Good Parliament had been reversed when Edward III died on June 21, 1377, at Sheen (now Richmond).

Edward's character

Edward III possessed extraordinary vigour and energy of temperament; he was an admirable tactician and a consummate knight. His court was the most brilliant in contemporary Europe, and he was himself well fitted to be the head of the gallant knights who obtained fame in the French wars. Though his main ambition was military glory, he was not a bad ruler of England, being liberal, kindly, good-tempered, and easy of access. His need to obtain supplies for carrying on the French wars made him favourable to his subjects' petitions and contributed to the growing strength of Parliament. His weak points were his wanton breaches of good faith, his extravagance, his frivolity, and his self-indulgence. His ambition ultimately transcended his resources, and before he died even his subjects had sensed his failure.

BIBLIOGRAPHY. W. STUBBS, *The Constitutional History of England*, vol. 2 (1866 and many later editions), dated but still very valuable; M. MCKISACK, *The Fourteenth Century, 1307–1399* (1959), contains the best modern account; G. UNWIN (ed.), *Finance and Trade Under Edward III* (1918), still useful; E. PERROY, *La Guerre de cent ans* (1945; Eng. trans., *The Hundred Years War*, 1951), good for the French point of view.

Edward IV of England

Edward IV was king of England from 1461 until October 1470, and again from April 1471 until his death in 1483, and was one of the leading participants in the Yorkist–Lancastrian civil conflict known as the Wars of the Roses. Edward was the eldest surviving son of Richard, duke of York, by Cicely, daughter of Ralph Neville, earl of Westmorland; he was born at Rouen, France, on April 28, 1442. His father was descended from two sons of the 14th-century king Edward III and, in the 1450s, led a revolt against Henry VI; in 1460, Richard's supporters declared him Henry's successor. When his father was killed in December of that year, Edward gathered an army in Wales, and defeated Henry's supporters (called Lancastrians because of Henry's descent from John of Gaunt, duke of Lancaster). Edward was crowned as King Edward IV in London on June 28, 1461.

Edward's claim to the throne

Edward's struggle with Warwick. Edward at this time showed little promise, apparently caring only for fighting, drinking, women, and pageantry. He owed his throne largely to his cousin Richard Neville, earl of Warwick, who was in the first years of Edward's reign the most powerful man in England. Warwick crushed Lancastrian resistance in the far north of England between 1462 and 1464 and conducted England's diplomacy. Edward, however, was winning many friends (especially in London) by his comeliness and charm and was determined to assert his independence. On May 1, 1464, he secretly married a young widow, Elizabeth Woodville, of no great rank, offending Warwick and other Yorkist nobles who were planning to marry him to a French princess. By showering favours on Elizabeth's two sons by her first husband and on her five brothers and her seven sisters, Edward began to build up a group of magnates who would be a counterpoise to the Nevilles. Gradually Warwick lost all influence at court, and when he was negotiating an alliance with France, Edward humiliated him by revealing that he had already concluded an alliance (1467) with France's enemy Burgundy. Edward's sister Margaret was married July 1468 with great pomp to Duke Charles the Bold of Burgundy, and the brothers-in-law planned a joint invasion of France.

Edward IV, portrait by an unknown artist. In the National Portrait Gallery, London.

Warwick, in a countermove encouraged by Louis XI of France, seized Edward and made him a prisoner in July 1469. But Edward had by now too many supporters (especially in London) for him to be kept under tutelage for long. He regained his freedom in October; Warwick fled to France, allied himself with the Lancastrians and with Louis, and invaded England in September 1470.

Surprised, Edward fled with a few faithful supporters to the Netherlands in October. Aided by Charles of Burgundy, he and his brother, Richard, duke of Gloucester, returned to England in March 1471. Taking London, he defeated and killed Warwick at Barnet on April 14. On the same day, Queen Margaret (Henry VI's wife) belatedly landed in Dorset from France with her only son, Edward, prince of Wales. Her advisers hoped to gain Lancastrian support in Wales, and it became a race for time between Edward IV's forces and hers as to whether she could get there before he overtook her. At Tewkesbury, after some remarkable forced marches (one of over 40 miles at a stretch), he caught up with her army on May 4. There he won another crushing victory. Nearly all the remaining Lancastrian leaders were killed on the field or executed afterward and, after murdering Henry VI

The Battle of Tewkesbury

(May 21–22) and repelling an attack on London, Edward was secure for the remainder of his life.

The second half of Edward's reign. He was now able to revive the project of an invasion of France in concert with the duke of Burgundy. He made great preparations in 1474 and obtained a large grant from Parliament. In 1475 he invaded France with the largest army, it was said, that had ever left England, but he found the Duke of Burgundy very ill-prepared and the French formidable and willing to buy him out. Hence the Treaty of Picquigny was made by which Edward agreed to withdraw from France in return for 75,000 gold crowns down and a pension of 50,000 gold crowns a year. These sums helped to free Edward from dependence on parliamentary grants. As he grew older, he showed considerable ingenuity in raising money by reviving obsolescent rights and using doubtfully legal devices. Commercial treaties with France (1475), Burgundy (1468), and the Hanseatic League (1474) combined with external peace and growing internal order to revive trade strikingly after 1475, and this benefitted the customs duties and other revenues. Edward became a trader himself, transporting goods in his own ships and those of foreign merchants. He began a reorganization of the revenues from the crown estates, experimenting with methods of improving yields and promoting more efficient auditing under officials of the flexible royal household treasury instead of the unadaptable exchequer. These and other measures enabled him to leave behind a fortune; some of his improved financial administration was continued and developed by his successors Richard III and Henry VII.

The last decade of Edward's reign also saw an improvement in law enforcement. One especially disturbed area was Wales and the Welsh marches; Edward used the royal estates there as a foundation on which to base a council that acted in the name of his infant heir, the Prince of Wales, and employed the royal prerogative to make a start in repressing disorder. It was the forerunner of the council of Wales and the marches that subjugated the area to English rule.

Achievements

Modern research has emphasized these administrative achievements of Edward IV, and contemporary and Tudor historians viewed his later years as a time of prosperity and success. He rebuilt St. George's Chapel, Windsor, and collected illuminated Flemish manuscripts. He was also a friend and patron of the printer William Caxton, and his book collection became the foundation of the Old Royal library, later one of the glories of the British Museum.

Edward's promiscuity enabled Richard of Gloucester, after his death, to question the validity of his marriage and so to ruin his sons. As a young man Edward had been trustful and openhanded, but his experiences made him increasingly suspicious, leading him in 1478 to execute his brother George, duke of Clarence, who in former years had sided with Warwick against him. In 1482, Louis XI, in order to come to terms with the rulers of Burgundy, tacitly repudiated the Treaty of Picquigny and the annual tribute that it provided. Edward contemplated a fresh invasion of France, but before it could be carried out he fell ill and died at Westminster on April 9, 1483, at the age of only 40. By Elizabeth Woodville he had seven children who survived him: two sons, Edward (afterward Edward V) and Richard, duke of York, who were probably murdered in the Tower of London in August 1483, and five daughters, of whom the eldest, Elizabeth, married Henry VII.

BIBLIOGRAPHY. C.L. SCOFIELD, *The Life and Reign of Edward IV*, 2 vol. (1923), is extremely detailed, accurate, and based on original sources; but the detail often obscures the argument, and the general outlook is now somewhat out of date. E.F. JACOB, *The Fifteenth Century, 1399–1485* (1961), provides a more up-to-date interpretation with an annotated bibliography. J.R. LANDER, *Conflict and Stability in Fifteenth Century England* (1969), puts the reign of Edward IV in its setting and has a useful annotated bibliography. A.R. MYERS, *English Historical Documents, 1327–1485* (1969), provides a large number of documents, translated into English, for the reign of Edward IV.

(A.R.M.)

Edward, the Black Prince

Son and heir of the English king Edward III (reigned 1327–77), Edward of Woodstock, the "Black Prince," was one of the outstanding commanders of the Hundred Years' War and is often considered the embodiment of the ideal of chivalry. His sobriquet, said to have come from his wearing black armour, has no contemporary justification and is found first in Richard Grafton's *Chronicle of England* (1568).

Edward, the Black Prince, electrotype from effigy in Canterbury Cathedral, c. 1376. In the National Portrait Gallery, London.
By courtesy of the National Portrait Gallery, London

Born at Woodstock on June 15, 1330, to Edward III and Philippa of Hainault, Edward was created earl of Chester (March 1333), duke of Cornwall (February 1337)—the first appearance of this rank in England—and prince of Wales (May 1343); he was prince of Aquitaine from 1362 to 1372. His first campaign was served under his father in northern France (1346–47) and at the Battle of Crécy (August 26, 1346) he won both his spurs and the famous ostrich plumes and with them the mottoes used by himself and subsequent princes of Wales, *houmout*; *ich dene* ("Courage; I serve"; the words are here spelled as Edward himself wrote them; later variants include *houmout* and *ich dien* or *ich diene*). One of the original Knights of the Garter, he was sent to France with independent command in 1355, winning his most famous victory over the French at Poitiers on September 19, 1356. The French king John II, brought captive to England, was treated by the Prince with a celebrated courtesy, but he was obligated to pay a ransom of 3,000,000 gold crowns and to negotiate the treaties of Brétigny and Calais (1360) by which Aquitaine was ceded to the English.

Victory at Poitiers

Edward married his cousin Joan, the divorced and widowed countess of Kent, in October 1361. He was created prince of Aquitaine in July 1362 and left England in 1363 to take up his duties. His powers and his opportunities were great, but his rule was a failure, and he himself was largely to blame. His court at Bordeaux, that of a foreign conqueror, was extravagant; the 13 *sénéchaussées* into which the principality was divided administratively followed their earlier French pattern and allowed local French loyalites to subsist; his relations with the many

bishops were unfriendly, while the greater nobles, Arnaud-Amanieu, sire d'Albret, Gaston II, comte de Foix, and Jean I, comte d'Armagnac, were hostile. He summoned several estates, or parliaments, but always to levy taxes. In 1367 he undertook to restore Peter the Cruel of Castile to his throne, and though he won a classic victory at Nájera on April 3, 1367, the campaign ruined his health, his finances, and any prospect of sound rule in Aquitaine, where, in 1368, the nobles and prelates appealed against him to Charles V of France as suzerain. Edward's reply to the French king's citation to answer the appellants before the *parlement* of Paris in May 1369 is well known—he would appear with 60,000 men at his back. He had, however, alienated the towns and peasantry as well as the nobles; and by March 1369 more than 900 towns, castles, and strong places had declared against him. Relying on mercenaries whom he could not afford to pay, he was powerless to quell the revolt, and the terrible sack of Limoges (October 1370) merely redounded to his discredit. He returned to England a sick and broken man in January 1371 and formally surrendered his principality to his father in October 1372, alleging that the revenues of the country were insufficient to defray his expenses. He had no successor as prince of Aquitaine.

His life in England

Edward's position in England, where, throughout his life, he was heir apparent, was that of a typical 14th-century magnate. The registers of his household from 1346 to 1348 and from 1351 to 1365 have survived and add to what is known of him from the chroniclers and from his biographer, the herald of Sir John Chandos. In one important respect all of these sources paint the same picture, that of a man constantly living beyond his means. His generosity, however, extended to his tenants as well as to his knightly companions, and faithful service was rewarded, as in 1356 when the ferry of Saltash was granted to William Lenche, who had lost an eye at Poitiers.

The Prince paid two visits to Chester—in 1353 and again in 1358. Cheshire furnished many of his archers, who wore a rudimentary uniform of a short coat and hat of green and white cloth with the green on the right. Despite his title, however, Edward did not visit Wales.

He appears to have shared the interests of his class—jousting, falconry, hunting, gaming. He was literate and conventionally pious, substantially endowing a religious house at Ashridge (1376). He had the customary fine presence of the Plantagenets and shared their love of jewels. The Black Prince's ruby in the present imperial state crown may or may not have been given to him by King Peter after the Battle of Nájera, but he would certainly have prized it, as a connoisseur. Similar artistic interest is shown in his seals, adorned with their ostrich feathers, and in the elegant gold coins that he issued as prince of Aquitaine.

The last five years of the Prince's life are obscure. Some contemporaries suggest that he supported the Commons when political discontent culminated in the Good Parliament of April 1376; but he knew he was dying, and he was probably seeking the best means to ensure the succession of his second, but only surviving son, Richard of Bordeaux (afterward Richard II). He died at Westminster on June 8, 1376, and was buried at Canterbury, where his tomb with his accoutrements, recently restored and renovated, still stands.

BIBLIOGRAPHY. M.K. POPE and E.C. LODGE (eds.), *The Life of the Black Prince, by the Herald of Sir John Chandos* (1910), written in French, probably in 1397, is a metrical biography, not at all critical, dealing with the knightly exploits of the Prince. The works of Robert of Avesbury and Thomas Walsingham in the "Rolls Series" are useful for general reference. T.F. TOUT, *Chapters in Administrative History*, vol. 5 (1930), is good on the central administrative system of the Black Prince's household. The most interesting and valuable records printed are *The Black Prince's Registers*, 4 vol. (HMSO, 1930–33); the first deals with the years 1346–48, the other three with the years 1351–66. For the affairs of Aquitaine, vol. 4 of R. DELACHENAL, *Histoire de Charles V* (1928), should be consulted.

(I.P.S.)

Edwards, Jonathan

Jonathan Edwards, the greatest theologian and philosopher of American Puritanism, stimulated the religious revival known as the Great Awakening (1740–42) by his sermons and reports and became its most able literary spokesman. His writings and example helped usher in the great age of Protestant missionary expansion in the 19th century. In *A Careful and Strict Inquiry into the Modern Prevailing Notions of that Freedom of Will* and other works, he attempted a philosophical defense of orthodox Calvinism but in so original a fashion as to found a distinct school of American theology. More highly esteemed today are his *Treatise Concerning Religious Affections* and *The Nature of True Virtue*, as major works in theological ethics.

In the Yale University Art Gallery.

Early life and ministry. Edwards was born October 5, 1703, at East Windsor, Connecticut. His father Timothy was pastor of the church there; his mother Esther was a daughter of Solomon Stoddard, pastor of the church at Northhampton, Massachusetts. Jonathan was the fifth child and only son among 11 children; he grew up in an atmosphere of Puritan piety, affection, and learning. After a rigorous schooling at home, he entered Yale College in New Haven, Connecticut, at the age of 13. He was graduated in 1720 but remained at New Haven for two years, studying divinity. After a brief New York pastorate (1722–23), he received the M.A. degree in 1723; during most of 1724–26 he was a tutor at Yale. In 1727 he became his grandfather's colleague at Northampton. In the same year, he married Sarah Pierrepont, who combined a deep, often ecstatic, piety with personal winsomeness and practical good sense. To them were born 11 children.

Early intellectual interests

The manuscripts that survive from his student days exhibit Edwards' remarkable powers of observation and analysis ("Of Insects"), the fascination that the English scientist Isaac Newton's optical theories held for him ("Of the Rainbow"), and his ambition to publish scientific and philosophical works in confutation of materialism and atheism ("Natural Philosophy"). Throughout his life he habitually studied with pen in hand, recording his thoughts in numerous hand-sewn notebooks; one of these, his "Catalogue" of books, demonstrates the wide variety of his interests.

Edwards did not accept his theological inheritance passively. In his "Personal Narrative" he confesses that, from his childhood on, his mind "had been full of objections" against the doctrine of predestination—*i.e.*, that God sovereignly chooses some to salvation but rejects others to everlasting torment; "it used to appear like a horrible doctrine to me." Though he gradually worked through his intellectual objections, it was only with his conversion (early in 1721) that he came to a "delightful

conviction" of divine sovereignty, to a "new sense" of God's glory revealed in Scripture and in nature. This became the centre of Edwards' piety: a direct, intuitive apprehension of God in all his glory, a sight and taste of Christ's majesty and beauty far beyond all "notional" understanding, immediately imparted to the soul (as a 1734 sermon title puts it) by "a divine and supernatural light." This alone confers worth on man, and in this consists his salvation. What such a God does must be right; hence, Edwards' cosmic optimism. The acceptance and affirmation of God as he is and does and the love of God simply because he is God, became central motifs in all of Edwards' preaching.

Under the influence of Puritan and other Reformed divines, the Cambridge Platonists, and British philosopher-scientists such as Newton and Locke, Edwards began to sketch in his manuscripts the outlines of a "Rational Account" of the doctrines of Christianity in terms of contemporary philosophy. In the essay "Of Being," he argued from the inconceivability of absolute Nothing to the existence of God as the eternal omnipresent Being. It was also inconceivable to him that anything should exist (even universal Being) apart from consciousness; hence, material things exist only as ideas in perceiving minds; the universe depends for its being every moment on the knowledge and creative will of God; and "spirits only are properly substance." Further, if all knowledge is ultimately from sensation (Locke) and if a sense perception is merely God's method of communicating ideas to the mind, then all knowledge is directly dependent on the divine will to reveal; and a saving knowledge of God and spiritual things is possible only to those who have received the gift of the "new sense." This grace is independent of human effort and is "irresistible," for the perception of God's beauty and goodness that it confers is in its very nature a glad "consent." Nevertheless, God decrees conversion and a holy life as well as ultimate felicity; and he has so constituted things that "means of grace" (*e.g.*, sermons, sacraments, even the fear of hell) are employed by the Spirit in conversion, though not as "proper causes." Thus, the predestinarian preacher could appeal to the emotions and wills of men.

Pastorate at Northampton, Massachusetts. At Stoddard's death in 1729, Edwards became sole occupant of the Northampton pulpit, the most important in Massachusetts outside of Boston. In his first published sermon, preached in 1731 to the Boston clergy and significantly entitled *God Glorified in the Work of Redemption, by the Greatness of Man's Dependence upon Him, in the Whole of It*, Edwards blamed New England's moral ills on its assumption of religious and moral self-sufficiency. Because God is the saints' whole good, faith, which abases man and exalts God, must be insisted on as the only means of salvation. The English colonists' enterprising spirit made them susceptible to a version of Arminianism (deriving from the Dutch theologian Jacobus Arminius), which was popular in the Anglican Church and spreading among dissenters; it minimized the disabling effects of original sin, stressed free will, and tended to make morality the essence of religion. Against these ideas Edwards also delivered a series of sermons on "Justification by Faith Alone" in November 1734. The result was a great revival in Northampton and along the Connecticut River Valley in the winter and spring of 1734–35, during which period more than 300 of Edwards' people made professions of faith. His subsequent report, *A Faithful Narrative of the Surprising Work of God* (1737), made a profound impression in America and Europe, particularly through his description of the types and stages of conversion experience.

The Great Awakening

In 1740–42 came the Great Awakening throughout the colonies. George Whitefield, a highly successful evangelist in the English Methodist movement, and Gilbert Tennent, a Presbyterian minister from New Jersey, drew huge crowds; their "pathetical" (*i.e.*, emotional) sermons resulted in violent emotional response and mass conversions. Edwards himself, though he held his own congregation relatively calm, employed the "preaching of terror" on several occasions, as in the Enfield sermon, "Sinners in the Hands of an Angry God" (1741). The Awakening produced not only conversions and changed lives but also excesses, disorders, and ecclesiastical and civil disruptions. Though increasingly critical of attitudes and practices associated with the revival, to the extent of personally rebuking Whitefield, Edwards maintained that it was a genuine work of God, which needed to be furthered and purified. In defense and criticism of the Awakening he wrote *The Distinguishing Marks of a Work of the Spirit of God* (1741), *Some Thoughts Concerning the Present Revival of Religion in New England* (1742), and *A Treatise Concerning Religious Affections* (1746). In the *Affections*, Edwards insisted, against the revival critics' ideal of sober, "reasonable" religion, that "the essence of all true religion lies in holy love," a love that proves its genuineness by its inner quality and practical results. In 1749 he edited, with "Reflections," the memoirs of David Brainerd, a young New Light revivalist who became a Presbyterian missionary to the Indians and died in 1747. The volume became a highly influential missionary biography. Edwards' *Humble Attempt to Promote Explicit Agreement and Visible Union of God's People in Extraordinary Prayer* (1747), written in support of a proposed international "concert of prayer" for "the Revival of Religion and the Advancement of Christ's Kingdom on Earth," helped to remove a major ideological barrier to missionary activity by arguing that the worst of the "great tribulations" (prophesied in the book of Revelation to John as preceding the millennium) were already past and that the church could look forward to an increasing success of the gospel among men.

Dismissal from the Northampton pulpit

Meanwhile, Edwards' relations with his own congregation had become strained; one reason for it was his changed views on the requirements for admission to the Lord's Supper. In the Halfway Covenant, baptized but unconverted children of believers might have their own children baptized by "owning the covenant"; Stoddard had instituted the subsequently widespread practice of admitting to the Eucharist all who were thus "in the covenant," even if they knew themselves to be unconverted. Edwards gradually came to believe that the profession required for admission to full communion should be understood to imply genuine faith, not merely doctrinal knowledge and good moral behaviour. The public announcement of his position in 1749 precipitated a violent controversy that resulted in his dismissal. On July 1, 1750, Edwards preached his dignified and restrained "Farewel-Sermon." In this controversy he wrote two books, *Qualifications for Communion* (1749) and *Misrepresentations Corrected, and Truth Vindicated, in a Reply to the Rev. Mr. Solomon Williams's Book* (1752), one to convince his congregation, the other to correct what he considered misrepresentations of his views by a kinsman, the pastor at Lebanon, Connecticut. Though Edwards himself was defeated, his position finally triumphed and provided New England Congregationalism with a doctrine of church membership more appropriate to its situation after disestablishment.

Pastorate at Stockbridge, Massachusetts. In 1751, Edwards became pastor of the frontier church at Stockbridge, Massachusetts, and missionary to the Indians there. Hampered by language difficulties, illness, Indian wars, and conflicts with powerful personal enemies, he nevertheless discharged his pastoral duties and found time to write his famous work on the *Freedom of Will* (1754). The will, said Edwards, is not a separate, self-determining faculty with power to act contrary to the strongest motives, as he understood the Arminians to teach. Rather, it is identical with feelings or preference, and a volition is simply the soul's "prevailing inclination" in action; the will "is as the greatest apparent good." Men are free to do as they please, and God therefore rightly holds them morally responsible for the quality of their volitions as expressions of their desires and intentions.

By 1757 Edwards had finished his *Great Christian Doctrine of Original Sin Defended* (1758), which was mainly a reply to the English divine, John Taylor of Norwich, whose works attacking Calvinism (based on the thought of the 16th-century Protestant Reformer John Calvin)

had "made a mighty noise in America." Edwards defended the doctrine not only by citing biblical statements about the corruption of man's heart but by arguing that the empirical evidence of men's universal commission of sinful acts points to a sinful predisposition in every man. In answering Arminian objections to the notion that God "imputed" Adam's guilt to his posterity, Edwards proposed a novel theory of identity by divine "constitution" to account for men's unity with Adam and suggested that their innate corruption is not a judicial punishment for Adam's guilt but is really their own because of their participation (being one with him) in the sinful inclination that preceded Adam's sinful act. Edwards' was the first major contribution to the long debate about human nature in American theology and helped set the terms of that debate.

Edwards' defense of Calvinism

Edwards perceived the threat in Taylor's notion of man's innate goodness and autonomy; the whole Christian conception of supernatural redemption seemed to be at stake. He therefore planned further treatises, of which he completed two posthumously published dissertations: *Concerning the End for Which God Created the World* and *The Nature of True Virtue* (1765). God's glory, not human happiness, is his end in creation; but this is because God in his all-sufficient fullness must communicate himself by the exercise of his attributes. God can be said to aim at the creature's happiness, but it is a happiness that consists in contemplating and rejoicing in God's glory manifested in creation and redemption. Edwards defines true virtue as disinterested love (benevolence) toward God as Being in general and toward all lesser beings according to their degree of being. True virtue, therefore, does not spring from self-love or from any earthbound altruism (two prime 18th-century views); love to self, family, nation, or even mankind is good only if these lesser systems of being do not usurp the place of highest regard that belongs to God alone.

Edwards also projected books on other subjects, notably *A History of the Work of Redemption* (he had preached a series of sermons—posthumously published—on that subject in 1739), which was to be a complete theology combining biblical, historical, and systematic materials "in an entire new method." Late in 1757, however, he accepted the presidency of the College of New Jersey (later Princeton University) and arrived there in January. He had hardly assumed his duties when he contracted smallpox and died at Princeton on March 22, 1758.

Influence. Edwards' immediate disciples, Joseph Bellamy (pastor at Bethlehem, Connecticut), Samuel Hopkins (pastor at Great Barrington, Massachusetts, later at Newport, Rhode Island), and Jonathan Edwards, Jr., developed some of his "improvements" into a distinct theological school; it was first called "Hopkinsianism" and later the "New England Theology." These men and their successors, in their effort to defend Calvinism against Arminians, Unitarians (those who denied the doctrine of the Trinity), and "infidels," made important modifications in some of its doctrines and thus prepared the way for later 19th-century evangelical liberalism.

Edwards' influence on American Protestantism for a century after his death was very pronounced, and he was widely read in the British Isles. In a general revolt against Puritanism and Calvinism after the U.S. Civil War (1861–65), Edwards' prestige declined, and he was remembered mainly as a hell-fire preacher or as an abstruse, absent-minded metaphysician. In the 1930s and after, he was rediscovered by theologians reacting against liberalism and by secular scholars seeking to delineate the "American mind." Edwards' ability to combine religious intensity with intellectual rigour and moral earnestness, the cosmic sweep of his theological vision, his emphasis on faith as an "existential" response to reality, his insistence that love is the heart of religion, and his uncompromising stand against all forms of idolatry are some of the reasons his life and writings are again being seriously studied.

BIBLIOGRAPHY. PERRY MILLER and JOHN E. SMITH (eds.), *The Works of Jonathan Edwards*, 4 vol. to date (1957–), will be a complete critical edition. OLA ELIZABETH WINSLOW, *Jonathan Edwards, 1703–1758* (1940), containing a delineation of Edwards the man; and ARTHUR C. MCGIFFERT, JR., *Jonathan Edwards* (1932), containing a good understanding of his thought, are regarded as the best biographies. PERRY MILLER, *Jonathan Edwards* (1949), an intellectual biography, is a brilliant interpretation that has been accused of unduly modernizing Edwards. Additional sources of information may be found in CLARENCE H. FAUST and THOMAS H. JOHNSON (eds.), *Jonathan Edwards: Representative Selections*, rev. ed. (1962), the best handbook, including an extensive annotated bibliography; and NELSON R. BURR, *A Critical Bibliography of Religion in America*, vol. 2, pp. 976–987 (1961), a bibliographical essay. THOMAS H. JOHNSON, *The Printed Writings of Jonathan Edwards, 1703–1758: A Bibliography* (1940), lists editions, reprints, and variants. Other interpretive studies include: DOUGLAS J. ELWOOD, *The Philosophical Theology of Jonathan Edwards* (1960), which stresses the Platonic and Augustinian elements; CONRAD CHERRY, *The Theology of Jonathan Edwards: A Reappraisal* (1966), an excellent theological study; and ROLAND A. DELATTRE, *Beauty and Sensibility in the Thought of Jonathan Edwards: An Essay in Aesthetics and Theological Ethics* (1968).

(T.A.S.)

Egg Production, Commercial

While the primary role of the egg obviously is to reproduce the species (for zoological information on eggs, see BIRD), most eggs produced by domestic fowl, except those specifically set aside for hatching purposes, are not fertilized, but are sold mainly for human consumption. They may be purchased by the consumer; or, in liquid, dehydrated, or frozen form, by quantity buyers for use in food service operations or for inclusion in commercially manufactured food products. Eggs produced in quantity come from chickens, ducks, geese, turkeys, guinea fowl, pigeons, pheasants, and quail. This article deals with world egg production and consumption; the selection of laying hens; the cleaning, oiling, sizing, and grading of eggs; and their preparation and use in the human diet.

PRODUCTION AND CONSUMPTION STATISTICS

Egg-producing fowl

Chicken eggs represent the bulk of egg production in the United States and Europe. Though some laying hens are known to produce an egg every day, in commercial installations the average for layers is about 220 eggs per year. In several parts of the world, the duck is important as an egg producer and the egg-laying ability of certain types excels that of chickens. Some ducks produce from 300 to 360 eggs a year, but the average is much less. Duck eggs are larger and heavier than chicken eggs, and are used as food in western Europe and the Orient. Geese are raised extensively in Poland and some of the western European countries, and their eggs are often used for foods. Commercial production of turkey and pigeon eggs is almost entirely confined to those used for producing turkey poults and young pigeons (squabs). Pheasant and quail eggs provide birds for hobby or sport use.

World production. Annual world production of hen eggs is about 390,000,000,000. The leading egg-producing country is China, with an annual production of 73,000,000,000 eggs. The United States ranks second, with some 314,000,000 laying birds whose yearly egg production of about 70,000,000,000 eggs yields a gross income of over $2,200,000,000. The Soviet Union ranks third as an egg-producing nation, and Japan fourth. Other countries in order of production are the United Kingdom, West Germany, France, Brazil, Italy, Spain, Poland, and Canada. In the United States during 1970, production for each of the ten major egg-producing states ranged from over 2,500,000,000 to over 8,300,000,000. Annual production in California alone equalled that of Italy.

European production. In Europe, egg production in the 1960s increased steadily at a rate of about 3 percent a year. The rate was somewhat higher for eastern than for western Europe; *i.e.*, 3.3 percent versus 2.7 percent. In the Soviet Union production jumped considerably, being 40 percent higher in 1970 than in 1960. There was a phenomenal increase in egg production of Japan, where during the period 1948–52, production averaged 2,245,000,000 eggs, rising in 1970 to 28,571,000,000.

U.S. production. In the U.S. production rose about 14 percent from 1960 to 1970, but a levelling off after 1967 was attributed to a lack of incentive for increasing production because of low farm prices and a reduction of exports. In 1958, the United States had exported about five times as many eggs as it had a decade later. Several countries that had formerly imported eggs attained self-sufficiency. This change in dependence on importation of eggs also affected other countries. For example, Denmark, traditionally an important exporter of eggs, cut back its output substantially because of reduced export outlets.

Imports and exports

Consumption. During the 20th century, use of eggs in the United States increased annually until, in 1951, it reached 392 eggs per person per year, after which the figure fell steadily until, by 1966, it was only 314. In the United Kingdom the per capita use of 270 eggs per year is somewhat higher than the average for other countries of western Europe (210). The number of eggs consumed in Japan per capita in 1960 was 98; in 1964, it was 180; and in 1969, it was 269. The increase in consumption reflects a rising standard of living in Japan. People of West Germany and Austria each consume about 250 eggs per year. Per capita egg consumption in the U.S.S.R. and eastern Europe is much lower: 140 and 190 respectively.

FACTORS IN PRODUCTION AND QUALITY OF EGGS

Selection of laying hens. Chickens are the world's most widely distributed domestic fowl. Commercially, the major chicken breeds for egg production include several of the varieties of the Leghorn in the Mediterranean class and such varieties as white Plymouth Rock and New Hampshire breeds in the dual-purpose, or American class. Breeders have selected birds with high rates of egg production and by inbreeding, single crossing of inbred lines, or multiple crossing of lines, have evolved pullets (immature hens) that can maintain good performance for a year or more. Ordinarily, pullets are placed in production at 5 to 6 months of age and are kept as layers until they are about 18 months old. While older layers produce large eggs, the shell usually does not have good quality and production is reduced after one year of laying.

Cleaning and oiling. In the United States shell eggs are shipped from the producer to the packing station in cardboard containers holding either 15 dozen or 30 dozen eggs separated by fillers and flats. Such eggs are unsorted as to size and grade. When received at the plant, eggs are placed into a cool 50°–60° F (10°–16° C) humidified room.

Soiled eggs

Soiled eggs cause heavy financial losses. Dirty eggs bring less per dozen because the cost of cleaning them is high and their keeping quality is poor. Such eggs are cleaned by washing or by dry cleaning the dirty or stained area with an abrasive emery cloth or fine sandpaper.

When eggs are washed, a solution at least 20° F warmer than the egg and having a temperature of 90° F (32° C) or more is used so that the egg's interior will not contract and allow polluted water to be drawn into the shell. The washed egg is rinsed immediately with warm water containing a sanitizer and dried before packing. Dry cleaning is little used because it is slow, does not do a thorough job, and often results in excessive breakage.

Oiling eggs reduces evaporation of moisture and replaces the cuticle lost during washing. As soon as possible after the eggs are laid or washed, a fine film of lightweight mineral oil, which is colourless, odourless, and tasteless, is sprayed over the egg shell to seal the pores. Oiling also cuts weight loss and halts air cell expansion.

The keeping quality of cleaned eggs also can be improved by holding them in water at 130° F (55° C) for 15 minutes or at slightly higher temperatures for shorter periods of time. This form of thermostabilization causes a slight thickening of the albumen adjacent to the shell membranes and acts as a seal. Thermostabilizing eggs is not common.

Egg weights. Eggs are graded on the basis of size and quality. There are four general weight classes: extra large, large, medium, and small. The minimum net weights per dozen for eggs in these grades are respectively 27, 24, 21, and 18 ounces. In addition to these classes, two others occasionally are sold: *i.e.*, jumbo (30 ounces per dozen) and peewee (15 ounces per dozen).

Both exterior and interior quality are used in determining the grade of an egg. Criteria used for this assessment include: shell condition and cleanliness, conformity and depth of air cell, clearness and firmness of white, and definition and shape of yolk. For these determinations, the interior of the egg is viewed by transmitted light, a process called candling.

Egg candling. When eggs are candled by hand, the operator supports the egg between the thumb and index finger with the small end toward the palm of the hand. Then by a twist of the hand and wrist the egg is quickly rotated through a 180° arc so that the contents are sent spinning. At that instant the large end is held before a candling lamp so that the light shines through and reveals the air cell and yolk, albumen, and shell conditions. Most commercial grading operations take place in cool, darkened rooms and hand candling is used only occasionally to check the accuracy of grading. Usually the quality of the egg is determined by mass scanning of several rows of eggs at a time as they move automatically over a light source that shines through them. During the same operation the eggs pass over tripping devices calibrated to sort them into various weight classes. Many types of automatic and semiautomatic candling and grading devices are available.

While most candling of eggs is done using incandescent light, the use of "black light," or ultraviolet candling, has proved valuable in detecting spoilage caused by the bacterium *Pseudomonas*, since many of these organisms produce a characteristic green or blue-green fluorescence when illuminated by ultraviolet light.

Egg quality

Grades. Four edible grades of shell eggs are recognized: AA (or fresh fancy), A, B, and C. For AA grade eggs, the shell eggs must be clean, unbroken, of good even texture and strength, free from visible stains, discolorations, rough areas, or thin spots. The air cell must be ⅛ inch (3.2 millimetres) or less in depth, the white clear and firm, and the outline of the yolk only slightly defined and practically free of defects. In shelled eggs, egg white thickness is indicated numerically in Haugh units. When broken out, the egg must cover a small area, have a firm albumen, or thick white portion (72 Haugh units minimum), with much thick white surrounding a round and upstanding yolk. In A grade eggs, the air cell may be 3/16 inch (4.8 millimetres) in depth and the yolk fairly well defined; when such eggs are broken out, they cover a moderate area due to a medium amount of thin white present (60 Haugh units minimum). The shell of a B grade egg may be slightly faulty in texture or strength and slightly stained (not over 1/16 of the shell surface); the air cell may be as much as ⅜ inch (9.5 millimetres) in depth. The white may be slightly weak and the yolk outline well defined, slightly enlarged and flattened, and have defects not considered serious. The broken-out B grade egg covers a wide area. The yolk is flattened and enlarged and the albumen slightly weak (31 Haugh units minimum). C grade eggs may be moderately stained (less than ¼ of the shell surface), misshapen, or faulty in texture or strength. The air cell may be over ⅜ inch in depth, bubbly or free moving. The white may be weak and watery and small blood clots or meat spots may be present. The yolk outline, which is plainly visible, shows that the yolk is enlarged or flattened; there may be germ development but no blood. When broken out, the egg covers a very wide area. There is no thick white (less than 31 Haugh units) but a very large amount of thin white and a very flat and enlarged yolk.

Substandard eggs. In addition to these four salable grades of shell eggs, dirty and check eggs are permitted for use in egg products providing there is no leakage of the interior egg content; *i.e.*, they may have moderate stains covering more than ¼ of the shell surface or even prominent stains or adhering dirt and, with check eggs, the shell may be broken, but there must be an intact membrane (as demonstrated by candled appearance).

Eggs are designated as inedible if black-, white-, or mixed-rots are present. Also, moldy, musty, sour, or

adulterated eggs are not permitted for sale as food nor are those with green or bloody whites or with stuck yolks, incubator rejects, or eggs containing embryo chicks at or beyond the blood ring condition, or any in such condition that washing and breaking result in contamination.

Shell colour. The shell varies in colour from white to brown but colour does not affect the quality of the egg. A pigment imparted to the shell while the egg is in the oviduct is laid down in the spongy layer of the shell and is derived from the blood. Leghorn hens lay much whiter-shelled eggs than do most American classes. In some areas, white eggs are preferred, while in other regions, those with brown shells are chosen. Usually, more difficulty is experienced in detecting the interior quality of brown shelled eggs; small meat or bloodspots are harder for the candler to see at the packing station. White eggs and brown eggs may be colour sorted. When eggs with mixed shell colours are cartoned together, the consumer may have the erroneous impression that these lots are heterogeneous in other respects as well.

Packaging. For retail use in the United States, eggs are repackaged in dozen and half-dozen paperboard cartons. In some other countries they are packed with straw or excelsior in long wooden boxes. In many parts of the world, they are marketed in baskets or boxes and the individual eggs are sold by weight. Several European countries stamp each egg with a date and number to meet the import restrictions of other nations.

USES AND PROCESSING OF EGGS AND EGG PRODUCTS

Use of sub-standard eggs

The bulk of egg production is sold directly to the consumer for table use. Those that are not, including most of the smaller sizes and undergrades, go to egg breaking firms where they are broken out for use as frozen or dried egg or egg products. A large percentage of the liquid egg is frozen for use by bakers and confectioners.

Uses. Some breakers use refrigerated bulk tank trucks for shipping broken out white, yolks, or a mixture to their freezing or drying plants. In addition, such refrigerated bulk tank shipments are often made directly to bakeries or confectioners.

Eggs are widely used as food product ingredients because of their leavening, emulsifying, binding, taste appeal, and nutritive values. In addition, eggs are used for purposes other than food, as in paints, varnishes, ink, soap, shampoos, animal feeds, fertilizers, and vaccines. The foaming ability and heat coagulability of the proteins in egg white have made this product invaluable to the candy and bakery trades. Foam is formed in egg white when air is incorporated during beating and a solid film results as the protein denatures at the surface. When heat is also applied, such as in cooking and baking, a solid structure is set up that supports other ingredients as well as the egg white foam. Excellent foam development and coagulation is also achieved when egg yolk is used in making some kinds of cakes and biscuits (cookies). Egg yolk is a stable emulsion that has unique value in the emulsification of products such as mayonnaise.

Pasteurization. Egg pasteurization is the process of heating liquid or whole egg products for sufficient time to destroy possible pathogens and organisms of fecal origin. In 1966, regulations of the U.S. Food and Drug Administration required that processed egg products in interstate commerce be pasteurized or otherwise treated to destroy all viable *Salmonella*, organisms that cause food poisoning and acute intestinal disorders in man. Efficient pasteurization is accomplished by what is called the "flash," or high temperature-short time (HTST) method or by the holding, or vat, procedure.

In the HTST process, liquid whole egg flows through a pipe at such speed that it is maintained at 140° F (60° C) for 3.5 minutes before the product is cooled, frozen, or dried. For plain liquid yolk, the temperature of pasteurization required is 142° F (61° C) and for salted or sugared yolk it is 146° F (63° C).

Egg white is more easily damaged by heat than liquid yolk or whole egg and cannot be pasteurized by ordinary methods without great loss of its functional properties. By the addition of lactic acid and aluminum salts, however, the albumen proteins are stabilized and the damage greatly reduced. Efficient pasteurization of liquid albumen also can be accomplished by adding 0.075–0.10 percent hydrogen peroxide to egg white heated for 1½ minutes and then holding for two more minutes at the same temperature. Albumen can be freed of *Salmonella* by storing the dried product in a "hot room" (122–125° F, 50°–52° C) for 5–7 days.

Protein stabilization

For the holding or vat method of pasteurization, liquid whole egg or egg white is held at 135° F (57° C) for 15 minutes, plain liquid yolk at 136° F (58° C) for 20 minutes, and salted or sugar yolk at 138° F (59° C) for 35 minutes.

Dried albumen. Since the turn of the century, dried albumen has been produced in China by allowing the organisms normally present in the broken-out liquid to ferment spontaneously and change the small amount of glucose to water, carbon dioxide, and cells before drying the product on pans, trays, or drums. It was recognized that when there was residual glucose, the dried product deteriorated quite rapidly during storage because of a "browning" reaction between the aldehyde group of the glucose and the amino groups of the proteins. Although solubility and other properties of the Chinese dried albumen were satisfactory, the sanitary shortcomings of the product made it necessary to replace the procedure by a controlled bacterial or yeast fermentation or by an enzymatic process utilizing a glucose oxidase to convert the glucose to gluconic acid.

Several procedures are employed by industry for the drying of albumen, including drying on trays, in cabinets or drying tunnels, on drums or belts, foam drying, and spray drying.

Dried whole egg. Whole egg solids are usually produced by spray drying. Glucose in whole-egg also was found to be responsible for the development of a glucose-cephalin reaction with the phospholipid fraction of the egg resulting in an off-flavoured product. Removal of the glucose prevented this reaction as well as the browning phenomenon described above for egg white. The addition of sucrose (a non-reducing sugar) to a level so that the dried product contains 20–30 percent sucrose has been found to decrease drying damage.

Dried yolk. Egg yolk solids are produced by spray drying. While this form of drying produces some damage to the residual sugar, the percentage is much less than with albumen or whole egg, and other considerations such as "oiling-off" and rancidification are of greater concern. Drying to a low moisture content and packing in an inert gas help to prevent rancidification.

BIBLIOGRAPHY. Much comprehensive literature on the production of eggs exists. General discussions of domesticated fowl are: M.A. JULL, "The Races of Domestic Fowl" and "Fowls of Forest and Stream Tamed by Man," *Natn. Geogr. Mag.*, 51:379–452 (1927), and 51:327–371 (1930).

Economic considerations and marketing information are presented in the following: "The European Egg Markets in the Sixties," *Monthly Bulletin of Agricultural Economics and Statistics*, Food and Agricultural Organization, Rome, vol. 17 (1968); and "Chickens and Eggs, April 1969," pub. by the Crop Reporting Board Statistical Reporting Service, United States Department of Agriculture (U.S.D.A.). Current information may be found in recent reports from these agencies.

Technical information on egg grading is given in the U.S.D.A. Agriculture Handbook No. 75, *Egg Grading Manual*, rev. ed. (1965).

Scientific background on factors affecting the use of eggs in the food industry, functional properties of eggs and egg products, and advances in egg processing technology is included in: R.H. FORSYTHE, "Some Factors Affecting the Use of Eggs in the Food Industry," *Cereal Sci. Today*, 2:211–216 (1957), "Recent Advances in Egg Processing Technology and Egg Products," *The Bakers' Dig.* 38:52–58 (1964); R.E. FEENEY, "The Properties of Eggs in Relation to Baking and Premixes," *ibid.*, 29:23–26 (1955); and G.J. BANWART and J.C. AYRES, "The Effect of High Temperature Storage on the Content of Salmonella and on the Functional Properties of Egg Whites," *Fd. Technol.*, 10:68–73 (1956).

The periodical *Poultry Science* (1922–), is devoted to the scientific study of poultry and eggs and provides much additional information on commercial production of eggs.

(J.C.A.)

Egypt, Arab Republic of

Egypt, or the Arab Republic of Egypt, to use its current title, consists of a rectangle of territory occupying the northeast corner of the African continent between the 22nd and 32nd parallels of latitude. It has a total area of about 386,900 square miles (1,002,000 square kilometres). Its land frontiers border Libya in the west, The Sudan in the south, and Israel in the northeast. In the north, its Mediterranean coastline is about 620 miles, and, in the east, its coastline on the Red Sea and the Gulf of Aqaba is about 1,835 miles. In 1971 the population was almost 34,130,000. The capital is Cairo.

Egypt's strategic location

Egypt has always been a nodal point for routes—westward along the coast of North Africa, northwest to Europe, northeast to the Levant, south along the Nile to Africa, and southeast to the Indian Ocean and the Far East. This natural advantage was enhanced in 1869 by the opening of the Suez Canal. The concern of the European powers to safeguard this link for strategic and commercial reasons is probably the most important single factor influencing the history of Egypt since the 19th century. The increasing presence of the United States and the Soviet Union in the Mediterranean since World War II has kept Egypt in the spotlight of world concern. It is not, however, simply in the context of the balance of power in the Mediterranean but also in Africa and in the Indian Ocean that its significance must be assessed.

Israeli forces have occupied the Sinai Peninsula and the Gaza Strip in eastern Egypt since the cease-fire following the Arab-Israeli War of 1967. (See the articles on ALEXANDRIA and CAIRO; for associated physical features, see NILE RIVER; RED SEA; SAHARA (DESERT); SINAI DESERT; and SUEZ CANAL; for historical aspects and for relations with Israel and Syria see EGYPT, HISTORY OF; and SYRIA AND PALESTINE, HISTORY OF.)

This article is divided into the following sections:

I. The landscape
  Description of the natural landscape
    Relief features
    Drainage and soils
    Climate

    Prospects for the future

I. The landscape

DESCRIPTION OF THE NATURAL LANDSCAPE

Relief features. The topography of Egypt is dominated by the Nile. For about 750 miles of its northward course through the country, the river cuts its way through bare desert—a sharply delineated strip of green, abundantly fecund in contrast to the desolation that surrounds it. From the Aswān High Dam in the south as far as Cairo in the north, it is hemmed into its trenchlike valley by bordering cliffs, but at Cairo these disappear, and the river begins to fan out into its delta. Although totally flat, apart from an occasional mound projecting through the alluvium, the delta is far from featureless; it is crisscrossed by a maze of canals and drainage channels, the banks of which project above the surface of the ground like brown veins.

The Nile divides the desert plateau through which it flows into two unequal sections—the Western Desert (Arabic aṣ-Ṣaḥrā' al-Gharbīyah), between the river and the Libyan frontier; and the Eastern Desert (Arabic aṣ-Ṣaḥrā' ash-Sharqīyah), extending to the Suez Canal, the Gulf of Suez, and the Red Sea. Each of them has its own different character, as does the third and smallest of the Egyptian deserts, that of Sinai. The Western (Libyan) Desert is arid and without wadis (dry beds of seasonal rivers), while the Eastern Desert is extensively dissected by wadis and fringed by rugged mountains in the east. The desert of central Sinai is open country, broken by isolated hills and scored by wadis.

The mountains

Contrary to popular belief, Egypt is not an unrelievedly flat country. Mountainous areas occur in the extreme southwest of the Western Desert, along the Red Sea coast, and in southern Sinai. The high ground in the southwest is associated with the Jabal al-'Uwaynāt mountain mass, which lies just outside Egyptian territory. A number of peaks in the Red Sea Hills (Ītbāy) rise to over 6,000 feet, and the highest, Jabal Shā'ib al-Banāt, reaches 7,173 feet (2,187 metres). The sharply serrated crests of the mountains of southern Sinai reach elevations of more than 8,000 feet; among them is Mt. Catherine, Egypt's highest mountain, which reaches an elevation of 8,668 feet (2,642 metres).

The coastal regions of Egypt, with the exception of the delta, are everywhere hemmed in either by desert or by mountain; they are arid or of very limited fertility. The coastal plain, in both the north and east, tends to be narrow; it seldom extends to more than 30 miles and is on average much less. With the exception of the cities of Alexandria, Port Said, and Suez and a scattering of small ports and resorts, the coastal regions are sparsely populated and underdeveloped.

Drainage and soils. Apart from the Nile, the only natural perennial surface drainage consists of a few meagre streams in the mountains of southern Sinai. Most of the valleys of the Eastern Desert drain westward to the Nile. They are water eroded but normally dry; only after heavy rainstorms in the Red Sea Hills do they carry torrents. The shorter valleys on the eastern flank of the Red Sea Hills drain toward the Red Sea; they, too, are normally dry. Drainage in the Sinai mountains is toward the gulfs of Suez and Aqaba; as in the Red Sea Hills, torrent action has produced deeply eroded valleys, normally dry.

The central plateau of Sinai drains northward toward Wādī al-'Arīsh, a depression in the desert that occasionally carries surface water. One of the features of the Western Desert is its aridity, as shown by the absence of drainage lines.

Outside the areas of Nile silt deposits, the nature of such cultivable soil as exists depends upon the availability of the water supply and the type of rock in the area. Thirty percent of the total land surface of Egypt consists of Nubian sandstone, which extends over the southern sections of both the Eastern and Western deserts. Limestone deposits of the Eocene Epoch (*i.e.*, from 38,000,000 to 54,000,000 years old) cover a further 20 percent of the land surface, including central Sinai and the central portions of both the Eastern and Western deserts. The north-

ern part of the Western Desert consists of Miocene limestone (from 7,000,000 to 26,000,000 years old). From 10 to 12 percent of the total area, notably the mountains of Sinai, the Red Sea, and the southwest part of the Western Desert, consists of igneous metamorphic rocks (rocks formed by the solidification of molten magma and structurally changed by heat and pressure).

The Nile silt

The silt, which constitutes the present-day cultivated land in the delta and the Nile Valley, has been carried down from the Ethiopian Highlands by the Nile's upper tributary system, consisting of the Blue Nile and the ʿAṭbarah rivers. The depth of the deposits ranges from over 30 feet in the northern delta to about 22 feet at Aswān. The White Nile, which is joined by the Blue Nile at Khartoum, in The Sudan, supplies important chemical constituents. The composition of the soil varies and is generally more sandy toward the edges of the cultivated area. A high clay content makes it difficult to work, and a concentration of sodium carbonate sometimes produces infertile black-alkali soils. In the north of the delta, salinization has produced the sterile soils of the so-called *barārī* (barren) regions.

Climate. Egypt lies within the North African desert belt; its general climatic characteristics, therefore, are low annual rainfall and a considerable seasonal and diurnal (daily) temperature range, with sunshine occurring throughout the year. In the desert, cyclones stir up sand or dust storms, called khamsin, which can occur from March to June; these are caused by tropical air from the south that moves northward as a result of the extension northeastward of the low-pressure system of the Sudan. The khamsin are accompanied by a sharp increase in temperature of from 14° to 20° F (8° to 11° C), a drop in relative humidity (often to 10 percent), and thick dust; they can reach gale force.

The climate is basically biseasonal, with winter lasting from November to March and summer from May to September, with short transitional periods intervening. The winters are cool and mild, and the summers are hot. Mean January minimum and maximum temperatures show a variation of between 51° and 65° F in Alexandria and 50° and 74° F at Aswān. Extremes of temperature can occur, and prolonged winter cold spells or summer heat waves are not uncommon.

Humidity diminishes noticeably from north to south and on the desert fringes. Along the Mediterranean coast the humidity is high throughout the year but is highest in summer. When high humidity levels coincide with high temperatures, oppressive conditions result.

The rainfall in Egypt occurs largely in the winter months; it is meagre on average but highly variable. The amount diminishes sharply southward; the annual average at Alexandria is about seven inches; Cairo has about an inch; Aswān receives only about a tenth of an inch. The Red Sea coastal plain is almost rainless.

Vegetation and animal life. In spite of the lack of rainfall, the natural vegetation of Egypt is varied. Much of the Western Desert is totally devoid of plant life of any kind, but where some form of water exists the usual desert growth of perennials and grasses is found; the coastal strip has a rich plant life in spring. The Eastern Desert receives sparse rainfall; it supports a varied vegetation that includes tamarisk, acacia, and markh (a leafless, thornless tree with bare branches and slender twigs), in addition to a great variety of thorny shrubs, small succulents, and aromatic herbs. This growth is even more striking in the wadis of the Red Sea Hills and of Sinai and in the Elba Mountains in the southeast.

Water plants

The Nile and irrigation canals and ditches support many varieties of water plants; the lotus of antiquity is to be found in drainage channels in the delta. There are more than 100 kinds of grasses, among them bamboo and *ḥalfā'* (a coarse, long grass growing near water). Robust perennial reeds such as the Spanish reed and the common reed are widely distributed in Lower Egypt, but the papyrus is now found only in botanical gardens.

The date palm, both cultivated and subspontaneous, is found throughout the delta, in the Nile Valley, and in the oases. The doum palm (an African fan palm) is identified particularly with Upper Egypt and the oases, although there are scattered examples elsewhere.

There are very few native trees. The Phoenician juniper is the only native conifer, although there are several cultivated conifer species. The acacia is widely distributed, as are eucalyptus and sycamore. The casuarina, one of the most important timber trees in the country, was introduced in the 19th century. Other foreign importations, such as jacaranda, poinciana (a tree with orange or scarlet flowers), and lebbek (a leguminous tree), have become a characteristic feature of the Egyptian landscape.

Domestic animals include buffalo, camels, donkeys, sheep, and goats, the last of which are particularly noticeable in the Egyptian countryside. The animals that figure so prominently on the ancient Egyptian friezes—hippopotamuses, giraffes, and ostriches—no longer exist; crocodiles occur only south of the Aswān High Dam. The largest wild animal is the mountain sheep, which survives in the southern fastnesses of the Western Desert. Other desert animals are the dorcas gazelle, the miniature desert fox, the mountain goat, the Egyptian hare, and two kinds of jerboa (a mouselike rodent with long hindlegs for jumping). The Egyptian jackal still exists, and the cony (a small rodent) is found in the Sinai mountains. There is a carnivorous wildcat; another carnivore is the striped Egyptian mongoose. Several varieties of lizard are found, including the large monitor. Poisonous snakes include more than one species of viper; the speckled snake is found throughout the Nile Valley and the Egyptian cobra in agricultural areas. Scorpions are common in desert regions. There are numerous species of rodents, among which can be found the powerfully built Pharaoh's rat. Many varieties of insects are to be found, including the Egyptian locust.

Bird life

Egypt is rich in bird life. Many birds pass through in large numbers on their spring and autumn migrations; in all, there are more than 200 migrating types to be seen, as well as more than 150 resident birds. The hooded crow is a familiar resident, and the black kite is a characteristic resident along the Nile Valley and in al-Fayyūm. Among the birds of prey are the lanner falcon and the kestrel. Lammergeier and golden eagles are resident in the Eastern Desert and Sinai. The sacred ibis (a long-billed wading bird) is no longer found, but the great egret and buffbacked heron are resident in the Nile Valley and al-Fayyūm, as is the hoopoe (a bird with an erectile, fanlike crest). Resident desert birds are a distinct category, numbering about 24 kinds.

The Nile contains about 190 varieties of fish, the most common being *bulṭī* (a coarse-scaled, spiny-finned fish) and the Nile perch. The lakes on the Delta coast contain mainly *būrī* (gray mullet). Lake Qārūn in the Fayyūm has been stocked with *būrī*, and Lake Nasser with *bulṭī*.

TRADITIONAL REGIONS

Physiographically, Egypt is usually divided into four major regions—the Nile Valley and Delta, the Eastern Desert, the Western Desert, and Sinai. When both physical and cultural characteristics are considered together, however, the country may be divided into six subregions—the Nile Delta; the Nile Valley from Cairo to south of Aswān; the Nubian Valley (now Lake Nasser); the Eastern Desert and the Red Sea coast; Sinai; and the Western Desert and its oases.

The Delta. The Delta, or Lower Egypt, covers an area of 9,650 square miles. It is 100 miles long from Cairo to the Mediterranean, with a coastline stretching 150 miles from Alexandria to Port Said. Much of the delta coast is taken up by the brackish lagoons of Lakes Maryūṭ, Idkū, Burullus, and Manzilah. The conversion of the Delta to perennial irrigation has made possible the raising of two or three crops a year, instead of one, over an area of 3,500,000 acres.

The Delta population

The majority of the Delta population are peasants—either landowners or labourers—living on the produce of the land. The remainder live in towns or cities, the largest of which is Cairo. As a whole, they have had greater contact with the outside world, particularly with the rest of the Middle East and Europe, than the inhabitants of the

more remote southern valley and are generally less traditional and conservative.

The Valley. The cultivated portion of the Valley between Cairo and Aswān varies from five to ten miles in width, although there are places where it narrows to a few hundred yards and others where it broadens to 14 miles. Since the completion of the Aswān High Dam in 1970, the 2,500,000-acre valley has been under perennial irrigation. The inhabitants of the Valley up to Aswān *muḥāfaẓah* (governorate) are referred to as Ṣaʿīdīs (Upper Egyptians) and are more conservative than the Delta people. In some areas women still do not appear in public without a veil, family honour is very important, and vendetta laws apply.

Until the building of the High Dam, the Aswān *muḥāfaẓah* was one of the poorest in the valley and the most remote from outside influences. There are some Ṣaʿīdīs living in the towns, but the majority of the population belong to other ethnic groups, such as the Jaʿāfirah, ʿAbābdah, or Nubians.

The Nubian Valley, or Lake Nasser. Until flooded by the waters of the High Dam to form Lake Nasser, the Nubian Valley of the Nile extended for 195 miles between the town of Aswān and The Sudan border—a narrow and picturesque gorge with a limited cultivable area. The 100,000 inhabitants were resettled, mainly in the government-built villages of New Nubia, at Kawm Umbū (Kom Ombo), north of Aswān.

Lake Nasser is being developed for its fishing and as a tourist area, and it is expected that new settlements will grow up around it.

The Eastern Desert. The Eastern Desert comprises 22 percent of the land surface of Egypt and covers an area of about 85,690 square miles. One-third of it consists of a limestone plateau stretching from the Mediterranean capital plain to a point roughly opposite Qinā on the Nile. Another third includes the sandstone plateau from Qinā southward; the remainder consists of the Red Sea Hills and the coastal plain. Moving southward from the Mediterranean, the limestone plateau consists at first of rolling hills, but approaching Qinā it breaks up into cliffs about 1,600 feet high and is deeply scored by wadis, which make the terrain very difficult to traverse. The outlets of some of the main wadis form deep bays, which contain small settlements of seminomads. The sandstone plateau farther south is also deeply indented by ravines; these, however, are relatively free from obstacles, and some are usable as routes. The Red Sea Hills run from near Suez to The Sudan border; they are not a continuous range but consist of a series of interlocking systems more or less in alignment. At their foot there is a narrow coastal plain widening southward, and, parallel to the shore, there are almost continuous coral reefs. In popular conception and usage, the Red Sea Littoral can be regarded as a subregion in itself.

The majority of the sedentary population of the Eastern Desert live in the few towns and settlements along the coast, the largest being Ras Gharib, with about 10,000 inhabitants (1966). The total population of Muḥāfaẓah al-Baḥr al-Aḥmar (or Red Sea Governorate, in the Eastern Desert) was estimated in the 1966 sample census at about 38,000. No accurate census figures are available for the nomadic population, but at that time they were believed to number around 6,000. They belong to various tribal groups, the most important being—from north to south—the Ḥuwayṭāt, Maʿāzah, ʿAbābdah, and Bishārīn. There are more true nomads in the Eastern than the Western Desert because of the greater availability of pasture and water. They live either by herding goats, sheep, and camels or by trading—mainly with mining and petroleum camps or with the fishing communities on the coast.

Nomads of the Eastern Desert

The Western Desert. The Western Desert covers an area of about 262,800 square miles. It is a rocky, low-altitude plateau rising, however, to altitudes of more than 3,300 feet (1,000 metres) on the plateau of al-Jilf al-Kabīr. From al-Jilf al-Kabīr, the plateau slopes gradually to the first of the depressions that are a characteristic feature of the Western Desert—that containing the oases of al-Khārijah and ad-Dākhilah. Farther north are the hollows containing the oases of al-Farāfirah and al-Baḥrīyah. Northwestward from the latter the plateau continues to fall toward the Sīwah and Qaṭṭārah depressions. South of the Qaṭṭārah Depression, the Western Desert is composed of great ridges of blown sand, interspersed with stony tracts. Beyond the Qaṭṭārah Depression northward, the edge of the plateau follows the Mediterranean, leaving a narrow coastal plain.

Outside the oases, the habitable areas of the Western Desert are occupied mainly by the Awlād ʿAlī tribe. Apart from small groups of camel herders in the south, the population is no longer totally nomadic. Somewhat less than half are seminomadic herdsmen; the remainder are settled and, in addition to maintaining herds of sheep and goats, pursue such activities as fruit growing, fishing, trading, and handicrafts.

The Western Desert supports a much larger population (estimated at about 124,000 in 1966) than the Eastern Desert. About 73,000 of these are seminomads. Maṭrūḥ, the provincial capital and an important summer resort, is the only real urban centre; it has a population of 11,000. Other scattered communities are found mainly near railway stations and along the northern cultivated strip.

The oases, although geographically a part of the Western Desert, are ethnically and culturally distinct. The southern oases of al-Khārijah and ad-Dākhilah are being developed as part of the New Valley project—reclamation, by exploiting underground water resources, of the five oases of al-Khārijah, ad-Dākhilah, al-Farāfirah, al-Baḥrīyah, and Sīwah.

Sinai. Sinai comprises a wedge-shaped block of territory with its base along the Mediterranean coast and its apex bounded by the Gulfs of Suez and Aqaba; it covers an area of approximately 23,000 square miles. Its southern portion consists of rugged, sharply serrated mountains. The central area of Sinai consists of two plateaus, at-Tīh and al-ʿAjmah, both deeply indented and dipping northward toward Wādī al-ʿArīsh. Toward the Mediterranean, the northward plateau slope is broken by dome-shaped hills; between them and the coast there are long, parallel lines of dunes, some of them more than 300 feet high. The most striking feature of the coast itself is the 60-mile-long salt lagoon, Lake Bardawīl.

The majority of the population are of Arab stock, now sedentary around al-ʿArīsh and in the northern coastal area but for the most part nomadic or semi-nomadic in the central plateau and the Sinai mountains. Another concentration of sedentary population is found at al-Qanṭarah ash-Sharqīyah (on the east side of the Suez Canal). The population of Sinai was estimated in 1966 at about 131,000, of which about 52,000 were nomads or seminomads.

The population of Sinai

THE LANDSCAPE UNDER HUMAN SETTLEMENT

Rural settlement. The settled Egyptian countryside, throughout the Delta and the Nile Valley to the High Dam, exhibits great homogeneity, although minor variations occur from north to south.

The typical rural settlement is a compact village surrounded by intensively cultivated fields. There are about 4,000 villages in Egypt, with populations varying from 500 to more than 10,000. Only about 2 percent of the rural population live in the smallest size villages; more than half the villages have 1,000 to 5,000 inhabitants, representing about 40 percent of the rural population. About a quarter of the villages have 5,000 to 10,000 inhabitants and contain about 40 percent of the rural population; the remainder have 10,000 or more inhabitants, representing 20 percent of the population.

The villages of the Delta and Nile Valley are basically similar in physical appearance and design, except for minor local variations in building materials, design, and decoration. The date palm, sycamore, eucalyptus, and casuerina are common features of the landscape. Until comparatively recently, the only source of drinking water was the Nile; in consequence, many of the villages are built along the banks of its canals. Some of the oldest villages are situated on mounds—a relic of the days of basin irrigation and annual flooding.

Villages of the Delta and Nile Valley

In the Delta the houses, one or two stories high, are built of mud bricks plastered with mud and straw; in the southern parts of the valley more stone is used. The houses are joined to one another in a continuous row. In a typical house, the windows consist of a few small round or square openings, barely permitting enough air or light to enter. The roofs are flat, built of layers of date leaves, with date-palm rafters; they are used to store corn and cotton stalks, as well as dung cakes used for fuel. Roofs are also a favourite sleeping place on hot summer nights. For grain storage, small cone-shaped silos of plastered mud are built on the roof and are then sealed to prevent the ravages of insects and climate.

The houses of the poorer peasants usually consist of a narrow hallway, a bedroom, and a courtyard; part of the courtyard may be used as an enclosure for farm animals. Furniture is sparse. Ovens are made of plastered mud and are built into the wall of the courtyard or inside the house. In the larger and more prosperous villages, houses are built of burnt bricks reinforced with concrete, are more spacious, and often house members of an extended family. Furniture, running water, bathroom installations, and electricity are additional signs of prosperity.

Typical features of the smaller Egyptian village, in both the Delta and the valley, are the mosque or the church, the primary school, the conical decorated pigeon cote, service buildings belonging to the government, and a few shops. Most of the people in the smaller villages are engaged in agriculture. In the larger villages, there may be some professional and semiprofessional inhabitants as well as more artisans, skilled workers, and shopkeepers. Outside the larger settlements, "combined service units" —consisting of modern buildings enclosing the social service unit, health unit, and school—are sometimes to be found, standing in striking contrast to the mud houses of the village itself.

The rural life-style

The population density of the inhabited area is such that the presence of people is obvious everywhere, even in the open countryside. In the early morning and the late afternoon, the peasants can be seen in large numbers on the roads, going to or coming from the fields with their farm animals. During the entire day the men, with their long tunics (*gallābīyahs*) tucked up around the waist, can be seen working the land with age-old implements such as the *fās* ("hoe") and *minjal* ("sickle"); occasionally a modern tractor is to be seen. In the Delta, older women in long, black robes, younger ones in more colourful cottons, and children over six years of age help with the less labourious tasks. In some parts of the valley, however, females over 16 do not work in the field, and their activities are confined to the household. They seldom appear in public except with a black-muslin headdress covering their heads and faces. Young children can be seen everywhere—an omnipresent reminder of the high birth rate.

Unless situated on a highway, villages are reached by unpaved dirt roads. Inside the villages the roads consist mainly of narrow, winding footpaths. All villages, however, have at least one motorable road.

The Western Desert oases are not compact villages but small, dispersed agglomerations surrounded by green patches of cultivation; they are often separated from each other by areas of sand. Al-Khārijah, for example, is the largest of five scattered villages. Traditionally, the houses in the oases were up to six stories high, made of packed mud, and clustered close together for defense. Modern houses are usually two stories high and further apart.

Urban settlement. Egyptian towns range in size between about 36,000 and 340,000 inhabitants. Although for census purposes they are considered urban centres, some of them are overgrown villages, containing large numbers of peasants and persons engaged in work relating to agriculture and rural enterprises. Some of the towns that have recently acquired urban status are still largely rural, although they also contain government officials, people engaged in trade and commerce, industrial workers, technicians, and professional people. One characteristic of towns and, indeed, of the larger cities is their rural fringe. Towns and cities have grown at the expense of agricultural land, with urban dwellings and apartment buildings mushrooming haphazardly among the fields. There is little evidence of town or city planning or of adherence to building regulations; often mud village houses are embraced within the confines of the city.

Urban characteristics

Buildings in towns and smaller cities are usually two-storied houses or apartment blocks four to six stories high. The better ones are lime washed, with flat roofs and numerous balconies; other houses and buildings are often of unpainted red brick and concrete.

Whereas most of the cities of Egypt do not have many distinctive features, some, such as Cairo, Alexandria, and Aswān, have special characteristics of their own. Cairo is a complex and crowded metropolis, with architecture representing its 1,000 years of history.

II. People and population

GROUPS HISTORICALLY ASSOCIATED WITH THE CONTEMPORARY COUNTRY

The use of Arabic

Linguistic groups. For nearly 13 centuries, Arabic has been the written and spoken language of Egypt. Before the Arab invasion in 639 AD, Coptic was the language of both religious and everyday life for the mass of the population; by the 12th century, however, it had been totally replaced by Arabic, continuing only as a liturgical language. Today, Arabic is the language of Egyptian Copt and Muslim alike.

The written form of the Arabic language, in grammar and syntax, has remained substantially unchanged since the 7th century. In other ways, however, the written language has changed—the style, word sequence, and phraseology used today are simpler and more flexible than in classical Arabic and are often directly derivative of English or French.

This neoclassical Arabic, which is developing out of classical or medieval Arabic, is the lingua franca shared by educated persons throughout the Arab world. Alongside it there exist the various regional dialects of Arabic, which differ widely from it as well as from each other. Within the amorphous grouping referred to as "Egyptian" colloquial, a number of separate dialects can be discerned—each fairly homogeneous but with further strata of variation within the group. One such is the dialect of the Bedouin of the Eastern Desert and of Sinai; the Bedouin of the Western Desert constitute a separate dialect group. Upper Egypt (aṣ-Ṣaʿīd, the Upland) has its own vernacular, markedly different from that of Cairo. The Cairo dialect is used, with variations, throughout the towns of the Delta; the rural people have their own vernacular. Cairene colloquial Arabic is extremely virile and expressive. Direct contact with foreigners over a long period has led to the incorporation of many loanwords. The long contact with foreigners and the existence of foreign-language schools also explains the polyglot character of Egyptian society. Most educated Egyptians are fluent in English or French or both, in addition to Arabic.

Non-Arabic languages

There are other minor linguistic groups. The Hamitic Beja (Bujah) of the southern section of the Eastern Desert use To Badawī. In Sīwah, an oasis due east of the Qaṭṭārah Depression, there are groups whose language is related to Berber. The Nubians speak a language containing both Sudanic and Hamitic features. Other minority linguistic groups also exist, notably Greek, Italian, and Armenian, although they are much smaller than they once were.

Ethnic groups. The population of riverain Egypt (comprising about 99 percent of the whole) forms a fairly homogeneous group whose dominant physical characteristics are the result of the admixture of the indigenous pre-Islāmic Hamitic–Armenoid population with Arab stock. The peasant, or fellah, is less racially mixed than the townsman. He is generally of middle stature, sturdy, dark haired, and dark eyed, with a wide-nostrilled nose and full lips. In the towns—the northern Delta towns especially—the foreign invader, Roman, Greek, Persian, crusader, and Turk, has left behind a more heterogeneous mixture. The inhabitants of the middle Nile Valley up to Aswān, the Ṣaʿīdīs, are of the same racial stock as the

inhabitants of the Delta but have darker skin and are slightly taller and sturdier. Settled communities in Aswān *muḥafaẓah* tend to be a mixture of Ṣaʿīdīs, long-settled nomads such as the Jaʿāfirah and ʿAbābdah, and Nubians.

The Nubians, although having Arab blood, have preserved racial characteristics that are non-Arab. They are tall and thin, with Caucasoid features, and are of a much darker colouring than the average Egyptian. They also differ from the Lower Egyptians in that their kinship structure goes beyond the lineage; they are divided into clans and broader segments, whereas among other Egyptians of the valley known members of the lineage are the only ones recognized as kin.

The deserts of Egypt contain nomadic, seminomadic, or sedentary nomadic groups, with distinct ethnic characteristics. Apart from a few tribal groups of non-Arab stock and the mixed urban population, the inhabitants of Sinai and the northern section of the Eastern Desert are all fairly recent immigrants from Arabia. Like the Arabian Bedouin, they are usually slightly built, hooknosed, and brown skinned. Their social organization is tribal, each group conceiving of itself as being united by a bond of blood and descended from a common ancestor. Originally tent dwellers and nomadic herdsmen, many have become seminomads or totally sedentary, as in northern Sinai.

The southern section of the Eastern Desert is inhabited by the Hamitic Beja. Although claiming Arab descent, they are of different racial stock, with oval faces, straight noses, and large eyes; they bear a distinct resemblance to the predynastic Egyptians. The Egyptian Beja are divided into two tribes—the ʿAbābdah and the Bishārīn. The ʿAbābdah occupy the Eastern Desert south of a line between Qinā and Ghurdaqah; there are also several groups settled along the Nile between Aswān and Qinā. The Bishārīn are mainly in The Sudan, although some of them are to be found in the Elba Mountain region, their traditional place of origin. Both the ʿAbābdah and Bishārīn are nomadic pastoralists, living on herds of camels, goats, and sheep.

The Saʿādī and the Mūrābiṭīn

The inhabitants of the Western Desert, outside the oases, although claiming Arab descent, are a mixture of Arab and Berber stock. They are divided into two groups, the Saʿādī and the Mūrābiṭīn. The Saʿādī regard themselves as descended from Banū Hilāl and Banū Sulaymān, the great Arab tribes that immigrated into North Africa in the 11th century. The most important and numerous of the Saʿādī group are the Awlād ʿAlī. The Mūrābiṭīn clans occupy a client status in relation to the Saʿādī and may be descendants of the original Berber inhabitants of the region. Originally herdsmen and tent dwellers, the Bedouin of the Western Desert are now either seminomadic or totally sedentary. They are not localized by clan, and members of a single group may be widely dispersed.

The original inhabitants of the oases of the Western Desert were of Berber stock, and the strain still survives in the lighter colouring of many of them. There has, however, been a considerable admixture of blood—Egyptian from the Nile Valley, Arab, Sudanese, Turkish, and, particularly in the case of al-Khārijah, black African—for this was the point of entry into Egypt of the famous caravan route from Darfur, the Darb al-Arbaʿīn.

In addition to the indigenous groups, there are in Egypt a number of small foreign ethnic groups. The 19th century saw the rapid growth of communities of unassimilated foreigners, mainly European, living in Egypt; these acquired a dominating influence over finance, industry, and government. In the 1920s, which was a peak period, the number of foreigners in Egypt was in excess of 200,000, the largest community being the Greeks, followed by the Italians, British, and French. Since Egypt's independence, the size of the foreign communities has been greatly reduced. The total number of resident foreigners, of all nationalities, is about 90,000.

Religious groups. Islām is the official religion of Egypt; about 93 percent of the population are Sunnī, or orthodox Muslims. A strong sense of piety is a characteristic of the Egyptian Muslim. Prayer is observed punctiliously, particularly public prayer in the mosques, and fasting during the month of Ramaḍān (the ninth month of the Islāmic calendar) is strictly observed. Almsgiving and pilgrimage to Mecca are, if possible, also enjoined.

The Christian population of Egypt numbers about 2,000,000; of these the majority are Copts. In language, dress, and way of life they are indistinguishable from the Muslims. Ever since it broke with the Eastern Church in the 5th century, the Coptic Church has maintained its autonomy, and its beliefs and ritual have remained basically unchanged. The Copts have been traditionally associated with certain handicrafts and trades and, above all, with accountancy, banking, commerce, and the civil service; there are, however, rural communities that are wholly Coptic, as well as mixed Coptic–Muslim villages. The Copts are most numerous in the middle Nile Valley provinces of Asyūṭ, al-Minyā, and Qinā. About one-quarter of the total Coptic population lives in Cairo.

The Copts

Other religious groups exist—Greek Orthodox, Greek Catholic, Armenian Orthodox and Catholic, Maronite, Syrian, Anglican, and Protestant. There is also a small Jewish community, which in the early 1970s numbered only several hundreds.

DEMOGRAPHY

Birth rates and death rates. The population of Egypt was estimated in 1971 at 34,130,000 by the Egyptian Census Department. In 1968, the crude birth rate was about 38 per thousand, while the death rate was about 16 per thousand, resulting in an annual rate of increase of 2.5 percent. The official figures for 1970 showed a decrease in the birth rate to 35 per 1,000 and in the death rate to about 15 per 1,000, giving a rate of increase of 2 percent.

Immigration and emigration. Immigration into Egypt is very slight and has little effect on population trends. Emigration has traditionally been slight also, but in more recent years there has been an increase in the number of persons emigrating or seeking temporary employment abroad; these have usually been from among the educated groups. The numbers, however, have never been large enough to affect population trends.

The distribution of population. The density of the population, in relation to the entire country, is 88 per square mile. When the inhabited area is considered separately, however, the density becomes very high—about 2,300 per square mile. In 1966, the Cairo density was as high as 51,028 per square mile. The population is concentrated largely in the highly fertile Nile Delta (Lower Egypt), where about 64 percent of the total population lives. Upper Egypt and the Valley, where the arable area is smaller and there are fewer large urban centres, has only 34 percent of the total population.

Population density

The majority of the population live in rural areas (about 58 percent in 1970). There has been a steady increase over the years in the proportion of population living in urban areas. The more recent increase is due, in part, to administrative changes, whereby some of the villages were converted into urban units or towns, even though they retained much of their rural character.

The Delta as a whole is more urbanized than the Valley. In 1970 it was estimated that more than 50 percent of the Delta population was urban, whereas about 73 percent of the Valley was rural. If, however, the cities of Cairo, Alexandria, and Port Said—which have *muḥafaẓah* status—are excluded from the Delta population, it can be seen that the other eight *muḥafaẓāt* are overwhelmingly rural (about 75 percent). And if the city of Giza (population over 700,000), which is an extension of the Cairo metropolis, is excluded from the valley population the remainder is almost 80 percent rural. The above figures reflect a striking feature of population distribution in Egypt—the concentration of a large proportion of the urban population in a few centres and the overwhelming dominance of the capital. Cairo alone, excluding its suburbs, contains more than 4,960,000 persons, representing over 14 percent of the total population of Egypt. Alexandria, the second-largest city, has more than 2,000,000 inhabitants.

Demographic trends. Until 1965 the crude birth rate in Egypt was among the highest in the world. Between 1965 and 1970, however, the rate declined somewhat. The mortality rate, on the other hand, has dropped dramatically over the years. At the turn of the century, it was estimated at 35 to 40 per 1,000, with an infant mortality rate of about 400 per 1,000. In 1945 it dropped to 27.7 per 1,000, and by 1970 it had fallen to 15 per 1,000 on average; infant mortality had fallen to 110 per 1,000. This reflects expanded medical and public-health services, the use of modern drugs and pesticides, and epidemic-control measures.

Population growth

Consistently high fertility and rapidly falling mortality rates have resulted in accelerated population growth. In 1907 the population of Egypt was a little less than 11,200,000, and it took 30 years to reach about 15,900,000 in 1937. In the following 30 years it nearly doubled, to about 30,900,000 in 1967. United Nations population projections estimate an average increase of more than 1,000,000 persons per year between 1970 and 1975. Within the decade 1970 to 1980, it is estimated that another 11,500,000 persons will be added. Clearly, such a rapid increase of population places a heavy burden on the country and impedes its efforts to promote social and economic development. (L.S.el-H./Ma.J.)

III. The national economy

A COMPARATIVE VIEW OF THE COUNTRY'S REGIONAL AND WORLDWIDE STANDING

Egypt is an overpopulated developing country. About 96 percent of its total area is desert. Lack of forests, permanent meadows, or pastures throws a heavy burden on the available arable land, which totals over 6,900,000 acres. This limited area, which sustains on average almost five persons per acre, is, however, highly fertile and is cropped more than once a year. Although at least half the population derive their livelihood from agriculture, a growing proportion of the labour force is engaged in manufacturing, and the contribution of the manufacturing sector to the domestic product is only a little less than that of agriculture—with service activities contributing the remainder. Owing to the shortage of land, underemployment of labour began to be manifest in agriculture two generations ago, and the development of nonagricultural production since then has failed to provide full employment to the increasing labour force.

The gross national product of Egypt was estimated at E£2,649,000,000 in 1968 to 1969 (E£0.43 = $1 U.S.; E£0.96 = £1 sterling, Dec. 1, 1970), representing an average per capita income of E£79.48. By the early 1970s national income had slowed down its growth from the fairly rapid development achieved in the early 1960s, largely under the impact of the increased expenditure on defense, so that per capita income was growing imperceptibly, if at all. Despite this, many aspects of the economy exhibited symptoms of relative development unusual in the developing world, such as the high yields per unit of agricultural land, the scale and progress of higher education, the rapid development of heavy industry, and the large contribution made by the manufacturing industry. A redundancy of labour remained, however, a fundamental problem.

Per capita income

THE EXTENT AND DISTRIBUTION OF RESOURCES

Mineral resources. Compared with the physical size of the country and the level of its population, the mineral resources of Egypt are scanty. The search for petroleum began earlier than elsewhere in the Middle East, but the results have been modest. In the early 1970s, discoveries of oil and gas, however, raised hopes that Egypt might become a major producer. Phosphate deposits were estimated in 1971 at 180,000,000 tons, all located in the Eastern Desert near the Red Sea, but it is anticipated that further investigation may reveal total reserves amounting to 400,000,000 tons or more. Coal deposits, amounting to some 80,000,000 tons, have been located near Suez, and the search for more coal continues, despite the low quality of the finds. Manganese deposits also are found in the Eastern Desert. Low-quality iron-ore deposits have been located near Aswān, as well as deposits of better quality in the proximity of al-Baḥrīyah oases in the Western Desert. It is anticipated that 4,000,000 tons of iron ore a year will be supplied to the Ḥulwān iron and steel complex south of Cairo.

Biological resources. The main natural resources with which Egypt is endowed are biological and centre on the Nile. There are no forests or any permanent vegetation of economic significance apart from the land under cultivation. In 1969–70 the animal population of Egypt included nearly 1,800,000 cows and oxen, about the same number of water buffalo, about 2,240,000 sheep, over 800,000 goats, and about 190,000 camels. Animal husbandry and poultry production were increasing in the early 1970s, but the total contribution of livestock and dairy production was only about one-third of all agricultural output.

Hydroelectric and other power resources. The Nile constitutes an incomparable source of energy; further sources are represented by coal, oil, and gas deposits.

SOURCES OF NATIONAL INCOME

Agriculture and fishing. Agriculture is the most important sector of the Egyptian economy, contributing 30 percent of its product, employing more than half of the labour force, and providing the country, through agricultural exports, with much of its foreign exchange. Increased pressure of population has led to an intensification of cultivation almost without parallel elsewhere. Heavy capital is invested in the form of canals, drains, dams, water pumps, and barrages; the investment of skilled labour, commercial fertilizers, and pesticides is also great. Thus, despite multiple cropping, the yields of the land are exceptionally high. Strict crop rotation—in

Investments in agriculture

addition to government controls on the allocation of area to crops, on varieties planted, on the distribution of fertilizers and pesticides, and on marketing—contributes to the high productivity of agriculture.

Since yields are already very high, increased use of manual labour meets with progressively diminishing returns. Apart from agriculture work, opportunities are scarce, and there is a constant stream of migrants from the rural areas to the cities. In 1960 it was estimated that nearly one agricultural worker out of four was redundant; it is thought that the ratio of redundancy may have increased since then, together with the increase in population.

Unlike the situation in comparable developing countries, Egyptian agriculture has an overwhelmingly commercial rather than a subsistence basis. Field crops contribute nearly three-quarters of the total value agricultural production, while the rest is made up by livestock products, fruits and vegetables, and other rural commodities. The main field crop is cotton, which occupies about a fifth of the arable land, absorbs much of the available labour, contributes about 40 percent of the value of field crops, and (in both raw and processed forms) represents up to 60 percent of the value of merchandise exports. Egypt is the world's principal producer of long-staple cotton, normally producing about 40 percent of the world crop of cotton that is one and one-eighth of an inch and longer, although total Egyptian production is only about 4 percent of all cotton produced in the world.

After cotton, which occupied 1,690,000 acres in 1970, the principal field crops are maize (corn; 1,690,000 acres), rice (about 1,200,000 acres), millet (about 520,000 acres), broad beans (314,000 acres), and wheat (1,350,000 acres). In the late 1960s, when Egypt became the world's fourth-largest rice exporter, about 600,000 tons, out of a total production of about 2,700,000 tons, were exported. Despite a considerable output, cereal production in Egypt falls short of total consumption; a substantial proportion of foreign exchange is spent annually on the import of cereals and milling products. Other important crops include sugarcane, lucerne, potatoes, and onions—the latter being normally a main export item. Many fruits are grown, and some, such as citrus, are also exported.

Reclaimed land

Between 1960–61 and 1968–69 about 896,100 acres (863,300 feddans) were reclaimed. Total land to be reclaimed as a result of the Aswān High Dam project should reach 1,300,000 acres by 1975, in addition to 700,000 acres to be converted from basin (*i.e.*, one crop a year) irrigation to perennial irrigation.

Egypt has been the scene of one of the most successful attempts at land reform. In 1952 a limit of 200 acres was imposed on individual ownership of land, and this was lowered to 100 acres in 1961 and to 50 acres in 1969. As a result, about 40 percent of land ownership has been redistributed, largely to landless peasants. The average area per owner is just under two acres.

The success of Egyptian land reform is indicated by the substantial rise of land yields between 1952 and the early 1970s. This was partly the result of several complementary measures of agrarian reform that accompanied the redistribution of the land.

The fishing industry is of relatively minor importance. The total catch reached a peak of 149,000 tons in 1964, but production has declined since the building of the High Dam. The containment of the freshwater that formerly flowed into the Mediterranean has resulted in lower production. Although some fish are being caught in Lake Nasser behind the High Dam, the catch is still small, although slowly increasing. Production of crustaceans, the bulk of which is exported, also declined in the late 1960s.

Manufacturing. The development of the manufacturing industry was handicapped by the policy of free trade imposed on Egypt from the middle of the 19th century until about 1930. Nationalism and World War II gave great impetus to the foundation of industrial projects that are largely agriculturally based and oriented toward import substitution. During the 1950s, manufacturing industry grew at the rate of about 7 percent a year, and the rate of growth was increased in the 1960s to about 10 percent a year. By 1969 manufacturing and mining amounted to over 21 percent of the gross domestic product. Large-scale manufacturing establishments, employing 25 workers or more, employed about 500,000 workers. In the late 1960s, industry employed over 11 percent of the total labour force. The largest section of Egypt's manufacturing industry in the late 1960s was represented by spinning and weaving (mainly cotton). This was followed by food processing, engineering industries, chemicals, and building-material industries. In 1969 the manufactured products included cotton yarn, cotton textiles, edible oils, refined sugar, cheese, bleached rice, cigarettes, vehicle tires and pneumatic tubes, paper, soap, commercial fertilizer, and glass products.

The development of manufacturing and industry

Emphasis has been placed on the development of heavy industry following a long-term agreement signed with the Soviet Union in 1964. Another agreement with the Soviet Union, signed in 1970, provided aid for the expansion of the iron and steel complex at Ḥulwān, the establishment of a number of power-based industries (including an aluminum plant to utilize the power generated by the High Dam), and the electrification of the countryside. An ammonium nitrate fertilizer plant was opened in 1971, based on the gases generated in the coking unit of the steel mill.

Energy. Before the completion of the Aswān High Dam power station in 1970, the bulk of Egypt's electricity was generated in thermal stations using coal or diesel fuel, but some hydroelectric power was also generated by the old Aswān Dam. A rapid rise in electricity production took place under the first five-year plan (1960 to 1965), and output reached more than 7,592,000,000 kilowatt hours in 1970, compared with only about 2,000,000 kilowatt hours in 1959. The 12 turbines of the High Dam power station have a capacity of about 2,000,000 kilowatts and are capable of producing 10,000,000,000 kilowatt hours a year; the present capacity of the thermal stations is about 40 percent of that of the High Dam. Transmission lines carry the current from Aswān to Cairo and farther north for use in urban centres and in manufacturing. A scheme, with Soviet assistance, for the electrification of all Egypt's 4,000 villages by connecting them to the High Dam power network was being implemented in the early 1970s.

Sinai contributed more than 60 percent of all the oil produced in Egypt before the 1967 Arab–Israeli War. Total Egyptian production in 1966 was about 130,000 barrels a day. By early 1971, production outside Sinai had reached 420,000 barrels a day and was being expected to reach 500,000 barrels by the end of 1972. The bulk of this oil comes from the rich Morgan fields (both onshore and offshore) in the Gulf of Suez, which are operated by a partnership of the Egyptian General Petroleum Corporation and a subsidiary of Standard Oil of Indiana. In cooperation with Phillips Petroleum Company, the Egyptians are extracting some 30,000 barrels a day from the al-ʿAlamayn field, discovered in the Western Desert in 1966. Active drilling for oil continues in both the Eastern and Western deserts, with United States, Japanese, and Soviet interests.

Natural gas

In the process of searching for oil some significant gas finds have been located. In the early 1970s a plan was put into effect using as fuel the 300,000,000 cubic feet of gas produced each day from the Morgan fields. Phillips has located wells producing some 35,000,000 cubic feet a day in the Abū Qīr area, northeast of Alexandria. A joint Egyptian–Italian gas discovery was made in the north delta near Abū Māḍī in 1970; this was being developed partly to supply a 750,000-ton-a-year fertilizer plant and partly to fuel the industrial centres in the north and northwest delta.

After the destruction by Israel of the two major refineries near Suez, Egypt has one refinery left; this is at al-Maks (Mex), near Alexandria, and it has a capacity of 65,000 barrels a day. Egypt still exports crude petroleum but has to import petroleum products. Another compli-

cating fact is that, with the Suez Canal closed, the Morgan crude oil cannot economically be shipped to Alexandria for refining, so that Egypt also has to import some crude oil. The continued closure of the Suez Canal and the development of large oil tankers have induced Egypt to plan a pipeline linking Suez to the Mediterranean near Alexandria. The proposed "Sumed" line has had the financial and technical support of a consortium of European companies led by the French. The pipeline is expected to transmit 120,000,000 tons a year; it is scheduled to be completed in 1974.

Financial services. The banking system of Egypt is centred on the Central Bank of Egypt, created in 1960 from the issue department of the National Bank of Egypt. In 1961 all banks operating in Egypt were nationalized, and their operations were concentrated in five commercial banks, in addition to the Central Bank, the government-sponsored Agricultural Credits and Co-operatives, and Industrial Bank, and three mortgage banks. Shortly after the nationalization measures of 1961, both the stock exchanges in Cairo and Alexandria and the cotton exchange in Alexandria closed down.

There are about 500 bank branches throughout Egypt; these include some 120 branches of the Agricultural Credits and Co-operatives, which is the main instrument for agricultural credit and marketing of crops, as well as for the distribution of seed, fertilizer, and pesticides.

The supply of money has, in general, followed the development of the economy; the authorities have aimed at tolerable increases in the price level, although since the 1967 war some prices have soared.

Egypt is a member of the International Monetary Fund. For a long time the international liquidity of the Egyptian economy, including the recently added Special Drawing Rights, has been depressed. In the early 1970s both internal and external debts were rising.

Imports and exports

Foreign trade. From 1965 to 1969, imports into Egypt averaged about 16 percent and exports 19 percent of the gross domestic product. Since World War II, exports have tended to fall short of imports. The trade deficit reached a peak in 1966 and was particularly sizable from 1960 to 1965 as expenditure on development rose. After the 1967 war there was a decided effort to restrict imports and stimulate exports.

Two-thirds of imports consist of raw materials and capital goods (mineral and chemical products, machinery, and transport equipment), a quarter of foodstuffs, and the remainder of other consumer goods. More than half of the exports by value consist of raw cotton, cotton yarn, and fabrics. Rice exports are also significant, and mineral and chemical products (crude oil, cement, petroleum products, phosphates) are also exported. Other exports include agricultural produce, notably onions, garlic, and citrus fruit.

Egypt's largest trading partner is the Soviet Union, followed by France, the United States, West Germany, Italy, India, Spain, East Germany, the United Kingdom, Poland, Japan, Czechoslovakia, and Yugoslavia.

With the closure of the Suez Canal and dwindling revenue from incoming tourists since the 1967 war, Egypt's foreign-trade balance in services is also in deficit, despite much reduced government expenditure abroad. The overall balance-of-payments deficit is financed by international borrowing (largely from Communist countries), transfers from Arab oil-producing countries, and changes in foreign assets and liabilities.

MANAGEMENT OF THE ECONOMY

The private sector. The economy of the country, according to the provisional constitution in force in 1971, is one based on Socialism, with the people controlling all means of production. The progress of Socialism after 1952 was initially hesitant, despite the land-reform measures, but gathered momentum after 1961, when major nationalization steps were taken in an attempt to curb the private sector and destroy the political power of capitalists. Practically all important sectors of the economy now either are public or are strictly controlled by the government. This includes large-scale industry, communications, banking and finance, the cotton trade, foreign trade as a whole, and many other sectors. Private enterprise came gradually to find its scope restricted, but some room for manoeuvre was still left in real estate and in agriculture and more recently in the export trade. Personal income is virtually limited to about E£4,800 a year and land ownership to 50 acres.

The public sector and the role of government. As the role of the private sector lessened in the 1950s and 1960s, that of the government continuously expanded. The government, when not actually in possession, regulates all important aspects of production and distribution. It imposes controls on agricultural prices, controls rent, runs the internal trade, regulates foreign travel and the use of foreign exchange, and appoints and supervises the boards of directors of corporations. The government initiates projects and allocates investment. Although the everyday running of corporations is left to the boards of directors, these receive instructions from public boards, and the chairmen of boards receive their instructions from the appropriate minister. Between 1964 and 1970, the bulk of all credit created by the banking system was for the use of the public sector.

The five-year plans

The government formulated a five-year development plan for the period 1960 to 1965, involving total investments of about E£1,513,000,000. The plan was highly successful; growth averaged 7 percent in the period, even though the economy was badly stretched and the trade deficit worsened. Annual investment allocations during the five-year period ending in the year 1969 to 1970 totalled E£1,513,000,000; while no plan was being implemented, this period was often referred to as the second five-year plan. A plan has been drawn up for the period ending 1974 to 1975, and annual investments in the plan form part of the annual budgets.

Taxation. With the majority of the population earning very low incomes, direct taxation falls on the few rich; income-tax rates are made sharply progressive in an attempt to achieve a degree of equality in the income distribution. Direct taxes on income, mostly levied on businesses, accounted for about one-fifth of governmental revenue; indirect taxes and duties provided about one-third, and the remainder came from various duties.

Trade unions and employer associations. Trade unions are closely controlled by the government. Workers obtain a share of the profits earned by corporations and elect their representatives to boards of directors; they are also heavily represented in the National Assembly. In all these activities, however, official selection works side by side with free elections. Trade unions are often vocally active in national policies but are seldom the instrument of negotiating higher wages or better work conditions. A few employers' associations are in existence, but these have little industrial power.

Economic adjustments

Contemporary economic policies. Much of the effort exerted by the government in the early 1970s was devoted to adjusting the economy to the situation resulting from the 1967 hostilities. With increased expenditure on defense, reduced allocations were made available for development; the country has also had to cope with the massive exodus of the urban population of the Suez Canal region, which moved toward the interior and away from Israeli guns. Israeli fire had destroyed vital economic targets such as the oil refineries and the industrial complex at Suez, and a metal factory near Cairo. Economic growth was slowed down roughly to the level of population growth. If a Middle East settlement were to be reached and resources freed for use in economic development, it was hoped that the policies of stimulating heavy industry, developing the oil and gas industry, and making use of the power generated by the High Dam would come to fruition.

The problem of population pressure on resources, however, was considered likely to remain for a long time, and underemployment had become endemic. (E.I.U.)

TRANSPORTATION AND COMMUNICATIONS

Almost the entire communication system is state owned. It is adequate in terms of coverage, but stresses arise

from excessive usage. The main patterns of transport flow reflect the topographical configuration of the country—that is to say, they follow the north–south course of the Nile, run along the narrow coastal plain of the Mediterranean Sea, and expand into a more complex system in the Delta.

Road network. There are about 29,400 miles of roads, of which about 5,900 miles (20 percent) are paved. Rural roads are of dried mud, usually following the lines of the irrigation canals; many of the desert roads are little more than tracks. The Cairo-to-Alexandria highway runs via Banhā, Ṭanṭā, and Damanhūr. The alternate desert road to Cairo from Alexandria has been extensively improved, and a good road links Alexandria with Libya by way of Maṭrūḥ. Paved roads exist between Cairo and al-Fayyūm and connect the various Delta and Suez Canal towns. There is a paved road from Asyūṭ to al-Khārijah and ad-Dākhilah. The coastal Red Sea route to Marsā 'Allām is poorly paved, as are the connecting sections inland.

Railways. Egypt has 2,600 miles of railway tracks, which connect Cairo with Alexandria and with the Delta and canal towns and which also run southward to Aswān and the High Dam. Branch lines connect Cairo with al-Fayyūm and Alexandria with Maṭrūḥ. A network of light railways connects the Fayyūm area and the Delta villages with the main lines; a narrow-gauge railway links al-Khārijah with the main north–south line near Naj' Ḥammādī. The main lines are used by diesel-driven trains; electric lines connect Cairo with Ḥulwān and Heliopolis.

Rivers and canals

Navigable waterways. The Suez Canal has been closed since June 1967. The Nile and its associated navigable canals provide an important means of transportation, primarily for heavy goods. There are approximately 2,000 miles of navigable waterways—about half of this total on the Nile itself, which is navigable throughout its length. The inland-waterway freight fleet consists of tugs, motorized barges, towed barges, and flat-bottomed feluccas (two- or three-masted lateen-rigged sailing ships).

Ports and shipping. In spite of its long coastline, the Arab Republic of Egypt has only three ports of any significance—Alexandria, Port Said, and Suez. Alexandria handles about four-fifths of both imports and exports, as well as the bulk of passenger traffic. It has a fine natural harbour. Port Said, at the northern entrance to the Suez Canal, lacks the berthing and loading facilities of Alexandria. Suez's main function is that of an entry port for petroleum and minerals from the Egyptian Red Sea coast and for goods from the Far East.

Air transport. Cairo is an important communication centre for world air routes. The enlarged airport at Heliopolis, with its modern terminal building, is used by major international airlines.

The national airline, Egyptian, runs external services throughout the Middle East, as well as to Europe and the Far East; it also operates a domestic air service linking Alexandria, Port Said, Luxor, Aswān, Asyūt, Maṭrūḥ, al-Minyā, the New Valley, and Ghurdaqah.

Postal, telegraph, and telephone services. There are about 7,000 post offices and postal agencies in Egypt. Both telegraph and telephone services are state owned. The number of telephones in use in 1969 totalled 365,000 —slightly fewer than one telephone for every 90 people.

IV. Administration and social conditions

THE STRUCTURE OF GOVERNMENT

The constitutional framework. Before the 1952 revolution, Egypt was a constitutional monarchy; the 1923 constitution, which followed the declaration of the end of the British protectorate, stated that Egypt was an independent sovereign Islāmic state with Arabic as its language and provided for a representative parliament. In 1953 this constitution was abolished by the new revolutionary regime and a temporary constitution substituted; political parties were dissolved. A Liberation Rally was organized in place of the parties—eventually to become, in 1962, the Arab Socialist Union (ASU). In 1953 Egypt was declared a republic.

In 1971, Egypt, Libya, and Syria agreed to the establishment of the Confederation of Arab Republics. A draft constitution was agreed to by the heads of state of each country, and was approved by referendum in each of the three member states. The capital of the confederation is Cairo.

On September 11, 1971, a new constitution for Egypt was approved by referendum. It declared the Arab Republic of Egypt to be "a democratic, socialist state" with Islām as its state religion and Arabic as its national language. It recognized three types of ownership—public, cooperative, and private. It guaranteed the equality of all Egyptians before the law and their protection against arbitrary intervention in the processes of law. It also affirmed the rights to peaceful assembly, education, health and social security, and the right to organize into associations or unions and to vote.

According to the constitution, the president of the republic is the head of state; together with the Cabinet, he constitutes the executive authority. The president must be Egyptian, born of Egyptian parents, and not less than 40 years old. The presidential term is six years, and may be extended to a second term. The president has the power to appoint and dismiss one or more vice presidents, the prime minister, ministers, and deputy ministers. The legislative body is comprised of the People's Assembly, which nominates the presidential candidate by a two-thirds majority. The candidate is then confirmed by national plebiscite.

The president is the supreme commander of the armed forces. He has the right to grant amnesty and reduce sentence. He appoints civil and military officials and can dismiss them in a manner prescribed by the law. He may call a referendum of the people on matters of supreme importance. He can, in exceptional cases and by investiture of the Assembly, issue decrees having the force of law—but only for a defined period of time.

The People's Assembly

Legislative power resides in the People's Assembly, which is composed of at least 350 elected members, representing 175 constituencies (two members per constituency). Fifty percent of the members of the Assembly must be workers and farmers. The president may appoint up to ten members. To be eligible for membership a candidate must be not less than 30 years old and must be a member of the ASU. The Assembly is elected for a five-year term. All males of 18 years of age and over are required to vote, as well as all women on the register of voters. The president of the republic convenes and closes the sessions of the People's Assembly.

The People's Assembly must ratify all laws and examine and approve the national budget. It also approves the program of each newly appointed Cabinet. Should it withdraw its confidence from the Cabinet or any of its members, they would then be required to resign. The president cannot dissolve the Assembly except under special circumstances and after a vote of approval by a people's referendum. Elections for a new Assembly must be held within 30 days.

The constitution also provides for a judiciary, independent of other authorities whose functions and authority are governed by special legislation. A Council of National Defence, presided over by the president of the republic, is responsible for matters relating to security and defense.

Local government and administration. Until 1960, government administration was highly centralized; in that year, however, the present local-government administrative system was established with the aim of promoting decentralization and greater citizen participation in local government.

Muḥāfaẓāt, districts, and villages

The 1960 Local Administration Law provides for three levels of local administration—the *muḥāfaẓāt* (governorates), the districts (or counties), and the villages. The structure combines features of both local administration and local self-government. The chief executives, for example, are appointed by the national authorities, but there are also councils at each administrative level composed of elected, appointed, and ex officio members. Although these councils exercise broad legislative powers, they are closely controlled by the central government.

The country is divided into 25 *muḥāfaẓāt;* all except Sinai apply the local-administration system. Four cities—Cairo, Alexandria, Port Said, and Suez—have *muḥāfaẓah* status. The governor is appointed and can be dismissed by the president of the republic. He is the highest executive authority in the *muḥāfaẓah*, has administrative authority over all government personnel (except judges) in his *muḥāfaẓah*, and is responsible for policy implementation and the supervision of the local branches of the various government ministries. He reports to the minister of interior on matters of security and to the minister of local administration on matters relating to local government.

The *muḥāfaẓah* council is composed of a majority of elected members—two representatives from each district or township (these must be from among the members of executive committees of the ASU), not more than 19 appointed members selected by the minister of local administration in consultation with the governor from among the active members of the ASU, and ex officio members representing various ministries such as education, health, agriculture, or social affairs. Although this has not been possible in practice, at least half the members of the council should be farmers and workers.

The town or district councils and the village councils are established on the same principles as those underlying the *muḥāfaẓah* councils. Apart from the ex officio members, there are 20 elected members on the town councils and up to five appointed members; there are 12 elected members on the village councils and two appointed members. Village councils may serve more than one village, depending on size.

The local councils have broad powers, even though limited by budget restrictions and central-government controls. They perform a wide variety of functions in education, health, public utilities, housing, agriculture, and communications; they are also responsible for promoting the cooperative movement and for implementing parts of the national plan. Local councils obtain their funds from national revenue, a tax on buildings and lands within the *muḥāfaẓah*, miscellaneous local taxes or fees, profits from public utilities and commercial enterprises, and national subsidies, grants, and loans.

The political process. The source of popular participation and representation in the political process is through the Arab Socialist Union. All Egyptians over 18 are eligible for membership, except those with criminal records or those who have been politically disfranchised. The ASU is viewed as a union representing all working classes—a category that includes the farmers, workers, soldiers, "intellectuals" (members of organized professions), and "national capitalists" (private businessmen or shopkeepers). Fifty percent of all the membership of ASU committees must consist of workers and farmers—a farmer being a person engaged in agriculture and owning ten acres or less and a worker being any person working for a living but not belonging to one of the four previously designated categories. The ASU has a pyramidal structure, with executive committees and congresses at each level of the hierarchy. At the grass-roots level, the basic units are the villages, the *shiyākhas* (subdistricts in the cities), or organizations with 200 or more employees (such as factories, universities, business firms, or ministries). Each basic unit has a congress made up of all active members, as well as an executive committee composed of ten elected members. There were about 6,900 basic units when the ASU was first formed; in the early 1970s the active members were estimated to number 5,000,000.

The Arab Socialist Union

The next level in the hierarchal organization of the ASU is the *markaz* (township) in the rural areas, the district in the cities, or the public organization consisting of more than one basic unit. The congress at this level consists of members elected from the committees of basic units and other members selected according to the regulations of the higher executive committee. The *markaz* elects an executive committee for a two-year term. At the *muḥāfaẓah* level, the congress, which is elected for a four-year term, is made up of delegates elected from the members of the *markaz*. The members of the *muḥāfaẓah* executive committees are elected for a four-year term from among the delegates to the *muḥāfaẓah* congress. The different governorate congresses form the general national congress, which elects a general committee from among its members. The latter elects, from its members, the higher executive committee.

The ASU organization is closely interwoven with that of the local administration, since members of local councils, at all levels, must be members of the ASU executive committees.

JUSTICE

The Egyptian constitution emphasizes the independent nature of the judiciary. There must be no external interference with the due processes of justice. Judges are subject to no authority other than the law; they cannot be dismissed and are disciplined in the manner prescribed by law. Judges are appointed by the state, with the prior approval of the Supreme Judicial Council under the chairmanship of the president. The Council is also responsible for the affairs of all judicial bodies; its composition and special functions are specified by law.

The courts

The court structure can be regarded as falling into two broad categories—the civil and criminal courts. The civil courts comprise summary courts, primary courts, courts of appeal, and the Court of Cassation. The criminal courts consist of petty sessional courts, courts of appeal, criminal courts, and the Court of Cassation (criminal division). Court sessions are public, except where consideration of matters of public order or decency decides otherwise. Sentence is passed in open session.

In addition, there are special courts, such as military courts and courts of public security—the latter dealing with crimes against the well-being or security of the state. The Council of State is a separate judicial body, dealing especially with administrative disputes and disciplinary actions. The Supreme Constitutional Court, held in Cairo, is responsible for judicial surveillance over the constitutionality of laws and regulations, and for the explanation of legal ordinances. Under the constitution, the Socialist Public Prosecutor is responsible for ensuring the rights of the people, the security of society and its political system, the guarding of socialist gains, and holding to the socialist way. The prosecutor is controlled by the People's Assembly.

ADMINISTRATIVE SERVICES

Educational services. At the end of the 19th century there were only three secondary and nine "higher" schools in Egypt; the educational structure continued to be based on the *kuttābs*, or Qur'ān schools. In 1916 the latter were turned into elementary schools, and in 1923 a law was passed providing free compulsory education between the ages of seven and 12. Following the revolution of 1952, educational progress already achieved was accelerated and was accompanied by both the Egyptianization and Arabicization of the educational system.

A sharp increase in the annual budgetary allocation devoted to education occurred between the end of World War II and 1970. By the later 1960s educational expenditure amounted to 17 percent of the general budget.

There are three stages of state general education—primary (six years), preparatory (three years), and secondary (three years). Primary education between the ages of six and 12 is compulsory. In 1969–70, 75 percent of those eligible entered the state primary system. Pupils who are successful in examinations have the opportunity to continue their education first at the preparatory and then at the secondary level. There are two types of secondary school, general and technical; most technical schools are either commercial, agricultural, or industrial and admit only boys. Technical education for girls takes the form of training for the electrical and electronics industries and in the manufacture of cosmetic and pharmaceutical products.

Alongside the Ministry of Education's system of general education, there is that provided by the institutes connected with al-Azhar. Instruction is given at levels

equivalent to those of the ministry, but in order to allow for greater emphasis on traditional Islāmic subjects, the duration of training is lengthened by one year at the preparatory stage and two at the secondary.

In the 1950s there were almost 300 foreign schools in Egypt, the majority of them French; many of these have since become, to varying degrees, Egyptianized. Pupils of these schools, at all levels, sit for the same state certificate examinations as those in the normal state system.

The universities

Apart from five universities—al-Azhar, Cairo, Alexandria, 'Ayn Shams, and Asyūṭ—there are also a number of other institutions for higher education.

Al-Azhar has been a teaching centre for the entire Muslim world for nearly a millennium. A large-scale modernization of the curriculum, making it comparable to those of other state universities, has been carried out since 1961. In 1970 to 1971, out of an enrollment of almost 25,000 students, al-Azhar had more than 22,000 males and 2,500 females. The student enrollment at Cairo University for the same year was 50,000 (36,000 males and 14,000 females); at Alexandria it was about 40,000 (30,000 males and 10,000 females); and at Asyūṭ it was 14,000 (11,000 males and 3,000 females).

In addition to the state university system, there is one private university—the American University in Cairo; enrollment is about 1,500, and males and females attend in approximately equal numbers.

There are about 40 institutes of higher learning, excluding institutes attached to universities or affiliated to the Ministry of Culture—such as the Institute of Dramatic Arts, the Cinema Institute, and the Institute of Ballet. These institutes specialize in commerce, industry, agriculture, the arts, physical culture, social service, domestic economy, and languages. Courses of study lead to a degree.

In spite of the rapid advance in the provision of education services, illiteracy remains a problem. Since 1964 funds have been available for a 15-year campaign to combat illiteracy.

Health and welfare services. In the early 1970s the budget of the Ministry of Health reflected a steadily increasing expenditure on public-health programs. The budget for 1968–69 alone exceeded the sum spent on health services during the 25 years prior to 1950.

The number of government health units increased from about 1,500 in 1960 to about 4,000 in 1969, and the number of beds in public hospitals almost doubled between 1952 and 1969, while the number of doctors quadrupled and the number of dentists increased 20 times over.

An important aspect of recent development has been the expansion of health facilities in the rural areas. In 1953 the government introduced what are termed combined service units; these differ from health centres in that they combine the functions of health centre, school, social-welfare unit, and agricultural extension services. In 1969 there were more than 300 of these units in operation. In addition, rural health units, of which by 1970 there were more than 1,100, further extended the health services available in rural communities; the eventual aim is to establish a total of 2,500, covering the entire countryside. Each unit is manned by a team of seven or eight persons, including one physician.

Well-trained physicians and specialists are available in large numbers in the cities and larger towns. The medical profession has prestige, and only the better qualified high school graduates are accepted in medical schools. In the decade 1960–70 more than 10,000 physicians, 1,300 dental surgeons, and 3,000 pharmacists were graduated. The paramedical level is also being given increasing attention. In 1970 almost 90 paramedical institutes provided training for medical visitors. There is also a university-level nursing school in Alexandria.

Public health campaigns

Significant efforts are being made to promote preventive medicine. Compulsory vaccination against smallpox, diphtheria, tuberculosis, and poliomyelitis is enforced for all infants during their first two years. Bilharzia (a parasitic disease) presents a most vexing health problem. It is curable, and all health centres offer treatment against it, but peasants become easily reinfected. Epidemics of malaria have been eliminated, but the disease still exists in endemic form, mainly in southern Egypt. Treatment for malaria is provided at all health centres, and the spraying of houses in mosquito-breeding areas is carried out regularly. Attention has also been given to the problem of tuberculosis; centres have been established in every *muḥāfaẓah*, and mass X-ray and immunization campaigns have been carried out.

The government has attempted to socialize medicine through such measures as the nationalization and control of pharmaceutical industries, the nationalization of hospitals run by private organizations and associations, and expanded health insurance. A health insurance law was passed in 1964; it provides for compulsory health insurance for workers in firms employing over 100 persons, as well as for all governmental and public employees.

Housing. Egypt faced a serious urban housing shortage after World War II. The situation subsequently became aggravated by increased immigration from rural to urban areas, resulting in extreme urban overcrowding. A Ministry of Housing survey (1970) showed that 55 percent of one-bedroom flats were occupied by four or more persons, 40 percent of two-bedroom flats were occupied by seven or more, and 36 percent of three-bedroom flats were occupied by ten or more persons.

Although there is considerable concern over the housing problem, the combined efforts of both public and private sectors have been unable to meet the demand. Between 1960 and 1970 about 300,000 housing units were built, representing an increase of about 18 percent in the housing available. Investment on housing in the 1960s represented between 10 and 15 percent of total national expenditure. The increase in the urban population, however, was estimated at more than 4,000,000 (over 40 percent) during the same period; *i.e.*, for every new housing unit built, 13 persons were added to the urban population. It is estimated that housing needs during the 1970s will amount to more than 1,200,000 units.

Housing construction

Between 1960 and 1970 about one-third of the units built were for those in low-income groups. The *muḥāfaẓāt* and the nine public-housing-development companies are responsible for public housing, but members of housing cooperatives can also apply for loans from the Co-operative Organization for Building Private Houses. These loans are made at a low rate of interest and are repayable within a period of five to 25 years. Private individuals can obtain loans for building at higher interest rates. Apart from public housing, large industrial firms, such as textile factories, steelworks, petroleum refineries, and chemical industries, have special housing projects for their workers.

In the rural areas, villagers build their own houses at little cost with the materials available. The government has experimented in aiding self-help projects with state loans. Ambitious rural housing projects have been carried out on newly reclaimed land; whole villages have been built with all the necessary utilities, and about 30,000 farming families from congested areas had been resettled in them by the early 1970s. It is estimated that 1,500,000 persons will eventually be resettled on the 1,250,000 acres of land reclaimed by irrigation as part of the Aswān High Dam project.

Police services. The Ministry of the Interior has direct control and supervision over all police and security functions at the *muḥāfaẓah*, district, and village levels. At the central level, the ministry is responsible for general security, immigration, naturalization, passports, civil defense, the traffic police, police training, and prisons. The General Security Department is responsible for police services, including criminal investigation, narcotics control, delinquency, smuggling, and emergency and tourist police. Every *muḥāfaẓah* has a motorized emergency police service, which is always on call and often renders services beyond normal police functions.

In the early 1970s efforts were being made to improve police services by raising the educational level of the police force and improving its technical facilities. Policemen had previously been recruited without any educational requirements other than literacy. A program

launched in 1969 aimed at the eventual replacement of the existing police force below the officer level with recruits who had received a high school education, as well as a full year of police training. Officers receive four years of university training.

SOCIAL CONDITIONS

Living standards

Wages and cost of living. The general standard of living in Egypt is rather low; the country is also subject to many of the ills common to other developing nations. In relation to the size of its population, its present economic resources are limited. Land remains its main source of natural wealth, but the amount of land is insufficient to support the population adequately.

Before 1952 the distribution of land was so disparate that less than 3 percent of the population owned more than 55 percent of the total, and only 13 percent owned any land at all. Subsequent legislation has limited land ownership, as mentioned above, to a maximum of 50 acres per person, with a 100-acre maximum for each family. Much of the land expropriated from the big landowners has been distributed to landless peasants. But the realization of the need to curb the rate of population increase led to the launching, in 1964, of a national family-planning program, to which high priority has been given.

The rural population, especially the portion represented by the landless agricultural labourer, has the lowest standard of living in the country. Industrial and urban workers enjoy, on the whole, a higher standard. The highest wages are earned in such industries as the petroleum and wine industries; many workers in industry receive additional benefits by way of social insurance and extra health and housing facilities. The salaries of professional groups are also low. Low wage levels are to some extent offset by the low cost of living, although by the early 1970s this was rising; bread, however, could still be bought cheaply, and the price of a basic staple, such as beans, was low enough to be within the reach of the poorest. Rent control also helped to keep housing costs at a reasonable level.

Health conditions. A generally low standard of health continues to be a major social problem. In spite of the great measure of progress achieved during the last few decades and the conducting of successful public-health campaigns against specific diseases, the endemic diseases that remain are a continuing threat to national well-being and progress.

The literacy rate

Educational conditions. Illiteracy—estimated at about 70 percent—also remains a serious social problem. The percentage is much higher among females than among males—about 87 percent as compared to 64 percent, respectively, in 1960. Even so, one of the most encouraging and significant features of the 1950s and 1960s has been the spread of education, particularly of women's education. In 1970 to 1971 about 30 percent of the students attending university were women. Women are no longer confined to the home; many fields of employment, including the professions and even politics, are now open to them. A further result of the expansion of education has been the emergence of an intellectual elite and the growth of a middle class, consisting of members of the professions, government officials, and businessmen.

CULTURAL LIFE AND INSTITUTIONS

The cultural milieu. In spite of the many ancient civilizations with which it has come into contact, Egypt unquestionably belongs to a sociocultural tradition that is Arabic and Islāmic. This tradition remains a constantly operative factor in determining Egyptian views both of self and of the world.

The story of the cultural development of modern Egypt is, in essence, that of the response of this traditional belief system to the intrusion into it, at first by conquest and later by the penetration of ideas, of the alien and materially superior civilization of the West. The response covered a broad spectrum—from the rejection of new ideas and reversion to traditionalism, through self-examination and reform, to an uncritical acceptance of new concepts and the values that went with them. The end result has been the emergence of an unselfconscious cultural identity, which has assimilated much that is new while remaining distinctively Egyptian. The process is to be seen at work in all branches of contemporary culture.

The state of the arts. The impact of the West is one of the recurring themes in the modern Egyptian novel, as in Tawfīq al-Ḥakīm's *ʿUsfūr min ash-Sharq* ("The Bird from the East") and Yaḥyā Ḥaqqī's novella *Qindīl Umm Hāshim* ("The Lamp of Umm Hāshim"). A further theme is that of the Egyptian countryside—romantically handled at first, as in Muḥammad Ḥusayn Haykal's *Zaynab*, and later realistically, as in ʿAbd al-Raḥmān ash-Sharqāwī's *al-Arḍ* ("The Land") and *al-Fallāḥ* ("The Peasant") and in Yūsuf Idrīs's *al-Ḥarām* ("The Forbidden"). A Dickensian capacity to catch the colour of life among the urban poor is a characteristic quality of the early and middle work of Egypt's greatest contemporary novelist, Najīb Maḥfūẓ, notably in *Zuqqāq al-Midaqq* ("The Alley of al-Midaqq").

The modern theatre in Egypt is a European importation—the first Arabic-speaking plays were performed in 1870. Two dramatists, both born at the turn of the century, have dominated its development—Maḥmūd Taymūr and Tawfīq al-Ḥakīm. The latter, a versatile and cerebral playwright, reflects in his themes not only the development of the modern theatre but also, in embryo, the cultural and social history of modern Egypt. The changes in Egyptian society during the 1950s and 1960s are also reflected in the themes adopted by younger contemporary dramatists.

Film making in Egypt

There is a relatively long tradition of film making in Egypt going back to World War I, but it was the founding of Miṣr Studios in 1934 that stimulated the growth of the Arabic-speaking cinema. Nowadays, Egyptian films are shown to audiences throughout the Arab world and are also distributed in Asian and African countries. The industry is both privately and state owned—there are almost a score of private film-production companies, as well as the Ministry of Culture's Egyptian General Cinema Corporation.

Contemporary Egyptian music embraces indigenous folk music, traditional Arabic music, and Western-style music. The revival of traditional Arabic music, both vocal and instrumental, owes much to state sponsorship. Popular Arabic music consists of a blend of classical Arabic music, folk songs, and Western music. Muḥammad ʿAbd al-Wahhāb has been one of the leading figures in the development of this genre, as both composer and singer. Of the same generation is Umm Kulthūm, the leading vocalist not only of Egypt but also of the whole Arab world for nearly half a century. Western-style music has been a familiar component in Egyptian musical culture since the 19th century. Pioneers such as Yūsuf Greiss (1905–61) and Abū Bakr Khayrat (1910–63) succeeded in giving a national colouring to their Western-style compositions.

A return to folklore as a source of inspiration for the arts is a generalized phenomenon in modern Egyptian culture. It has resulted in a revived interest in traditional crafts, in the collection of folk music, and the maintaining, with government sponsorship, of two folk-dance ensembles—the Riḍa Troupe and the National Folk Dance Ensemble. In the plastic arts, the highly original use of local themes is particularly striking. An active school of Egyptian painting and sculpture has emerged.

Cultural institutions. The oldest learned academy in Egypt, the Institut d'Égypte, was founded in 1859, but its antecedents go back to the institute established by Napoleon in 1798. The Academy of the Arabic Language, founded in 1932 and presided over by the veteran man of letters Taha Husein, is, in terms of prestige and influence, one of the most important cultural institutions in Egypt. Linked to the Ministry of Culture, it enjoys a large measure of autonomy, guaranteed by its own charter. Also attached to the Ministry of Culture is the Higher Council for Arts, Letters, and the Social Sciences. Intended as a consultative body on cultural matters, the Higher Council is also a means of channelling state patronage.

The learned societies

There are some 30 learned societies catering to a wide variety of subject interests—such as the physical and natural sciences, medicine, agriculture, the humanities, and social sciences. Increased government concern with research, especially in science and technology, was reflected in the establishment of the Atomic Energy Commission and the National Research Centre in 1956. In addition to the latter, there are almost 20 specialized research institutes in the country.

Most of the learned societies and research institutes have library collections of their own. In addition to large collections at the universities, the municipalities of Alexandria, al-Manṣūrah, and Ṭanṭā maintain libraries. There is also a central public library in each *muḥāfaẓah*, with branches in small towns, and service points in the villages. The Ministry of Culture is responsible for the Egyptian National Library (Dār al-Kutub), the National Archives, and the Public Libraries Administration. The Egyptian National Library, which has a large collection, is also a centre for the collection and preservation of manuscripts.

The Ministry of Culture is also responsible, through its department of antiquities, for the Egyptian Museum, the Coptic Museum, the Museum of Islāmic Art, and other institutions, including such fine-arts museums as the Mukhtār Museum, the Nājī Museum, and the Museum of Modern Art.

Press and broadcasting. Ownership of major newspapers is vested in the ASU. Control is exercised through four large publishing houses—al-Ahrām, Akhbār al-Yawn, al-Jumhūrīyah (al-Gumhouriya), and al-Hilāl; among them they publish all the large-circulation dailies, weeklies, and periodicals.

Among the daily newspapers, *al-Ahrām* remains the most authoritative. Other dailies (with estimated circulations of about 250,000) are *Akhbār al-Yawm* and *al-Jumhūrīyah*. The Jumhūrīyah group also publishes the evening paper *al-Masā'*, as well as the foreign-language dailies printed in English, French, Greek, and Armenian. In addition to widely read weeklies and cultural monthlies, there are many publications catering to particular professional interests.

Radio and television

Radio and television services are grouped together to form one corporation under the aegis of the Ministry of Information. In 1971, radio broadcasting consisted of 11 programs, with a total average transmission time of more than 180 hours per day. In addition to programs intended for other Arabic-speaking countries, such as *The Voice of the Arabs*, the Overseas Programme transmits in 32 foreign languages—representing, next to the United States, the most extensive range of foreign-language broadcasting in the world.

There is one television station, and television plays a role in relation to national policies. It has been used, for example, in the literacy campaign, as well as to advocate agricultural improvements. In 1970 there were about 560,000 television sets in use.

Prospects for the future. In the early 1970s Egypt found itself playing an increasingly important role in Africa and in the developing world. It belongs, however, both culturally and politically, in the Arab Middle East. As the most populous and technologically advanced of the Arab states, it has inevitably played a major role in Arab cultural and political affairs.

Like other Asian and African countries, Egypt has faced many problems of development since World War II, such as the limitations imposed by an agriculture-based economy, a high rate of population growth, a low per capita income, and a lack of resources. Cheap electric power from the Aswān High Dam and recent discoveries of petroleum deposits will undoubtedly facilitate economic growth and the process of industrialization. The nature and pace of Egypt's future development will be determined to a large extent, however, by the course of events in the Middle East region as a whole.

BIBLIOGRAPHY

General works: *Egypte*, new ed., "Les Guides Bleus Series" (1971), the best of the popular guides; GEORGE L. HARRIS (ed.), *Egypt* (1957), provides general coverage, also important as a source of information on agriculture and social change; RAYE R. PLATT and BAHY MOHAMMED HEFNY, *Egypt: A Compendium* (1958), provides general background and information on detailed aspects of contemporary Egypt.

The landscape: W.B. FISCHER, *The Middle East: A Physical, Social and Regional Geography*, 4th ed. (1961), contains basic geographical information; RUSHDI SAID, *The Geology of Egypt* (1962), an authoritative specialized study; CAIRO UNIVERSITY, *Bulletin of the Faculty of Science*, no. 17, 28, 30, 36, *The Flora of Egypt*, as yet incomplete, is the standard work on the subject; RICHARD MEINERTZHAGEN, *Nicoll's Birds of Egypt*, 2 vol. (1930), a primary source copiously illustrated; G.A. BOULENGER, *Zoology of Egypt: The Fishes of the Nile* (1907, reprinted 1965), the authoritative and amply illustrated standard work; HENRY HABIB AYROUT, *Fellahs* (1942; Eng. trans., *The Fallaheen*, 1945), although written before 1952, contains observations on the customs, dress, and psychology of the Egyptian peasant that are still valid; HAMED AMMAR, *Growing Up in an Egyptian Village* (1954), the best and fullest account of village life in Egypt; SAYED MAREI, *Agrarian Reforms in Egypt* (1957), general work on agricultural reform; TOM LITTLE, *High Dam at Aswan* (1965), on the building of the High Dam and its effect on landscape and people.

Peoples and population: ABBAS M. AMMAR, *The Peoples of Sharqiya*, 2 vol. (1944), a physical anthropologist's description of the inhabitants of the eastern Delta; WILLIAM H. WORRELL, *A Short Account of the Copts* (1945), a concise study of the indigenous Christian population of Egypt; ANWAR G. CHEJNE, *The Arabic Language: Its Role in History* (1969), background on the role of classical Arabic and the dichotomy between it and the various dialects. For information on European and other ethnic minorities, see Platt and Hefni, already cited, and the works of Issawi and Little listed below.

Administration and social conditions: LUTHER GULICK and JAMES K. POLLOCK, *Government Reorganization in the U.A.R.* (1962), a report on the reorganization of the machinery of government; HAROLD F. ALDERFER and M. FATHALLA EL KHATIB, *Local Government in the United Arab Republic*, 2nd ed. (1964), a descriptive outline; MORROE BERGER, *Bureaucracy and Society in Modern Egypt* (1957), one of the few English-language statements on the subject; P.J. VATIKIOTIS, *The Egyptian Army in Politics: Pattern for New Nations?* (1961), a provocative interpretation of the role of the army in politics and its transformation into a political elite; AMIR BOKTOR, *The Development and Expansion of Education in the United Arab Republic* (1963), an important general survey; BAYARD DODGE, *Al-Azhar: A Millennium of Muslim Learning* (1961), deals with the special role of al-Azhar in Islamic education; HARRY HOPKINS, *Egypt, the Crucible* (1969), a graphic, if personalized, description of contemporary Egyptian politics and society; TOM LITTLE, *Modern Egypt* (1967), a fuller and improved version of the author's earlier work (*Egypt*), with greater emphasis on social and political structures; PETER MANSFIELD, *Nasser's Egypt*, 2nd ed. (1969), a clear and orderly description of political, economic, and social changes in Egypt since 1952; CHARLES ISSAWI, *Egypt in Revolution* (1963), an informative study of economic and social conditions in modern Egypt, replacing the author's earlier books—*Egypt: An Economic and Social Analysis* and *Egypt at Mid-Century*.

The cultural scene: MUSTAFA HABIB (ed.), *Cultural Life in the United Arab Republic* (1968), a collection of articles by Egyptian specialists; MAGDI WAHBA, *Cultural Policy in the United Arab Republic* (in press), an authoritative statement on inter-ministerial responsibility for cultural affairs, with particular emphasis on the Ministry of Culture; ALBERT HOURANI, *Arabic Thought in the Liberal Age* (1962), deals with the interaction of Western and indigenous culture in its historical context; JACOB M. LANDAU, *Studies in the Arab Theatre and Cinema* (1958), on the origins of the theatre and cinema; ABD AL-MONEM ISMAIL, *Drama and Society in Contemporary Egypt* (1967), an analysis of political and social themes in contemporary Egyptian drama, with synopses of plots; ABDEL-AZIZ ABDEL-MEGUID, *The Modern Arabic Short Story* (n.d.), deals mainly with the genesis and early development of the modern Arabic short story; HAMDI SAKKUT, *The Egyptian Novel and Its Main Trends from 1913 to 1952* (1971), a much-needed study on the growth of the Egyptian novel.

Egyptian government publications: CENTRAL AGENCY FOR PUBLIC MOBILIZATION AND STATISTICS, *Statistical Abstract of the United Arab Republic 1951/52–1968/1969* (1970); *Statistical Handbook* (1968); *The Increase of Population in the United Arab Republic and Its Impact on Development* (1969); MINISTRY OF CULTURE, *Cinema in the United Arab Republic* (1970); INFORMATION DEPARTMENT, *The Charter* (1962); and *The Constitution, March 25, 1964* (1964).

Egypt, History of

Egypt was the home of one of the principal civilizations of the ancient Near East and, like Mesopotamia, of one of the very earliest urban and literate societies. Its culture had an important influence on both ancient Israel and ancient Greece, which in turn helped to form the civilization of the modern West. Egypt also provided Africa with its earliest civilization and may well have had considerable influence on the development of other African cultures. Long known to readers of the Bible and of the Greek historian Herodotus, ancient Egypt first became an object of scholarly research with the development of archaeology in the early 19th century.

This article is divided into the following sections:

    Struggle for power
    Egypt and the U.A.R. (1955–*c.* 1971)

The special character evident in the civilization of ancient Egypt over a period of 3,000 years developed very rapidly at the time when the country first achieved unity. This great event happened in about 3100 BC, and while some of the seeds of Egyptian culture had sprouted before this time, it is proper to regard the start of the 1st dynasty as the virtual beginning of Egypt, as the country and its civilization are now generally envisaged.

Perhaps the first and most important quality that typified this civilization was continuity. In every aspect of Egyptian life, in every manifestation of its culture, a deep conservatism can be observed. This clinging to the traditions and ways of earlier generations was the particular strength of the Egyptians. It can also be regarded as a weakness; but for a relatively primitive culture there was more to be gained than lost in attachment to the past. Regularity was a built-in characteristic of Egypt; life in the Nile Valley was determined to a great extent by the behaviour of the river itself. The pattern of inundation and falling water, of high Nile and low Nile, established the Egyptian year and controlled the lives of the Egyptian farmers—and most Egyptians were tied to a life on the land—from birth to death, from century to century. On the regular behaviour of the Nile rested the prosperity, the very continuity, of the land. The three seasons of the Egyptian year were even named after the land conditions produced by the river; *akhet*, the "inundation"; *peret*, the season when the land emerged from the flood; and *shomu*, the time when water was short. When the Nile behaved as expected, which most commonly was the case, life went on as normal; when the flood failed or was excessive, disaster followed.

Importance of the Nile

I. Egypt to the end of the 17th dynasty

INTRODUCTION TO EGYPTIAN CIVILIZATION

The nature of ancient Egyptian civilization. That Egypt was a land in which civilization was nurtured was the direct result of the Nile; the Nile made Egypt, and the valley of the Nile was Egypt. Only that part of the country susceptible to flooding could provide a livelihood for the population. The vast areas of desert to the east and west of the green, fertile valley were barren, inhospitable wastes; it was possible to find interesting things in these deserts—fine, hard stones, precious metals, and some game—but such places could hardly be considered parts of the country of Egypt. In a sense Egypt was an island, cut off from other habitable lands—to the north by the sea and in all other directions by deserts. Being thus isolated it was both protected from invasion and insulated from external influences.

Isolation and self-sufficiency of ancient Egypt

This isolation contributed in no small degree toward the conservative, inward-looking character of life in Egypt. For the Egyptian there could be no doubt that his country was quite distinct; it was a universe on its own, unrelated to other lands abroad. To be away from Egypt was to be divorced from reality; being an Egyptian meant living in Egypt, worshipping Egyptian gods (who had nothing to do with the world outside), dying and, above all, being buried in Egypt. The special features of Egyptian life reflected this egocentric view, which treated all things Egyptian as being of their kind unique. Egyptian techniques in working materials were in many respects different from those practiced elsewhere in the ancient world; artistic methods and conventions, established at the very beginning of the Dynastic Period, were quite peculiar to Egypt; even Egyptian writing, the hieroglyphic script, was a medium of communication developed specifically for the use of the tongue spoken in Egypt, and it was incapable of adaptation to the requirements of other languages. In techniques, art, and writing, the methods developed in the earliest times remained, in general terms, satisfactory for the needs of the Egyptian people and over the centuries required only the modifications resulting from natural development within a fairly closed culture. This self-sufficiency, which amounted almost to a sort of cultural stagnation, is well demonstrated in the matter of writing. When it became necessary to correspond diplomatically with other countries, the cuneiform script and the Akkadian language were used; this script, which was employed for many different ancient languages, displayed a versatility that Egyptian hieroglyphs never acquired.

One unfortunate result of the isolated but comfortable character of Egyptian life was that people outside regarded Egypt as specially favoured and therefore as a desirable prize to be conquered. For many centuries the greedy aspirations of foreigners amounted to no great threat because of the difficulties of invading Egypt across broad desert tracts or the sea; furthermore, the likely invaders were never of sufficient power and strength to undertake full-scale warfare. There was, however, noth-

ing to prevent small groups of nomads and traders from entering Egypt and settling down, particularly in the sparsely populated region of the Delta. The threat posed by such groups eventually became very real; but at first there seemed to be no cause for alarm, and the rulers of Egypt were rarely obliged to engage in serious defensive warfare. In general Egypt was a peaceful country; its people were pacific—they made poor soldiers and always despised the military life, preferring the peaceful lives of the farmer and the scribe.

From the New Kingdom (1567–1085 BC) onward Egypt became more and more involved in the affairs of its foreign neighbours and, in consequence, in warlike activities; but the peaceful character of its people was not much modified by foreign adventures, nor was the basically pastoral nature of life in Egypt much changed. The stability and regularity of most Egyptians' existence imparted to Egyptian civilization the notable continuity from which, in turn, sprang the best and most enduring achievements of ancient Egypt. In the earliest dynasties, after the period when Upper and Lower Egypt were united into a single realm, the country was organized administratively and agriculturally in such a way that thereafter, even in periods of little central control, the ideal of the well-regulated life remained strong in the memories and desires of men.

Despotism of Pharaohs

The king and his chief ministers controlled life in all its aspects, but there is much to suggest that the pharaonic despotism was inspired by noble ideals of responsibility toward the ordinary Egyptians. Below the central authority, administration of the royal will was exercised provincially through the nomes, or districts, into which Upper and Lower Egypt were divided. These nomes, probably based on primitive tribal areas, were retained for administrative purposes; and at nome level was organized most of the governmental activity that directly affected the life of the ordinary Egyptians: the administration of justice; the control of waterways, canals, and irrigation; the carrying out of local works; the raising of levies for the annual corvée after the inundation or for occasional military service. Inscriptional evidence declares the high moral intention of local administration; literary evidence suggests that on the whole the system operated in a just manner. In a society as hierarchically organized as that of ancient Egypt, the interests of the lowly were subordinated to those of the great, but in this respect Egypt differed little from most ancient societies. Within the limits set by such a system, the people of Egypt lived a reasonably happy and comfortable life.

In matters of agriculture, very high standards were achieved; by careful control of water at all seasons, the best was made of the fertile soil of the country. Good crops were raised, often as many as three in succession throughout the year; fine herds of cattle were reared, pastured mostly in the Delta. Splendid results were attained in breeding, and many experiments were carried out in extending the range of domestic animals and fowl. The actual techniques of farming and husbandry were simple throughout the three millennia of dynastic history, but they were finely judged to obtain good results. The peculiar nature of Egypt's cultivable land, with the unusual character of the country's climate, required a form of agriculture that differed in many respects from that practiced in less favoured lands. The Egyptian peasant did not have to toil for long hours, scratching a living from a barren soil; the relative ease of cultivation enabled the cultivator to concentrate his attention on more advanced horticulture. Egyptian domestic gardening was of a high standard and well-adapted for a culture in which much emphasis was laid on the excellence of garden produce and on viticulture and its subsidiary, wine making.

Beyond the fields—in the workshops of the great estates, the temples, and the towns—other crafts were practiced and, for their contemporary purposes, perfected. On the practical level, the Egyptians were outstanding among the peoples of antiquity. The manipulation of difficult materials seemed to present few problems to their craftsmen. In the techniques of stoneworking they particularly excelled. The Nile Valley served as a vast quarry from north to south, providing the building stone that Egyptian architects employed so magnificently; the Eastern Desert was the source of other fine stones used for vessels and statuary, of semiprecious stones, and of metals. The only important material lacking was timber, but adequate supplies could usually be obtained from Lebanon and Syria. Working with simple but efficient tools, the Egyptian craftsmen mastered all available materials, while Egyptian artists wrought masterpieces in many media. Sculpture was undoubtedly the field in which the greatest results were achieved; but Egyptian painters, both when working with carvers in producing low-relief scenes and in the execution of flat wall paintings in gouache, displayed a complete mastery of their art.

The Egyptians were a practical people, and they reveal through the products of their arts and crafts their particular genius. In classical times these early Egyptians were also credited by the Greeks with great knowledge and wisdom; but the evidence provided by Egyptian writings does not support this Greek opinion. It is probable that Greek travellers in Egypt, impressed by the grandeur and antiquity of the monuments of the land and misled by the accounts of past ages given to them by their priestly guides, grossly misinterpreted the evidence and jumped to unwarranted conclusions. Unlike the Greeks, the Egyptians were not philosophically inclined, intellectually inquisitive, or prone to theorizing. They tended to accept the world as they saw it and to make use of its advantages without looking too deeply into the properties of its parts. They were good engineers and builders but not good mathematicians, limiting their interest in calculation to the solution of practical problems. As astronomers they knew the sky well, enjoying exceptionally good conditions for observing; but they did not use the knowledge derived from astronomical observation to correct their civil calendar of 365 days. In medicine, for which they subsequently achieved a great reputation, they were again skilled practitioners, making use of the knowledge derived from the dissection of bodies in the course of mummification; but in the treatment of illnesses they never abandoned the magic of primitive times, and their pharmacopoeia was a strange amalgam of efficacious drugs and magical ingredients of no therapeutic value.

Classical misinterpretations of early Egypt

Nevertheless Egyptian civilization, through its continuity, stability, and age, was properly revered in antiquity; while the country itself was desired, the achievements of its people were greatly honoured. Much of this reputation may have been slenderly based, but its reality cannot be denied.

Sources and chronology. Strictly speaking, Egyptian history can only be written for those periods from which written records survive. Earlier periods, which elsewhere would be called prehistoric, are in Egypt's case termed predynastic. This term derives from the habit of calling the historic period in Egypt the Dynastic Period—the time covered between the 1st dynasty and the Ptolemaic Period. Dynasty was the word used by the annalist Manetho, an Egyptian priestly writer who lived in the 3rd century BC, to designate each of the 30 "houses," or groups, into which he organized the successive kings of Egypt. He began with the union of Egypt, making the uniter, whom he named Menes, the founder of the 1st dynasty. The 30th dynasty ended in 343 BC with the death of the last native Egyptian pharaoh, Nectanebo II. Manetho's original text has not survived; but abstracts, or epitomes, preserved in later writers, give the gist of his account, usually including the lengths of the various reigns. There are serious drawbacks to using these epitomes of Manetho as sources of Egyptian history—they are very summary, imperfect, and in some cases display a corrupt text; the Greek forms of names are not easy to translate into Egyptian forms; the dynasties themselves do not always conform to the sequence of succession and of changes of houses as they can be observed from more ancient sources. Nevertheless, Manetho does provide a serviceable framework that is sufficiently in accord

The annals of Manetho

with Egyptian history as it is now known; and it is more convenient to retain the use of his dynasties than to evolve a new system.

Before the discovery of the Rosetta Stone and the consequent decipherment of hieroglyphs, Manetho's account formed the principal source for the history of Egypt. His framework has subsequently been strengthened and modified by older lists of kings, most of which date from the 19th dynasty, approximately 1,000 years before the time of Manetho. The most important list, called the Turin Canon, is preserved on a papyrus in the Egyptian Museum in Turin. It, like the abstracts of Manetho, contains lists of names with lengths of reigns, the lists being interrupted from time to time by totals of groups of reigns, which correspond in part to the dynasties of Manetho. Unfortunately the document is badly damaged and otherwise rendered obscure by the inclusion of ephemeral rulers whose existence cannot be confirmed from other sources. But for the best known periods of Egyptian history before the 19th dynasty there is considerable agreement, at least in the matter of the number of reigns, between the Turin Canon and Manetho.

Lists of kings were also set up in temples and tombs. Two examples from Abydos and one from Ṣaqqārah were inscribed during the 19th dynasty, and one was inscribed at Karnak in the reign of Thutmose III of the 18th dynasty. The weakness of these lists as historical records is that they include only the names of kings deemed worthy of honour; many modest and certain unpopular rulers are wholly overlooked—expunged from the record.

The above records only provide the barest outline of Egyptian history. For further information the historian has to make use of the inscriptional, documentary, and other remains recovered in the course of excavation or still preserved on standing monuments. Thus the historical inscriptions set up by kings provide much detailed information about campaigns and conquests, but the reliability of any text has to be estimated carefully in the context of its time. Certain kings were particularly boastful in their claims and often incorporated into accounts of their conquests details culled from the inscriptions of their predecessors. To establish a reliable account of any period of Egyptian history requires much patient weighing of evidence. Even so, and in spite of the wealth of material remains, the narrative of Egyptian history is insubstantial and full of gaps. This inadequacy becomes more marked the farther back the story goes. For the earliest dynasties the account would be very slight but for the royal annals preserved on a large stone slab, the Palermo Stone, only a fragment of which has survived. This stone when complete contained a yearly record of the reigns of all Egyptian kings from late predynastic times down to the 5th dynasty. Each year is characterized by one or more significant events, some of which are of little historical interest (*e.g.*, the making of a cult statue) but others of which provide important information such as the dispatch of foreign expeditions.

The Palermo Stone

Because evidence of the sequence of events and reigns in Egyptian history is incomplete, dating can only be approximate. Some control of the chronology derived from the king lists is provided by the records of an annual natural phenomenon known as the heliacal rising of Sirius, the Dog Star (also known as Sothis). The rising of this star on the horizon occurs in the morning just before sunrise on approximately the 19th of July in the Julian calendar; it was observed particularly by the ancient Egyptians, possibly because it happened each year at about the time the Nile began to rise rapidly. The day of the rising was thus held to be the true New Year's Day. The Egyptian civil year of 365 days, being astronomically one-quarter of a day too short, gradually fell out of step with the astronomical year and thus with the rising of Sirius; the two years coincided again only after a period of about 1,460 years. The Roman scholar Censorinus, writing in the 3rd century AD, recorded a coincidence of the heliacal rising of Sirius with New Year's Day in the Egyptian civil calendar in AD 139. By calculation it follows that similar coincidences happened in about 1317 and 2773 BC. More precise calculation corrects these dates to 1314 and 2770 BC. Three records of heliacal risings of Sirius between these two dates provide reasonably fixed dates of 1872 for Year 7 of Sesostris III of the 12th dynasty, 1539 for Year 9 of Amenhotep (Amenophis) I of the 18th dynasty, and 1469 for an unspecified year of Tuthmose III of the same dynasty. A further reasonably well-established date, based on lunar observations and other evidence, is 1304 for the first year of the reign of Ramses II of the 19th dynasty.

Dates earlier than 1872 BC can be calculated with some degree of certainty back to the 11th dynasty, but before that time the paucity of detailed information allows only reasonable estimates to be made. Happily, a fragment of the Turin Canon preserves the total of years from the start of the 1st dynasty to the end of the 8th dynasty. This total, together with a reasonable estimate for the shadowy period before the 11th dynasty, yields a date for the beginning of the 1st dynasty of about 3100 BC. Some confirmation for the dates accepted below is provided by radiocarbon dating. Recent examination of material of the period from the 1st dynasty down to the 12th dynasty has produced carbon-14 dates that in general confirm the commonly agreed chronology. The margin of error inherent in such dates as at present calculated does not permit a precise check to be made on accepted historical dates.

Egyptian archaeology. The modern study of ancient Egypt dates from the French military expedition to Egypt in 1798, led by Napoleon Bonaparte. Before that time, visitors to the Nile Valley were few and opportunities for working there were practically nonexistent. There had been interest in the country and its monuments among European scholars during the Middle Ages and the Renaissance, but the difficulties of access thwarted serious study. During the 18th century it became increasingly easy for travellers to visit Egypt, and the illustrated publications of travels by the English bishop Richard Pococke in 1743 and by the Dane F.L. Norden in 1755 greatly stimulated interest. The French expedition, therefore, came at the right moment for scholarly exploitation, and it was important for another reason: in the course of military operations the Rosetta Stone was discovered. Thus were two keys provided—one opening the door to Egypt, the other the door to the ancient Egyptian language and thence to knowledge of ancient Egyptian history and civilization. Simultaneously, a commission of scholars brought from France by Napoleon was hard at work recording, among the natural and other wonders of Egypt, many of its ancient monuments. The work of these scholars was ultimately published in the *Description de l'Égypte*, itself a monument to scholarly industry.

Beginning of modern study

Fieldwork in Egypt has always taken two forms, excavation and recording. The former has, by the nature of its discoveries, ever been more dramatic; but the latter over the years has provided much of the material from which knowledge of ancient Egypt has been derived. Early excavation tended to be a search for buried treasure or at least for fine museum objects. Visitors to the country and consular officials, obtaining official permission by persuasion or bribery, dug where they wished and destroyed in the process as much as they discovered. The French scholar Auguste Mariette put a stop to this pillaging. In 1858 he founded, and became first director of, the Antiquities Service of Egypt, which thenceforth controlled archaeological work in Egypt. Mariette, himself a great excavator, introduced a new element of responsibility into excavation; but it was an Englishman, Sir Flinders Petrie, who (beginning in 1880) first worked in a truly scientific manner in this field.

Petrie laid great emphasis on control, observation, attention to detail, and, especially, on the publication of results. He often worked too quickly, but his intentions were always scholarly. His working life in Egypt extended from the last years of Mariette until well after World War I. He not only established a school of excavators who carried on and extended his work but he also incidentally created a climate of trust that enabled excavators of other countries to work profitably in Egypt.

20th-century expeditions

The first three decades of the 20th century saw many expeditions from American museums at work, a great increase on the part of French excavators working principally through the French Institute of Oriental Archaeology in Cairo, and missions from many other countries engaged in fieldwork among the seemingly inexhaustible ancient sites of Egypt. George Andrew Reisner, who conducted excavations for a number of American institutions—particularly the Museum of Fine Arts in Boston—established standards of recording and methods of classification that went far beyond what most workers in the field were prepared to emulate; Reisner's excavations at Giza, which continued up to the outbreak of World War II, were particularly important. Of all the discoveries in Egyptian archaeology, that of the tomb of Tutankhamen by Howard Carter in 1922 was undoubtedly the most remarkable. Pertinacity and a shrewd judgment of slender evidence inspired Carter to continue digging when most excavators would have abandoned work; great manual skill, immense patience, and superlative draftsmanship rendered his work on the contents of the tomb beyond praise.

The recording, or epigraphic, side of Egyptian archaeology, after the initial example provided by the Napoleonic Commission, achieved high standards of scholarly accuracy with the work of a Prussian expedition led by Karl Richard Lepsius in 1842–45. The volumes of Lepsius' *Denkmäler aus Ägypten und Äthiopien* contain drawings of reliefs and inscriptions on standing monuments throughout Egypt and the Sudan, which are still much consulted. In view of the date when the expedition worked, the results are remarkably accurate; furthermore, much was recorded that has since perished.

The copying of scenes and texts for accurate reproduction in publication was not, however, pursued as a positive ideal until the late 19th century. Norman de Garis Davies, working for the Egypt Exploration Fund of London and later for the Metropolitan Museum of Art, New York, combined accuracy, artistry, and scholarship in his many publications of tombs. His wife, Nina, has never been surpassed as a facsimile copyist of Egyptian paintings. The finest epigraphic publications since World War I have been produced by the Egyptian Expedition of the Oriental Institute of the University of Chicago, whose great folio volumes of Theban temples represent the ultimate achievement in accuracy.

After World War II, Egyptian archaeology became dominated by the campaign, sponsored by the United Nations, for saving ancient monuments and sites in Egyptian and Sudanese Nubia. The construction of a great new dam a few miles to the south of Aswān threatened with inundation all archaeological sites southward for 300 miles (480 kilometres). From 1960 the archaeologists of many countries cooperated in the vast scheme to record and, where necessary, to excavate every identifiable ancient site threatened with submersion. All monuments still standing in the doomed area were to be recorded and, again where possible, moved to higher ground. For eight years the campaign continued; many dozens of sites were excavated, and many ancient buildings were moved—the most extraordinary operation was the removal and reconstruction of the two great rock-cut temples of Abu Simbel to a site well above the expected level of the new lake. The whole campaign was a remarkable example of international cooperation; Egyptian and Sudanese Nubia, though now lost beneath the waters of Lake Nasser, is probably the best recorded area in the world from an archaeological point of view.

Reconstruction of Abu Simbel

THE PREDYNASTIC AND EARLY DYNASTIC PERIODS

The Predynastic Period (to c. 3100 BC). The favourable environmental conditions existing in the Nile Valley enabled man to achieve advances in his ways of life at a very early date. In remote antiquity the character of the culture enjoyed by man in Egypt, as far as it can be judged from the few surviving tools and weapons, seems to have differed very little from that of other inhabitants of northern Africa. In late Paleolithic times, as a result of climatic changes in this region, vast tracts of land became inhospitable to man and he was obliged to retreat from the open plains, which now became deserts, to the coastal belt along the Mediterranean and to the Nile Valley.

Remains of occupation sites of the Neolithic Period (before *c.* 4000 BC) have been found in a few places in Egypt, but the majority of settlements have probably been lost beneath the deposits of Nile silt in the river valley. On the edge of the valley, however, traces of villages have been found in Middle and Lower Egypt and in the Fayyūm, northwest of Hawāra. The inhabitants of the Fayyūm settlements, which are probably to be dated to the mid-5th millennium BC, were fishers and hunters; they also grew grain and stored it in silos made of woven straw. They made tools from stone, flint, and bone; pottery was crude and very simple in shape; ornaments were made from shells and coloured pebbles, roughly shaped and pierced. Settlers such as those at Merimda Banī Salāmah on the southwestern edge of the Delta enjoyed a more advanced culture than did the Fayyūm people; a varied series of artifacts has been recovered from their villages, including pottery of finer quality than that of the Fayyūm, and many objects modelled in clay. The dwellings at Merimda Banī Salāmah were oval- or horseshoe-shaped light huts of wickerwork posts, probably covered with skins; here the dead were buried among their dwellings. In this respect they reveal similarities to the inhabitants of Neolithic sites in western Asia; in other respects, particularly in their skilled working of stone, they may be compared with their African contemporaries to the west and south.

These early peoples of Middle and Lower Egypt were not metal users. For the first traces of copper implements and ornaments it is necessary to turn to Upper Egypt. The settlements and cemeteries of the earliest identifiable copper-using Egyptians were discovered at al-Badāri, Mostagedda, and Matmar. The Egyptians who lived in this region took their first steps in metalworking early in the 4th millennium BC. A distinct advance can be noticed between the stages of culture found in the remains at Dayr Tāsā and those of al-Badāri. The so-called Tasian culture, primitive and metal-free, is probably to be taken as an early phase of the Badarian culture. Badarian sites are characterized by the high quality of the pottery produced—particularly a very thin, polished red ware, partly blackened and often decorated with a ripple pattern—and also by the presence of simple ornaments and a few small implements made of copper, and of steatite beads covered with a primitive glaze. The glazing of steatite was characteristically Egyptian, and its appearance during Badarian times heralds the existence of a culture that can confidently be termed Egyptian. Badarian is taken to be the earliest stage of Egyptian predynastic civilization and, as such, distinct from earlier cultures in the Nile Valley.

The earliest metal users

In manners of burial the Badarians differed from the Neolithic people of Middle and Lower Egypt because they possessed cemeteries set apart from their dwellings. In this practice they were followed by the later predynastic cultures of the Nile Valley, which are now generally named in sequence Naqādah I and Naqādah II, after the modern village of Naqādah in Upper Egypt, where Petrie first excavated and identified the predynastic cultures of Egypt. (Petrie himself called the first phase Amratian, after the village of al-ʿĀmrah near Abydos, and he called the second phase Gerzean, after al-Girza, a village much farther north.) In temporal terms it is difficult to make a strict division between the two Naqādah cultures; and there is some reason to believe that Naqādah II represents a more highly developed form of civilization that originated in Lower Egypt and gradually impinged upon and ultimately replaced the more simple civilization of Naqādah I, which was basically Upper Egyptian. This does not necessarily imply an actual conquest of south by north, but it perhaps rather indicates a cultural domination of the south by the north. In general terms Naqādah I displays a distinct advance on Badarian; techniques for the working of basic raw materials are much improved, and the products of such simple

The Naqādah cultures

crafts as pottery and stoneworking are better designed and more finely finished. Slate palettes for the grinding of cosmetics, which had first appeared in Badarian times, became more common and took more interesting shapes, although they cannot be compared with those in the form of animals, birds, and fish found in Naqādah II burials. Stone maceheads and well-worked flint javelin heads and arrowheads testify to the development of warlike activities, although it cannot be determined if they were produced for offensive or defensive purposes.

In Upper Egypt the graves of the Naqādah I people were relatively simple, shallow holes, in which the bodies were buried in contracted position with the faces turned to the west. They were commonly wrapped in skins or placed in wicker baskets. In addition to the pottery and palettes, grave goods included bone cosmetic objects like combs and armlets, beads of pottery and stone, and occasionally rough figurines of men and women, the significance of which remains in much doubt. The actual bodies reveal that the predynastic inhabitants of Upper Egypt were short and slimly built and had delicate features.

The inhabitants of Lower Egypt had broader heads, and they were buried in more highly developed graves, often carefully walled with wickerwork or matting and sometimes having more than one chamber. The goods found in the Lower Egyptian tombs, and also in Upper Egyptian graves of somewhat later date, are superior in craftsmanship and design. The pottery, made of a light baking clay, is often painted with representations of boats and human figures; stone vessels are cut from all kinds of hard stone mostly found in the Eastern Desert—*e.g.*, schist, diorite, volcanic ash, porphyritic rock, granite, basalt. A greater use of copper and of glazed steatite suggests a better technology, while the presence of non-Egyptian materials like lapis lazuli postulates contacts with western Asia.

Early political organization

Politically, little is known about Egypt at this remote time. Motifs in pottery decoration and marks on other objects suggest that a form of nome organization already existed and that there were probably two principal centres of power—Naqādah in the south, with the god Seth as tutelary deity, and Behdet in the Delta, with the falcon Horus as god. It is probable that around these two centres confederations of nomes were built up that in time took on the form of "kingdoms," the rulers of which assumed crowns—that of the south being white and that of the north being red (the two crowns that were subsequently joined into the double crown of the king of Upper and Lower Egypt). As time advanced toward the final clash that resulted in the union of these two lands, new capitals were established—at Hierakonpolis in Upper Egypt and at Buto in the Delta. In spite of the apparent cultural supremacy of the north, victory eventually went to the south; and the unification of Upper and Lower Egypt was achieved by the man known to later tradition as King Menes. So far no monument of that time has been discovered certainly bearing the name Menes, although one small table of ivory from Naqādah may bear it. Most scholars now hold that Menes should be identified with Narmer, the king whose great ceremonial palette from Hierakonpolis shows him in an indubitably victorious role, triumphing over northern enemies.

The Early Dynastic Period (c. 3100–c. 2686 BC). Historically speaking, the union of Upper and Lower Egypt by Menes was the most important event in the chronicle of the country's existence; and so it must have been regarded in antiquity. This was the moment when Egypt's history began for the ancient Egyptians, the time from which the succession of dynasties progressed. Unification was the political necessity of the land; unification remained the sought-after political ideal, prompting the actions of the Theban kinglets who much later brought to an end the anarchic First and Second Intermediate Periods. The first unification, therefore, was felt to be so important that it liberated great creative forces in the land. Overnight, as it were, Egyptian civilization achieved maturity; and in its physical manifestations it revealed the characteristics that were to be constantly visible for the next three millennia. It became a literate civilization; from the early 1st dynasty, hieroglyphs were used for secular and religious purposes and for official and private texts. It is true that none of the surviving texts from this period are very long and that only the simplest of ideas and facts are conveyed, but in the use and form of the unique hieroglyphic script they exhibit all the characteristics of long texts of later periods. These same early texts also provide valuable evidence of political organization, of the titles of officials, and of names of people and places. Inasmuch as most of the inscribed material comes from burials, it is not surprising that the resulting picture is somewhat one-sided. Nevertheless, such information as can be retrieved shows a country fully organized, with an efficient bureaucracy, well-established practices in accounting, recording, and general administration, and a social hierarchy similar in kind to that known for the Old Kingdom.

Texts from the early period

The king was, without a doubt, supreme; and his high officials and nobles attended him in death as in life, to judge from the placing of tombs in royal cemeteries. There is a debate about the location of the principal royal cemetery at this time—the choice lying between Abydos in the south and Ṣaqqārah in the north. At both places great tombs have been found that can be assigned to kings of the first two dynasties; but the evidence is at present insufficient to allow a certain decision to be made between the two. These and other tombs of the period, although badly robbed, have yielded enough fragments of funerary equipment to show that the products of Early Dynastic culture in Egypt were of fine quality. Much use was made of rare materials like gold, ivory, and lapis lazuli, some of which must have been imported, while the great timbers used in the tombs provide positive evidence of trading expeditions to Syria. The imposing brick superstructures of the tombs, far superior to anything built in predynastic times, equally reveal the amazing step forward in achievement made during the 1st and 2nd dynasties. The early architects, perhaps inspired by western Asiatic prototypes, were complete masters of building monumentally in mudbrick; and they even began to experiment in the use of stone for such architectural elements as lintels, steps, pavements, and portcullis blocks.

The 1st dynasty. In adopting a panelled design for the outside walls of the earliest tombs, the architects may have been reproducing in smaller scale the great walls that surrounded the new capital built by Menes in the valley near Ṣaqqārah, the city later called Memphis. The capital was placed strategically at the junction of Upper and Lower Egypt, and Menes is credited with having diverted the Nile in order to obtain the best situation for it. This political act demonstrates the intention of the earliest ruler of a united Egypt to govern the country as a whole and not to treat Lower Egypt simply as a conquered territory of Upper Egypt. But Upper Egyptian traditions, particularly religious ones, were evidently given greater prominence; the king was the embodiment of the Horus falcon, the great deity of Hierakonpolis (the old capital of the southern realm).

Enterprises of the new regime

Under the new regime great enterprises were undertaken of a kind impossible in earlier times. Menes conducted operations in the Eastern Desert; Aha, his successor, waged a campaign against the Nubians; the third king, Djer, sent expeditions to the east, probably to Sinai, and to the south as far as the Second Cataract; Den, the fifth king of the 1st dynasty, seems not only to have sent expeditions abroad but also to have done much to regulate the administration of the country. This last king of the 1st dynasty also apparently introduced the double crown as the royal diadem of the joined kingdoms.

The 2nd dynasty. The circumstances that led to a change of dynasty are not known, but shreds of evidence suggest that the last reigns of the 1st dynasty were troubled by internal dissension and probably that the royal line had lost the initial strength of purpose, which had helped it in the beginning to succeed so brilliantly. The first king of the 2nd dynasty gained power in about 2890 BC. His name was Hetepsekhemui, meaning "the

two powers are at peace," possibly a reference to the end of the struggle between the two parts of the country. Little is known about the first reigns of the new dynasty. The fourth king, Peribsen, may have been an usurper; he chose to call himself a Seth-king, not a Horus-king, which may indicate that he represented an opposing faction. Khasekhem, who is usually taken as Peribsen's successor, may have been in part his contemporary and rival for power; he was a Horus-king, and his monuments suggest that he was not only an energetic and warlike monarch but also a very successful one. The last king of the dynasty, Khasekhemui, designated himself a Horus- and a Seth-king, and it is possible that he is not to be distinguished from Khasekhem; it has been suggested that when Khasekhem overcame Peribsen he changed his name and designation as acts of reconciliation.

In spite of its generally shadowy character, there is enough evidence to prove that the Early Dynastic Period was in almost all respects the great formative epoch for Egypt. Government, administration, artistic convention, technical skills, writing, and building all were nurtured and developed at this time; they were to come to fruition in the Old Kingdom.

THE OLD KINGDOM AND THE FIRST INTERMEDIATE PERIOD

The Old Kingdom (c. 2686–c. 2160 BC). Under the rule of Khasekhemui, Egypt again made great strides forward in cultural development; and there is good reason to regard this king as the founder of the Old Kingdom and as the man who prepared the ground for the triumph of his successor Djoser.

The 3rd dynasty. The reign of Djoser (Zoser), which because of its monuments stands out particularly as a high-water mark of achievement, assumed a similar importance for the ancient Egyptians; in the king list of the Turin Canon his name is selected for the rare honour of being written in red. Yet he was not, apparently, the first king of the 3rd dynasty. After Khasekhemui it seems that Sanakht initiated the new dynasty. But of Sanakht's reign the only important event now known is an expedition to Sinai, possibly the first of many similar expeditions during to Old Kingdom, to search for the much prized turquoises of the region. Djoser, the immediate successor of Sanakht, also sent an expedition to Sinai; and it was he who probably established Egypt's southern boundary at the First Cataract on the Nile.

Djoser's funerary monument

But Djoser is especially important because he can be seen as the first Egyptian king who so organized and developed the resources and administration of the country that he was able to embark on the construction of a mighty funerary monument. In demonstrating his power in this way he established a new tradition, one by which his successors for many hundreds of years would demonstrate their own claims to glory. Building was the Egyptian medium of expression, above all. Whether it was Djoser or his principal official, Imhotep, who deserves the credit for this innovation cannot be decided.

Tradition assigns to Imhotep the credit for the achievements of Djoser's reign. According to contemporary records, Imhotep was a royal official, bearing important secular and priestly titles; by tradition he was much more—a great seer, physician, thinker, and, above all, an architect. Of these posthumous elements in his reputation only the last can be certainly attached to the Imhotep of Djoser's reign. Manetho made him responsible for the invention of building with hewn stone, and there seems no reason to doubt that as a senior official of Djoser's court, perhaps the most important nonroyal person of the time, he was in fact the builder of the Step Pyramid and the wonderful complex of buildings that surround it.

Simply, the Step Pyramid was to be Djoser's tomb; it consisted of a stepped structure built of the local limestone of Ṣaqqārah and faced with fine limestone from Turā across the Nile. It was set in an enclosure surrounded by a fine limestone wall, within which, in addition, were many smaller structures. The whole may have reproduced in stone part of the palace complex at Memphis. It was a noble conception, wonderfully executed—the first great stone building. It demonstrated what could be accomplished by fine craftsmanship allied with good organization; it was a permanent testimony to Djoser's greatness. Imhotep may have been the architect, but Djoser provided the raison d'être.

Precedent for Djoser's successors

The long-term effect of this partnership was fundamental to the development of Egypt and, in particular, to the growth of the idea of divine royalty. The Step Pyramid provided positive proof of what the king could do, and it demonstrated what he symbolized. It served as a notable precedent for Djoser's successors.

Sekhemkhet, Djoser's immediate successor, is known principally from the remains of his unfinished step pyramid, also at Ṣaqqārah, which was only discovered in 1951 and partially excavated in the years following. It is evident that Sekhemkhet embarked on a funerary monument that would at least equal that of Djoser. Parts of the great enclosure wall have been uncovered, and in scale it rivals Djoser's wall. The masonry, however, is less well prepared than that of the earlier monument. From this last fact it may perhaps be deduced that less care was taken in constructing Sekhemkhet's monument, that it was built in a great hurry, or that standards of construction had been relaxed. The complete absence of other evidence about Sekhemkhet's reign, apart from the record of a visit to Sinai, prevents any certain reason to be given for the difference in quality between the two monuments. It is, however, strange that not only Sekhemkhet but also the other kings of the 3rd dynasty left so few positive memorials of their reigns. The lack of material remains is, of course, to a great extent due to the passage of time and the natural causes of destruction. Nevertheless, the general impression remains that after the high peak of achievement attained during the reign of Djoser, a time of moderate development followed in which the rapid successes early in the dynasty were no more than consolidated.

Some indication of the general prosperity of the country during the reigns of Sekhemkhet, Khaba, and Huni—who are the best identified successors of Djoser—can be gained from the size and surviving remains of their funerary monuments and from the mastaba tombs of the nobles of the dynasty at Ṣaqqārah. The tombs in particular demonstrate the abilities of the craftsmen of the time and reveal something of the great men who served the kings of Egypt; these men were at least allowed some independence and the freedom to express their pride in the construction of grandiose monuments. Their status was to be reduced in the years to come, even as the power of the king was to increase.

The 4th dynasty. With the accession of Snefru (Sneferu) in about 2613 BC came a change in dynasty and the beginning of an epoch, the surviving manifestations of which still strongly influence the general impression of ancient Egyptian culture. Snefru was the builder of the first true pyramid, and his two vast structures at Dahshūr usher in the Pyramid Age as it is now generally understood. The change in design from step pyramid to true pyramid may represent a change in religious beliefs; it certainly represents a change in building methods. The design of the true pyramid was successfully achieved only after much experimentation, in which great engineering problems were solved. Huni, the last king of the 3rd dynasty, was possibly the first to attempt a true pyramid; and the present ruined state of his construction at Maydūm testifies to his long-term lack of success. Snefru's two pyramids reveal developments: one shows how the angle of inclination had to be changed in the course of construction, probably to avoid a structural collapse; the other possesses an unusually shallow angle of inclination in which the builders were clearly aiming at safety in construction. The ideal pyramid was eventually built by Snefru's successor, Khufu, and the first—the Great Pyramid at Giza—was the finest and most successful. But in the size of its base the Khufu pyramid was only a little larger than Snefru's northern pyramid at Dahshūr.

The beginning of the Pyramid Age

Achievements in mighty constructions during the first reign of the 4th dynasty show in striking manner how

capable the Egyptian administration was at this time. It may be assumed that the relatively quiet years of the 3rd dynasty left the country in a sound economic state and that Snefru took control of a land whose resources were capable of supporting great undertakings. Literary tradition of the Middle Kingdom suggests that, in his time, Snefru was a well-loved king with whom his more autocratic son and successor, Khufu, was subsequently compared, to the latter's detriment. It was probably Khufu's misfortune that he followed up too successfully the policies and practices instituted in his father's reign. Snefru had been an active king. From the laconic entries on the Palermo Stone it is known that he sent expeditions southward to Nubia and westward into Libya. Traces of a settlement in which copper smelting was carried on have been discovered in the region of the Second Cataract in Nubia; scraps of inscribed material show that it was occupied as early as the 4th dynasty, and its foundation may have been due to Snefru. Inscriptions in the Wadi Maghara in Sinai also record expeditions sent there by Snefru; so important were his activities there that his name remained associated with enterprises in Sinai for hundreds of years. He also sent expeditions by sea to Byblos to obtain timber for shipbuilding and other great works; balks of Syrian timber have been found inside his pyramids at Dahshūr.

In his great projects Snefru relied to a considerable extent on the support of relatives; most of the high officials in the land seem to have been princes. In the formal inscriptions set up in the chapels of their tombs at Maydūm and Dahshūr, they list the honours and titles that they held in their lifetimes. The enumerations are long and varied, and they cover all branches of activity; some titles indicate administrative duties, others are concerned with religious or military matters. These princely officials covered all departments of state; and while it is unlikely that they actively exercised the duties implied by their titles, there can be no doubt that they were ultimately responsible for all that happened. Their responsibility stemmed directly from the king, and they were answerable directly to him. This closely centralized form of government provided the great strength of the kings of the 4th dynasty. All the important officials of the time, whether their duties lay with national or provincial matters, fulfilled their offices at the royal residence, where they could be observed and prevented from becoming too powerful. Throughout Egyptian history the periods in which the country was strongest were those in which the ruler held the reins firmly in his own hands, curbing the activities of his provincial officers. The physical nature of Egypt, a land that for 500 miles (800 kilometres) had length but scarcely any breadth, rendered it difficult to rule, even under the most favourable conditions. A king who delegated control in the nomes to powerful local officials courted disaster.

Centralized government

Some idea of the artistic quality, refined taste, and superb workmanship of the products of the 4th dynasty can be gained from the residual funerary furniture and ornaments found in the second tomb of Hetepheres, the mother of Khufu, which that king had transferred to Giza from Dahshūr after the burial had been found plundered. Otherwise the majority of tombs of this time, whether royal or private, have yielded little, apart from fine sculpture and inscriptions of a funerary character. The great cemeteries at Giza, laid out around the pyramid of Khufu, reflect vividly the way everything circulated around the king. These cemeteries, with neat rows of mastaba tombs of the princes, notables, and high officials of the court, provided the means by which the king's servants were kept under control even in death. All the evidence suggests that it was in Khufu's reign that Egypt was most strictly centralized. The king, the living Horus, was Egypt; everyone else was subservient; everything planned was for the glory of the king; everything completely reflected this glory.

The Great Pyramid at Giza

The Great Pyramid is in every way the embodiment of this autocratic idea. It also offers the complete demonstration of what can be done when all resources are controlled by one man and directed solely for his purposes. In a society like that of Egypt at this remote time, the Great Pyramid could only have been built if national resources were concentrated and used with great efficiency. It is now thought that the construction of this pyramid was not effected by slaves but by the ordinary peasants of Egypt, employed in the months of the inundation when work on the land was impossible. Comparatively small gangs of quarrymen cut stone throughout the year; and it was moved by the bulk of the labour force during the inundation, when transport by water over the flooded land was relatively easy. Nevertheless, the transporting, preparing, and laying of about 2,300,000 blocks of an average weight of 2½ tons was no small task of organization; it could not have been completed without first-class planning. The completed monument on the desert plateau at Giza testifies to the efficiency of the whole operation.

Only the smallest of indications suggest that important public works other than funerary monuments were carried out during the 4th dynasty. But inscriptions in some tombs show that much effort was directed into the agricultural activities of the land—the improving of irrigation, of crops, of cattle; the farming of great estates in the Delta. Such unspectacular activities did not form part of the public image of the dynasty's kings, but they undoubtedly contributed immensely to the prosperity of the land and to the happiness of its inhabitants.

Khufu's successor, Redjedef, may have been an usurper of the throne. Little is known of his reign except that he probably supervised the funeral of Khufu and built his own pyramid at Abū Ruwaysh, a few miles to the north of Giza. After about nine years he was succeeded by Khafre, a younger son of Khufu, who was a king more in the tradition established for the dynasty. Khafre's pyramid at Giza is only a little smaller than that of Khufu; very considerable remains have survived, both of the funerary temple beside the pyramid and of the so-called valley temple on the edge of the desert escarpment, in which the final obsequies were celebrated before the royal burial took place. The vast granite blocks that make up most of the surviving parts of the valley temple present a grim and awesome aspect and also show how rapidly Egyptian stonemasons had developed the craft of stoneworking and how ready the Egyptian architects were to make use of intractable materials. Near the valley temple is the great Sphinx, generally thought to have been cut from the living rock in Khafre's reign as a symbolic guardian of the royal necropolis. Both Khufu and Khafre were remembered as hard and difficult kings in traditions that survived until Greek times. It seems not improbable that the immense resources in material and manpower needed to build their funerary monuments impoverished the country and imposed great strains on the people. They clearly attempted to do more than was reasonably within the competence of their times, both in building bigger than ever before and in using materials that required great effort to work. After their time such display and virtuosity were much modified. Menkaure, who built his pyramid at Giza like his great predecessors, was content with something quite modest; and Shepseskaf was satisfied with a stone-built mastaba, admittedly of great size and embellished with granite, at Ṣaqqārah.

Development of stoneworking

In many ways the 4th dynasty marks a summit in the history of Egyptian achievement, of which the great monuments provide the most obvious testimonies. More is revealed by the remarkable sculptures that dignified both the royal monuments and the tombs of nobles and high officials. This was the period of strong, impressive statuary, of portraiture, and of wonderfully subtle carving of hard stones. They sprang from a situation in which the king, the centre and pivot of the realm, was supreme. As the embodiment of divine royalty, he controlled everything. Such a powerful situation could not last for long; it could not easily be improved upon, but it could deteriorate.

The 5th dynasty. No contemporary records preserve any account of the events that led to the change of dynasty, which occurred in about 2494 BC. The change,

however, was very distinctive and marked by political and religious developments of far-reaching consequence. A romanticized tradition concerning the change is preserved in a story according to which the first three kings of the 5th dynasty were the sons of the wife of a priest of Re (Ra) and of the god Re himself. This tradition finds its source in the undoubted predominance given by the kings of the new dynasty to the worship of Re, the sun god, whose principal shrine was at Heliopolis, a few miles to the north of Memphis on the eastern side of the Nile. The adherence to Re was further emphasized by the regular adoption by the 5th-dynasty kings of the title "'Son of Re," which had only occasionally been used before. From the 5th dynasty this title and its concomitant name, in a cartouche, became a constant element in the royal titulary. Userkaf, the first king of the 5th dynasty, also built a special sun temple in honour of Re at Abū Jirāb (Abu Gurab), some miles to the south of Giza; five of his successors followed his example.

Worship of Re

The kings of the dynasty built pyramids at Abū Ṣīr and Ṣaqqārah, but in these they scarcely emulated the works of their predecessors. But if the pyramids of the 5th dynasty were small, they were made unusually handsome and interesting by the varied architectural detail of the dependent temples and by the fine reliefs with which they were decorated. Although they are now much damaged and largely lost, these reliefs reveal some of the activities in which the kings of the dynasty engaged. From the pyramid of Sahure, the successor of Userkaf, it emerges that a large punitive expedition had been sent against the Libyans, in the course of which much booty was taken; other scenes suggest expeditions perhaps by land and sea to Syria. The activities of Sahure outside Egypt are confirmed by entries on the Palermo Stone recording the bringing of produce from Syria and from Punt (an exotic, unidentified southern land, possibly part of Somalia); evidence of operations during Sahure's reign has also been found in Nubia.

Scenes of the smiting of foreign enemies regularly decorate royal funerary monuments in this dynasty and they soon become stereotyped and conventional. In consequence, it is hard to judge to what extent they truly record events that actually took place. In later times such scenes undoubtedly were wholly conventional and magical in intention; that they may have retained an element of truth in all earlier cases may be postulated. Inscriptions in Sinai show that at least four kings of the 5th dynasty sent expeditions there, and a text of Djedkare Izezi, the eighth king of the dynasty, preserves the first detailed account of the personnel making up an expeditionary force. Other inscriptions record forays into Nubia for raw materials and perhaps also for military purposes by this same Izezi.

Some of the most interesting scenes from the royal monuments of the 5th dynasty occur in the sun temple of Neuserre, the sixth king of the line. Here are shown episodes in the celebration of the Sed festival of the king—the ceremony by which an Egyptian monarch renewed his royal power after many years (perhaps 30) on the throne. The Sed festival was of great antiquity and may have had its origin in a barbaric, primitive custom of slaying the ruling monarch after a certain time in order to avoid having the throne occupied by an elderly, useless, infertile ruler. Buildings that can clearly be associated with the Sed festival were included within the enclosure of the Step Pyramid of Djoser at Ṣaqqārah.

Modification of Egyptian government in the 5th dynasty

The style of Egyptian government was modified during the 5th dynasty, much more freedom being granted to the nobility and high officials. Devolution of power to provincial administrators weakened the central hold on the country; highest office was no longer restricted to members of the royal house. In death high officials were allowed to enjoy more individual and lavish tombs than formerly. From the lively scenes carved on the chapel walls of these tombs, a vivid picture of the daily life on the great estates can be obtained. In the inscriptions set up in their tombs the same officials were able to record their deeds and honours.

Scribal activity flourished as never before, and from this time has come the earliest surviving collection of inscribed papyri. They were found in the funerary temple of Neferirkare, the third king of the 5th dynasty, and were written in the reign of Djedkare Izezi. Relating to the administration of the temple foundation, they contain much material about temple ceremonies, priestly duties, temple equipment and its periodic inspections, income and expenditure—in fact all the details concerning the running of a large establishment of many years' standing. The documents produce a profound impression of careful and well-organized administration.

With regard to religion and to an understanding of the peculiarly complicated beliefs concerning the king and his destiny, the most important written records of the 5th dynasty are the Pyramid Texts, first inscribed monumentally in his pyramid by Unas, the last king of the dynasty. This body of religious texts, consisting partly of ancient incantatory hymns and partly of more recent invocatory utterances designed to help the king achieve his solar destiny, was compiled for royal use only. The humble Egyptian could scarcely expect to share in such an apotheosis; his expectations in death were more modest. But already the conception of a judgment of the dead by the god Osiris was gaining ground and providing a form of hope for posthumous grace. The possibility of enjoying some kind of identifiable existence after death added a new dimension to the spiritual life of the Egyptian, who was already finding life on earth considerably freer and easier than had his ancestors. This expansion of an individual's potential opportunities was to increase greatly during the 6th dynasty and was ultimately to become a significant element in the dissolution of central power at the end of that dynasty.

Major religious texts

The 6th dynasty. As is so often the case regarding the first 1,000 years of Egyptian history, the most positive information about the reign of Teti, first king of the 6th dynasty, can be derived from the burials of high officials. Why a new dynasty began with Teti in about 2345 BC is not known, but the later king lists suggest that a new epoch began with his reign. In the shadow of his own modest pyramid at Ṣaqqārah, two of his viziers, Kagemni and Mereruka, built their mastaba tombs. In the proximity of their tombs to that of their king, they might seem to be following the custom of the 4th dynasty nobles, who derived what advantages they had in death from a burial close to the pyramid of their royal ruler. In the case of Kagemni and Mereruka, however, their tombs seem so placed as if to vie with that of Teti. Already in the 5th dynasty great nobles had been buried in tombs with elaborate, well-decorated rooms in the superstructures above the burial chambers. But such tombs were tactfully built apart from the king's pyramid. Teti's viziers seem to flaunt their own power blatantly by their display. The two tombs are huge, that of Mereruka in particular having more rooms than any other Old Kingdom mastaba. The varied scenes that decorate the walls of these rooms demonstrate clearly how powerful Mereruka was. No informative texts tell of his career, but little imagination is needed to appreciate that the vizier had in the 6th dynasty attained a position which was closer than ever before to that of the king in actual power.

Decentralization of power

The vizier, however, was not the only official to enjoy power and influence. Decentralization of administration led to the growth of provincial centres as independent focuses of power. This decentralization was based on the system of nomes, and the nomarchs were the agents of royal rule throughout the land. They administered justice locally, supervised irrigation, saw to the rehabilitation of the land after the annual flood, maintained the nome sanctuaries, raised men for military and other expeditions as directed by the king, and generally looked after the welfare of the inhabitants of their districts. These high officials were not buried in the royal necropolis; they had developed roots in their provincial homes, and they built their tombs nearby. In their tombs—often decorated in unusual ways and sometimes in a gauche, provincial style—they felt free to inscribe texts of a more personal nature than their ancestors had ever

dared. They described their principal triumphs and extolled without shame their own good qualities. It emerges that nomarchs could institute important activities in quarries and even undertake expeditions; there is always the implication that everything is done in the king's name, but this implication may in some cases have been more a fiction than a true expression of fact. In addition to such freedom of action, the successful, dutiful noble would also expect rewards from the king of a kind unheard of in earlier times.

Served by active, ambitious officers, who for most of the dynasty appear to have served their masters with loyalty, the kings of the 6th dynasty felt capable of entering upon continuous activity in foreign countries. The biographical inscriptions in private tombs tell of many enterprises. Teti set the example; his agents visited Byblos and, probably, Punt; they traded with Nubia and exploited the quarries in the Eastern Desert. The officers of Pepi I continued these activities on his behalf and extended their attentions eastward to the mines of Sinai and into Palestine, where military action was conducted by sea and land. Merenre, son and successor of Pepi I, who may have served as co-regent with his father for a few years, records a visit to the southern boundary of Egypt proper at Elephantine to receive the homage of Nubian chiefs. His personal interest in the land to the south typified the principal concern of foreign policy during the 6th dynasty—the development of trade with Nubia.

Trade with Nubia

It is arguable that this exploitation of trade with Nubia was the direct result of another development—the appointment of the nomarchs of Elephantine as governors of Upper Egypt, with exceptional powers over the southern nomes of Egypt and with a commission to lead expeditions into Nubia. Cause and effect cannot be disentangled now, but it is evident that a powerful noble at Elephantine would seek to enhance his position by taking full advantage of his opportunities to march southward. Trade with Nubia yielded ivory, incense, fine woods, oil, and animal skins; later it was to yield gold as well. But trade in Nubia was hazardous, so caravans needed protection. The governor of Upper Egypt, therefore, had to raise troops and maintain a garrison ready to meet emergencies. He was ideally placed to improve his own position both directly and indirectly by gratifying the king through his activities. Thus the governor Harkhuf ingratiated himself with the child-king Pepi II by acquiring a dancing dwarf for him on one of his expeditions to Nubia.

Pepi II, coming to the throne in about 2294 BC at a very early age, is reputed to have reigned for 94 years. His was the last effective reign of the 6th dynasty; in it there took place many activities characteristic of the dynasty, but in it also a fatal weakness developed, which ultimately led to a complete breakdown of central government. The existence of many tombs of important provincial officials shows that for much of Pepi II's reign there was no noticeable diminution in the style of life and control in the country. The funerary monument of the king himself equally testifies to the fact that he came to the end of his long reign without apparent mishap. Nevertheless, within a few years of his death, Egypt was a divided country.

Division of Egypt

The First Intermediate Period (c. 2160–c. 2040 BC). The weakness that led to the dissolution of centralized control after the reign of Pepi II was compounded of several elements, of which one was political and another religious. The gradual decentralization of government and the consequent increase in the power of provincial nobles has already been noted. The culmination of this movement seems to have coincided with the end of the reign of a very old king. In addition, the temper of the times had been much affected by the growth of the religious ideas associated with Osiris, to the detriment of the old, authoritarian, state religion of Re, in which the king was central and omnipotent. At the same time life in Egypt had become much more humane for the peasant as well as for the noble; much emphasis was placed on justice and moral virtues in the inscriptions of the nomarchs. Egyptians had become more conscious of the possibility of happiness in the earthly life and of a dignified existence in the life to come. These desirable changes in the Egyptian way of life seem not to have brought contentment, however, but instead a loss of orientation and troubled consciences.

The physical and mental anguish brought about by the crisis through which Egypt passed at this time is reflected in literary compositions, in which a doleful picture is painted of the land. For the first time men considered their human lot in a thoughtful and even pessimistic way. The happy, carefree attitude found in so much Egyptian art of earlier and later periods is absent. The malaise was general; the country had lost its sense of direction, and the struggle for power was on. The sequence of events at this time is hard to determine. It is unlikely that foreign invaders contributed to the overall disruption. Some infiltration undoubtedly took place into the Delta from Asia and also, possibly, from Libya, but the numbers involved were probably not great. Politically they may have been influential, but their presence was a symptom of the unrest rather than a cause.

The 7th and 8th dynasties. Attempts to reconcile wholly the dynastic traditions recounted by Manetho with the names in the king lists and the surviving monuments have been unsuccessful. There are, however, patches of firm ground in the morass of uncertainty; inscriptions found at Coptos in Upper Egypt give substance to kings ruling at Memphis and controlling at least part of Upper Egypt. These kings, none of whom seems to have reigned more than a few years, may be identified as the 8th dynasty. The preceding 7th dynasty may have been nothing more than an ephemeral series of princely nobles who attempted to carry on a form of royal power, also from Memphis. Meanwhile in the country the general collapse of authority led to a proliferation of local rulers, grouping and regrouping in alliances of mutual protection or aggrandizement.

Proliferation of local rulers

The 9th and 10th dynasties. Out of this turmoil the most positive coalition to emerge was based on the 20th nome of Upper Egypt, the Heracleopolitan nome, the ruler of which at this time (about 2160 BC) was Akhtoy (Achthoes). He declared himself king of Egypt and began to win over to his side by energetic methods the neighbouring nomes. Gradually he extended his power to the Delta and southward to Elephantine. His victories were not, apparently, maintained by his immediate successors, who made up the 9th dynasty. The situation in Egypt remained disturbed, although it appears, from surviving literary texts of the Middle Kingdom, that the Heracleopolitan rulers were able to support a court in which literature could flourish. Nevertheless the success of the 9th dynasty was limited, and in about 2130 BC the 10th dynasty, an extension of the 9th, succeeded to power at Heracleopolis. The change may have been due to a deterioration in the fortunes of the earlier dynasty, brought about by the rise of a new grouping of nomes in the south led by the nomarchs of Thebes.

A struggle for control in the southern part of Upper Egypt had resolved itself into a conflict between Thebes and Edfu. Theban victory in time led to an inevitable clash with Heracleopolis. The kings of the 10th dynasty seemed well-established in their realm; they even conducted expeditions to Syria. But the southern threat was considerable.

The 11th dynasty. The first Theban to claim the title "king of Upper and Lower Egypt" was Sehertowy Intef. He and his successors were to establish the new 11th dynasty in Upper Egypt, which in turn was to oust the vigorous Heracleopolitan line completely. Little in the known early history of Thebes hints at the power that was to emerge toward the end of the 3rd millennium BC. Nothing especially distinguishes the Old Kingdom nomarchs of Thebes from their contemporaries elsewhere. Sehertowy Intef's father Mentuhotep II was traditionally credited with establishing the victorious line of the 11th dynasty, but, as has been seen, he was not the first to assume the royal titles.

The three 11th dynasty kings named Intef were periodically engaged in extending their control northward, eroding the territory nominally under the sway of the kings at Heracleopolis. But the struggle was not continuous. References in texts suggest that there were long periods of relative peace, in which trade continued between south and north. The situation, however, was unsatisfactory for Egypt as a whole; and the land suffered in consequence, particularly because no general policy for irrigation could be enforced. Inscriptions of the period speak of famine and of steps taken by local officials to combat the shortages. Intef II ruled for more than 50 years and succeeded in establishing a fairly firm frontier north of the Thinite nome in which Abydos lay.

The end of the struggle came eventually in the reign of Mentuhotep II, who came to the throne at Thebes in about 2060 BC. An insurrection in the Thinite nome seems to have provoked the final clash. The details of the hostilities have not been preserved, but it is plausibly thought that the death of Merikare, the last-but-one ruler of the 10th dynasty, may have left the northern regime in a parlous state politically. The Thebans were now set on a victorious course, and the final defeat of the Heracleopolitans took place in about 2040 BC. Mentuhotep II had reunited Upper and Lower Egypt under a single king; he had founded the Middle Kingdom. In retrospect the Egyptians of the New Kingdom linked his name with those of Menes and Ahmose—the three were unifiers of the Two Lands.

Reunification of Upper and Lower Egypt

THE MIDDLE KINGDOM AND THE SECOND INTERMEDIATE PERIOD

The Middle Kingdom (c. 2040–1786 BC). Mentuhotep II marked the reunification of Egypt by adopting a new Horus name, Smatowy, which means "He who unites the Two Lands." While it is known that the reunification was secured only by force, there is no evidence to suggest that the new, effective king of Upper and Lower Egypt imposed a harsh rule on the parts of the country not formerly under his control. Support for the Heracleopolitan house was a political matter, as it was for the Theban house. No rival ideologies were involved in the struggle; throughout its ancient history the two conflicting forces were toward unity and disunity. A united Egypt functioned better and provided superior living conditions for peasant and noble alike; consequently the ending of disunity was undoubtedly welcomed by the majority of Egyptians, who would give no trouble to the new regime if it functioned well.

Reorganization and expansion. All the surviving evidence suggests that Mentuhotep II set about to reorganize the land with great energy, and he soon was able to undertake expeditions into Nubia, Libya, Syria, and Sinai. To satisfy the revived needs of sculptors and architects, he reopened many of the quarries, which had been little exploited for many years. He paid particular attention to Nubia, where an independent kingdom had been established in the days when expeditions southward from Elephantine were discontinued. In accord with the martial character of the times, an effort seems to have been made to occupy the northern part of Nubia. It was no longer enough just to control the trade routes and to police the oases in the Western Desert from which trouble might come.

Foreign expeditions under Mentuhotep II

The active foreign policy of Mentuhotep II was continued by his successor Sankhkare Mentuhotep III, whose principal claim to fame lies in the reopening of the transdesert route from Coptos through the Wadi Hammamat to the Red Sea, from which expeditions could be dispatched to Punt. This approach to Punt may have been an innovation of this reign; for the voyages, large boats of the kind normally found on the run to Byblos were employed. The quarries of the Wadi Hammamat contain many inscriptions of royal officials who came there in the late 11th dynasty. One such official, sent to obtain stone for the royal sarcophagus by Mentuhotep IV, bore the name Amenemhet. He was vizier and governor of Upper Egypt, and he apparently toppled his royal master to become first king of the 12th dynasty in about 1991 BC. The change seems to have been accompanied by some violence, but the struggle may have been more between Amenemhet and other powerful nobles than between Amenemhet and Mentuhotep.

The 12th dynasty. Under Amenemhet began one of the most brilliant periods in the whole of Egyptian history. The kings of the 12th dynasty, fired by a remarkable spirit and endowed with great administrative talents, succeeded in inspiring their subjects to great deeds in all fields. Politically, the 12th dynasty rulers were most adroit in using and then discarding institutions that could be manipulated for their special purposes. The initial success of Amenemhet seems to have depended to some extent on support from powerful nomarchs; in consequence he reinforced the nome system by securing provincial boundaries and re-establishing powers and privileges. With their positions enhanced in this way, the nomarchs became influential and, in time, dangerous. Eventually their power was suppressed again by Sesostris III, but for the time being Amenemhet was happy to reward his loyal nobles. A further shrewd move was to establish a new capital in the north for the reunited kingdom. Although a native of Upper Egypt and a devotee of the god Amon of Thebes, who gained new and significant importance in the 12th dynasty, Amenemhet appreciated the need for a capital from which he could rule all Egypt efficiently. The new capital was built some miles to the south of Memphis and was called Itj-towy, "Seizer of the Two Lands." In the neighbourhood of Itj-towy (near modern al-Lisht) he built his pyramid tomb, and, in the Old Kingdom manner, his courtiers constructed their mastabas around it. In foreign affairs a more positive policy was adopted toward Nubia. Egypt's need of southern products and the necessity of protecting the trade routes led Amenemhet to annex the northern region of Nubia and to place fortresses in the Second Cataract area. The use of permanent fortifications also provided a solution for the perennial problem of Asiatic infiltration into the Delta; in the Wadi Tummilat on the eastern edge of the Delta the "Walls of the Ruler" were constructed—a fortified position that remained a strategic asset for many years.

Increased power of monarchs

Amenemhet I was also an important innovator in another respect. After 20 years of rule he made his son Sesostris co-ruler with himself, and for ten years they ruled together. In this way he ensured that Sesostris would succeed him and so provided a means of continuity for his line, which contributed greatly to the stability of the state. The practice of co-regency was followed by his successors in the 12th dynasty, and it was resumed as an important element of government in the New Kingdom. The co-regency of Amenemhet I and Sesostris I undoubtedly prevented trouble when the old king was assassinated while Sesostris was on campaign in Libya. Sesostris, hearing of his father's death, returned in haste to the capital, anticipating the takeover planned by the conspirators. His prompt action established him as a strong and astute ruler.

For the rest of his reign Sesostris was able to concentrate on reviving Egypt's greatness. He sent punitive expeditions into Nubia and Libya and secured peace in those quarters; he established farther outposts in the south; he developed diplomatic relations with western Asiatic countries; he opened up and actively exploited many quarries. Internally, the effects of his policy were seen in the building activities he initiated throughout the land. Unhappily, only fragments of the structures erected in his reign have survived, apart from an exquisite small shrine recovered from the filling of a pylon of later date at Karnak.

The internal development of Egypt continued increasingly in the reigns of Sesostris II and Amenemhet II. Perhaps the most important project begun at this time was the reclamation of land in the Fayyūm depression—an area neglected in earlier times—which was to become one of the most fertile provinces of the country. Associated with this project was the fostering of the cult of Sebek (Sobk), the crocodile god, in Shedet, the capital of the Fayyūm. Sebek was already much honoured dur-

ing the 12th dynasty at another cult centre a few miles to the south of Thebes. Prosperity, which accompanied the successful policies of the early 12th dynasty kings, attracted to Egypt many foreigners, especially Asiatics, who were now to be found in domestic and artisan situations throughout the land. Trade and diplomacy both with Asia and with the Aegean world flourished, and for the first time Egypt was exposed to foreign influences and ideas in a significant way.

Sesostris III, who became king in about 1878 BC, was the greatest ruler of the 12th dynasty. His energy was especially needed to deal with situations that had developed during the peaceful reigns of his predecessors. Renewed trouble in Nubia obliged him to take various steps to improve arrangements for the control of that land and to facilitate communications. Armed forays were followed by the building of a series of strong forts in the Second Cataract region, the establishing of permanent garrisons and customs posts to control the entry of foreigners, and the cutting of channels through the granite rapids of the First Cataract to enable ships to sail between Elephantine and the south.

Sesostris III's reforms were far-reaching for the future of government in Egypt. The power of the nomarchs, boosted by great responsibilities placed on them early in the dynasty, had again developed to a point where some clearly presented a threat to the state. By means that are no longer clear, Sesostris III clipped their wings completely; the great provincial houses suddenly came to an end. In place of the old system, a new bureaucratic regime was created, based on the capital at Itj-towy. The whole land was divided into three departments, each controlled by high officials responsible for law, agriculture, finance, and general administration; the new system came under the jurisdiction of the vizier.

The golden age of Sesostris III and Amenemhet III

The golden age made possible by the activities of Sesostris III continued through the reign of his son Amenemhet III. With peace abroad, and with the possibility of insurrection at home stifled, Egypt was able to enjoy an unprecedented period of prosperity. The surviving monuments testify in no uncertain way to the artistic brilliance of the period. Sculpture reflected the level of achievement; the fine royal statues of the two reigns are distinguished by a spirituality and humanity quite lacking in the royal sculpture of earlier periods. The kings are not shown as quintessential royalty—divine, aloof, unemotional. Likewise the statues of private persons have qualities of individuality never before found in Egyptian sculpture. But apart from sculpture, the surviving products of order arts and crafts show complete mastery of a great variety of materials. In many respects this was a great age in which the Egyptian emerged as a literate, humane person, appreciative of fine and beautiful things. This was the time when many of the classics of Egyptian literature were written, when the ability to read and write was honoured particularly, and when scribal activity, stimulated by a growing bureaucracy, increased in public and private life. The cult of Osiris, which had become the dominant element in funerary religion, gave hope of salvation for all; everyone who could afford it sought to enjoy the closest communion with the god by setting up a cenotaph, or memorial stela, at the most sacred sanctuary of the god at Abydos.

The 45-year reign of Amenemhet III provided such a long period of peace and prosperous growth that its effects were not easily eradicated by the unstable reigns that followed. The energies of the Egyptians had been channelled so successfully into large-scale, profitable activities that the advantages derived therefrom were not willingly discarded. Outstanding among the public works of the period was the further development of the Fayyūm, where by careful control of irrigation large tracts of land were recovered for cultivation. The attachment of Amenemhet III to that region led him to construct his pyramid at Hawāra, near its northern entrance. Near the pyramid he built a vast structure known in classical times as the Labyrinth, which may have been partly funerary temple and partly administrative centre. It was the great memorial by which the king would be remembered. For many centuries it fulfilled this function, but now only the smallest traces indicate where it once was.

Amenemhet IV and Queen Sebeknefru, the two last rulers of the 12th dynasty, were able in their short reigns to do little more than maintain the character of rule so brilliantly instituted by Sesostris III and Amenemhet III. Egypt's reputation stood high among the nations of the ancient world; its envoys and traders were welcomed in Asia and Crete. The great trading post of Karmah at the Third Cataract in Nubia was a flourishing entrepôt for goods from tropical Africa; the demands of its industries and crafts made Egypt a good customer. Chiefly by peaceful activities, after the more belligerent policies of Sesostris III, did Amenemhet III achieve this peak of reputation for his land. The prosperity did not go unnoticed by foreigners, who were inevitably attracted toward a land offering great opportunities. They provided new skills and techniques; they also introduced an alien element, which in time was to have dire effects on Egypt politically.

Egypt's world reputation at the end of the 12th dynasty

The Second Intermediate Period (1786–1567 BC). The Second Intermediate Period—the time between the end of the 12th dynasty and the beginning of the 18th dynasty—was very different in character from the First Intermediate Period. The First Intermediate Period, although a very confused time, was distinguished more by political troubles than by social upheaval; but the Second Intermediate Period was a time when central control collapsed, and with it the whole fabric of Egyptian life. The reasons for the dissolution of the centralized, well-administered state of the 12th dynasty are to be found, first, in the nature of the bureaucracy set up after the abolition of the nomarchic system and, second, in the growth of foreign enclaves in the Delta. Under the new system of internal government the greatest power in the land rested in the hands of the vizier, the king's principal officer of state.

The 13th–16th dynasties. During the 13th dynasty, which is credited by Manetho with 60 kings, the vizier seems to have been the person who provided not only the power for ruling but also continuity. A great vizier like Ankhu was more important than Sebekemsaf I and Sebekhotep III, the kings he theoretically served. It has been suggested that the kings of this dynasty were appointed or elected for short terms of office. Nevertheless, there is plenty of documentary evidence to show that the state continued to operate efficiently for many years and that the influence of Egypt was still recognized in Syria and Nubia.

Signs of disintegration were already apparent in the emergence in the western Delta of a small but tenacious regime centred on Xois. Manetho describes this line of petty rulers as the 14th dynasty; it had, according to him, 76 kings, and it lasted 184 years. The existence of this line is not confirmed by much evidence, and it can only have been of local importance. More significant were developments in the eastern Delta, where, as in the First Intermediate Period, had grown up concentrations of Asiatics, organized probably on a tribal basis and controlling their domestic affairs with very little reference to the central government of Egypt. The chiefs of these Asiatics were known in Egyptian as *heqau khasut*, "princes of foreign uplands," and it is from this designation that the Manethonian term Hyksos is probably to be derived.

Although the kings of the 13th dynasty remained in general control of most of Egypt for the first 100 years of their rule, there can be no doubt that their authority began to run rather sluggishly in the north from about 1720 BC, when the Asiatics occupied the town of Avaris in the eastern Delta and began to foster the worship of Seth, the local deity, as their own particular cult. The old idea that the Hyksos regime was established as the result of an invasion by Asiatic tribes is now generally discounted in favour of the view that it evolved from a confederation of small tribal groups already settled in the Delta from the time of the 12th dynasty. The growth of the Hyksos power was gradual, and it increased significantly as central control weakened. The steps by which

The growth of Hyksos power

this power developed are not known. But in about 1674 BC Memphis fell to them. At that time the Theban king was Dudimose and the leader of the Hyksos, according to Manetho, was Salitis. It is now thought that this Salitis was Mayebre Sheshi, the first Hyksos ruler to assume the formal trappings of an Egyptian king, to enclose his name in a cartouche, and to use the Egyptian royal titles. He is taken to be the founder of the 15th dynasty, the "Great Hyksos." Perhaps contemporaneously with this line there existed in the Delta also the 16th dynasty, a second Hyksos line; but beyond some of their names scarcely anything is known of the kings that made up this dynasty, and they may have been ephemeral.

Hyksos domination. The extent of Hyksos rule in Egypt has not been established with certainty. The discovery of objects with Hyksos names in Upper Egypt and in Nubia as far south as Karmah has led some historians to conclude that all Egypt was at first conquered by Salitis, as later tradition reported, and that the later Hyksos preferred to confine their active control to the Delta and Middle Egypt. Alternatively, it is suggested that the Hyksos only exercised a nominal suzerainty over Upper Egypt and that the Theban line of kings continued to rule their reduced kingdom uninterruptedly. The situation in Egypt may, however, have been very different from that which was described in later tradition. It is possible that once the Hyksos were in firm control of the north, they established a *modus vivendi* with the Theban kings, which allowed much freedom for travel and trade between the two parts of Egypt and also with Nubia.

Hyksos rule was not, apparently, inimical to Egyptians or to the Egyptian way of life. Under the Hyksos kings no attempt was made to suppress Egyptian religion or culture; in fact, evidence suggests that Egyptian culture flourished more in the Hyksos half of the country than in Thebes at this time. As far as Nubia was concerned, the political developments in Egypt allowed local Nubian princes to set up an independent kingdom, which was supported in alliance by the Hyksos. Relations between the Nubian princes and their Theban neighbours may have been friendly; the evidence of Nubian burials throughout Upper Egypt in graves known as "pan-graves," shows that large numbers of southerners entered Egypt in the late Middle Kingdom and Second Intermediate Period, possibly to serve as mercenaries under the Theban kings. Their rather primitive grave goods form a marked contrast to the highly developed possessions of their Egyptian contemporaries.

The Hyksos rulers Khayan and Auserre Apopi I, particularly the latter, who ruled Egypt for at least 50 years, maintained a rule that was strong and largely Egyptian in character. Good relations were fostered with foreign countries, objects bearing Khayan's name having been found as far away as Baghdad and Knossos. These kings used the title "king of Upper and Lower Egypt," and it is possible that they even allied themselves with the Theban house.

New rulers at Thebes

The 17th dynasty. A new line of rulers had meanwhile assumed control at Thebes, beginning (in *c.* 1650 BC) what Manetho called the 17th dynasty. Although probably descended from the kings of the 13th dynasty, they may be distinguished from their predecessors by being liberated from the control of high officials. At first they were unable to achieve much more than the building of power within the reduced Theban domain. Their situation was similar to that of the Theban nomarchs in the First Intermediate Period, before the reunification of the two lands by Mentuhotep II. By the reign of Seqenenre II, in about 1580 BC, the Theban rulers had so far improved their political position that a clash with the Hyksos became increasingly inevitable. The only record of the fighting that eventually broke out is contained in a literary composition of the New Kingdom. From this biased account it appears that the Hyksos king Apopi picked a quarrel with Seqenenre over a matter interpreted as a religious insult. In the ensuing struggle, no details of which have survived, it is possible that Seqenenre secured some local successes in Middle Egypt but may have lost his life. His mummy, which has survived, bears wounds which were perhaps obtained on the battlefield.

Hyksos–Theban war

Under Kamose, the son and successor of Seqenenre, began the ultimate clash between the Hyksos and the Theban kingdoms. It seems likely that some years had elapsed since the conflict between Apopi and Seqenenre. A contemporary account suggests that fairly peaceful relations existed for the time being, so that the Thebans were even able to pasture their cattle in the Delta. Pride, however, and the desire to reunite the whole of Egypt under a Theban king led Kamose to declare war on Apopi. Initial surprise brought considerable success. The Hyksos adherents in Middle Egypt put up little resistance. Kamose anticipated a move by Apopi to bring in help from his Nubian allies; Kamose also succeeded in penetrating as far as the Hyksos stronghold of Avaris. The final stages of Kamose's victorious campaign are not known, but it is possible that he was obliged to withdraw after Apopi had recovered from the surprise of the initial onslaught and successfully counterattacked. The end of Hyksos rule was, however, now in sight; while it was to remain for Kamose's successor, Ahmose, the first king of the 18th dynasty, to complete the expulsion of the hated foreigners, to Kamose belongs the credit for striking the first really victorious blow. (T.G.H.J.)

II. From the beginning of the 18th dynasty to c. 330 BC

THE NEW KINGDOM

The 18th dynasty. Although King Ahmose (ruled 1570–1546 BC) had been preceded by his older brother, King Kamose, Egyptian tradition regards Ahmose as the founder of a new dynasty because it was he who first unified Egypt under a native ruler. Continuing a practice inaugurated late in the 17th dynasty, Ahmose married his full-blooded sister Ahmose-Nofretari. Such consanguineous marriages were accorded important theological significance in that the queen was given the title of God's Wife of Amon. Further, they reflected a renewed emphasis on divine kingship, which had suffered during earlier periods. Although full-blooded consanguineous marriages failed to survive beyond the first two reigns of the 18th dynasty, the title of God's Wife was thereafter bestowed upon principal heiresses in childhood, and the pharaoh customarily married the most legitimate heiress to validate his right to the throne. Like her predecessors of the 17th dynasty, Queen Ahmose-Nofretari was an influential and highly honoured woman. A measure of her importance is her posthumous veneration at Thebes, where later pharaohs were depicted offering to her as a goddess among the gods.

Consanguineous marriages of the pharaohs

Ahmose. Upon his accession Ahmose had to expel the Hyksos from the delta and regain former Egyptian territory to the south. Destroying the Hyksos stronghold at Avaris, in the eastern delta, he finally drove them beyond the eastern frontier and then besieged Sharuhen (Tall al-Far'ah) in southern Palestine. Ahmose's officers and soldiers were handsomely rewarded with spoil and captives, who became personal slaves. This marked the creation of an influential military class. Later, Ahmose campaigned in the south as far as the Second Cataract (rapids) of the Nile, where a new temple was built at the old fortress of Buhen. For the administration of the regained territory he created a new office—overseer of southern foreign lands, which ranked second only to the vizier. Its incumbent was accorded the honorific title of king's son, indicating that he was directly responsible to the king as deputy, supervising military installations and the delivery of tribute.

The Hyksos domination of Egypt had not been as cataclysmic as Egyptian sources later tended to portray it; thus, the founders of the New Kingdom did not face such difficult problems of internal reconstruction as those at the end of the First Intermediate Period. The early New Kingdom bureaucracy was modelled after that of the Middle Kingdom. The vizier was the chief administrator and the highest judge of the realm. By the end of the 16th century BC the complexity of administration required two viziers, one for Upper and one for Lower

Administration

Egypt. During the 18th dynasty, young bureaucrats received their scribal education in the temple school. There was no essential cleavage between civil servants and priests, and state administrators frequently received priestly appointments (and vice versa). Early in the dynasty many administrative posts were inherited, but royal appointment of capable officials, often selected from military officers who had served the king on his campaigns, later became the rule. The trend was thus away from bureaucratic families and the inheritance of office.

Amenhotep I. Initially, Ahmose's son and successor, Amenhotep I (ruled 1546–1526 BC), directed his attention to the south, where, motivated by the desire to expand Egypt's frontiers, he pushed beyond the old Middle Kingdom boundaries. Such an incentive may also have prompted his little-known ventures in Asia, though in these he may have been responding to pressure from soldiers eager for more rewards. The emerging kingdom of Mitanni perhaps threatened Egyptian security to the north. Mitanni is mentioned on a stela of Amenemhat, who served Amenhotep I.

Foreign wars increased Egypt's wealth. The state god Amon-Re benefitted as the spoils of war entered the god's treasuries or were utilized to finance construction of sacred monuments at Thebes. The New Kingdom saw continued devotion to Amon-Re, whose cult gave the king, as his representative, the mission of expanding Egypt's frontiers. Under Amenhotep I the pyramidal form of royal tomb was abandoned in favour of a rock-cut tomb, which he hoped would provide a more secure burial place, and, except for Akhenaton, all subsequent New Kingdom rulers were buried in concealed tombs within the famous Valley of the Tombs of the Kings in western Thebes. Separated from the tombs royal mortuary temples were erected at the edge of the desert. Perhaps because of this innovation, Amenhotep I later became the patron saint of the workmen who excavated and decorated the royal tombs.

Thutmose I. Lacking a surviving heir, Amenhotep I was succeeded by one of his generals, Thutmose I (ruled 1525–*c.* 1512 BC), who had married the royal heiress and God's Wife Ahmose. The new king first directed his attention to maintaining military domination in the south. Assisted by able generals, he then executed a brilliant campaign into Syria and across the Euphrates, where he erected a victory stela near Carchemish.

Thutmose II. Although born of a minor wife of Thutmose I, Thutmose II's (ruled *c.* 1512–1504 BC) claim to the throne was validated by his marriage to the God's Wife Hatshepsut. In his first year of rule Thutmose II launched an attack against rebels in the south, wherefrom gold and other costly products, now vital to the economy, were obtained. During his reign there was still no forceful assertion of empire in Asia, military activity there being limited to a raid among the Bedouin, who were an irritation to overland trade; the port of Byblos (in Lebanon) supplied Egypt with pine timber, used, for example, in the construction of columned halls at Karnak.

Joint rule of Hatshepsut and Thutmose III. At Thutmose II's death his major queen, Hatshepsut, had only a young daughter; but a minor wife had borne him a boy, now nearly ten years old, who served as a priest in the Temple of Amon. This son, Thutmose III (ruled 1504–1450 BC), created the Egyptian Asiatic empire and became Egypt's greatest ruler. During his first two years as king Thutmose III theoretically controlled the land, but actually it was the mature Hatshepsut who governed as regent. In Thutmose III's second regnal year she boldly assumed the kingship herself. According to one version of the history of the event, the oracle of Amon proclaimed her king at Karnak, where she was crowned. A more propagandistic account, promulgated in texts and reliefs of her splendid mortuary temple at Dayr al-Baḥrī, ignores the reign of Thutmose II and asserts that her father, Thutmose I, announced her accession. Upon becoming king, Hatshepsut became the dominant partner in a joint rule that lasted until her death in 1482 BC; there are monuments dedicated by Hatshepsut that depict both pharaohs. She had the support of various powerful personalities, who significantly did not form a homogeneous faction. In styling herself king, Hatshepsut adopted the royal titulary but avoided the epithet mighty bull, regularly employed by other kings. Although in her reliefs she was depicted as a male, pronominal references in the texts generally reflect her womanhood. Similarly, much of her statuary portrays her as male, but there are rarer examples that render her as a woman. In less formal documents she was referred to as "King's Great Wife," while Thutmose III was "Pharaoh." There is, thus, a certain ambiguity in the treatment of Hatshepsut as king.

Hatshepsut's assumption of the kingship

Her temple gives the impression of a monarch concerned with pacific enterprises, such as the transporting of obelisks for Amon's temple and a commercial expedition to Punt. It has been suggested that her policy and art reflect a return to Middle Kingdom ideals. There is evidence of bellicose tendencies, however, and it is probable that she appeared on the battlefield in Nubia; as she grew older, it was natural that her participation in warfare lessened, so that her monuments generally lauded her ability in other directions. The notion of a struggle between a pacific queen backed by a peace party and a warrior king supported by a war party can no longer be maintained, nor does the romantic tale of Thutmose III's minority being filled with hatred of Hatshepsut really reflect the true situation (the persecution of Hatshepsut's memory was not pursued until late in his reign, and not all her officials were purged by Thutmose III at her death).

Thutmose III. During Hatshepsut's floruit Egypt's position in Asia deteriorated because of the expansion of Mitannian power and influence in Syria. Shortly after her death, the Prince of Kadesh, representing Mitannian interests, stood with troops of 330 princes of a Syro-Palestinian coalition at Megiddo; such a huge force was more than a defensive massing of troops, and probably the intention was to advance against Egypt.

Thutmose III proceeded to Gaza with his army and then to Yehem, subjugating rebellious Palestinian towns along the way. At a famous consultation with his officers concerning the best route to reach the coalition stationed on the other side of the Mt. Carmel ridge, the King overruled his officers' advice and selected a shorter but more dangerous route through the ʿArūnah Pass and then led the troops himself. The march went smoothly; and, when the Egyptians attacked at dawn, they prevailed over the enemy troops and besieged Megiddo. Egyptian sources describe the battle only briefly; but it must be considered one of the decisive ones in world history, because it was fundamental to the establishment of Egyptian Empire in Asia.

Establishment of an Egyptian Empire in Asia

Thutmose III meanwhile coordinated ancillary operations involving the landing of other army divisions on the Syro-Palestinian littoral, whence they proceeded inland, so that the total strategy resembled a pincer technique. The seige ended in a treaty by which Syrian princes swore an oath never to rebel against Thutmose III. Significantly, this oath was binding only upon the parties immediately concerned and not upon future generations. This reflects an aspect of Egyptian bureaucracy —that officials were bound only to the reigning pharaoh, and old appointments required reconfirmation upon the accession of a new king.

By the end of the first campaign Egyptian domination extended northward to a line linking Byblos and Damascus. Although the Prince of Kadesh still remained to be vanquished, Assyria sent lapis lazuli as tribute; Asiatic princes surrendered their weapons, including a large number of horses and chariots, at Megiddo. By contrast, Thutmose III took only a limited number of captives; and in this respect he was magnanimous, eschewing the large-scale deportations of prisoners. The King appointed Asiatic princes to govern the towns and took their brothers and sons to Egypt, where they were educated at the court. Most eventually returned home to serve as loyal vassals, though some remained in Egypt as

court pages. In order to insure the continued fealty of Asiatic princes, Egypt maintained garrisons that could quell insurrection and supervise the delivery of tribute. This organization was necessary in order to prevent an excessive drain on Egyptian manpower, for capable administrators were needed more at home than abroad.

Thutmose III conducted numerous subsequent campaigns in Asia. The submission of Kadesh was finally achieved, but Thutmose III's ultimate aim was the destruction of Mitanni. He used the navy to transport troops to Asiatic coastal towns, thus avoiding arduous overland marches from Egypt. His great eighth campaign led him across the Euphrates; although the countryside around Carchemish was ravaged, the city apparently was not taken, and the Mitannian prince fled to another land. The psychological gain of the eighth campaign was perhaps greater than its military success, for Babylonia, Assyria, and the Hittites all sent tribute in recognition of Egyptian dominance in Syria. Although Thutmose III never subjugated Mitanni, he firmly established an empire in Asia. This necessitated constant campaigning that contrasts with the forays of his predecessors. Egyptian royal inscriptions generally abound in exaggerations and pomposity; but the annals of Thutmose III are remarkably succinct and accurate, and autobiographies of his officials display a similar tendency toward factual reporting. The objectivity of narrative texts is a measure of the greatness of the King, who brought back to Karnak Asiatic flora and fauna, which were carefully depicted in his festival hall.

Amenhotep II. About two years before his death the aging king appointed his 18-year-old son, Amenhotep II (ruled 1450–1425 BC), as coregent. Just prior to his father's death Amenhotep II set out on a campaign to an area near Kadesh, in Syria, whose city-states were now caught up in the power struggle between Egypt and Mitanni; Amenhotep II killed seven princes, whose bodies he shipped back to Egypt to be suspended from the ramparts of Thebes and Napata in the Sudan. In his seventh and ninth years Amenhotep II made further campaigns into Asia, where the Mitannian king pursued a more vigorous policy. The revolt of the coastal city of Ugarit was a serious matter, because Egyptian control over Syria required bases along the littoral for inland operations and the provisioning of the army. Ugarit was pacified, and subsequently the fealty of Syrian cities, including Kadesh, was reconfirmed. The number of prisoners of war recorded for Amenhotep II's ninth-year campaign is an extraordinary 89,600. Although it had an estimated population of 4,500,000, the amount of free cultivable land in Egypt was relatively small; thus, the situation was economically unfavourable to the institution of large-scale slavery (the bulk of the land was tilled by native tenant farmers, who delivered from one-third to one-half of their crop to the landowners). Amenhotep II's enormous figure cannot represent a large-scale introduction of slaves into Egypt but, rather, probably a census of Syrians under Egyptian domination.

Amenhotep II's campaigns into Asia

Thutmose IV. Under Amenhotep II's son Thutmose IV (ruled 1425–1417 BC), the Asiatic empire was maintained but not expanded. The Mitannian king Artatama, having been successful against the Hittites, posed a problem for Egypt, and Thutmose IV sought to establish peaceful relations with him through a diplomatic marriage. Artatama gave his daughter in marriage, the prerequisite for which was probably an Egyptian concession clarifying which Syrian city-states belonged within the Mitannian sphere. This was the first of such diplomatic marriages, paving the way for the age of Amenhotep III, when the emphasis shifted from war to diplomacy and the enjoyment of the luxury of empire.

Foreign influences during the early 18th dynasty. During the empire period Egypt maintained commercial ties with Phoenicia, Crete, and the Aegean islands. The Egyptians portrayed goods obtained through trade as foreign tribute. In the Theban tombs there are representations of Syrians bearing Aegean products and of Aegeans carrying Syrian bowls and amphorae—indicative of close commercial interconnections among Mediterranean lands. Egyptian ships trading with Phoenicia and Syria journeyed beyond to the Aegean islands and Crete, a route that explains the occasional confusion of products and ethnic types in Egyptian representations. The most prized raw material from the Aegean world was silver, which was lacking in Egypt, where gold, especially from the Nubian mines, was relatively abundant.

One result of empire was a new appreciation of foreign culture. Not only were foreign *objets d'art* imported into Egypt but Egyptian artisans copied Aegean wares as well. Imported textiles inspired the ceiling patterns of Theban tomb chapels, and Aegean art with its spiral motifs and rendition of movement influenced Egyptian artists. Under Amenhotep II a deeper recognition of the value of things foreign is manifest in the acceptance of Asiatic gods in Egypt, where Astarte and Resheph became revered for their reputed potency in warfare; and, later, Astarte was honoured in connection with medicine, love, and fertility. Some Asiatic gods were eventually amalgamated with similar Egyptian deities; thus, Astarte was combined with Sekhmet, the goddess of pestilence, and Resheph with Mont, the war god. Just as Asiatics themselves tended to be accepted as members of Egyptian society and could on occasion rise to important positions, so their gods, though represented as foreign, were worshipped according to Egyptian cult practices. The breakdown of Egyptian isolationism and increased cosmopolitanism in religion were also reflected in Amon-Re's concern for the welfare of Asiatics.

Late in his reign Thutmose III extended the Egyptian boundary southward to the Fourth Cataract of the Nile. Egypt's superior military equipment, notably the horse and chariot, had already pacified the south, and only occasional forays into the desert were required to protect gold-mining operations. In Nubia there was peaceful symbiosis of Egyptians and Nubians, who gradually became Egyptianized—sons of chiefs were educated at the Egyptian court, some remaining as pages, others returning to Nubia to serve as administrators and be buried in Egyptian fashion. Gradually, Nubian fortresses lost their strategic value and became commercial and administrative centres. Open towns developed around the forts, and in several of the temples outside the walls the cult of the divine pharaoh was established. Lower Nubia supplied Egypt with raw materials: gold, semiprecious stones, and building stone; from further south came African woods, perfumes, oils, ivory, panther skins, and ostrich plumes. With the introduction of the shadoof, an irrigation device, Nubia's agricultural productivity increased, and Nubian farmers worked on lands belonging to the king or temples, raising grain for Egypt.

Extension of Egypt's boundary southward

Amenhotep III. Queen Mutemuia, a commoner, was the honoured mother of Thutmose IV's son Amenhotep III (ruled 1417–1379 BC), who acceded to the throne at about the age of 12. Amenhotep III soon wed a commoner, Tiy, who became his principal wife. This marriage represented a departure from the concept of God's Wife and the principle of marrying the royal heiress, who would become the chief queen. Earlier in the dynasty military men had served as royal tutors; but Tiy's father was a commander of the chariotry, and now the royal line was even more directly influenced by the military. In his fifth year Amenhotep III claimed to have achieved a considerable victory over Kushite rebels, but the Viceroy of Kush probably actually led the troops. Several temples, erected under Amenhotep III in the Sudan, attest to the prosperity of the south under Egyptian domination; peaceful relations also prevailed with Asia during this reign. A commemorative scarab from the king's tenth year announced the arrival of the Mitannian princess Gilukhepa, along with 317 women; thus, another diplomatic marriage helped maintain friendly relations between Egypt and its former foe. Another Mitannian princess was later received into Amenhotep III's harem, and during his final illness the Hurrian goddess Ishtar of Nineveh was sent to his aid. Although military activity was at a minimum, Egypt maintained garrisons of troops in Asia to deter local insurrection. At the expense of older bureaucratic families and the principle of in-

heritance of office, military men acquired high posts in the civil administration. Most influential was the scribe and commander of the elite troops Amenhotep, son of Hapu, whose reputation as a sage survived into the Ptolemaic period.

Amenhotep III sponsored much building, especially in the Theban area. At Karnak he erected the huge third pylon, and at Luxor he dedicated a magnificent new temple to the Amon of Opet. The King's own mortuary temple in western Thebes was unrivalled in its size; little remains of it today, but its famous Colossi of Memnon reflect a penchant for the colossal in art and architecture. One of these statues served as an object of public veneration, before which men could appeal to the king's *ka* (spiritual self), representing the transcendent aspect of kingship. In Karnak, smaller but exquisitely carved statues of Amenhotep, son of Hapu, were placed to hear the petitions of passersby.

Thutmose III had shifted the centre of administration to Memphis, though Thebes had retained its religious importance. Amenhotep III renewed the emphasis upon Thebes and erected a huge palace complex on the west side of the river. Among the highest-ranking officials at Thebes were men of Lower Egyptian background, who received tombs in the Theban necropolis that were both large and highly refined in their decoration. An academic quality is evident in the tombs, certain scenes of which were copied from Old Kingdom reliefs. The subsequent revolutionary art of the Amarna period perhaps reflects a reaction against the studied perfection of Theban artists. Antiquarianism is evidenced in Amenhotep III's celebration of his jubilees (anniversaries of his accession), which were performed at his Theban palace in accordance, it was claimed, with ancient writings. Tiy participated in these ceremonies connected with the renewal of kingly power. Although Amenhotep III's benefactions to Amon were many, he was not thereby placating a powerful priesthood at Thebes; in fact, the important post of second prophet of Amon was held by the Queen's brother, who was of military background. Amenhotep III's last years were spent in ill health. To judge from his mummy and less formal portraits of him from Amarna, he was obese when, in his 38th regnal year, he died and was succeeded by his son Amenhotep IV (ruled 1379–1362 BC), the most controversial of all the pharaohs.

Renewed emphasis upon Thebes

Amenhotep IV (Akhenaton). Problems surrounding the reign of Amenhotep IV, who in his fifth year of rule altered his name to Akhenaton, have been complicated by the possibility that a major portion of his reign was spent as a coregent with his father, a view unsupported by the weight of evidence. Akhenaton's earliest monuments are entirely conventional in their iconography and style. Certain high officials initially continued in the posts they had acquired under Amenhotep III, and the high priest of Amon functioned as late as Akhenaton's fourth year. In his first years a temple was erected to the god Re-Harakhti at Karnak. Although the style of art was conventional, the hawk-headed sun god was given a didactic name mentioning Aton, the solar disk. This term had long been in use, but under Thutmose IV there had been a reference to the Aton as a god, and under Amenhotep III instances of the Aton treated as a deity became more frequent. Akhenaton, therefore, did not create a new god but rather singled out this god from among others.

A major change occurred in about his fourth year, when, to the east of the great Amon temple at Karnak, a large temple to the Aton was erected. In this temple the radical art of the King's reign is found in its most extreme form, and large statues of Akhenaton depict him as the primordial god in a most bizarre fashion. Adorning the temple walls were scenes of the jubilee that the king cocelebrated with the Aton, whose names were written as a king's within cartouches. No anthropomorphic representations of the deity were used; the supreme god was depicted as a sun disk, from which arms bearing the symbol of life emanate. During the construction of this temple the cult of Amon and other gods was suspended, and the worship of the Aton in an unroofed sanctuary superseded that of Amon, who had dwelt in a dark shrine of the Karnak temple. Frequently portrayed in the brightly painted reliefs was the King's wife Nefertiti, whom he had married before his accession. Like Queen Tiy, she may have come from a military family. Her father was possibly Ay, who became prominent at Amarna and later held the throne briefly.

At about the time that he altered his name to conform with the new religion, the King transferred the capital to a virgin site at Tell el-Amarna in Middle Egypt. There, he constructed a well-planned city—Akhetaton—comprising temples to the Aton, palaces, official buildings, villas for the high ranking, and quarters for the labourers. In the eastern desert cliffs surrounding the city, tombs were excavated for the courtiers; and deep within a secluded *wādī* the royal sepulchre was prepared. Reliefs from these tombs have been invaluable for reconstructing life at Amarna. The murals stress the life of the royal family more intimately than heretofore. In Akhenaton's ninth year a more monotheistic didactic name was given to the Aton, and an intense persecution of the older gods, especially Amon, was pursued. Amon's name was excised from many older monuments throughout the land, and occasionally the word gods was expunged. Evidence suggests that the King's monotheistic fervour intensified.

The transfer of the capital to Amarna

Akhenaton's will undoubtedly was a major factor in this religious and cultural revolution. There was an emphasis upon Maat—truth as determined by the king's view of things—so that, for example, his peculiar physiognomy became the norm for representing not only members of the royal family but also commoners as well. In religion the accent was upon the sun's life-sustaining power, and naturalistic scenes adorned the walls and floors of Amarna buildings. The king's role in determining the composition of the court is expressed in epithets given to officials he selected from the lesser ranks of society, including the military. Few officials had any connection with the old aristocracy, and certain courtiers who had been accepted at the beginning of Akhenaton's reign were purged.

The view that Akhenaton was too concerned with religious matters to be interested in the fate of the empire and that as a pacifist he opposed military action is questionable. Wall scenes at Amarna frequently depict soldiers at the capital; and cuneiform tablets dealing with Egyptian foreign relations with Asia show evidence of the maintenance of Egyptian garrisons in Asia. Akhenaton even responded on occasion to the frantic pleas of Asiatic princes for additional military assistance, although rival princes tended to portray the situation as worse than it actually was.

Akhenaton's religion was not entirely monotheistic—he himself was a god, the son and manifestation of the Aton; thus, the Amarna theology bolstered the King's divine status. As the King was the Aton's high priest, so there was a high priest of Akhenaton; and the Aton and Akhenaton uniquely shared their jubilees. Because the King had the most direct access to the Aton, he worshipped the Aton on the commoner's behalf. With the discarding of traditional myths, old beliefs were undermined, and the religious needs of the people were poorly provided for. Actually, there is evidence that commoners in their private lives had not completely abandoned the old deities. In the field of ethics there is no discernable advance over the older polytheistic religion.

Smenkhkare. Perhaps because of the supremely exalted status accorded to Akhenaton in his association with the Aton, his religious experiment was short-lived. Texts from Amarna speak of an eternal process of daily revitalization of Akhenaton by the Aton's rays, but unfortunately the King was mortal. Toward the end of his reign he selected Smenkhkare (ruled 1364–61 BC), his son by a minor wife, to serve as coregent. By this time Queen Nefertiti, who had achieved unprecedented status in the iconography of Amarna, had died; and Smenkhkare's wife, Akhenaton's eldest daughter, Meritaton, became the first lady. Although the royal residence was still maintained at Amarna, by Smenkhkare's third year the cult of Amon had been revived at Thebes, where the King's mortuary temple was built.

Tutankhamen. Smenkhkare was succeeded by his child brother Tutankhaton (ruled 1361–1352 BC), who likewise married one of Akhenaton's daughters, Ankhesenpaaten. For two years the young couple lived at Amarna, pursuing the worship of the Aton. Amon-Re, however, becomes increasingly manifest in the documentation as there was a transition back to orthodoxy. Finally, the decision was made to abandon Amarna, and the King and Queen altered their names to Tutankhamen and Ankhesenamen. An inscription of Tutankhamen's fourth year testifies to the complete restoration of the old cults. The Aton is not mentioned, and the Amarna period is described as one of misery and of the withdrawal of the gods from Egypt.

Restoration of the old cults at Thebes

Under Tutankhamen a considerable amount of building was accomplished in Thebes. His Luxor colonnade bears detailed reliefs depicting the great traditional Beautiful Feast of Opet. Tutankhamen honoured Amenhotep III, the builder of the Luxor temple, whom he even referred to as his father. Although Tutankhamen's inscriptions credit him with the restoration, in point of fact there were actually two powerful individuals behind the scene: the God's Father, Ay, who served as vizier and regent (his title "the God's Father," indicates a close relationship to the royal family), and the general Horemheb, who functioned as royal deputy.

The Amarna period evidently had not occasioned as marked a withdrawal from empire as early historians, stressing Akhenaton's pacifism, maintained. Military campaigns during Tutankhamen's reign are difficult to trace, but Horemheb probably fought in Asia, supporting vassal princes against the Hittites. Effective administration continued in Nubia and the Sudan. Tutankhamen achieved fame because of the discovery of his rich burial in the Valley of the Tombs of the Kings. There is some reason to suspect that because of his return to orthodoxy his burial equipment was extraordinarily lavish.

Ay. Tutankhamen's funeral was conducted by his successor, the aged Ay (ruled 1352–1348 BC). Hittite sources indicate that, upon the plea of the widowed Ankhesenamen, the Hittite king Suppiluliumas dispatched to Egypt a prince for her to wed, but Egyptians treacherously murdered the prince on his journey. Although some scholars hold Ay responsible for this action, Horemheb was more likely involved in the plot. Ay was succeeded by Horemheb (ruled 1348–1320 BC), who married Queen Nefertiti's sister Mutnedjemet to secure his claim to the throne.

Horemheb. Horemheb dismantled many monuments erected by Akhenaton and his successors and used the blocks as fill for huge pylons at Karnak. At the Luxor temple, Horemheb appropriated Tutankhamen's reliefs by surcharging the latter's cartouches with his own. Although certain scholars have minimized Horemheb's devotion to Amon and his persecution of the memory of the Amarna pharaohs, it is significant that he was crowned in the Amon temple at Luxor. Horemheb appointed new officials, not from established families but from the army. Horemheb concentrated on domestic problems. He issued a series of police regulations dealing with the misbehaviour of palace officials and military personnel, and he reformed the judicial system, reorganizing the courts and selecting competent new judges. As a reaction against the Amarna period, Horemheb's royal tomb reflects a trend away from the theology of the solar religion and emphasizes Osirian beliefs of the afterlife.

The 19th and 20th dynasties. Having no son, the aged Horemheb selected his general and vizier, Ramses, to succeed him.

Ramses I and Seti I. This new king, as Ramses I (ruled 1320–1318 BC), hailed from the eastern delta, and with the new 19th dynasty there was a noticeable political shift to the north. Ramses I was succeeded by his son and coregent, Seti I (ruled 1318–1304 BC), who completed his father's burial and provided him with mortuary chapels at Thebes and Abydos. Seti I was a competent warrior and a builder of impressive monuments.

Political shift to the north

A noteworthy development in narrative art is evident in scenes showing Seti in various stages of battle, on the north wall of the Great Hypostyle Hall at Karnak. These reliefs and stelae found in Palestine testify to Egypt's determination to reassert authority over its weakened empire. The Hittites had become the dominant Asiatic power. Before tackling them, Seti I laid the groundwork for military operations in Syria—he fought against the troublesome Bedouin and brought important Palestinian cities to submission; then, following the strategy of Thutmose III, he secured the coastal cities and gained Kadesh. Although the engagement with the Hittites was successful, Egypt acquired only temporary control of a portion of the north Syrian plain. A treaty was concluded with the Hittite king Muwatallis, but the Hittites subsequently pushed farther southward and gained Kadesh by the time of Ramses II. Seti I ended a new threat to Egyptian security when he defeated Libyans attempting to enter the delta.

Seti I's reign was called a renaissance, and Egypt's prosperity is reflected in his considerable monuments and their refined decoration. In his fourth year he issued a lengthy decree intended to prevent arbitrary action by government officials against the personnel and property of his mortuary temple at Abydos, invoking harsh physical penalties and the curse of the gods upon malefactors. Some scholars regard this as a reflection of the tensions of a church–state rivalry, but it may simply have been a means of insuring good government.

Ramses II. Seti I appointed his son Ramses II (ruled 1304–1237 BC) as coregent. Early Egyptologists called Ramses II "the Great." During his long reign, there was a prodigious amount of building, ranging from religious edifices throughout Egypt and Nubia to a new cosmopolitan capital, Pi-Ramesse, in the eastern delta; his cartouches were carved ubiquitously, even on monuments that were not his own; his penchant for decorating vast areas of temple walls with battle scenes gives the false impression of a warrior-king mightier than Thutmose III. But scholars today are cautious in evaluating his exploits. His most famous series of reliefs are those pertaining to the Battle of Kadesh, fought in his fifth year; and the texts accompanying the pictorial record a comprehensive account of the battle. Egyptian sources regard the battle as an Egyptian victory, but the Hittite coalition actually fared better than did the Egyptian army. After the arduous struggle, his officers advised him to make peace, saying, "There is no reproach in reconciliation when you make it." In succeeding years Ramses II campaigned in Syria; after a decade of stalemate, a treaty in his 21st year was concluded with Hattusilis III, the Hittite king.

Treaty with the Hittites

The rise of Assyria and unrest north of the eastern Mediterranean had forced the Hittites into accepting this treaty, while Ramses II may have feared a new Libyan threat to the western delta. Egyptian and Hittite versions of the treaty survive. It contained a renunciation of further hostilities, a mutual alliance against outside attack and internal rebellion, and the extradition of fugitives. Illustrative of cosmopolitanism in religion was the role of gods of both lands as witnesses. The treaty was further cemented 13 years later by Ramses II's marriage to a Hittite princess. The second half of his long reign was, thus, relatively peaceful and prosperous. By his numerous wives the King had an immense family. Although Isinofre was the important queen for the succession, he especially honoured Nefertiri by dedicating a temple to her at Abu Simbel, in Nubia, and by supplying her with a magnificent tomb in the Valley of the Tombs of the Queens.

Merneptah. Ramses II's 13th son, Merneptah (ruled 1236–1223 BC), was his successor. Several of Merneptah's inscriptions, of unusual literary style, treat an invasion of the western delta in his fifth year by Libyans, supported by a number of groups of Sea Peoples who had travelled from Anatolia by sea to Libya in search of new homes. The Egyptians defeated this confederation and settled captives in military camps to serve as Egyptian mercenaries. One of the inscriptions concludes with a poem of victory, famous for its words "Israel is desolated and has no seed." This is the earliest documented mention of

Israel; and, on the basis of it, many have assumed that Ramses II was the pharaoh of the oppression and Merneptah the king at the time of the Exodus. Certain cities in Syria, such as Tyre and Simyra, were still in Egyptian hands, but nomadic movements in southern Palestine were a source of concern for Egypt. Early in his reign Merneptah asserted Egyptian suzerainty in Palestine and destroyed Gezer. In the Libyan war, slain soldiers were enumerated by counting their severed hands or phalli, and certain captives were impaled through the stomach; but Merneptah displayed more humane qualities when he dispatched grain to the Hittites during a famine. Recognizing the terms of the Hittite treaty, the Egyptians aided the Hittites militarily in the protection of Syrian possessions.

Last years of the 19th dynasty. Upon the death of Merneptah, competing factions contended for the succession—possibly an unfortunate consequence of Ramses II's immense family. Following a five-year reign of a usurper, Amenmesse (ruled 1222–1217 BC), Merneptah's son Seti II (ruled 1216–1210 BC) acquired the throne. Although little is known of his political activities, his presence is well attested on monuments at Karnak, some of which he usurped. References to an enemy may reflect the unstable political situation, because his successor, Siptah (ruled 1209–1203 BC), was actually installed in the kingship through the efforts of a powerful Syrian royal butler who had become chancellor of Egypt. The young Siptah was married to Tausert, who, upon Siptah's death, herself ruled as king in 1202–1200 BC, appropriating Siptah's regnal years as her own and restoring her first husband's name (Sethos II) over Siptah's. A description in a later papyrus of the end of the dynasty alludes to a Syrian usurper, probably the chancellor, who subjected the land to harsh taxation and treated the gods as mortals with no offerings in their temples.

Beginning of the 20th dynasty

Setnakht. Order was restored by a man of obscure origin, Setnakht (ruled 1200–1198 BC), the founder of the 20th dynasty, who ruled only briefly and appropriated Tausert's tomb in the Valley of the Tombs of the Kings.

Ramses III. Setnakht's son Ramses III (ruled 1198–1166 BC) was the last great pharaoh. There are problems in evaluating his achievements because he emulated Ramses II and copied numerous scenes and texts of Ramses II in his mortuary temple at Madīnat Habu, one of the best preserved temples of the empire period. Thus, the historicity of certain Nubian and Syrian wars depicted as accomplishments of Ramses III is subject to doubt. There are, however, certain battles actually fought by Ramses III that were more decisive in world history than any of Ramses II's. In his fifth year Ramses III defeated a Libyan invasion of the delta. The figures given in one scene on the walls of his mortuary temple indicate that several tens of thousands of the Libyan enemy perished; but another, similar scene gives less inflated figures, in the thousands.

A greater menace lay to the north, where a confederation of Sea Peoples was progressing by land and sea toward Egypt. These barbarians, who had overrun the Hittite kingdom, had camped in Amor in Syria. In his eighth year Ramses III engaged them successfully on two frontiers—a land battle in Palestine and a naval engagement in one of the mouths of the delta. These two victories were significant for the civilized world; they permitted the survival of Egyptian culture for another millennium. Forced away from the borders of Egypt, the Sea Peoples sailed farther westward, and there is reason to believe that Sicilians, Sardinians, and Etruscans originated from groups of them. The Philistine and Tjekker Sea Peoples, who had come by land, were established by the Egyptians in military camps in the southern Palestinian coastal district in an area where the overland trade route to Syria was threatened by Bedouin attacks. Initially created to protect Egyptian commercial interest, these groups later became independent of Egypt. Ramses III utilized certain groups of these peoples as mercenaries, even in battle against their own kinfolk. Reliefs at Madīnat Habu differentiate among the various groups of Sea Peoples on the basis of their costumes and weapons. In his 11th year Ramses III successfully repulsed another great Libyan invasion by the Meshwesh tribes. Meshwesh prisoners of war, branded with the king's name, were settled in military camps in Egypt, and their descendants subsequently became politically important because of their military role.

These great defensive wars in the first half of Ramses III's reign were less profitable economically than the Asiatic campaigns of the 18th dynasty. Under Ramses III the estate of Amon received only one-fifth as much gold as in Thutmose III's time. Although there are masterpieces of Egyptian art at Madīnat Habu, much of the relief inside the temple and the quality of the masonry betray a decline. Toward the end of his reign, administrative inefficiency in coping with a deteriorating economic situation resulted in the government's failure to deliver grain rations on time to necropolis workers, whose dissatisfaction was expressed in demonstrations and in the first recorded sit-down strikes in history. A different sort of internal trouble originated in the royal harem, where a minor queen plotted to murder Ramses III so that her son might become king. Involved in the plot were palace and harem personnel, government officials, and army officers. A special court of 12 judges was formed to try the accused, who received the death sentence. It is noteworthy that among both the accused and the judges were persons of foreign origin—a clear illustration of how far foreigners could advance in influence. An indication of moral decay is the conduct of certain judges, five of whom were punished for carousing with the women on trial. There is no evidence that this harem conspiracy caused Ramses III's death.

Harem conspiracy against Ramses III

Ramses IV. Ramses III was succeeded by his son Ramses IV (ruled 1166–1160 BC). In an apparent act of piety, Ramses IV saw to the compilation of a long papyrus in which the deceased Ramses III confirmed the temple holdings throughout Egypt; Ramses III had provided the largest benefactions to the Theban temples, in terms of donations of both land and personnel. Of the annual income to temples, 86 percent of the silver and 62 percent of the grain was awarded to Amon. The document demonstrates the economic power of the Theban temples, for the tremendous landholdings of Amon's estate throughout Egypt involved the labour of a considerable portion of the population; but the ratio of temple to state income is not known, and there is some later evidence that, unless exempted by special decree, the temples were obliged to deliver taxes to the state. Indeed, the Amon temple, which figures prominently in the papyrus, is the King's own mortuary temple, for the deified Ramses III was himself a form of Amon-Re, known as United with Eternity.

The later Ramesside kings. The Ramesside period saw a tendency toward the formation of high-priestly families, which the pharaohs sometimes tried to control by appointing outside men to the high priesthood. Such a family had developed at Thebes in the second half of the 19th dynasty, and Ramses IV tried to control it by installing Ramessesnakht, the son of a royal steward, as Theban high priest. Ramessesnakht participated in affairs normally outside the scope of the high priest's office; he personally led an expedition to the Wadi Hammamat (modern Wādī Rawḍ ʿĀid) quarries in the eastern desert, and at Thebes he supervised the distribution of rations to the workmen decorating the royal tomb. Under Ramses V (ruled 1160–1156 BC), Ramessesnakht's son not only served as steward of Amon but also held the post of administrator of royal lands and chief taxing master. Thus, this high-priestly family had acquired extensive authority over the wealth of Amon and over state finances; but to what degree this represented a threat to the crown and led to the decline of royal authority is uncertain. Part of the problem in evaluating the evidence is that Ramesside history is viewed from a Theban bias, because Thebes is the major source of information. Documentary evidence from Lower Egypt, where the king normally resided, is meagre because of unfavourable conditions there for the preservation of monuments or papyri.

A long papyrus from the reign of Ramses V contains

valuable information on the ownership of land and taxation. In Ramesside Egypt most of the land belonged to the state and the temples, while most peasants served as tenant farmers. Some scholars interpret this document as indicating that the state retained its right to tax temple property (at an estimated one-tenth of the crop).

Ramses VI (ruled 1156–1148 BC), a probable son of Ramses III, next took the throne. He usurped much of his two predecessors' work, including the tomb of Ramses V; a papyrus refers to a possible civil war at Thebes. Following the death of Ramses III the Asiatic empire had rapidly withered away, and Ramses VI is the last king whose name appears at the Sinai turquoise mines. The next two Ramses (ruled 1148–1140 BC) were obscure rulers, whose sequence has been questioned. During the reigns of Ramses IX (ruled 1140–1121 BC) and Ramses X (1121–1113 BC) there are frequent references in the papyri to the disruptive presence of marauding Libyans near the Theban necropolis.

Loss of the Asiatic empire

By the time of Ramses IX the Theban high priest had attained great influence, though textual references suggest that royal authority still outranked that of the high priest. Early in the reign of Ramses XI (ruled 1113–1085 BC), during a civil war at Thebes, the high priest Amenhotep, the son of Ramessesnakht, was suppressed from his office for nine months; evidence indicates that the King called upon the Viceroy of Kush and his Nubian troops to restore order and reinstate the high priest to his office. For many years scholars have believed that the growth of priestly power culminated with the assumption of kingship by the high priest Herihor at Thebes. This interpretation has, however, been seriously challenged, and it is now believed that Herihor had no connection with the preceding high-priestly family but was an army officer, who subsequently not only assumed the high priestship but also the secular offices of viceroy of Kush and vizier. In the Khons temple at Karnak, Herihor was represented as high priest of Amon in scenes adjoining those of Ramses XI. This in itself was unusual, but subsequently he took an even bolder step in having himself depicted as king to the exclusion of the still-reigning Ramses XI. Herihor's kingship was a purely Theban matter, and at Thebes these years were referred to as a renaissance, which lasted a decade.

With the shrinkage of the empire, the supply of silver and copper was cut off, and the amount of gold entering the economy was reduced considerably. The economically distressed inhabitants of western Thebes took to pillaging the tombs of kings and nobles during the reign of Ramses IX; the despoiling continued into the reign of Ramses XI, and even the royal mortuary temples were stripped of their valuable furnishings. Nubian troops, called in to restore order at Thebes, themselves contributed to the depredation of monuments. This pillaging brought fresh gold and silver into the economy, and there was a rise in the price of copper. The price of grain, which had been inflating, dropped.

While Ramses XI was still king, Herihor died and was succeeded as high priest by Piankh, a man of similar military background. A series of letters from Thebes tell of Piankh's military venture in Nubia against the former Viceroy of Kush, while Egypt was on the verge of losing control of the south. With the death of Ramses XI, the governor of Tanis, Smendes, became king, founding the 21st dynasty.

Society and culture in the New Kingdom. Although Egyptians readily personified abstract concepts and at an early period represented their cities and local areas as divine personifications, there was no such divinization of Egypt itself.

The king. Instead, the divine king embodied the state, so that Egypt's success in war was conceived of as an accomplishment not of the state or the people but of the pharaoh, who was always regarded as the victor, even in battles he personally had not fought. Theologically, the birth and death of the king were linked with the concepts of order and chaos in nature and society, for without a king no organized state and society could be maintained. Upon the king the people pinned their hopes for the success of their collective endeavours; anarchy not only could produce genuine hardship in a land so much dependent upon a centrally controlled irrigation system but it partook of the chaos of nonexistence.

In addition to the many inscriptions referring to the king as a god, there are texts in which he is treated as a human, subordinate to the gods. An argument that such humanizing texts detract from the pharaoh's divinity fails to account for the fact that the highest gods themselves displayed very human qualities in Egyptian myths. Although Egyptians of the New Kingdom frequently prayed to gods, they did not pray directly to the person of the king but rather to his transcendent essence, the *ka*, which might be embodied in a statue. The dual nature of the king, both divine and human, can be explained by distinguishing between the institution of divine kingship and the actual person filling the divine office. During the 18th dynasty there was a tendency, especially in texts describing the king engaged in sport, to portray him as a superhuman among humans. Perhaps as a reaction to this trend, Akhenaton stressed his divine nature through his unique relation with the Aton. In Ramesside times the divine aspect of the king's personality was emphasized in royal inscriptions and through the cult of the king in temples.

Dual nature of the king in the New Kingdom

Actually, much depended upon the strength of the individual ruler. Law was simply the expression of the king's will through royal decrees regulating the functioning of society. During the height of the New Kingdom, kings had the power to make appointments in the civil service, the army, and the priesthood. Courtiers surrounding a king might present their plans to him, but he would frequently ignore their advice and act independently; this became a literary device serving to emphasize the pharaoh's superior wisdom. Only in the king were such vast legislative, executive, and judicial powers concentrated, for the dualism of the vizierate and the rest of the administration served as a check upon any one person acquiring too much authority. The New Kingdom town mayors, who were subject to the two viziers, became the principal provincial administrators, and their large number tended to consolidate the king's authority over them.

The civil service. Efficient administration demanded the perpetuation of an educated class. Literary texts, designed during the Middle Kingdom to make the scribal profession attractive, were constantly utilized in schools of the New Kingdom; in addition, new texts extolling the scribal occupation were composed to counteract the allure of the military and priestly professions (the hardships of the soldier's life were emphasized). During the New Kingdom an individual of humble background could receive a scribal education and enter the civil service, sometimes rising to a position of considerable importance. Although there was a tendency toward the formation of families of high officials, especially early in the 18th dynasty, the buildup of such an aristocracy was moderated by the king's power to appoint and remove government officials. Frequently, the names and representations of high officials were destroyed in Theban tombs because of a family's fall from royal favour. Increased social mobility, emphasizing an individual's merit, made the New Kingdom officialdom more fluid in composition than it had been in earlier periods.

The military. A distinguishing feature of New Kingdom society was the emergence of an influential military class and the increased number of career military men; the empire depended upon the armed forces for its growth and maintenance. Military tutors educated young princes; and, when the king set out to war, he was assisted by skilled officers and soldiers, who were rewarded for their valour on the battlefield with lands, captured slaves, and other booty. In order to persuade sons to follow their father's military profession, families could hold the lands as long as each new generation provided a son who would make the army his career. Thus did military families develop. In addition, a small percentage of the male population was conscripted; apparently, only civil-service officials were exempted from the draft. Dur-

Development of military families

ing the 18th dynasty the bulk of the army was composed of native Egyptian soldiers, supplemented with Nubian troops; under Amenhotep III the Sherden group of Sea Peoples entered the army. The use of prisoners of war increased during the Ramesside period, when Libyans, Sea Peoples, and Bedouins were settled in military camps.

The military was the closest to the king; it rivalled the civil service and the priesthood in terms of individual advancement on the basis of merit. The fact that a distinguished military officer or a king's old companion at arms could receive royal appointment to a high position in the civil administration or in the priesthood was a potential source of tension with the established bureaucracy. During the Ramesside age, royal butlers, who functioned as a sort of royal bodyguard on the king's campaigns, were frequently foreigners; they had considerable political influence and often more effective power than the vizier.

The priesthood. In practice, the king's role as the god's high priest was delegated to members of the priesthood, whose activities included the daily ritual of provisioning the god. In return, the priests received income from the temple endowments, which was ritually offered to the god but then became the priests' sustenance. As temple property increased through the expansion of the empire and royal donations, the personnel connected with the temples and their estates multiplied. During the 18th dynasty the administration of the Amon temple was generally supervised by a high state official such as the vizier. An ecclesiastical background was not a prerequisite for the highest priestly posts; the pharaoh often appointed high state officials or even military men to top positions in the priestly hierarchy. Priestly positions were often inherited, but the power of royal appointment served as a check upon the growth of priestly power. At least the lower grades of priests and temple personnel were subject to conscription into the army or for corvée labour. Today, scholars are more cautious in evaluating the evidence from the Ramesside period that had once been interpreted as demonstrating a church–state conflict.

Artisans. Another important segment of the society consisted of the craftsmen. During the New Kingdom the number of specialized artisans producing wares for a more urban and cosmopolitan society increased. Most were freemen producing goods for their patrons—*e.g.*, the government, the temples, or nobles—in return for wages. A wealthy patron might honour the best of his artisans by naming them in his tomb or by rewarding them with land or a funerary endowment. That craftsmen took pride in their profession is indicated by instances in which son followed father in his skilled trade. Artisans also produced products for the market. A seller would evaluate his ware in terms of copper or silver weights or pieces, and the purchaser would in turn offer some product or products of equal evaluation. Thus, trading was not simple barter but involved reckoning in terms of a sort of abstract monetary unit.

Commerce and trade. Private industry in the New Kingdom apparently did not expand significantly beyond that which an individual household might produce. Private commerce was limited to trading at the village marketplace and to waterfront transactions of private merchants plying the Nile with very modest commodities. More developed industry and commerce was a function of the state or temples, and international trade was a royal monopoly.

The common people. The masses consisted of uneducated labourers, with peasants forming the backbone of a basically agrarian economy. Slavery was not of fundamental importance to New Kingdom agriculture; most of those who were free serfs or tenant farmers tilled the fields and received a share of the harvest. At those times of year when a larger work force was required for irrigation or harvesting, the institution of the corvée was utilized. Only the official class was generally exempted from such compulsory labour, and even priests could be compelled to perform menial work; but, because wealthier Egyptians could afford to hire substitutes, the corvée was hardest on the poor.

Corvée labour

Slaves. Slaves were either acquired in foreign wars or bought from merchants. The number of slaves per household rarely exceeded two. A considerable number were donated to the temples and employed in the temple workhouses, and state mining and quarrying operations made use of slave labour. An owner could sell or even hire out his slaves, and a slave could be emancipated by his owner. Occasionally a slave even married a member of his household.

Social mobility. The potential for social mobility existed, so that New Kingdom Egypt was devoid of anything like a caste system. Many persons rose to prominence from humble beginnings, and the careers of many officials indicate that the classes were not mutually exclusive. Some historians of the New Kingdom have emphasized power struggles among the various classes, but little positive evidence exists, and the propagandistic quality of Egyptian texts might easily lead to wrong interpretations. The evidence also suggests that such conflicts as there may have been were utilized by the king to support his supreme authority.

Women. The Egyptian wife enjoyed considerable prestige as "mistress of the house." So far as is known, marriage involved no formal religious ceremony but was a contractual arrangement, initiated by the suitor applying to the girl's father, and it could be dissolved relatively easily by the husband and probably by the wife. Among commoners, brother–sister marriages did not exist, and monogamy prevailed, though there were concubines who did not have the legal status of wife. A woman's legal status, whether single or married, was in law and in fact equal to a man's, and she could initiate and perform a broad range of legal acts, including the willing of property and the bringing of suit. Women also functioned significantly in religious affairs; many wives of Theban officials were chantresses of Amon, and the role of women in the religious education of the family must have been important.

Culture and religion. As a result of the empire and increased foreign contacts, the ethos of Egyptian culture became more cosmopolitan, and foreigners and elements of their culture and religion were accepted. While the empire was being fashioned, there was confidence and optimism, reflected in autobiographical inscriptions; the appreciation of life and the acceptance of new trends are discernible in scenes from Theban tomb chapels. The beautifully executed tomb chapels of the 18th dynasty are testimonials that Egyptians enjoyed life and sought its prolongation beyond death.

Both the Amarna revolution and altered political circumstances had a reaction on the culture of the Ramesside period. Few tombs of the 19th and 20th dynasties contain biographies of the tomb owner, and there is a significant shift to the depiction of the gods and the netherworld. Ramesside tombs present a sombre impression of withdrawal from earthly life.

The Ramesside period has often been characterized as an age of personal piety. An increased dependence of man upon god is clearly evident in the wisdom literature that stresses man's fragile nature and god's omnipotence. Long introductions in private letters often contain references to the writer's piety and prayerful approach to problems. The common expression in letters, "I am all right today; tomorrow is in the hands of god," reflects the ethos of the age.

Role of the oracle in daily affairs

A manifestation of the increased dependence upon god was the frequency with which the divine oracle of the god entered into daily affairs. The oracle of Amon was consulted on matters pertaining to the state and temple as well as on community problems. To some extent, Amon made decisions in conformance with the king's will; but not all oracular decisions were rigged to conform to the king's will or the priests' wishes. The method of making oracular decisions involved a portable bark, or litter, of the god on the shoulders of lay priests in a public appearance. The god's pronouncements on a wide variety of matters, including legal disputes, were conveyed by the motions of the bark indicating approval or disapproval to questions requiring a yes or no answer. After the New

Kingdom, oracles became even more prominent in determining the course of events.

The religiosity of the Ramesside period is reflected in surviving biographical inscriptions. They are chiefly autobiographies of high priests inscribed on sections of the temple wall or on statues set up in the temple. Such inscriptions had a didactic function in urging future priests to follow the same paths of piety and devotion to the god. The religious context for the expression of personal achievement was carried over into the postempire period.

EGYPT FROM 1085 BC TO THE MACEDONIAN INVASION

Weakness and foreign domination to the mid-7th century. During the Tanite 21st dynasty (1085–945 BC), certain Theban high priests locally assumed the title of king. There is no indication of conflict, however, between the priests and the Tanite pharaohs. Indeed, the dating of documents, even at Thebes, was in terms of the Tanite reigns, and apparently there were close family ties between the Tanite kings and the Theban high priests. Piankh's son, Pinudjem I, who relinquished the office of high priest and assumed the kingship at Thebes, was probably the father of the Tanite pharaoh Psusennes I. Beginning with Herihor and continuing through the 21st dynasty, the high priests' activities included the pious rewrapping and reburial of New Kingdom royal mummies. The ransacking of the royal tombs during the 20th dynasty necessitated the transfer of the royal remains to two caches—the tomb of Amenhotep II and a cliff tomb at Dayr al-Baḥrī—where they remained undisturbed until modern times. Dockets pertaining to the reburial of these mummies contain important chronological data from the 21st dynasty.

The 21st dynasty. Little is known of the political activities of the Tanite pharaohs, although the burials of King Psusennes I and his successor, King Amenemope, were discovered at Tanis. This was a period of the usurpation of statuary and the reuse of material of earlier periods. At Karnak, Pinudjam I, who decorated the facade of the Khons temple, usurped a colossal statue of Ramses II, and Psusennes I's splendid sarcophagus from Tanis had originally been hewn for King Merneptah. Much of the archaeological remains from Tanis, the capital of the 21st and 22nd dynasties, comprises material transported from other sites, notably from Pi-Ramesse. During the 21st dynasty, Egypt lost control of Nubia; and, with the demise of Egypt's Asiatic empire, the kingdom of Israel developed under the kings David and Solomon. During David's reign, Philistia served as a buffer between Egypt and Israel; but upon David's death the next to the last king of the 21st dynasty, Siamon, invaded Philistia and captured Gezer. If Egypt had any intention of attacking Israel, Solomon's power forestalled Siamon, who presented Gezer to Israel as a dowry in the diplomatic marriage of his daughter to Solomon. This is indicative of the reversal of Egypt's status in foreign affairs since the time of Amenhotep III, who had written the Babylonian king, "From of old, a daughter of the king of Egypt has not been given to anyone."

The 22nd and 23rd dynasties. During the 20th dynasty captive Meshwesh Libyans had been settled in military colonies in Egypt; the leader of the colony at Bubastis was designated great chief of the Meshwesh. Toward the end of the 21st dynasty the great chief of the Meshwesh Sheshonk (the biblical Shishak) secured special privileges from King Psusennes II and the oracle of Amon for the mortuary cult of his father at Abydos. The oracle proffered good wishes not only for Sheshonk and his Libyan family but, significantly, also for his army. With a strong military backing, Sheshonk eventually took the throne, founding the 22nd dynasty (945–*c.* 730 BC). Military controls were established, with military garrisons under Libyan commandants serving to quell local insurrections, so that the structure of the state became more feudalistic. The dynasty's success is also attributable to the Libyans' willingness to adopt Egyptian mores and to express their piety to the Egyptian gods through the building of temples. The dynasty tried to cement relations with Thebes through political marriages with members of priestly families. King Sheshonk's son Osorkon married Psusennes II's daughter, and their son eventually became high priest at Karnak. By installing their sons as high priests and promoting such marriages, kings of the 22nd dynasty strove to terminate the inheritance of important priestly offices at Thebes. But frequent conflicts arose over the direct appointment of the Theban high priest from the sons of Libyan kings and over the inheritance of the post by men of mixed Theban and Libyan descent. This tension took place against a background of Theban resentment of the northern dynasty. During the reign of Takelot II, strife concerning the high priestship led to civil war at Thebes. The King's son was appointed high priest, and he achieved some semblance of order during his visits to Thebes.

Libyan rule

The 22nd dynasty revived Egyptian influence in Asia. Five years after Solomon's death (*c.* 931), Sheshonk I entered Palestine and plundered Jerusalem; booty from this campaign financed an enlargement of the Amon temple, and Egypt regained some of its lost commercial prestige. There is no evidence of further military intervention in Palestine. Under King Osorkon II Peywed Libyans posed a threat to the western delta, perhaps necessitating a withdrawal of attention from Asia. The latter part of the dynasty was marked by increasing fragmentation of the land. The kings of a contemporary 23rd dynasty (*c.* 817–*c.* 730 BC) were recognized at Thebes.

Renewed influence in Asia

With the collapse of the New Kingdom, Egypt ceased to control territories to its south; but Kushites (Ethiopians) in the area of the Fourth Cataract in the Sudan maintained a brand of Egyptian culture. The earliest known member of the Kushite royal family was Alara, whose piety toward Amon is mentioned in several inscriptions. His brother and successor, Kashta, proceeded into Upper Egypt, forcing Osorkon III to retire to the delta. Although Kashta did not adopt a pharaonic titulary, he assumed the title of king and compelled Osorkon III's daughter Shepenwepe I, the God's Wife of Amon at Thebes, to adopt his daughter Amonirdis I. While the Libyans sought to control Thebes through the high priesthood, the Kushites stressed the role of the God's Wife of Amon, who no longer was the spouse of a king but remained a virgin as the consecrated partner of Amon.

The 24th and 25th dynasties. Meanwhile, the eastern delta capital, Tanis, lost its importance to the commercial city of Sais in the western delta. A Libyan prince of Sais, Tefnakhte, attempting to gain control over all Egypt, proceeded southward to Heracleopolis after acquiring Memphis. This advance irritated the Kushites, whose ruler Piankhi (more correctly, Piy) proceeded into Egypt (*c.* 730 BC), where he received the submission of the northern coalition. Piankhi, in his victory stela, is portrayed as a man conforming strictly to Egyptian traditions; and his piety, especially to Amon, is stressed. In this campaign an internal slave trade developed, involving the sale of prisoners of war from the north in Thebes.

Upon Piankhi's return to Kush, Tefnakhte reasserted his authority in the north, where he was eventually succeeded by his son Bocchoris, the sole king of the 24th dynasty (720–714 BC), identified by the historian Manetho (flourished *c.* 300 BC). Piankhi's brother Shabaka meanwhile founded the Ethiopian 25th dynasty (716–656 BC); he burned Bocchoris alive and brought all Egypt under his rule. In this period Egypt's internal politics were affected by the growth of the Assyrian Empire. In Palestine and Syria frequent revolts against Assyria were aided by Egyptian forces. Against the power of Assyria, the Ethiopian troops met with little success, partly because the base of the Egyptian military lay in the Sudan and partly because the Libyan–Egyptian princes of the delta, strategically the most important part of Egypt, rendered the Ethiopians only nominal allegiance.

Growth of the Assyrian Empire

Although the earlier years of King Taharqa, who as second son of Shabaka had succeeded his brother Shebitku, were prosperous, the confrontation with Assyria became acute. In 671 BC the Assyrian king Esarhaddon entered Egypt and drove Taharqa into his homeland. Two years later Taharqa regained a battered Memphis,

but in 667 BC Assyria's King Ashurbanipal forced Taharqa to Thebes, where the Ethiopians held ground. Taharqa's successor, Tanutamon, defeated at Memphis a coalition of delta princes who supported Assyria, but Ashurbanipal's reaction to this was to humiliate Thebes, which the Assyrians plundered. The Kushites then withdrew from the Egyptian political scene, although Kushite culture survived in the Sudanese Meroitic kingdom for another millennium.

Independence and cultural revival under the 26th dynasty. Assyria, unable to maintain a large force in Egypt, supported several loyal delta vassal princes, including the powerful Psamtik. But the Assyrians faced serious problems closer to home, and Psamtik was able to assert his independence and extend his authority as king over all Egypt without extensive use of arms, inaugurating the Saite 26th dynasty (664–525 BC). Psamtik I took Thebes peacefully, and his policy toward Thebes was wise. The most influential man there was its mayor and the fourth prophet of Amon—Montemhat. Psamtik I allowed Montemhat to retain his post and, in an effort to appeal to pro-Ethiopian sentiments at Thebes, allowed the God's Wife of Amon and the Votaress of Amon (the sister and daughter of the late king Taharqa) to remain. Psamtik I's own daughter Nitocris was adopted by the incumbent Votaress of Amon and thus became heiress to the important position of God's Wife. In the text relating to this adoption, Psamtik I carefully acknowledged the preceding Ethiopian dynasty. Essential to the settling of internal conflicts was the Saite dynasty's superior army, composed of Libyan soldiers, whom the Greeks called Machimoi (warriors), and Greek and Carian mercenaries. Because Greece was overpopulated, many Greeks emigrated to Egypt. Greek pirates raiding the delta coast were induced by Psamtik I to serve in his army and were settled like the Machimoi in colonies at the delta's strategically important northeastern border. Trade developed between Egypt and Greece, and more Greeks emigrated to Egypt.

Foreign policy under Saites

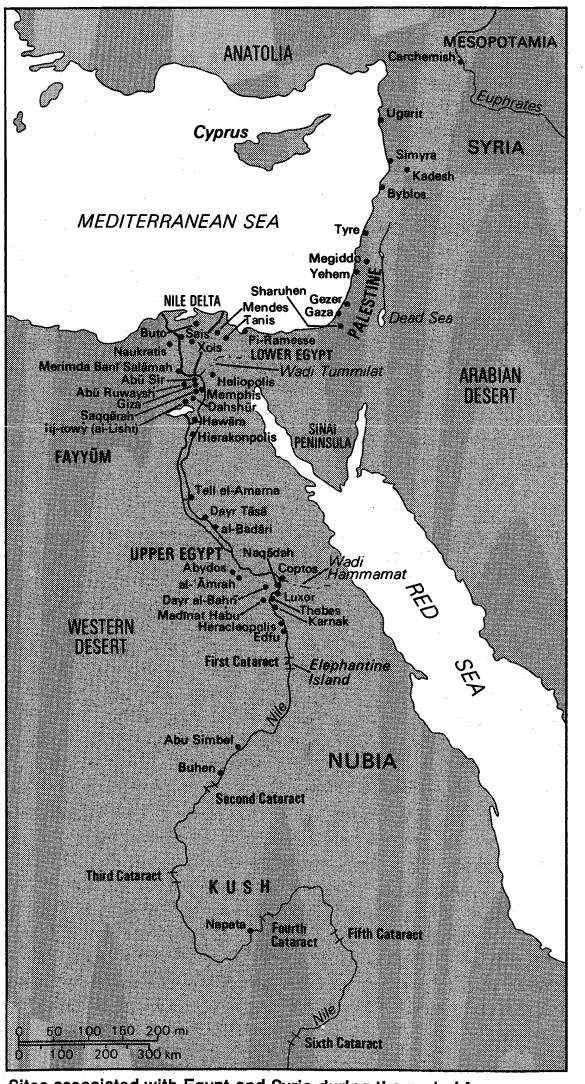
The Saite dynasty generally pursued a foreign policy that avoided territorial expansion and tried to preserve the status quo. Assyria's power was waning. In 655 BC Psamtik I marched into Philistia in pursuit of the Assyrians, and in 620 BC he apparently repulsed Scythians from the Egyptian frontier. During the reign of his son Necho, Egypt supported Assyria as a buffer against the potential threat of the Medes and the Babylonians. Necho was successful in Palestine and Syria until 605 BC, when the Babylonian Nebuchadrezzar inflicted a severe defeat on Egyptian forces at Carchemish. After withdrawing his troops from Asia, Necho concentrated on developing Egyptian commerce; the grain that was delivered to Greece was paid for in silver. Although a canal linking the Nile with the Red Sea remained unfinished, the circumnavigation of Africa by Phoenician ships sent by Necho may have succeeded. During the short reign of Psamtik II, there was a campaign into Nubia, involving the use of Greek and Carian mercenaries who left their inscriptions at Abu Simbel; the reason for this unusual campaign may be found in the erasure at this time of the names of the Ethiopian kings from monuments in Egypt. Psamtik II also made an expedition to Phoenicia accompanied by priests; whether it was a goodwill mission is subject to question.

The next king, Apries, tried unsuccessfully to end Babylonian domination of Palestine and Syria. With the withdrawal of Egyptian forces, Nebuchadrezzar destroyed the temple in Jerusalem. Apries' army was then defeated in Libya when it attacked the Greek colony at Cyrene; this led to an army mutiny and to civil war in the delta. A new Saite king, Ahmose (Amasis), usurped the throne and returned to a more conservative foreign policy in a reign characterized by internal tranquillity. In order to secure the loyalty of Greek soldiers who had sided with Apries in the civil war, Ahmose withdrew them from the military colonies and transferred them to Memphis, where they formed a sort of royal bodyguard. At the same time he limited Greek trade in Egypt to Sais, Memphis, and Naukratis, the latter becoming the only port to which Greek wares could be brought so that the government could enforce taxes on imports and on business. In following a status quo foreign policy, Ahmose supported a waning Babylonia, now threatened by Persia; but not long after his death the Persian Cambyses penetrated Egypt, reaching Nubia (525 BC).

The political policy of the Saite kings was to utilize foreigners as mercenaries in order to prevent foreign invasions. An element within Egyptian culture, however, resisted this; and the presence of foreigners in Egypt, both as invaders and settlers, led to the rise of a nationalism that provided psychological security in days of political uncertainty. An important manifestation of this nationalism was a cultural revival recalling Egypt's glorious past. In this revival the Old Kingdom tended to provide the norm. The god Seth, who had been an antithetic element in Egyptian religion, came to be detested as the god of foreign lands, and his worship was proscribed. While pursuing their pragmatic foreign policy, the Saite kings were careful not to offend the nationalistic sensitivity of the people and priests. One problem that arose was the financing of restorations and construction of new temples; in addition to state contributions for this purpose, private people, inspired by nationalistic fervour, donated parcels of land to the temples in return for a priestly office and its income.

Nationalism and cultural revival

Egypt under Achaemenid rule. According to the account of the Greek historian Herodotus, Cambyses' conquest of Egypt was ruthless and sacrilegious. Contemporary Egyptian sources, however, treat him in a more favourable light.



Sites associated with Egypt and Syria during the period from the Old Kingdom to the Macedonian conquest.

The 27th dynasty. As founder of the Persian 27th dynasty (525–404 BC), Cambyses assumed the full titulary of an Egyptian pharaoh and paid honour to the goddess Neith of Sais. Cambyses' unfavourable later reputation probably resulted from adverse propaganda by Egyptian priests, who resented his reduction of temple income. Cambyses' successor, Darius I, was held in higher esteem because he was actively concerned with improving the temples and restored part of their income, and he codified laws from the earliest times to Ahmose. Darius I's tolerance and his attempt to win over priests and learned Egyptians was part of his politics to retain Egypt as a lasting part of the Persian Empire. Egypt, together with the Libyan oases and Cyrenaica, formed the sixth Persian satrapy (province), whose satrap resided at Memphis, while Persian governors under him held posts in cities throughout the land. Under Darius I the tax burden upon Egyptians was relatively light, and Persians aided Egypt's economy through irrigation projects and improved commerce, enhanced by the completion of the canal to the Red Sea.

The Persian defeat by the Athenians at Marathon in 490 BC had significant repercussions in Egypt. In 486 BC a revolt broke out in the delta, perhaps instigated by Libyans of the west delta. The result was that the Persian king Xerxes reduced Egypt to the status of a conquered province. Egyptians dubbed him the "criminal Xerxes." He never visited Egypt and showed no interest in the temples; he appears not to have utilized Egyptians in high positions in the administration. Xerxes' murder in 465 BC was the signal for another revolt in the western delta by a Libyan dynast, Inaros, who succeeded in acquiring control over the delta and was supported by Athenian forces against the Persians. Inaros was crucified by the Persians (454 BC), who regained most of the delta. Herodotus made a famous visit to Egypt around 450 BC. During the reign of Darius II there was a fanaticism against the Jewish colony at Elephantine by Egyptians who resented the exclusiveness of the colony's religion; the priests of Khnum bribed the Persian commander there to lead Egyptian troops and destroy the Jewish temple in 410 BC.

The 28th, 29th, and 30th dynasties. The death of Darius II prompted another rebellion by Libyan dynasts in the delta, and Amyrtaeus alone formed a Saite 28th dynasty (404–399 BC); his rule was recognized in Upper Egypt at a time when Persia's troubles elsewhere forestalled an attempt to regain Egypt.

Native rule

Following internal troubles in the delta, a 29th dynasty (399–380 BC) emerged from the eastern delta city of Mendes. Achoris, its third ruler, was especially vigorous, and the prosperity of his reign is indicated by many monuments in Upper and Lower Egypt. Once again Egypt was active in world politics, a result of the balance of power between Persia and Greece and a buildup of the Egyptian army and navy. Achoris' policy was based on the principle that any enemy of Persia was a friend of Egypt, so his envoys were busy setting up alliances abroad. The Egyptian army comprised not only Greek mercenaries but also Greek commanders; the mercenaries were not permanent residents of military camps in Egypt but native Greeks seeking payment for their services in gold. Gold coins were minted to pay these new mercenaries, but gold and silver were scarce in Egypt, which no longer possessed the Nubian gold mines. Aided by the Greek commander Chabrias of Athens and his elite Greek troops, Achoris prevented a Persian invasion; but upon Achoris' death his son Nepherites II lasted only four months before a general, Nectanebo I (Nekhtnebef) of Sebennytos, usurped the throne, founding the 30th dynasty (380–343 BC). In 373 BC the Persians attacked Egypt, and, although Egyptian losses were heavy, disagreement between the Persian satrap Pharnabazus and his Greek commander over strategy and an inundation of the delta saved the day for Egypt. With the latent dissolution of the Persian Empire under the weak Artaxerxes II, Egypt was relatively safe from further invasion, and relative stability is reflected in the considerable building achieved in Nectanebo's name.

Egypt had a more aggressive foreign policy under Nectanebo's son Tachos. Possessing a strong army and navy composed of Egyptian Machimoi and Greek mercenaries and supported by Chabrias and the Spartan king Agesilaus, Tachos (also known as Zedhor) invaded Palestine. But friction between Tachos and Agesilaus and the cost of financing the venture proved to be Tachos' undoing. In an attempt to secure quick money, Tachos had imposed taxes and seized temple property. Egyptians, especially the priests, resented this increased burden and supported Tachos' nephew Nectanebo II (Nekhtharehbe) in his usurpation of the throne. The ill-fated venture into Asia proved too costly for a basically agrarian economy, and Egypt henceforth had to be content with defensive military action.

Agesilaus supported Nectanebo in his defensive foreign policy, and the priests sanctioned the new king's building activities. Meanwhile, Persia enjoyed a resurgence under Artaxerxes III; but a Persian attack upon Egypt in 350 BC was repulsed. In 343 BC the Persians once again marched against Egypt. The first battle was fought at Pelusium and proved the superiority of Persia's strategy. Eventually the whole delta, then the rest of Egypt, fell to Artaxerxes III, while the Egyptian king fled to Nubia.

The 31st dynasty. Artaxerxes founded the 31st dynasty; he dealt harshly with Egypt, razing city walls, rifling temple treasuries, and removing sacred books. Persia acquired rich booty in its determination to prevent Egypt from further rebelling.

Return of Persian rule

After the murder of Artaxerxes III, in 338 BC, there was a brief obscure period during which a Nubian prince, Khababasha, seems to have gained control over Egypt, but Persian domination was re-established in 335 BC under Darius III. In 333 BC Alexander the Great of Macedonia defeated the Persians at Issus; and, although Gaza resisted his advance, Egypt was handed over to him in 332 BC by the Persian satrap. Alexander was acclaimed pharaoh at Memphis and greeted as the son of Amon by the priest of the god's oracle at the oasis of Siwa.

(E.F.W.)

III. Hellenistic and Roman Egypt

MACEDONIAN AND PTOLEMAIC EGYPT (332–30 BC)

The Macedonian conquest. When Alexander the Great marched his army of Macedonians and Greeks into Egypt in the fall of 332, he found a country ready to throw off Persian control and a people who looked upon him as something of a liberator: the ancient kingdom of the pharaohs fell to him without a battle. Alexander at once visited the oasis of Siwa, the seat of the oracle of Amon that had been famous throughout the Greek world for generations. There he was told by the oracle that he was the son of Amon and thereby acquired in Egyptian eyes confirmation of his newly acclaimed position as pharaoh.

Perhaps Alexander's most important act was the founding of a new city, Alexandria, west of the Nile Delta near the small village of Rakotis, on a site suitable for a major port. Offshore was an island that, connected to the shore by a causeway, would act as protection from the open waters of the Mediterranean to afford two good harbours for shipping. The city flourished in later years, became the seat of government of Egypt, and, as a major cultural centre of the East for centuries, was by far the most famous and successful of Alexander's city foundations.

Founding of Alexandria

In the spring of 331 Alexander marched east, leaving Egypt under the divided administration of Macedonians, Greeks, and Egyptians. The Persian satrap was replaced by two Egyptian governors or nomarchs, but the military forces were divided among a number of commanders. The system, however, does not seem to have long survived Alexander's departure. A Greek, Cleomenes of Naukratis, seems to have been entrusted with taxation and soon gained, with Alexander's consent, absolute control of the country. Ancient writers attest his deviousness in securing revenue, but Cleomenes nevertheless seems to have played a major part in the completion of the construction of Alexandria.

Alexander's sudden death in Babylon in June 323 altered everything. His campaigns of ten years had given rise to a number of generals who if nothing else were eager to enjoy their hard-won conquests; it took them a week to divide Alexander's empire among themselves. The division was intended to be amicable. The old general Perdiccas was to have served as regent for Alexander's yet unborn son and successor, Philip Arrhidaeus. But the generals, who for a number of years acted as satraps (governors) under the regency, behaved increasingly like independent dynasts. Civil war ensued, and soon the fiction of a unified kingship was abandoned. By 305 the generals had become kings in their own territories, and the empire built by Alexander had fallen into a number of independent states. Egypt fell to Ptolemy I, the son of an obscure Macedonian named Lagus.

The Ptolemaic dynasty. The history of Egypt in the next century was deeply influenced by these changes in the nature of Alexander's kingdom. When Alexander assumed control of Egypt, he had assumed also the trappings of divinity of the pharaohs; so too did Ptolemy after he proclaimed himself king. But though he and his successors played the part of Egyptian kings to Egyptians, their need for Greeks in administration and in the army kept them a part of the Hellenic world. A creative tension emerged between Hellenic and Egyptian cultures whereby each preserved its own characteristics but affected and changed the other.

During the 3rd century the country was wholly reorganized. Ptolemy I had fought a number of battles against other Macedonian generals in the 4th century, defeating Antigonus at Gaza in 312, and finally, at Ipsus in 301, in a battle which brought to an end the wars of the Diadochoi ("successors"). But the turmoil of these wars little changed the political picture that had obtained after the death of Alexander when Ptolemy took over Egypt from Cleomenes. By the end of the century Ptolemy still held Egypt securely, had extensive interests and influence in the Aegean, controlled Cyprus and Cyrene, and was quarrelling with his neighbour over control of Palestine.

Battle of Ipsus

Ptolemy II, 284–246. Ptolemy's son, Ptolemy II, was associated on the throne with his father in 284 and became sole ruler in 282. His reign saw the continuance of the first Ptolemy's foreign policy, although, with Alexander's generals now dead, struggles were now between the kings of the second generation. Ptolemy II engaged in a massive administrative and economic reorganization of Egypt. His father may have begun it, but it is from the time of Ptolemy II that there are extensive remains of papyri of official documents, private letters, royal decrees, and the like, that make it possible to read directly the evidence of the nature of the bureaucratic, social, and economic life of the country during the period.

Ptolemy II revived the custom of the Egyptians, followed later by many of his successors, of the king marrying his sister. His queen and full sister, Arsinoe II, was one of the most remarkable women of the Hellenistic Age. After being involved in several intrigues in Asia Minor, she returned to Egypt when the prospect of success, or even survival, outside seemed bleak and, with the determination typical of the women of this dynasty, supplanted her predecessor and became queen. She was in the fullest sense co-ruler. Each of the pair was known as Philadelphus, "brother-loving," "sister-loving," and, so far as is known, while Arsinoe lived she played a considerable, perhaps dominant, role in the formulation of royal policy. She was displayed on the coinage, and soon after her death (270 BC), if not before, she was worshipped as a goddess in the Greek ruler cult in Egypt.

Ptolemy II Philadelphus did much to advance the cultural and economic life of his kingdom. He promoted scholarship and literature, bringing to Alexandria such prominent writers as Theocritus and Callimachus. The museum called the Temple of the Muses in Alexandria was perhaps founded by Ptolemy I but was certainly active by the reign of his son; it was a centre of scientific and scholarly activity during his reign, and its attached library attracted great men of learning from all over the Greek world. It was during Ptolemy II's reign that the Greek Septuagint translation of the Old Testament was begun, and the occurrence of some peculiarly Ptolemaic administrative terminology suggests an Egyptian background as well as location for the translators. Philadelphus' activity also extended to administrative organization and agricultural innovation. New crops were introduced into the country, and new irrigation works opened up new agricultural lands.

Ptolemy III, 246–222. When Ptolemy II died in 246, he left the country in good condition to his son, Ptolemy III Euergetes I. Euergetes ("doer of good") received his name from his success in war against his eastern neighbour, Seleucus II of Syria. The war was occasioned by the murder of Euergetes' sister, Berenice, in Syria. One of the last acts of Ptolemy II had been the arrangement of the marriage of Berenice to Antiochus II of Syria. With the birth of a son to Berenice, Ptolemy II died expecting peace between the two realms and hoping to have his grandson king of Syria. The arrangement was disturbed by Laodice, the former queen of Antiochus, who murdered Berenice and the young prince and set her own son, Seleucus, on the throne. To save, and then avenge, Berenice, Euergetes marched into Syria; his campaign ended in victory, and he gained great popularity with the Egyptians with the recapture of the statues of their gods, originally taken by the Persians.

War with Syria

Euergetes spent the remainder of his reign in Egypt, losing some of his conquests in northern Syria and eventually signing a peace in Palestine. Like his father, he nourished culture and began the building of the great temple at Edfu, which still survives intact.

Ptolemy IV, 222–205. When Euergetes died (221), he was succeeded by his 23-year-old son Ptolemy IV Philopator. An unfavourable Greek tradition portrays Philopator as a corrupt and weak ruler, controlled by a court circle led by an Alexandrian named Sosibius. At the very beginning of his reign Egypt was unsuccessfully attacked by Antiochus III, who later launched a more determined attack that ended, however, in a great Ptolemaic victory at Raphia in southern Palestine in 217, a battle in which for the first time Egyptians, equipped and trained in the Macedonian fashion, fought beside Macedonian and Greek troops against a Hellenic enemy.

Ptolemy V, 205–180. Philopator died in 205 and left an infant son, Ptolemy V Epiphanes. The palace was under the influence of the court circle, which announced Philopator's death and Epiphanes' accession only in the following year. Soon, however, the Alexandrians rose against the court group and installed Tlepolemus, a soldier, as regent. But Tlepolemus had no success in holding back Antiochus III, who took advantage of Egypt's internal instability to expel Ptolemaic forces from the Levant and its Aegean dependencies. Tlepolemus' successor, Aristomenes, was successful for a while in pushing Antiochus' forces back in Palestine. Epiphanes' reign saw the growing strength of native revolts that had begun under his predecessors. By 197, when Epiphanes reached his majority at age 12, there seems to have been enough trouble, both internally and externally, to necessitate that Epiphanes celebrate his coming of age, in a bid for the support of the Egyptians. Honours were accorded the Egyptian religion, as recorded on the celebrated Rosetta Stone, during a religious synod in 196. Throughout this period Antiochus III pressed on Egypt from the east, while Philip V of Macedon seized Egyptian territory overseas. The Battle of Panium (*c.* 200) transferred Palestine to the Seleucids. A peace with Antiochus was concluded in 193 whereby Epiphanes married Antiochus' daughter Cleopatra, making Egypt something of a Seleucid protectorate. Ephiphanes had more success in internal affairs and by 183 had managed to suppress the remnants of native revolt. He died in 180 and was succeeded by his son Ptolemy VI Philometor.

Native revolts

Ptolemy VI, 180–145. Philometor, like his father, came to the throne a child, but he had the benefit of the firm rule of his mother, Cleopatra I, who governed the country with a strong hand until her death in 176. Her death was followed by a rupture between the Seleucid and Ptolemaic courts. Philometor married his sister Cleo-

patra II, and after some disturbances in Alexandria, which resulted in the reuniting of Philometor's younger brother with the reigning couple, the Egyptians sent an expedition into Palestine that was defeated by Antiochus IV. Antiochus returned the compliment, and by 169 he and his army were in Egypt, in control of part of the country and, in some way, of the person of Philometor as well. But Philometor escaped from the guard imposed by Antiochus, and when Antiochus returned with an army in the following year he faced a reunited trio.

He faced Rome as well. The Romans had been involved in the eastern Mediterranean for a long time, and their influence was growing. With the defeat of Philip V of Macedonia in 197, and his son Perseus in 168, Rome controlled the whole of Greece. After the defeat of Antiochus III at Magnesia in 190, Antiochus had withdrawn from conflict with Rome, and Rome's power was recognized throughout the East. The Ptolemies saw the advantage of friendship with Rome and placed themselves under its patronage. Thus when Antiochus IV returned to Egypt in 168, it was in line with Roman policy to oppose him. Gaius Popillius Laenas had been sent to Egypt, and as soon as he learned of the Roman victory over Perseus in 168 he knew it was safe to act. He ordered Antiochus to withdraw, and the latter's rapid compliance was a recognition of Roman dominance in the East. Thereafter, Roman protection of Egypt was to be a feature of international life as the Hellenistic kingdoms slid more and more toward impotence.

Friendship with Rome

Dynastic strife and the rise of Rome, 145–52 BC. The rest of the reign of Philometor, and much of that of his successor and brother, Ptolemy VIII Euergetes II, was marked by dynastic quarrelling. The association of Philometor, his wife, Cleopatra II, and Euergetes II lasted until 164, when Philometor was expelled; the solution imposed by the Romans gave Egypt to Philometor and Cyrenaica to Euergetes; he remained there until his brother died on campaign in Syria in 145. Philometor's attempt to have his young son Neos Philopator reign as Ptolemy VII was foiled by Euergetes, who returned to Egypt in that year to begin his long reign. Euergetes killed Neos Philopator and married Philometor's widow, Cleopatra II, who was sister to them both. Later he divorced Cleopatra II and married her daughter Cleopatra III. Disagreement between brother and sister persisted, and in 131 or 130 Cleopatra II was in formal revolt from Euergetes and was recognized as ruler in parts of Upper Egypt. By 118, after a long period of dissension, brother and sister made peace, and a long decree announced amnesty to the partisans of both sides.

Ancient historians portrayed Euergetes as a tyrant who massacred a number of Alexandrians and expelled the representatives of Hellenic culture. But monuments and papyri show him a capable administrator and a friend and patron of the native Egyptians. And, though detested by the Greeks, there is evidence that he was a supporter also of Greek culture.

Cleopatra II and her brother both died in 116. This left Cleopatra III, to whom Euergetes had bequeathed the throne, with two sons, Ptolemy, later to be known as Soter II, and Alexander. Cyrenaica had been given to Ptolemy Apion, an illegitimate son of Euergetes. Cleopatra wanted her younger and favourite son Alexander to share her throne, but it was Soter II who ruled with her as Ptolemy IX. In 110 Soter II was briefly supplanted by Alexander, but in 109 he returned, only to be expelled again in 107. Alexander ruled with Cleopatra III until her death in 101, and then with Cleopatra Berenice until his own expulsion in 88 by Soter, who ruled until his death in 81.

The years of these kings were marked by the growing power of Rome and the loss of more and more Ptolemaic independence. As early as the reign of Ptolemy VIII, Hellenistic kingdoms were falling to Rome: in 133, Attalus III of Pergamum bequeathed his kingdom to Rome, and in 96 Ptolemy Apion died, leaving the Romans Cyrenaica. In the latter kingdom the Romans left the cities independent for a while, but the area was formally annexed as a province in 74. After Soter's death, Cyprus became more or less independent and was eventually annexed by Rome in 58. Soter's son, who ruled as Ptolemy XII, succeeded to the throne in 80 after a rapid succession of unsuccessful claimants early in the year, and depended upon Rome for his tenuous hold on the throne during his life.

Increasing loss of independence

Ptolemy XII, nicknamed Auletes ("flute player"), was the last king to maintain the long-standing Ptolemaic policy of neutrality in the internal disputes of Rome. Soter II at the end of his reign had been able to keep Egypt out of the war between Rome and Mithradates, the strong king of Pontus in Anatolia. Auletes managed in general to avoid the struggle that centred on the Roman general Pompey's activities in the East. This did not mean that Egypt stayed out of the Roman sphere. On the contrary, in 58, after convincing Julius Caesar to recognize him as king in Egypt, Auletes was forced to go to Rome to plead his case and ask for support. He was away two years, during which time Cleopatra Tryphaena and his daughter Berenice IV took turns ruling. He spent so much money arranging support in Rome that when he was restored to the throne in 55 by one of Pompey's commanders, Aulus Gabinius, he had to bring his creditor, the banker Rabirius, back to Egypt to act as finance minister. The arrangement was probably struck to ensure that Rabirius would recover at least as much money as he had lent.

Cleopatra. In 52 Auletes associated with himself on the throne his daughter Cleopatra VII and his elder son Ptolemy XIII, both of whom succeeded him when he died the following year. The reign of Cleopatra VII, the famous queen of history and romance, was dominated by her struggle to survive her brother on the throne and by her attempts to join herself to the winning side in the civil wars of the late Roman Republic.

The arrival of Julius Caesar

Her first success was with Julius Caesar, when, after his victory over Pompey, he came to Alexandria in 48 in pursuit of his fleeing enemy. Caesar was trapped in the city by Egyptian forces who resented the Roman intruder. In control of the palace, the King, and Cleopatra, Caesar established a more than political relationship with the queen, so that after the siege was broken in 47 he established her firmly upon the throne with her younger brother, who ruled as Ptolemy XIV (47–44), Ptolemy XIII (51–47) having died.

Later in 47, Cleopatra gave birth to a son, who according to her assertion was the child of Caesar and to whom she gave the name Caesarion ("little Caesar"). In the following year Cleopatra followed Caesar to Rome and took up quarters there. With Caesar's support she was safely queen of Egypt and could come to Rome with her boy brother-king without risking trouble at home. Indeed, she bid fair as Caesar's consort to be queen of the Mediterranean world.

Her security ended abruptly with Caesar's assassination in 44. Cleopatra quickly got back to Egypt, in hope of riding out the storm that would surely come. For a while, she played the old Ptolemaic game of neutrality, trying to remain friendly to both the Caesarian and anti-Caesarian parties, hostile to neither. She did nothing to help Antony and his ally Octavian against Caesar's enemies at Rome until they had won, but when she met Antony at Tarsus in 41 he returned to Egypt with her, and a new liaison was begun. Antony left Egypt for campaign in 40, not to return until 36, in which year he signalled his affiliation with Cleopatra by giving her large tracts of the Levant.

In the following years a breach between Antony and Octavian opened. Antony's personal commitment to the East, staying as he did with Cleopatra, became useful propaganda against him in Italy that Octavian employed to build his strength for the coming showdown. It came in September of 31, in the naval battle at Actium in western Greece, where Cleopatra and Antony were both present. During the battle, Cleopatra and the Egyptian squadron left precipitately. Why, no one knew, in antiquity or today, but as Antony saw her ships pull away, he too left the battle, abandoning any possibility of victory. The two returned to Alexandria amid the trappings of pretended

triumph, while they were in reality only playing out the drama of defeat as they waited for Octavian, now master of the Roman world, to arrive.

On Octavian's arrival in August of 30, Antony stabbed himself, and Cleopatra is said to have committed suicide by the bite of an asp. Much as Octavian might have liked to exhibit the notorious queen at Rome, the last of the Ptolemies controlled her own end and died in Egypt. Though less successful than her ancestor, she had all the verve and vigour of that first Ptolemy who had commanded the troops of Alexander the Great and started the longest and most successful of the Hellenistic dynasties.

Government and civilization of Hellenistic Egypt. The multitude of papyri, both private and public, from the Ptolemaic period, has left a remarkably clear picture of the nature of everyday life. The absence of any connected ancient source makes knowledge of the period as a whole rather fragmentary, but the historian can get a better sense of the internal working of the country than he can for any other place in the ancient world. Fortunately, the documentation is particularly heavy for the mid-3rd century BC, when Ptolemy II was in the process of organizing the country's administration that served his successors so well.

Administration. The early Ptolemies had numerous problems. They needed Greeks for their armies and administration. Greeks who served in the army were assigned plots of land in Egypt to use for their support, and these soldiers, called cleruchs, initially formed the backbone of the legal, economic, and administrative system. Many took care of minor and major official duties in an economic system arranged to produce the highest possible revenue for the crown. This administrative structure was quite elaborate. There were parallel bureaucracies, each with its own hierarchy, for the various departments of government: a department of revenue oversaw the collection and transfer of taxes to the crown; a department of land administration assigned acreage for seeding of various crops and saw to the proper physical operation of agriculture; and a clerical department kept records of landholding, sowing assignments and requirements, and the assessment and payment of taxes. These three departments operated at various levels: at the level of the nome, the country's major subdivision (of which there were about 40), the *oikonomos* supervised revenue administration, while the *nomarchēs* supervised the land, and the *basilikos grammateus* (royal scribe) was in charge of records. Junior to them were assistants to the *oikonomos*, juniors to the *nomarchēs* called *kōmarchēs* (in charge of villages), and village scribes. A *strategus* (general) not only commanded the military in each nome but also, and more importantly, administered justice. Above all these was an official in Alexandria called the *dioikētēs* (finance minister), who directed economic activities for the entire country.

The parallel bureaucracies of Hellenistic Egypt

Such was the theoretical organization of the bureaucracy, but it is clear from the papyri that the tripartite structure did not always work as neatly in practice. There were not always enough officials, and the complexity of administration in some areas required a more articulated division of authority. As a consequence, there were more divisions and more levels in some areas than the structure seems to have called for, and fewer in others. All in all, however, it seems to have worked well.

Both Greeks and Egyptians were employed in bureaucracy. Even at the highest ranks, and in the earliest period of Ptolemaic control, native Egyptians served the king, as attested by Egyptian-style statues with the Egyptian names and ranks of their dedicators. The papyri indicate also numerous Egyptians in the lower levels of government.

Economy. The economic system established by the Ptolemies was a mixture of royal monopolistic control and private enterprise. Royal revenues came both from ordinary taxes and from the proceeds deriving from exploitation of the monopolies. A long papyrus of the 3rd century BC preserves many of the regulations imposed by Ptolemy II to ensure that the oil monopoly brought him maximum revenues. Fragments of the papyrus preserve references to other royal enterprises: the production of textiles, the manufacture and sale of beer (the national drink of the Egyptians), and the distribution of salt. What was not monopoly was taxed. The crown imposed taxes at different rates, depending upon the product, so that there was a special tax, for example, on vine and orchard lands and another on grain-producing lands.

Sources of royal revenue

While it is not possible to determine the direction of expenditure of these revenues, it is clear that, for the 3rd century at least, a good deal of money must have gone to maintain the large Ptolemaic military establishment. Within the country itself, some of the money went for the administration, although in such circumstances that the expenditure for staff was undertaken in pursuit of revenue. There are directions in a papyrus detailing the revenue laws for the exploitation of the oil-bearing plants, and as part of the instructions the king specifies the salaries to be paid for the various tasks. Many papyri mention salaries to be paid to underlings, and although many of these seem only quasi-official or even unofficial personages, in many cases the payments come from the royal account or from crown officials. Even the tax farmers who collected the oil tax were paid by salary rather than out of the profit of excess collection—the method favoured by the Romans.

Role of banking in economy

The economy itself was highly sophisticated and included a number of specialized occupations. Bankers, for example, served both the king and private persons. The royal bank, with branches throughout the country, served in a way as a treasury, receiving all payments due the king and making official disbursements on proper authority. At the same time, the banks carried on all kinds of private business, such as making loans, accepting deposits, and making payments on private accounts. All this was carried on with written instructions and drafts, so that the system bore something of a modern character. In addition to banking services, there was extensive use of private credit, and the papyri preserve many loan transactions. Land itself was the object of many transactions, and even though in theory ownership of much of it was vested in the king, there are records of many leases of land as well as of houses and even parts of houses.

Religion. Throughout the Ptolemaic period the relations between the king's officials and the priestly bureaucracy created problems. From the beginning, the temple land seems to have been managed by government officials, much as royal land was managed. Out of the revenues, and perhaps in some instances in addition to the revenues, the government paid the expenses of the temples. This close economic involvement between state and religious enterprises illustrates both how closely the Ptolemaic system supervised important activities and how carefully the Ptolemies maintained the religious practices of Egypt.

The Greeks had always respected the antiquity of Egyptian religion, and individual Greeks were fully prepared to worship Egyptian deities as they had Greek; so that in Egypt, as in much of the rest of the Hellenistic world, the growing cults of Isis, for example, mark the spread of mystery, salvation, and healing religions three centuries before Christ.

The Ptolemies did nothing to discourage Egyptian cults, although from time to time there seems to have been some attempt to restrict the political influence of the priesthood. From the beginning of their dynasty, the Ptolemies built new temples in the Egyptian style and fostered the worship of Sarapis, a god encountered by the Greeks perhaps as early as Alexander's founding of Alexandria, and under the Ptolemies represented as a Hellenic deity, often as Zeus. The centre of his worship was the new Ptolemaic capital of Alexandria, where a number of Sarapeums were supported by the Ptolemies with an elaborate priesthood.

Worship of Sarapis

The Ptolemies too were worshipped as gods, as had been the pharaohs before them, and Egyptian inscriptions refer to Ptolemies in the same language that had been addressed to pharaohs of native descent. New to Egypt, however, was a formalized royal cult, more Greek than

Egyptian, dedicated to the worship of Alexander the Great and of each of the Ptolemies. By the end of the period, the number of priests in the cults had swelled to serve the many divinities of the dynasts who had reigned. Inscriptions record the synods of these priests meeting to issue decrees in the service of the reigning monarchs, and it is easy to see that the royal cult could serve political as well as religious and psychological needs.

Law. Although there was a blending of Greek and Egyptian religion, Ptolemaic law seems to have kept the two strains of culture apart. Egyptian custom received the status of law by royal decree of the Ptolemies. Egyptians were judged by their native judges, and their contracts were judged according to native custom. Greeks wrote Greek contracts to be assessed in different courts. In general, the language of the contract determined the court of resort in civil law. Much law, however, was by administrative decision, and, in an economic system strongly controlled by the monarchy, much private activity and many private disputes were resolved by bureaucrats rather than by judges.

Culture. Greek culture flourished under the Ptolemies. Many famous writers came to Alexandria, particularly during the reigns of the first Ptolemies, and the city became a centre of writing and culture. Major poets, such as Theocritus, Callimachus, and Apollonius of Rhodes, took up residence under the patronage of Ptolemy II and formed a literary school, though they did not always like each other's work. Callimachus, for example, one of the most esteemed writers of the ancient world, referred disparagingly to the lengthiness of the poems of Apollonius. The original literary product of Alexandria was considerable; much of the writing in Greek of the Hellenistic period was done there. In addition, a school of scholarship was active (from the mid-3rd century on) that is probably responsible for the preservation of a great deal of earlier Greek writings. Such scholars as Zenodotus and Aristarchus, famous for their work on Homer, made new editions, corrected and refined manuscripts, and wrote commentaries on the great writings of the past. The Library of Alexandria collected all the manuscripts it could, while throughout the period new texts were made and sold to Greeks throughout the country.

Alexandrian poets

Alexandria was also a centre for scientific research. The great mathematician and astronomer Eratosthenes did his work there in the 3rd century, serving as librarian and carrying on his experiments. The school of mathematics at Alexandria is said to have been established by Euclid. As the home of so many scholars, philosophers, and literary figures, Alexandria became one of the great centres of education and culture, rivalling Athens, and it retained its importance and status long after the end of the Ptolemaic dynasty.

The Ptolemies endured through the great shift in the centre of power in the Mediterranean world from Greece and the East to Rome and the West. The security of Egypt permitted Greek culture to flourish, and the Greeks in Egypt developed and expanded. Although it has been common to see in the Hellenistic period, particularly in Egypt, a blending of cultures, and although that seems to have occurred to some extent in religious affairs, the two cultures in fact merely coexisted. The Ptolemies exploited the resources of the country and promoted Greek culture, but they allowed native institutions to continue, not only in religious affairs but in law, literature, and custom. There seems to have been no conscious "racial" discrimination against Egyptians, and there was much intermarriage. There does, however, seem to have been a deliberate policy to maintain the Greek language in the administration of the country. Egyptians who chose to learn Greek could rise in government, but then they and their descendants became Hellenized. The language policy may have been merely administrative convenience, but it must have contributed, as a side effect, to the great Alexandrian efflorescence of Greek studies.

Interaction of the two cultures

ROMAN EGYPT (30 BC–AD 642)

The Egypt taken over by Octavian after the suicide of Cleopatra in 30 BC was a country that, despite some internal struggles and dynastic quarrels, was still relatively well organized, and still wealthy. With the introduction of a new stability under the Romans, Egypt had great promise of prosperity and profit. In the century before it became the property of Rome, Egypt had been carrying on extensive trade with the West; and even though the Ptolemies had been forced on occasion to borrow from Roman bankers to maintain themselves against other claimants to the throne, Cleopatra had been able to lend financial support to Antony's adventures and supply a fleet in his final attempt to defeat Octavian. Much of this wealth must have come from shipments of grain to Italy. Egypt had long produced a grain surplus, and the land remained fertile and productive despite political unrest and international upheaval. As Italy became more urbanized and populous, and required increasing imports of grain, Egypt became more and more important as a reliable source of its food. Octavian (later known as Augustus) saw that the stability of his new empire depended, to some extent, upon the security of Egypt and its grain supply and upon the assurance that the supply would remain controlled by his government. He thus treated Egypt differently from other Roman provinces. The country was treated as his personal property, just as the country, the people, and all its resources had been the personal property of the Ptolemies. No Roman of senatorial class was allowed to enter Egypt without the explicit permission of the emperor. This reduced the danger that adventurers challenging imperial rule might fasten upon Egypt and its grain supply to control events in Italy.

Egypt's role as the granary of Rome

But Egypt was a special province for other reasons. Just as in Hellenistic times Egypt differed from its neighbouring states in its centralized bureaucracy and royally directed economy, so in Roman times it differed from other provinces in that it had greater geographic and administrative cohesion. In other provinces of the Roman Empire, administration seems to have been centred in the major cities, which seem to have continued as "free" states, governed under their own laws and impinged upon only as the Roman provincial governors saw need to provide for security for the continued collection of taxes. The tax collections in these provinces were undertaken by companies of private Roman citizens, supported by governors and armies. Egypt, on the other hand, continued to be governed by its Ptolemaic bureaucracy, and although more and more tasks came to be undertaken as "voluntary" duties by residents of the countryside and towns, government, through the prefect of Egypt, an agent of the emperor, was direct and pervasive. And in Egypt, the emperor was king, pharaoh, god, just as had been his predecessors, the Ptolemies.

Nevertheless, the influence of Egypt must have been considerable, particularly as this form of government was a success. Egypt by and large was one of the more stable parts of the empire, and although there were occasional revolts beginning there, or political movements to which the governors of Egypt adhered, more often than not the armies in Egypt did not initiate changes in emperors but rather joined the side of the successful claimant. And as the bureaucracy of Egypt continued to supply money and material through changes of imperial house and through convulsions of empire, the merits of a standing bureaucracy became more and more obvious. Egypt thus served to some extent as an impulse toward the growth of Roman bureaucracy.

Roman administration. Egypt was administered directly by the imperial house through a prefect of equestrian, or knightly, class appointed by the emperor. Emperors seldom visited the province, and visits by the imperial family were discouraged for the same reason as visits by those of senatorial rank. The emperor used servants and prefects rather than dangerous nobility to communicate with Egypt and carry imperial decisions; the emperor Tiberius reprimanded his nephew Germanicus for an unauthorized visit in AD 19. When residents of Egypt or Alexandria required direct audience with the emperor, they had to go to Rome, as did representatives of the citizens and Jews of Alexandria, petitioning against

each other about the recurring disputes and disorders that arose between them. The visit of the emperor Septimius Severus to Egypt in AD 199 or 200 was exceptional.

Duties of the Roman prefect

The Roman prefect headed the bureaucracy of the country; he commanded the army, dispensed justice, administered taxes, and directed the economy as a whole. Though much of the lower bureaucracy seems to have continued under the Romans, at least in name, a fundamental change in fact came over the country. It has been conventional to speak of Greco-Roman Egypt as though there were a continuum (and in some areas of life there was such); but in most matters affected by government, the advent of Roman control brought significant changes.

The most obvious changes were in law. Although the practices of Greek law, particularly in the private sphere, seem to have continued, the administration of that law was different. Jurisdiction was centred in the office of prefect, who was assisted by an official called the *juridicus*. The Ptolemaic courts were eliminated or radically changed; under the prefect, Egypt was divided into three judicial districts or assizes (*conventus*), where cases were heard and decisions rendered. For the country as a whole, edicts were issued to establish specific practices, and these edicts established precedents. Surviving records contain judgments and appeals citing particular decisions or directives by former prefects. Roman law was in effect for Roman citizens in Egypt, and in the Greek city of Alexandria the Roman government supplanted the law courts of Ptolemaic times.

City government

Egyptian cities also received different treatment by the Romans. Alexandria, which may have had a senate in Ptolemaic times, petitioned the emperor Claudius (ruled 41–54) for the establishment of one. The petition was denied, so that no such institution existed there in the first centuries of Roman rule. Septimius Severus, however, established senates (*boulai*) for all the Greek cities and for the metropolitan cities of the nomes as well. The establishment of a Greek form of government for the cities conformed to the Roman practice of relying upon local administration and magistracies insofar as possible, even though in Egypt those cities must have been less autonomous than they were in the less organized provinces of the empire. At the time of Augustus' conquest, there were only three autonomous Greek cities in Egypt, the old Greek *polis* of Naukratis, along with Alexandria and Ptolemais. In 130 the emperor Hadrian established a new city, Antinoöpolis, named after his friend Antinoüs, which was lavished with privileges and set up with all the institutions characteristic of a Greek city, including a *boulē*. But the other cities, although they had many of the magistracies associated with the autonomous city in the time of Greek independence, were not to have their *boulai* until they were set up for all cities, including nome capitals, by Septimius Severus at the beginning of the 3rd century.

The new *boulai* illustrate well the Roman system of local administration in Egypt. These councils (and their members) were responsible for carrying out, each within its own city, the duties of administration and the collection of taxes. They were responsible to the central bureaucracy and to superior officials in this, but they were to use their own resources in carrying out their tasks. This was the system of "liturgies": individual Egyptians were nominated by the civil authority to carry out administrative responsibilities and were designated to hold offices for fixed periods, the nominator's property and that of the "liturgist" serving as guarantee in case of failure. The *boulai* were responsible for nomination to offices, thus placing in local hands the unpopular task of distributing burdens. The system worked well for a while and gave the Romans a maximum return from Egypt, as the costs of running the country and the collection of taxes were paid by the residents, not by the Roman administration.

"Liturgy" system

Another characteristic of Roman administration was the introduction of a clear-cut and formalized classification of population. In Ptolemaic times the government recognized different ethnic backgrounds and provided for distinctions and different treatments for them under the law. But there was little formal attempt to keep the distinctions permanent. The Romans, on the other hand, made a very strong attempt to formalize and control the ethnic groupings, particularly as they affected Roman citizenship. The so-called *Gnomon*, or consolidation of rules, issued in the 2nd century by the office of the *idios logos* (controller), makes it clear that changes of status were discouraged, that cross-inheritance was limited, that Romans were not allowed to make Greek wills, and that Egyptians were not to be granted citizenship by serving in the legions. The manifold regulations of the *Gnomon* describe a situation in which citizenship, whether Roman or in the "Greek" cities, was protected and guarded as a privilege.

Throughout the first two centuries of Roman rule, Roman citizenship, in Egypt as elsewhere, could be granted a non-Roman either as a reward or as a result of serving in the legions. In 212, by the imperial decree known as the Constitutio Antoniniana de Civitate, better known as the Edict of Caracalla, the citizenship was broadened, but its interpretation remains problematical. It appears, however, that citizenship was granted to all but certain specified groups, and it is clear that citizenship was taken up extensively throughout Egypt after the issuance of that decree.

Although changes in detail of administration in Egypt can be traced in the first two centuries, down to the accession of Septimius Severus in 193, the systems established by Augustus and his Julio-Claudian successors continued to function without fundamental modification. By the time of Severus, however, the structure was showing signs of strain, and Severus' changes were aimed at shoring up an administrative structure that was under stress, although still working. By granting municipal councils to the chief city of each nome and to the Greek cities, Severus altered the bureaucratic structure without changing the nature or types of taxes collected, and he maintained the position and nature of Egypt as a single province in the empire without modification of the higher offices in the administration in Egypt. His change was aimed at throwing more of the responsibility onto the residents of the cities.

The end of Roman rule. By the end of the 3rd century the strain of political and economic unrest told not only upon Egypt but upon the whole Roman Empire. A succession of short-lived military adventurers holding power at Rome could not meet the needs of a complex empire; and the recurrent struggles for power had themselves contributed much to the troubles of government. The need for reform was met with the accession of Diocletian as emperor in 284. He was something of a genius at administration, and in his reorganization of the empire he broke completely with tradition. He divided the empire into East and West, each under a reigning Augustus and an heir apparent called a Caesar. All provinces were reorganized and given completely new bureaucracies, and many had their boundaries redrawn. Within the provinces, local administration was radically altered to fit a new concept of taxation, wherein each year each province was allotted its "indiction," an estimate based on 15-year assessments. The intention of the fiscal reform, based as it was on estimates of productivity, was to distribute the burden of taxation more fairly, and Diocletian hoped through his reforms to stabilize the capitation and land taxes and to rely less on the special taxes, which had been a particular burden in the years before his accession.

Reforms of Diocletian

Egypt itself was divided into three provinces—the Thebaid, Aegyptus Herculia, and Aegyptus Jovia—each under a governor called a *praeses*. The prefect of Egypt continued to function, but his responsibility was limited to the civil administration of the northern province, Aegyptus Jovia, including Alexandria. Military authority was invested in a new official called the *dux*, or duke, of Egypt. Another major change occurred soon after Diocletian's abdication in 305. Within the country, the administration was changed from the structure based on nomes, each with its capital and central administrators, to a structure based on self-governing municipalities. Each city was assigned a territorial district, and that district was divided into numbered sections, each called a *pagus*,

with each pagus under the administration of an official called *praepositus*. Administrative duties centred on the cities themselves, and thence extended to the higher reaches of government. Latin replaced Greek as the language of the upper bureaucracy.

Growth of Christianity

In these years and in the years following, even more changes took place. Christianity was spreading throughout the empire, and, despite attempts during the reign of Diocletian to suppress it, by the mid-4th century Egypt seems to have become predominantly Christian, and the religion had penetrated throughout the native population. The native Egyptian language, Coptic, newly rendered into a script based on the Greek alphabet, transmitted the Bible and the writings of the Christian Fathers to the peasants. The granting of tolerance in 313 to the Christians by the emperor Constantine I (306–337) gave impetus to the development of a formal Egyptian church that soon vied with that of Constantinople. The Orthodox Alexandrian patriarchs were often at odds with large segments of the Egyptian population, which tended to favour heterodox Christian teachings (*e.g.*, Arianism and Monophysitism). Throughout the countryside the growing enthusiasm for anchoritism, the hermit life, took vigorous and intellectual men into the desert.

Consolidation of large estates

Meanwhile, the economic structure of the country underwent a harsh transition in the 4th century. Large estates became concentrated in the hands of wealthy families throughout the country. Smaller landholders often turned to these powerful families for protection, and turned over their small holdings to them in return for the right to farm the land as lessees. This was the solution to the growing pressure of taxation, which large landholders could meet more easily than the small. With this transfer of land, the rich became more powerful, and despite the attempts of the state to restrict the trend the great estates grew apace, until they were officially recognized in the early 5th century.

The people themselves were officially bound to the land. In 415 a government decree restored vagrant tenants (*coloni*) to their masters and villagers to their towns. The restriction on freedom of movement and occupation characteristic of the empire as a whole was enforced in Egypt, and the extensive agricultural value of the countryside made it a useful adjunct to the exploitation of the large estates. This contributed to the growth of the power of the landowners, so that these great nobles became more and more part of the government structure, as it was through them that taxes were collected and law enforced.

Momentous events would prevent this system from evolving into the feudal structure of the West. Although Constantine reunited the empire at the beginning of the 4th century, it was divided permanently into East and West after the death of Theodosius in 395. Egypt was thenceforward administered from Constantinople. Under this administration the strength of Christianity and the great nobles increased. Byzantine Egypt was the Egypt of Christianity, monasticism, Coptic culture, and the gulf between wealthy noble and poor farmer. This was the structure against which the growing power of the Sāsānid Persians pressed. Justinian, in the mid-6th century, reorganized Egypt into four parts, each under a governor with both military and civil powers. The government, however, could not resist the attacks of hostile powers. In 616 the Persians invaded and conquered Egypt, holding it until the death of their king in 628, when, by terms of a treaty, Egypt reverted to Byzantium under Heraclius I. But this did not last. The armies of Islām swept out of Arabia, first against the Persians, then against Egypt and the West. In 639 the army of ʿUmar invaded Egypt, and after a series of campaigns Alexandria was evacuated by the Byzantine army in 642. Egypt was now part of the Muslim world, and transmitted to Islāmic scholars the traditions and science of Hellenism, on which the Muslims themselves built and expanded. (A.E.S.)

IV. Egypt from c. 630 to c. 1800

Medieval Egyptian history opens and closes with foreign conquests of Egypt: the Arab invasion led by ʿAmr ibn al-ʿĀṣ in 639 and the Napoleonic expedition of 1798 mark the beginning and end of an era. Within the context of Egyptian internal history alone, this era was one in which Egypt cast off the heritage of the past to embrace a new language and a new religion—in other words, a new culture. While it is true that the past was by no means immediately and completely abandoned and that many aspects of Egyptian life, especially rural life, continued virtually unchanged, it is nevertheless clear that the civilization of Islāmic Egypt diverged sharply from that of the Greco-Roman period and was transformed under the impact of Western occupation. The history of medieval Egypt is therefore largely a study of the processes by which Egyptian Islāmic civilization evolved, particularly the processes of Arabization and Islāmization. But to confine Egyptian history to internal developments is to distort it, for during the entire medieval period Egypt was a part of a great world empire; and within this broader context, Egypt's history is a record of its long struggle to dominate an empire—a struggle that is not without its parallels, of course, both in ancient and modern times.

FROM THE ISLAMIC CONQUEST TO 1250

Period of Arab and Turkish governers (639–868). The sending of a military expedition to Egypt from the caliphal capital in Medina came in a second phase of the first Arab conquests. Theretofore the conquests had been directed against lands on the northern borders of Arabia and were in the nature of raids for plunder; they had grown in scale and momentum as the Byzantines and Persians put up organized resistance. By 635 the Arabs had realized that in order to meet this resistance effectively they must begin the systematic occupation of enemy territory, especially Syria, where the Byzantine army was determined to halt the Arab forays.

The Arab expedition to Egypt

The Arab conquest. The Arabs defeated the Byzantines and occupied the key cities of Syria and Palestine, and they vanquished the Persian army on the eastern front in Mesopotamia and Iraq. The next obvious step was to secure Syria against a possible attack launched from the Byzantine province of Egypt. Beyond this strategic consideration, Arab historians call attention to the fact that ʿAmr ibn al-ʿĀṣ, who later conquered Egypt, had visited Alexandria as a youth and had himself witnessed Egypt's enormous wealth. In spite of the obvious economic gain to be had from conquering Egypt, the caliph ʿUmar, according to some sources, showed reluctance to detach ʿAmr's expedition from the Syrian army and even tried to recall the mission once it had embarked; but ʿAmr, with or without the caliph's permission, undertook the invasion in 639 with a small army of some 4,000 men (later reinforced). With what seems astonishing speed the Byzantine forces were routed and had withdrawn from Egypt by 642. An attempt by a Byzantine fleet and army to reconquer Alexandria in 645 was quickly defeated by the Arabs.

Various explanations have been given for the speed with which the conquest was achieved, most of which stress the weakness of Byzantine resistance rather than Arab strength. Certainly the division of the Byzantine government and army into autonomous provincial units militated against the possibility of a concerted and coordinated response. Although there is only dubious evidence for the claim that the Copts welcomed the Arab invasion in the belief that Muslim religious tolerance would be preferable to Byzantine enforced orthodoxy and repression, Coptic support for their Byzantine oppressors was probably unenthusiastic at best.

Arab policies

Early Arab rule. In Egypt—as in Syria, Iraq, and Iran—the Arab conquerors did little in the beginning to disturb the status quo; as a small religious and ethnic minority, they thus hoped to make the occupation permanent. Treaties concluded between ʿAmr and the *muqawqis* (presumably a title referring to Cyrus, archbishop of Alexandria) granted protection to the native population in exchange for the payment of tribute. There was no attempt to force, or even to persuade, the Egyptians to convert to Islām; the Arabs even pledged to preserve the

Christian churches. The Byzantine system of taxation, combining a tax on land with a poll tax, was maintained, though it was streamlined and centralized for the sake of efficiency. The tax was administered by Copts, who staffed the tax bureau at all but the highest levels.

To the mass of inhabitants, the conquest must have made little practical difference, because the Muslim rulers left them alone, in the beginning at least, as long as they paid their taxes; if anything, their lot may have been slightly easier, because Byzantine religious persecution had ended. Moreover, the Arabs deliberately isolated themselves from the native population, according to ʿUmar's decree that no Arab could own land outside the Arabian Peninsula; this policy aimed at preventing the Arab tribal armies from dispersing and at ensuring a steady revenue from agriculture, on the assumption that the former landowners would make better farmers than would the Arab nomads.

As was their policy elsewhere, the conquerors refrained from using an established city such as Alexandria as their capital; instead, they founded a new garrison town laid out in tribal quarters. As the site for this town they chose the strategic apex of the triangle formed by the Nile Delta—at that time occupied by the Byzantine fortified township of Babylon. They named the town Fusṭāṭ, which is probably an Arabized form of the Greek term for "encampment" and gives a good indication of the nature of the earliest settlement. Like garrison towns founded by the Arabs in Iraq—Basra and Kūfah—Fusṭāṭ became the main agency of Arabization in Egypt inasmuch as it was the only town with an Arab majority and therefore required an extensive knowledge of Arabic from the native inhabitants.

The process of Arabization, however, was slow and gradual. Arabic did not displace Greek as the official language of state until 706, and there is evidence that Coptic continued to be used as a spoken language in Fusṭāṭ. Given the lack of pressure from the conquerors, the spread of their religion must have been even slower than that of their language. A mosque was built in Fusṭāṭ bearing the name of ʿAmr ibn al-ʿĀṣ, and each quarter of the town had its own smaller mosque. ʿAmr's mosque served not only as the religious centre of the town but also as the seat of certain administrative and judicial activities as well.

Although Alexandria was maintained as a port city, it should not be forgotten that Fusṭāṭ, being built on the Nile bank, was itself an important port and remained so until the 14th century. ʿAmr enhanced its commercial significance by clearing and reopening Trajan's Canal, so that shipments of grain destined for Arabia could be sent from Fusṭāṭ to the Red Sea by ship rather than by caravan.

Egypt under the caliphate. For more than 200 years —that is, throughout the Umayyad caliphate and well into the ʿAbbāsid—Egypt was ruled by governors appointed by the caliphs. As a province in an empire, Egypt's status was much the same as it had been for centuries under foreign rulers whose main interest was to supply the central government with Egyptian taxes and grain. In spite of evidence that the Arab governors tried in general to collect the taxes equitably, taking into account the capacities of individual landowners to pay and the annual variations in agricultural yield, resistance to paying the taxes increased in the 8th century and sometimes erupted into rebellion in times of economic distress. Periodically, religious unrest was manifested in the form of political insurrections, especially in those exceptional times when a governor openly discriminated against the Copts by forcing them to wear distinctive clothing or, worse, by destroying their icons. Still, the official policy, especially in Umayyad times, was tolerance, partly for fiscal reasons. In order to maintain the higher tax revenues collected from non-Muslims, the Arab governors discouraged conversion to Islām and even required those who did convert to continue paying the non-Muslim tax. New Christian churches were sometimes built, and the government took an interest in the selection of patriarchs.

Resistance to taxation

More than just a source of grain and taxes, Egypt also became a base for Arab-Muslim expansion, both by land and sea. The former Byzantine shipyards in Alexandria provided the nucleus of the Egyptian navy, which between 649 and 669 joined in expeditions with the Syrian navy against Rhodes, Cyprus, and Sicily and defeated the Byzantine navy in a major battle at Phoenix in 655. By land, the Arab armies advanced both to the south and to the west. As early as 651–652 the governor of Egypt invaded Nubia and imposed a treaty that required the Nubians to pay an annual tribute and to permit the unmolested practice of Islām in the province. Raids against North Africa by Arab armies based in Egypt began in 647; by 670 the Arabs had succeeded in establishing a garrison city in Ifrīqīyah (now Tunisia), called al-Qayrawān (Kairouan), which thenceforth displaced Egypt as the base for further expansion.

While some Arabs were passing through Egypt on their way to campaign in North Africa, others were being sent to the Nile Valley on a permanent basis. In addition to tribal contingents that at times escorted newly appointed governors to Egypt (some of which settled in towns), tribesmen were sometimes imported and settled in an effort to increase the Arab-Muslim concentration in the vicinity of Fusṭāṭ. The settlement of large numbers of anarchic tribesmen in Egypt, with tribal ties and allegiances elsewhere in the empire, meant that Egypt became embroiled in political difficulties with the central government. Civil strife centring around the assassination of the caliph ʿUthmān (656) began in Egypt, where the tribesmen resented the favouritism shown by the caliph to members of his own family. Uprisings led by the dissident Khārijite sect (the Seceders) were frequent in the mid-8th century. In the 9th century the caliph Maʾmun himself led an army from Iraq to put down a rebellion raised both by tribesmen and by Copts; repression of the Copts accompanying their defeat in 829–830 is usually cited as an important factor in accelerating conversion to Islām.

Civil strife

The difficulty inherent in ruling Egypt from Baghdad, which was itself undergoing stress and turbulence, is evident from the rapid turnover in governors assigned to Egypt; the ʿAbbāsid caliph Hārūn ar-Rashīd (ruled 786–809), for example, appointed 24 governors in a reign of 23 years. Possibly as a means both of removing the governorship from the level of tribal strife and paying the central government's Turkish troops, the caliphs began assigning Egypt to Turks rather than to Arabs. But this policy resulted in no tangible improvement in the administration of Egyptian affairs until 868, when the reign of Aḥmad ibn Ṭūlūn inaugurated a new phase of medieval Egyptian history.

The Ṭūlūnid dynasty (868–905). Though short-lived, the Ṭūlūnid dynasty succeeded in restoring a measure of Egypt's ancient glory. For the first time since the pharaohs, Egypt became virtually autonomous and the bulk of its revenues remained within its borders. What is more, Egypt became the centre of a small empire when Ibn Ṭūlūn conquered Syria in 878–879. These developments were paralleled in other provinces of the ʿAbbāsid Empire and were the direct result of the decline of the caliph's power. In order to strengthen their armies, the ʿAbbāsid caliphs had begun early in the 9th century to form contingents of Turkish slaves. To finance these new military formations and, in particular, to pay the Turkish commanders who headed them, the caliphs began to give them administrative grants (*iqṭāʿ* in Arabic, usually translated "fief") consisting of tax revenues from certain territories. In 868 Egypt was granted as a fief to the Turkish general Babak, who chose to remain in Iraq but appointed his stepson, Aḥmad ibn Ṭūlūn, as his agent in Egypt. Ibn Ṭūlūn's great achievement was that he quickly established his own authority in Egypt and backed it up with an army of his own creation, powerful enough to defy the central government of Baghdad and to embark upon foreign expansion.

Ibn Ṭūlūn's first step was to eliminate possible rivals in Egypt. From an early date the administration of Egypt had been divided between the *amīr* (military governor), appointed by the caliph, and the *ʿāmil* (fiscal officer), who

was sometimes appointed by the caliph, sometimes by the governor. When Ibn Ṭūlūn entered Egypt in 868 he found the office of *ʿāmil* filled by one Ibn al-Mudabbir, who over a period of years had gained control of Egyptian finances, enriching himself in the process, and was therefore reluctant to acknowledge Ibn Ṭūlūn's authority. A struggle for power soon broke out between the two, which ended four years later with the transfer of Ibn al-Mudabbir to Syria and the assumption of his duties and powers by Ibn Ṭūlūn. An even more important step was the acquisition of an army that would be independent of the caliphate and loyal to Ibn Ṭūlūn. To build such an army, Ibn Ṭūlūn resorted to the same method the caliphs themselves used—the purchase of slaves who could be trained as military units loyal to their owner.

In 877, when Ibn Ṭūlūn failed to pay Egypt's full contribution to the ʿAbbāsid campaign against a black slave uprising in Iraq, the caliphal government, dominated by the caliph's brother al-Muwaffaq, realized that Egypt was slipping from imperial control. An expedition dispatched by al-Muwaffaq to remove Ibn Ṭūlūn from the governorship failed. Taking advantage of the caliphate's preoccupation with the revolt, Ibn Ṭūlūn in 878 invaded Syria, where he occupied the principal cities and garrisoned them with his troops. Thereafter he signified his autonomy by imprinting his name on the coinage along with the name of the caliph. Although the regent al-Muwaffaq lacked the resources to engage Ibn Ṭūlūn in battle, he did have him publicly cursed in the mosques of the empire as a means of retaliation.

Autonomy under Ibn Ṭūlūn

Internally, Ibn Ṭūlūn took active measures to raise Egyptian agricultural productivity and thereby to increase tax revenues; the huge surplus he left in the state treasury at his death in 884 is a measure of his success. Another tangible indication of his achievement for Egypt is an enormous mosque (still standing) that he erected in a suburb of Fusṭāṭ; in contrast, no building comparable in grandeur had even been contemplated by the governors who preceded him.

The great benefits Ibn Ṭūlūn had gained for Egypt by using its resources within the country were squandered by his son and successor, Khumārawayh. He expended huge sums on luxurious appointments for his residence and paid a fortune as a dowry for a daughter he married to the caliph al-Muʿtaḍid in 895. Nevertheless, Khumārawayh was able to maintain the Egyptian armies in the field, and he led them to victory both in Syria and in Mesopotamia. He resolved his father's conflict with the caliphate by a combination of arms and diplomacy, so that Khumārawayh's authority over Egypt, Syria, and Mesopotamia was given official caliphal recognition. This apparent strength evaporated when Khumārawayh was murdered in 896, leaving no funds with which his heir, a 14-year-old youth, could pay the troops. Both Egypt and Syria fell into anarchy, which lasted until 905 when a caliphal army invaded Egypt and momentarily restored it to the status of a province ruled by governors sent from Baghdad.
