## Livingstone, David

David Livingstone, through 30 years of heroic travel and Christian missionary work in southern, central, and eastern Africa—often in places where no white man had previously ventured—may have influenced Western attitudes toward Africa more than any other individual before him or since.

**Early life.** Born March 19, 1813, at Blantyre in Scotland, Livingstone grew up in a distinctively Scottish family environment of personal piety, poverty, hard work, zeal for education, and a sense of mission. His father's family was from the island of Ulva, off the west coast of Scotland; his mother, a Lowlander, was descended from a family of Covenanters, a group of militant Presbyterians. Both were poor; and Livingstone was reared as one of seven children in a single room at the top of a tenement building for the workers of a cotton factory on the banks of the Clyde. At the age of ten he had to help his family and was put to work in a cotton mill; and with part of his first week's wages he bought a Latin grammar. Brought up in the Calvinist faith of the established Scottish church, Livingstone, like his father, joined an independent Christian congregation of stricter discipline when he came to manhood. By this time he had acquired those characteristics of mind and body that were to fit him for his African career.

In 1834 an appeal by British and American churches for qualified medical missionaries in China made Livingstone determine to become a medical missionary. To prepare himself, while continuing to work part-time in the mill, he studied Greek, theology, and medicine for two years in Glasgow. In 1838 he was accepted by the London Missionary Society. The Opium War (1839–42) put an end to his dreams of going to China, but a meeting with Robert Moffat, the notable Scottish missionary in southern Africa, convinced him that Africa should be his sphere of service. On November 20, 1840 he was ordained as a missionary; he set sail for South Africa at the end of the year and arrived at Cape Town on March 14, 1841.

**Initial explorations.** For the next 15 years, Livingstone was constantly on the move into the African interior: strengthening his missionary determination; responding wholeheartedly to the delights of geographical discovery; clashing with the Boers and the Portuguese, whose treatment of the Africans he came to detest; and building for himself a remarkable reputation as a dedicated Christian, a courageous explorer, and a fervent antislavery advocate. Yet so impassioned was his commitment to Africa that his duties as husband and father were relegated to second place.

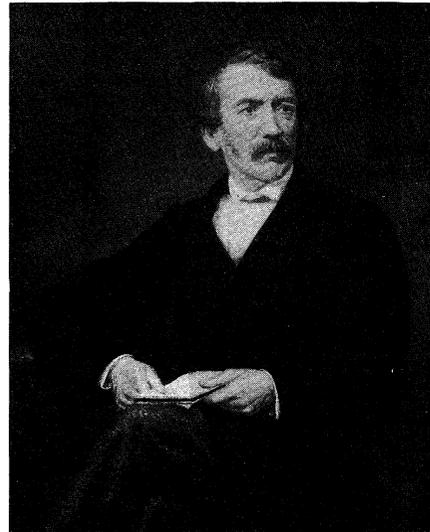

From Moffat's mission at Kuruman on the Cape frontier, which Livingstone reached on July 31, 1841, he soon pushed his search for converts northward into untried country where the population was reputed to be more numerous. This suited his purpose of spreading the Gospel through "native agents." By the summer of 1842, he had already gone further north than any other white man into the difficult Kalahari country and had familiarized himself with the local languages and cultures. His mettle was dramatically tested in 1844, when, during a journey to Mabotsa to establish a mission station, he was mauled by a lion. The resulting injury to his left arm was complicated by another accident, so that he could never again support the barrel of a gun steadily with his left hand and was obliged to fire from his left shoulder and to take aim with his left eye.

Ordained  
as mis-  
sionary

On January 2, 1845, Livingstone married Moffat's daughter, Mary, and she accompanied him on many of his journeys until her health and the family's needs for security and education forced him to send her and their four children back to Britain in 1852. Before this first parting with his family, Livingstone had already achieved a small measure of fame when, as surveyor and scientist of a small expedition, he had assisted in the discovery of Lake Ngami on August 1, 1849, and was awarded a gold medal and monetary prize by the British Royal Geographical Society. This was the beginning of his lifelong association with the society, which continued to encourage his ambitions as an explorer and to champion his interests in Britain.

**Opening the interior.** With his family safely in Scotland, Livingstone was ready to push Christianity, commerce, and civilization—the trinity that he believed was destined to open up Africa—northward beyond the frontiers of South Africa and into the heart of the continent. In a famous statement in 1853 he made his purpose clear: "I shall open up a path into the interior, or perish." On November 11, 1853, from Linyanti at the approaches to the Zambezi and in the midst of the Makololo peoples whom he considered eminently suitable for missionary work, Livingstone set out northwestward with little equipment and only a small party of Africans. His intention was to find a route to the Atlantic coast that would permit legitimate commerce to undercut the slave trade and that would also be more suitable for reaching the Makololo than the route leading through Boer territory. (In 1852 the Boers had destroyed his home at Kolobeng and attacked his African friends.) After an arduous journey that might have wrecked the constitution of a lesser man, Livingstone reached Luanda on the west coast on May 31, 1854. In order to take his Makololo followers back home and to carry out further explorations of the Zambezi, as soon as his health permitted he began the return journey September 20, 1854. He reached Linyanti nearly a year later on September 11, 1855. Continuing eastward on November 3, Livingstone explored the Zambezi regions and reached Quilimane in Mozambique on May 20, 1856. His most

## Discovery of Victoria Falls

spectacular visit on this last leg of his great journey was to the thundering, smokelike waters on the Zambezi at which he arrived on November 17, 1855, and with typical patriotism named Victoria Falls after his queen. Livingstone returned to England on December 9, 1856, as a national hero. News from and about him during the previous three years had stirred the imagination and pride of English-speaking peoples everywhere to an unprecedented degree.

Livingstone recorded his accomplishments modestly but effectively in his *Missionary Travels and Researches in South Africa* (1857), which quickly sold over 70,000 copies and took its place in publishing history as well as in that of exploration and missionary endeavour. Honours flowed in upon him. His increased income meant that he was now able to provide adequately for his family, which had lived in near poverty since their return to Britain. He was also able to make himself independent of the London Missionary Society. After the completion of his book, Livingstone spent six months speaking all over the British Isles. In his Senate House address at Cambridge on Dec. 4, 1857, he foresaw that he would be unable to complete his work in Africa, and he called on young university men to take up the task that he had begun. The publication of *Dr. Livingstone's Cambridge Lectures* (1858) roused almost as much interest as his book; and out of his Cambridge visit came the Universities' Mission to Central Africa in 1860, on which Livingstone set high hopes during his second expedition to Africa.

**The Zambezi expedition.** This time Livingstone was away from Britain from March 12, 1858 to July 23, 1864. He went out originally as British Consul at Quilimane "for the Eastern Coast and independent districts of the interior, and commander of an expedition for exploring eastern and central Africa, for the promotion of Commerce and Civilization with a view to the extinction of the slave-trade." This expedition was infinitely better organized than Livingstone's previous solitary journeys. It had a paddle steamer, impressive stores, ten Africans, and six Europeans (including his brother Charles and an Edinburgh doctor, John Kirk). That Livingstone's by then legendary leadership had its limitation was soon revealed. Quarrels broke out among the Europeans and some were dismissed. Disillusionment with Livingstone set in among members of both his own expedition and of the abortive Universities' Mission that followed it to central Africa. It proved impossible to navigate the Zambezi by ship; and Livingstone's two attempts to find a route along the Rovuma River bypassing Portuguese territory to districts around Lake Nyasa (Malawi) also proved impractical. Livingstone and his party had been the first Britons to reach (September 17, 1859) these districts that held out promise of colonization. To add to Livingstone's troubles, his wife, who had been determined to accompany him back to Africa, died at Shupanga on the Zambezi on April 27, 1862. His eldest son, Robert, who was to have joined his father in 1863, never reached him and went instead to the United States, where he died fighting for the North in the Civil War on December 5, 1864. The British government recalled the expedition in 1863, when it was clear that Livingstone's optimism about economic and political developments in the Zambezi regions was premature. Livingstone, however, showed something of his old fire when he took his little vessel, the "Lady Nyasa," with a small, untrained crew and little fuel, on a hazardous voyage of 2,500 miles across the Indian Ocean and left her for sale in Bombay. Furthermore, within the next three decades the Zambezi expedition proved to be anything but a disaster. It had amassed a valuable body of scientific knowledge; and the association of the Lake Nyasa regions with Livingstone's name and the prospects for colonization that he envisaged there were important factors for the creation in 1893 of the British Central Africa Protectorate, which in 1907 became Nyasaland, and in 1966 the republic of Malawi.

Back in Britain in the summer of 1864, Livingstone, with his brother Charles, wrote his second book, *Narrative of an Expedition to the Zambesi and Its Tributaries* (1865). Livingstone was advised at this time to have a surgical

The expeditions of David Livingstone.

operation for the hemorrhoids that had troubled him since his first great African journey. He refused; and it is probable that severe bleeding hemorrhoids were the cause of his death at the end of his third and greatest African journey.

**The quest for the Nile.** Livingstone returned to Africa, after another short visit to Bombay, on January 28, 1866, with support from private and public bodies and the status of a British Consul at large. His aim, as usual, was the extension of the Gospel and the abolition of the slave trade on the East African coast; but a new object was the exploration of the central Africa watershed and the possibility of finding the ultimate sources of the Nile. This time Livingstone went without European subordinates and took only African and Asian followers. Trouble, however, once more broke out among his staff; and Livingstone, prematurely aged from the hardships of his previous expeditions, found it difficult to cope with. Striking out from Mikindani on the east coast, he was compelled by Ngoni raids to give up his original intention of avoiding Portuguese territory and reaching the country around Lake Tanganyika by passing north of Lake Nyasa. The expedition was forced south, and in September some of Livingstone's followers deserted him. To avoid punishment when they returned to Zanzibar, they concocted the story that Livingstone had been killed by the Ngoni. Although it was proved the following year that he was alive, a touch of drama was added to the reports circulating abroad about his expedition.

Drama mounted as Livingstone moved north again from the south end of Lake Nyasa. Early in 1867 a deserter carried off his medical chest, but Livingstone pressed on into central Africa. On November 8, 1867, he discovered Lake Mweru, and on July 18, 1868, Lake Bangweulu. Assisted by Arab traders, Livingstone reached Lake Tanganyika in February 1869. Despite illness, he went on, and arrived on March 29, 1871, at his ultimate northwesterly point, Nyangwe, on the Lualaba leading into the Congo River. This was farther west than any European had penetrated. Returning to Ujiji on the eastern shore of Lake Tanganyika on October 23, 1871, Livingstone was a sick and failing man, and the arrival of H.M. Stanley, a cor-

Recall to England

Rescue by  
Stanley

respondent of the *New York Herald*, provided him with desperately needed food and medicine. Livingstone felt strong enough to join Stanley in exploring the northern reaches of Lake Tanganyika and then accompanied him to Unyanyembe, 200 miles eastward. But he refused all of Stanley's pleas to leave Africa with him, and on March 14, 1872, Stanley departed for England to add, with journalistic fervour, to the saga of David Livingstone.

Replenished by Stanley's supplies, Livingstone moved south again, obsessed by his quest for the Nile sources and his desire for the destruction of the slave trade. But his illness overcame him. On May 1, 1873, at Chitambo's village in the Ilala district of what is now Zambia, Livingstone's African servants found him dead, kneeling by his bedside as if in prayer. In order to embalm Livingstone's body, they removed his heart and viscera and buried them in African soil. In a difficult journey of nine months, they carried his body to the coast. It was taken to England and, in a great Victorian funeral, was buried in Westminster Abbey on April 18, 1874. *The Last Journals of David Livingstone* were published in the same year.

**Influence.** In his time and since, the example of Livingstone has been one of the most powerful in stimulating the interest of the outside world in Africa. His discoveries—geographic, technical, medical, and social—provided a complex body of knowledge that is still being explored. In spite of his paternalism and Victorian prejudices, Livingstone believed wholeheartedly in the African's ability to advance into the modern world. He was, in this sense, a forerunner not only of European imperialism in Africa but also of African nationalism.

**BIBLIOGRAPHY.** The following books by DAVID LIVINGSTONE himself are fundamental: *Missionary Travels and Researches in South Africa* (1857); *Dr. Livingstone's Cambridge Lectures*, ed. by W. MONK (1858); *Narrative of an Expedition to the Zambesi and its Tributaries and of the Discovery of Lakes Shirwa and Nyassa, 1858–1867* (1865); *The Last Journals of David Livingstone in Central Africa, From 1865 to his Death*, 2 vol., ed. by H. WALLER (1874).

Although there is still no definitive biography of Livingstone, the most useful is GEORGE SEAVER, *David Livingstone: His Life and Letters* (1957). A much older work, which suffers from "bowdlerization" but is still useful for personal details, is W.G. BLAIR, *The Personal Life of David Livingstone* (1880). Various aspects of Livingstone's life and work are examined in: OWEN CHADWICK, *Mackenzie's Grave* (1959); REGINALD COUPLAND, *Kirk on the Zambesi* (1928) and *Livingstone's Last Journey* (1945); FRANK DEBENHAM, *The Way to Ilala* (1955), valuable for Livingstone as a geographer; MICHAEL GELFAND, *Livingstone the Doctor, His Life and Travels: A Study in Medical History* (1957); I. SCHAPERA (ed.), *David Livingstone: Family Letters, 1841–1856*, 2 vol. (1959), *Livingstone's Private Journals, 1851–1853* (1960), and *Livingstone's African Journal, 1853–1856*, 2 vol. (1963); GEORGE SHEPPERSON (ed.), *David Livingstone and the Rovuma* (1965); J.P.R. WALLIS (ed.), *The Zambesi Expedition of David Livingstone, 1858–1863* (1956); JAMES STEWART, *The Zambesi Journal, 1862–1863* (1952); and GEORGE MARTELLI, *Livingstone's River: A History of the Zambesi Expedition, 1858–1864* (1970). The following articles are also useful: R.C. BRIDGES, "The Sponsorship and Financing of Livingstone's Last Journey," *African Historical Studies*, 1:79–104 (1968); THOMAS PRICE, "Portuguese Relations with David Livingstone," *The Scottish Geographical Magazine*, 71:138–145 (1955); and GEORGE SHEPPERSON, "David Livingstone the Scot," *The Scottish Historical Review*, 39:113–121 (1960).

(G.A.S.)

## Livy

With Sallust and Tacitus, Livy ranks as one of the three great Roman historians. His history of Rome from the foundation of the city (*Ab urbe condita*) established itself as a classic in his own lifetime and exercised a profound influence on the style and philosophy of historical writing down to the 18th century.

**Early years and career.** Livy (Titus Livius) was born at Patavium (Padua) in northern Italy in 59 BC (or possibly 64 BC). Little is known about his life and nothing about his family background. Patavium, a rich city, famous for its strict morals, suffered severely in the Civil Wars of the 40s. The wars and the unsettled condition of the Roman world after the death of Caesar in 44 BC

probably prevented Livy from studying in Greece, as most educated Romans did. Although widely read in Greek literature, he made mistakes of translation that would be unnatural if he had spent any length of time in Greece and had acquired the command of Greek normal among his contemporaries. His education was based on the study of rhetoric and philosophy, and he wrote some philosophical dialogues that do not survive. There is no evidence about his early career. His family apparently did not belong to the senatorial class, however distinguished it may have been in Patavium itself, and Livy does not seem to have embarked on a political or forensic profession. He is first heard of in Rome after Octavian (later known as the emperor Augustus) had restored stability and peace to the empire by his decisive naval victory at Actium in 31 BC. Internal evidence from the work itself shows that Livy had conceived the plan of writing the history of Rome in or shortly before 29 BC, and for this purpose he must have already moved to Rome, because only there were the records and information available. It is significant that another historian, the Greek Dionysius of Halicarnassus, who was to cover much the same ground as Livy, settled in Rome in 30 BC. A more secure age had dawned.

Most of his life must have been spent at Rome, and at an early stage he attracted the interest of Augustus and was even invited to supervise the literary activities of the young Claudius (the future emperor), presumably about AD 8. But he never became closely involved with the literary world of Rome—the poets Horace, Virgil, and Ovid, as well as the patron of the arts, Maecenas, and others. He is never referred to in connection with these men. He must have possessed sufficient private means not to be dependent on official patronage. Indeed, in one of the few recorded anecdotes about him, Augustus called him a "Pompeian," implying an outspoken and independent turn of mind. His lifework was the composition of his history.

**Livy's history of Rome.** Livy began by composing and publishing in units of five books, the length of which was determined by the size of the ancient papyrus roll. As his material became more complex, however, he abandoned this symmetrical pattern and wrote 142 books. So far as it can be reconstructed, the shape of the history is as follows (books 11–20 and 46–142 have been lost):

- 1–5 From the foundation of the city until the sack of Rome by the Gauls (386 BC)
- 6–10 The Samnite wars
- 11–15 The conquest of Italy
- 16–20 The First Punic (Carthaginian) War
- 21–30 The Second Punic War (until 201 BC)
- 31–45 Events until the end of the war with Perseus (167 BC)
- 46–70 Events until the Social War (91 BC)
- 71–80 Civil wars until the death of Marius (86 BC)
- 81–90 Civil wars until the death of Sulla (78 BC)
- 91–103 Events until the triumph of Pompey in 62 BC
- 104–108 The last years of the Republic
- 109–116 The Civil War until the murder of Caesar (44 BC)
- 117–133 From the death of Caesar to the Battle of Actium
- 134–142 From 29 to 9 BC

Apart from fragments, quoted by grammarians and others, and a short section dealing with the death of the orator and politician Cicero from Book 120, the later books after Book 45 are known only from summaries. These were made from the 1st century AD onward, because the size of the complete work made it unmanageable. There were anthologies of the speeches and also concise summaries, two of which survive in part, a 3rd-century papyrus from Egypt (containing summaries of Books 37–40 and 48–55) and a 4th-century summary of contents (known as the *Periochae*) of the whole work. A note in the *Periocha* of Book 121 records that that book (and presumably those that followed) was published after Augustus' death in AD 14. The implication is that the last 20 books dealing with the events from the Battle of Actium until 9 BC were an afterthought to the original plan and were also too politically explosive to be published with impunity in Augustus' lifetime.

The sheer scope of the undertaking was formidable. It presupposed the composition of three books a year on

Plan of  
the history

average. Two stories reflect the magnitude of the task. In his letters the statesman Pliny the Younger records that Livy was tempted to abandon the enterprise but found that the task had become too fascinating to give it up; he also mentions a citizen of Cádiz who came all the way to Rome for the sole satisfaction of gazing at the great historian.

**Livy's historical approach.** The project of writing the history of Rome down to the present day was not a new one. Historical research and writing had flourished at Rome for 200 years, since the first Roman historian Quintus Fabius Pictor. There had been two main inspirations behind it—antiquarian interest and political motivation. Particularly after 100 BC, there developed a widespread interest in ancient ceremonies, family genealogies, religious customs, and the like. This interest found expression in a number of scholarly works: Titus Pomponius Atticus, Cicero's friend and correspondent, wrote on chronology and on Trojan families; others compiled lengthy volumes on Etruscan religion; Marcus Terentius Varro, the greatest scholar of his age, published the encyclopaedic work *Divine and Human Antiquities*. The standard of scholarship was not always high, and there could be political pressures, as in the attempt to derive the Julian family to which Julius Caesar belonged from the legendary Aeneas and the Trojans; but the Romans were very conscious and proud of their past, and an enthusiasm for antiquities was widespread.

Previous historians had been public figures and men of affairs. Fabius Pictor had been a praetor, the elder Cato had been consul and censor, and Sallust was a praetor. So, too, many prominent statesmen such as Sulla and Caesar occupied their leisure with writing history. For some it was an exercise in political self-justification (hence, Caesar's *Gallic War* and *Civil War*); for others it was a civilized pastime. But all shared a common outlook and background. History was a political study through which one might hope to explain or excuse the present.

Livy was unique among Roman historians in that he played no part in politics. This was a disadvantage in that his exclusion from the Senate and the magistracies meant that he had no personal experience of how the Roman government worked, and this ignorance shows itself from time to time in his work. It also deprived him of firsthand access to much material (minutes of Senate meetings, texts of treaties, laws, etc.) that was preserved in official quarters. So, too, if he had been a priest or an augur, he would have acquired inside information of great historical value and been able to consult the copious documents and records of the priestly colleges. But the chief effect is that Livy did not seek historical explanations in political terms. The novelty and impact of his history lay in the fact that he saw history in personal and moral terms. The purpose is clearly set out in his preface:

I invite the reader's attention to the much more serious consideration of the kind of lives our ancestors lived, of who were the men and what the means, both in politics and war, by which Rome's power was first acquired and subsequently expanded, I would then have him trace the process of our moral decline, to watch first the sinking of the foundations of morality as the old teaching was allowed to lapse, then the final collapse of the whole edifice, and the dark dawning of our modern day when we can neither endure our vices nor face the remedies needed to cure them.

What chiefly makes the study of history wholesome and profitable is this, that in history you have a record of the infinite variety of human experience plainly set out for all to see, and in that record you can find for yourself and your country both examples and warnings.

Although Sallust and earlier historians had also adopted the outlook that morality was in steady decline and had argued that people do the sort of things they do because they are the sort of people they are, for Livy these beliefs were a matter of passionate concern. He saw history in terms of human personalities and representative individuals rather than of partisan politics. And his own experience, going back perhaps to his youth in Patavium, made him feel the moral evils of his time with peculiar intensity. He punctuates his history with revealing comments:

Fortunately in those days authority, both religious and secu-

lar, was still a guide to conduct and there was as yet no sign of our modern scepticism which interprets solemn compacts to suit its own convenience (3.20.5). Where would you find nowadays in a single individual that modesty, fairness and nobility of mind which in those days belonged to a whole people? (4.6.12).

In looking at history from a moral standpoint, Livy was at one with other thinking Romans of his day. Augustus attempted by legislation and propaganda to inculcate moral ideals. Horace and Virgil in their poetry stressed the same message—that it was moral qualities that had made and could keep Rome great.

The preoccupation with character and the desire to write history that would reveal the effects of character outweighed for Livy the need for scholarly accuracy. He showed little if any awareness of the antiquarian research of his own and earlier generations; nor did he seriously compare and criticize the different histories and their discrepancies that were available to him. For the most part he is content to take an earlier version (from Polybius or a similar author) and to reshape it so as to construct moral episodes that bring out the character of the leading figures. Livy's descriptions of the capture of Veii and the expulsion of the Gauls from Rome in the 4th century BC by Marcus Furius Camillus are designed to illustrate his piety; the crossing of the Alps shows up the resourceful intrepidity of Hannibal. Unfortunately, it is not known how Livy dealt with the much greater complexity of contemporary history, but the account of Cicero's death contains the same emphasis on character displayed by surviving books.

It would be misplaced criticism to draw attention to his technical shortcomings, his credulity, or his lack of antiquarian curiosity. He reshaped history for his generation so that it was alive and meaningful. It is recorded that the audiences who went to his recitations were impressed by his nobility of character and his eloquence. It is this eloquence that is Livy's second claim to distinction.

Together with Cicero and Tacitus, Livy set new standards of literary style. The earliest Roman historians had written in Greek, the language of culture. Their successors had felt that their own history should be written in Latin, but Latin possessed no ready-made style that could be used for the purpose: for Latin prose had to develop artificial styles to suit the different genres. Sallust had attempted to reproduce the Greek style of Thucydides in Latin by a tortured use of syntax and a vocabulary incorporating a number of archaic and unusual words, but the result, although effective, was harsh and unsuitable for a work of any size. Livy evolved a varied and flexible style that the ancient critic Quintilian characterized as a "milky richness." At one moment he will set the scene in long, periodic clauses; at another a few terse, abrupt sentences will mirror the rapidity of the action. Bare notices of archival fact will be reported in correspondingly dry and formal language, whereas a battle will evoke poetical and dramatic vocabulary, and a speech will be constructed either in the spirit of a contemporary orator such as Cicero or in dramatically realistic tones, designed to recapture the atmosphere of antiquity. "When I write of ancient deeds my mind somehow becomes antique," he wrote. Livy died at Patavium in AD 17.

The work of a candid man and an individualistic thinker, Livy's history was deeply rooted in the Augustan revival and owed its success in large measure to its moral seriousness. But the detached attempt to understand the course of history through character (which was to influence later historians from Tacitus to Lord Clarendon) represents Livy's great achievement.

### Llanos

The Llanos (Plains), a grassland, or savanna, that stretches across northern South America, occupy one-third of Venezuela and about one-fifth of Colombia. The Llanos are delimited by the Andes Mountains in the west and north, the Lower Orinoco River and the Guiana Highlands in the east, and the Río Guaviare and the Amazonian rain forest in the south. The region covers an area of some 220,000 square miles (570,000 square kilometres) and is comparable in size to France or Texas.

The savanna was named by the Spaniards in the 16th century and has been used as a vast cattle range since then. Until the mid-1900s, settlement was limited to widely scattered ranches known as *hatos* ("cow herds"), a few villages, and missionary stations along the lower courses of the region's rivers. Since the 1930s the region has experienced economic growth. (For a related physical feature, see ORINOCO RIVER.)

*Relief.* Most of the Llanos lies within 1,000 feet above sea level. The High Plains (Llanos Altos) are most conspicuous near the Andes, where they form extensive platforms between rivers and are some 100 to 200 feet above the valley floors. Away from the mountains they are increasingly fragmented, as in the dissected tableland of the central and eastern Venezuelan Llanos (the Sabana de Mesas) and the hill country south of the Río Meta in Colombia (the Serranía).

The Low Plains (Llanos Bajos) are defined by the Río

Apure in the north and the Río Meta in the south. The lowest portion of the Llanos, west of the Orinoco Valley, is annually converted into an inland lake by the flooding of the region's rivers.

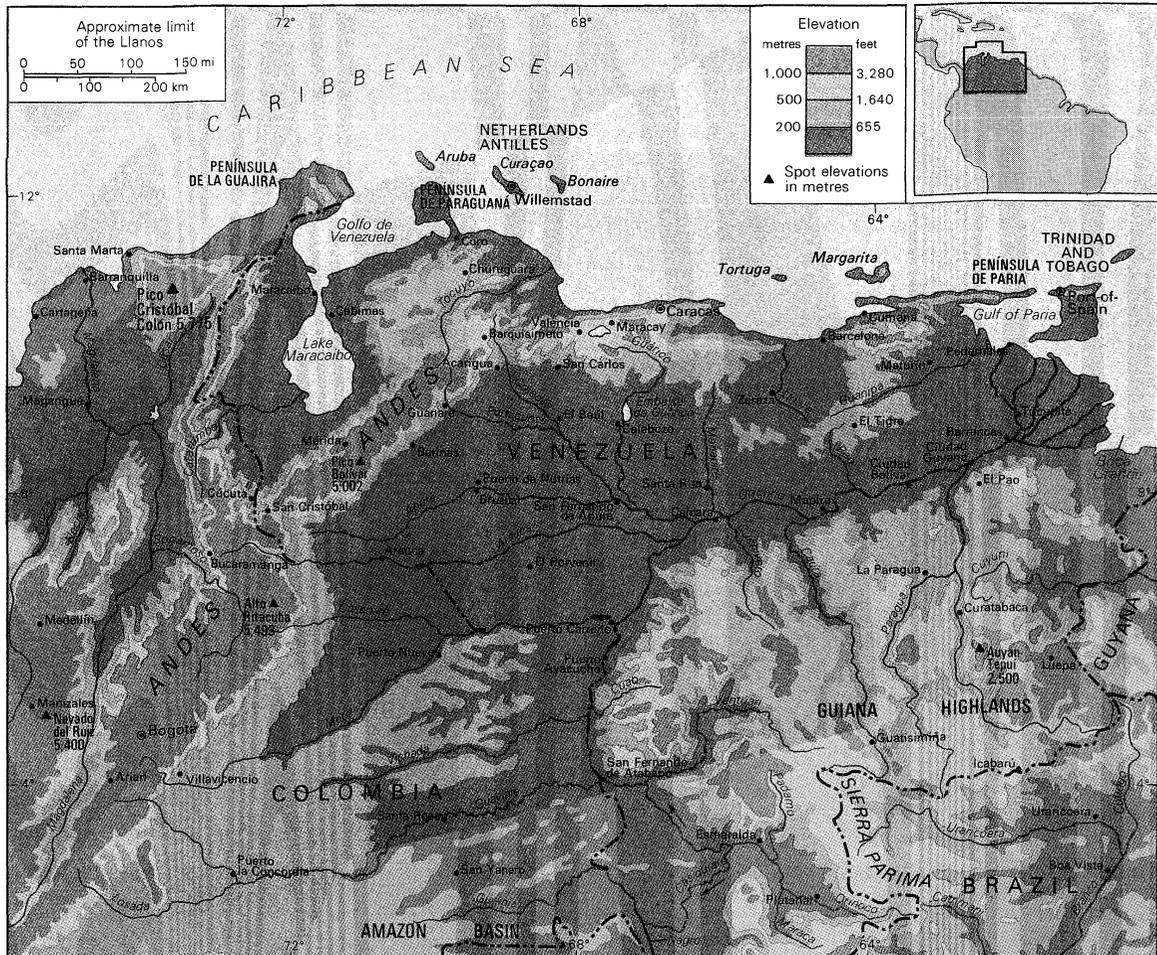

*Soils and drainage.* The Llanos are drained by the Orinoco River and its left-bank tributaries, including the Guaviare, Meta, Apure, and Cojedes rivers. Seasonal changes between saturation and dehydration have led to advanced laterization of the soil, the process in which the base minerals have been leached away or incorporated into insoluble iron and aluminum silicates. Fine-grained soils form hardpans (cemented layers of soils), and in gravel regions, iron-cemented quartz conglomerates underlie the surface. Excessive acidity and the lack of nutrient bases, organic matter, and nitrogen make virtually all mature soils infertile.

*Climate.* The wet and dry seasons result from the annual migration of the Intertropical Convergence Zone, a low-pressure trough between the hemispheric easterlies, or trade winds. The zone remains south of the Equator from December to March, bringing the entire Llanos under the influence of the Northeast Trades, which cause the dry and hot summer weather. The zone enters the Llanos from the south in April, reaches its northernmost position along the north coast in July, and moves south again until December. The passage of the zone brings the rainy winter period.

Monthly precipitation is seldom less than ten inches in the Colombian Llanos between April and November. The rains peak about midyear in the Venezuelan north, with monthly totals of around ten inches. Annual precipitation is highest near the Andes, where Villavicencio receives 180 inches; and there is a pronounced decrease toward the central plains, where Puerto de Nutrias receives 45 inches.

Mean daily temperatures are above 75° F (24° C) throughout the year, and the annual range does not sur-

Physical features

The Llanos.

pass 7° F (4° C). Daily maximum temperatures rise above 95° F (35° C) in the dry period; the dry winds and nocturnal cooling bring relief with normal minimum temperatures between 65° and 75° F (18° and 24° C).

**Vegetation and animal life.** Most of the Llanos is treeless savanna. In the low-lying areas, swamp grasses and sedges are to be found, as also is bunchgrass (*Trachypogon*). Long-stemmed grass dominates the dry savanna and is mixed with carpet grass (*Axonopus affinis*), the only natural grass to provide green forage during the dry season.

The most conspicuous trees occur in the gallery forests along the rivers and in the narrower files of trees known as *morichales*, after the dominant moriche palm that follow minor water courses. Broadleaved evergreens originally occupied the high-rainfall zone in the Andean piedmont. There is a handful of xerophytic trees (*i.e.*, those adapted to arid conditions), including the *chapparro* (scrub oak) and the dwarf palm scattered on the open savanna.

The Llanos have few animals. Most mammals nest in the gallery forests and feed on the grassland. The only true savanna dwellers are a few burrowing rodents and more than 20 species of birds (among them the white and scarlet ibis, the *morichal* oriole, and the burrowing owl). There are several species of deer and rabbit, the anteater and armadillo, the tapir, the jaguar, and the largest living rodent, the capybara. Crocodiles, caimans (a crocodile-like amphibian), and snakes, including the boa constrictor, inhabit the rivers, which also teem with little-known varieties of fish. Insects include butterflies, beetles, ants, and mound-building termites.

**Population and resources.** Cattle raising remains the mainstay of the economy, the base of which was widened by the discovery of petroleum in the 1930s. Oil strikes in the eastern and central Venezuelan Llanos at El Tigre (1937) and Barinas (1948) initiated industrial and urban development. Several of the "boom towns" of that period, such as El Tigre, have grown into sizable cities.

An expansion of intensive agriculture has occurred with the settlement, which began in the 1950s, of pioneer farmers in the Andean piedmont and along the river valleys. Major concentrations of these small farms are located in the Barinas-Guanare-Acarigua district of Venezuela and the Ariari region in Colombia.

Population growth connected with these developments has been impressive. The population of Venezuela's Llanos states reached 1,800,000 (18 percent of Venezuela's population) in 1970. There is a high degree of urbanization; more than half of the people of the Venezuelan Llanos live in cities of more than 10,000 inhabitants. A few thousand Indians (of Carib and Arawak origin) are left on reservations in the Lower Orinoco area.

Population increase has been modest in the Colombian areas. In the Departamento del Meta, Colombia, the population expanded to 210,000 in 1970. Villavicencio, the department's capital, is the only city with more than 10,000 inhabitants (65,000 in 1970) in the Colombian Llanos. The rest of the area remains sparsely inhabited; the population of the Llanos Orientales numbers less than 2 percent of Colombia's total population of 22,000,000.

**Prospects for the future.** The Venezuelan Llanos benefit from Venezuela's continuing policy of exploiting the rich mineral and water-power resources of the Lower Orinoco and the Guiana Highlands. Flood-control schemes include the dams at Calabozo, San Carlos, and Guanare. Excellent trans-Andean roads, a highway along the Andes, and all-weather access routes to the Orinoco contribute to growing economic vitality.

Economic development in the Colombian Llanos is less promising. Agriculture is limited by the small proportion of cultivable land and by the low grazing capacity of the savanna. No mineral deposits had been found by 1970, but a road along the foot of the Andes has been planned.

**BIBLIOGRAPHY.** Published literature on the Llanos in English is scarce. No book deals with the region as a whole. General information on the geographic aspects of the Llanos and their importance to Venezuela and Colombia is found in P.E. JAMES, *Latin America* (1969). Problems of resource development, particularly on the agricultural side, are dis-

cussed in a report of the INTERNATIONAL BANK FOR RECONSTRUCTION AND DEVELOPMENT, *The Economic Development of Venezuela* (1961); and in the FOOD AND AGRICULTURAL ORGANIZATION, *Soil Survey of the Llanos Orientales, Colombia*, 4 vol. (1964-66). Ecological insights on the Llanos are given in J.S. BEARD, "Savanna Vegetation of Northern Tropical America," *Ecol. Monogr.*, 23:149-215 (1953); and in E.J. FITTKAU *et al.* (eds.), *Biogeography and Ecology in South America*, 2 vol. (1968-69). Accounts on the progress of colonization are given in R.E. CRIST, "Along the Llanos-Andes Border in Venezuela: Then and Now," *Geogr. Rev.*, 46:187-208 (1956), and with ERNESTO GUHL, "Pioneer Settlement in Eastern Colombia," *An. Rep. Smithson. Inst.*, pp. 391-414 (1956). Still the most worthwhile reading is found in ALEXANDER VON HUMBOLDT's essays on the Llanos contained in his and A. BONPLAND's *Voyage de Humboldt et Bonpland*, pt. 1, *Voyage aux régions équinoxiales du nouveau continent*, 3 vol. (1814-34; Eng. trans., *Personal Narrative of Travels to the Equinoctial Regions of the New Continent During the Years 1799-1804*, 7 vol., 1814-29, reprinted 1966).

(Di.B.)

## Lloyd George, David

For 16 years, from 1906 to 1922, English political life was dominated by the fiery personality of David Lloyd George. As leader of the radicals within the Liberal Party before World War I, he pushed through legislation that laid the foundation of the modern welfare state. A former pacifist, he headed a coalition government that guided Britain to victory in what then seemed the greatest of all wars. After 1922 he remained in the shadows of public life, but in the words of Winston Churchill, addressing the House of Commons after his death, "When the English history of the first quarter of the twentieth century is written it will be found that the greater part of our fortunes in peace and in war were shaped by this one man."

Lloyd George was born in Manchester on January 17, 1863. His father was a Welshman from Pembrokeshire and had become headmaster of an elementary school in Manchester. His mother was the daughter of David Lloyd, a Baptist minister. His father died in June 1864, leaving Mrs. George in poverty. She moved to Llanystumdwy in Carnarvonshire where her brother Richard, a shoemaker and Baptist minister, supported her and her children; and it was from him that David Lloyd George imbibed many of his formative beliefs. His uncle enabled him to embark at the age of 14 on the career of a solicitor; he became articled (1879) to a firm at Portmadoc, passing his final examination in 1884. In Wales, as in Ireland, an anglicized and Anglican Tory "ascendancy" class of landed gentry dominated a Celtic people of different race and religion. The cause of the Liberal Party, the Welsh nation, and Nonconformity were inseparable in the atmosphere in which Lloyd George was raised, and he first made his name by a successful battle in the courts to establish the right of Nonconformists to burial in the churchyard of their parish. Ironically, he who came to be the standard-bearer of the oppressed religious sects had lost his faith even as a boy.

As a young man, Lloyd George had the romantic, good

EB Inc.

Lloyd George, 1908.

looks that ensured success with women. After numerous love affairs, he was married in 1888 to Margaret Owen who bore him two sons and three daughters. It cannot be described as a happy marriage. Lloyd George was incapable of fidelity, and his affairs with other women were notorious. His wife stood by him on many occasions, but in the end his behaviour was too much for even her long-suffering tolerance.

Pro-Boer  
sentiment

Lloyd George entered Parliament in 1890, winning a by-election at Carnarvon Boroughs, the seat he retained for 55 years. He soon made a name for himself in the House of Commons by his audacity, charm, wit, and mastery of the art of debate. During the ten years of Liberal opposition that followed the election of 1895, he became a leading figure in the radical wing of the party. He bitterly and courageously opposed the South African War; and in 1901 was nearly lynched in Birmingham, the stronghold of Joseph Chamberlain and Conservative imperialism. With the arrival of peace, Lloyd George worked up a great agitation in Wales against tax-aided grants to church schools established by Balfour's Education Act (1902). This period saw him at the height of his reputation as the leader of Welsh nationalism. Cabinet office later somewhat reduced his fervour in this field, and with the passage of time his nationalism became cultural rather than political.

Arthur J. Balfour resigned in December 1905 and Sir Henry Campbell-Bannerman formed a Liberal administration, appointing Lloyd George to the Cabinet as president of the Board of Trade. In that office, he was responsible for important legislation: the Merchant Shipping Act (1906), improving seamen's living conditions, but also endangering their lives by raising the Plimsoll line on newly constructed ships; the Patents and Designs Act (1907), preventing foreign exploitation of British inventions; and the Port of London Act (1908), setting up the Port of London Authority. He also earned a high reputation by his patient work in settling strikes. He suffered a cruel bereavement in November 1907, when his daughter Mair died of appendicitis at the age of 17. Years afterward, the sight of her portrait could plunge him into tears.

#### CHANCELLOR OF THE EXCHEQUER

Campbell-Bannerman's health failed in 1908. He was succeeded as prime minister by the chancellor of the exchequer, Herbert Henry Asquith, who appointed Lloyd George to take his own place. This was a notable promotion and made him at least a very strong competitor for the premiership after Asquith. By this time, the Liberal Party's fortunes were beginning to languish. The House of Lords had blocked much of its social reform legislation, and the radical wing of the party was concerned that its thunder might be stolen by the nascent Labour Party unless the deadlock could be broken. At the same time, the demand for more battleships to match the German naval program threatened the finances available for social reform. It was to meet these difficulties that Lloyd George framed the famous "People's Budget" of 1909, calling for taxes upon unearned increment on the sale of land and on land values, higher death duties, and a super-tax on incomes above £3,000. Moreover, it seemed for a time that the House of Lords' veto on progressive legislation would be bypassed, since the custom of the constitution forbade the upper house from interfering with the budget. In fact, however, the Conservative majority in the House of Lords, against the advice of some of its wiser members, decided to reject it. The consequences of this rejection were two general elections, a major constitutional crisis, and the ultimate passage of the Parliament Act of 1911, which severely curtailed the powers of the upper house. The principal burden of all this fell upon Asquith, but Lloyd George gave him vigorous support in a series of notable philippics against the aristocracy and the rich. The most famous of all was his speech at Limehouse, where he denounced the rapacity of the landlord class, especially the dukes, in unforgettable language.

Promulga-  
tion of the  
"People's  
Budget"

In 1913 he faced one of the gravest personal crises in his career. In April 1912, along with Rufus Isaacs, the attorney general, he had purchased shares in the Marconi

Wireless Telegraph Company of America at a rate well below that available to the general public. The American Marconi company was legally independent of the British concern, but the two companies were closely connected, and the latter's shares had recently boomed as a result of the government's decision to accept its proposal to construct a chain of radio stations throughout the empire, Lloyd George and Isaacs unluckily denied, in somewhat ambiguous language, any transactions in the shares of "the Marconi company," a denial that technically referred only to the British company but was generally assumed to cover the American as well. A select committee of the House of Commons revealed the facts and, although by a party majority it acquitted the ministers of blame, Lloyd George's reputation for integrity was damaged.

**Social reform and the outbreak of war.** Lloyd George's major achievement during the years immediately before the war was in the field of social insurance. Inspired by a visit to Germany (1908), where he studied the Bismarckian scheme of insurance benefits, Lloyd George decided to introduce health and unemployment insurance on a similar basis in Britain. This he did in the National Insurance Act of 1911. The measure inspired bitter opposition and was even unpopular with the working class who were not convinced by Lloyd George's slogan "ninepence for fourpence," the difference in these two figures being the employer's and the state's contribution. Lloyd George, undeterred, piloted his measure through Parliament with great skill and determination. He thus laid the foundations of the modern welfare state and, if he had done nothing else, would deserve fame for that achievement.

Though much of the government's time during these years was occupied by the Irish question, Lloyd George played little part in it and, on the whole, left foreign policy to his colleagues. It was, therefore, something of a surprise when, in July 1911, after careful consultation with Asquith and Sir Edward Grey, he issued a formidable warning to Germany over the Moroccan crisis. When the question of entry into the war convulsed the Cabinet in late July and early August 1914, he seemed at first to incline to the isolationist section. For a brief moment he contemplated retirement. But the tide of events swept him to the other side. As chancellor, he plunged into the financial problems posed by the war.

#### Minister of munitions and secretary of state for war.

Throughout the remainder of 1914 and the early months of 1915, Lloyd George was a vigorous advocate of increased munitions production. Here he came into sharp conflict with Lord Kitchener in the War Office. The resignation of Admiral Fisher in 1915 forced Asquith to reconstruct the government on a coalition basis and admit the Conservatives. In the new administration, Lloyd George became minister of munitions. In this capacity, he made one of the most notable contributions to the victory of the Allies. His methods were unorthodox and shocked the civil service, but his energy was immense. He imported able assistants from big business and used his eloquence to induce the cooperation of organized labour. When, in the summer of 1916, the great Battle of the Somme began, supplies were forthcoming.

Lloyd George acquired definite views on war strategy at an early stage. He doubted the possibility of breaking through on the Western front and advocated instead a flank attack from the Near East. He was thus at loggerheads with the view of the official military hierarchy, cogently pressed by Sir Douglas Haig and Sir William Robertson, that the war could only be won in the West. On June 5, 1916, Kitchener was drowned on his way to Russia, when his ship struck a German mine. A last-minute accident—acute developments in the Irish situation—alone had prevented Lloyd George from travelling with him. After some hesitation, Asquith appointed him to the vacant position at the War Office.

Lloyd George held the post for five months, but Robertson as chief of the imperial general staff possessed nearly all the really important powers of the war minister. Lloyd George chafed under these restrictions, the more so because he profoundly disagreed with Robertson on vital

Disagree-  
ment with  
military  
leaders

issues of strategy. Thus frustrated, he began to survey the whole direction of the war with increasing skepticism; and he did not conceal his doubts from his friends who, by the end of November, had become convinced that Asquith should delegate the day-to-day running of the war to a small committee whose chairman should be Lloyd George. There was undoubtedly widespread uneasiness at Asquith's conduct of affairs, particularly in the Conservative Party. Asquith was manoeuvred into resigning on December 5 and was replaced two days later by Lloyd George. He was supported by the leading Conservatives, Bonar Law becoming chancellor of the exchequer, leader of the house, and second in command of the government, and Balfour becoming foreign secretary. But the most prominent Liberal ministers resigned with Asquith, and, although about half the rank and file of the party supported the new government, Lloyd George was never forgiven by the old guard of his party for having jockeyed Asquith out of office.

#### PRIME MINISTER

Lloyd George was now 54 and at the height of his powers. His energy, eloquence, and ability had already made him the leading statesman of the day, and his accession to the premiership was highly popular in the country generally. A sense of renewed vigour, of "push and go," was given to the war effort. He immediately substituted a small War Cabinet of five, which was to be in constant session, for the unwieldy body of 23 that had hitherto conducted affairs. The result was a general speeding up of decisions and the disappearance of the procrastination that had marred the previous government.

One of Lloyd George's most notable efforts was in combatting the submarine menace which, in the early months of 1917, threatened to starve Britain into submission. He achieved this by forcing the adoption of the convoy system upon a reluctant admiralty. The food shortage resulting from the submarine war was acute. Drastic action had to be taken to step up agricultural production, and eventually a system of food rationing had to be introduced (1918). In these matters Lloyd George was at his best, contemptuous of red tape, determined to take action and to make his will prevail.

It was in the field of grand strategy that he was least successful. Lloyd George remained profoundly skeptical of the ability of the British high command to conduct even a "Western" strategy successfully. Without warning Haig or Robertson in advance, he confronted them at the Calais Conference of February 1917 with a plan to place the British Army under French command for Gen. Robert-Georges Nivelle's forthcoming offensive. Haig and Robertson deeply distrusted Lloyd George from that moment onward. The Nivelle offensive was a total failure, and Lloyd George was, as a result, on shaky ground when he endeavoured to resist Haig's proposals for a major British campaign in Flanders in the summer. After much hesitation, he gave way, and on July 31, 1917, the ill-fated Passchendaele offensive began. Although it may have forestalled a possible German attack on the French, Passchendaele, with enormous loss of life, achieved none of its main objectives. He was now convinced of the incompetence of the British high command.

He still dared not take action against them openly. Instead, he began what Sir Winston Churchill calls "a series of extremely laborious and mystifying maneuvers," with the object of creating a unified command under someone other than Haig. In February 1918, Robertson offered his resignation, which Lloyd George accepted, but Haig remained as commander in chief. Such was Lloyd George's distrust of Haig that, during the winter of 1917-18, he had deliberately kept him short of troops for fear that he might renew the attack. The result was that the Germans came near to launching a successful offensive. The emergency caused a unified command under Marshal Foch to be established (April), and by May the situation became stabilized. Out of these events arose the famous Maurice debate. Maj. Gen. Sir Frederick Maurice, who was in the War Office, published a letter claiming that Lloyd George had given incorrect figures in reply to a question about

manpower on the Western front. Lloyd George made a brilliant speech at the subsequent debate in Parliament, though later evidence shows that Maurice was undoubtedly right. The Asquithian Liberals pressed the matter to a division and were heavily beaten.

The Armistice of November 1918 faced Lloyd George with a dilemma. Should he allow a return to peacetime party politics or continue the coalition? There was little doubt of the answer. Bonar Law was willing to cooperate. A somewhat perfunctory offer to include Asquith was declined. The ensuing election in December gave the coalitionists an overwhelming victory. Many of those who followed Asquith at the Maurice debate were not granted the "coupon," the joint letter from Lloyd George and Bonar Law that certified the candidate as a coalitionist. Nearly all, Asquith included, lost their seats. The rift in the Liberal Party became wider, and Lloyd George was now largely dependent on Conservative support.

As one of the three great statesmen at Versailles, Lloyd George must bear a major responsibility for the peace settlement. He pursued a middle course between Georges Clemenceau and Woodrow Wilson. But, throughout, Lloyd George was under strong pressure at home to pursue the more draconian policy. It is to his credit that the final settlement was not far worse than it was. The treaty was well-received in Britain, and in August 1919 the king conferred on him the Order of Merit.

A major domestic problem was Ireland, where the Sinn Fein refused to recognize the British Parliament, and from 1919 to 1921 a civil war of massacre and reprisal raged. In the summer of 1921, Lloyd George, with full agreement of his Conservative colleagues, reversed the policy of repression in Ireland and initiated the negotiations that culminated in Irish independence in December 1921. The more rigid Tories never forgave this "surrender," as they deemed it. In 1922 Lloyd George ran into further trouble over the so-called honours scandal, when accusations against the coalition were made in both houses of Parliament that peerages and other honours were being regularly sold for large campaign contributions. Tory discontent was rife, when, from a wholly unexpected quarter, a crisis occurred that drove Lloyd George from power forever. This was the Çanak incident (see OTTOMAN EMPIRE AND TURKEY, HISTORY OF), when it seemed to critics that the reckless foreign policy of the government had led Britain to the verge of an unnecessary war with Turkey. When the Conservative leaders decided to appeal to the country on a coalition basis once again, a party revolt ensued. Bonar Law returned to the political scene; and on October 19 a two-to-one majority of Conservative members of Parliament endorsed his and Stanley Baldwin's plea to fight as an independent party. Lloyd George at once resigned.

**Later years and assessment.** The long twilight of Lloyd George's career was a melancholy anticlimax. The feud with the Asquithians was never healed, and from 1926 to 1931 he headed an ailing Liberal Party. He devoted himself thereafter to writing his *War Memoirs* (1933-36) and *The Truth About the Peace Treaties* (1938). Lengthy, yet supremely readable and interspersed with brilliant pen portraits, these volumes are an exercise in the forensic, rather than the historian's, art. He seldom admits error, and the endless diatribes against his opponents carry little conviction. In 1936 he visited Germany and met Hitler and was temporarily taken in by him; but in 1938 and 1939 he was a leading opponent of appeasement. In 1940 Churchill invited him to join his war cabinet, but Lloyd George declined, ostensibly on grounds of age and health. On January 1, 1945, he was elevated to the peerage as Earl Lloyd-George of Dwyfor. He died on March 26, 1945.

Lloyd George's personality is something of an enigma to the historian. It is easy to list his qualities: his eloquence; his extraordinary charm and persuasiveness; his sense of wit and fun; his capacity to see the heart of problems whose complexity baffled lesser men; his profound sympathy with oppressed classes and races; his genuine hatred of those who abused power, whether that power was based on wealth or caste or military might. But there

The  
"coupon  
election"

War  
cabinet  
reorganized

Publication  
of his  
memoirs

was an obverse side to these virtues: his love of devious methods; his remarkable, albeit temporary, gullibility in the face of Hitler and the Nazis; his carelessness and want of discretion—some would use severer words—over appointments and honours; his defeatism in World War II, which contrasted so sadly with his earlier courage.

Lloyd George, for all his greatness, aroused in many persons a profound sense of mistrust, and it was in the upper-middle class, represented in politics by Stanley Baldwin and Neville Chamberlain, that he inspired the most acute misgivings. They were both determined to exclude him from office, and it would be wrong to ascribe his long years in the political wilderness solely to the declining fortunes of the Liberal Party. It is perhaps significant of his defects that Lloyd George, though possessing a host of acquaintances, never had a really intimate friend. There was in him a streak of ruthlessness that left little room for the cultivation of personal friendship. For these and other reasons, he was never able to recover the position he had lost in 1922. It was one of the tragedies of the interwar years that, in an era not notable for political talent, the one man of genius in politics should have had to remain an impotent spectator. But his earlier achievements make his place in history secure.

## Lobachevsky, Nikolay Ivanovich

Nikolay Ivanovich Lobachevsky, Russian mathematician, is, with his Hungarian contemporary János Bolyai, the founder of non-Euclidean geometry. This geometry is not based on Euclid's parallel postulate, according to which one and only one line can be drawn through a point in a plane parallel to a given line in the plane. First announced in 1826 and published in 1829, Lobachevsky developed it further in subsequent publications. By showing that a non-Euclidean geometry (*q.v.*) was logically possible, he and Bolyai (who published his theory in 1832) discovered the final solution of a problem—whether Euclid's parallel postulate could be deduced as a consequence of his other postulates—that had baffled mathematicians for 2,000 years. Their discovery that it could not would profoundly influence the mathematics, physics, and philosophy of the 20th century.

Novosti Press Agency

Lobachevsky, detail of a portrait by an unknown artist.

Lobachevsky was born on December 1 (November 20, old style), 1792, in Nizhny Novgorod (now Gorky), the son of an impecunious government official. His entire life centred around the University of Kazan, beginning at age 14, when he entered as a student. In 1811 he received the M.A. degree and then taught, from 1816 as extraordinary professor and from 1822 as ordinary professor.

His administrative talents were soon recognized; in 1820 he became dean of the faculty of mathematics and physics, in 1825 university librarian, and in 1827 rector of the university, a position he held, with repeated reelections, until 1846. In all of his duties, he exercised remarkable organizing and educational skill in rescuing the university from the chaotic conditions into which it had drifted. The previous administration had reflected the spirit of the later years of Tsar Alexander I, who was distrustful of modern science and philosophy, particularly that of the German philosopher Immanuel Kant, as evil products of the French Revolution and a menace to orthodox religion. The results at Kazan during the years 1819–26 were factionalism, decay of academic standards, dismissals, and departure of some of the best professors, including Johann Martin Christian Bartels, friend of the German mathematician Carl Friedrich Gauss, and Lobachevsky's teacher of mathematics.

In 1826, a more tolerant period was inaugurated with the accession of Tsar Nicholas I, and Lobachevsky became the leading innovator at the university, restoring academic standards and faculty harmony. He was active in saving lives during the cholera epidemic of 1830, in rebuilding several university buildings after a devastating fire in 1842, and in popularizing science and modernizing primary and secondary education in the region of Kazan. Although burdened with this work, in addition to a heavy administrative teaching load, he still found time for extensive mathematical research.

Lobachevsky's ideas were rooted in his opposition to Kant's transcendental Idealism, which maintains that such ideas as space, time, and extension, are a priori, and that the mind imposes order on sense experience. For him space was an a posteriori concept, derived by the human mind from external experience.

In addition to geometry, Lobachevsky also did distinguished work in the theory of infinite series, especially trigonometric series, integral calculus, and probability; in algebra he found, in 1834, a method for approximating the roots of algebraic equations, often called after the Swiss mathematician Carl Heinrich Gräffe (1837).

His fame, like that of Bolyai, was posthumous. During his lifetime, few were impressed by his geometry, and the leading Russian mathematician of his day, Mikhail Vasilievich Ostrogradsky, who was well-known in western Europe, could not appreciate it. Moreover, Lobachevsky's first publications, in Russian—in 1829 in a local general periodical and in 1835–39 in the Kazan academic transactions—were little known abroad. But Lobachevsky, in contrast to Bolyai, refused to be discouraged. With characteristic perseverance he continued the publication of his ideas not only in Russian but also in French and German. In 1837 his "Géométrie imaginaire" ("Imaginary Geometry") appeared in *Crelle's Journal* (Berlin), and in 1840 his book *Geometrische Untersuchungen zur Theorie der Parallellinien* (*Geometrical Researches on the Theory of Parallels*, 1891) was published. There was no general recognition of his work, despite the praise bestowed on it by Gauss, the leading mathematician of Europe, who had reached, but never published, the same conclusions.

Toward the end of his life, nearly blind and grieved by domestic losses, Lobachevsky in 1855 once more presented his theory in French in the book *Pangéométrie*, also appearing in Russian.

He died in Kazan on February 24 (February 12, O.S.), 1856. Acceptance of non-Euclidean geometry had to wait until, under the influence of the German mathematician Bernhard Riemann's ideas on the principles underlying geometry in 1866, the Italian mathematician Eugenio Beltrami in 1868 and the German mathematician Felix Klein in 1871 demonstrated the consistency and general applicability of this geometry.

Academic career

Opposition to Kant

**BIBLIOGRAPHY.** The collected works of Lobachevsky were published in Russian, 5 vol. (1946–51). The *Geometrische Untersuchungen* of 1840 was translated by G.B. HALSTED as *Geometrical Researches on the Theory of Parallels*, new ed. (1914). It was republished in ROBERTO BONOLA, *Non-Euclidean Geometry* (1911, reprinted 1955), a good book for the study of this geometry, with biographical and bibliographical references. Halsted also published (1897) translations of Lobachevsky's early Russian papers from the German translation in F. ENGEL, *N.I. Lobatschewskij: Zwei geometrische Abhandlungen*, 2 vol. (1898–99)—vol. 2 contains an extensive biography. There is no modern biography in English, but much biographical and bibliographical information is presented in A. VUCINICH, "Nicolai Ivanovich Lobachevskii: The Man Behind The First Non-Euclidean Geometry," *Isis*, 53:465–481 (1962). SOPHIE PICCARD, *Lobachevsky, grand mathématicien russe, sa vie, son oeuvre* (1957), is a short, popularly written account.

## Lock

A lock is a mechanical device for securing a door or receptacle so that it cannot be opened except by a key or by a series of manipulations that can be carried out only by a person knowing the secret or code.

### EARLY HISTORY

The lock originated in the Near East; the oldest known example was found in the ruins of the palace of Khorsabad near Nineveh. Possibly 4,000 years old, it is of the type known as a pin-tumbler or, from its widespread use in Egypt, an Egyptian lock. It consists of a large wooden bolt, which secures the door, through which is pierced a slot with several holes in its upper surface. An assembly attached to the door contains several wooden pins positioned to drop into these holes and grip the bolt. The key is a large wooden bar, something like a toothbrush in shape; instead of bristles it has upright pegs that match the holes and the pins. Inserted in the large keyhole below the vertical pins it is simply lifted, raising the pins clear and allowing the bolt, with the key in it, to be slid back (Figure 1A). Locks of this type have been found in Japan, Norway, and the Faeroe Islands, and are still in use in Egypt, India, and Zanzibar. An Old Testament reference, in Isaiah, "And I will place on his shoulder the key of the house of David," shows how the keys were carried. The falling-pin principle, a basic feature of many locks, was developed to the full in the modern Yale lock (see below).

In a much more primitive device used by the Greeks, the bolt was moved by a sickle-shaped key of iron, often with an elaborately carved wooden handle. The key was passed through a hole in the door and turned, the point of the sickle engaging the bolt and drawing it back. Such a device could give but little security. The Romans introduced metal for locks, usually iron for the lock itself and often bronze for the key (with the result that keys are found more often today than locks). The Romans invented wards—*i.e.*, projections around the keyhole, inside the lock, which prevent the key from being rotated unless the flat face of the key (its bit) has slots cut in it in such a fashion that the projections pass through the slots. For centuries locks depended on the use of wards for security, and enormous ingenuity was employed in designing them and in cutting the keys so as to make the lock secure against any but the right key (Figure 1B). Such warded locks have always been comparatively easy to pick, since instruments can be made that clear the projections, no matter how complex. The Romans were the first to make small keys for locks—some so small that they could be worn on the fingers as rings. They also invented the padlock, which is found throughout the Near and Far East, where it was probably independently invented by the Chinese.

In the Middle Ages, great skill and a high degree of workmanship were employed in making metal locks, especially by the German metalworkers of Nürnberg. The moving parts of the locks were closely fitted and finished, and the exteriors were lavishly decorated. Even the keys were often virtual works of art. The security, however, was solely dependent on elaborate warding, the mechanism of the lock being developed hardly at all. One

refinement was to conceal the keyhole by secret shutters, another was to provide blind keyholes, which forced the lock picker to waste time and effort. The 18th-century French excelled in making beautiful and intricate locks.

After F.P. Gillman

### DEVELOPMENT OF MODERN LOCK TYPES

**The Barron lock.** The first serious attempt to improve the security of the lock was made in 1778 when Robert Barron, in England, patented a double-acting tumbler lock. A tumbler is a lever, or pawl, that falls into a slot in the bolt and prevents it being moved until it is raised by the key to exactly the right height out of the slot; the key then slides the bolt. The Barron lock (see Figure 1C) had two tumblers and the key had to raise each tumbler by a different amount before the bolts could be shot. This enormous advance in lock design remains the basic principle of all lever locks.

**The Chubb lock.** But even the Barron lock offered little resistance to the determined lock picker, and in 1818 Jeremiah Chubb of Portsmouth, England, improved on the tumbler lock by incorporating a detector, a retaining spring that caught and held any tumbler which, in the course of picking, had been raised too high. This alone prevented the bolt from being withdrawn and also showed that the lock had been tampered with.

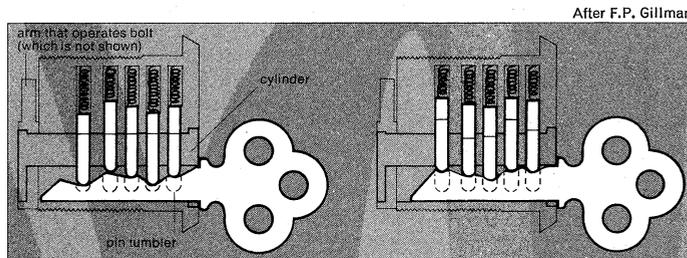

**The Bramah lock.** In 1784 (between Barron's lock and Chubb's improvements on it) a remarkable lock was patented in England by Joseph Bramah. Working on an entirely different principle, it used a very small light key, yet gave an unprecedented amount of security. Bramah's locks are very intricate (hence, expensive to make), and for their manufacture Bramah and his young assistant Henry Maudslay (later to become a famous engineer) constructed a series of machines to produce the parts mechanically. These were among the first machine tools designed for mass production. The Bramah key is a small metal tube that has narrow longitudinal slots cut in its end. When the key is pushed into the lock, it depresses a number of slides, each to the depth controlled by the slots. Only when all the slides are depressed to exactly the right distance can the key be turned and the bolt thrown (Figure 1D). So confident was Bramah of the security of his lock that he exhibited one in his London shop and offered a reward of £200 to the first person who could open it. For over 50 years it remained unpicked, until 1851 when a skilled American locksmith, A.C. Hobbs, succeeded and claimed the reward.

Tube-like key of the Bramah lock

**Lockmaking in the mid-19th century.** The lock industry was in its heyday in the mid-19th century. With the rapidly expanding economy that followed the Industrial Revolution, the demand for locks grew tremendously.

**The Newell lock.** In this period lock patents came thick and fast. All incorporated ingenious variations on the lever or Bramah principles. The most interesting was Robert Newell's Parautoptic lock made by the firm of Day and Newell of New York. Its special feature was that not only did it have two sets of lever tumblers, the first working on the second, but it also incorporated a plate that revolved with the key and prevented the inspection of the interior, an important step in thwarting the lock picker. It also had a key with interchangeable bits so that the key could be readily altered. Newell displayed an example in London in the Great Exhibition of 1851. Despite many attempts, there is no record that it has ever been picked.

**The Yale lock.** In 1848 a far-reaching contribution was made by an American, Linus Yale, who patented a pin tumbler lock working on an adaptation of the ancient Egyptian principle. In the 1860s his son Linus Yale, Jr., evolved the Yale cylinder lock, with its small, flat key with serrated edge, now probably the most familiar lock and key in the world. Pins in the cylinder are raised to the proper heights by the serrations, making it possible to turn the cylinder. The number of combinations of heights of the pins (usually five), coupled with the warding effect of the crooked key and keyhole, give an almost unlimited number of variations (see Figure 2). It has come to be

After F.P. Gillman

Figure 2: Contemporary version of the Yale lock, patented in the 1860s: (Left) Correct key lifts all pins to proper height and key can be turned. (Right) Wrong key lifts pins to incorrect height and lock will not open.

almost universally used for outside doors of buildings and automobile doors, although in the 1960s there was a trend toward supplementing it on house doors with the sturdy lever lock.

**Time locks.** In the 1870s a new criminal technique swept the United States: robbers seized bank cashiers and forced them to yield keys or combinations to safes and vaults. To combat this type of crime, James Sargent of Rochester, New York, in 1873 devised a lock based on a principle patented earlier in Scotland, incorporating a clock that permitted the safe to be opened only at a preset time.

**Combination locks.** The keyless combination lock derives from the "letter-lock," in use in England at the beginning of the 17th century. In it a number of rings (inscribed with letters or numbers) are threaded on a spindle; when the rings are turned so that a particular word or number is formed, the spindle can be drawn out because slots inside the rings all fall in line. Originally, these letter locks were used only for padlocks and trick boxes. In the last half of the 19th century, as developed for safes and strong-room doors, they proved to be the most secure form of closure. The number of possible combinations of letters or numbers is almost infinite and they have no keyholes into which an explosive charge can be placed. Furthermore, they are easy to manufacture.

A simple combination lock with four rings (tumblers, in the U.S.) and 100 numbers on the dial (i.e., 100 positions for each ring) presents 100,000,000 possible combinations. Figure 3 shows how the single knob can set all the wheels; in this case the lock has three rings, or wheels, giving 1,000,000 possible combinations. If, for example,

Possible combinations in multiple-ring locks

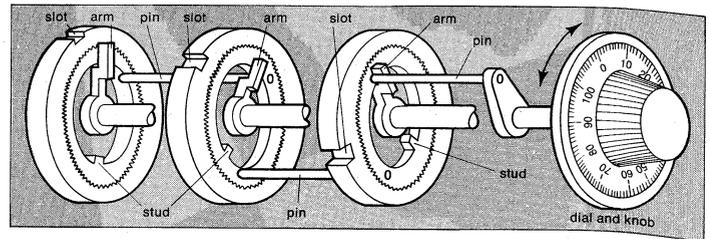

Figure 3: Combination safe lock. The lock cannot be opened until the slots of the three wheels are in line. The movement of the dial is transmitted to each wheel by a system of pins (in practice much shorter than shown), arms, and studs.

the combination is 48, 15, 90, the knob is turned counterclockwise until the 48 comes opposite the arrow for the fourth time, a process that ensures that there is no play between the other wheels. The slot on the first wheel (on the left in the diagram) is then in the correct position for opening and it will not move in subsequent operations. The knob is then turned clockwise until the 15 is opposite the arrow for the third time; this sets the slot of the middle wheel in line with the first. Finally, the knob is turned counterclockwise to bring the 90 for the second time to the arrow. All three slots are then in line and a handle can be turned to withdraw the bolts. The combination can easily be changed, for the serrations shown on each wheel enable the slot to be set to a different position relative to the stud for that wheel.

**Master keys.** It is frequently necessary, particularly in hotels and office buildings, for a manager or caretaker to have a master key that will open all the locks in the building. To design a set of single locks each of which can be opened by its own key, and also by the master key, requires a coordinated arrangement of the warding. The master key is so shaped as to avoid the wards of all the locks. Another method involves two keyholes, one for the normal key, the other for the master key, or two sets of tumblers or levers, or in the case of Yale locks, two concentric cylinders.

**Electronic elements.** In the 1960s an electronic cash dispenser for banks was introduced. This system allows a customer to withdraw money when the bank is closed. The customer has a personal card that is coded with magnetic and other markings. He inserts the card into the machine, located in the wall of the bank. The card is drawn inside and automatically checked for genuineness. The customer then sets up his personal account number (not marked on the card) by pressing a series of numbered buttons. This is also checked electronically and, if correct, a fixed amount of cash is ejected. The card remains within and is later returned to the customer by mail. The whole device constitutes a lock, but it is not a mechanical device, since all the information given by the card, which constitutes the key, is sorted by electronic circuits. Other electronic devices are being increasingly used in connection with security systems (see POLICE TECHNOLOGY).

Basic types remaining in use

*Present status of locks and safes.* Over the years, locks have been constructed with many specialized functions. Some have been designed to resist being blown open, others to shoot or stab intruders or seize their hands. Locks have been made that can be opened or closed by different keys but can be unlocked only by the key that closed them. So-called unpickable locks are usually devised to prevent a thief from exploring the positions of the lock parts from the keyhole or from sensing with his picking tool slight changes of resistance when pressure is applied to the bolt. The basic types, however, remain the Bramah, lever, Yale, and combination locks, though innumerable variations have been made, sometimes combining features of each. The Swiss Kaba lock, for example, employs the Yale principle but instead of having a serrated-edge key, the flat sides of the key are marked with deep depressions into which four complete sets of pin-tumblers are pressed. The Finnish Abloy lock is a compact combination lock, but the rings, instead of being turned separately by hand, are moved to the correct positions by a single turn of a small key.

Magnetic forces can be used in locks working on the Yale principle. The key has no serrations; instead, it contains a number of small magnets. When the key is inserted into the lock, these magnets repel magnetized spring-loaded pins, raising them in the same way that the serrations on a Yale-type key raise them mechanically. When these pins are raised the correct height, the cylinder of the lock is free to rotate in the barrel.

The importance of locks as a protection against professional thieves declined after World War II, during which the knowledge and use of explosives was widely disseminated. As most safe locks and strong-room locks became almost unpickable, criminals tended to ignore the locks and to use explosives to blow them off. An attempt to blow up the mechanism of a lock by detonating an explosive in the keyhole can be foiled by introducing a second series of bolts, not connected to the lock mechanism, but automatically inserted by springs when an explosion occurs; the safe then cannot be opened except by cutting through the armour.

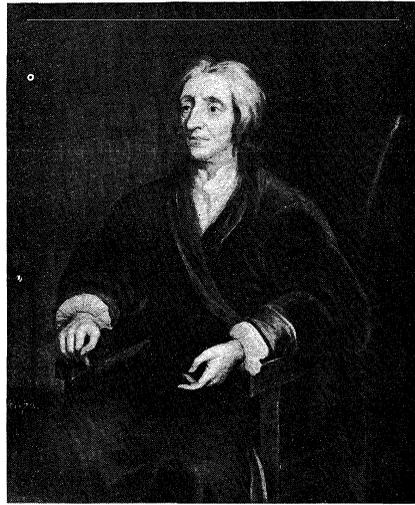

Another method used by criminals is to burn away the plating or hinge of a safe by an electric arc or an oxyacetylene flame, an operation requiring many hours' work. To resist this type of entry, safe makers produced even more resistant materials and new methods of construction to carry away the heat of the cutting flame.

**BIBLIOGRAPHY.** G. PRICE, *A Treatise on Fire and Thief-Proof Depositories, and Locks and Keys* (1856); and C. TOMLINSON (ed.), *Rudimentary Treatise on the Construction of Locks* (1853, 1868), are the classic books on the history of locks and their mechanisms up to the mid-19th century (fully illustrated). For a great variety of types of locks, especially American locks, see A.A. HOPKINS, *The Lure of the Lock* (1928), a catalogue of the Mossman collection in New York that also includes historical notes and interesting, illustrated accounts of great robberies. V.J.M. ERAS, *Sloten en Sleutels door de eeuween Heen* (1941; Eng. trans., *Locks and Keys Throughout the Ages*, 1957), is an account of the Lips collection of locks at their factory in Dordrecht, The Netherlands. It also contains illustrations and descriptions of locks from many other collections throughout the world. J. PARKES AND SONS, LTD., *An Encyclopaedia of Locks and Builders' Hardware*, comp. by F.J. BUTTER (1958), is in the form of a lexicon and is an indispensable guide to the vocabulary and nomenclature of the locksmith's craft. For descriptions of the latest developments in locks and the announcement of new varieties, see the weekly London journals *The Engineer and Engineering*.

(G.B.L.W.)

## Locke, John

John Locke was an English philosopher who was expert in many fields, more particularly in epistemology (theory of knowledge), politics, education, and medicine. His chief contributions were, first, a clear and emphatic formulation of the social and political principles that, in his opinion, emerged from the turbulence of 17th-century Britain and, second, an account of human knowledge, including his examination of the "new science" of his day—*i.e.*, of modern science.

Locke, oil painting by Sir Godfrey Kneller (1646/49–1723). In Christ Church, Oxford.

**Early life.** Locke was born in Wrington, Somerset, on August 29, 1632, and reared in Pensford, six miles south of Bristol. His family was Anglican with Puritan leanings. His father was a country attorney of modest means who fought on the Parliamentary side in the Civil War—a fact that later helped him to find a place for his son in Westminster School, then controlled by a Parliamentary committee (though its headmaster, Dr. Richard Busby, was a Royalist). The training there was thorough, but Locke later complained of the severity of its discipline. In 1652 Locke entered Christ Church, Oxford. Though the Puritans, led by the eminent John Owen, had introduced some reforms into Oxford life, they had made little change in the traditional curriculum of rhetoric, grammar, moral philosophy, geometry, and Greek, and Locke found the course insipid. Nonetheless, this link with traditional Scholastic methods was not wholly valueless. He graduated B.A. in 1656 and M.A. two years later.

During his student years Locke had interested himself in studies not in the traditional curriculum; in particular, he had been drawn to experimental science (brilliantly taught at Oxford by John Wilkins) and to medicine. In 1660, the year of the restoration of the monarchy, Locke was appointed a tutor in Christ Church. He remained a student (*i.e.*, a fellow) with rooms in the college until 1684; but, not wishing to make teaching his permanent vocation, he taught undergraduates for four years only. He gained some experience in diplomacy as secretary to a diplomatic mission to Brandenburg in 1665, and on his return he was immediately offered, but refused, another diplomatic post. Nor did he feel called to the ministry of the Church, a fact that for him was definitive since entry into holy orders without being called would have been culpable. His papers of this period (1656–66), his correspondence, and his commonplace books all testify to his chief interests at the time, *viz.*, natural science, on the one hand, and the study of the underlying principles of moral, social, and political life, on the other. In the latter connection, his "Essays on the Law of Nature," which he wrote in 1663–64 but never published, indicate how far this study had then proceeded. To remedy the narrowness of his education he read contemporary philosophy, particularly that of René Descartes, the father of modern philosophy. But more than all, experimental science engaged his interest. He collaborated with Robert Boyle, one of the founders of modern chemistry, who was a close friend, and, toward the end of the period, with another friend, Thomas Sydenham, an eminent medical scientist.

**Association with Shaftesbury.** It was as a physician that Locke first came to the notice of the statesman Lord Ashley (later to become the 1st earl of Shaftesbury), who at once recognized his worth and in 1667 invited him to

Student years

become part of his household staff serving as physician. Locke accepted the invitation and very soon was Ashley's personal adviser not merely on medical matters but on his general affairs as well. Ashley was a forceful, aggressive politician who had many enemies (some of them men of letters—for instance, Locke's schoolfellow, the poet laureate John Dryden). It is doubtful, however—if only in view of Locke's respect for him—whether Ashley was as evil as his enemies sometimes made him out to be. It is known that he stood firmly for a constitutional monarchy, for a Protestant succession, for civil liberty, for toleration in religion, for the rule of Parliament, and for the economic expansion of Britain; and that he continued to make this stand when many influential men were working against these aims. Since these were already aims to which Locke had dedicated himself, there existed from the first a perfect understanding between the statesman and his adviser, one that meant much to both. Ashley entrusted Locke with the task of negotiating his son's marriage with the daughter of the Earl of Rutland; he also made him secretary of the group that he had formed to increase trade with America, particularly with the southern colonies.

Private studies and discussions

During the following decades, Locke persevered in his private studies, and many of his social meetings were in effect meetings with friends to discuss philosophical and scientific problems. As early as 1668 he had become a fellow of the newly formed (1663) Royal Society, which kept him in touch with scientific advances. It is known, too, that groups of friends met in his rooms (Lord Ashley; John Mapletoft; Thomas Sydenham; Sydenham's physician colleague, James Tyrrell, who was also a divine; and others), for one of its meetings is mentioned in the preface of his *Essay Concerning Human Understanding*, in which he reports that, because of the difficulties that beset the participants, they resolved to devote their next meeting to discussing the powers of the mind in order, as they said, "to examine our own abilities and see what objects our understandings were, or were not, fitted to deal with." Locke himself opened the discussion and, following the meeting, set out his view of human knowledge in two drafts (1671), still extant, which show the beginnings of the thinking that 19 years later would blossom into his famous *Essay*. In these London years, too, Locke encountered representatives of Cambridge Platonism, a school of Christian humanists, who, though sympathetic to empirical science, nonetheless opposed Materialism because it failed to account for the rational element in human life. They tended to be liberal both in politics and religion. Insofar as they taught a Platonism that rested on belief in innately known Ideas, Locke could not follow them; but their tolerance, their emphasis on practical conduct as a part of the religious life, and their rejection of Materialism were features that he found most attractive. This school was closely related in spirit to another school that influenced Locke at this time, viz., that of Latitudinarianism. For the latter school, if a man confessed Christ, that alone should be enough to entitle him to membership in the Christian Church; conformity in nonessentials should not be demanded. These movements prepared Locke for the anti-dogmatic, liberal school of theology that he would later encounter in Holland, a school in revolt against the narrowness of traditional Calvinism.

In 1672 Ashley was raised to the peerage as the 1st Lord Shaftesbury and at the end of that year was appointed lord high chancellor of England. Though he soon lost favour and was dismissed, he did, while in office, establish the Council of Trade and Plantations, of which Locke was secretary for two years. Locke, however, who suffered greatly from asthma, found the London air and his heavy duties unhealthful; and in 1675 he had to return to Oxford.

Intellectual contacts in France

Six months later he departed for France, where he stayed for four years (1675–79), spending most of his time at Paris and Montpellier. In France during the 1670s, Locke made contacts that deeply influenced his view of metaphysics (the nature of being) and epistemology, viz., with the Gassendist school, and particularly with

its leader, François Bernier. Pierre Gassendi, a philosopher and scientist, had rejected overspeculative elements in Descartes's philosophy and had advocated a return to Epicurean doctrines—i.e., to empiricism (stressing sense experience), to hedonism (holding pleasure to be the good), and to corpuscular physics (with reality made of atomic particles). Knowledge of the external world, Gassendi held, depends upon the senses, though it is through reasoning that man may derive much further information from empirically gained evidence.

Upon Locke's return to England, he found the country torn by dissension. The heir to the throne, James (the brother of Charles II), was a Catholic, whom the Protestant majority led by Shaftesbury wished to exclude from the succession. For a year Shaftesbury had been imprisoned in the Tower, but by the time Locke returned he was back in favour once more as lord president of the Privy Council. When he failed, however, to reconcile the interests of the King and Parliament, he was dismissed; in 1681 he was arrested, tried, and finally acquitted by a London jury. A year later he fled to Holland, where, in 1683, he died.

**Later life.** No one of Shaftesbury's known friends was now safe in Britain; and Locke himself, who was being closely watched, crossed to Holland in September 1683.

*Exile in Holland.* Locke remained in Holland for over five years, until James II, who had become king in 1685, was overthrown. As an exile Locke's sojourn in Holland was happier than he had expected it to be: his health improved, he made many new friends, and he found the leisure that enabled him to bring his thoughts on many subjects to fruition. Locke spent his first winter in Amsterdam and soon became friendly with a distinguished Arminian theologian, Philip van Limborch, pastor of the Remonstrants' church there—a friendship that lasted till Locke's death. The companionship of Philip and other friends made it easier to bear bad news from home: at Charles II's express command, Locke (in 1684) was deprived of his studentship at Christ Church. The next year his name appeared on a list sent to The Hague that named 84 traitors wanted by the English government. Locke went into hiding for a while, but soon was able to move freely over Holland and became familiar with its different provinces.

*Return to England and retirement to Oates.* In the autumn of 1688, William left for England; and Locke himself in February 1689 crossed in the party that accompanied the Princess of Orange, now to be crowned Queen Mary II of England. The triumph was complete; Locke was home again, although not without a nostalgia for the Holland that he had come to love. He now took little part in public life. He refused ambassadorial posts but accepted a membership in the Commission of Appeals. (Much later, in 1696, he was appointed a commissioner in the resuscitated Board of Trade and Plantations, however, and for four years played a leading part in its deliberations.) But the London air again bothered him, and he was forced to leave the city for long visits to his friends in the country. In 1691 he retired to Oates in Essex, to the house of his friends Sir Francis and Lady Masham, and subsequently made only occasional visits to London. Nonetheless, he was not without influence in these last years of his life (1689–1704), for he was the intellectual leader of the Whigs. Their principal parliamentarians were frequently old friends of Locke, and the younger generation—particularly the ablest of them all, John Somers, who soon became lord chancellor—turned to him constantly for guidance. In "the glorious, bloodless revolution," the main aims for which Shaftesbury and Locke had fought were achieved—even though in William's reign strong Tory pressures limited the extent of the reform. First and foremost, England became a constitutional monarchy, controlled by Parliament. Second, real advances were made in securing the liberty of the subject in the law courts, in achieving a greater (though far from complete) measure of religious toleration, and in assuring freedom of thought and expression. Locke himself drafted the arguments that his friend Edward Clarke used in the House of Commons in arguing

Influence during retirement

for the repeal of the restrictive Act for the Regulation of Printing. The act was abolished in 1695 and the freedom of the press secured. These were major reforms.

*Publication of his works.* The main task of this last period of his life, however, was the publication of his works, which had been the product of long years of gestation. The *Epistola de Tolerationia* (Eng. trans., *A Letter Concerning Toleration*, 1689) was published anonymously at Gouda in 1689. Locke had been reflecting on this topic from his early days at Oxford. Though his correspondence and a paper that he wrote in 1667 show his support for toleration, in 1660–61 he wrote two tracts on this theme (published in 1967), which are surprisingly conservative. How he came to write them is rather mysterious. The 1667 paper is very much in line with the 1689 *Letter* in its demand for toleration of religion: (1) No man has such complete wisdom and knowledge, he held, that he can dictate the form of another man's religion; (2) each individual is a moral being, responsible before God, and this presupposes freedom; and (3) no compulsion that is contrary to the will of the individual can secure more than an outward conformity. *Two Treatises of Government* (1690) was also the fruit of years of reflection upon the true principles in politics, a reflection resting on Locke's own observations. Government, Locke held, is a trust; its purpose is the security of the citizen's person and property; and the subject has the right to withdraw his confidence in the ruler when the latter fails in his task. Government and political power are necessary, but so is the liberty of the citizen; and in a democratic, constitutional monarchy, a type of government is possible in which the people are still free.

In all of these social and political issues, Locke saw that the ultimate factor is man's nature. To understand man, however, it is not enough to observe his actions; one must also inquire about his capacities for knowledge. Locke had been conscious of this point in writing his paper on the *Law of Nature* as early as 1663. In 1671, as has been seen, he set out to write a book about human knowledge, the *Essay*, which was not published, however, until 1690—nor was it wholly completed even then, for Locke made changes, sometimes substantial ones, in three of the four following editions.

*Development of his epistemology.* Epistemology was a main concern in the last 30 years of his life. Human knowledge, he argued, rests (1) on the experience of the external world acquired through the senses, and (2) on that of the inner world of psychological happenings achieved through intuition (or, in Locke's terminology, "reflection"). The empirical knowledge derived from these sources is uncertain and never provides more than probability, whereas the ideal of knowledge is certainty. In Locke's opinion, this ideal is in fact attainable in some fields—for instance, in mathematics. Though knowledge originates in sensory and introspective experience, this is only the beginning; for many other factors are to be attended to as well—factors such as the reasoning that enables a person to derive, from empirically based propositions, more general conclusions about the world, both physical and mental. Such reasoning may be inductive (resting on the assumption that what usually happens always happens) or it may be deductive. Mathematical reasoning, for example, is deductive; and this kind of knowledge is only to be understood, Locke believed, in terms of an intellectual intuition of relations between ideas, which, though empirically derived, have the status of defined archetypes of such a nature that their empirical reference is irrelevant. In addition, the knower, by means of intuition, can discern the relations between statements that warrant the drawing of inferences. Through such intellectual intuitions, necessary and universal knowledge is possible. To facilitate his presentation of this theory, Locke considered the nature of (1) idea and (2) language. He concluded that, in the case of human beings, intuitive knowledge is limited in extent; for the most part, knowledge is only probable, and Locke examined the degrees of probability and the nature of evidence. He acknowledged that the natural sciences cannot give complete certainty: nonetheless, careful rea-

soning, with the application of mathematical reasoning wherever possible, will heighten the probability of attaining true knowledge in these fields. In the *Essay*, Locke set down the foundations of an epistemology of modern science.

*Last years.* Locke's last years were spent in the peaceful retreat of Oates. His hostess was a woman with whom he had been acquainted for many years, viz., Lady Masham, or Damaris, the daughter of Ralph Cudworth, one of the Cambridge Platonists, by whom Locke had been significantly influenced. He found friendship and comfort in this household, for which he never ceased to be thankful. Many of his friends visited him here: Sir Isaac Newton, who came to discuss the Epistles of Saint Paul, a subject of great interest to both; his nephew and heir Peter King, destined to become lord high chancellor of England; and Edward Clarke with his wife and children, Edward and Elizabeth, for whom Locke had great affection (as he had, too, for the children of the Oates household). Locke had written a series of letters to Edward Clarke from Holland, advising him on the best upbringing for his son. These letters formed the basis of his influential *Some Thoughts Concerning Education* (1693), setting forth new ideals in that field. He wrote and published pamphlets on matters of economic interest, on rates of interest, on the coinage of the realm, and more widely on trade (defending mercantilist views). In 1695 he published a dignified plea for a less dogmatic Christianity in *The Reasonableness of Christianity*. It is, finally, interesting to note that Locke never produced a book on morals, though this subject was possibly his greatest interest: for in this field he never succeeded in working out a coherent theory that would reconcile differences within his thinking.

John Locke died on October 28, 1704, and was buried in the parish church of High Laver. "His death," wrote Damaris Cudworth, "was like his life, truly pious, yet natural, easy and unaffected." This account of his character by one who knew him well seems singularly appropriate. There is adequate evidence of his piety, as there is of his natural simplicity, grace, and unaffectedness. He was orderly, careful about money, occasionally parsimonious, abstemious, and, though naturally emotional and hot-tempered, controlled and disciplined. He had a great love of children, and friendship was for him a necessity. Both in his books and in his life are found the marks of the prudence and wisdom for which he was famed.

#### MAJOR WORKS

PHILOSOPHY AND RELIGION: *Essays on the Law of Nature* (eight essays written c. 1662–64 in Latin with various Latin titles; first published, with Eng. trans., in 1954); *An Essay Concerning Human Understanding* (1690); *Epistola de Tolerationia* (1689); *A Letter Concerning Toleration*, 1689; *A Second Letter Concerning Toleration* (1690); *A Third Letter for Toleration* (1692); *The Reasonableness of Christianity* (1695); *Some Thoughts on the Conduct of the Understanding in the Search of Truth* (1762).

POLITICAL PHILOSOPHY AND ECONOMICS: *Two Treatises of Government* (1690); *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money* (1692); *Short Observations on a Printed Paper, Intituled "For Encouraging the Coining of Silver Money in England"* (1695); *Further Considerations Concerning Raising the Value of Money* (1695).

EDUCATION: *Some Thoughts Concerning Education* (1693).

**BIBLIOGRAPHY.** HANS O. CHRISTOPHERSEN, *A Bibliographical Introduction to the Study of John Locke* (1930). At present, no modern standard edition of Locke's works exists, but the first volume of the Oxford edition is expected to appear soon.

*Biography:* PETER KING, *The Life of John Locke* (1829, fuller edition 1830), a poor biography, but King possessed and quoted from what is now known as the Lovelace Collection of Locke papers, and this gives the book great value; H.R. FOX BOURNE, *The Life of John Locke* (1876), an excellent study, still indispensable though not now definitive; MAURICE W. CRANSTON, *John Locke: A Biography* (1957), the best and most up-to-date biography, very readable and most illuminating.

*On Locke's philosophy:* RICHARD I. AARON, *John Locke,*

Ideas of sense and of reflection

Later writings

3rd ed. (1971), a general study, with bibliography; SAMUEL ALEXANDER, *Locke*, "Philosophies Ancient and Modern Series" (1908), brief, but a jewel; D.J. O'CONNOR, *John Locke* (1952), a concise, enlightening, and well-written introductory commentary; J. GIBSON, *Locke's Theory of Knowledge and Its Historical Relations* (1917), a thorough study of the topic; J.W. YOLTON, *John Locke and the Way of Ideas* (1956), much information on Locke's sources and early critics.

(R.Aa.)

## Locomotion

Animals are, by definition, motile organisms. Large or small, their locomotor ability is expressed by their structural organization, from external shape to tissue and cell morphology. A fusiform (tapering) body, for example, suggests speed and a high level of activity, whether this shape is possessed by a protozoan (one-celled animal), molluscan (e.g., squid), insect, or vertebrate. In contrast, a globular body enclosed in a protective shell, such as a clam, indicates slow or sedentary habits. Animals, however, are not machines; each individual is a precisely blended and balanced amalgamation of structures that enable it to perform the many functions necessary for its survival and reproduction. The fact that an animal's structure clearly reflects locomotor habits indicates the importance of mobility in all phases of its life.

### GENERAL CONSIDERATIONS ABOUT LOCOMOTION

To locomote, all animals require both propulsive and control mechanisms. The diversity of animal propulsive mechanisms, all of which involve a contractile structure—muscle in most cases—to generate a propulsive force, are dealt with in the sections that follow. The quantity, quality, and position of contractions are initiated and coordinated by the nervous system: through this coordination, rhythmic movements of the appendages or body produce locomotion. Control of locomotion by the nervous system, locomotion as a learned behaviour, and physiological problems associated with locomotion, such as temperature control, metabolism, nutrition, and respiration, are described elsewhere in the articles NERVES AND NERVOUS SYSTEMS; BEHAVIOUR, ANIMAL; MUSCLE SYSTEMS; and MUSCLE CONTRACTION.

**Physical restraints to movement.** Animals successfully occupy a majority of the vast number of different physical environments (ecological niches) on earth; in a discussion of locomotion, however, these environments can be divided into four types: aerial (including arboreal), aquatic, fossorial (underground), and terrestrial. The physical restraints to movement—gravity and drag—are the same in each environment: they differ only in degree. Gravity is here considered as the weight and inertia (resistance to motion) of a body, drag as any force reducing movement. Although these are not the definitions of a physicist, they are adequate for a general understanding of the forces that impede animal locomotion.

**Gravity.** To counteract the force of gravity, which is particularly important in aerial, fossorial, and terrestrial locomotion, all animals that live in these three environments have evolved skeletal systems to support their body and to prevent the body from collapsing upon itself. The skeletal system may be internal or external, and it may act either as a rigid framework or as a flexible hydraulic (fluid) support.

To initiate movement, a sufficient amount of muscular work must be performed by aerial, fossorial, and terrestrial animals to overcome inertia. Aquatic animals must also overcome inertia; the buoyancy of water, however, reduces the influence of gravity on movement. Actually, because many aquatic animals are weightless—i.e., they possess neutral buoyancy by displacing a volume of water that is equal in weight to their dry weight—little muscular work is needed to overcome inertia. But not all aquatic animals are weightless. Those with negative buoyancy sink as a result of their weight; hence, the greater their weight, the more muscular energy they must expend to remain at a given level. Conversely, an animal with positive buoyancy floats to and rests on the surface, and must expend muscular energy to remain submerged.

Buoyancy

**Drag.** In water, the primary force that retards or resists forward movement is drag, the amount of which depends upon the animal's shape and how that shape cleaves the water. Drag results mainly from the friction of the water as it flows over the surface of the animal and the adherence of the water to the animal's surface (i.e., the viscosity of the water). Because of the water's viscosity, its flow tends to be lamellar; i.e., different layers of the water flow at different speeds, with the slowest layer of flow being the one adjacent to the body surface. As the flow speed increases, the lamellar pattern is lost, and turbulence develops, thereby increasing the drag.

Another component of drag is the retardation of forward movement by the backward pull of the eddies of water behind the tail of the animal. As they flow off an animal, the layers of water from each side meet and blend. If the animal is streamlined (e.g., has a fusiform shape), the turbulence is low; if, however, the water layers from the sides meet abruptly and with different speeds, the turbulence is high, causing a strong backward pull, or drag, on the animal.

Aerial locomotion also encounters resistance from drag, but, because the viscosity and density of air are much less than those of water, drag is also less. The lamellar flow of air across the wing surfaces is, however, extremely important. The upward force of flight, or lift, results from air flowing faster across the upper surface than across the lower surface of the wing. Because this differential in flow produces a lower air pressure on the upper surface, the animal rises. Lift is also produced by the flow of water across surfaces, but aquatic animals use the lift as a steering aid rather than as a source of propulsion.

Lift  
and drag

Drag is generally considered a negligible influence in terrestrial locomotion; and, in fossorial locomotion, the friction and compactness (friability) of soils are the two major restraints. If the soil is extremely friable, as is sand, some animals can "swim" through it. Such fossorial locomotion, however, is quite rare; most fossorial animals must laboriously tunnel through the soil and thereafter depend upon the tunnels for active locomotion.

**Axial and appendicular locomotion.** Movement in animals is achieved by two types of locomotion, axial and appendicular. In axial locomotion, which includes the hydraulic ramjet method of ejecting water (e.g., squid), production of a body wave (eel), or the contract-anchor-extend method (leech), the body shape is modified, and the interaction of the entire body with the surrounding environment provides the propulsive force. In appendicular locomotion, on the other hand, special body appendages interact with the environment to produce the propulsive force.

There are also many species of animals that depend upon their environment for transportation, a type of mobility that is called passive locomotion. Some jellyfish, for example, develop structures called floats that extend above the water's surface and act as sails. A few spiders have developed an elaborate means of kiting; when a strand of their web silk reaches a certain length after being extended into the air, the wind resistance of the strand is sufficient to lift and carry it away with the attached spider. In one fish, the remora, the dorsal (top) fin has moved to the top of the head and become modified into a sucker; by attaching itself to a larger fish, the remora is able to ride to its next meal.

### AQUATIC LOCOMOTION

**Micro-organisms.** Most motile protozoans, which are strictly aquatic animals, move by locomotion involving one of three types of appendages: flagella, cilia, or pseudopodia. Cilia and flagella are indistinguishable in that both are flexible filamentous structures containing two central fibrils (very small fibres) surrounded by a ring of nine double fibrils. The peripheral fibrils seem to be the contractile units and the central ones, neuromotor (nerve-like) units. Generally, cilia are short and flagella long, although the size ranges of each overlap.

**Flagellar locomotion.** Most flagellate protozoans possess either one or two flagella extending from the anterior (front) end of the body. Some protozoans, however,

Types of flagellar movement

have several flagella that may be scattered over the entire body; in such cases, the flagella usually are fused into distinctly separate clusters. Flagellar movement, or locomotion, occurs as either planar waves, oarlike beating, or three-dimensional waves. All three of these forms of flagellar locomotion consist of contraction waves that pass either from the base to the tip of the flagellum or in the reverse direction to produce forward or backward movement. The planar waves, which occur along a single plane and are similar to a sinusoid (S-shaped) wave form, tend to be asymmetrical; there is a gradual increase in amplitude (peak of the wave) as the wave passes to the tip of the flagellum. In planar locomotion the motion of the flagella is equivalent to that of the body of an eel as it swims. Although symmetrical planar waves have been observed, they apparently are abnormal, because the locomotion they produce is erratic. Planar waves cause the protozoan to rotate on its longitudinal axis, the path of movement tends to be helical (a spiral), and the direction of movement is opposite the propagation direction of the wave.

In oarlike flagellar movements, which are also planar, the waves tend to be highly asymmetrical, of greater side to side swing, and the protozoan usually rotates and moves with the flagellum at the forward end. In the three-dimensional wave form of flagellar movement, the motion of the flagella is similar to that of an airplane propeller; *i.e.*, the flagella lash from side to side. The flagellum rotates in a conical configuration, the apex (tip) of which centres on the point at which the flagellum is attached to the body. Simultaneous with the conical rotation, asymmetrical sinusoidal waves pass from the base to the end of the flagellum. As a result of the flagellar rotation and its changing angle of contact, water is forced backward over the protozoan, which also tends to rotate, and the organism moves forward in the direction of the flagellum.

**Ciliary locomotion.** Cilia operate like flexible oars; they have a unilateral (one-sided) beat lying in a single plane. As a cilium moves backward, it is relatively rigid; upon recovery, however, the cilium becomes flexible, and its tip appears to be dragged forward along the body. Because the cilia either completely cover as in ciliate protozoans or are arranged in bands or clumps, the movement of each cilium must be closely coordinated with the movements of all other cilia. This coordination is achieved by metachronal rhythm, in which a wave of simultaneously beating groups of cilia moves from the anterior to the posterior end of the organism. In addition to avoiding interference between adjacent cilia, the metachronal wave also produces continuous forward locomotion because there are always groups of cilia beating backward. Moreover, because the plane of the ciliary beat is diagonal to the longitudinal axis of the body, ciliate organisms rotate during locomotion.

**Pseudopodial locomotion.** Although ciliary and flagellar locomotion are clearly forms of appendicular locomotion, pseudopodial locomotion (Figure 1) can be classed as either axial or appendicular, depending upon the definition of the pseudopodium. Outwardly, pseudopodial locomotion appears to be the extension of a part of the body that anchors itself and then pulls the remainder of the body forward. Internally, however, the movement is quite different. The amoeba, a protozoan, may be taken as an example. Its cytoplasm (the living substance surrounding the nucleus) is divided into two parts: a peripheral layer, or ectoplasm, of gel (a semisolid, jellylike substance) enclosing an inner mass, or endoplasm, of sol (a fluid containing suspended particles; *i.e.*, a colloid). As a pseudopodium, part of the ectoplasmic gel is converted to sol, whereupon endoplasm begins flowing toward this area, the cell wall expands, and the pseudopodium is extended forward. When the endoplasm, which continues to flow into the pseudopodium, reaches the tip, it extends laterally and is transformed to a gel. Basically, the movement is one of extending an appendage and then emptying the body into the appendage, thereby converting the latter into the former. Although the flow of the cytoplasm is produced by the same pro-

teins involved in the mechanism of muscle contraction, the actual molecular basis of the mechanism is not yet known. Even the mechanics of pseudopodial formation are not completely understood.

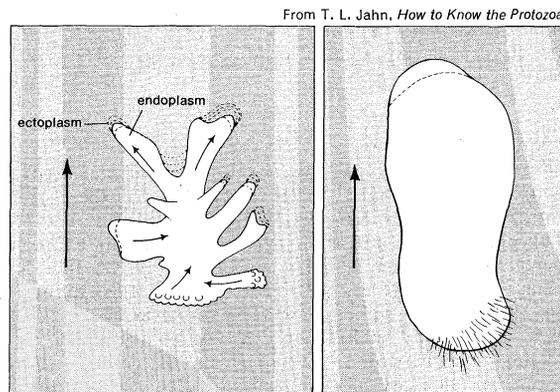

Figure 1: Pseudopodial locomotion. Arrows indicate the direction of cytoplasmic flow (see text).

**Undulating and gliding locomotion.** Two other types of locomotion are observed occasionally in protozoans. Some protozoans, usually flagellates, have along their bodies a longitudinal membrane that undulates, thereby producing a slow forward locomotion. A gliding locomotion is commonly seen in some sporozoans (parasitic protozoans), in which the organism glides forward with no change in form and no apparent contractions of the body. Initially, the movement was thought to be produced by ejecting mucus, a slimy secretion; small contractile fibrils have been found that produce minute contraction waves that move the animal forward.

**Invertebrates.** As in the protozoans, aquatic locomotion in invertebrates (animals without backbones) consists of both swimming and bottom movements. When swimming, the propulsive force is derived entirely from the interaction between the organism and the water; in bottom movements, the bottom surface provides the interacting surface. Whereas some bottom movements are identical with terrestrial locomotor patterns, others can occur effectively only in the water, where buoyancy is necessary to reduce body weight.

**Bottom locomotion.** Small flatworms (Platyhelminthes) and some of the smaller molluscan species move along the bottom by ciliary activity. On their ventral (bottom) surface, a dense coat of cilia extends from head to tail. The direction of the ciliary beat is tailward, causing the animal to glide slowly forward. Generally, all animals that move by this type of ciliary activity secrete a copious stream of mucus over which the animal glides. The mucus not only attaches the animal to the surface but also raises its body so that the cilia can beat. Because ciliary forces are too weak for the movement of large flatworms, they must use muscular contraction for their propulsive force.

Aquatic invertebrates possess several other types of bottom locomotion. In species with well-developed legs, such as crabs and lobsters, bottom walking is common. Whereas the gaits in such cases are identical to those used on land, they tend to be slightly faster in water, because the buoyancy increases the animal's stability. (Walking gaits are described below; see *Terrestrial locomotion*.)

Another form of bottom locomotion is bottom creeping, which employs the contract-anchor-extend method of movement. Bottom creeping is best developed in leeches, which have two suckers, one at the anterior end and one at the posterior end. After the posterior sucker anchors the animal, it stretches its body forward and attaches the anterior one. It then releases the posterior sucker and contracts its body toward the anterior end. For effective contract-anchor-extend locomotion, the body musculature must consist of both circular and longitudinal muscles: the contraction of the circular muscles extends or elongates the body; the contraction of the longitudinal muscles flexes and shortens the body. Moreover, the skeleton should be hydrostatic; that is, a fluid skeleton that

Meta-chronal rhythm

Bottom creeping

changes shape but not volume, thereby providing a firm but flexible base.

In pedal locomotion, which is a slow, continuous gliding that is superficially indistinguishable from ciliary locomotion, propulsion along the bottom is generated by the passage of contraction waves through the ventral musculature, which is in contact with the bottom surface. The pedal contraction waves are either direct (in the same direction as the movement) or retrograde (in the direction opposite to the movement). The direct waves produce locomotion in a manner analogous to that in which a caterpillar walks. When a direct wave reaches a muscle, the muscle contracts and lifts a small part of the body; the body is carried forward and set down anterior to its original position as the wave passes. With direct waves, the surfaces of the body touching the bottom surface are not the ones that contract; with retrograde waves, however, these are the surfaces that do contract. As the retrograde wave approaches, the body area immediately adjacent to it is extended upward. The body surface within the contraction area then anchors itself to the bottom surface, after which the body is pulled forward.

Large flatworms use pedal locomotion instead of or in alternation with ciliary activity. In the gastropod and amphineuran molluscs (*e.g.*, snails and chitons, respectively), pedal locomotion is the primary locomotor mode and has become highly complex. The foot of these creeping animals is extremely muscular, penetrated by nerves, and capable of generating one, two, or four laterally adjacent contraction waves. If the foot generates a pair of waves, the lateral halves of the foot may alternate, thereby producing a shuffling movement, or they may be opposite. Generally, a foot can contain no more than one whole and two partial waves moving along a single axis.

Peristaltic locomotion is a common locomotor pattern in elongated, soft-bodied invertebrates, particularly in segmented worms, such as earthworms. It involves the alternation of circular- and longitudinal-muscle-contraction waves. Forward movement is produced by contraction of the circular muscles, which extends or elongates the body; contraction of the longitudinal muscles shortens and anchors the body. (This pattern is described more completely below; see *Fossorial locomotion*.)

Although peristaltic locomotion is frequently used by sea cucumbers, they and other echinoderms, such as sea urchins and starfishes, possess rows of tube feet that provide the main locomotor force. In starfishes, each arm bears hundreds of tube feet. Only one arm, however, becomes dominant in locomotion; while the tube feet on that arm move toward the tip of the arm, the tube feet of the other arms move in the same plane as those of the lead arm. Because there is no apparent metachronal wave of contraction within an arm, the movement of the tube feet is poorly coordinated, but small areas of the tube feet do move in synchrony. Each tube foot is a hollow elastic cylinder capped by a hollow muscular ampulla (a small, bladder-like enlargement). When the ampulla contracts, it forces fluid into the tube foot and extends it. Preferential contraction of muscles in the wall of the tube foot controls the direction of and the retraction of the tube foot. When the tube foot is fully contracted, fluid is withdrawn from it by relaxation of the ampulla, after which the muscles of the tube foot swing it forward in preparation for another step.

*Swimming.* Invertebrates have developed two distinct propulsive mechanisms for swimming: some use hydraulic propulsion; all others utilize undulations of all or parts of their bodies. The medusa (umbrella-shaped) body of coelenterates and ctenophores (*e.g.*, jellyfish and comb jelly, respectively) is a flexible hemisphere with tentacles and sense organs suspended from the edge; a manubrium (handle-shaped structure) bearing the digestive system hangs from the internal tip of the hemisphere. Enclosed in the outer margin of the medusa is a wide muscular band; when this band contracts, the opening of the medusa narrows. Simultaneously, water is ejected from the medusa through the narrow opening, and the animal is propelled upward. Because the contractions tend to be regular but slow, locomotion is somewhat jerky.

Scallops are the best swimmers among bivalve molluscs that can swim. Locomotion is produced by rapid clapping movements of the two shells, creating a water jet that propels the scallop. The muscular mantle (a membranous fold beneath the shell) acts as a valve and controls the direction of flow of the ejected water, thereby controlling the direction of movement. Normally, the flow is directed downward on each side of the hinge that joins the two shells, and the resulting water jet lifts the scallop and moves it in the direction of the shell's opening. If necessary, however, escape movement may occur in the opposite direction. The scallop is adapted to swim even though it is two or three times as dense as seawater. The hinge is elastic and opens the shell rapidly; this action, coupled with rapid and repeated contractions of the adductor muscle, which closes the shell, produces a powerful and nearly continuous water jet. Moreover, the body form of a closed scallop is an airfoil (like a wing, the curvature of its upper surface is greater than that of its lower surface); this shape, combined with the downward ejection of water, produces lift.

Cephalopods (*e.g.*, squids, octopuses) are another group of mollusks that use hydraulic propulsion. Unlike the scallops, they have lost most of their heavy shell and have developed fusiform bodies. The mantle of cephalopods encloses a cavity in which are contained the gills and other internal organs. It also includes, on its ventral surface, a narrow, funnel-shaped opening (siphon) through which water can be forcibly ejected when all the circular muscles surrounding the mantle cavity contract rapidly and simultaneously. This water jet shoots the cephalopod in a direction opposite to that in which the siphon is pointed.

Many invertebrates, particularly elongated ones such as open-sea-dwelling annelids and mollusks, swim by undulatory movements produced by contraction waves that alternate on each side of the body. Although the arrangement of the musculature differs between invertebrates and vertebrates, the mechanics of undulatory swimming are the same in both and are described in the following section.

**Fish and fishlike vertebrates.** Undulatory swimming is roughly analogous to using one oar at the stern of a boat. The side-to-side movements of the oar force the water backward and the boat forward. The undulatory movement of a fish acts similarly, although the motions involved are much more complex.

*Anguilliform locomotion.* When an elongated fish such as an eel swims, its entire body, which is flexible throughout its complete length, moves in a series of sinuous waves passing from head to tail. In this type of movement, which is called anguilliform (eel-like) locomotion, the waves cause each segment of the body to oscillate laterally across the axis of movement. Unlike the simple side-to-side movement of the oar, however, each oscillating segment describes a figure-eight loop, the centre of which is along the axis of locomotion. It is these oscillations and the associated orientation of each body segment that produce the propulsive thrust.

The undulatory body waves are created by metachronal contraction waves alternating between the right and left axial musculature. During steady swimming, several contraction waves simultaneously pass down the body axis from head to tail; the resultant undulatory waves move backward along the body faster than the body moves forward. As the undulatory wave passes backward, its amplitude and speed increase, thereby producing the greatest propulsive thrust in the tail (caudal) region. Propulsion, however, is not limited to the caudal region, for all undulating segments contribute to the thrust. Because the speed, amplitude, and inclination of each body segment differ, the thrust of each differs. In all segments, the greatest thrust is obtained as the segment crosses the locomotor axis, for here it is travelling at its greatest speed and inclination.

*Carangiform and ostraciiform locomotion.* All undulatory swimming movements generate forward thrust in the manner described above. Not all swimming animals, however, possess the elongated shape of an eel; only those

Undulatory swimming

Tube feet

with a similar body form, in which the surface area of the head end is the same as that of the tail end, have anguilliform locomotion. Fish with fusiform bodies exhibit carangiform locomotion, in which only the posterior half of the body flexes with the passage of contraction waves. This arrangement of body form and locomotion apparently is the most efficient one, for it occurs in the most active and fastest of fish. The advantage of carangiform locomotion appears to be related to the effectiveness of the posterior half of the body as a propulsive unit and the fact that the shape of the body and its small lateral displacement create little water turbulence. In contrast to ostraciiform locomotion, in which only the caudal fin oscillates from side to side in a manner similar to moving a boat with one oar, the length of the propulsive unit of carangiform fish enables the unit to obtain maximum oscillatory speed and inclination.

Whales also use undulatory body waves, but unlike any of the fishes, the waves pass dorsoventrally (from top to bottom) and not from side to side. In fact, many mammals that swim mainly by limb movements tend to flex their body in a dorsoventral plane. Whereas the body musculature of fish and tail musculature of amphibians and reptiles is highly segmental—that is, a muscle segment alternates with each vertebra—an arrangement that permits the smooth passage of undulatory waves along the body, mammals are unable to produce lateral undulations because they do not have this arrangement. Nor does the muscle arrangement of mammals permit true dorsoventral undulations; however, with an elongated caudal region, as in whales, they can attain a form of carangiform locomotion as effective as that of any fish.

*Stabilization and steering.* To stabilize and steer, most aquatic vertebrates have, in addition to the caudal fin, a large dorsal fin and a pair of large anterolateral fins. Although they may possess other fins, these are of less importance. The balance of a swimming animal may be maintained in several ways. Rolling, or rotation, along the longitudinal axis of the body is reduced or controlled by any fins that extend at right angles to the body. Pitching, or dorsoventral seesawing, movements are counteracted by the anterolateral fins, which are also the major steering organs of fish, whales, and seals. Yawing, or lateral seesawing, is prevented by the dorsal fin and, if present, a ventral fin; for these fins to be effective, however, most of their exposed surface area should be behind the fish's centre of gravity. Because fins of the above type are not common in most invertebrates that swim by undulation, their locomotion is less stable.

**Tetrapodal vertebrates.** Many of the various types of undulatory locomotion described above are also widely used by aquatic tetrapods (those with walking appendages). Larval frogs, crocodilians, aquatic salamanders, and lizards, for example, have long muscular tails that propel them by undulatory motion. Most aquatic tetrapods, however, move by appendicular locomotion, for which the major propulsive units are the hindlegs. The exceptions are sea turtles, auks, penguins, and fur seals; in these, the hindfeet are webbed and are used as rudders. For propulsion, these animals use their forelegs, which have become bladelike flippers in which the forearm and hand region are dorsoventrally compressed to form a single, inflexible unit. The movements of such flippers are analogous to the aerial flight of birds; by moving synchronously, they provide lift and thrust in the water. Unlike aerial flight, however, the upper arms do not produce lift or thrust; instead, they serve only as a pivotal or leverage point for driving the flippers.

Swimming movements in sea turtles, penguins, and auks are accomplished by the rotation of the flippers or wings through a figure-eight configuration. In the birds, however, the stroke is relatively faster than in sea turtles, because the entire cycle appears to be proportionately smaller in amplitude. Moreover, because the birds' bodies are more streamlined, they can attain greater speeds than the turtles. Penguins may attain speeds of 25 miles (40 kilometres) per hour in water and have sufficient speed and thrust to enable them to leap six or more feet above the water. The wings of penguins are so highly modified,

however, that they have lost the ability to fly. The auks, on the other hand, are able to use their wings for both aerial and aquatic locomotion.

Some of the other aquatic birds, such as ducks and water ouzels, are said to propel themselves underwater through wing movements, but the evidence for such propulsion is incomplete and still open to question. The wing movements of ducks may be for steering and hydroplaning (skimming through the water) rather than for actual propulsion. The wings of the water ouzels, or dippers, were once thought to function as hydroplanes, but investigations have revealed that, although the wings are flapped underwater, the ability of dippers to bottom walk or fly underwater depends upon the velocity of the water flowing past the wings rather than the movement of the wings themselves.

Most aquatic birds are propelled by their webbed hindfeet, which tend to move alternately in surface swimming and in unison when the bird is submerged. Of all the swimming birds that use their hindfeet, the loons show the most extreme adaptations: the body, head, and neck are elongated and streamlined; the hindlegs are at the very posterior end of the body; the lower legs are compressed and bladelike; and the feet are strongly webbed. The webbing increases the surface area exposed to the water during limb retraction and also permits the folding of the foot, thereby reducing water resistance during protraction.

In frogs and freshwater turtles, the hindlegs are elongated and the feet enlarged and strongly webbed. But, whereas the hindlegs of frogs move synchronously, except occasionally in slow swimming, when they alternate, the limb movements always alternate in freshwater turtles. Some aquatic turtles, however, such as snapping, mud, and musk turtles, are very poor swimmers and will swim only under extreme conditions. These turtles are bottom walkers, and their limb movements in water are identical to those on land except that they can move faster in water than on land.

The swimming movements of many mammals are also identical with their terrestrial limb movements. Hippopotamuses spend much of their time in the water, yet they bottom walk rather than swim. Most of the aquatic mammals—e.g., otters, hair seals, aquatic marsupials, insectivores, and rodents—use their hindlegs and frequently their tails for swimming. The feet are webbed and usually move alternately; the tail tends to be flattened. Fur seals, polar bears, and platypuses swim mainly with forelimbs; only in the seals, however, are the movements of the forelimbs similar to those of sea turtles and penguins.

#### FOSSORIAL LOCOMOTION

The speed, manner, and ease with which animals move depends directly upon the compactness of the material and its cohesiveness. Many aquatic animals can swim through semisolid mud or muck suspensions, which lack compactness. Some lizards and snakes that live in an arid environment can swim through friable sand, which is compact but lacks strong cohesiveness. Although these swimming movements can be considered a form of fossorial locomotion, the following discussion considers only locomotor patterns in which most of the activity of the animals involved is confined to tunnels that they leave behind.

**Fossorial invertebrates.** Burrowing or boring invertebrates have evolved a number of different locomotor patterns to penetrate soil, wood, and stone, of which soil or mud is the easiest to penetrate. The soft-bodied invertebrates, such as worms and sea cucumbers, burrow either by peristaltic locomotion or by the contract-anchor-extend method. Their hydrostatic, or fluid, skeleton, combined with their circular and longitudinal musculature, permits controlled deformation of their shape, which allows them to squeeze into narrow spaces and then enlarge the spaces, thus creating a burrow or tunnel. Worms with a protrusible proboscis (a tubular extension of the oral region) generally burrow by the contract-anchor-extend method. Contraction of the circular muscles in the posterior half of the body drives the body

Loco-  
motion of  
aquatic  
mammals

Aquatic  
birds

Burrowing

fluids forward, causing the proboscis to evert (turn outward) and forcing it into the soil. When the proboscis is fully everted, the part of the body (collar) directly behind it dilates and anchors the proboscis in the soil. The entire body is then pulled forward by the longitudinal muscles and reanchored. This pattern produces the very jerky and slow forward progression typical of most fossorial locomotion.

Peristaltic locomotion (see Figure 2), which is generated by the alternation of longitudinal- and circular-muscle-contraction waves flowing from the head to the tail, is similar to the above pattern. Forward progression is

From J. Gray, *Animal Locomotion*; Weidenfeld & Nicolson Limited

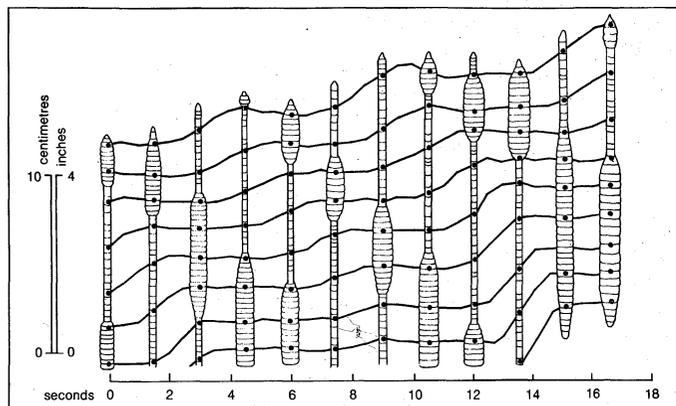

Figure 2: *Peristaltic locomotion in worms.* Segments move forward except when they are longitudinally contracted (shown as wide areas with large dots). Individual points on the worm's body and their movements relative to each other are shown by the oblique lines.

more continuous, however, because of the contraction waves. The sites of longitudinal contraction are the anchor points; body extension is by circular contraction. The pattern of movement is initiated by anchoring the anterior end. As the longitudinal contraction wave moves posteriorly, it is slowly replaced by the circular contraction wave. The anterior end slowly and forcefully elongates, driving the tip farther into the surface as the circular contraction wave moves down the body. The tip then begins to dilate and anchor the anterior end as another longitudinal contraction wave develops. This sequence is repeated continuously, and the worm moves slowly forward. Reversing the direction of the contraction waves enables the worm to back up.

Burrowing bivalve mollusks, such as clams, use the contract-anchor-extend locomotor mode. Such bivalves have a large muscular foot that contains longitudinal and transverse muscles as well as a hemocoel (blood cavity). The digging cycle begins with the extension of the foot by contraction of the transverse muscles. The siphons (tubular-shaped organs that carry water to and from the gills) are closed, and the adductor muscle of the shell contracts, thereby forcing blood into the tip of the foot and causing it to dilate. With the tip acting as an anchor, the longitudinal muscles then contract, pulling the body down to the anchored foot. Frequently, the longitudinal muscles contract in short steps and alternate between the left and right sides; this causes the shell to wobble and penetrate deeper as it is pulled down.

Rock  
borers

Some invertebrates are able to bore through rock. Most of the rock borers are mollusks; they bore either mechanically by scraping or chemically by the secretion of acid. The piddock, or angel's wing, bivalves, for example, attach themselves to a rock with a sucker-like foot. The two valves, held against the rock, grind back and forth by the alternate contraction of two adductor muscles; the grinding slowly produces a tunnel.

**Fossorial vertebrates.** The fossorial vertebrates are found in three classes: amphibians, reptiles, and mammals. Although some fishes and birds dig or bore shallow burrows, they can hardly be considered truly fossorial, as are moles or earthworms. Locomotion of fossorial amphibians and reptiles tends to be axial; it is appendicular only in mammals. Fossorial mammals have strong fore-

legs with a tendency toward flattening; their hands and particularly the claws are enlarged. Forelegs show the greatest modification in such species as moles and gophers, whose entire lives are spent in burrows. These animals tend to dig with a breast stroke, either synchronously or alternately, by extending the foreleg straight forward in front of the snout and then retracting it in a lateral arc. The loosened soil is compacted against the side walls of the burrow. In those fossorial species that dig burrows as nests but forage above the ground—many rodents, such as prairie-dogs, ground squirrels, and groundhogs—the digging movements tend to be dorsoventral with alternating limb movement. The forelegs are extended forward and then retracted downward and backward; the loosened soil passes beneath the body and is frequently pushed to the surface.

Fossorial reptiles and amphibians are usually legless, or the legs are so reduced that they serve no locomotor function; in most species, the head is flattened dorsoventrally, and the snout extends beyond and somewhat over the mouth. Burrowing is accomplished by one of three patterns analogous to the contract-anchor-extend locomotion of invertebrates. In the most common of these, the snout is driven straight forward along the bottom of the tunnel, the head is then raised, and the soil is compacted to the roof. The head tends to be laterally compressed in animals that use the other two patterns. In one of these patterns, the snout is shoved forward and then swung from side to side; in the other, the snout is rotated as it swings from side to side and seems to shave the walls of the tunnel.

#### TERRESTRIAL LOCOMOTION

**Walking and running.** Only arthropods (*e.g.*, insects, spiders, and crustaceans) and vertebrates have developed a means of rapid surface locomotion. In both groups, the body is raised above the ground and moved forward by means of a series of jointed appendages, the legs. Because the legs provide support as well as propulsion, the sequences of their movements must be adjusted to maintain the body's centre of gravity within a zone of support; if the centre of gravity is outside this zone, the animal loses its balance and falls. It is the necessity to maintain stability that determines the functional sequences of limb movements, which are similar in vertebrates and arthropods. The apparent differences in the walking and in slow running gaits of these two groups are caused by differences in the tetrapodal (four-legged) sequences of vertebrates and in the hexapodal (six-legged) or more sequences of arthropods. Although many legs increase stability during locomotion, they also appear to reduce the maximum speed of locomotion. Whereas the fastest vertebrate gaits are asymmetrical, arthropods cannot have asymmetrical gaits, because the movements of the legs would interfere with each other.

**Cycle of limb movements.** The cycle of limb movements is the same in both arthropods and vertebrates. During the propulsive, or retractive, stage, which begins with footfall and ends with foot liftoff, the foot and leg remain stationary as the body pivots forward over the leg. During the recovery, or protractive, stage, which begins with foot liftoff and ends with footfall, the body remains stationary as the leg moves forward. The advance of one leg is a step; a stride is composed of as many steps as there are legs. During a stride, each leg passes through one complete cycle of retraction and protraction, and the distance the body travels is equal to the longest step in the stride. The speed of locomotion is the product of stride length and duration of stride. Stride duration is directly related to retraction: the longer the propulsive stage, the more time required to complete a stride and the slower the gait. A gait is the sequence of leg movements for a single stride. For walking and slow running, gaits are usually symmetrical—*i.e.*, the footfalls are regularly spaced in time. The gaits of fast-running vertebrates, however, tend to be asymmetrical—*i.e.*, the footfalls are irregularly spaced in time.

The different gaits of insects are based on the synchrony of leg movements on the left (*L*) and right (*R*) sides of

the animal. The wave of limb movement for each side passes anteriorly; the posterior leg protracts first, then the middle leg, and finally the anterior leg, producing the sequence  $R_3 R_2 R_1$ , or  $L_3 L_2 L_1$ . There is no limb interference, because the legs of one side do not have footfalls along the same longitudinal axis. The slowest walking gait of insects is the sequence  $R_3 R_2 R_1$  followed by the sequence  $L_3 L_2 L_1$ . As the rate of protraction increases, the protractive waves of the right and left sides begin to overlap. Eventually, the top speed is reached when the posterior and anterior legs of one side move synchronously. This gait occurs because the protraction times for all legs are constant, the intervals between posterior and middle legs and between middle and anterior legs are constant, and the interval between posterior and anterior legs decreases with faster movements. Other gaits are possible in addition to those indicated above by altering the synchrony between left and right sides.

Limb movements in millipedes and centipedes

The limb movements of centipedes and millipedes follow the same general rules as those of insects. The protraction waves usually pass from posterior to anterior. Because each leg is slightly ahead of its anteriorly adjacent leg during the locomotory cycle, one leg touches down or lifts off slightly before its anteriorly adjacent one. This coordination of limb movement produces metachronal waves, the frequency of which equals the duration of the complete protractive and retractive cycle. The length of the wave is directly proportional to the phase lag between adjacent legs.

Whereas the millipedes must synchronize leg movements to eliminate interference, the tetrapodal vertebrates must synchronize leg movements to obtain maximum stability. Four legs are the minimum requirement for symmetrical terrestrial gaits. Although bipedal (two-legged) gaits require extensive structural modifications of the body and legs, they still retain the leg-movement sequence of tetrapodal gaits (see Figure 3). The basic

From A. Howell, *Speed in Animals*, © 1944; University of Chicago Press

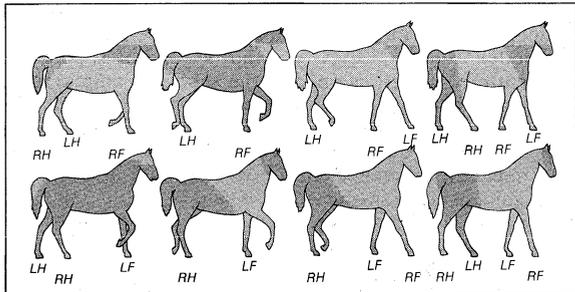

Figure 3: Walking sequence of a five-gaited horse. LH and RH refer to left and right hindlegs; LF and RF refer to left and right forelegs.

walking pattern of all tetrapodal vertebrates is left hindleg (LH), left foreleg (LF), right hindleg (RH), right foreleg (RF), and then a cyclic repetition of this sequence, which is equivalent to the slow walking gait of insects but with the middle legs removed. Unlike the insects, however, vertebrates can begin to walk with any of the four legs and not just the posterior pair. The faster symmetrical gaits of vertebrates are obtained by overlapping the leg-movement sequences of the left and right sides in the same manner as insects; for example, an animal can convert a walk to a trot by moving diagonally contralateral legs (those on opposite sides) simultaneously, or to a pace by moving the ipsilateral legs (those on the same side) simultaneously. Many other symmetrical gaits occur between the walk and the pace and the trot, which are extreme modifications of the walk.

**Cursorial vertebrates.** Cursorial (running) vertebrates are characterized by short, muscular upper legs and thin, elongated lower legs. This adaptation decreases the duration of the retractive-protractive cycle, thereby increasing the animal's speed. Because the leg's cycle is analogous to the swing of a pendulum, reduction of weight at the end of the leg increases its speed of oscillation. Cursorial mammals commonly use either the pace or the trot for steady, slow running. The highest running speeds,

such as the gallop, are obtained with asymmetrical gaits. When galloping, the animal is never supported by more than two legs and occasionally is supported by none. The fastest runners, such as cheetahs or greyhounds, have an additional no-contact phase following hindfoot contact.

In cursorial birds and lizards, both of which are bipedal, the feet are enlarged to increase support, and the body axis is held perpendicular to the ground, so that the centre of gravity falls between the feet or within the foot-support zone. The running gait is, of course, a simple alternation of left and right legs. In lizards, however, bipedal running must begin with quadrupedal (four-footed) locomotion. As the lizard runs on all four legs, it gradually builds up sufficient speed so that its head end tilts up and back, after which it then runs on only its two hindlegs.

**Saltation.** The locomotor pattern of saltation (hopping) is confined mainly to kangaroos, anurans (tailless amphibians), rabbits, and some groups of rodents in the vertebrates and to a number of insect families in the arthropods. All saltatory animals have hindlegs that are approximately twice as long as the anteriormost legs. Although all segments of the hindleg are elongated, two of them—the tibial (between upper segment and ankle) and tarsal (ankle) segments—are the most elongated.

There are at least four different saltatory patterns, but all are similar in that the simultaneous retraction or extension of the hindlegs is followed by an aerial phase of movement. The aerial phase in all patterns is governed by the physical principles of ballistics (the flight characteristics of an object): the height and the length of the jumps are functions of the takeoff velocity and angle. The longest jumps are attained when the takeoff angle is 45°.

Before jumping, the femur (upper segment of the hindleg) of the flea is held perpendicular to the ground, the tibia extends obliquely posterior, and the remainder of the hindleg extends posteriorly along the ground. Just prior to the jump, the middle legs flex and tilt the body upward; then the femur of the hindlegs swings sharply backward simultaneously with the extension of the tibia. This retraction forces the animal upward and forward at an angle of 50°. As the flea approaches touchdown, the front legs are swung forward and downward, the middle legs are held perpendicular to the body axis, and the hindlegs project obliquely posterior. The anterior two pairs of legs thus act to absorb the landing shock.

The frog jump (Figure 4) is initiated with three simultaneous movements: the forelegs flex, and the back arches to tilt the entire body upward; the tarsus of the hindleg swings to a vertical position and locks; and the femur, extending anteriorly along the body, swings in a horizontal plane. When the femur is perpendicular to the body, the knee joint snaps open, and the frog jumps forward at a 30° to 45° angle. As the frog begins to land, the forelegs are protracted and held downward in front of the chest. The forefeet touch down first, the forelegs acting as shock absorbers. Simultaneously, the hindlegs are protracted so that they can be in jumping posture by the completion of landing.

The positions and movements of the hindlegs in rabbits and kangaroos are similar to those of the frog. The major difference is that rabbits, kangaroos, and all other mammals move their legs in a vertical plane instead of a

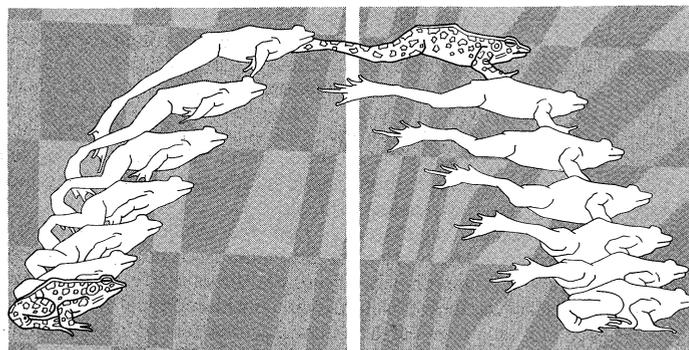

Figure 4: (Left) Jumping and (right) landing sequences of frogs.

Types of saltatory patterns

horizontal plane, as do the frogs; because the femur and tibia move vertically, the tarsus need not be elevated to prevent the hindleg from hitting the ground. The saltatorial gait of rabbits is quadrupedal, whereas that of kangaroos is bipedal. A jumping rabbit stretches forward and lands on its forefeet; generally, both forefeet do not touch ground simultaneously, however. As the forefeet touch, the back flexes, and the hind end rotates forward and downward. The hindfeet touch down lateral to the forefeet, and, as the back extends, a new jump begins. In contrast, the kangaroo lands on its hindfeet, and the back is held fairly straight through all phases of the jump, although the body inclines forward at takeoff and posteriorly when landing.

### Crawling patterns

**Crawling.** Invertebrates crawl either by peristaltic locomotion or by contract-anchor-extend locomotion, both of which have been described previously (see above *Fossorial locomotion*). Limbless vertebrates, however, crawl in one of four patterns: serpentine, rectilinear, concertina, and sidewinding. The most common pattern, serpentine locomotion, is used by snakes, legless lizards, amphisbaenids (worm lizards), and caecilians (wormlike amphibians). Rectilinear locomotion is used by the giant snakes and almost exclusively by fossorial vertebrates when burrowing. Concertina and sidewinding locomotion are largely confined to snakes.

**Serpentine locomotion.** In serpentine locomotion, in which the body is thrown into a series of sinuous curves, the movements appear identical to those of anguilliform swimming, but the similarity is more apparent than real. Unlike anguilliform swimming, when a snake starts to move, the entire body moves, and all parts follow the same path as the head. When the snake stops moving, the entire body stops simultaneously. Propulsion is not by contraction waves undulating the body but by a simultaneous lateral thrust in all segments of the body in contact with solid projections (raised surfaces). The muscular thrust against the projection is perpendicular to the axis of the pushing segment. To go forward, therefore, it is necessary for the strongest thrust to act against the side of the projection facing in the direction of movement. Because of this, thrust tends to occur at the anterior end of the concave (inward-curving) side of the loop of the snake's body.

**Concertina locomotion.** Concertina locomotion is used when there is not enough frictional resistance along the locomotor surface for serpentine locomotion. After the body is thrown into a series of tight, sinuous loops, forming a frictional anchor, the head slowly extends forward until the body is nearly straight or begins to slide. The anterior end forms a small series of loops and, with this anchor, pulls the posterior regions forward, after which the sequence of movements is repeated. This crawling pattern is analogous to the contract-anchor-extend locomotion of invertebrates, but, because snakes lack the body flexibility provided by a hydrostatic skeleton, they must depend upon the body loops.

**Sidewinding.** Sidewinding, which is also used when the locomotor surface fails to provide a rigid frictional base, is a specific adaptation for crawling over friable sandy soils. Like serpentine locomotion but unlike concertina locomotion, the entire body moves forward continuously in sidewinding locomotion (see Figure 5). Although the body moves through a series of sinuous curves, the track made by the snake is a set of parallel lines that are roughly perpendicular to the axis of movement. This is because only two parts of the body touch the ground at any instant; the remainder of the body is held off the ground. To begin sidewinding, the snake arches the anterior part of the body forward and forms an elevated loop with only the head and the middle of the body in contact with the ground. Because each part of the body touches the ground only briefly before it begins to arch forward again, the snake seems to roll forward like a short, coiled spring. In a continuously repeating cycle, as a segment arches forward, the posteriorly adjacent segment touches down.

**Rectilinear locomotion.** Unlike the three preceding patterns of movement, in which the body is thrown into a

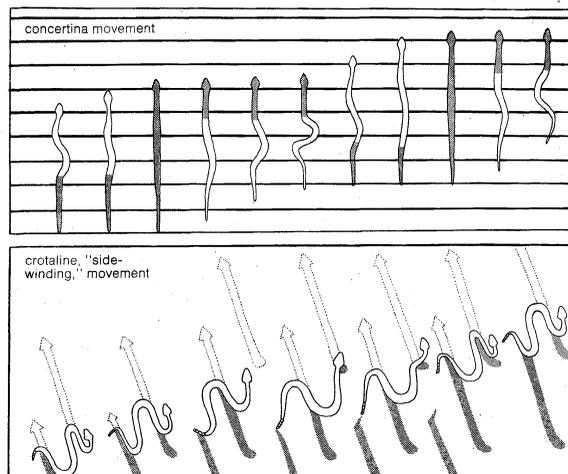

Figure 5: Two modes of locomotion in the snake. From J. Gray, *Animal Locomotion*, Weidenfeld & Nicolson Ltd.

series of curves, in rectilinear locomotion in snakes the body is held relatively straight and glides forward in a manner analogous to the pedal locomotion of snails. The ventral (belly) surface of snakes is covered by scales elongated crosswise that overlap like roof shingles, with the opening of the overlap facing toward the posterior. Each ventral scale is moved by two pairs of muscles, both of which are attached to ribs but not to ribs of the same segment as the scale. One pair of muscles is inclined posterior at an angle (obliquely); the other is inclined anterior at an angle. As contraction waves move rearward from the head simultaneously on both sides, the anterior oblique muscles of a scale contract first and lift the scale upward and forward. When the posterior oblique muscles contract, the scale is pulled rearward, but its edge anchors it, and the body is pulled forward. This sequence is repeated by all segments as the contraction wave passes posteriorly, and, as a series of contraction waves follow one another, the body slowly inches forward.

### ARBOREAL AND AERIAL LOCOMOTION

**Climbing.** The adaptation for climbing is unique for each group of arboreal animals. All climbers must have strong grasping abilities, and they must keep their centre of gravity as close as possible to the object being climbed. Because arthropods are generally small and, thus, not greatly affected by the pull of gravity, they show little specific structural adaptation for climbing. In contrast, the larger and heavier bodied vertebrates have many climbing specializations. In both arthropods and vertebrates, however, no leg is moved until the others are firmly anchored.

**Arboreal amphibians and reptiles.** Arboreal frogs are slender-bodied anurans with tapering legs and feet. The tips of the toes (digits) are expanded into large, circular disks that may function as suction cups, although such an action has not yet been definitely demonstrated. The disks, however, do increase the contact area, thereby improving grasping ability. The leg-movement sequence during climbing is that of a walking gait.

Arboreal lizards have the same type of climbing gait as arboreal frogs, and their climbing specializations are also similar to those of anurans. They have a different type of climbing foot, however, because of the presence of claws and scales on the digits. Moreover, the entire digits, rather than just their tips, may be expanded. On the bottom of each of these spatula-shaped expansions are one or two rows of transversely elongated scales. Although not visible to the naked eye, the surface of these scales is covered with fine projections that increase their ability to adhere to a surface. Because of this strong adherence, the toes roll off and on the surface on which the animal is walking. Unlike other arboreal lizards, chameleons possess a prehensile (grasping) tail and zygodactylous feet—*i.e.*, the toes are fused into two opposable units. Although

Surface  
adherence

these adaptations are inferior for vertical climbing, they are superior for locomotion on vertical or inclined, slender branches. Arboreal snakes tend to have either prehensile tails or extremely elongated bodies.

**Climbing birds and mammals.** Although the strong, clawed feet of birds permit many of them to climb occasionally, most truly scansorial (climbing) birds cling with their strong feet and brace themselves with stiffened tail feathers. Birds such as woodpeckers and tree creepers usually climb vertically upward, usually with both feet moving simultaneously in short, vertical hops. This mode of locomotion, however, prevents vertical descent. Only the nuthatch can descend as easily as it can ascend; it climbs obliquely, using the upper foot for clinging and the lower foot as a brace. Parrots have developed zygodactylous feet as an aid to climbing; in addition, they frequently use their bills when climbing vertically.

Use of  
prehensile  
fingers  
or claws

Several locomotor patterns for climbing are used by arboreal mammals, the grasping ability of which has been enhanced by the presence of either strong claws or prehensile fingers. Many monkeys use a climbing gait similar to the leg sequence of walking. Occasionally, however, they use a leg sequence equivalent to that of a trot. Small-bodied climbers with sharp claws, such as squirrels, climb by the alternate use of forelegs and hindlegs; essentially, they hop up a tree. Prehensile-fingered climbers descend backward and generally with a walking type of leg sequence. Sharp-clawed species descend with a similar gait sequence but with the head downward.

**Leaping.** The mechanics of arboreal leaping do not differ from those of terrestrial saltation; the upward thrust in both is produced by the rapid, simultaneous extension of the hindlegs. Because of the narrowness of the arboreal landing site, however, landing behaviour does differ. Arboreal leaping also tends to be a discontinuous locomotor behaviour that is used only to cross wide gaps in the locomotor surface. Leaping from limb to limb, although occasionally employed by most climbers, appears to occur most frequently in animals with opposable or at least prehensile forefeet, particularly tree frogs and primates. Such forefeet enable the animal to grasp and hold onto the landing site.

**Brachiation.** True brachiation (using the arms to swing from one place to another) is confined to a few species of primates, such as gibbons and spider monkeys. Because the body is suspended from a branch by the arms, brachiation is strictly foreleg locomotion. When the animal moves, it relaxes the grip of one hand, and the body pivots on the shoulder of the opposite arm and swings forward; then the free arm reaches forward at the end of the body's swing and grabs a branch. The sequence is then repeated for the other arm. This locomotor pattern produces a relatively rapid and continuous forward movement but is restricted to areas with thick canopies of trees. Brachiators have arms that may be as long or longer than the body and a very motile shoulder joint.

**Gliding.** There are two functionally distinct forms of gliding, gravitational gliding and soaring: the former is used by gliding amphibians, reptiles, and mammals; the latter is restricted to birds. All gliders are able to increase the relative width of their bodies, thereby increasing the surface area exposed to wind resistance. The few gliding frogs flatten their bodies dorsoventrally and spread their limbs outward. Gliding snakes not only flatten their bodies but also draw in the ventral scales, thereby creating a trough. The best adapted gliding lizards have elongated ribs that open laterally like a fan.

Gliding mammals, such as the African flying squirrel and the colugo, usually have, on each side of the body, a fold of skin (the patagium) that extends from their wrist or forearm backward along the body to the shank of the hindleg or the ankle. When gliding, they assume a spread-eagle posture, and the patagia unfold.

**Gravitational gliding.** Gravitational gliding is equivalent to parachuting. Because the expanded lateral surface of the body increases the wind resistance against the body, the speed of falling is reduced. The directions of gliding can be controlled by adjusting the surface area—to curve to the right, the right patagium is relaxed. Glid-

ers can land on vertical surfaces by suddenly turning the anterior end of the body up as it reaches the surface. Mechanically, this stalls the flight—*i.e.*, the horizontal component of flight is eliminated.

**Soaring.** Gravitational gliding is one of the basic mechanisms of soaring, which is restricted to birds, although birds must obtain their initial elevation by means of flapping flight. The second basic mechanism of soaring involves wind or air currents. Soaring requires that air currents meet one of two conditions: either the air must have a vertical velocity exceeding the rate of descent in gravitational gliding, or it must have a horizontal velocity that is nonuniform in time and space. Whereas static soaring depends upon vertical air currents, dynamic soaring depends upon horizontal air currents. Both types of soaring are described below.

Vertical air currents for static soaring are produced when wind strikes an obstruction and is deflected upward. The sites of deflection are very local and discontinuous and seldom extend more than 100 feet above the obstruction. The height of deflection and the vertical velocity of the air are a function of the angle of deflection and the velocity of the wind. If the vertical velocity of the air equals the descent speed of the bird, the bird remains stationary in height relative to the ground. If, however, the vertical velocity is greater, the bird rises, and, if less, the bird falls at a speed equal to the gravitational descent speed minus the air's vertical ascent speed. The horizontal velocity of the air determines the bird's movements relative to the ground in the same manner as that of the vertical velocity.

Static  
and  
dynamic  
soaring

The soaring flights of vultures and hawks depend upon vertical hot-air currents called thermals. Such currents are not continuous updrafts or downdrafts originating from a specific spot; instead, as a local region of the ground is heated, a vertical, hot-air updraft is created. At the top of the column, a thermal bubble is formed by the hot air curving outward, downward, and then around the bubble. It is then pinched off by cool air flowing into the column and floats upward. The free-floating thermal bubble is doughnut shaped, with the air rising in the centre and cycling outward and downward. Soaring birds spiral downward in the updraft; however, because the bubble rises faster than birds descend, soaring birds are carried upward, but at a speed less than that of the bubble. When a bird reaches the bottom of the bubble, it begins a straight gravitational glide until it reaches the next thermal bubble. Thus, static soaring in a thermal bubble can be recognized by its alternating flight pattern of circling and straight gliding.

Unlike static soaring, which is done at relatively high altitudes over land, dynamic soaring is done at low levels and is usually restricted to oceanic areas. Dynamic soaring depends upon a steady horizontal sea wind, which is laminated into layers of different velocities because of the frictional interaction between the water and the air; the lower layers have the lowest velocity. The flight path of a bird performing dynamic soaring tends to be a series of inclined loops that are perpendicular to the direction of the wind. A soaring albatross, for example, will begin its gravitational glide approximately 50 feet (15 metres) above the sea. Because it glides downwind, its velocity is increased both by descent and by the wind at its tail. As the bird nears the sea, it makes a turn into the wind, and the forward flight velocity derived from the downwind glide and the tailwind combine to lift the albatross slowly back to its initial gliding height, but with a loss of horizontal velocity. The bird therefore turns downwind again and begins to repeat the soaring cycle.

Because it depends upon the presence of a horizontal air current, the flight of flying fish is more akin to soaring than to true flying. As a flying fish approaches the water surface, its pectoral and pelvic fins, which are analogous to the forelimbs and hindlimbs of quadrupeds, are pressed along the side of the body. The greatly enlarged, winglike pectoral fins then spread out as the fish leaves the water. The wind against the fins provides lift to raise the body above the water, and the tail continues to undulate to provide additional thrust. When the entire body is out of

the water, the enlarged pelvic fins extend, and the fish glides for a short distance until its forward velocity is lost. Occasionally, as a fish drops back into the water, it will undulate its tail to initiate another short flight.

**True flight.** Three animal groups have developed true flight: insects, birds, and mammals. All generate forward thrust by flapping lateral appendages, and all are free of any dependence on gravitational descent or air currents. It should be noted at the outset, however, that, although the aerodynamics of flight are identical in all three, the following cycles of wing movements described for the different animal groups are generalizations; each species in a group has a distinctive flight pattern and, therefore, a distinctive pattern of wing movement.

Wing  
move-  
ments

Flight is produced by the simultaneous rotation of the left and right wings in a circle or in a figure eight. This rotation produces the upward thrust, or lift, necessary to overcome gravity and the forward thrust required to overcome drag. As the downward and backward phase of rotation forces the air backward and the body forward, lift is produced by the unequal velocities of the air across the upper and lower wing surfaces.

**Wings of insects.** In flies with one pair of wings, the rotation of the tip inscribes a posterior inclined oval. At the top of the wing cycle, the tip lies above the junction of the thorax and abdomen. The wing then beats downward and forward so that the tip ends anterior and below the head. To insure maximum thrust, the broad surface of the wing lies parallel to the horizontal body plane during the downstroke. During the path of the upstroke, which is the reverse of the downstroke, the wing is feathered (turned) by inclining it perpendicular to the body plane. Although the rotational cycle of those insects with two pairs of wings follows a similar path, the upward and downward strokes of the anterior and posterior wings are not simultaneous; the anterior pair usually lags behind the posterior pair.

The wings of insects are rotated by pulsation of the thorax, not by a set of muscles. Basically, the thorax is a rigid box to which the wings are attached by a pair of longitudinal lateral hinges that enable the thorax to move dorsoventrally. Four sets of muscles control the major movements. Contraction of a perpendicular set, which extends from the centre of the floor of the thorax to its roof, depresses the thorax and, because of a reverse linkage between wing and thorax, raises the wing. Contraction of a diagonal set, which extends from the anterior roof of the thorax to its posterior floor, elevates the thorax and lowers the wing. Two diagonal sets of muscles extend laterally from the floor to the wall of the thorax and are responsible for maintaining a relatively constant width in the thorax.

**Wings of birds and bats.** Unlike insect wings, the wings of birds and bats are linked structures, the lateral extent and regional inclination of which are altered intrinsically by muscular and bony segments. The up-and-down strokes of a bird's wing are produced by large chest (pectoral) muscles that extend from the sternum (breastbone) to the lower surface of the humerus (a bone in the upper arm). When these muscles contract, the wing is lowered; it is raised by the contraction of a small anterior pectoral muscle that is attached to the upper surface of the humerus by a long tendon.

Hovering  
and  
propulsive  
flight

Birds exhibit two major flight patterns, hovering flight and propulsive flight. Hovering flight is of fairly restricted use and is observed most frequently in the hummingbirds. The path of the wings inscribes a horizontal figure eight whose centre is perpendicular to the shoulder joint. The downward stroke of the wings is actually a slightly inclined anterior stroke, and, because the longitudinal body axis is nearly perpendicular to the ground, the upward stroke is a horizontal posterior stroke. Both strokes are power strokes that produce lift: on the downstroke the dorsal wing surface is the top of the airfoil surface; on the upstroke the ventral surface is the top of the airfoil surface.

Most birds and bats, however, utilize propulsive flight. Because the body is not stationary, as it is in hovering flight, the wing always moves forward relative to the air,

and its tip generally inscribes an oval or figure-eight path. In a pigeon, for example, the downstroke begins with the wing fully extended and perpendicular to the back (Figure 6). As the wing moves downward and anterior, it

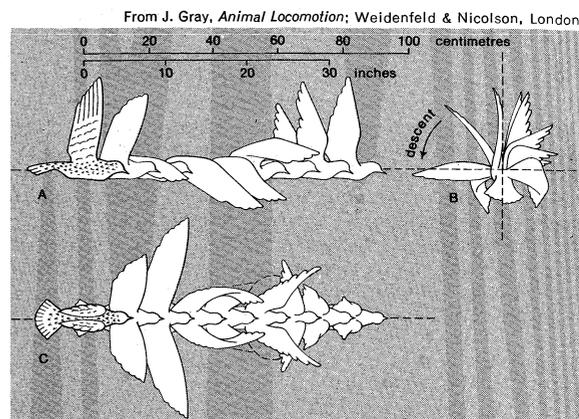

Figure 6: *Wing movements of a pigeon.*  
(A) View from right side; (B) View from behind; (C) View from above.

draws level with the body, at which point the upper arm section stops while the distal part completes the downward path. At the bottom of the downstroke, the distal part turns outward and is elevated rapidly by the combined protraction of the humerus and the extension of the distal section.

#### DIRECTIONAL CONTROL

Although an animal's locomotor pattern may be controlled by its nervous system, directional control is impossible without sensory input. Two factors are involved in directional control: orientation, the ability of an animal to determine and to alter its position in the environment; and steering, the mechanical alteration of the locomotor pattern through which the animal adjusts its position.

**Orientation.** Orientation of locomotor behaviour is usually categorized as either kinesis or taxis. In kinesis, an animal's body is not oriented in relation to a sensory stimulus; rather, the stimulus causes an alteration in speed or direction of movement. In wood lice, for example, the kinetic response alters only the rate of movement. Because wood lice tend to aggregate in moist areas, their ambulatory activity increases or decreases as the relative humidity decreases or increases, respectively. In the planarian (an aquatic, ciliated flatworm), on the other hand, the kinetic response affects only the rate at which the planarian changes its direction. Because planaria tend to stay in or return to darker areas, an increase in light intensity causes an increase in their turning responses. Generally, however, animals tend to alter both direction and speed as a single kinetic response.

In taxis, an animal orients itself in a specific spatial relationship to a stimulus. The orientation may be simply an alteration of body position or it may be an alteration of locomotor direction so that the animal moves toward, away from, or at a fixed angle to the source of the stimulus. Sources that elicit a taxis response, which may cause a modification of speed, direction, or both, seem to encompass the entire range of environmental stimuli, such as gravity (geotaxis), temperature (thermotaxis), light (phototaxis), or chemicals (chemotaxis). If the response is negative, the animal moves away from the source; if it is positive, the animal moves toward the source.

The control of the response to a taxis is of two types. In open-system control, the initial response to a stimulus has no effect on subsequent responses to the same stimulus. A male firefly, for example, locates a female by the latter's brief flashes of light. When a male sees a female's flash, the male turns in the direction of the female, even though the source is no longer visible. If another female flashes, however, the male responds to the second flash in exactly the same manner as it did to the first. In close-system control, on the other hand, the response is progressively

Kinesis  
and taxis

altered by feedback so that all subsequent responses are adjusted to the initial response. A bat chasing a flying insect will alter its flight path to intercept that of the insect. The bat's initial change in direction is only a general alteration of its course, but, as it approaches the insect, the bat constantly modifies its course to obtain an accurate interception.

**Steering.** Animals obtain accurate directional response (steering) by changing their propulsive response. Because steering relies heavily on continuous feedback (the communication cycle in which the motor output, or behaviour, is constantly being modified by the sensory input, or stimulus), it requires a precise integration of the central and peripheral nervous systems. (The central nervous system—in vertebrates, the brain and spinal cord—is that part of the nervous system that receives sensory impulses and sends out motor impulses; the peripheral nervous system consists of all the nerves that carry impulses between the central nervous system and other parts of the body.) Exteroceptive stimuli (those that originate outside the body) received by the peripheral nervous system establish the animal's spatial position in the environment; proprioceptive stimuli (those that originate inside the body), also received by the peripheral nervous system, establish the relative position of the body units to each other (see further SENSORY RECEPTION). Through integration of these two sets of stimuli, the central nervous system continuously adjusts the contraction of the motor units (*e.g.*, muscles) in order to obtain the desired orientation.

During locomotion, steering is a continual process. The direction of movements must be constantly adjusted to counteract environmentally produced deviations of direction. The apparently simple act of a bird flying from a tree to the ground illustrates the complexity of directional control. As the bird flies to the ground, it must be constantly aware of its height above the ground, the orientation of its body axis relative to the ground, deviations in flight direction resulting from air currents, and its speed of fall. All these parameters are determined primarily by exteroceptive stimuli received through the eyes and inner ears. The downward flight is constantly adjusted in response to these exteroceptive stimuli, and the fine control necessary for these adjustments is obtained by proprioceptive feedback.

## Loess

True loess is a pale-yellow sedimentary deposit composed largely of silt-size grains that are loosely cemented by calcium carbonate. It is usually homogeneous, unstratified, highly porous, and is traversed by vertical capillaries that permit the sediment to fracture and form vertical bluffs. The word loess, with connotations of origin by eolian (wind-deposited) accumulation, is of German origin and means loose. It was first applied to Rhine Valley loess about 1821.

Thick loess blankets are composed of loess packets one to five metres thick, each of which contains intercalated strata of loessial and loess-like sediments, paleosols (ancient soils), sand layers, and similar material. The totality of these constitutes the loess complex. There are several regional variants of loess that, together with true loess, constitute a loess series, including loessial sand, sandy loess, loess loam, and clayey loess. The individual elements of the loess series are hard to distinguish, and the

several sediment types composing it are interpreted differently by workers in different regions or countries.

Most widespread in today's temperate zones and in the marginal semi-arid zones of the deserts, loess covers about 10 percent of the land surface of the earth. Loess usually exhibits a surficial cover of fertile soil that is conducive to intensive agriculture and consequently, has always had a concentrating influence on population. In densely populated loess regions, as in China, farming populations used to dig cellar-like dwellings in steep bluffs. In semi-arid regions people such as the Pueblo Indians made houses and fortress-like closed edifices from loess-based adobe. The present importance of loess for building construction, soil conservation and improvement, and soil engineering is enhanced by its erodibility, peculiar strength, and chemical properties.

This article is concerned with the physical and chemical properties of loess, its occurrence and distribution, and the several theories of loess formation. For further information on the transportation of silt by wind and water, see WIND ACTION and FLUVIAL PROCESSES, respectively. See also PLEISTOCENE EPOCH, for a discussion of the climatic significance of eolian deposits, and SEDIMENTARY ROCKS, for the relation of fine-grained rocks in general to others of sedimentary origin.

**Physical and chemical properties.** The dominant grain-size fraction of loess, called the loess fraction, ranges from 0.02 to 0.05 millimetre and includes grains of coarse and medium-grained dust. Grain-size analyses by various methods indicate that the abundance of this fraction is about 50 weight percent. Clay-size particles (less than 0.005 millimetre) make up another five to 10 percent. In some loess regions, the grain-size distribution shifts toward finer grains with increasing distance from the source of dust (*e.g.*, eastward from Sand Hills, Nebraska). The relative abundances of the dust, clay, and sand fractions may vary vertically, as well as horizontally, from one loess packet to another.

Loess typically exhibits a low moisture content of 10 to 15 percent that increases as porosity decreases. Its porosity is 50 to 55 percent, decreasing slightly downward to a depth of about 10 metres (33 feet). Below this depth, porosity varies as a function of the grain-size distribution. If the loess is enriched in clay, then the porosity may decrease to 34 to 45 percent. The porosity of sandy loess is about 60 percent. The bulk density of sandy loess is 1.5 grams per cubic centimetre and its specific gravity is 2.7 on the average.

With respect to mineralogical composition, loess contains 60 to 70 percent quartz with extremes of 40 and 80 percent. Feldspars and micas make up 10 to 20 percent and carbonates five to 35 percent. About two to five percent of the silt is composed of such heavy minerals as amphiboles, apatite, biotite, chlorite, disthene (cyanite), epidote, garnet, glauconite, pyroxenes, rutile, sillimanite, staurolite, tourmaline, and zircon. Grains are typically slightly weathered. In the finest grain-size fractions (below 0.002 millimetres), such clay minerals as montmorillonite, illite, and kaolinite predominate over the detrital (fragmental) constituents. Clay minerals may be formed by various colloidal and physicochemical processes during and after the accumulation of loess.

The mineralogical composition of loess is fairly uniform, but there are some local deviations due to differences in grain size and area of origin. The area of origin of the dust fraction is revealed by the heavy mineral assemblage and research has shown that the dust sources may be local, neighbouring, or distant.

The chemical composition of loess most often falls within the following percentage ranges: silica, SiO<sub>2</sub>, 50 to 60; alumina, Al<sub>2</sub>O<sub>3</sub>, eight to 12; iron oxide as Fe<sub>2</sub>O<sub>3</sub>, two to four; iron oxide as FeO, 0.8 to 1.1; titanium dioxide, TiO<sub>2</sub>, and manganese oxide, MnO, about 0.5; lime, CaO, four to 16; and magnesium oxide, MgO, two to six.

The characteristic carbonate content of loess depends on the nature of the dust source, on geochemical and biological processes that occur during and after deposition, and on precipitation and leaching by groundwater. Carbonates are present in loess in a variety of forms, primarily as

Grain-size distribution and mineralogy

#### Structure and strength of loess

incrustations on quartz grains and clay-particle aggregates and as small granules and shell fragments. Secondary concentrations include concretions of nodules (Loess-doll) and layers of lime accumulation (caliche). Lime forms frequent tubular incrustations along decayed plant roots, fissure fillings, and similar avenues.

Loess is a rather ill-consolidated sediment of low compressive strength ranging from 0.5 to 1.5 kilograms per square centimetre (7 to 21 pounds per square inch). It is stable, however, as long as it remains dry. Parting surfaces are vertical because capillary incrustations of lime, developed around the roots of a grassy plant cover, lend a vertical texture to loess. This is why the coefficient of permeability (a measure of ease of fluid penetration) is two to four times higher in the vertical than in the horizontal sense. This also is the cause of the cliff-forming ability of loess.

Soaked and loaded loess, however, is liable to collapse and slumping. Wetting decreases cohesion between grains by two-thirds, and the angle of internal friction also decreases (*e.g.*, from 32 to 20°). Groundwater flow in loess will carry away fine, insoluble mineral particles and this mechanical separation in loess can be accompanied by solution of mineral particles. This process gives rise to depressions, sinkholes, loess wells, and collapse ravines and is much accelerated by gully erosion.

Loess is generally pale yellow or buff in colour, but brownish-yellow and grayish-yellow varieties also occur. Variations in colour largely depend on the finely dispersed limonite (iron oxide) content, which is higher in the hotter, semi-arid regions than in the cooler areas of loess formation. Loess that is richer in limonite tends to be a darker yellow with a pink tint.

**Distribution and classification.** The world's largest loess-covered areas lie between latitude 55° and 24° N: in China on the banks of the Huang Ho; on the margins of the continental deserts of Inner Asia; in Central Asia in Kazakhstan, Uzbekistan, in the foreland of the Tien Shan, and east of the Caspian Sea; in Siberia along Lake Baikal and the Lena River, and in vast regions in the southern parts of the catchment areas of the Ob and Yenisey rivers. In Europe there is an extensive, uninterrupted loess cover in the South Russian Plain, large spots and belts in the Danube Basin, along the Rhine, along the margin of the former inland ice cap in the German-Polish

and in the Paris Basin. In North America loess covers the plains of the Platte, Missouri, Mississippi, and Ohio rivers and the Columbia Plateau. In the Southern Hemisphere, between latitude 30° and 40° S, the most significant loess regions include the "pampas loesses" of Uruguay and Argentina and parts of New Zealand.

Loess blankets may cover a variety of relief forms; they occur most often in plains, on river valley slopes, flats, and rises, and on pediments in the forelands of mountains, and on alluvial fans. On mountain slopes and intermontane basins, loess occurs to a maximum elevation of 400 to 600 metres (1,300 to 2,000 feet) in Europe, 1,000 to 2,000 metres (3,300 to 6,600 feet) in Inner Asia, and up to 4,000 metres (13,000 feet) in China. Slope loesses tend to thicken downslope. The thickest loess blanket known occurs on mountain slopes in Shensi Province and the Canton area in China (up to 175 metres). The North China Plain is covered with 10 to 30 metres (30 to 100 feet) of redeposited loess and loam. In the southern zone of Asian loesses, the yellow loess is underlain by a thick complex of up to 100 metres (330 feet) of pink, so-called petrified loess. In the South Russian Plain, in the Danube Basin, and in Nebraska and Iowa loess attains thicknesses as great as 60 metres (200 feet). On floodplains, on alluvial fans, and on the margins of loess zones, however, typical thicknesses range from one to ten metres. Although adjacent loess and windblown sand covers often may represent the same deposit, they may also alternate in a vertical profile. In the marginal zone of the Pleistocene ice sheet, for example in Illinois, loess may overlie tills (glacial deposits) or may be interfingering with them.

The lithological classification of loess is based on physical and chemical properties, and the conditions of origin are partly or entirely neglected. In addition to typical loess, loessial deposits also are quite frequent in occurrence. The proportions of silt and other fractions and constituents (clay, sand, lime), as well as colour, porosity, strength, and plasticity of loessial deposits differ significantly from comparable properties of typical loess. This group of deposits includes sandy loess, loessial sand, loess loam, clayey loess, and loess that is altered pedogenically—*i.e.*, during soil-forming processes. Loess-like deposits, on the other hand, include sediments that resemble typical loess only in certain features (mineralogical composition, dominant dust fraction, colour, etc.). These de-

Lithological and environmental factors in classification

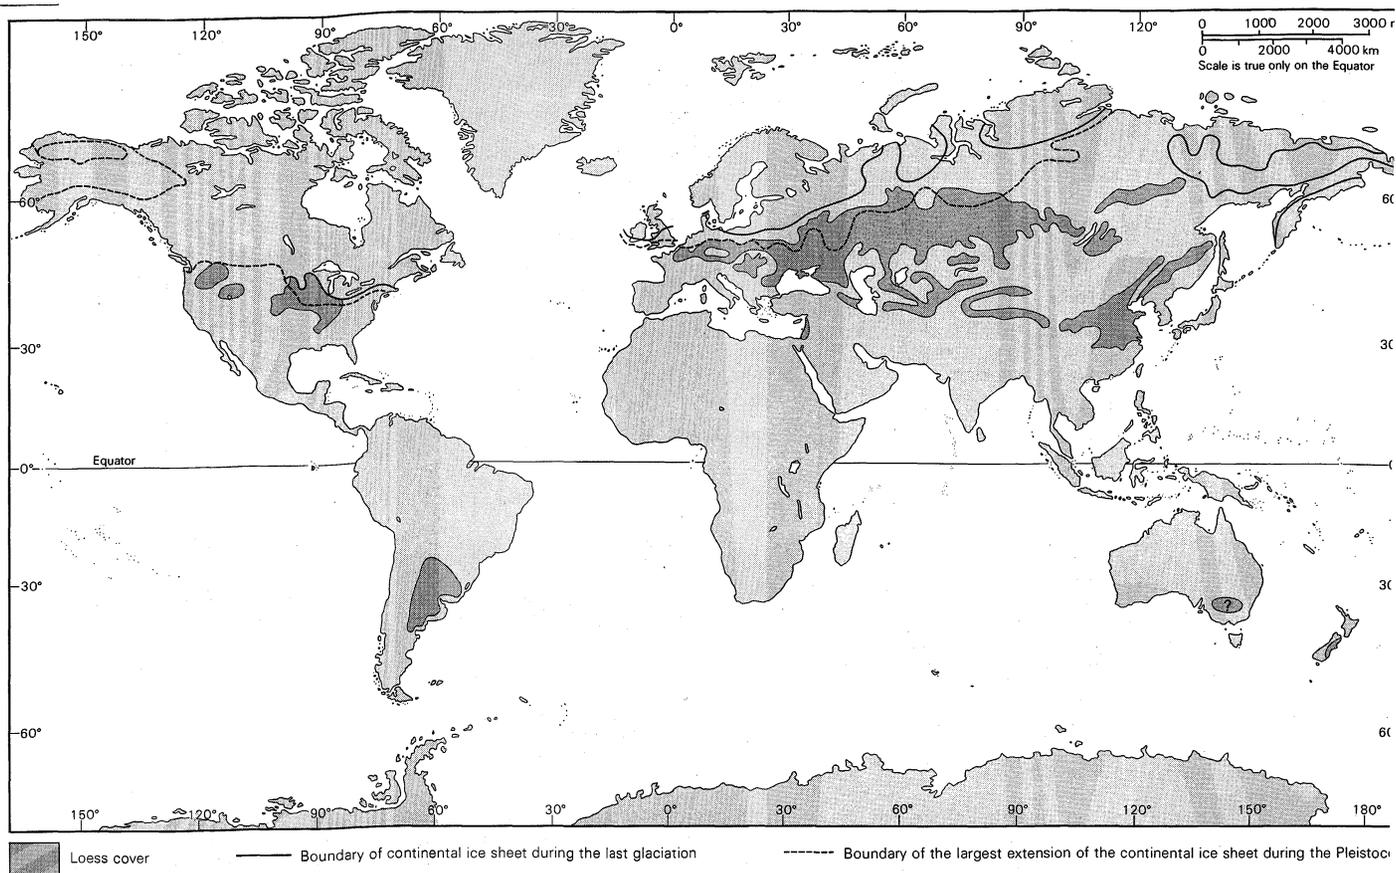

Figure 2: World distribution of loess and loess-like deposits.

posits also are terrestrial, occur within or on the margins of loess regions, and are most often mixed with other types of sediment. The group of loess-like deposits is not rigidly circumscribed; it usually is understood to include loess loam, loess mud, loess-containing rock debris, and stratified loess.

Genetic classifications of loess, in contrast to this lithological classification, are based on the origin of the silt and on the processes that have brought about its accumulation. This requires knowledge of the circumstances of loess formation, which involves many complications and, in all its ramifications, is termed the loess problem.

Environmental conditions in the areas of loess formation are revealed by bones, animal burrows, snail shells, pollen, bits of charcoal, and in many instances by the implements and habitats of Paleolithic man. The more frequent mammalian remains include mammoth, bison, musk ox, lemming, marmot, Siberian mouse, polar fox, cave bear, deer, elk, and reindeer. These lived in the Arctic tundra in cold, wooded steppes. Snail assemblages in loess indicate a cyclic alternation of species, reflecting both cold and humid climates and cold and dry climates; extremely dry conditions also may be indicated for restricted areas. The snails present in the loamy paleosols (ancient soils) that are intercalated between loess packets usually are indicative of a warmer climate. The cyclic alternation of forest and steppe snails shows that the climatic conditions during loess formation could not be exclusively cold and dry; such is the evidence of contained animal remains.

Pollen analysis reveals only the broad outlines of ancient plant ecology but pollen assemblages also indicate that cool grasslands, steppes, wooded steppes, and wooded tundras and tundras were among the preferred environments of loess deposition. These climatic zones lay south of the margins of the extensive Pleistocene ice sheets, significantly displaced from their normal (non-Ice Age) position, together with the zone of westerly winds. The dominant westerly winds were influenced and deflected by the high-pressure anticyclonic system that developed over the ice sheet and by high mountain chains.

The semi-arid zones on the margins of such continental deserts as those in Inner and Central Asia, however, were more humid during the period of Pleistocene loess formation than they are today. This is also indicated by the pollen spectra of Central Asian loesses.

**Origin and age.** For over a century a number of partly conflicting and partly complementary hypotheses have been put forward to explain the origin of the silt fraction of loess. The mineral constituents of loess, quartz and feldspar, for example, are reduced to minute particles by weathering (*q.v.*) action, principally in semi-arid and arid regions. But the source of dust may also be a silty, sandy unconsolidated sediment of Tertiary Age (from 65,000,000 to 2,500,000 years ago), as for instance, the Ogallala Group of the United States. The sand and silt may have been size sorted by the wind, which then transported and deposited the silt. Dust storms derived from such rock units are frequent even today in the continental deserts of Asia; the silt content of "continental loesses" is derived in this manner.

Another significant source of dust may have been the marginal zone of the Pleistocene ice sheet over Europe and North America. During the several ice advances, or glaciations, huge amounts of glacial till, rich in silt, could accumulate in the zone. The silt fraction, accumulating in the outwash plains, could then be carried away by the westerly winds and deposited on the lee side of some relief feature; this is sometimes called the theory of glacial loess.

Silt may also be removed from its site of origin of first deposition and be sorted by fluvial processes. Abundant silt is borne by rivers and deposited in times of flood in basins and on alluvial fans that border mountain regions. Some of the silt is then removed from broad floodplains by winds; this results in a double sorting, once by water and once by wind, and hence a more sharply defined typical grain size. In this case loess accumulation is not necessarily connected with a glaciation; indeed, most of the alluvial loesses do not date back to a glaciation.

The arguments made in support of wind transport as the origin of loess constitute the eolian theory and include

Origin of silt: the eolian and fluvial theories

the following points: (1) loess forms a blanket over a variety of relief forms; (2) the mean grain size of silt varies inversely with the distance from the dust source, and so does the thickness of loess; (3) the zones of loess and windblown sand are so arranged that they bear an obvious relation to the prevailing wind; (4) the mineralogical composition of loess is independent of the underlying rock formations; and (5) in some places there are interbedded layers of volcanic ash (a wind-derived deposit) between packets of loess.

The arguments supporting the fluvial theory, that the silt fraction of loess is transported and deposited by water, include these points: (1) detailed studies of mineral content in loess and in neighbouring rock formations have proved that the loess deposits covering vast areas of floodplains and alluvial fans are of flood-laid, alluvial origin; (2) rivers carry a great deal of suspended sediment in the silt-size range, particularly in semi-arid steppe and wooded steppe regions; (3) in stratified loessial or loess-like deposits, there are local significant enrichments of clay or sand; and (4) even existing divide areas could acquire fluvial silt deposits under appropriate circumstances of river damming.

Still another theory is invoked for loess deposits that occur on hillslopes because it would seem likely that the downhill movement of earth materials is involved. Loess and loess-like deposits on hillslopes often exhibit a rhythmic stratification parallel to the slope and the strata often alternate with rock debris and thin beds of reworked soils. The lithological character and field relations of such sediments indicate deposition from sheetwash or flash floods, but redeposition could occur because of soil movements over permafrost, downslope creep, or from similar processes.

The reason for conflicting opinions on loess formation is that the silt fraction may have been deposited or reworked by any of the various processes; and, depending on environment and other circumstances, the dominant process may change through time.

Processes  
in loess  
formation

There is a consensus that the accumulated dust fraction must have undergone diagenesis (physical and chemical changes after deposition) in order to turn into loess. Diagenesis includes the weathering of fine grains of lime, aluminum silicates, and other substances by hydration in arid climates. In near-surface silt the finest clay particles are cemented by migrating solutions of calcium carbonate and iron oxides and colloidal iron compounds; the quartz grains acquire crusts or coatings of lime or iron and adjacent grains are cemented together. As a result of these processes, some of the finer particles also attain loess fraction size of 0.01 to 0.05 millimetre. It has been proved that a grain size of about 0.05 millimetre is the most favourable for thriving grassy vegetation. Essentially, diagenesis turns sediment deposited in the form of dust into a loosely cemented siltstone.

The peculiar features of loess are thus developed during a process of loess genesis that is akin to that of soil formation. This circumstance served as a basis for the pedogenic (soil origin) theory of loess formation, which basically held that loess is a product of weathering and pedogenesis under semi-arid conditions in grasslands and wooded steppes. It would be difficult to explain the formation of a thick loess blanket subdivided by several horizons of paleosols in this way, however. More reasonable would be a polygenetic origin, in which dust can accumulate as the result of any process alternating in time and space, with loess formation resulting from pedogenic processes acting under favourable climatic conditions.

These pedogenic processes may take place in three different ways. Epigenesis is an accumulation of a mineral mass without loess properties, perhaps with a high silt and lime content, which under weathering and soil formation acquires loess properties and is transformed into loess. In syngeneses, the accumulation of a mineral mass that is mainly of eolian origin and the acquisition of all loess properties occurs simultaneously, under the influence of soil formation. In protogeneses the accumulated mineral matter already has all the main loess proper-

Loess complex on the right bank of the Danube River in the Great Hungarian Plain, showing the vertical fracturing that is typical in loess deposits.

ties because transport occurred after weathering and soil formation.

The optimum conditions of loess formation are thought to have existed along the border of the continental ice sheet, including the cold steppes, wooded steppes, loess tundras, and in the steppes bordering the continental deserts. Under conditions other than optimum, the accumulated dust would likely turn into a loess-like deposit differing from typical loess, namely loess loam, limeless loess, brown earth, or reddish loam, or, alternatively, into a soil.

The formation of loess packets is correlated with the cold, dry climatic phases of the Pleistocene glaciations in regions marginal to the ice. The climatic phases, and the occasions of loess formation, recurred three to five times as within the last glaciation. The sediment of a single loess packet can be subdivided; in the lower and upper third of each packet, finely stratified loesses tend to predominate, whereas the central third is composed largely of typical loess that is not stratified.

Loess  
chronol-  
ogy

Within the loess series, the various paleosols, clay-rich sands, and water-laid sands, hiatuses (interruptions of the sedimentary record) due to erosion in Europe and North America usually represent warmer Pleistocene climatic stages—interglacial time intervals—or the more humid episodes of such climatic changes. The hiatuses in the accumulation of loess material in China and in Middle Asia are correlative with moist episodes. A more detailed subdivision must be restricted to the upper part of the loess series because in the lower portions the original texture of the loess layers underwent significant alteration.

A loess chronology can be based upon subdivision of the loess series, relating individual loess packets to geological formations or landforms such as river terraces, glacial moraines, etc., as well as to the paleontological and archaeological finds in the loess proper. Some of the younger loesses have been dated by the radiocarbon method. The loess chronology established in this way has revealed that upper Pleistocene “young loesses” are the most widespread in Eurasia and North America. These are subdivided by two to four paleosol horizons into three to five loess packets. The unconsolidated “young loess” developed in a full profile usually overlies a well-developed forest soil or a wooded-steppe-type soil complex of the last interglacial episode.

Loess tended to decay rather rapidly during periods of more abundant precipitation—e.g., during the interglacials. Consequently, the “older loesses” formed during the middle and lower Pleistocene, subdivided by closely spaced paleosols and lime concretion Loess-doll horizons, were preserved largely in the areas that are driest

today: Columbia Plateau, Danube Basin, South Russian Plain, Central Asia and parts of China, and elsewhere. Although these older loess series tend to be incomplete, they may represent almost complete Pleistocene sequences in restricted areas. The deeper, older levels of the exposures usually consist of pink silt deposits alternating with red-earth paleosols.

**BIBLIOGRAPHY.** There are few if any books devoted entirely to loess. One of the best short summaries of the world distribution and inferred climatic significance of loess deposits is contained in R.F. FLINT, *Glacial and Quaternary Geology* (1971). Details of some deposits in eastern Europe, together with many references to the specialized literature, are given in M. PECSI, *Ten Years of Physico Geographic Research in Hungary* (Eng. trans., 1964); and by E. LITEANU, "Contributions to the Study of Loess-Like Deposits in the Wallach Depression, Rumania," *Spec. Pap. Geol. Soc. Am.*, no. 84 (1965). Also of interest is A.L. LUGN, *The Origin and Sources of Loess* (1962).

(Ma.P.)

## Logic, Applied

The general discipline of logic embraces the principles by which concepts and propositions are related to one another and, consequently, the techniques of thought by which these relationships can be explored and valid inferences made about them. This discipline can be divided into pure and applied logic, a distinction that parallels that between pure and applied mathematics: pure logic develops a body of strictly abstract machinery—e.g., the syllogism—that displays only the skeletal form of the argument without regard to its content (example: "No  $s$  is  $m$ ; some  $p$  are  $m$ ; therefore, some  $p$  are not  $s$ ."); in applied logic one adapts this machinery for deployment over concrete issues of a certain range of special subject matter—such as beliefs, commands, or duties. Such arguments often are not governed only by strictly formal issues (which alone are relevant in pure logic); they involve also certain subject-matter considerations of a particular area, generally called the material aspects. Applied logic, to be sure, has its formal aspects, as well, and so cannot be equated with material logic as such; nor can it be equated with practical logic (analysis of statements of the form "I choose . . ."; "I prefer . . ."; "I do . . ."), which is only one of its branches.

Range of applications

The applications envisaged in applied logic cover a vast range, relating to reasoning in the sciences and in philosophy, as well as in everyday discourse. They include: (1) the various sorts of reasoning affecting the conduct of ordinary discourse as well as the theory of the logical relations that exist within special realms of discourse—between two commands, for example, or between one question and another; (2) special forms of logic designed for scientific applications, such as temporal logic (of what "was" or "will be" the case), or mereology (the logic of parts and wholes); and (3) special forms for concepts bearing upon philosophical issues, such as logics that deal with statements of the form "I know that . . ."; "I believe that . . ."; "It is permitted to . . ."; "It is obligatory to . . ."; or "It is prohibited to . . ."

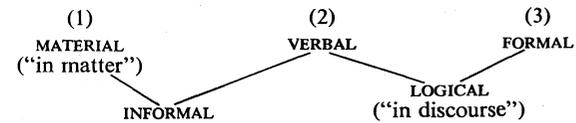

### The critique of forms of reasoning

#### CORRECT AND DEFECTIVE ARGUMENT FORMS

An argument (in logic) is a body of discourse that presents evidence—or purported evidence—in support of some thesis. Correspondingly, an argument has two components: a conclusion, the thesis argued for; and certain premises, the considerations adduced on behalf of the conclusion. (The conclusion is said to be drawn, or inferred, from the premises.) An argument is deductively valid when its premises provide conclusive evidence for the conclusion—i.e., if the conclusion must be true whenever the premises are true. An argument that fails to be conclusively deduced is invalid; it is also said to be fallacious (unless reclassified as a nondeductive argument and reinstated by appeal to material or substantive considerations beyond its merely formal aspects).

An argument may be fallacious in three ways: in its material content, through a misstatement of the facts; in its wording, through an incorrect use of terms; or in its

structure (or form), through the use of an improper process of inference. As shown in the diagram below, fallacies are correspondingly classified as (1) material, (2) verbal, and (3) formal. Groups (2) and (3) are called logical fallacies, or fallacies "in discourse," in contrast to the substantive, or material, fallacies of group (1), called fallacies "in matter"; and groups (1) and (2) are called informal fallacies, in contrast to group (3).

#### KINDS OF FALLACIES

**Material fallacies.** The material fallacies are also known as fallacies of presumption, because the premises "presume" too much—they either covertly assume the conclusion or avoid the issue in view.

The classification that is still widely used is that of Aristotle's *Sophistical Refutations*: (1) The fallacy of accident is committed by an argument that applies a general rule to a particular case in which some special circumstance ("accident") makes the rule inapplicable. The truth that "men are capable of seeing" is no basis for the conclusion that "blind men are capable of seeing." This is a special case of the fallacy of *secundum quid* (more fully: *a dicto simpliciter ad dictum secundum quid*, which means "from a saying [taken too] simply to a saying according to what [it really is]"; i.e., according to its truth as holding only under special provisos). This fallacy is committed when a general proposition is used as the premise for an argument without attention to the (tacit) restrictions and qualifications that govern it and invalidate its application in the manner at issue. (2) The converse fallacy of accident argues improperly from a special case to a general rule. The fact that a certain drug is beneficial to some sick persons does not imply that it is beneficial to all men. (3) Thus, the fallacy of irrelevant conclusion is committed when the conclusion changes the point that is at issue in the premises. Special cases of irrelevant conclusion are presented by the so-called fallacies of relevance. These include: (a) the argument *ad hominem* (speaking "against the man" rather than to the issue), in which the premises may only make a personal attack on a person who holds some thesis, instead of offering grounds showing why what he says is false; (b) the argument *ad populum* (an appeal "to the people"), which, instead of offering logical reasons, appeals to such popular attitudes as the dislike of injustice; (c) the argument *ad misericordiam* (an appeal "to pity"), as when a trial lawyer, rather than arguing for his client's innocence, tries to move the jury to sympathy for him; (d) the argument *ad verecundiam* (an appeal "to awe"), which seeks to secure acceptance of the conclusion on the grounds of its endorsement by persons whose views are held in general respect; (e) the argument *ad ignorantiam* (an appeal "to ignorance"), which argues that something (e.g., extrasensory perception) is so since no one has shown that it is not so; and (f) the argument *ad baculum* (an appeal "to force"), which rests on a threatened or implied use of force to induce acceptance of its conclusion. (4) The fallacy of circular argument, known as *petitio principii* ("begging the question"), occurs when the premises presume, openly or covertly, the very conclusion that is to be demonstrated (example: "Gregory always votes wisely." "But how do you know?" "Because he always votes Libertarian."). A special form of this fallacy, called a vicious circle, or *circulus in probando* ("arguing in a circle"), occurs in a course of reasoning typified by the complex argument in which a premise  $p_1$  is used to prove  $p_2$ ;  $p_2$  is used to prove  $p_3$ ; and so on, until  $p_{n-1}$  is used to prove  $p_n$ ; then  $p_n$  is subsequently used in a proof of  $p_1$ , and the whole series  $p_1, p_2, \dots, p_n$  is taken as established. (Example: "McKinley College's baseball team is the best in the Association [ $p_n = p_1$ ]; they are the best because of their strong batting potential [ $p_2$ ]; they have this potential because of the ability

Accident,  
converse  
accident,  
irrelevant  
conclusion

Circular  
argument

## Other material fallacies

of Jones, Crawford, and Randolph at the bat [ $p_1$ ].” “But how do you know that Jones, Crawford, and Randolph are such good batters?” “Well, after all, these men are the backbone of the best team in the Association [ $p_2$  again].”) Strictly speaking, *petitio principii* is not a fallacy of reasoning but an ineptitude in argumentation: thus the argument from  $p$  as a premise to  $p$  as conclusion is not deductively invalid but lacks any power of conviction, since no one who questioned the conclusion could concede the premise. (5) The fallacy of false cause (*non causa pro causa*) mislocates the cause of one phenomenon in another that is only seemingly related. The most common version of this fallacy, called *post hoc ergo propter hoc* (“after which hence by which”), mistakes temporal sequence for causal connection—as when a misfortune is attributed to a “malign event,” like the dropping of a mirror. Another, more sophisticated, and purely logical version of this fallacy occurs, however, in a complex form of the *reductio ad absurdum*—an argument that, in its simple form, declares that an assumption is false if a contradiction can be drawn from it. In the present case, a contradiction drawn jointly from several premises—say,  $p_1$ ,  $p_2$ ,  $p_3$ , and  $p_4$ —is taken to establish the falsity of one of them—say,  $p_2$ —when another—say,  $p_3$ —is really the source of the difficulty. Thus, the premises  $p_1$  through  $p_4$  may be those, for example, of the following two syllogisms:

$p_1$ : “All statesmen are political figures who act in the public interest.”

$p_2$ : “Jones is a statesman.”

$C_1$ : Therefore, “Jones is a political figure who is acting in the public interest.”

and

$p_3$ : “Anyone who shamelessly campaigns for re-election is not acting in the public interest.”

$p_4$ : “Jones is shamelessly campaigning for re-election.”

$C_2$ : Therefore, “Jones is not acting in the public interest.”

But conclusions  $C_1$  and  $C_2$  are contradictory. A critic might therefore argue that  $p_2$  is false and that Jones is not a statesman. But he could be wrong, for the trouble could lie in  $p_3$ : far from acting at variance with the public interest, a man might campaign in the belief that he cannot accomplish his legislative program, which he believes to be in the public interest, unless he wins another term in office. His campaigning may, thus, be in the public interest; and he may be a statesman after all. (6) The fallacy of many questions (*plurimum interrogationum*) consists in demanding or giving a single answer to a question when this answer could either be divided (example: “Do you like the twins?” “Neither yes nor no; but Ann yes and Mary no.”) or refused altogether, because a mistaken presupposition is involved (example: “Have you stopped beating your wife?”). (7) The fallacy of *non sequitur* (“it does not follow”), still more drastic than the preceding, occurs when there is not even a deceptively plausible appearance of valid reasoning, because there is a virtually complete lack of connection between the given premises and the conclusion drawn from them. Some authors, however, identify *non sequitur* with the fallacy of the consequent (see below *Formal fallacies*).

**Verbal fallacies.** These fallacies, called fallacies of ambiguity, arise when the conclusion is achieved through an improper use of words.

## Equivocation, amphiboly, and others

The principal instances are as follows: (1) Equivocation occurs when a word or phrase is used in one sense in one premise and another sense in some other needed premise or in the conclusion (example: “The loss made Jones mad [= angry]; mad [= insane] people should be institutionalized; so Jones should be institutionalized.”). The figure-of-speech fallacy is the special case arising from confusion between the ordinary sense of a word and its metaphorical, figurative, or technical employment (example: “For the past week Joan has been living on the heights of ecstasy.” “And what is her address there?”). (2) Amphiboly occurs when the grammar of a statement is such that several distinct meanings can obtain (example: “The king hopes you the enemy will slay. So he wishes you well.”). (3) Accent is a counterpart of amphiboly arising when a statement can bear distinct meanings

depending upon which word is stressed (example: “Men are *considered* equal.” “Men are considered *equal*.”). (4) Composition occurs when the premise that the parts of a whole are of a certain nature is improperly used to infer that the whole itself must also be of this nature (example: a story made up of good paragraphs is thus said to be a good story). (5) Division—the reverse of composition—occurs when the premise that a collective whole has a certain nature is improperly used to infer that a part of this whole must also be of this nature (example: in a speech that is long winded it is presumed that every sentence is long). But this fallacy and its predecessor can be viewed as versions of *equivocation*, in which the distributive use of a term—*i.e.*, its application to the elements of an aggregate (example: “the crowd,” viewed as individuals)—is equivocally confused with its collective use (“the crowd,” as a unitary whole)—compare “The crowd were filing through the turnstile” with “The crowd was compressed into the space of a city block.”

**Formal fallacies.** Strictly logical, or formal, fallacies arise not from the specific matter of the argument but from a structural pattern of reasoning that is generically incorrect.

A classic case is Aristotle’s fallacy of the consequent, relating to reasoning from premises of the form: “If  $p_1$ , then  $p_2$ .” The fallacy has two forms: (1) denial of the antecedent, in which one mistakenly argues from the premises “If  $p_1$ , then  $p_2$ ” and “not- $p_1$ ” (symbolized  $\sim p_1$ ), to the conclusion “not- $p_2$ ” (example: “If George is a man of good faith, he can be entrusted with this office; but George is not a man of good faith; therefore, George cannot be entrusted with this office”); and (2) affirmation of the consequent, in which one mistakenly argues from the premises “If  $p_1$ , then  $p_2$ ” and “ $p_2$ ,” to the conclusion “ $p_1$ ” (example: “If Amos was a prophet, then he had a social conscience; he had a social conscience; hence, Amos was a prophet”). Most of the traditionally considered formal fallacies, however, relate to the syllogism (see SYLLOGISTIC). One example may be cited, that of the fallacy of illicit major (or minor) premise, which violates the rules for “distribution.” (A term is said to be distributed when reference is made to all members of the class. Example: in “Some crows are not friendly,” reference is made to all friendly things, but not to all crows.) The fallacy arises when a major (or minor) term that is undistributed in the premise is distributed in the conclusion (example: “All tubers are high-starch foods [undistributed]; no squashes are tubers; therefore, no squashes are high-starch foods [distributed]”).

**Epistemic logic**

Epistemic logic deals with the logical issues arising within the gamut of such epistemological concepts as knowledge, belief, assertion, doubt, question-and-answer, or the like. Instead of dealing with the essentially factual issues of alethic logic (Greek *alētheia*, “truth”)—*i.e.*, with what is actually or must necessarily or can possibly be the case—it relates to what people know or believe or maintain or doubt to be the case.

**THE LOGIC OF BELIEF**

From the logical standpoint, a belief is generally analyzed as a relationship obtaining between the person who accepts some thesis on the one hand, and the thesis that he accepts, on the other. Correspondingly, given a person  $x$ , it is convenient to consider the set  $B_x$  of  $x$ ’s beliefs and represent the statement “ $x$  believes that  $p$ ” as  $p \in B_x$ . (The symbol  $\in$  represents membership in a set,  $\notin$  its denial.)

**Alternative ways of construing belief.** Before the formulation of any logical theory of belief can get under way, however, it is essential to specify the precise sense at issue when a person is said to believe something. It is necessary to choose between three alternative constructions of “ $x$  believes that  $p$ ”:

1. The disposition-to-explicit-assent construction, according to which “ $x$  believes that  $p$ ” obtains if he overtly professes to do so (and is candid) or would overtly so profess (if candid) once the matter is duly explained to him. That is,  $x$  is

simply asked if he believes  $p$ , and the matter is settled by his response, if there is no reason to suspect disingenuousness.

2. The commitment-to-assent construction, according to which "x believes that  $p$ " if he either (a) explicitly assents to  $p$  in the preceding manner or (b) is logically committed to giving assent, because  $p$  follows logically from propositions to which he does give assent.

3. The behavioristic construction, according to which "x believes that  $p$ " if  $x$  acts as though  $p$  were the case.

Short-comings of the three constructions

The behavioristic construction has serious shortcomings insofar as it strays from the ordinary, presystematic concept at issue in ordinary discourse about beliefs. Fiji Islanders may well act as though Julius Caesar had never existed but cannot be said to have beliefs in the matter. The other two approaches also have shortcomings. The commitment-to-assent construction gives rise, for example, to the entailment principle (EP): "If  $p$  is one of the beliefs held by  $x$ , and if  $q$  follows deductively from  $p$ , then  $q$  is one of the beliefs held by  $x$ "; or, symbolically:

$$(EP) \quad \text{If } p \in \mathbf{B}_x \text{ and } p \vdash q, \text{ then } q \in \mathbf{B}_x,$$

in which the symbol  $\vdash$  signifies that the proposition on the right side follows as a deductively valid consequence from those on the left. Example: "That there are more people in Kōbe than the number of hairs that any human head can hold ( $p$ )" is a member of ( $\in$ ) the set of Joe's beliefs ( $\mathbf{B}_{Joe}$ ). It can be deduced from  $p$ , however, that "there are at least two people in Kōbe having the same number of hairs in their head ( $q$ )." The conclusion can be seen by supposing that one person is found (so far as possible) for each number of hairs, from a man with one hair to one with the maximum possible number. If these people are then seated in an amphitheatre in order by their number of hairs, there will still be people left unseated—each a contender for a seat already filled. Hence, Joe believes  $q$ , that "there are at least two people in Kōbe (viz., those pairs contending for seats) having the same number of hairs in their head," whether he realizes it or not. But while a person is certainly committed to accepting the consequences of his beliefs, it is implausible to say that he believes them; very possibly Joe may disavow that there are two such people in Kōbe. It is only in some strange and artificial sense of the term that one's belief in certain axioms can be held to entail belief in some extremely remote consequence thereof.

On the other hand, with the preparedness-for-explicit-assent construction, it seems impossible to build up any sort of logic whatsoever. On this construction, it may well be that:

1. " $p$  is among the beliefs of  $x$  and not- $p$  is among the beliefs of  $x$ "; i.e.,  $p \in \mathbf{B}_x$  and  $\sim p \in \mathbf{B}_x$  (example: "x believes that he can jump the chasm"; "x believes that he cannot jump the chasm"); or that

2. A man may assent to (believe in) each of two statements,  $p$  and  $q$ , taken separately—i.e., both  $p \in \mathbf{B}_x$  and  $q \in \mathbf{B}_x$ —but fail to assent to their conjunction—( $p \cdot q$ )  $\notin \mathbf{B}_x$  in which the centred dot means "and." For example, someone might assent to each of the statements "God is benevolent" and "There is evil in the world" but fail to assent to (or, perhaps, even deny) their conjunction; i.e., "God is benevolent but there is evil in the world."

Clearly, one may fail to develop a logic of belief when the beliefs at issue turn out to be highly illogical—as well they may.

**Theory of belief.** To articulate a viable logic of belief, it is, at the very least, essential to postulate certain minimal conditions of rationality regarding the parties whose beliefs are at issue:

1. Consistency: "If  $x$  believes that  $p$ , then  $x$  does not believe that not- $p$ "; i.e.,

$$\text{If } p \in \mathbf{B}_x, \text{ then } \sim p \notin \mathbf{B}_x.$$

"If not- $p$ , then  $x$  does not believe that  $p$ "; i.e.,

$$\text{If } \sim p, \text{ then } p \notin \mathbf{B}_x.$$

Example: If "Jesus was a Zealot" ( $p$ ) is among ( $\in$ ) the beliefs of Ralph ( $\mathbf{B}_{Ralph}$ ), then "Jesus was not a Zealot" ( $\sim p$ ) is not among ( $\notin$ ) Ralph's beliefs. It is an accepted thesis ( $\vdash$ ) that "Jesus was not a Zealot." Hence, "Jesus was a Zealot" is not among Ralph's beliefs. (Note that the symbol  $\vdash$ , in cases where it appears as an isolated prefix, represents

"thesis-hood"; i.e., a deductive consequence—as it were—from no premises.)

2. Conjunctive composition and division: "If  $x$  believes that  $p_1$ , and  $x$  believes that  $p_2$ , etc., to  $x$  believes that  $p_n$ , then  $x$  believes that  $p_1$  and  $p_2$ , etc., and  $p_n$ "; i.e.,

$$\text{If } (p_1 \in \mathbf{B}_x, p_2 \in \mathbf{B}_x, \dots, p_n) \in \mathbf{B}_x, \\ \text{then } (p_1 \cdot p_2 \cdot \dots \cdot p_n) \in \mathbf{B}_x,$$

and conversely. Example: If "cats are affectionate" ( $p_1$ ), "cats are clean" ( $p_2$ ), etc., to "cats are furry" ( $p_n$ ) are among ( $\in$ ) Bob's beliefs ( $\mathbf{B}_{Bob}$ ), then "cats are affectionate and clean, etc., and furry" ( $p_1 \cdot p_2 \cdot \dots \cdot p_n$ ) is also a belief of Bob's.

3. Minimal inferential capacity: "If  $x$  believes that  $p$ , and  $q$  is an obvious consequence of  $p$ , then  $x$  believes that  $q$ "; i.e.,

$$\text{If } p \in \mathbf{B}_x \text{ and } p \models q, \text{ then } q \in \mathbf{B}_x.$$

Example: "If  $x$  believes that his cat is on the mat, and his cat's being on the mat has an obvious consequence that *something* is on the mat."

Here item 3 is a form of the entailment principle, but with  $\models$  representing entailment of the simplest sort, designating obvious consequence—say, deducibility by fewer than two (or  $n$ ) inferential steps, employing only those primitive rules of inference that have been classified as obvious. (In arguments about beliefs, however, all repetitions of the application of this version of the entailment principle must be avoided.) These principles endow the theory with such rules as:

1. "If  $x$  believes that not- $p$ , then he does not believe that  $p$ "; i.e.,

$$\text{If } \sim p \in \mathbf{B}_x, \text{ then } p \notin \mathbf{B}_x.$$

2. "If  $x$  believes that  $p$ , and  $x$  believes that  $q$ , then  $x$  believes that both  $p$  and  $q$  taken together"; i.e.,

$$\text{If } p \in \mathbf{B}_x \text{ and } q \in \mathbf{B}_x, \text{ then } p \cdot q \in \mathbf{B}_x.$$

3. "If  $x$  believes that  $p$ , then  $x$  believes that either  $p$  or  $q$ "; i.e.,

$$\text{If } p \in \mathbf{B}_x, \text{ then } p \vee q \in \mathbf{B}_x,$$

given " $p \vdash p \vee q$ " as an "obvious" rule of inference (where  $\vee$  means "either—or").

One key question of the logical theory of belief relates to the area of iterative beliefs (example: "Andrews believes that I believe that he believes me to be untrustworthy"). Clearly, one would not want to have such theses as:

1. "If  $y$  believes that  $x$  believes that  $p$ , then  $x$  believes that  $p$ "; i.e.,

$$\text{If } (p \in \mathbf{B}_x) \in \mathbf{B}_y, \text{ then } p \in \mathbf{B}_x \quad (y \neq x)$$

nor

2. "If  $y$  believes that  $x$  believes that  $p$ , then  $y$  believes that  $p$ "; i.e.,

$$\text{If } (p \in \mathbf{B}_x) \in \mathbf{B}_y, \text{ then } p \in \mathbf{B}_y \quad (y \neq x).$$

But when the iteration is subject-uniform rather than subject-diverse, it might be advantageous to postulate certain special theses, such as:

$$\text{If } p \in \mathbf{B}_x, \text{ then } (p \in \mathbf{B}_x) \in \mathbf{B}_x,$$

which in effect limits the beliefs at issue to conscious beliefs. The plausibility of this thesis also implicates its converse; viz., whether there are circumstances under which someone's believing that he believes something would necessarily vouch for his believing of it—i.e., whether it is legitimate to argue that "If  $x$  believes that he believes that  $p$ , then he believes that  $p$ "; i.e.,

$$\text{If } (p \in \mathbf{B}_x) \in \mathbf{B}_x, \text{ then } p \in \mathbf{B}_x.$$

According to this thesis, the belief set  $\mathbf{B}_x$  is to have the feature of second-order—as opposed to direct—applicability. From  $q \in \mathbf{B}_x$  it is not, in general, permissible to infer  $q$ , but one is entitled to do so when  $q$  takes the special form  $p \in \mathbf{B}_x$ ; i.e., when the belief at issue is one about the subject's own beliefs.

A theory of belief along these lines is a halfway house between the commitment-to-assent conception of belief, which is too inclusive and the explicit-assent approach, which is too restrictive. The theory is predicated on the

Conditions of rationality

Iterative beliefs

view that belief is subject to logical compulsion but that the range of this compulsion is limited since men are not logically omniscient. Belief here is like sight: man has a limited range of logical vision; he can see clearly in the immediate logical neighbourhood of his beliefs but only dimly afar.

**THE LOGIC OF KNOWING**

The propositional sense of knowing (*i.e.*, knowing that something or other is the case), rather than the operational sense of knowing (*i.e.*, knowing how something or other is done), is generally taken as the starting point for a logical theory of knowing. Accordingly, the logician may begin with a person  $x$  and consider a set of propositions  $K_x$  to represent his "body of knowledge." The aim of the theory then is to clarify and to characterize the relationship " $x$  knows that  $p$ " or " $p$  is among the items known to  $x$ ," which is here represented as:  $p \in K_x$ .

"Knowing as" and "being" true

There can be false knowledge only in the sense that "he thought he knew that  $p$ , but he was mistaken." When the falsity of purported knowledge becomes manifest, the claim to knowledge must be withdrawn. "I know that  $p$ , but it may be false that  $p$ " is a contradiction in terms. When something is asserted or admitted as known, it follows that this must be claimed to be true. But what sort of inferential step is at issue in the thesis that " $x$  knows  $p$ " leads to " $p$  is true"? Is the link deductive, inductive, presuppositional, or somehow "pragmatic"? Each view has its supporters: on the deductive approach,  $p \in K_x$  logically implies (deductively entails)  $p$ ; on the inductive approach,  $p \in K_x$  renders  $p$  extremely probable, though not necessarily certain; on the presuppositional approach,  $p \in K_x$  is improper (nonsensical) whenever  $p$  is not true; and on the pragmatic approach, the assertion of  $p \in K_x$  carries with it a rational commitment to the assertion of  $p$  (in a manner, however, that does not amount to deductive entailment). From the standpoint of a logic of knowing, the most usual practice is to assume the deductive approach and to lay it down as a rule that if  $p \in K_x$ , then  $p$  is true. This approach construes knowledge in a very strong sense.

According to a common formula, knowledge is "true, justified belief." This formulation, however, seems defective. Let the expression  $Jxp$  be defined as meaning " $x$  has justification for accepting  $p$ ," then:

$$p \in K_x = p \cdot Jxp \cdot p \in B_x.$$

Example: The proposition " $J_{Jane} p$  (the gown is priceless ( $p$ ))" means ( $=$ ) "The gown is priceless, and Jane has justification for accepting that it is priceless ( $J_{Jane} p$ ) and Jane believes that it is priceless ( $p \in B_{Jane}$ )." One cannot but assume that the conceptual nature of  $J$  is such as to underwrite the rule: "If  $x$  is justified in accepting  $p$ , then he is justified in accepting 'Either  $p$  or  $q$ '"; *i.e.*,

$$(J) \quad \text{If } Jxp, \text{ then } Jx(p \vee q),$$

in which  $q$  can be any other proposition whatsoever. The components  $p$ ,  $q$ , and  $x$  may be such that all of the following obtain:

1. not- $p$
2.  $q$
3.  $x$  believes that  $p$ ; *i.e.*,  $p \in B_x$
4.  $x$  does not believe that  $q$ ; *i.e.*,  $q \notin B_x$  and, indeed,  $x$  believes that not- $q$ ; *i.e.*,  $\sim q \in B_x$
5.  $x$  is justified in accepting  $q$ ; *i.e.*,  $Jxq$
6.  $x$  believes that either  $p$  or  $q$ ; *i.e.*,  $p \vee q \in B_x$ .

Clearly, on any reasonable interpretation of  $B$  and  $J$ , this combination of six premises is possible. But the following consequences would then obtain:

7.  $p \vee q$  by item 2 above
8.  $Jx(p \vee q)$  by item 5 above and by  $J$
9.  $(p \vee q) \in K_x$  by items 6, 7, and 8.

However the conclusion 9 is wrong:  $x$  cannot properly be said to know that either  $p$  or  $q$  when  $p \vee q$  is true solely because of the truth of  $q$  (which  $x$  rejects), but  $p \vee q$  is believed by  $x$  solely because he accepts  $p$  (which is false). This example shows that the proposed definition of knowledge as "true, justified belief" cannot be made to

work; and the best plan, therefore, seems to be to treat the logic of knowing directly, rather than through the mediation of acceptance (belief) and justification.

Since Aristotle's day, stress has been placed on the distinction between actual, overt knowledge that requires an explicit, consciously occurring awareness of what is known and potential, tacit knowledge that requires only implicit dispositional awareness. Unless  $p \in K_x$  is construed in the tacit sense, the following principles will not hold:

- If  $p \in K_x$  and  $p \vdash q$ , then  $q \in K_x$ .
  - If  $p \in K_x$  and  $q \in K_x$ , then  $(p \cdot q) \in K_x$ .
- These two rules, if accepted, however, suffice to guarantee the principle:
- If  $p_1, p_2, \dots, p_n \vdash q$ , then  $p_1 \in K_x, p_2 \in K_x, \dots, p_n \in K_x \vdash q \in K_x$ .

Overt versus tacit knowledge

Similar considerations regarding the potential construction of knowledge govern the answer to the question of whether, when something is known, this fact itself is known: if  $p \in K_x$ , then  $(p \in K_x) \in K_x$ . This principle is eminently plausible, provided that the membership of  $K_x$  is construed in the implicit (tacit) rather than in the explicit (overt) sense.

**THE LOGIC OF QUESTIONS**

Whether a given grouping of words is functioning as a question may hinge upon intonation, accentuation, or even upon context, rather than upon overt form: at bottom, questions represent a functional rather than a purely grammatical category. The very concept of a question is correlative with that of an answer; and every question correspondingly delimits a range of possible answers. One way of classifying questions is in terms of the surface characteristics of this range. On this basis, the logician can distinguish (among others):

1. Yes/no questions (example: "Is today Tuesday?");
2. Item-specification questions (example: "What is an instance of a prime number?");
3. Instruction-seeking questions (example: "How does one bake an apple pie?"); etc.

From the logical standpoint, however, a more comprehensive policy and one leading to greater precision is to treat every answer as given in a complete proposition ("Today is not Tuesday"; "Three is an example of a prime number"; etc.). From this standpoint, questions can be classed in terms of the nature of the answers. There would then be factual questions (example: "What day is today?") and normative questions (example: "What ought to be done in these circumstances?").

Propositional approach

The advantage of the propositional approach to answers is that it captures the intrinsically close relationship between question and answer. The possible answers to (1) "What is the population of A-ville?" and (2) "What is the population of B-burgh?" are seemingly the same; namely, numbers of the series 0, 1, 2, . . . . But once complete propositions are taken to be at issue, then an answer to (1), such as "The population of A-ville is 5,238," no longer counts as an answer to (2), since the latter must mention B-burgh. This approach has the disadvantage, on the other hand, of obscuring similarities in similar questions. One can now no longer say of two brothers that the questions "Who is Tom's father?" and "Who is John's father?" have the same answer.

With every question  $Q$  can be correlated the set of propositions  $A(Q)$  of possible answers to  $Q$ . Thus, "What day of the week is today?" has seven conceivable answers, of the form "The day of the week today is Monday," and the like. A possible answer to a question must be a possibly true statement. Accordingly, the question "What is an example of a prime number?" does not have "The Washington Monument is an example of a prime number" among its possible answers.

A question can be said to be true if it has a true answer; *i.e.*, if  $(\exists p) [p \cdot p \in A(Q)]$ —which (taking the existential quantifier  $\exists$  to mean "there exists . . .") can be read "There exists a proposition  $p$  such that  $p$  is true and  $p$  is among the answers of  $Q$ "; otherwise it is false; *i.e.*, when all of its answers are false. If he never came at all, the question "On what day of the week did he come?"

Truth-values in question theory

is a false question in the sense that it lacks any true answer.

A true question can be called contingent if it admits of possible answers that are false, as in "Where did Jones put his pen?" In logic and mathematics there are, presumably, no contingent questions.

Questions can have presuppositions, as in "Why does Smith dislike Jones?" Any possible answer here must take the form "Smith dislikes Jones because . . ." and so commits one to the claim that "Smith dislikes Jones." Every such question with a false presupposition must be a false question: all of its possible answers (if any) are false.

Besides falsity, questions can exhibit an even more drastic sort of "impropriety." They can be illegitimate in that they have no possible answers whatsoever. (Example: "What is an example of an even prime number different from two?") The logic of questions is correspondingly three valued: a question can be true (*i.e.*, have a true answer); illegitimate (*i.e.*, have no possible answer at all); or false (*i.e.*, have possible answers but no true ones).

One question,  $Q_1$ , will entail another,  $Q_2$ , if every possible answer to the first deductively yields a possible answer to the second, and every true answer to the first deductively yields a true answer to the second. In this sense the question "What are the dimensions of that box?" entails the question "What is the height of that box?"

**Practical logic**

The theory of reasoning with concepts of practice—of analyzing the logical relations obtaining among statements about actions and their accompaniments in choosing, planning, commanding, permitting, etc.—comprises the domain of practical logic.

**THE LOGIC OF PREFERENCE**

The logic of preference—also called the logic of choice, or proairetic logic (Greek *proairesis*, "a choosing")—seeks to systematize the formal rules that govern the conception "x is preferred to y." A diversity of things can be at issue here: (1) Is x preferred to y by some individual (or group), or is x preferable to y in terms of some impersonal criterion? (2) Is on-balance preferability at issue or preferability in point of some particular factor (such as economy or safety or durability)? The resolution of these questions, though vital for interpretation, does not affect the formal structure of the preference relationships.

**Symbolization and approach taken in proairetic logic.** The fundamental tools of the logic of preference are as follows: (1) (strong) preference: x is preferable to y, symbolically  $x \gg y$ ; (2) indifference: x and y are indifferent,  $x \cong y$ , defined as "neither  $x \gg y$  nor  $y \gg x$ "; (3) weak preference: x is no less preferred than y,  $x \geq y$ , defined as "either  $x \gg y$  or  $x \cong y$ ." Since preference comprises a relationship, its three types can be classed in terms of certain distinctions commonly drawn in the logic of relations: that of reflexivity (whether holding of itself: "John supports himself"), of symmetry (whether holding when its terms are interchanged: "Peter is the cousin of Paul"; "Paul is the cousin of Peter"), and of transitivity (whether transferable: "a > b"; "b > c"; therefore, "a > c"). Once it is established that the (strong) preference relation ( $\gg$ ) is an ordering (*i.e.*, is irreflexive, asymmetric, and transitive), it then follows that weak preference ( $\geq$ ) is reflexive, nonsymmetric, and transitive and that indifference ( $\cong$ ) is an equivalence relation (*i.e.*, reflexive, symmetric, and transitive).

One common approach to establishing a preference relation is to begin with a "measure of merit" to evaluate the relative desirability of the items x, y, z, . . . , that are at issue. Thus for any item x, a real-number quantity is obtained, symbolized # (x). (Such a measure is called a utility measure, the units are called utiles, and the comparisons or computations involved comprise a preference calculus.) In terms of such a measure, a preference ordering is readily introduced by the definitions that: (1)  $x \gg y$  is to be construed as  $\#(x) > \#(y)$ ; (2)  $x \geq y$  as

$\#(x) \geq \#(y)$ ; and (3)  $x \cong y$  as  $\#(x) = \#(y)$ , in which  $\geq$  means "is greater than or equal to." Given these definitions, the relationships enumerated above must all obtain. Thus, the step from a utility measure to a preference ordering is simple.

**Construction of a logic of preference.** In constructing a logic of preference, it is assumed that the items at issue are propositions p, q, r, . . . and that the logician is to introduce a preferential ordering among them, with  $p \gg q$  to mean "p's being the case is preferred to q's being the case." The problem is to systematize the logical relationships among such statements in order to permit a determination of whether, for example, it is acceptable to argue that: If either p is preferable to q or p is preferable to r, then p is preferable to either q or r,

$$(p \gg q \vee p \gg r) \supset [p \gg (q \vee r)]$$

(in which  $\supset$  means "implies" or "if . . . then"), or to argue similarly that

$$(p \gg q \cdot r \gg q) \supset [(p \cdot r) \gg q].$$

Example: "If eating pears (p) is preferable to eating quinces (q) and eating rhubarb (r) is preferable to eating quinces, then eating both pears and rhubarb is preferable to eating quinces." The task is one of erecting a foundation for the systematization of the formal rules governing such a propositional preference relation—a foundation that can be either axiomatic or linguistic (*i.e.*, in terms of a semantical criterion of acceptability).

One procedure—adapted from the ideas of the well-known contemporary Finnish philosopher, Georg Henrik von Wright (born 1916), a prolific contributor to applied logic—is as follows: beginning with a basic set of possible worlds (or states of affairs)  $w_1, w_2, \dots, w_n$ , all of the propositions to be dealt with are first defined with respect to these by the usual logical connectives ( $\vee, \cdot, \supset$ , etc.). Given two elementary propositions p and q, there are just the following possibilities: both are true, p is true and q is false, p is false and q is true, or both are false. Corresponding to each of these possibilities is a possible world; thus,

$$\begin{aligned} w_1 &= p \cdot q \\ w_2 &= p \cdot \sim q \\ w_3 &= \sim p \cdot q \\ w_4 &= \sim p \cdot \sim q. \end{aligned}$$

The truth of p then amounts to the statement that one of the worlds  $w_1, w_2$  obtains, so that p is equivalent to  $w_1 \vee w_2$ . Moreover, a given basic preference/indifference ordering among the  $w_i$  is assumed. On this basis the following general characterization of propositional preference is stipulated: If delta ( $\delta$ ) is taken to represent any (and thus every) proposition independent of p and q, then p is preferable to q,  $p \gg q$ , if for every such  $\delta$  it is the case that every possible world in which p and not-q and  $\delta$  are the case,  $p \cdot \sim q \cdot \delta$  is w-preferable to every possible world in which not-p and q and  $\delta$  is the case,  $\sim p \cdot q \cdot \delta$ ; *i.e.*, when  $p \cdot \sim q$  is always preferable to  $\sim p \cdot q$  provided that everything else is equal. It is readily shown that through this approach such general rules as the following are obtained:

1. If p is preferable to q, then q is not preferable to p; *i.e.*,  
$$p \gg q \vdash \sim(q \gg p).$$
2. If p is preferable to q, and q is preferable to r, then p is preferable to r; *i.e.*,

$$(p \gg q \cdot q \gg r) \vdash (p \gg r).$$

3. If p is preferable to q, then not-q is preferable to not-p; *i.e.*,

$$p \gg q \vdash \sim q \gg \sim p.$$

4. If p is preferable to q, then having p and not-q is preferable to having not-p and q; *i.e.*,

$$p \gg q \vdash (p \cdot \sim q) \gg (\sim p \cdot q).$$

The preceding construction of preference requires only a preference ordering of the possible worlds. If, however, a measure for both probability and desirability (utility) of possible worlds is given, then one can define the corre-

Approach in terms of possible worlds

The "Measure of Merit"

sponding # -value (see below) of an arbitrary proposition  $p$  as the probabilistically weighed utility value of all of the possible worlds in which the proposition obtains. As an example,  $p$  may be the statement, "The Franklin Club caters chiefly to business people" and  $q$  the statement, "The Franklin Club is sports oriented." It may then be supposed as given that the following values hold:

World	Probability	Desirability
$w_1 = p \cdot q$	1/6	-2
$w_2 = p \cdot \sim q$	2/6	+1
$w_3 = \sim p \cdot q$	3/6	-1
$w_4 = \sim p \cdot \sim q$	1/6	+3.

The # -value of a proposition is determined by first multiplying the probability times the desirability of each world in which the proposition is true, and then taking the sum of these. For example, the # -value of  $p$  is determined as follows:  $p$  is true in each of  $w_1$  and  $w_2$  (and only these); the probability times the desirability of  $w_1$  is  $\frac{1}{6} \times (-2)$  and of  $w_2$  is  $\frac{2}{6} \times (+1)$ ; thus #-( $p$ ) is  $\frac{1}{6} \times (-2) + \frac{2}{6} \times (+1) = 0$ . (The # -value corresponds to the decision theorists' notion of expected value.) By this procedure it can easily be determined that

$$\begin{aligned} \#(p) &= 0 & \#(\sim p) &= \frac{1}{6} \\ \#(q) &= -(\frac{1}{6}) & \#(\sim q) &= \frac{5}{6}. \end{aligned}$$

Since both  $\#(p) > \#(q)$  and  $\#(\sim q) > \#(\sim p)$ , one correspondingly obtains both  $p \geq q$  and  $\sim q \geq \sim p$  in the example at issue; i.e., "That the Franklin Club should cater chiefly to business people is preferable to its being sports oriented" and "Its not being sports oriented is preferable to its not catering chiefly to business people." (The result is, of course, relative to the given desirability schedule specified for the various possible-world combinations in the above tabulation.)

A more complex mode of preference results, however, if —when some basic utility measure,  $\#(x)$ , is given—instead of having  $p \geq q$  correspond to the condition that  $\#(p) > \#(q)$ , it is taken to correspond to  $\#(p) - \#(\sim p) > \#(q) - \#(\sim q)$ . This mode of preference will be governed by characteristic rules, specifically including all of those that were listed above.

**THE LOGIC OF COMMANDS**

Some scholars have maintained that there cannot be a logic of commands (instructions, orders), inasmuch as there can be no logic in which validity of inference cannot be defined. Validity, however, requires that the concept of truth be applicable (an argument being valid when its conclusion must be true if its premises are true). But since commands—and, for that matter, also instructions, requests, etc.—are neither true nor false, it is argued that the concept of validity cannot be applied; so there can be no valid inference in this sphere. This line of thought, however, runs counter to clear intuitions that arise in specific cases, in which one unhesitatingly reasons from commands and sets of commands. If an examination has the instructions "Answer no fewer than three questions! Answer no more than four questions!" one would not hesitate to say that this implies the (tacitly contained) instruction, "Answer three or four questions!"

This seeming impasse can be broken, in effect, by importing truth into the sphere of commands through the back door: with any command one can associate its termination statement, which, with future-tense reference, asserts it as a fact that what the command orders will be done. Thus, the command "Shut all of the windows in the building!" has the termination statement "All of the windows in the building will be shut." In case of a pure command argument—i.e., one that infers a command conclusion from premises that are all commands—validity can be assessed in the light of the validity of the purely assertoric syllogism composed of the corresponding termination statements. Thus the validity of the command argument given above is a derivative from the (orthodox) validity of the inference, from the premises "No fewer than three questions will be answered; no more than four questions will be answered" to

the conclusion "Three or four questions will be answered."

The logical issues of pure command inference can be handled in this manner. But what of the mixed cases in which some statement—premise or conclusion—is not a command?

Special cases

*Special case 1.* One mixed case is that in which the premises nontrivially include noncommands, but the inferred conclusion is a command. Some writers have endorsed the rule that there is no validity unless the command conclusion is forthcoming from the command premises alone. This, however, invalidates such seemingly acceptable arguments as "Remove all cats from the area; the shed is in the area; so, remove all cats from the shed." It is more plausible, however, to stipulate the weaker condition that an inference to a command conclusion cannot count as valid unless there is at least one command premise that is essential to the argument. Subject to this restriction, a straightforward application of the above-stated characterization of validity can again be made. This approach validates the above-mentioned command inference via the validity of the assertion inference: "All cats will be removed from the area; the shed is in the area; so, all cats will be removed from the shed." (The rule under consideration suffices to block the unacceptable argument from the factual premise "All the doors will be shut" to the command conclusion "Shut all the doors.")

*Special case 2.* Another mixed case is that in which the premises nontrivially include commands, but the inferred conclusion is an ordinary statement of fact. Some authorities stipulate that no indicative conclusion can be validly drawn from a set of premises which cannot validly be drawn from the indicative among them alone. This rule would seem to be acceptable, though subject to certain significant provisos: (1) It must be restricted to categorical rather than conditional commands. "If you want to see the world's tallest building, look at the Empire State Building" conveys (*inter alia*) the information that "The Empire State Building is the world's tallest building." (2) Exception must be made for those commands that include in their formulation—explicitly or by way of tacit presupposition—reference to a factual datum. "John, give the book to Tom's brother Jim" yields the fact that Jim is Tom's brother; and "John, drive your car home" (= "John, you own a car: drive it home") yields "John owns a car." With suitable provisos, however, the rule can be maintained to resolve the issues of the special case in view.

**DEONTIC LOGIC**

The propositional modalities relating to normative (or valuational) classifications of actions and states of affairs, such as the permitted, the obligatory, the forbidden, or the meritorious, are characterized as deontic modalities (Greek *deontos*, "of that which is binding") and systematized in deontic logic. Though this subject was first treated as a technical discipline in 1926, its current active development dates from a paper published in 1951. As a highly abstracted branch of logical theory, it leaves to substantive disciplines—such as ethics and law—the concrete questions of what specific acts or states of affairs are to be forbidden, permitted, or the like (just as deductive logic does not meddle with what contingent issues are true but tells only what follows when certain facts or assumptions about the truth are given). It seeks to systematize the abstract, purely conceptual relations between propositions in this sphere, such as the following: if an act is obligatory, then its performance must be permitted and its omission forbidden. In given circumstances, any act is either permitted itself or its omission is permitted.

**The systematization and relation to alethic modal logic.**

In the systematization of deontic logic, the symbols  $p, q, r, \dots$  may be taken to range over propositions dealing both with impersonal states of affairs and with the human acts involved in their realization. Certain special deontic operations can then be introduced:  $\mathbf{P}(p)$  for "It is permitted that  $p$  be the case";  $\mathbf{F}(p)$  for "It is forbidden that  $p$  be the case"; and  $\mathbf{O}(p)$  for "It is obligatory that  $p$  be the

Reduction to permissibility terms

Truth involvements

case." In a systematization of deontic logic, it is only necessary to take one of these three operations as primitive (i.e., as an irreducible given), because the others can then be introduced in terms of it. For example, when **P** alone is taken as primitive (as is done here), the following can be introduced by definition: "It is obligatory that *p*" means "It is not permitted that not-*p*"; and "It is forbidden that *p*" means "It is not permitted that *p*"; i.e.,

$$\mathbf{O}(p) = \sim\mathbf{P}(\sim p) \text{ and } \mathbf{F}(p) = \sim\mathbf{P}(p).$$

The logical grammar of **P** is presumably to be such that one wants to insist upon the rule:

$$\text{Whenever } \vdash p \supset q, \text{ then } \vdash \mathbf{P}(p) \supset \mathbf{P}(q).$$

Example: "Since one's helping Jones who has been robbed entails that one help someone who has been robbed, being permitted to help Jones (who has been robbed) entails that one be permitted to help someone who has been robbed." This yields such principles as: "If both *p* and *q* are permitted, then *p* is permitted and *q* is permitted"; and "If *p* is permitted, then either *p* or *q* is permitted"; i.e.,

$$\vdash \mathbf{P}(p \cdot q) \supset [\mathbf{P}(p) \cdot \mathbf{P}(q)] \text{ and } \vdash \mathbf{P}(p) \supset \mathbf{P}(p \vee q).$$

And, once it is postulated that "A *p* exists that is permitted"—i.e.,  $\vdash (\exists p)\mathbf{P}(p)$ —then the statement that "It is not permitted that both *p* and not-*p*"—i.e.,  $\sim\mathbf{P}(p \cdot \sim p)$ —is also yielded. Moreover, on any adequate theory of **P** it is necessary to have such principles as "Either *p* or not-*p* is permitted"; i.e.,  $\vdash \mathbf{P}(p \vee \sim p)$ .

On the other hand, certain principles must be rejected, such as that "If *p* is permitted and *q* is permitted, then both *p* and *q* taken together is permitted"; i.e.,  $\vdash [\mathbf{P}(p) \cdot \mathbf{P}(q)] \supset \mathbf{P}(p \cdot q)$ , in which  $\vdash$  symbolizes the rejection of a thesis, and that "If either *p* or *q* is permitted, then *p* is permitted"; i.e.,  $\vdash \mathbf{P}(p \vee q) \supset \mathbf{P}(p)$ .

The first of these, accepted unqualifiedly, would lead to the untenable result that there can be no permission-indifferent acts; i.e., no acts such that both they and their omission are permitted—since this would then lead to  $\mathbf{P}(p \cdot \sim p)$ . The second thesis would have the unacceptable result of asserting that, when at least one member of a pair of acts is permitted, then both members are permitted.

In all of the respects that so far have been considered, deontic logic is wholly analogous to the already well developed field of alethic modal logic, which deals with statements of the form "It is possible that . . ." (symbolized  $\diamond$ ), "It is necessary that . . ." (symbolized  $\square$ ), etc. (see LOGIC, FORMAL: IV. *Other special systems of logic: Traditional logic and its developments: Modal logic*), with **P** in the role of possibility ( $\diamond$ ) and **O** in that of necessity ( $\square$ ). This parallel, however, does not extend throughout. In alethic logic, the principle that "necessity implies actuality" obviously holds (i.e.,  $\vdash \square p \supset p$ ). But its deontic analogue, that "obligation implies actuality" (i.e.,  $\vdash \mathbf{O}p \supset p$ ), must be rejected, or rather an analogous thesis holds only in the weakened form that "obligation implies permissibility" (i.e.,  $\vdash \mathbf{O}p \supset \mathbf{P}p$ ). There is continuing controversy about the relation of deontic to alethic modal logic, principally in the context of Kant's thesis that "ought implies can" (i.e.,  $\vdash \mathbf{O}p \supset \diamond p$ ), but also about the theses that "necessity implies permissibility" (i.e.,  $\vdash \square p \supset \mathbf{P}p$ ) and *Ad impossibile nemo obligatur*—"no one is obliged to [do] the impossible" (i.e.,  $\vdash \sim \diamond p \supset \sim \mathbf{O}p$ ). Although this thesis is generally accepted, some scholars want to strengthen the thesis to "necessity implies obligation" (i.e.,  $\vdash \square p \supset \mathbf{O}p$ ), or, equivalently, to "permissibility implies possibility" (i.e.,  $\vdash \sim \diamond p \supset \sim \mathbf{P}p$ ), with the result that only what is possible can count as permitted, so that the impossible is forbidden. Some would deny that it is wrong (i.e., impermissible) to act to realize the impossible, rather than merely unwise or imprudent.

It has been proposed that deontic logic may perhaps be reduced to alethic modal logic. This approach is based on the idea of a normative code delimiting the range of the permissible. In this context, what signals an action as impermissible is that it involves a violation of the code:

the statement that the action has occurred entails that the code has been violated and so leads to a "sanction." This line of thought leads to the definition of a modal operator  $\mathbf{F}p = \square(p \supset \sigma)$ , "*p* necessarily implies a sanction," in which sigma ( $\sigma$ ) is the sanction produced by code violation. Correspondingly, one then obtains: "For *p* to be permitted means that *p* does not imply by necessity a sanction"—i.e.,  $\mathbf{P}p = \sim \square(p \supset \sigma)$ —and "For *p* to be obligatory means that not doing *p* implies by necessity a sanction"—i.e.,  $\mathbf{O}p = \square(\sim p \supset \sigma)$ . Assuming a systematization of the alethic modal operator  $\square$ , these definitions immediately produce a corresponding system of deontic logic that—if  $\square$  is a normal modality—has many of the features that are desirable in a modal operator. It also yields, however—through the "paradoxes of strict implication" (see LOGIC, FORMAL: IV. *Other special systems of logic: Traditional logic and its developments: Modal logic: Alternative systems of modal logic*)—the disputed principle that "The assumption that *p* is not possible implies that *p* is not permissible"; i.e.,  $\vdash \sim \diamond p \supset \sim \mathbf{P}p$ . This and other similar consequences of the foregoing effort to reduce deontic logic to modal logic have been transcended by other scholars, who have resorted to a mode of implication (symbolized as  $\rightarrow$ ) that is stronger than strict implication (as necessary material implication is called) and then defining  $\mathbf{F}p$  as  $p \rightarrow \sigma$  instead of as above.

**Alternative deontic systems.** Each of the three principal deontic systems that have been studied to date is analogous to one of the alethic modal systems that were developed in the mid-20th century.

These foundational alethic systems differ by virtue of the different axioms and rules adopted for such modalities as necessity, possibility, and contingency. In the system designated **M**, for example, developed by the aforementioned Finnish logician G.H. von Wright, the adverb "possibly," symbolized *M*, is taken as the fundamental undefined modality in terms of which the other modalities are constructed. "Necessarily *p*," symbolized *Lp*, for example, is defined in the system **M** as "not possibly not-*p*"; i.e.,  $Lp = \sim M\sim p$ . Alternatively, in an equivalent system, **T**, "necessarily *p*" is taken as primitive, and "possibly *p*" is defined as "not necessarily not-*p*"; i.e.,  $Mp = \sim L\sim p$ . Several nonequivalent systems have been developed by the conceptual Pragmatist C.I. Lewis (1883–1964), primary author of *Symbolic Logic* (1932), the foundational work in this field. Of these systems, that known as **S4** includes all of the system **M** but adds also the axiom that "Necessarily *p* implies 'It is necessary that necessarily *p*'"—i.e.,  $Lp \supset LLp$ —whereas, that known as **S5** adds still another axiom, that "'Possibly *p*' implies 'It is necessary that possibly *p*'"—i.e.,  $Mp \supset LMp$  (see LOGIC, FORMAL: IV. *Other special systems of logic: Traditional logic and its developments: Modal logic: Alternative systems of modal logic*). The analogous deontic systems are then as follows:

1. **DM** (the deontic analogue of the system **M** of von Wright or of the system **T**). To a standard system of propositional logic the following rule is added: "Any proposition, if true, ought to be true"; i.e., If  $\vdash p$  then  $\vdash \mathbf{O}p$ . Example: Given that "To forgive is divine," (*p*) then "To forgive ought to be divine" ( $\mathbf{O}p$ ). Axioms:

(A1): "If *p* is obligatory, then not-*p* is not obligatory"; i.e.,  $\mathbf{O}p \supset \sim \mathbf{O}\sim p$ .

(A2): "If *p* ought to imply *q*, then if *p* is obligatory *q* is obligatory"; i.e.,  $\mathbf{O}(p \supset q) \supset (\mathbf{O}p \supset \mathbf{O}q)$ .

2. **DS4** (the deontic analogue of Lewis's system **S4**). To **M** one adds the axiom:

(A3): "If *p* is obligatory, then *p* ought to be obligatory"; i.e.,  $\mathbf{O}p \supset \mathbf{O}p$ . Example: "If John ought to pay his debts," ( $\mathbf{O}p$ ) then it is obligatory that John ought to pay his debts" ( $\mathbf{O}p$ ).

3. **DS5** (the deontic analogue of Lewis's system **S5**). To **M** one adds the axiom:

(A4): "If *p* is not obligatory, then *p* ought to be nonobligatory"; i.e.,  $\sim \mathbf{O}p \supset \mathbf{O}\sim \mathbf{O}p$ .

A straightforward semantical systematization of systems of deontic logic can be provided as follows: given a domain of complex propositions built up from atomic propositions (*p*, *q*, *r*, . . .) with the use of propositional connectives ( $\sim$ ,  $\cdot$ ,  $\vee$ ,  $\supset$ ) and **O**, a deontic model set  $\Delta$  for this domain can be characterized as any set chosen

Analogy with possibility and necessity

Analogies with "M," "S4," and "S5"

Semantic systematization

from these propositions that meets the following conditions (in which "iff" means "if and only if"):

1. Not- $p$  is in the set if and only if  $p$  is not in the set; *i.e.*,  $\sim p \in \Delta$  iff  $p \notin \Delta$ .
2. "Both  $p$  and  $q$  together" is in the set if and only if  $p$  is in the set and  $q$  is in the set; *i.e.*,  $(p \cdot q) \in \Delta$  iff  $p \in \Delta$  and  $q \in \Delta$ .
3. "Either  $p$  or  $q$ " is in the set if and only if either  $p$  is in the set or  $q$  is in the set; *i.e.*,  $(p \vee q) \in \Delta$  iff  $p \in \Delta$  or  $q \in \Delta$ .
4. "That  $p$  implies  $q$ " is in the set if and only if either  $p$  is not in the set or  $q$  is in the set; *i.e.*,  $(p \supset q) \in \Delta$  iff  $p \notin \Delta$  or  $q \in \Delta$ .
5. "That  $p$  is obligatory" is in the set whenever  $p$  is posited; *i.e.*,  $\mathbf{O}p \in \Delta$  whenever  $\vdash p$ .
6. "That not- $p$  is not obligatory" is in the set whenever " $p$  is obligatory" is in the set; *i.e.*,  $\sim \mathbf{O} \sim p \in \Delta$  whenever  $\mathbf{O}p \in \Delta$ .
7. "That  $q$  is obligatory" is in the set whenever both " $p$  is obligatory" is in the set and "That  $p$  implies  $q$  is obligatory" is in the set; *i.e.*,  $\mathbf{O}q \in \Delta$  whenever both  $\mathbf{O}p \in \Delta$  and  $\mathbf{O}(p \supset q) \in \Delta$ .

A proposition can be characterized as a deontic thesis (D-thesis) if it can be shown that, in virtue of these rules, it must belong to every deontic model set. It can be demonstrated that the D-thesis in this sense will coincide exactly with the theorems of **DM**—No. 1 of the above three systems. Furthermore, if one adds one of the additional rules:

- 8'. "That  $p$  ought to be obligatory" is in the set whenever " $p$  is obligatory" is in the set; *i.e.*,  $\mathbf{O} \mathbf{O}p \in \Delta$  whenever  $\mathbf{O}p \in \Delta$ .
- 8". "That  $p$  ought to be non-obligatory" is in the set whenever " $p$  is not obligatory" is in the set; *i.e.*,  $\mathbf{O} \sim \mathbf{O}p \in \Delta$  whenever  $\sim \mathbf{O}p \in \Delta$ .

then the corresponding D' or D" theses will coincide exactly with the theorems of the deontic systems **DS4** and **DS5**, respectively—Nos. 2 and 3 above.

**Logics of physical application**

Certain systems of logic are built up specifically with particular physical applications in view. Within this range lie temporal logic; spatial, or topological, logic; mereology, or the logic of parts and wholes generally; as well as the logic of circuit analysis.

Since the field of topological logic is new and relatively undeveloped, the reader is referred to the bibliography for a recent source that provides some materials and references to the literature.

Of the physical applications of logic, the logic of circuit analysis is perhaps the most important and certainly the most extensively developed. Since the course of the analysis in this case, however, soon veers off from logical into mathematical considerations, this subject is not treated here.

**TEMPORAL LOGIC**

The object of temporal logic—variously called chronological logic or tense logic—is to systematize reasoning with time-related propositions. Such propositions generally do not involve the timeless "is" (or "are") of the mathematicians' "three is a prime," but rather envisage an explicitly temporal condition (examples: "Bob *is* sitting," "Robert *was* present," "Mary *will have been* informed"). In this area, statements are employed in which some essential reference to the before-after relationship or the past-present-future relationship is at issue; and the ideas of succession, change, and constancy enter in.

**Classic historical treatments.** Chronological logic originated with the Megarians of the 4th century BC, whose school (not far from Athens) reflected the influence of Socrates and of Eleaticism.

In the Megarian conception of modality, the *actual* is that which is realized *now*, the *possible* is that which is realized at *some time or other*, and the *necessary* is that which is realized at *all times*. These Megarian ideas can be found also in Aristotle, together with another temporalized sense of necessity according to which certain possibilities are *possible* prior to the event, *actual* then, and *necessary* thereafter, so that their modal status is not omnitemporal (as in the Megarian concept), but changes in time. The Stoic conception of temporal modality is

yet another cognate development, according to which the *possible* is that which is realized at *some time* in the present or future and the *necessary* that which is realized at *all such times*. The Diodorean concept of implication (named after the 4th-century BC Megarian logician Diodorus Cronus) holds, for example, that the conditional "If the sun has risen, it is daytime" is to be given the temporal construction "All times after the sun has risen are times when it is daytime." The Persian logician Avicenna (980–1037), the foremost philosopher of medieval Islām, treated this chronological conception of implication in the framework of a general theory of categorical propositions (such as "All A is B," etc.) of a temporalized type and considerably advanced and developed the Megarian-Stoic theory of temporal modalities.

**Fundamental concepts and relations of temporal logic.** The statements "It sometimes rains in London," "It always rains in London," and "It is raining in London on January 1, AD 3000, is a fact" are all termed chronologically definite in that their truth or falsity is independent of their time assertion. By contrast, the statements "It is now raining in London," "It rained in London yesterday," and "It will rain in London sometime next week" are all chronologically indefinite, in that their truth or falsity is not independent of their time of assertion. The notation  $|t \vdash p$  is here introduced to mean that the proposition  $p$ , often in itself chronologically indefinite, is represented as being asserted at the time  $t$ . For example, if  $p_1$  is the statement "It is raining in London today," and  $t_1$  is January 1, 1900, then " $|t_1 \vdash p_1$ " represents the assertion made on January 1, 1900, that it is raining today—an assertion that is true if and only if the statement "It is raining in London on January 1, 1900, is a fact" is true. If the statement  $p$  is chronologically definite, then (by definition) the assertions " $|t \vdash p$ " and " $|t' \vdash p$ " are materially equivalent (*i.e.*, have the same truth value) for all values of  $t$  and  $t'$ . Otherwise  $p$  is chronologically indefinite. The time may be measured, for example, in units of days, so that the time variable is discretized. Then  $(t + 1)$  will represent "the day after  $t$ -day,"  $(t - 1)$  will represent "the day before  $t$ -day," and the like. And, further, the statements  $p_1$ ,  $q_1$ , and  $r_1$ , can then be as follows:

- $p_1$ : "It rains in London today."
- $q_1$ : "It will rain in London tomorrow."
- $r_1$ : "It rained in London yesterday."

The following assertions can now be made:

- (P):  $|t \vdash p_1$
- (Q):  $|t - 1 \vdash q_1$
- (R):  $|t + 1 \vdash r_1$ .

Clearly, for any value of  $t$  whatsoever, the assertions (P), (Q), and (R) must (logically) be materially equivalent (*i.e.*, have the same truth value). This illustration establishes the basic point—that the theory of chronological propositions must be prepared to exhibit the existence of logical relationships among such propositions of such a kind that the truth of the assertion of one statement at one time may be bound up essentially with the truth (or falsity) of the assertion of some very different statement at another time.

A (genuine) date is a time specification that is chronologically stable (such as "January 1, 3000," or "the day of Lincoln's assassination"); a pseudodate is a time specification that is chronologically unstable (such as "today" or "six weeks ago"). These lead to very different results depending upon the nature of the fundamental reference point—the "origin" in mathematical terms. If the origin is a pseudodate—say, "today"—the style of dating will be such that its chronological specifiers are pseudodates; *e.g.*, tomorrow, day before yesterday, four days ago, etc. If, on the other hand, the origin is a genuine date, say that of the founding of Rome, or the accession of Alexander, the style of dating will be such that all of its dates are of the type: two hundred and fifty years *ab urbe condita* ("since the founding of the city"). Clearly, a chronology of genuine dates will then be chronologically definite, and one of pseudodates will be chronologically indefinite.

Definite versus indefinite reference

Dated versus pseudodated statements

Megarian and Stoic logics

Let  $p$  be some chronologically indefinite statement. Then, in general, another statement can be formed, asserting that  $p$  holds (obtains) at the time  $t$ . Correspondingly, let the statement-forming operation  $\mathbf{R}_t$  be introduced. The statement  $\mathbf{R}_t(p)$ , which is to be read " $p$  is realized at the time  $t$ ," will then represent the statement stating explicitly that  $p$  holds (obtains) specifically at the time  $t$ . Thus, if  $t_1$  is 3 PM Greenwich time on January 1, 2000, and  $p_1$  is the (chronologically indefinite) statement "all men are (*i.e.*, are now) playing Chess," then " $\mathbf{R}_{t_1}(p_1)$ " is the statement "It is the case at 3 PM Greenwich time on January 1, 2000, that all men are playing Chess."

If  $t$  is a proper date (not a pseudodate), then " $\mathbf{R}_t(p)$ " is always temporally definite. For example, if  $p_1$  is the temporally indefinite statement "It is raining in London today," and  $t_1$  is as specified in the last paragraph, then " $\mathbf{R}_{t_1}(p_1)$ " is the temporally definite statement "It is raining in London at 3 PM Greenwich time on January 1, 2000." On the other hand, if  $t$  is a pseudodate, " $\mathbf{R}_t(p)$ " is temporally indefinite if  $p$  is indefinite. Thus, if  $t_2$  is the pseudodate tomorrow, then " $\mathbf{R}_{t_2}(p_1)$ " means "It is the case tomorrow that it is raining in London today." How is the  $\mathbf{R}$ -operation to be construed in a chronology based on the indexical pseudodate "now" as origin? When two  $t$ 's are involved, shall the second  $t$  be measured from the original now-point or from the now point newly established by the first  $t$ ? That is, should " $\mathbf{R}_{t'}[\mathbf{R}_t(p)]$ " be interpreted as:

1. It will be the case  $t'$  time units from now that it will be the case  $t$  time units from (the original) now that  $p$ —or, equivalently, simply as " $\mathbf{R}_{t'}(p)$ "; or as
2. It will be the case  $t'$  time units from now that it will be the case  $t$  time units thence (*i.e.*, from the new now) that  $p$ —or, equivalently, as " $\mathbf{R}_{(t'+t)}(p)$ "?

Since each of these represents a feasible alternative policy for the construction of  $\mathbf{R}$ , it is necessary in fact to deal with the consequences of the adoption of either.

**Systematization of temporal reasoning.** On the basis of these ideas, the logical theory of chronological propositions can be developed in a systematic, formal way. It may be postulated that the operator  $\mathbf{R}$  is to be governed by the following rules:

- (T1) The negation of a statement  $p$  is realized at a given time if and only if it is not the case that the statement is realized at that time; *i.e.*,  $\mathbf{R}_t(\sim p) \equiv \sim \mathbf{R}_t(p)$ , in which  $\equiv$  signifies equivalence and means "holds if and only if."
- (T2) A conjunction of two statements is realized at a given time if and only if each of the two statements is realized at that time:  $\mathbf{R}_t(p \cdot q) \equiv [\mathbf{R}_t(p) \cdot \mathbf{R}_t(q)]$ . Example: "John and Jane will be at the railroad station at 10 AM— $\mathbf{R}_t(p \cdot q)$ —if and only if John is at the station at 10 AM— $\mathbf{R}_t(p)$ —and Jane is at the station at 10 AM— $\mathbf{R}_t(q)$ ."

If a statement is realized universally—*i.e.*, at any and every time whatsoever—it can then be expressed more simply as being true without any temporal qualifications; hence, the rule:

- (T3) If for every time  $t$  the statement  $p$  is realized ( $\mathbf{R}$ ), then  $p$  obtains unqualifiedly; *i.e.*,  $(\forall t)\mathbf{R}_t(p) \supset p$ , in which  $\forall$  is the universal quantifier (meaning "for all . . .").

If two times are involved, however (as in 1 and 2 above), then the left-hand term in rule T3 can be expressed within the second time frame as "It will be the case  $t'$  from now that, for every time  $t$  ( $\forall t$ ), it will be the case  $t$  from the first now that  $p$ "; *i.e.*,  $\mathbf{R}_{t'}[(\forall t)\mathbf{R}_t(p)]$ . It is an algebraic rule, however, that an  $\mathbf{R}_t$  operator can be moved to the right past an irrelevant quantifier; hence,

$$\mathbf{R}_{t'}[(\forall t)\mathbf{R}_t(p)] \equiv (\forall t)\{\mathbf{R}_t[\mathbf{R}_{t'}(p)]\};$$

and, correspondingly, with the existential quantifier  $\exists$ : "It will be the case  $\tau$  from now that there exists a time  $t$  ( $\exists t$ ) such that  $p$  will be realized at  $t$ " is equivalent to saying "There exists a time  $t$  such that it will be the case  $\tau$  from now that  $p$  will be realized  $t$  from the first now" (in which  $\tau$  is a second time); *i.e.*,

$$(T4) \quad \mathbf{R}_{t'}[(\exists t)\mathbf{R}_t(p)] \equiv (\exists t)\{\mathbf{R}_t[\mathbf{R}_{t'}(p)]\}.$$

It is notable that the left-hand side of this equivalence is

itself equivalent with  $(\exists t)\mathbf{R}_t(p)$  since what follows the initial  $\mathbf{R}_t$  is a chronologically definite statement.

Finally, there are—as shown above—two distinct ways of construing iterations of the  $\mathbf{R}_t$  operator, which provides a choice between the rules:

- (T5-I)  $\mathbf{R}_t[\mathbf{R}_t(p)] \equiv \mathbf{R}_t(p)$   
 (T5-II)  $\mathbf{R}_t[\mathbf{R}_t(p)] \equiv \mathbf{R}_{t+\tau}(p)$ .

Taking these rules as a starting point, two alternative axiomatic theories are generated for the logic of the operation of chronological realization.

Apart from strictly technical results establishing the formal relationships of the various systems of chronological logic to one another, the most interesting findings regarding the systems of tense logic relate to the theory of temporal modalities. The most striking finding here concerns the logical structure of the system of modalities, be it Megarian or Stoic:

- Megarian possibly  $p$ :  $(\exists t)\mathbf{R}_t(p)$   
 necessarily  $p$ :  $(\forall t)\mathbf{R}_t(p)$   
 Stoic possibly  $p$ :  $(\exists t)[\mathbf{F}(t) \cdot \mathbf{R}_t(p)]$   
 necessarily  $p$ :  $(\forall t)[\mathbf{F}(t) \supset \mathbf{R}_t(p)]$

in which  $\mathbf{F}(t)$  signifies " $t$  is future." It has been shown that the forms, or structures, of both of these systems of temporal modalities are given by the aforementioned system S5 of C.I. Lewis (see further LOGIC, FORMAL: IV. Other special systems of logic: A. Traditional logic and its developments: 2. Modal logic: a. Alternative systems of modal logic).

**MEREOLGY**

The founder of mereology (Greek *meros*, "part") was a Polish logician, Stanislaw Leśniewski (1886–1939), a dominant figure in the Warsaw school of logic and author of an original and elegant system of the philosophy of mathematics. Leśniewski was much exercised about Russell's paradox of the class of all classes not elements of themselves, so called after Bertrand Russell (1872–1970), an outstanding creative logician and polymath philosopher—if this class is a member of itself, then it is not; and if it is not, then it is. (Example: "This barber shaves everyone in town who does not shave himself." Does the barber then shave himself? If he does, he does not; if he does not, he does.)

**Basic concepts and definitions.** The paradox results, Leśniewski argued, from a failure to distinguish the distributive and the collective interpretations of class expressions. The statement " $x$  is an element of the class of  $X$ 's" is correspondingly equivocal. When its key terms (element of, class of) are used distributively, it means simply that  $x$  is an  $X$ . But if these terms are used collectively, it means that  $x$  is a part (proper or improper) of the whole consisting of the  $X$ 's; *i.e.*, that  $x$  is a part of the object that meets the following two conditions: (1) that every  $x$  is a part of it; and (2) that every part of it has a common part with some  $x$ . On either construction of class membership, one of the inferences essential to the derivation of Russell's paradox is blocked.

Leśniewski presented his theory of the collective interpretation of class expressions in a paper published in 1916. Eschewing symbolization, he formulated his theorems and their proofs in ordinary language. Later he sought to formalize the theory by embedding it within a broader body of logical theory. This theory comprised two parts, *viz.*, protothetic (Greek *prōtos*, "first"; *tithēmi*, "I set up"), a logic of propositions (not analyzed into their parts); and ontology (Greek *on*, "being"), which contains counterparts to the predicational logic (of subjects and predicates), including the calculus of relations and the theory of identity. On his own approach, mereology was developed as an extension of ontology and protothetic; but the practice of most later writers has been to develop as a counterpart to mereology a theory of parts and wholes that is simply an extension of the more familiar machinery of quantificational logic employing  $\exists$  and  $\forall$ . This is the course adopted here.

An undefined relation  $\mathbf{Pt}$  serves as the basis for an axiomatic theory of the part relation. This relation is opera-

Rules and modalities

Leśniewski's encounter with the paradoxes

tive with respect to the items of some domain **D**, over which the variables  $\alpha, \beta, \gamma, \dots$  (alpha, beta, gamma, etc.) are assumed to range. Thus,  $\alpha Pt\beta$  is to be read "alpha is a part of beta"—with "part" taken in the wider sense in which the whole counts as part of itself. Two definitions are basic:

Disjointness and summation

1. " $\alpha$  is disjoint from  $\beta$ "; i.e.,  $\alpha \perp \beta$  is defined as obtaining when "there exists no item  $\gamma$  such that  $\gamma$  is a part of  $\alpha$  and  $\gamma$  is a part of  $\beta$ "; i.e.,  $\sim(\exists \gamma)(\gamma Pt\alpha \cdot \gamma Pt\beta)$ . Example: "The transmission ( $\alpha$ ) is disjoint from the motor ( $\beta$ ) if there exists no machine part ( $\gamma$ ) such that it is a part of the transmission and also a part of the motor."

2. " $S$  has the sum of (or sums to)  $\alpha$ "; i.e.,  $S\Sigma\alpha$  is defined as obtaining when "for every  $\gamma$ , this  $\gamma$  is disjoint from  $\alpha$  if and only if, for every  $\beta$ , to be a member of  $S$  is to be disjoint from  $\gamma$ "; i.e.,

$$(\forall \gamma)[\gamma \perp \alpha \equiv (\forall \beta)(\beta \in S \supset \beta \perp \gamma)].$$

$S\Sigma\alpha$  thus obtains whenever everything disjoint from  $\alpha$  is disjoint from every  $S$ -element ( $\beta$ ) as well, and conversely. Example: "A given group of buildings ( $S$ ) comprises ( $\Sigma$ ) Oxford University ( $\alpha$ ) when, for every room in the world ( $\gamma$ )—office, classroom, etc.—this room is disjoint from the university if and only if, in the case of each building ( $\beta$ ), for it to be a member ( $\in$ ) of the group that comprises the university ( $S$ ) it must not have this room as a part ( $\beta \perp \gamma$ )."

**Axiomatization of mereology.** A comprehensive theory of parts and wholes can now be built up from three axioms:

The first axiom expresses the fact that "For every  $\alpha$  and every  $\beta$ , if  $\alpha$  is a part of  $\beta$  and  $\beta$  is a part of  $\alpha$ , then  $\alpha$  and  $\beta$  must be one and the same item"; i.e.,

$$(\forall \alpha)(\forall \beta)(\alpha Pt\beta \cdot \beta Pt\alpha \supset \alpha = \beta);$$

hence, the axiom:

(A1) Items that are parts of one another are identical. (This is analogous to the principle in number theory that given any pair of natural numbers  $n$  and  $m$ , if  $n$  is less than or equal to  $m$  and  $m$  is less than or equal to  $n$ , then  $n$  is equal to  $m$ .)

The second axiom expresses the fact that "For every  $\alpha$  and every  $\beta$ ,  $\alpha$  is a part of  $\beta$  if and only if, for every  $\gamma$ , if this  $\gamma$  is disjoint from  $\beta$  it is then disjoint from  $\alpha$  as well"; i.e.,

$$(\forall \alpha)(\forall \beta)[\alpha Pt\beta \equiv (\forall \gamma)(\gamma \perp \beta \supset \gamma \perp \alpha)];$$

hence, the axiom:

(A2) One item is part of another only if every item disjoint from the second is also disjoint from the first. (Example: "This grain of sand ( $\alpha$ ) is a part of this pile of sand ( $\beta$ ) just in case whatever is disjoint from the pile is disjoint from the grain.")

The third axiom expresses the fact that "If there exists an  $\alpha$  that is a member of a nonempty set of items  $S$ , then there also exists a  $\beta$  that is the sum of this set"; i.e.,

$$(\exists \alpha)(\alpha \in S) \supset (\exists \beta) S \Sigma \beta;$$

hence, the axiom:

(A3) Every nonempty set has a sum. (If one considers the set of grains of sand in a given pile of sand, since such a set is nonempty, it will have a sum—namely, the pile of sand itself.)

Deduced theorems

Several theorems follow from these axioms:

The first states that "For every  $\alpha$ ,  $\alpha$  is a part of  $\alpha$ "; i.e.,

$$(\forall \alpha) \alpha Pt\alpha;$$

hence, the theorem:

(T1) Every item is part of itself. (Example: "Not only are the pages parts of a book [ $\alpha$ ], but the book is a part of the book.")

The second theorem states that "For every  $\alpha$ , for every  $\beta$ , and for every  $\gamma$ , if  $\alpha$  is a part of  $\beta$ , and  $\beta$  is a part of  $\gamma$ , then  $\alpha$  is a part of  $\gamma$ "; i.e.,

$$(\forall \alpha)(\forall \beta)(\forall \gamma)[(\alpha Pt\beta \cdot \beta Pt\gamma) \supset \alpha Pt\gamma];$$

hence, the theorem:

(T2) The **Pt**-relation is transitive.

The third theorem states that "For every  $\alpha$ , for every  $\beta$ , and for every  $\gamma$ , if  $\gamma$  is a part of  $\alpha$  only when it is also a part of  $\beta$  then  $\alpha$  is identical with  $\beta$ "; i.e.,

$$(\forall \alpha)(\forall \beta)(\forall \gamma)[(\gamma Pt\alpha \equiv \gamma Pt\beta) \supset \alpha = \beta];$$

hence, the theorem:

(T3) Any item is completely determined by its parts; items are identical when they have the same parts in common.

The fourth theorem states that "For every  $\alpha$  and every  $\beta$ , there exists a  $\gamma$  that is the sum of  $\alpha$  and  $\beta$ "; i.e.,

$$(\forall \alpha)(\forall \beta)(\exists \gamma)((\alpha, \beta) \Sigma \gamma);$$

hence, the theorem:

(T4) Any two items whatsoever may be summed up.

In this form as a formal theory of the part relation, the history of mereology can be dated from some drafts and essays of the classic early modern Rationalist G.W. Leibniz prepared in the late 1690s.

**Hypothetical reasoning and counterfactual conditionals**

A simply conditional, or "if," statement asserts a strictly formal relationship between antecedent ("if" clause) and consequent ("then" clause) ("If  $p$ , then  $q$ "), without any reference to the status of the antecedent. The knowledge status of this antecedent, however, may be problematic (unknown), or known-to-be-true, or known-to-be-false. In these three cases, one obtains, respectively, the problematic conditional ("Should it be the case that  $p$ —which it may or may not be—then  $q$ "); the factual conditional ("Since  $p$ , then  $q$ "); and the counterfactual conditional ("If it were the case that  $p$ —which it is not—then  $q$ "). Counterfactual conditionals have a special importance in the area of thought experiments in history as well as elsewhere.

Material implication  $p \supset q$ , construed simply as the truth-functional "either not- $p$  or  $q$ ," is clearly not suited to represent counterfactual conditionals because any material implication with a false antecedent is true: when  $p$  is false, then  $p \supset q$  and  $p \supset \sim q$  are both true, regardless of what one may choose to put in place of  $q$ . But even when a stronger mode of implication is invoked, such as strict implication or its cognates, the problem of auxiliary hypotheses (soon to be explained) would still remain.

It seems most natural to view a counterfactual conditional in the light of an inference to be drawn from the contrary-to-fact thesis represented by its antecedent. Thus, "If this rubber band were made of copper, then it would conduct electricity" would be construed as an incomplete presentation of the argument resulting from its expansion into:

Assumption: "This rubber band is made of copper";

Known fact: "Everything made of copper conducts electricity";

Conclusion: "This rubber band conducts electricity."

On the analysis, the conclusion (= the consequent of the counterfactual) appears as a deductive consequence of the assumption (= the antecedent of the counterfactual). This truncated-argument analysis of counterfactuals is a contribution, in essence, of a Polish linguistic theorist, Henry Hiż (born 1917). On Hiż's analysis, counterfactual conditionals are properly to be understood as metalinguistic; i.e., as making statements about statements. Specifically, "If  $A$  were so, then  $B$  would be so" is to be construed in the context of a given system of statements  $S$ , saying that when  $A$  is adjoined as a supplemental premise to  $S$ , then  $B$  follows. This approach has been endorsed by Roderick Chisholm of Brown University, an important writer in applied logic, and has been put forward in one form or another by many recent writers, most of whom incline to take  $S$ , as above, to include all or part of the corpus of scientific laws.

The approach warrants a closer scrutiny. On fuller analysis, the following situation, with a considerably enlarged group of auxiliary hypotheses, comes into focus:

- Known facts: 1. "This band is made of rubber";
- 2. "This band is not made of copper";
- 3. "This band does not conduct electricity";
- 4. "Things made of rubber do not conduct electricity";
- 5. "Things made of copper do conduct electricity."

Assumption: Not-(2); i.e., "This band is made of copper."

Hiż's analysis

Evaluation through hypotheses, facts, and laws

When this assumption is introduced within the framework of known facts, a contradiction obviously ensues. How can this situation be repaired? Clearly, the logician must begin by dropping items 1 and 2 and replacing them with their negations—the assumption itself so instructs him. But a contradiction still remains. The following alternatives are open:

Alternative 1:	Retain: 3, 4. Reject: 1, 2, 5.
Alternative 2:	Retain: 4, 5. Reject: 1, 2, 3.

That is, the analyst actually has a choice between rejecting 3 in favour of 5 or 5 in favour of 3, resulting in the following conditionals:

1. "If this rubber band were made of copper, then it would conduct electricity" (since copper conducts electricity), or
2. "If this rubber band were made of copper, then copper would not (always) conduct electricity" (since this band does not conduct electricity).

If the first conditional seems more natural than the second, this is owing to the fact that, in the face of the counterfactual hypothesis at issue, the first invites the sacrifice of a particular fact (viz., that the band does not conduct electricity) in favour of a general law (viz., that copper conducts electricity), whereas the second counterfactual would have sacrificed a law to a purely hypothetical fact. On this view, there is a fundamental epistemological difference between actual and hypothetical situations: in actual cases one makes laws give way to facts, but in hypothetical cases one makes the facts yield to laws.

In more complex cases, however the fact/law distinction may not help matters. For example, assume a group of three laws  $L_1, L_2, L_3$ , where  $\sim L_1$  is inconsistent with the conjunction of  $L_2$  and  $L_3$ . If asked to hypothesize the denial of  $L_1$ —so that the "fact" that one is opposing is itself a law—then what remains is a choice between laws; the distinction between facts and laws does not resolve the issue, and some more sophisticated mechanism for a preferential choice among laws is necessary.

## Logic, Formal

The discipline known as formal logic takes as its main subject matter propositions (or statements, or assertively used sentences) and deductive arguments, and it abstracts from their content the structures or logical forms that they embody. The logician customarily uses a symbolic notation to express these structures clearly and unambiguously and to enable manipulations and tests of validity to be more easily applied. Although this article freely employs the technical notation of modern symbolic logic, its symbols are introduced gradually and with accompanying explanations so that the serious and attentive general reader should be able to follow the development of ideas.

Formal logic is an a priori, and not an empirical, study. In this respect it contrasts with the natural sciences and with all other disciplines that depend on observation for their data. Its nearest analogy is with pure mathematics; indeed, many logicians and pure mathematicians would regard their respective subjects as indistinguishable, or as merely two stages of the same unified discipline. Formal logic, therefore, is not to be confused with the empirical study of the processes of reasoning, which belongs to psychology. It must also be distinguished from the art of correct reasoning, which is the practical skill of applying logical principles to particular cases; and, even more sharply, it must be distinguished from the art of persuasion, in which invalid arguments are sometimes more effective than valid ones.

The main divisions of the article are as follows:

For discussions of formal logic considered as a discipline, of its foundational philosophical issues, and of its relations to (and applications in) other disciplines, see LOGIC, PHILOSOPHY OF; and LOGIC, HISTORY OF.

**I. Introduction**

Probably the most natural approach to formal logic is through the idea of the soundness or validity of an argument of the kind known as deductive. A deductive argument can be roughly characterized as one in which the claim is made that some proposition (the *conclusion*) follows with strict necessity from some other proposition or propositions (the *premises*)—*i.e.*, that it would be inconsistent or self-contradictory to assert the premises but deny the conclusion. Not all arguments are of this type. Some involve only the weaker claim that the premises lend a certain degree of probability to the conclusion or that acceptance of the premises would make acceptance of the conclusion more reasonable than not. Such arguments, which are known as inductive, are dealt with in the articles SCIENCE, PHILOSOPHY OF; and PROBABILITY, THEORY OF, and will not be considered here.

Deductive validity

If a deductive argument is to succeed in establishing the truth of its conclusion, two quite distinct conditions must be met: first, the conclusion must in fact follow from the premises—*i.e.*, the deduction of the conclusion from the premises must be logically sound; and, second, the premises themselves must be true. Of these two conditions, the logician as such is concerned only with the first; the second, the determination of the truth or falsity of the premises, is the task of some special discipline or of common observation, etc., appropriate to the subject matter of the argument. When the conclusion of an argument is correctly deducible from its premises, the *inference* from the premises to the conclusion is said to be (deductively) *valid*, irrespective of whether the premises are true or false. Other ways of expressing the fact that an inference is deductively valid are to say that the truth of the premises gives (or would give) an absolute guarantee of the truth of the conclusion or that it would involve a logical inconsistency (as distinct from a mere mistake of fact) to suppose that the premises were true but the conclusion false.

The deductive inferences with which formal logic is concerned are, as the name suggests, those for which validity depends not on any features of their subject matter but on their form or structure. Thus the two inferences

(A) "Every dog is a mammal"; "Some quadrupeds are dogs"; therefore, "Some quadrupeds are mammals"

and

(B) "Every anarchist is a believer in free love"; "Some members of the Government party are anarchists"; therefore, "Some members of the Government party are believers in free love"

differ in subject matter and hence require different procedures to check the truth or falsity of their premises. But their validity is ensured by what they have in common, *viz.*, that the argument in each is of the form:

(C) "Every *X* is a *Y*"; "Some *Z*'s are *X*'s"; therefore "Some *Z*'s are *Y*'s."

Inference forms

Line (C) above may be called an *inference form*, and (A) and (B) are then *instances* of that inference form. The letters—*X*, *Y*, and *Z*—in (C) mark the places into which expressions of a certain type may be inserted. Symbols used for this purpose are known as *variables*; their use is analogous to that of the *x* in algebra, which marks the place into which a numeral can be inserted. An instance of an inference form is produced by replacing all of the variables in it by appropriate expressions—*i.e.*, ones that make sense in the context—and by doing so uniformly—*i.e.*, by substituting the same (or some synonymous) expression wherever the same variable recurs. The feature of (C) that guarantees that every instance of it will be valid is its construction in such a manner that every uniform way of replacing its variables to make the premises true automatically makes the conclusion true, too; or in other words that no instance of it can have true premises but a false conclusion. In virtue of this feature, the form (C) is called a *valid* inference form. In contrast,

(D) "Every *X* is a *Y*"; "Some *Z*'s are *Y*'s"; therefore, "Some *Z*'s are *X*'s"

is not a valid inference form, for although instances of it

can be produced in which premises and conclusion are all true, instances of it can also be produced in which the premises are true but the conclusion is false—*e.g.*,

(E) "Every dog is a mammal"; "Some winged creatures are mammals"; therefore, "Some winged creatures are dogs."

Formal logic as a study is concerned with inference forms rather than with particular instances of them; one of its tasks is to discriminate between valid and invalid inference forms and to explore and systematize the relations that hold among valid ones.

Closely related to the idea of a valid inference form is that of a valid proposition form. A proposition form is an expression of which the instances (produced as before by appropriate and uniform replacements for variables) are not inferences from several propositions to a conclusion but propositions taken individually; and a *valid* proposition form is one for which all of the instances are true propositions. A simple example is

Valid proposition forms

(F) "Nothing is both an *X* and a non-*X*."

An invalid proposition form is one that has at least some false instances. Formal logic is concerned with proposition forms as well as with inference forms. The study of proposition forms can, in fact, be made to include that of inference forms in the following way: let the premises of any given inference form (taken together) be abbreviated by alpha ( $\alpha$ ) and its conclusion by beta ( $\beta$ ). Then the condition stated above for the validity of the inference form " $\alpha$ , therefore  $\beta$ " amounts to saying that no instance of the proposition form " $\alpha$  and not- $\beta$ " is true—*i.e.*, that every instance of the proposition form

(G) "Not both:  $\alpha$  and not- $\beta$ "

is true—or that line (G), fully spelled out, of course—is a valid proposition form. The study of proposition forms, however, cannot be similarly accommodated under the study of inference forms, and so for reasons of comprehensiveness it is usual to regard formal logic as the study of proposition forms. Because a logician's handling of proposition forms is in many ways analogous to a mathematician's handling of numerical formulas, the systems he constructs are often called *calculi*.

Much of the work of a logician proceeds at a more abstract level than that of the foregoing discussion. Even a formula such as (C) above, though not referring to any specific subject matter, contains expressions like "every" and "is a," which are thought of as having a definite meaning; and the variables are intended to mark the places for expressions of one particular kind (roughly, common nouns or class names). It is possible, however—and for some purposes it is essential—to study formulas without attaching even this degree of meaningfulness to them. The construction of a system of logic, in fact, involves two distinguishable processes: one consists in setting up a symbolic apparatus—a set of symbols, rules for stringing these together into formulas, and rules for manipulating these formulas; the second consists in attaching certain meanings to these symbols and formulas. If only the former is done, the system is said to be *uninterpreted*, or *purely formal*; if the latter is done as well, the system is said to be *interpreted*. This distinction is important because systems of logic turn out to have certain properties quite independently of any interpretations that may be placed upon them. An axiomatic system of logic can be taken as an example—*i.e.*, a system in which certain unproved formulas, known as axioms, are taken as starting points, and further formulas (theorems) are proved on the strength of these. As will appear later (II. *Axiomatization of PC*), the question whether a proof of a given theorem in an axiomatic system is a sound one or not depends solely on which formulas are taken as axioms and on what the rules are for deriving theorems from axioms, and not at all on what the theorems or axioms mean. Moreover, a given uninterpreted system is in general capable of being interpreted equally well in a number of different ways; hence in studying an uninterpreted system, one is studying the structure that is common to a variety of interpreted systems. Normally a logician who constructs a purely formal system does have a particular in-

terpretation in mind, and his motive for constructing it is the belief that when this interpretation is given to it the formulas of the system will be able to express sound or true principles in some field of thought; but, for the above reasons among others, he will usually take care to describe the formulas and state the rules of the system without reference to interpretation and to indicate as a separate matter the interpretation that he has in mind.

Problems in the philosophy of logic

Many of the ideas used in the exposition of formal logic, including some that have already occurred above, raise problems that belong to philosophy rather than to logic itself (see the two articles PHILOSOPHY, HISTORY OF WESTERN; and LOGIC, PHILOSOPHY OF). Examples are: What is the correct analysis of the notion of truth? What is a proposition, and how is it related to the sentence in which it is expressed? Are there some kinds of sound reasoning that are neither deductive nor inductive? Fortunately, it is possible to learn to do formal logic without having satisfactory answers to such questions, just as it is possible to do mathematics without answering questions belonging to the philosophy of mathematics such as: Are numbers real objects or mental constructs?

**II. The propositional calculus**

GENERAL FEATURES OF PC

Fundamental definitions

The simplest and most basic branch of logic is the propositional calculus, hereafter called PC, named from the fact that it deals only with complete, unanalyzed propositions and certain combinations into which they enter. Various notations for PC are used in the literature (see below, V. *Varieties of notation in symbolic logic*). In that used here the symbols employed in PC comprise first, variables (for which the letters  $p, q, r, \dots$  are used, with or without numerical subscripts); second, operators (for which the symbols  $\sim, \cdot, \vee, \supset, \equiv$  are employed); and third, brackets or parentheses. The rules for constructing formulas are deferred to II. *Formation rules for PC*; and the intended interpretations—i.e., the meanings to be given to these symbols—are indicated here immediately: The variables are to be viewed as representing unspecified propositions, or as marking the places in formulas into which propositions, and only propositions, may be inserted. (This is sometimes expressed by saying that they *range over* propositions, or that they take propositions as their *values*.) Hence they are often called *propositional variables*. It is assumed that every proposition is either true or false and that no proposition is both true and false. Truth and falsity are said to be the *truth values* of propositions. The function of an operator is to form a new proposition from one or more given propositions, called the *arguments* of the operator. The operators  $\sim, \cdot, \vee, \supset,$  and  $\equiv$  correspond respectively to the English expressions “not,” “and,” “or,” “if . . . then” (or “implies”), and “is equivalent to,” when these are used in the following senses:

- (i) Given a proposition  $p$ , then  $\sim p$  (“not  $p$ ”) is to count as false when  $p$  is true and true when  $p$  is false;  $\sim$  (when thus interpreted) is known as the *negation sign* and  $\sim p$  as the *negation of  $p$* .
- (ii) Given any two propositions,  $p$  and  $q$ , then  $p \cdot q$  (“ $p$  and  $q$ ”) is to count as true when  $p$  and  $q$  are both true and as false in all other cases (viz., when  $p$  is true and  $q$  false, when  $p$  is false and  $q$  true, and when  $p$  and  $q$  are both false);  $p \cdot q$  is said to be the *conjunction of  $p$  and  $q$* ;  $\cdot$  is known as the *conjunction sign* and its arguments ( $p, q$ ) as *conjuncts*.
- (iii)  $p \vee q$  (“ $p$  or  $q$ ”) is to count as false when  $p$  and  $q$  are both false and true in all other cases; thus it represents the assertion that at least one of  $p$  and  $q$  is true.  $p \vee q$  is known as the *disjunction of  $p$  and  $q$* ;  $\vee$  is the *disjunction sign* and its arguments ( $p, q$ ) are known as *disjuncts*.
- (iv)  $p \supset q$  (“if  $p$  [then]  $q$ ” or “ $p$  [materially] implies  $q$ ”) is to count as false when  $p$  is true and  $q$  is false, and as true in all other cases; hence it has the same meaning as “either not- $p$  or  $q$ ,” or as “not both;  $p$  and not- $q$ .” The symbol  $\supset$  is known as the (*material*) *implication sign*, the first argument as the *antecedent*, and the second as the *consequent*;  $q \supset p$  is known as the *converse of  $p \supset q$* .
- (v) Finally,  $p \equiv q$  (“ $p$  is [materially] equivalent to  $q$ ” or “ $p$  if and only if  $q$ ”) is to count as true when  $p$  and  $q$  have the same truth value (i.e., either when both are true or when both are false), and false when they have different truth values;

the arguments of  $\equiv$  (the [*material*] *equivalence sign*) are called *equivalents*.

Brackets are used to indicate grouping; they make it possible to distinguish, for example, between  $p \cdot (q \vee r)$  (“Both  $p$  and either- $q$ -or- $r$ ”) and  $(p \cdot q) \vee r$  (“Either both- $p$ -and- $q$  or  $r$ ”). Precise rules for bracketing are given below.

The above account is meant solely as an explanation of the meaning to be attached to the PC operators in logic; it is not intended as an explanation or theory of the meaning in everyday speech of the English expressions by which they have here been roughly translated. Reading  $p \supset q$  as “If  $p, q$ ,” for example, is made convenient by the fact that “if” is often used in English in a “material-implication” sense (someone who asserted “If it isn’t raining, it’s snowing” would usually be held to have spoken truly *unless* the antecedent were true but the consequent false; i.e., unless it was neither raining nor snowing); but no claim is thereby being made that this is the only standard use of “if.” Other uses of “if” have in fact led to the construction of various other systems of logic (see below, IV. *Alternative systems of modal logic* and also *Applied logic*) and have also raised important questions in the philosophy of logic; but these are irrelevant to the understanding of the relation expressed by  $\supset$  in PC, which is one of fundamental importance for logic.

All PC operators take propositions as their arguments, and the result of applying them is also in each case a proposition. For this reason they are sometimes called *proposition-forming operators on propositions*, or more briefly *propositional connectives*. An operator that, like  $\sim$ , requires only a single argument is known as a *monadic* operator; operators that, like all the others listed, require two arguments are known as *dyadic*.

All PC operators also have the following important characteristic: given the truth values of the arguments, the truth value of the proposition formed by them and the operator is determined in every case. An operator that has this characteristic is known as a *truth-functional* operator, and a proposition formed by such an operator is called a *truth function* of the operator’s argument(s). The truth functionality of the PC operators is clearly brought out by summarizing the above account of them in Table 1. In

Truth functionality

**Table 1: Truth Table for Most Common Operators**

monadic operator		dyadic operators					
$p$	$\sim p$	$p \cdot q$	$p \cdot q$	$p \vee q$	$p \supset q$	$p \equiv q$	
1	0	1 1	1	1	1	1	
0	1	1 0	0	1	0	0	
		0 1	0	1	1	0	
		0 0	0	0	1	1	

it, “true” is abbreviated by “1” and “false” by “0,” and to the left of the vertical line are tabulated all possible combinations of truth values of the operators’ arguments. The columns of 1s and 0s under the various truth functions indicate their truth values for each of the cases; these columns are known as the *truth tables* of the relevant operators. It should be noted that any column of four 1s and/or 0s or both will specify a dyadic truth-functional operator. Because there are precisely  $2^4$  (i.e., 16) ways of forming a string of four symbols each of which is to be either 1 or 0 (1111, 1110, 1101, . . . , 0000), there are 16 such operators in all; the four that are listed here are only the four most generally useful ones.

**Formation rules for PC.** In any system of logic it is necessary to specify which sequences of symbols are to count as acceptable formulas—or, as they are usually called, *well-formed formulas (wff’s)*. Rules that specify this are called *formation rules*. From an intuitive point of view it is desirable that the *wff’s* of PC be just those sequences of PC symbols that, in terms of the interpretation given above, make sense and are unambiguous; and this can be ensured by stipulating that the *wff’s* of PC are to be all of those expressions constructed in accordance with the following PC formation rules, and only these:

Well-formed formulas (wff’s)

- FR1. A variable standing alone is a *wff*
- FR2. If  $\alpha$  is a *wff*, so is  $\sim \alpha$
- FR3. If  $\alpha$  and  $\beta$  are *wff*s,  $(\alpha \cdot \beta)$ ,  $(\alpha \vee \beta)$ ,  $(\alpha \supset \beta)$ , and  $(\alpha \equiv \beta)$  are *wff*s.

(In these rules  $\alpha$  and  $\beta$  are variables representing arbitrary formulas of PC. They are not themselves symbols of PC but are used in discoursing about PC. Such variables are known as *metalogical* variables. For further explanation, see METALOGIC.) It should be noted that the rules, though designed to ensure unambiguous sense for the *wff*s of PC under the intended interpretation, are themselves stated without any reference to interpretation and in such a way that there is an effective procedure for determining, again without any reference to interpretation, whether any arbitrary string of symbols is a *wff* or not. (An *effective* procedure is one that is "mechanical" in nature and can always be relied on to give a definite result in a finite number of steps. The notion of effectiveness plays an important role in formal logic.)

Examples of *wff*s are:  $p$ ;  $\sim q$ ;  $\sim (p \cdot q)$ , "not both  $p$  and  $q$ ";  $[\sim p \vee (q \equiv p)]$ , "Either not  $p$  or else  $q$  is equivalent to  $p$ ."

For greater ease in writing or reading formulas the formation rules are often relaxed in various ways. The following relaxations are common:

- (a) Brackets enclosing a complete formula may be omitted
- (b) The typographical style of brackets may be varied within a formula, to make the pairing of brackets more evident to the eye
- (c) Conjunctions and disjunctions may be allowed to have more than two arguments; e.g.,  $p \cdot (q \supset r) \cdot \sim r$  may be written instead of  $[p \cdot (q \supset r)] \cdot \sim r$ . (The conjunction  $p \cdot q \cdot r$  is then interpreted to mean that  $p$ ,  $q$ , and  $r$  are all true,  $p \vee q \vee r$  to mean that at least one of  $p$ ,  $q$ , and  $r$  is true, and so forth.)

**Validity in PC.** Given the standard interpretation, a *wff* of PC becomes a proposition, true or false, when all of its variables are replaced by actual propositions. Such a *wff* is therefore a proposition form in the sense explained in the Introduction and hence is valid if and only if all its instances are true propositions. A *wff* of which all instances are false is said to be *unsatisfiable* or *inconsistent*; and one with some true and some false instances is said to be *contingent*.

Decision procedure with truth tables

An important problem for any logical system is the *decision problem* for the class of valid *wff*s of that system (sometimes simply called the decision problem for the system). This is the problem of finding an effective procedure, in the sense explained in II. *Formation rules for PC*, for testing the validity of any *wff* whatsoever of the system. Such a procedure is called a *decision procedure*. For some systems a decision procedure can be found; the decision problem for that system is then said to be *solvable*, and the system is said to be a *decidable* one. For other systems it can be proved that no decision procedure is possible; the decision problem for that system is then said to be *unsolvable*, and the system is said to be an *undecidable* one.

PC is a decidable system. In fact, several decision procedures for it are known. Of these the simplest and most important theoretically (though not always the easiest to apply in practice) is the method of *truth tables*, which will now be explained briefly. Since all of the operators in a *wff* of PC are truth-functional, in order to discover the truth value of any instance of such a *wff*, it is unnecessary to consider anything but the truth values of the propositions replacing the variables. In other words, the assignment of a truth value to each of the variables in a *wff* uniquely determines a truth value for the whole *wff*. Since there are only two truth values and each *wff* contains only a finite number of variables, there are only a finite number of truth-value assignments to the variables to be considered (if there are  $n$  distinct variables in the *wff*, there are  $2^n$  such assignments); these can easily be systematically tabulated. For each of these assignments the truth tables for the operators then enable one to calculate the resulting truth value of the whole *wff*; and if and only if this truth value is *truth* in each case,

is the *wff* valid. As an example,  $[(p \supset q) \cdot r] \supset [(\sim r \vee p) \supset q]$  may be tested for validity. This formula states that "If one proposition implies a second one, and a certain third proposition is true, then if either that third proposition is false or the first is true, the second is true." The calculation is shown in Table 2. As before, 1 repre-

Table 2: Test for Validity by Truth Table

$p$	$q$	$r$	$[(p \supset q) \cdot r] \supset [(\sim r \vee p) \supset q]$					
1	1	1	1	1	1	0	1	1
1	1	0	1	0	1	1	1	1
1	0	1	0	0	1	0	1	0
1	0	0	0	0	1	1	1	0
0	1	1	1	1	1	0	0	1
0	1	0	1	0	1	1	1	1
0	0	1	1	1	1	0	0	1
0	0	0	1	0	1	1	1	0
			(1)	(2)	(6)	(3)	(4)	(5)

sents truth and 0 falsity. Since the *wff* contains three variables, there are  $2^3$  (i.e., 8) different assignments to the variables to be considered, which therefore generate the eight lines of the table. These assignments are tabulated to the left of the vertical line. The numbers in parentheses at the foot indicate the order in which the steps (from 1 through 6) are to be taken in determining the truth values (1 or 0) to be entered in the table. Thus column (1), falling under the symbol  $\supset$ , sets down the values of  $p \supset q$  for each assignment, obtained from the columns under  $p$  and  $q$  by the truth table for  $\supset$ ; column (2), for  $(p \supset q) \cdot r$ , is then obtained by employing the values in column (1) together with those in the column under  $r$  by use of the truth table for  $\cdot$ ; . . . until finally column (6), which gives the values for the whole *wff*, is obtained from columns (2) and (5). This column is called the truth table of the whole *wff*. Since it consists entirely of 1s, it shows that the *wff* is true for every assignment given to the variables and is therefore valid. A *wff* for which the truth table consists entirely of 0s is inconsistent, and a *wff* for which the truth table contains at least one 1 and at least one 0 is contingent. It follows from the formation rules and from the fact that an initial truth table has been specified for each operator that a truth table can be constructed for any given *wff* of PC.

Among the more important valid *wff*s of PC are those of Table 3:

Table 3: Some Valid Formulas of Propositional Calculus

law	formula
Law of Identity	$p \equiv p$
Law of Double Negation	$p \equiv \sim \sim p$
Law of Excluded Middle	$p \vee \sim p$
Law of Noncontradiction	$\sim(p \cdot \sim p)$
De Morgan Laws	$(p \cdot q) \equiv \sim(\sim p \vee \sim q)$ $(p \vee q) \equiv \sim(\sim p \cdot \sim q)$
Commutative Laws	$(p \vee q) \equiv (q \vee p)$ $(p \cdot q) \equiv (q \cdot p)$
Associative Laws	$[(p \vee q) \vee r] \equiv [p \vee (q \vee r)]$ $[(p \cdot q) \cdot r] \equiv [p \cdot (q \cdot r)]$
Law of Transposition	$(p \supset q) \equiv (\sim q \supset \sim p)$
Distributive Laws	$[p \cdot (q \vee r)] \equiv [(p \cdot q) \vee (p \cdot r)]$ $[p \vee (q \cdot r)] \equiv [(p \vee q) \cdot (p \vee r)]$
Law of Permutation	$[p \supset (q \supset r)] \equiv [q \supset (p \supset r)]$
Law of Syllogism	$(p \supset q) \supset [(q \supset r) \supset (p \supset r)]$
Law of Importation	$[p \supset (q \supset r)] \equiv [(p \cdot q) \supset r]$
Law of Exportation	$[(p \cdot q) \supset r] \supset [p \supset (q \supset r)]$

All of the above *wff*s can be shown to be valid by a mechanical application of the truth-table method. They can also be seen to express intuitively sound general principles about propositions. For instance, because "not (. . . or—)" can be rephrased as "neither . . . nor—," the first De Morgan law can be read as: "Both  $p$  and  $q$  if and only if neither not- $p$  nor not- $q$ "; thus it expresses the principle that two propositions are jointly true if and only if neither of them is false.

Whenever, as is the case in most of the examples given, a *wff* of the form  $\alpha \equiv \beta$  is valid, the corresponding *wff*s

Construction of valid *wff*s

$\alpha \supset \beta$  and  $\beta \supset \alpha$  are also valid. For instance, because  $(p \cdot q) \equiv \sim(\sim p \vee \sim q)$  is valid, so are  $(p \cdot q) \supset \sim(\sim p \vee \sim q)$  and  $\sim(\sim p \vee \sim q) \supset (p \cdot q)$ .

Moreover, although  $p \supset q$  does not mean that  $q$  can be deduced from  $p$ , yet whenever a *wff* of the form  $\alpha \supset \beta$  is valid, the inference form “ $\alpha$ , therefore  $\beta$ ” is likewise valid. This fact is easily seen from the fact that  $\alpha \supset \beta$  means the same as “Not both:  $\alpha$  and not- $\beta$ ”; for, as was noted in the *Introduction*, whenever the latter is a valid proposition form, “ $\alpha$ , therefore  $\beta$ ” is a valid inference form.

Let  $\alpha$  be any *wff*. If any variable in it is now uniformly replaced by some *wff*, the resulting *wff* is called a *substitution-instance* of  $\alpha$ . Thus  $[p \supset (q \vee \sim r)] \equiv [\sim(q \vee \sim r) \supset \sim p]$  is a substitution-instance of  $(p \supset q) \equiv (\sim q \supset \sim p)$ , obtained from it by replacing  $q$  uniformly by  $(q \vee \sim r)$ . It is an important principle that whenever a *wff* is valid so is every substitution-instance of it (the *rule of [uniform] substitution*).

A further important principle is the *rule of substitution of equivalents*. Two *wff*s,  $\alpha$  and  $\beta$ , are said to be *equivalents* when  $\alpha \equiv \beta$  is valid. (The *wff*s  $\alpha$  and  $\beta$  are equivalents if and only if they have identical truth tables.) The rule states that if any part of a *wff* is replaced by an equivalent of that part, the resulting *wff* and the original are also equivalents. Such replacements need not be uniform. The application of this rule is said to make an *equivalence transformation*.

**Interdefinability of operators.** The rules that have just been stated would enable the first De Morgan law listed in Table 3 to transform any *wff* containing any number of occurrences of  $\cdot$  into an equivalent *wff* in which  $\cdot$  does not appear at all but in place of it certain complexes of  $\sim$  and  $\vee$  arise. Similarly, since  $\sim p \vee q$  has the same truth table as  $p \supset q$ ,  $(p \supset q) \equiv (\sim p \vee q)$  is valid, and any *wff* containing  $\supset$  can therefore be transformed into an equivalent *wff* containing  $\sim$  and  $\vee$  but not  $\supset$ . And since  $(p \equiv q) \equiv [(p \supset q) \cdot (q \supset p)]$  is valid, any *wff* containing  $\equiv$  can be transformed into an equivalent containing  $\supset$  and  $\cdot$  but not  $\equiv$ —and thus in turn by the previous steps it can be further transformed into one containing  $\sim$  and  $\vee$  but neither  $\equiv$  nor  $\supset$  nor  $\cdot$ . Thus for every *wff* of PC there is an equivalent *wff*, expressing precisely the same truth function, in which the only operators are  $\sim$  and  $\vee$ , though the meaning of this *wff* will usually be much less clear than that of the original.

An alternative way of presenting PC, therefore, is to begin with the operators  $\sim$  and  $\vee$  only and to define the others in terms of these. The operators  $\sim$  and  $\vee$  are then said to be *primitive*. If “ $\equiv_{\text{df}}$ ” is used to mean “is defined as,” then the relevant definitions can be set down as follows:

$$\begin{aligned} (\alpha \cdot \beta) &\equiv_{\text{df}} \sim(\sim \alpha \vee \sim \beta) \\ (\alpha \supset \beta) &\equiv_{\text{df}} (\sim \alpha \vee \beta) \\ (\alpha \equiv \beta) &\equiv_{\text{df}} [(\alpha \supset \beta) \cdot (\beta \supset \alpha)] \end{aligned}$$

in which  $\alpha$  and  $\beta$  are any *wff*s of PC. These definitions are not themselves *wff*s of PC, nor is  $\equiv_{\text{df}}$  a symbol of PC; they are metalingual statements about PC, used to introduce the new symbols  $\cdot$ ,  $\supset$ , and  $\equiv$  into the system. If PC is regarded as a purely uninterpreted system, the expression on the left in a definition is simply a convenient abbreviation of the expression on the right. If, however, PC is thought of as having its standard interpretation, the meanings of  $\sim$  and  $\vee$  will first of all have been stipulated by truth tables, and then the definitions will lay it down that the expression on the left is to be understood as having the same meaning (*i.e.*, the same truth table) as the expression on the right. It is easy to check that the truth tables obtained in this way for  $\cdot$ ,  $\supset$ , and  $\equiv$  are precisely the ones that were originally stipulated for them.

An alternative to taking  $\sim$  and  $\vee$  as primitive is to take  $\sim$  and  $\cdot$  as primitive and to define  $(\alpha \vee \beta)$  as  $\sim(\sim \alpha \cdot \sim \beta)$ , to define  $(\alpha \supset \beta)$  as  $\sim(\alpha \cdot \sim \beta)$ , and to define  $(\alpha \equiv \beta)$  as before. Yet another possibility is to take  $\sim$  and  $\supset$  as primitive and to define  $(\alpha \vee \beta)$  as  $(\sim \alpha \supset \beta)$ ,  $(\alpha \cdot \beta)$  as  $\sim(\alpha \supset \sim \beta)$ , and  $(\alpha \equiv \beta)$  as before. In each case, precisely the same *wff*s that were valid in the original presentation of the system are still valid.

**Axiomatization of PC.** The basic idea of constructing an *axiomatic system* is that of choosing certain *wff*s (known as *axioms*) as starting points and giving rules for deriving further *wff*s (known as *theorems*) from them. Such rules are called *transformation rules*. Sometimes the word “theorem” is used to cover axioms as well as theorems; the word “thesis” is also used for this purpose.

An *axiomatic basis* consists of:

- (1) A list of primitive symbols, together with any definitions that may be thought convenient;
- (2) A set of formation rules, specifying which sequences of symbols are to count as *wff*s;
- (3) A list of *wff*s selected as axioms;
- (4) A set of (one or more) transformation rules, which enable new *wff*s (theorems) to be obtained by performing certain specified operations on axioms or previously obtained theorems.

Definitions, where they occur, can function as additional transformation rules, to the effect that, if in any theorem any expression of the form occurring on one side of a definition is replaced by the corresponding expression of the form occurring on the other side, the result is also to count as a theorem. A *proof* or *derivation* of a *wff*  $\alpha$  in an axiomatic system  $S$  is a sequence of *wff*s of which the last is  $\alpha$  itself and each *wff* in the sequence is either an axiom of  $S$  or is derived from some axiom(s) or some already-derived theorem(s) or both by one of the transformation rules of  $S$ . A *wff* is a theorem of  $S$  if and only if there is a proof of it in  $S$ .

Care is usually taken, in setting out an axiomatic basis, to avoid all reference to interpretation. It must be possible to tell purely from the construction of a *wff* whether it is an axiom or not. Moreover, the transformation rules must be so formulated that there is an effective way of telling whether any purported application of them is a correct application or not and hence whether a purported proof of a theorem really is a proof or not. An axiomatic system will then be a purely formal structure, on which any one of a number of interpretations, or none at all, may be imposed without affecting the question of which *wff*s are theorems. Normally, however, an axiomatic system is constructed with a certain interpretation in mind; the transformation rules are so formulated that under that interpretation they are *validity-preserving* (*i.e.*, the results of applying them to valid *wff*s are always themselves valid *wff*s); and the chosen axioms either are valid *wff*s or are expressions of principles of which it is desired to explore the consequences.

Probably the best known axiomatic system for PC is the following one, which, since it is derived from *Principia Mathematica*, by Alfred North Whitehead and Bertrand Russell (published in 1910), is often called PM:

*Primitive symbols:*  $\sim$ ,  $\vee$ ,  $($ ,  $)$ , and an infinite set of variables,  $p$ ,  $q$ ,  $r$ , . . . (with or without numerical subscripts). *Definitions* of  $\cdot$ ,  $\supset$ ,  $\equiv$  as above (II. *Interdefinability of operators*). *Formation rules* as above (II. *Formation rules for PC*), except that Rule 3 can be abbreviated to “If  $\alpha$  and  $\beta$  are *wff*s,  $(\alpha \vee \beta)$  is a *wff*,” since  $\cdot$ ,  $\supset$ , and  $\equiv$  are not primitive. *Axioms:*

- (1)  $(p \vee p) \supset p$ ; (3)  $(p \vee q) \supset (q \vee p)$ ;
- (2)  $q \supset (p \vee q)$ ; (4)  $(q \supset r) \supset [(p \vee q) \supset (p \vee r)]$ .

Axiom (4) can be read “If  $q$  implies  $r$ , then, if either  $p$  or  $q$ , either  $p$  or  $r$ .” *Transformation rules:* (1) The result of uniformly replacing any variable in a theorem by any *wff* is a theorem (*rule of substitution*); and (2) if  $\alpha$  and  $(\alpha \supset \beta)$  are theorems, then  $\beta$  is a theorem (*rule of detachment*, or *modus ponens*).

Relative to a given criterion of validity, an axiomatic system is *sound* if every theorem is valid, and it is *complete* (or, more specifically, *weakly complete*) if every valid *wff* is a theorem. The axiomatic system PM can be shown to be both sound and complete relative to the criterion of validity given in II. *Validity in PC*.

An axiomatic system is *consistent* if, whenever a *wff*  $\alpha$  is a theorem,  $\sim \alpha$  is not a theorem. (In terms of the standard interpretation, this means that no pair of theorems can ever be derived one of which is the negation of the other.) It is *strongly complete* if the addition to it (as an

Axiomatic basis and interpretation

Alternative primitives

Properties of an axiomatic system: PM

extra axiom) of any *wff* whatever that is not already a theorem would make the system inconsistent. Finally, an axiom or transformation rule is *independent* (in a given axiomatic system) if it cannot be derived from the remainder of the basis (or—what comes to the same thing—if its omission from the basis would make the derivation of certain theorems impossible). It can, moreover, be shown that PM is consistent and strongly complete and that each of its axioms and transformation rules is independent.

A considerable number of other axiomatic bases for PC, each having all of the above properties, are known. The task of proving that they have these properties belongs to metalogic (*q.v.*).

Axiom schemata

In some standard expositions of formal logic, the place of axioms is taken by *axiom schemata*, which, instead of presenting some particular *wff* as an axiom, lay it down that any *wff* of a certain form is an axiom. For example, in place of Axiom (1) in PM one might have the axiom schema "Every *wff* of the form  $(\alpha \vee \alpha) \supset \alpha$  is an axiom"; and analogous schemata can be substituted for the other axioms. The number of axioms would then become infinite; but, on the other hand, the *rule of substitution* would no longer be needed and *modus ponens* could be the only transformation rule. This method makes no difference to the theorems that can be derived; but in some branches of logic (though not in PC), it is simpler to work with axiom schemata rather than with particular axioms and substitution rules. Having an infinite number of axioms causes no trouble provided that there is an effective way of telling whether a *wff* is an axiom or not.

**SPECIAL SYSTEMS OF PC**

**Partial systems of PC.** Various propositional calculi have been devised to express a narrower range of truth functions than those of PC as expounded above. Of these, the one that has been most fully studied is the Pure Implicational Calculus (PIC), in which the only operator is  $\supset$ , and the *wff*'s are precisely those *wff*'s of PC that can be built up from variables,  $\supset$ , and brackets alone. Formation rules 2 and 3 of II. *Formation rules for PC* are therefore replaced by the rule that if  $\alpha$  and  $\beta$  are *wff*'s,  $(\alpha \supset \beta)$  is a *wff*. As in ordinary PC,  $p \supset q$  is interpreted as "*p* materially implies *q*"; *i.e.*, as true except when *p* is true but *q* false. The truth-table test of validity can then be straightforwardly applied to *wff*'s of PIC.

The task of axiomatizing PIC is that of finding a set of valid *wff*'s, preferably few in number and relatively simple in structure, from which all other valid *wff*'s of the system can be derived by straightforward transformation rules. The best-known basis, which was formulated in 1930, has the transformation rules of *substitution* and *modus ponens* (as in PM), and the axioms:

- (1)  $p \supset (q \supset p)$
- (2)  $[(p \supset q) \supset p] \supset p$
- (3)  $(p \supset q) \supset [(q \supset r) \supset (p \supset r)]$

Axioms (1) and (3) are closely related to axioms (2) and (4) of PM respectively (see above, II. *Axiomatization of PC*). It can be shown that the basis is complete and that each axiom is independent.

Under the standard interpretation the above axioms can be thought of as expressing the following principles: (1) "If a proposition *p* is true, then if some arbitrary proposition *q* is true, *p* is (still) true." (2) "If the fact that a certain proposition *p* implies some arbitrary proposition *q* implies that *p* itself is true, then *p* is (indeed) true." (3) "If one proposition (*p*) implies a second (*q*), then if that second proposition implies a third (*r*), the first implies the third." The completeness of the basis is, however, a formal matter, not dependent on these or any other readings of the formulas.

An even more economical complete basis for PIC contains the same transformation rules but the sole axiom

$$[(p \supset q) \supset r] \supset [(r \supset p) \supset (s \supset p)].$$

It has been proved that this is the shortest possible single axiom that will give a complete basis for PIC with these transformation rules.

Since PIC contains no negation sign, the previous account of consistency is not significantly applicable to it. Alternative accounts of consistency have, however, been proposed, according to which a system is consistent (a) if no *wff* consisting of a single variable is a theorem, or (b) if not every *wff* is a theorem. The bases stated are consistent in these senses.

**Nonstandard versions of PC.** Qualms have sometimes been expressed about the intuitive soundness of some formulas that are valid in "orthodox" PC, and these qualms have led some logicians to construct a number of propositional calculi that deviate in various ways from PC as expounded above.

Underlying ordinary PC is the intuitive idea that every proposition is either true or false, an idea that finds its formal expression in the stipulation that variables shall have two possible values only, *viz.*, 1 and 0. (For this reason the system is often called the *two-valued* propositional calculus.) This idea has been challenged on various grounds. Following a suggestion made by Aristotle, some logicians have maintained that propositions about those events in the future that may or may not come to pass are neither true nor false but "neuter" in truth value. Aristotle's own example, which has been discussed frequently down to the present day, is "There will be a sea-battle tomorrow." It has also been maintained that for propositions with subjects that do not have anything actual corresponding to them—such as "The present King of France is wise" (assuming that France has no king) or "All John's children are asleep" (assuming that John has no children)—the question of truth or falsity "does not arise." Yet another view is that a third truth value (say "half-truth") ought to be recognized intermediate between truth and falsity; thus it has been held that certain familiar states of the weather make the proposition "It is raining" neither definitely true nor definitely false but something in between.

**Three-valued logics.** The issues raised by the above examples no doubt differ significantly; but they all suggest a threefold rather than a twofold division of propositions and hence the possibility of a logic in which the variables may take any of three values (say 1, 1/2, and 0), with a consequent revision of the standard PC account of validity. Several such three-valued logics have been constructed and investigated; a brief account will be given here of one of them, in which the most natural interpretation of the additional value (1/2) is as "half-true," with 1 and 0 representing truth and falsity as before. The formation rules are as they were for orthodox PC, but the meaning of the operators is extended to cover cases in which at least one argument has the value 1/2, by the following five entries in Table 4. (Adopting one of the

The true-false dichotomy: its problems

**Table 4: Truth Values for Common Operators in a Three-Valued Logic**

	negation ( $\sim p$ )	conjunction ( $p \cdot q$ ) <i>q</i>	disjunction ( $p \vee q$ ) <i>q</i>	implication ( $p \supset q$ ) <i>q</i>	equivalence ( $p = q$ ) <i>q</i>
		1 1/2 0	1 1/2 0	1 1/2 0	1 1/2 0
1	0	1 1/2 0	1 1 1	1 1/2 0	1 1/2 0
1/2	1/2	1/2 1/2 0	1 1/2 1/2	1 1 1/2	1 1/2 1/2
0	1	0 0 0	1 1/2 0	1 1 1	0 1/2 1

three values of the first argument, *p*, given in the leftmost column [1, 1/2, or 0] and, for the dyadic operators, one of the three values of the second, *q*, in the top row—above the line—one then finds the value of the whole formula by reading across for *p* and down for (*q*.) It will be seen that these tables, which are from Łukasiewicz, are the same as the ordinary two-valued ones when the arguments have the values 1 and 0. The other values are intended to be intuitively plausible extensions of the principles underlying the two-valued calculus to cover the cases involving half-true arguments. Clearly, these tables enable a person to calculate a determinate value (1, 1/2, or 0) for any *wff*, given the values assigned to the variables in it; and a *wff* is valid in this calculus if it has the value 1 for every assignment to

Validity of *wff*'s in three-valued logic

its variables. Since the values of formulas when the variables are assigned only the values 1 and 0 are the same as in ordinary PC, every *wff* that is valid in the present calculus is also valid in PC. Some *wff*'s that are valid in PC are, however, now no longer valid. An example is  $(p \vee \sim p)$ , which, when  $p$  has the value  $\frac{1}{2}$ , also has the value  $\frac{1}{2}$ . This reflects the idea that if one admits the possibility of a proposition's being half-true, he can no longer hold of every proposition without restriction that either it or its negation is true.

Given the above tables for the operators, it is possible to take  $\sim$  and  $\supset$  as primitive and to define  $(\alpha \vee \beta)$  as  $[(\alpha \supset \beta) \supset \beta]$ —though not as  $(\sim \alpha \supset \beta)$  as in ordinary PC;  $(\alpha \cdot \beta)$  as  $\sim(\sim \alpha \vee \sim \beta)$ ; and  $(\alpha \equiv \beta)$  as  $[(\alpha \supset \beta) \cdot (\beta \supset \alpha)]$ . With these definitions as given, all valid *wff*'s constructed from variables and  $\sim, \cdot, \vee, \supset,$  and  $\equiv$  can be derived by *substitution* and *modus ponens* from the four axioms:

- (1)  $p \supset (q \supset p)$ ;
- (2)  $(p \supset q) \supset [(q \supset r) \supset (p \supset r)]$ ;
- (3)  $[(p \supset \sim p) \supset p] \supset p$ ;
- (4)  $(\sim p \supset \sim q) \supset (q \supset p)$ .

Other three-valued logics can easily be constructed. For example, the above tables might be modified so that  $\sim \frac{1}{2}, \frac{1}{2} \supset 0, \frac{1}{2} \equiv 0,$  and  $0 \equiv \frac{1}{2}$  all have the value 0 instead of  $\frac{1}{2}$  as before, leaving everything else unchanged. The same definitions are then still possible, but the list of valid formulas is different; e.g.,  $\sim \sim p \supset p$ , which was previously valid, now has the value  $\frac{1}{2}$  when  $p$  has the value  $\frac{1}{2}$ . This system can also be successfully axiomatized. Other calculi with more than three values can also be constructed along analogous lines.

*Intuitionistic calculus.* Other nonstandard calculi have been constructed by beginning with an axiomatization instead of a definition of validity. Of these the best known is the *intuitionistic calculus*, devised by Arend Heyting, one of the chief representatives of the Intuitionist school of mathematicians, which denies the validity of certain types of proof used in classical mathematics. At least in certain contexts, members of this school regard the demonstration of the falsity of the negation of a proposition (a proof by *reductio ad absurdum*) as insufficient to establish the truth of the proposition in question. Thus they regard  $\sim \sim p$  as an inadequate premise from which to deduce  $p$  and hence do not accept the validity of the *law of double negation* in the form  $\sim \sim p \supset p$ . They do, however, regard a demonstration that  $p$  is true as showing that the negation of  $p$  is false and hence accept  $p \supset \sim \sim p$  as valid. For somewhat similar reasons, they also refuse to accept the validity of arguments based on the *law of excluded middle* ( $p \vee \sim p$ ). The intuitionistic calculus aims at presenting in axiomatic form those and only those principles of propositional logic that are accepted as sound in intuitionist mathematics. In this calculus,  $\sim, \cdot, \vee,$  and  $\supset$  are all primitive, the transformation rules as before are *substitution* and *modus ponens*, and the axioms are the following:

- (1)  $p \supset (p \cdot p)$
- (2)  $(p \cdot q) \supset (q \cdot p)$
- (3)  $(p \supset q) \supset [(p \cdot r) \supset (q \cdot r)]$
- (4)  $[(p \supset q) \cdot (q \supset r)] \supset (p \supset r)$
- (5)  $p \supset (q \supset p)$
- (6)  $[p \cdot (p \supset q)] \supset q$
- (7)  $p \supset (p \vee q)$
- (8)  $(p \vee q) \supset (q \vee p)$
- (9)  $[(p \supset r) \cdot (q \supset r)] \supset [(p \vee q) \supset r]$
- (10)  $\sim p \supset (p \supset q)$
- (11)  $[(p \supset q) \cdot (p \supset \sim q)] \supset \sim p$

From this basis neither  $p \vee \sim p$  nor  $\sim \sim p \supset p$  can be derived, though  $p \supset \sim \sim p$  can. In this respect this calculus resembles the second of the three-valued logics described above. It is, however, not possible to give a truth table account of validity—no matter how many values are used—that will bring out as valid precisely those *wff*'s that are theorems of the intuitionistic calculus and no others (see also MATHEMATICS, FOUNDATIONS OF: *The crisis in foundations following 1900: Intuitionism*).

Dubious logical principles

NATURAL DEDUCTION METHOD IN PC

PC is often presented by what is known as the method of *natural deduction*. Essentially this consists of a set of rules for drawing conclusions from hypotheses (assumptions, premises) represented by *wff*'s of PC and thus for constructing valid inference forms; but it also provides a method of deriving from these inference forms valid proposition forms, and in this way it is analogous to the derivation of theorems in an axiomatic system. One such set of rules is presented in Table 5 (and there are various other sets that yield the same results):

rule	given	one may then conclude
1. Modus ponens	$\alpha$ and $\alpha \supset \beta$	$\beta$
2. Modus tollens	$\sim \beta$ and $\alpha \supset \beta$	$\sim \alpha$
3. Double negation	$\alpha$	$\sim \sim \alpha$
	$\sim \sim \alpha$	$\alpha$
4. Conjunction introduction	$\alpha$ and $\beta$	$\alpha \cdot \beta$
5. Conjunction elimination	$\alpha \cdot \beta$	$\alpha$ and also $\beta$
6. Disjunction introduction	either $\alpha$ or $\beta$ separately	$\alpha \vee \beta$
7. Disjunction elimination	$\alpha \vee \beta$ , a derivation of $\gamma$ from $\alpha$ , and a derivation of $\gamma$ from $\beta$	$\gamma$
8. Conditional proof	a derivation of $\beta$ from the hypothesis $\alpha$ (perhaps with the help of other hypotheses)	$\alpha \supset \beta$ as a conclusion from these other hypotheses (if any)
9. Reductio ad absurdum	a derivation of $\beta \cdot \sim \beta$ from the hypothesis $\alpha$ (perhaps with the help of other hypotheses)	$\sim \alpha$ as a conclusion from these other hypotheses (if any)

A natural deduction proof is a sequence of *wff*'s beginning with one or more *wff*'s as hypotheses; fresh hypotheses may also be added at any point in the course of a proof. The rules may be applied to any *wff* or group of *wff*'s, as appropriate, that have already occurred in the sequence. In the case of rules 1–7, the conclusion is said to *depend on* all of those hypotheses that have been used in the series of applications of the rules that have led to this conclusion; i.e., it is claimed simply that the conclusion follows from these hypotheses, not that it holds in its own right. An application of rule 8 or rule 9, however, reduces by one the number of hypotheses on which the conclusion depends; and a hypothesis so eliminated is said to be a *discharged hypothesis*. In this way a *wff* may be reached that depends on no hypotheses at all. Such a *wff* is a *theorem*. It can be shown that the theorems derivable by the rules stated above—together with the definition of  $\alpha \equiv \beta$  as  $(\alpha \supset \beta) \cdot (\beta \supset \alpha)$ —are precisely the valid *wff*'s of PC. A set of natural deduction rules yielding as theorems all of the valid *wff*'s of a system is *complete* (with respect to that system) in a sense obviously analogous to that in which an axiomatic basis was said to be complete in II. *Axiomatization of PC*.

As an illustration, the formula  $[(p \supset q) \cdot (p \supset r)] \supset [p \supset (q \cdot r)]$  will be derived as a theorem by the natural deduction method. (The sense of this formula is that, if a proposition  $[p]$  implies each of two other propositions  $[q, r]$ , then it implies their conjunction.) Explanatory comments follow the proof.

1	(1)	$(p \supset q) \cdot (p \supset r)$	hypothesis
2	(2)	$p$	hypothesis
1	(3)	$p \supset q$	1, conjunction elimination
1	(4)	$p \supset r$	1, conjunction elimination
1,2	(5)	$q$	2,3, <i>modus ponens</i>
1,2	(6)	$r$	2,4, <i>modus ponens</i>
1,2	(7)	$q \cdot r$	5,6, conjunction introduction
1	(8)	$p \supset (q \cdot r)$	2,7, conditional proof
	(9)	$[(p \supset q) \cdot (p \supset r)] \supset [p \supset (q \cdot r)]$	1,8, conditional proof

Rules of inference and their application

Sample proof of a theorem

The figures in parentheses immediately preceding the *wff*'s are simply for reference. To the right is indicated either that the *wff* is a hypothesis or that it is derived

from the *wff*'s indicated by the rules stated. On the left are noted the hypotheses on which the *wff* in question depends (either the first or the second line of the derivation, or both). Note that since (8) is derived by *conditional proof* from hypothesis (2) and from (7), which is itself derived from hypotheses (1) and (2), (8) depends only on hypothesis (1), and hypothesis (2) is discharged. Similarly (9) depends on no hypotheses and is therefore a theorem.

By varying the above rules it is possible to obtain natural deduction systems corresponding to other versions of PC. For example, if the second part of the *double negation* rule is omitted and the rule is added that, given  $\alpha \cdot \sim \alpha$ , one may then conclude:  $\beta$ , it can be shown that the theorems then derivable are precisely the theorems of the Intuitionistic Calculus. Natural deduction rules have also been formulated for some other branches of logic mentioned in this article—*e.g.*, for the lower predicate calculus (III.) and for various systems of modal logic (IV. *Alternative systems of modal logic*).

**III. The predicate calculus**

Propositions may also be built up, not out of other propositions but out of elements that are not themselves propositions. The simplest kind to be considered here are propositions in which a certain object or individual (in a wide sense) is said to possess a certain property or characteristic; examples are: "Socrates is wise" and "The number 7 is prime." Such a proposition contains two distinguishable parts: (1) an expression that names or designates an individual and (2) an expression, called a *predicate*, that stands for the property that the individual in question is said to possess. If  $x, y, z, \dots$  are used as individual variables (replaceable by names of individuals) and the symbols  $\phi$  (phi),  $\psi$  (psi),  $\chi$  (chi),  $\dots$  as predicate variables (replaceable by predicates), the formula  $\phi x$  is used to express the form of the propositions in question. Here  $x$  is said to be the *argument* of  $\phi$ ; a predicate (or predicate variable) with only a single argument is said to be a *monadic*, or *one-place*, predicate (variable). Predicates with two or more arguments stand not for properties of single individuals but for relations between individuals. Thus the proposition "Tom is a son of John" is analyzable into two names of individuals ("Tom" and "John") and a dyadic or two-place predicate ("is a son of"), of which they are the arguments; and the proposition is thus of the form  $\phi xy$ . Analogously, " $\dots$  is between  $\dots$  and  $\dots$ " is a three-place predicate, requiring three arguments, and so on. In general, a predicate variable followed by any number of individual variables is a *wff* of the predicate calculus. Such a *wff* is known as an *atomic* formula, and the predicate variable in it is said to be of *degree n*, if  $n$  is the number of individual variables following it. The degree of a predicate variable is sometimes indicated by a superscript—*e.g.*,  $\phi xyz$  may be written as  $\phi^3xyz$ ;  $\phi^2xy$  would then be regarded as not well formed. This practice is theoretically more accurate, but the superscripts are commonly omitted for ease of reading when no confusion is likely to arise.

Atomic formulas may be combined with truth-functional operators to give formulas such as  $\phi x \vee \psi y$  [Example: "Either the customer ( $x$ ) is friendly ( $\phi$ ) or else John ( $y$ ) is disappointed ( $\psi$ )"];  $\phi xy \supset \sim \psi x$  [Example: "If the road ( $x$ ) is above ( $\phi$ ) the flood line ( $y$ ), then the road is not wet ( $\sim \psi$ )"]; and so on. Formulas so formed, however, are valid when and only when they are substitution-instances of valid *wff*'s of PC and hence in a sense do not transcend PC. More interesting formulas are formed by the use, in addition, of *quantifiers*. There are two kinds of quantifiers: *universal* quantifiers, written as " $(\forall \_)$ "—or often simply as " $(\_)$ "—where the blank is filled by a variable, which may be read "For all $\_$ "; and *existential* quantifiers, written as " $(\exists \_)$ ," which may be read "For some $\_$ ," or "There is a  $\_$  such that." ("Some" is to be understood as meaning "at least one.") Thus  $(\forall x)\phi x$  is to mean "For all  $x, x$  is  $\phi$ ," or more simply, "Everything is  $\phi$ "; and  $(\exists x)\phi x$  is to mean "For some  $x, x$  is  $\phi$ ," or more simply, "Something is  $\phi$ ," or "There is a  $\phi$ ." Slightly more complex examples are:  $(\forall x)(\phi x \supset \psi x)$  for "Whatever is  $\phi$  is  $\psi$ ";  $(\exists x)(\phi x \cdot \psi x)$

for "Something is both  $\phi$  and  $\psi$ ";  $(\forall x)(\exists y)\phi xy$  for "Everything bears the relation  $\phi$  to at least one thing"; and  $(\exists x)(\forall y)\phi xy$  for "There is something that bears the relation  $\phi$  to everything." To take a concrete case, if  $\phi xy$  means " $x$  loves  $y$ ," and the values of  $x$  and  $y$  are taken to be human beings, then the last two formulas mean, respectively, "Everybody loves somebody" and "Somebody loves everybody."

Intuitively, the notions expressed by the words "some" and "every" are connected in the following way: to assert that something has a certain property amounts to denying that everything lacks that property (for example, to say that something is white is to say that not everything is nonwhite); and similarly, to assert that everything has a certain property amounts to denying that there is something that lacks it. These intuitive connections are reflected in the usual practice of taking one of the quantifiers as primitive and defining the other in terms of it. Thus  $\forall$  may be taken as primitive, and  $\exists$  introduced by the definition:

$$(\exists a)\alpha =_{Df} \sim(\forall a)\sim\alpha$$

in which  $a$  is any variable and  $\alpha$  is any *wff*; or alternatively,  $\exists$  may be taken as primitive, and  $\forall$  introduced by the definition:

$$(\forall a)\alpha =_{Df} \sim(\exists a)\sim\alpha$$

**THE LOWER PREDICATE CALCULUS**

A predicate calculus in which the only variables that occur in quantifiers are individual variables is known as a *lower* (or *first-order*) predicate calculus. Various lower predicate calculi have been constructed. In the most straightforward of these, to which the most attention will here be devoted and which will be referred to simply as LPC, the *wff*'s can be specified as follows: Let the primitive symbols be (a)  $x, y, \dots$  (individual variables); (b)  $\phi, \psi, \dots$ , each of some specified degree (predicate variables); and (c) the symbols  $\sim, \vee, \forall, (, \text{ and } )$ . An infinite number of each type of variable can now be secured as before by the use of numerical subscripts. The symbols  $\cdot, \supset, \text{ and } \equiv$  are defined as in PC and  $\exists$  as explained above. The formation rules are:

1. An expression consisting of a predicate variable of degree  $n$  followed by  $n$  individual variables is a *wff*.
2. If  $\alpha$  is a *wff*, so is  $\sim\alpha$ .
3. If  $\alpha$  and  $\beta$  are *wff*'s, so is  $(\alpha \vee \beta)$ .
4. If  $\alpha$  is a *wff* and  $a$  is an individual variable, then  $(\forall a)\alpha$  is a *wff*. (In such a *wff*,  $\alpha$  is said to be the *scope* of the quantifier.)

If  $a$  is any individual variable and  $\alpha$  is any *wff*, every occurrence of a  $a$  in  $\alpha$  is said to be *bound* (by the quantifiers) when occurring in the *wff*'s  $(\forall a)\alpha$  and  $(\exists a)\alpha$ . Any occurrence of a variable that is not bound is said to be *free*. Thus in  $(\forall x)(\phi x \vee \phi y)$ —the  $x$  in  $\phi x$  is bound, since it occurs within the scope of a quantifier containing  $x$ , but  $y$  is free. In the *wff*'s of a lower predicate calculus, every occurrence of a predicate variable ( $\phi, \psi, \chi, \dots$ ) is free. A *wff* containing no free individual variables is said to be a *closed wff* of LPC. If a *wff* of LPC is considered as a proposition form, instances of it are obtained by replacing all free variables in it by predicates or by names of individuals, as appropriate. A bound variable, on the other hand, indicates not a point in the *wff* where a replacement is needed but a point (so to speak) at which the relevant quantifier applies.

For example, in  $\phi x$ , in which both variables are free, each variable must be replaced appropriately if a proposition of the form in question (such as "Socrates is white") is to be obtained; but in  $(\exists x)\phi x$ , in which  $x$  is bound, it is necessary only to replace  $\phi$  by a predicate in order to obtain a complete proposition (*e.g.*, replacing  $\phi$  by "is white" yields the proposition "Something is white").

**Validity in LPC.** Intuitively, a *wff* of LPC is valid if and only if all of its instances are true—*i.e.*, if and only if every result of replacing each of its free variables appropriately and uniformly is a true proposition. A formal definition of validity in LPC to express this intuitive notion more precisely can be given as follows: for any *wff* of LPC any number of LPC *models* can be formed. An

Fundamental definitions

Quantifiers  $\forall$  and  $\exists$

Bound and free variables

Value assignments in the domain of a model

LPC model has two elements: One is a set,  $D$ , of objects, known as a *domain*.  $D$  may contain as many or as few objects as one chooses, but it must contain at least one, and the objects may be of any kind. The other element,  $V$ , is a system of value assignments satisfying the following conditions. To each individual variable there is assigned some member of  $D$  (not necessarily a different one in each case). Assignments are next made to the predicate variables in the following way: if  $\phi$  is monadic, there is assigned to it some subset of  $D$  (possibly the whole of  $D$ ); intuitively this subset can be viewed as the set of all the objects in  $D$  that have the property  $\phi$ . If  $\phi$  is dyadic, there is assigned to it some set of ordered pairs (*i.e.*, pairs of objects of which one is marked out as the first and the other as the second) drawn from  $D$ ; intuitively these can be viewed as all of the pairs of objects in  $D$  in which the relation  $\phi$  holds between the first object in the pair and the second. In general, if  $\phi$  is of degree  $n$ , there is assigned to it some set of ordered  $n$ -tuples (groups of  $n$  objects) of members of  $D$ . It is then stipulated that an atomic formula is to have the value 1 in the model if the members of  $D$  assigned to its individual variables form, in that order, one of the  $n$ -tuples assigned to the predicate variable in it; otherwise, it is to have the value 0. Thus in the simplest case,  $\phi x$  will have the value 1 if the object assigned to  $x$  is one of the set of objects that was assigned to  $\phi$ ; and if it is not, then  $\phi x$  will have the value 0. The values of truth functions are determined by the values of their arguments as in PC. Finally, the value of  $(\forall x)\alpha$  is to be 1 if both (a) the value of  $\alpha$  itself is 1 and (b)  $\alpha$  would always still have the value 1 if a different assignment were made to  $x$  but all of the other assignments were left precisely as they were; otherwise  $(\forall x)\alpha$  is to have the value 0. Since  $\exists$  can be defined in terms of  $\forall$ , these rules cover all of the *wff*'s of LPC. A given *wff* may of course have the value 1 in some LPC models but the value 0 in others. But a valid *wff* of LPC may now be defined as one that has the value 1 in every LPC model. If 1 and 0 are viewed as representing truth and falsity, respectively, then validity is defined as truth in every model.

Although the above definition of validity in LPC is quite precise, it does not yield, as did the corresponding definition of PC validity in terms of truth tables, an effective decision procedure. It can, indeed, be shown that no generally applicable decision procedure for LPC is possible—*i.e.*, that LPC is not a decidable system. This does not mean that it is never possible to prove that a given *wff* of LPC is valid—the validity of an unlimited number of such *wff*'s can in fact be demonstrated—but it does mean that in the case of LPC, unlike that of PC, no advance assurance can be given that no matter what *wff* is produced it will always be possible to determine whether it is valid or not (see also METALOGIC: *Model theory*).

**Logical manipulations in LPC.** The intuitive connections between *some* and *every* noted at the end of the introduction to III. *The predicate calculus* are reflected in the fact that the following equivalences are valid:

$$\begin{aligned} (\exists x)\phi x &\equiv \sim(\forall x)\sim\phi x \\ (\forall x)\phi x &\equiv \sim(\exists x)\sim\phi x. \end{aligned}$$

The former of these asserts that "Something is  $\phi$ " is equivalent to "Not everything fails to be  $\phi$ ", and the latter that "Everything is  $\phi$ " is equivalent to "Nothing fails to be  $\phi$ " (literally, "It is not the case that there is something which is not  $\phi$ "). These equivalences remain valid when  $\phi x$  is replaced by any *wff*, however complex; *i.e.*, for any *wff*  $\alpha$  whatsoever,

$$(\exists x)\alpha \equiv \sim(\forall x)\sim\alpha$$

and

$$(\forall x)\alpha \equiv \sim(\exists x)\sim\alpha$$

are valid. Because the rule of substitution of equivalents can be shown to hold in LPC, it follows that  $(\exists x)$  may be replaced anywhere in a *wff* by  $\sim(\forall x)\sim$ , or  $(\forall x)$  by  $\sim(\exists x)\sim$ , and the resulting *wff* will be equivalent to the original. Similarly, because the law of double negation permits the deletion of a pair of consecutive negation signs,  $\sim(\exists x)$  may be replaced by  $(\forall x)\sim$ , and  $\sim(\forall x)$  by  $(\exists x)\sim$ .

These principles are easily extended to more complex cases. To say that there is a pair of objects satisfying a certain condition is equivalent to denying that every pair of objects fails to satisfy that condition; and to say that every pair of objects satisfies a certain condition is equivalent to denying that there is any pair of objects that fails to satisfy that condition. These equivalences are expressed formally by the validity, again for any *wff*  $\alpha$ , of:

$$(\exists x)(\exists y)\alpha \equiv \sim(\forall x)(\forall y)\sim\alpha$$

and

$$(\forall x)(\forall y)\alpha \equiv \sim(\exists x)(\exists y)\sim\alpha$$

—and by the resulting replaceability anywhere in a *wff* of  $(\exists x)(\exists y)$  by  $\sim(\forall x)(\forall y)\sim$ , or of  $(\forall x)(\forall y)$  by  $\sim(\exists x)(\exists y)\sim$ .

Analogously,  $(\exists x)(\forall y)$  can be replaced by  $\sim(\forall x)(\exists y)\sim$  [*e.g.*,  $(\exists x)(\forall y)(x \text{ loves } y)$ —"There is someone who loves everyone"—is equivalent to  $\sim(\forall x)(\exists y)\sim(x \text{ loves } y)$ —"It is not true of everyone that there is someone whom he does not love"];  $(\forall x)(\exists y)$  can be replaced by  $\sim(\exists x)(\forall y)\sim$ ; and in general the following rule, covering sequences of quantifiers of any length, holds:

(i) If a *wff* contains an unbroken sequence of quantifiers, then the *wff* that results from replacing  $\forall$  by  $\exists$  and vice versa throughout that sequence and inserting or deleting  $\sim$  at each end of it is equivalent to the original *wff*.

This may be called the *rule of quantifier transformation*. It reflects, in a generalized form, the intuitive connections between *some* and *every* that were noted at the end of the introduction to III. *The predicate calculus*.

The following are also valid, again where  $\alpha$  is any *wff*:

$$\begin{aligned} (\forall x)(\forall y)\alpha &\equiv (\forall y)(\forall x)\alpha \\ (\exists x)(\exists y)\alpha &\equiv (\exists y)(\exists x)\alpha \end{aligned}$$

The extensions of these lead to the following rule:

(ii) If a *wff* contains an unbroken sequence either of universal or of existential quantifiers, these quantifiers may be rearranged in any order and the resulting *wff* will be equivalent to the original *wff*.

This may be called the *rule of quantifier rearrangement*.

Two other important rules concern implications, not equivalences:

(iii) If a *wff*  $\beta$  begins with an unbroken sequence of quantifiers, and  $\beta'$  is obtained from  $\beta$  by replacing  $\forall$  by  $\exists$  at one or more places in the sequence, then  $\beta$  is *stronger* than  $\beta'$ —in the sense that  $(\beta \supset \beta')$  is valid but  $(\beta' \supset \beta)$  is in general not valid.

(iv) If a *wff*  $\beta$  begins with an unbroken sequence of quantifiers in which some existential quantifier  $Q_1$  precedes some universal quantifier  $Q_2$ , and if  $\beta'$  is obtained from  $\beta$  by moving  $Q_1$  to the right of  $Q_2$ , then  $\beta$  is stronger than  $\beta'$ .

As illustrations of these rules, the following are valid for any *wff*  $\alpha$ :

$$\begin{aligned} (\forall x)(\forall y)\alpha \supset (\exists x)(\forall y)\alpha &\quad \text{Rule (iii)} \\ (\exists x)(\forall y)(\forall z)\alpha \supset (\exists x)(\forall y)(\exists z)\alpha &\quad \text{Rule (iii)} \\ (\exists x)(\forall y)\alpha \supset (\forall y)(\exists x)\alpha &\quad \text{Rule (iv)} \\ (\exists x)(\exists y)(\forall z)\alpha \supset (\exists y)(\forall z)(\exists x)\alpha &\quad \text{Rule (iv)} \end{aligned}$$

In each case the converses are not valid (though they may be valid in particular cases in which  $\alpha$  is of some special form).

Some of the uses of the above rules can be illustrated by considering a *wff*  $\alpha$  that contains precisely two free individual variables. By prefixing to  $\alpha$  two appropriate quantifiers and possibly one or more negation signs, it is possible to form a closed *wff* (called a *closure* of  $\alpha$ ) that will express a determinate proposition when a meaning is assigned to the predicate variables. The above rules can be used to list exhaustively the nonequivalent closures of  $\alpha$  and the implication relations between them. The simplest example is  $\phi xy$ , which for illustrative purposes can be taken to mean "x loves y." Application of Rules (i) and (ii) will show that every closure of  $\phi xy$  is equivalent to one or another of the following 12 *wff*'s (none of which is in fact equivalent to any of the others):

- (a)  $(\forall x)(\forall y)\phi xy$  ("Everybody loves everybody");
- (b)  $(\exists x)(\forall y)\phi xy$  ("Somebody loves everybody");
- (c)  $(\exists y)(\forall x)\phi xy$  ("There is someone whom everybody loves");

Application of the rules

Laws concerning quantifiers

- (d)  $(\forall y)(\exists x) \phi xy$  ("Each person is loved by at least one person");
- (e)  $(\forall x)(\exists y) \phi xy$  ("Each person loves at least one person");
- (f)  $(\exists x)(\exists y) \phi xy$  ("Somebody loves somebody");
- (g-1) The respective negations of each of the above.

Rules (iii) and (iv) show that the following implications among formulas (a)–(f) are valid:

- (a)  $\supset$  (b); (d)  $\supset$  (f); (c)  $\supset$  (e);
- (b)  $\supset$  (d); (a)  $\supset$  (c); (e)  $\supset$  (f).

The implications holding among the negations of (a)–(f) follow from these by the *law of transposition*; e.g., since (a)  $\supset$  (b) is valid, so is  $\sim(b) \supset \sim(a)$ . The quantification of *wff*'s containing three, four, etc., variables can be dealt with by the same rules.

Relettering of bound variables

Intuitively,  $(\forall x)\phi x$  and  $(\forall y)\phi y$  both "say the same thing," viz., that everything is  $\phi$ , and  $(\exists x)\phi x$  and  $(\exists y)\phi y$  both mean simply that something is  $\phi$ . Clearly, so long as the same variable occurs both in the quantifier and as the argument of  $\phi$ , it does not matter what letter is chosen for this purpose. The procedure of replacing some variable in a quantifier, together with every occurrence of that variable in its scope, by some other variable that does not occur elsewhere in its scope is known as *relettering a bound variable*. If  $\beta$  is the result of relettering a bound variable in a *wff*  $\alpha$ , then  $\alpha$  and  $\beta$  are said to be *bound alphabetical variants* of each other; and bound alphabetical variants are always equivalent. The reason for restricting the replacement variable to one not occurring elsewhere in the scope of the quantifier can be seen from an example: If  $\phi xy$  is taken as before to mean "x loves y," the *wff*  $(\forall x)\phi xy$  expresses the proposition form "Everyone loves y," in which the identity of y is left unspecified, and so does its bound alphabetical variant  $(\forall z)\phi zy$ ; but if x were replaced by y, the closed *wff*  $(\forall y)\phi yy$  would be obtained, which expresses the proposition that everyone loves himself and is clearly not equivalent to the original.

Prenex normal form

A *wff* in which all of the quantifiers occur in an unbroken sequence at the beginning, with the scope of each extending to the end of the *wff*, is said to be in *prenex normal form* (PNF—Latin: *pre*, "in front"; and *nectere*, "to bind"). *Wff*'s that are in PNF are often more convenient to work with than those that are not. For every *wff* of LPC, however, there is an equivalent *wff* in PNF (often simply called its PNF). One effective method for finding the PNF of any given *wff* is the following:

1. Reletter bound variables as far as is necessary to ensure (a) that each quantifier contains a distinct variable and (b) that no variable in the *wff* occurs both bound and free.
2. Use definitions or PC equivalences to eliminate all operators except  $\sim$ ,  $\cdot$ , and  $\vee$ .
3. Use the *De Morgan laws* and the *rule of quantifier transformation* to eliminate all occurrences of  $\sim$  immediately before parentheses or quantifiers.
4. Gather all of the quantifiers into a sequence at the beginning in the order in which they appear in the *wff* and take the whole of what remains as their scope.

Example:  $(\forall x)\{[\phi x \cdot (\exists y)\psi xy] \supset (\exists y)\chi xy\} \supset (\exists z)(\phi z \supset \psi zx)$ .

Step 1 can be achieved by relettering the third and fourth occurrences of y and every occurrence of x except the last (which is free); thus:

$$(\forall w)\{[\phi w \cdot (\exists y)\psi wy] \supset (\exists u)\chi wu\} \supset (\exists z)(\phi z \supset \psi zx)$$

Step 2 now yields:

$$\sim(\forall w)\{\sim[\phi w \cdot (\exists y)\psi wy] \vee (\exists u)\chi wu\} \vee (\exists z)(\sim\phi z \vee \psi zx)$$

By step 3 this becomes:

$$(\exists w)\{[\phi w \cdot (\exists y)\psi wy] \cdot (\forall u)\sim\chi wu\} \vee (\exists z)(\sim\phi z \vee \psi zx)$$

Finally, step 4 yields:

$$(\exists w)(\exists y)(\forall u)(\exists z)\{[(\phi w \cdot \psi wy) \cdot \sim\chi wu] \vee (\sim\phi z \vee \psi zx)\}$$

which is in PNF.

**Classification of dyadic relations.** Consider the closed *wff*,

$$(\forall x)(\forall y)(\phi xy \supset \phi yx)$$

which means that, whenever the relation  $\phi$  holds between one object and a second, it also holds between that second object and the first. This expression is not valid, since it is true for some relations but false for others. A relation for which it is true is called a *symmetrical* relation. (Example: "is parallel to.") If the relation  $\phi$  is such that whenever it holds between one object and a second it fails to hold between the second and the first; i.e., if  $\phi$  is such that

$$(\forall x)(\forall y)(\phi xy \supset \sim\phi yx)$$

then  $\phi$  is said to be *asymmetrical*. (Example: "is greater than.") A relation that is neither symmetrical nor asymmetrical is said to be *nonsymmetrical*. Thus  $\phi$  is nonsymmetrical if

$$(\exists x)(\exists y)(\phi xy \cdot \phi yx) \cdot (\exists x)(\exists y)(\phi xy \cdot \sim\phi yx)$$

(Example: "loves.")

Dyadic relations can also be characterized in terms of another threefold division: A relation  $\phi$  is said to be *transitive* if, whenever it holds between one object and a second and also between that second object and a third, it holds between the first and the third; i.e., if

$$(\forall x)(\forall y)(\forall z)[(\phi xy \cdot \phi yz) \supset \phi xz]$$

(Example: "is greater than.") An *intransitive* relation is one that, whenever it holds between one object and a second and also between that second and a third, fails to hold between the first and the third; i.e.,  $\phi$  is intransitive if

$$(\forall x)(\forall y)(\forall z)[(\phi xy \cdot \phi yz) \supset \sim\phi xz]$$

(Example: "is father of.") A relation that is neither transitive nor intransitive is said to be *nontransitive*. Thus  $\phi$  is nontransitive if

$$(\exists x)(\exists y)(\exists z)(\phi xy \cdot \phi yz \cdot \phi xz) \cdot (\exists x)(\exists y)(\exists z)(\phi xy \cdot \phi yz \cdot \sim\phi xz)$$

(Example: "is a first cousin of.")

A relation  $\phi$  that always holds between any object and itself is said to be *reflexive*; i.e.,  $\phi$  is reflexive if

$$(\forall x)\phi xx$$

(Example: "is identical with.") If  $\phi$  never holds between any object and itself—i.e., if

$$\sim(\exists x)\phi xx$$

—then  $\phi$  is said to be *irreflexive* (Example: "is greater than.") If  $\phi$  is neither reflexive nor irreflexive—i.e., if

$$(\exists x)\phi xx \cdot (\exists x)\sim\phi xx$$

—then  $\phi$  is said to be *nonreflexive* (Example: "admires.")

A relation such as "is of the same length as" is not strictly reflexive, since some objects do not have a length at all and therefore are not of the same length as anything, even as themselves. Nevertheless, this relation is reflexive in the weaker sense that whenever an object is of the same length as anything it is of the same length as itself. Such a relation is said to be *quasi-reflexive*. Thus  $\phi$  is quasi-reflexive if

$$(\forall x)[(\exists y)\phi xy \supset \phi xx].$$

A reflexive relation is of course also quasi-reflexive.

For the most part, these three classifications are independent of each other; thus a symmetrical relation may be transitive (like "is equal to") or intransitive (like "is perpendicular to") or nontransitive (like "is one mile distant from"). There are, however, certain limiting principles, of which the most important are:

1. Every relation that is symmetrical and transitive is at least quasi-reflexive;
2. Every asymmetrical relation is irreflexive;
3. Every relation that is transitive and irreflexive is asymmetrical.

A relation that is reflexive, symmetrical, and transitive is called an *equivalence* relation.

Symmetry, transitivity, reflexivity

Axiomatic basis and undecidability of theorems

**Axiomatization of LPC.** Rules of uniform substitution for predicate calculi, though formulable, are mostly very complicated; and, to avoid the necessity for these rules, axioms for these systems are therefore usually given by axiom schemata in the sense explained in II. *Axiomatization of PC.* Given the formation rules and definitions stated in the introductory paragraph of III. *The lower predicate calculus*, the following is presented as one standard axiomatic basis for LPC:

*Axiom schemata:*

1. Any LPC substitution-instance of any valid *wff* of PC is an axiom.

2. Any *wff* of the form  $(\forall a)\alpha \supset \beta$  is an axiom, if  $\beta$  is either identical with  $\alpha$  or differs from it only in that, wherever  $\alpha$  has a free occurrence of  $a$ ,  $\beta$  has a free occurrence of some other individual variable  $b$ .

3. Any *wff* of the form  $(\forall a)(\alpha \supset \beta) \supset [\alpha \supset (\forall a)\beta]$  is an axiom, provided that  $\alpha$  contains no free occurrence of  $a$ .

*Transformation rules:*

1. *Modus ponens* (as given above, II. *Axiomatization of PC*).

2. If  $\alpha$  is a theorem, so is  $(\forall a)\alpha$ , where  $a$  is any individual variable (*rule of universal generalization*).

The axiom schemata call for some explanation and comment. By an LPC substitution-instance of a *wff* of PC is meant any result of uniformly replacing every propositional variable in that *wff* by a *wff* of LPC. Thus one LPC substitution-instance of  $(p \supset \sim q) \supset (q \supset \sim p)$  is  $[\phi xy \supset \sim(\forall x)\psi x] \supset [(\forall x)\psi x \supset \sim\phi xy]$ . Axiom schema 1 makes available in LPC all manipulations such as commutation, transposition, and distribution, which depend only on PC principles. Examples of *wff*'s that are axioms by axiom schema 2 are:  $(\forall x)\phi x \supset \phi x$ ;  $(\forall x)\phi x \supset \phi y$ ;  $(\forall x)(\exists y)\phi xy \supset (\exists y)\phi zy$ . To see why it is necessary for the variable that replaces  $a$  to be free in  $\beta$ , consider the last example: Here  $a$  is  $x$ ,  $\alpha$  is  $(\exists y)\phi xy$ , in which  $x$  is free, and  $\beta$  is  $(\exists y)\phi zy$ , in which  $z$  is free and replaces  $x$ . But had  $y$ , which would be bound by the quantifier  $(\exists y)$ , been chosen as a replacement, instead of  $z$ , the result would have been  $(\forall x)(\exists y)\phi xy \supset (\exists y)\phi yy$ , the invalidity of which can be seen intuitively by taking  $\phi xy$  to mean "x is a child of y": for then  $(\forall x)(\exists y)\phi xy$  will mean that everyone is a child of someone, which is true; but  $(\exists y)\phi yy$  will mean that someone is a child of himself, which is false. The need for the proviso in axiom schema 3 can also be seen from an example. Defiance of the proviso would give as an axiom  $(\forall x)(\phi x \supset \psi x) \supset [\phi x \supset (\forall x)\psi x]$ ; and if  $\phi x$  were taken to mean "x is a Spaniard,"  $\psi x$  to mean "x is a European," and the free occurrence of  $x$  (the first occurrence in the consequent) to stand for General Franco, then the antecedent would mean that every Spaniard is a European, but the consequent would mean that, if General Franco is a Spaniard, then everyone is a European.

It can be proved—though the proof is not an elementary one—that the theorems derivable from the above basis are precisely the *wff*'s of LPC that are valid by the definition of validity given in III. *Validity in LPC.* Several other bases for LPC are known that also have this property. The axiom schemata and transformation rules here given are such that any purported proof of a theorem can be effectively checked to determine whether it really is a proof or not; nevertheless, theoremhood in LPC, like validity in LPC, is not effectively decidable, in that there is no effective method of telling with regard to any arbitrary *wff* whether it is a theorem or not. In this respect axiomatic bases for LPC contrast with those for PC.

**Special systems of LPC.** LPC as expounded above may be modified by either restricting or extending the range of *wff*'s in various ways.

*a. Partial systems of LPC.* Some of the more important systems produced by restriction are here outlined:

1. It may be required that every predicate variable be monadic, while still allowing an infinite number of individual and predicate variables. The atomic *wff*'s are then simply those consisting of a predicate variable followed by a single individual variable. Otherwise, the formation

rules remain as before, and the definition of validity is also as before, though simplified in obvious ways. This system is known as the monadic LPC; it provides a logic of properties but not of relations. One important characteristic of this system is that it is decidable. (The introduction of even a single dyadic predicate variable, however, would make the system undecidable; and in fact, even the system that contains only a single dyadic predicate variable and no other predicate variables at all has been shown to be undecidable.)

2. A still simpler system can be formed by requiring (a) that every predicate variable be monadic; (b) that only a single individual variable (e.g.,  $x$ ) be used; (c) that every occurrence of this variable be bound; (d) that no quantifier occur within the scope of any other. Examples of *wff*'s of this system are:  $(\forall x)[\phi x \supset (\psi x \cdot \chi x)]$  ("Whatever is  $\phi$  is both  $\psi$  and  $\chi$ ");  $(\exists x)(\phi x \cdot \sim\psi x)$  ("There is something that is  $\phi$  but not  $\psi$ ");  $(\forall x)(\phi x \supset \psi x) \supset (\exists x)(\phi x \cdot \psi x)$  ("If whatever is  $\phi$  is  $\psi$ , then something is both  $\phi$  and  $\psi$ "). The notation for this system can be simplified by omitting  $x$  everywhere and writing  $\exists\phi$  for "Something is  $\phi$ ,"  $\forall(\phi \supset \psi)$  for "Whatever is  $\phi$  is  $\psi$ ," and so on. Although this system is more rudimentary even than the monadic LPC (of which it is a fragment), the forms of a wide range of inferences can be represented in it. It is also a decidable system, and decision procedures of an elementary kind can be given for it.

*b. Extensions of LPC.* More elaborate systems, in which a wider range of propositions can be expressed, have been constructed, by adding to LPC new symbols of various types. The most straightforward of such additions are:

(a) One or more *individual constants* (say  $a, b, \dots$ ): these constants are interpreted as names of specific individuals; formally they are distinguished from individual variables by the fact that they cannot occur within quantifiers: e.g.,  $(\forall x)$  is a quantifier but  $(\forall a)$  is not.

(b) One or more *predicate constants* (say  $\Phi, \Psi, \dots$ ), each of some specified degree, thought of as designating specific properties or relations.

A further possible addition, which calls for somewhat fuller explanation, consists of symbols designed to stand for *functions*. The notion of a function may be sufficiently explained for present purposes as follows: There is said to be a certain function of  $n$  arguments (or, of degree  $n$ ) when there is a rule that specifies a unique object (called the *value* of the function) whenever all of the arguments are specified. In the domain of human beings, for example, "the mother of—" is a monadic function (a function of one argument) since for every human being there is a unique individual who is his mother; and in the domain of the natural numbers (i.e., 0, 1, 2, ...), "the sum of — and —" is a function of two arguments since for any pair of natural numbers there is a natural number that is their sum. A function symbol can be thought of as forming a name out of other names (its arguments): thus whenever  $x$  and  $y$  name numbers, "the sum of  $x$  and  $y$ " also names a number, and similarly for other kinds of functions and arguments.

To enable functions to be expressed in LPC there may be added:

(c) One or more *function variables* (say  $f, g, \dots$ ) or one or more *function constants* (say,  $F, G, \dots$ ) or both, each of some specified degree. The former are interpreted as ranging over functions of the degrees specified, and the latter as designating specific functions of that degree.

When any or all of (a) – (c) are added to LPC, the formation rules listed in the first paragraph of III. *The lower predicate calculus* need to be modified to enable the new symbols to be incorporated into *wff*'s. This can be done as follows: A *term* is first defined as either (i) an individual variable or (ii) an individual constant or (iii) any expression formed by prefixing a function variable or function constant of degree  $n$  to any  $n$  terms (these terms—the arguments of the function symbol—are usually separated by commas and enclosed in parentheses). Formation rule 1 is then replaced by:

1'. An expression consisting of a predicate variable or predicate constant of degree  $n$  followed by  $n$  terms is a *wff*.

Definitions:  
"function,"  
"degree,"  
"term"

Monadic LPC and subsystem

The axiomatic basis given in III. *Axiomatization of LPC* also requires the following modification: in axiom schema 2 any term is allowed to replace  $\mathbf{a}$  when  $\beta$  is formed, provided that no variable that is free in the term becomes bound in  $\beta$ . The following examples will illustrate the use of the aforementioned additions to LPC: Let the values of the individual variables be the natural numbers; let the individual constants  $a$  and  $b$  stand for the numbers 2 and 3, respectively; let  $\Phi$  mean "is prime"; and let  $F$  represent the dyadic function "the sum of." Then  $\Phi F(a,b)$  expresses the proposition "The sum of 2 and 3 is prime" and  $(\exists x)\Phi F(x,a)$  expresses the proposition "There exists a number such that the sum of it and 2 is prime."

Special axioms

The introduction of constants is normally accompanied by the addition, to the axiomatic basis, of special axioms containing those constants, designed to express principles that hold of the objects, properties, relations, or functions represented by them—though they do not hold of objects, properties, relations, or functions in general. It may be decided, for example, to use the constant  $\Phi$  to represent the dyadic relation "is greater than" (so that  $\Phi xy$  is to mean "x is greater than y", etc.). This relation, unlike many others, is transitive; i.e., if one object is greater than a second and that second is in turn greater than a third, then the first is greater than the third. Hence, the following special axiom schema might be added:

If  $t_1, t_2$ , and  $t_3$  are any terms, then

$$(\Phi t_1 t_2 \cdot \Phi t_2 t_3) \supset \Phi t_1 t_3$$

is an axiom. By such means systems can be constructed to express the logical structures of various particular disciplines. The area in which most work of this kind has been done is that of natural-number arithmetic (see IV. *Axiomatization of arithmetic*).

PC and LPC are sometimes combined into a single system. This may be done most simply by adding propositional variables to the list of LPC primitives, adding a formation rule to the effect that a propositional variable standing alone is a *wff*, and deleting "LPC" in axiom schema 1. This yields as *wff*'s such expressions as:  $(p \vee q) \supset (\forall x)\phi x$ ;  $(\exists x)[p \supset (\forall y)\phi xy]$ .

Identity propositions

c. *LPC-with-identity*. The word "is" is not always used in the same way. In a proposition such as (i) "Socrates is snub-nosed," the expression preceding the "is" names an individual and the expression following it stands for a property attributed to that individual. But in a proposition such as (ii) "Socrates is the Athenian philosopher who drank hemlock," the expressions preceding and following the "is" both name individuals, and the sense of the whole proposition is that the individual named by the first is the same individual as the individual named by the second. Thus in (ii) "is" can be expanded to "is the same individual as," whereas in (i) it cannot. As used in (ii), "is" stands for a dyadic relation, viz., identity, that the proposition asserts to hold between the two individuals. An identity proposition is to be understood in this context as asserting no more than this; in particular it is not to be taken as asserting that the two naming expressions have the same meaning. A much discussed example to illustrate this last point is "The morning star is the evening star." It is false that the expressions "the morning star" and "the evening star" mean the same, but true that the object referred to by the former is the same as that referred to by the latter.

To enable the forms of identity propositions to be expressed, a dyadic predicate constant is added to LPC, for which the most usual notation is  $=$  (written between, rather than before, its arguments). The intended interpretation of  $x = y$  is that  $x$  is the same individual as  $y$ , and the most convenient reading is "x is identical with y." Its negation  $\sim(x = y)$  is commonly abbreviated to  $x \neq y$ . To the definition of an LPC model in III. *Validity in LPC*, there is now added the rule (which accords in an obvious way with the intended interpretation) that the value of  $x = y$  is to be 1 if the same member of  $D$  is assigned to both  $x$  and  $y$  and that otherwise its value is to be 0; validity can then be defined as before. The following additions (or some equivalent ones) are made to the axiomatic basis for LPC: the axiom (I1)  $x = x$ ; and the axiom schema (I2) that where  $\mathbf{a}$  and  $\mathbf{b}$  are any individual

variables and  $\alpha$  and  $\beta$  are *wff*'s that differ only in that, at one or more places where  $\alpha$  has a free occurrence of  $\mathbf{a}$ ,  $\beta$  has a free occurrence of  $\mathbf{b}$ ,  $(\mathbf{a} = \mathbf{b}) \supset (\alpha \supset \beta)$  is an axiom. Such a system is known as a *lower-predicate-calculus-with-identity*; it may of course be further augmented in the other ways referred to in III. *Extensions of LPC*, in which case any term may be an argument of  $=$ .

Identity is an equivalence relation; i.e., it is reflexive, symmetrical, and transitive. Its reflexivity is directly expressed in Axiom I1, and theorems expressing its symmetry and transitivity can easily be derived from the basis given.

Certain *wff*'s of LPC-with-identity express propositions about the number of things that possess a given property. "At least one thing is  $\phi$ " could, of course, already be expressed by  $(\exists x)\phi x$ ; "At least two distinct (non-identical) things are  $\phi$ " can now be expressed by  $(\exists x)(\exists y)(\phi x \cdot \phi y \cdot x \neq y)$ ; and the sequence can be continued in an obvious way. "At most one thing is  $\phi$ " (i.e., "No two distinct things are both  $\phi$ ") can be expressed by the negation of the last mentioned *wff* or by its equivalent,  $(\forall x)(\forall y)[(\phi x \cdot \phi y) \supset x = y]$ ; and the sequence can again be easily continued. A formula for "Exactly one thing is  $\phi$ " may be obtained by conjoining the formulas for "At least one thing is  $\phi$ " and "At most one thing is  $\phi$ "; but a simpler *wff* equivalent to this conjunction is  $(\exists x)[\phi x \cdot (\forall y)(\phi y \supset x = y)]$ , which means "There is something that is  $\phi$ , and anything that is  $\phi$  is that thing." "Exactly two things are  $\phi$ " can be represented by

$$(\exists x)(\exists y)(\phi x \cdot \phi y \cdot x \neq y \cdot (\forall z)[\phi z \supset (z = x \vee z = y)]);$$

i.e., "There are two non-identical things each of which is  $\phi$ , and anything that is  $\phi$  is one or the other of these." Clearly, this sequence can also be extended to give a formula for "Exactly  $n$  things are  $\phi$ " for every natural number  $n$ . It is convenient to abbreviate the *wff* for "Exactly one thing is  $\phi$ ," however, to  $(\exists^1 x)\phi x$ , and in general to abbreviate the *wff* for "Exactly  $n$  things are  $\phi$ " to  $(\exists^n x)\phi x$ , and in this way to obtain a sequence of *numerical* quantifiers each, however, definable in terms of the primitives of LPC-with-identity.

When a certain property  $\phi$  belongs to one and only one object, it is convenient to have an expression that names that object. A common notation for this purpose is  $(\iota x)\phi x$ , which may be read as "the thing that is  $\phi$ " or more briefly as "the  $\phi$ ." In general, where  $\mathbf{a}$  is any individual variable and  $\alpha$  is any *wff*,  $(\iota \mathbf{a})\alpha$  then stands for the single value of  $\mathbf{a}$  that makes  $\alpha$  true. An expression of the form "the so-and-so" is called a *definite description*; and  $(\iota x)$ , known as a *description operator*, can be thought of as forming a name of an individual out of a proposition form.  $(\iota x)$  is analogous to a quantifier in that, when prefixed to a *wff*  $\alpha$ , it binds every free occurrence of  $x$  in  $\alpha$ . Relettering of bound variables is also permissible: in the simplest case,  $(\iota x)\phi x$  and  $(\iota y)\phi y$  can each be read simply as "the  $\phi$ ."

Numerical quantification

Definite descriptions

As far as formation rules are concerned, definite descriptions can be incorporated into LPC by letting expressions of the form  $(\iota \mathbf{a})\alpha$  count as terms; rule 1' of III. *Extensions of LPC* will then allow them to occur in atomic formulas (including identity formulas). "The  $\phi$  is (i.e., has the property)  $\psi$ " can then be expressed as  $\psi(\iota x)\phi x$ ; "y is (the same individual as) the  $\phi$ " as  $y = (\iota x)\phi x$ ; "The  $\phi$  is (the same individual as) the  $\psi$ " as  $(\iota x)\phi x = (\iota y)\psi y$ ; and so forth. The correct analysis of propositions containing definite descriptions has been the subject of considerable philosophical controversy. One widely accepted account, however—substantially that presented in *Principia Mathematica* and known as *Russell's theory of descriptions*, after Bertrand Russell, one of its co-authors—holds that "The  $\phi$  is  $\psi$ " is to be understood as meaning that exactly one thing is  $\phi$  and that thing is also  $\psi$ . In that case it can be expressed by a *wff* of LPC-with-identity that contains no description operators, viz.,

$$(1) (\exists x)[\phi x \cdot (\forall y)(\phi y \supset x = y) \cdot \psi x].$$

Analogously "y is the  $\phi$ " is analyzed as "y is  $\phi$  and nothing else is  $\phi$ ," and hence as expressible by

$$(2) \phi y \cdot (\forall x)(\phi x \supset x = y);$$

and "The  $\phi$  is the  $\psi$ " is analyzed as "Exactly one thing is  $\phi$ , exactly one thing is  $\psi$ , and whatever is  $\phi$  is  $\psi$ ," and hence as expressible by

$$(3) (\exists x)[\phi x \cdot (\forall y)(\phi y \supset x = y)] \cdot (\exists x)[\psi x \cdot (\forall y)(\psi y \supset x = y)] \cdot (\forall x)(\phi x \supset \psi x)$$

or more briefly, using the abbreviations introduced earlier, by

$$(3') (\exists 1x)\phi x \cdot (\exists 1x)\psi x \cdot (\forall x)(\phi x \supset \psi x).$$

$\psi(1x)\phi x$ ,  $y = (1x)\phi x$ , and  $(1x)\phi x = (1y)\psi y$  can then be regarded as abbreviations for (1), (2), and (3), respectively; and by generalizing to more complex cases, all *wff*'s that contain description operators can be regarded as abbreviations for longer *wff*'s that do not.

The analysis that leads to (1) as a formula for "The  $\phi$  is  $\psi$ " leads to the following for "The  $\phi$  is not  $\psi$ ":

$$(4) (\exists x)[\phi x \cdot (\forall y)(\phi y \supset x = y)] \cdot \sim \psi x.$$

It is important to note that (4) is not the negation of (1); this negation is, instead,

$$(5) \sim (\exists x)[\phi x \cdot (\forall y)(\phi y \supset x = y)] \cdot \psi x.$$

The difference in meaning between (4) and (5) lies in the fact that (4) is true only when there is exactly one thing that is  $\phi$  and that thing is not  $\psi$ , but (5) is true both in this case and also when nothing is  $\phi$  at all and when more than one thing is  $\phi$ . Neglect of the distinction between (4) and (5) can cause serious confusion of thought: in ordinary speech it is often unclear whether someone who denies that the  $\phi$  is  $\psi$  is conceding that exactly one thing is  $\phi$  but denying that it is  $\psi$ , or denying that exactly one thing is  $\phi$ . Moreover, if (4) were mistakenly thought of as the negation of (1), the *law of excluded middle* would lead to the conclusion that at least one of them is true; and then, since each asserts *inter alia* that exactly one thing is  $\phi$  and since, in addition, the argument would hold whatever property  $\phi$  is taken to represent, the absurd result would be obtained that every property has exactly one instance.

The basic contention of Russell's theory of descriptions is that a proposition containing a definite description is not to be regarded as an assertion about an object of which that description is a name but rather as an existentially quantified assertion that a certain (rather complex) property has an instance. Formally, this is reflected in the rules for eliminating description operators that were outlined above. Some logicians, however, prefer instead to introduce  $\iota$  as a new primitive symbol, accompanied by special axioms, and to treat expressions of the form  $(\iota a)\alpha$  always as naming expressions, allowing them to replace individual variables in theorems (subject only to the restrictions about quantification mentioned in III. *Axiomatization of LPC*). The formula  $(\forall x)\phi x \supset \phi(\iota y)\psi y$ —"If everything is  $\phi$ , then the  $\psi$  is  $\phi$ "—will then, for example, count as an axiom by axiom schema 2 and as a valid *wff*; whereas by Russell's theory of descriptions it will be invalid, since it is possible for everything to be  $\phi$  without there being exactly one thing that is  $\psi$ . This approach gives rise to the problem of deciding, in constructing an *LPC* model, which member of  $D$  to assign to  $(\iota x)\phi x$  in cases in which either nothing or more than one thing is  $\phi$ . The solution usually adopted is to select some arbitrary member of  $D$  as the assignment in all such cases throughout the model. While this device may seem intuitively "unnatural," it proves to be technically satisfactory and convenient for many purposes.

#### HIGHER-ORDER PREDICATE CALCULI

A feature shared by *LPC* and all of its extensions so far mentioned is that the only variables that occur in quantifiers are individual variables. It is in virtue of this feature that they are called *lower* (or *first-order*) calculi. Various predicate calculi of higher order can be formed, however, in which quantifiers may contain other variables as well, hence binding all free occurrences of these that lie within their scope. In particular, in the *second-order* predicate calculus quantification is permitted over both individual and predicate variables; hence *wff*'s such as  $(\forall \phi)(\exists x)\phi x$  can be formed. This last formula, since it con-

tains no free variables of any kind, expresses a determinate proposition, viz., the proposition that every property has at least one instance. One important feature of this system is that in it identity need not be taken as primitive but can be introduced by defining  $x = y$  as  $(\forall \phi)(\phi x \equiv \phi y)$ —*i.e.*, "Every property possessed by  $x$  is also possessed by  $y$  and vice versa." Whether such a definition is acceptable as a general account of identity is a question that raises philosophical issues too complex to be discussed here; they are substantially those raised by the principle of the identity of indiscernibles, best known for its exposition in the 17th century by the German philosopher G.W. Leibniz.

#### IV. Other special systems of logic

##### SYLLOGISTIC LOGIC

Syllogistic logic was the earliest branch of formal logic to be developed—in its original form by Aristotle about 350 BC. Only a very brief account of the topic is given here; for a fuller treatment see SYLLOGISTIC. The system as outlined here combines elements contributed by Aristotle with others that are considerably later in origin; for the historical development of the subject see LOGIC, HISTORY OF.

Syllogistic logic deals with propositions of the four forms:

"Every . . . is (a) —";

"No . . . is (a) —";

"Some (*i.e.*, at least one) . . . is (a) —";

"Some . . . is not (a) —"

(*Examples*: "Every club member is a Bostonian"; "No club member is a Bostonian"; etc.)

Propositions of these forms are known as A, E, I, and O propositions, respectively. The expressions that fill the blanks are called *terms*; and in each case the first is the *subject(-term)* and the second the *predicate(-term)*. (The use of the words "term" and "predicate" here should not be confused with their use in the account of *LPC* above.) As term variables, the letters S, P, and M are employed. "Every S is (a) P" is abbreviated to "SaP"; "No S is (a) P" to "SeP"; "Some S is (a) P" to "SiP"; and "Some S is not (a) P" to "SoP." A and E propositions are called *universal*, I and O propositions *particular*; A and I propositions are called *affirmative*, E and O propositions *negative*.

These propositional forms are to be so understood that the following are true for any terms S and P:

(1) Not both: SaP and SeP;

(2) If SaP, then SiP;

(3) If SeP, then SoP;

(4) Either SiP or SoP;

(5) SaP is equivalent to the negation of SoP;

(6) SeP is equivalent to the negation of SiP.

The *simple converse* of a proposition is formed by reversing the order of its terms. If, in addition, an A proposition is changed to an I, or an E to an O, the result is called the *limited converse* of the original. The logical relations holding between propositions and their converses are as follows: E and I propositions are equivalent to their simple converses; *i.e.*, SeP and SiP are equivalent to PeS and PiS, respectively. Moreover, an A proposition SaP though not equivalent to its simple converse PaS, implies, though it is not implied by, its limited converse PiS. SoP, however, neither implies nor is implied by PoS; this fact is often expressed by saying that an O proposition does not convert.

A (*categorical*) syllogism is an inference with two premises and one conclusion, in which (i) each of the three propositions is an A, E, I, or O proposition; (ii) the subject of the conclusion (called the *minor* term) also occurs in one of the premises (the *minor* premise); (iii) the predicate of the conclusion (called the *major* term) also occurs in the other premise (the *major* premise); and (iv) the two remaining term positions in the premises are filled by the same term (the *middle* term). A syllogistic *mood* is an inference form of which the instances are syllogisms (*e.g.*, MaP, SiM,  $\therefore$  SiP). If S, P, and M are used for minor, major, and middle terms, respectively, and the convention of writing the major premise first is observed, the exhaustive list displayed in Table 6 is obtained

The syllogism

Negations with differing scopes

Binding of predicate variables

I	II	III	IV
M - P S - M	P - M S - M	M - P M - S	P - M M - S
∴ S - P	∴ S - P	∴ S - P	∴ S - P

showing four arrangements of terms in a syllogistic mood.

These arrangements of terms are known as the first, second, third, and fourth figures of the syllogism, respectively. A mood can then be succinctly specified by mentioning its figure and indicating to which of the four forms each of the three propositions, in the conventional order, belongs. Thus "IIaoo" specifies the mood: PaM, SeM, ∴ SoP. The 24 moods shown in Table 7, and only these, are normally regarded as valid.

Figure 1	aaa, aai, eae, eao, aii, eio
Figure 2	eae, eao, aee, aeo, eio, aoo
Figure 3	aai, iai, aii, eao, oao, eio
Figure 4	aai, aee, aeo, iai, eao, eio

Syllogistic logic is commonly extended by the introduction of negative terms. For any term S the corresponding negative term non-S applies to exactly those things to which S does not apply. A convenient notation for non-S is S̄. Negative terms enable additional proposition forms to be constructed, and the logical relations holding among them to be studied. Among the most important of these are:

1. The *obverse* of a proposition, which is formed by negating its predicate and changing the proposition from affirmative to negative or vice versa. (Example: "No mineral is phototropic"; obverse: "Every mineral is non-phototropic.") The obverses of SaP, SeP, SiP, and SoP, are SeP, SaP, SoP, and SiP, respectively. Every proposition is equivalent to its obverse.

2. The *contrapositive* of a proposition, which is formed by reversing the order of its terms and negating each, though keeping the proposition affirmative or negative as the case may be. (Example: "Every Italian is a European"; contrapositive: "Every non-European is a non-Italian.") SaP and SoP are equivalent to their respective contrapositives P̄aS̄ and P̄oS̄. SeP is not equivalent to P̄eS̄; but it implies, though it is not implied by, its limited contrapositive P̄oS̄. SiP, however, neither implies nor is implied by P̄iS̄.

Axiomatic basis: affinities with LPC

In the present century axiomatic bases have been devised for syllogistic logic. It has been shown that if a and i are taken as primitive and SeP is defined as ∼(SiP) and SoP as ∼(SaP), then all of the valid formulas in syllogistic logic that do not involve negative terms can be derived from PC together with the four axioms

- (1) (MaP · SaM) ⊃ SaP; (3) SaS;
- (2) (MaP · MiS) ⊃ SiP; (4) SiS

by the usual rules of *uniform substitution* and *modus ponens* and a rule of uniform substitution for term variables. A complete basis for deriving the valid formulas involving negative terms as well can be formed by replacing axioms (1) and (3) by

- (1') SeP̄ ⊃ SaP and (3') SeS̄

and extending the last mentioned rule to allow a term variable to be replaced not only by another term variable but also by a term variable with one or more superimposed bars.

The formulas SaP, SeP, SiP, and SoP have obvious affinities with the LPC wff's

$$(\forall x)(\phi x \supset \psi x), (\forall x)(\phi x \supset \sim \psi x), (\exists x)(\phi x \cdot \psi x), \text{ and } (\exists x)(\phi x \cdot \sim \psi x),$$

respectively. The analogy is not, however, complete; e.g., SiP follows from SaP, but

$$(\forall x)(\phi x \supset \psi x) \supset (\exists x)(\phi x \cdot \psi x)$$

is not valid in LPC; and IIIaai is a valid mood, but its suggested analogue

$$[(\forall x)(\phi x \supset \psi x) \cdot (\forall x)(\phi x \supset \chi x)] \supset (\exists x)(\chi x \cdot \psi x)$$

is not valid. Nevertheless, one change in the definition of LPC validity given in III. *Validity in LPC* would make the proposed analogue of every valid syllogistic formula valid in (monadic) LPC; this change is that, in the construction of an LPC model when value assignments are made, V should be required to assign to each predicate variable not any subset of D that one cares to choose but, more restrictively, some nonempty proper subset of D (i.e., some subset that has at least one member and is not coextensive with D itself). This suggests that one way of regarding syllogistic logic is as a logic of properties that have both instances and counterinstances.

MODAL LOGIC

True propositions can be divided into those—like "2 + 2 = 4"—that are true by logical necessity (*necessary* propositions), and those—like "France is a republic"—that are not (*contingently true* propositions). Similarly, false propositions can be divided into those—like "2 + 2 = 5"—that are false by logical necessity (*impossible* propositions), and those—like "France is a monarchy"—that are not (*contingently false* propositions). Contingently true and contingently false propositions are known collectively as *contingent* propositions. A proposition that is not impossible (i.e., one that is either necessary or contingent) is said to be a *possible* proposition. Intuitively, the notions of necessity and possibility are connected in the following way: to say that a proposition is necessary is to say that it is not possible for it to be false; and to say that a proposition is possible is to say that it is not necessarily false.

If it is logically impossible for a certain proposition, p, to be true without a certain proposition, q, being also true (i.e., if the conjunction of p and not-q is logically impossible), then it is said that p *strictly implies* q. An alternative, equivalent way of explaining the notion of strict implication is by saying that p strictly implies q if and only if it is necessary that p materially implies q. "John's tie is scarlet," for example, strictly implies "John's tie is red," because it is impossible for John's tie to be scarlet without being red (or: it is necessarily true that if John's tie is scarlet it is red); and in general, if p is the conjunction of the premises, and q is the conclusion, of a deductively valid inference, p will strictly imply q.

The notions just referred to—necessity, possibility, impossibility, contingency, strict implication—and certain other closely related ones are known as *modal* notions; and a logic designed to express principles involving them is called a *modal logic*.

The most straightforward way of constructing such a logic is to add to some standard nonmodal system a new primitive operator intended to represent one of the modal notions mentioned above, to define other modal operators in terms of it, and to add certain special axioms or transformation rules or both. A great many systems of modal logic have been constructed; but attention will be restricted here to a few closely related ones in which the underlying nonmodal system is ordinary PC.

**Alternative systems of modal logic.** All of the systems to be considered here have the same wff's, but differ in their axioms. The wff's can be specified by adding to the symbols of PC a primitive monadic operator L, and to the formation rules of PC the rule that if α is a wff, so is Lα. L is intended to be interpreted as "It is necessary that," so that Lp will be true if and only if p is a necessary proposition. The monadic operator M and the dyadic operator ⊃ (to be interpreted as "It is possible that" and "strictly implies," respectively)

can then be introduced by the following definitions, which reflect in an obvious way the informal accounts given above of the connections between necessity, possibility, and strict implication: if  $\alpha$  is any *wff*, then  $M\alpha$  is to be an abbreviation of  $\sim L\sim\alpha$ ; and if  $\alpha$  and  $\beta$  are any *wff*'s, then  $\alpha \supset \beta$  is to be an abbreviation of  $L(\alpha \supset \beta)$  [or alternatively of  $\sim M(\alpha \cdot \sim\beta)$ ].

The modal system known as T has as axioms some set of axioms adequate for PC (such as those of PM), and in addition

- (1)  $Lp \supset p$
- (2)  $L(p \supset q) \supset (Lp \supset Lq)$ .

Axiom (1) expresses the principle that whatever is necessarily true is true and (2) the principle that, if  $q$  logically follows from  $p$  then, if  $p$  is a necessary truth, so is  $q$  (i.e., that whatever follows from a necessary truth is itself a necessary truth). These two principles appear to have a high degree of intuitive plausibility, and almost all modal systems contain (1) and (2) as theorems. The transformation rules of T are *uniform substitution*, *modus ponens*, and a third rule to the effect that if  $\alpha$  is a theorem so is  $L\alpha$  (the *rule of necessitation*). The intuitive rationale of this last rule is that in a sound axiomatic system it is expected that every instance of a theorem  $\alpha$  will be not merely true but necessarily true—and in that case every instance of  $L\alpha$  will be true.

Among the simpler theorems of T are:

$$p \supset Mp; L(p \cdot q) \equiv (Lp \cdot Lq); M(p \vee q) \equiv (Mp \vee Mq); (Lp \vee Lq) \supset L(p \vee q)$$

(but not its converse);

$$M(p \cdot q) \supset (Mp \cdot Mq)$$

(but not its converse);

$$LMp \equiv \sim ML\sim p; (p \supset q) \supset (Mp \supset Mq); (\sim p \supset p) \equiv Lp; L(p \vee q) \supset (Lp \vee Lq).$$

There are many modal formulas that are not theorems of T but that have a certain claim to express truths about necessity and possibility. Among these are

$$Lp \supset LLp; Mp \supset LMp; \text{ and } p \supset LMp.$$

The first of these means that if a proposition is necessary, its being necessary is itself a necessary truth; the second means that if a proposition is possible, its being possible is a necessary truth; and the third means that if a proposition is true, then not merely is it possible but its being possible is a necessary truth. These are all various elements in the general thesis that a proposition's having the modal characteristics it has (such as necessity, possibility) is not a contingent matter but is determined by logical considerations. Though this thesis may be philosophically controversial, it is at least plausible, and its consequences are worth exploring; and one way of exploring them is to construct modal systems in which the formulas listed above are theorems. None of these formulas, as was said, is a theorem of T; but each could be consistently added to T as an extra axiom to produce a new and more extensive system. The system obtained by adding  $Lp \supset LLp$  to T is known as S4; that obtained by adding  $Mp \supset LMp$  to T is known as S5; and the addition of  $p \supset LMp$  to T gives the (less important) Brouwerian system, here called B for short.

The relations between these four systems are as follows: S4 is stronger than T; i.e., it contains all of the theorems of T and others besides. B is also stronger than T. S5 is stronger than S4 and also stronger than B. S4 and B, however, are independent of each other in the sense that each contains some theorems that the other does not have. It is of particular importance that if  $Mp \supset LMp$  is added to T then  $Lp \supset LLp$  can be derived as a theorem, but that if one merely adds the latter to T the former cannot then be derived.

Examples of theorems of S4 that are not theorems of T are:  $Mp \equiv MMp$ ;  $MLMp \supset Mp$ ;  $(p \supset q) \supset (Lp \supset Lq)$ ; and examples of theorems of S5 that are not theorems of S4 are:

$$Lp \equiv MLP; L(p \vee Mq) \equiv (Lp \vee Mq); M(p \cdot Lq) \equiv (Mp \cdot Lq); (Lp \supset Lq) \vee (Lq \supset Lp).$$

One important feature of S5 but not of the other sys-

tems mentioned is that any *wff* that contains an unbroken sequence of monadic modal operators ( $L$ 's and/or  $M$ 's) is provably equivalent to the same *wff* with all of these operators deleted except the last.

Considerations of space preclude an account of the many other axiomatic systems of modal logic that have been investigated. Some of these are weaker than T: such systems normally contain the axioms of T either as axioms or as theorems but have only a restricted form of the *rule of necessitation*. Another group comprises systems that are stronger than S4 but weaker than S5; some of these have proved fruitful in developing a logic of temporal relations. Yet another group includes systems that are stronger than S4 but independent of S5 in the sense explained above.

Modal predicate logics can be formed also by making analogous additions to LPC instead of to PC.

**Validity in modal logic.** The task of defining validity for modal *wff*'s is complicated by the fact that, even if the truth values of all of the variables in a *wff* are given, it is not obvious how one should set about calculating the truth value of the whole *wff*. Nevertheless, a number of definitions of validity applicable to modal *wff*'s have been given, each of which turns out to match some axiomatic modal system in the sense that it brings out as valid those *wff*'s, and no others, that are theorems of that system. Most, if not all, of these accounts of validity can be thought of as variant ways of giving formal precision to the idea that necessity is truth in every "possible world" or "conceivable state of affairs." The simplest such definition is this: Let a *model* be constructed by first assuming a (finite or infinite) set  $W$  of "worlds." In each world, independently of all the others, let each propositional variable then be assigned either the value 1 or the value 0. In each world the values of truth functions are calculated in the usual way from the values of their arguments in that world. In each world, however,  $L\alpha$  is to have the value 1 if  $\alpha$  has the value 1, not only in that world but in every other world in  $W$  as well, and is otherwise to have the value 0; and in each world  $M\alpha$  is to have the value 1 if  $\alpha$  has the value 1 either in that world or in some other world in  $W$ , and is otherwise to have the value 0. These rules enable one to calculate a value (1 or 0) in any world in  $W$  for any given *wff*, once the values of the variables in each world in  $W$  are specified. A model is defined as consisting of a set of worlds together with a value assignment of the kind just described. A *wff* is *valid* if and only if it has the value 1 in every world in every model. It can be proved that the *wff*'s that are valid by this criterion are precisely the theorems of S5; for this reason models of the kind here described may be called S5-models, and validity as just defined may be called S5-validity.

A definition of T-validity (i.e., one that can be proved to bring out as valid precisely the theorems of T) can be given as follows: a T-model consists of a set of worlds  $W$  and a value assignment to each variable in each world, as before; but in addition it includes a specification, for each world in  $W$ , of some subset of  $W$  as the worlds that are "accessible" to that world. Truth functions are evaluated as before; but in each world in the model,  $L\alpha$  is to have the value 1 if  $\alpha$  has the value 1 in that world and in every other world in  $W$  that is accessible to it, and is otherwise to have the value 0. And in each world,  $M\alpha$  is to have the value 1 if  $\alpha$  has the value 1 either in that world or in some other world accessible to it and is otherwise to have the value 0. (In other words, in computing the value of  $L\alpha$  or  $M\alpha$  in a given world, no account is taken of the value of  $\alpha$  in any other world not accessible to it.) A *wff* is T-valid if and only if it has the value 1 in every world in every T-model.

An S4-model is defined as is a T-model except that it is required that the accessibility relation be transitive; i.e., that where  $w_1$ ,  $w_2$ , and  $w_3$  are any worlds in  $W$ , if  $w_1$  is accessible to  $w_2$  and  $w_2$  is accessible to  $w_3$ , then  $w_1$  is accessible to  $w_3$ . A *wff* is S4-valid if and only if it has the value 1 in every world in every S4-model. The S4-valid *wff*'s can be shown to be precisely the theorems of S4.

The system T and its limitations

Models for the four systems

The systems S4, S5, and B

Adaptations  
to other  
systems

Finally, a definition of validity is obtained that will match the system B by requiring that the accessibility relation be symmetrical but not that it be transitive.

For all four systems, effective decision procedures for validity can be given. Further modifications of the general method described have yielded validity definitions that match many other axiomatic modal systems; and the method can also be adapted to give a definition of validity for the Intuitionistic PC mentioned earlier. For a number of axiomatic modal systems, however, no satisfactory account of validity has yet been devised. Validity can also be defined for various modal predicate logics by combining the definition of LPC-validity given in III. *Validity in LPC* with the relevant accounts of validity for modal systems; but a modal logic based on LPC is, like LPC itself, an undecidable system.

#### SET THEORY

Only a sketchy account of set theory is given here; for further information see the article SET THEORY. Set theory is a logic of classes; *i.e.*, of collections (finite or infinite) or aggregations of objects of any kind, which are known as the *members* of the classes in question. Some logicians use the terms "class" and "set" interchangeably; others distinguish between them, defining a set (for example) as a class that is itself a member of some class and defining a proper class as one that is not a member of any class. It is usual to write "∈" for "is a member of" and to abbreviate  $\sim (x \in y)$  to  $x \notin y$ . A particular class may be specified either by listing all of its members or by stating some condition of membership, in which (latter) case the class consists of all of those things and only those that satisfy that condition (it is used, for example, when one speaks of the class of inhabitants of London or the class of prime numbers). Clearly, the former method is available only for finite classes and may be highly inconvenient even then; the latter, however, is of more general applicability. Two classes that have precisely the same members are regarded as the same class or are said to be *identical* with each other, even if they are specified by different conditions; *i.e.*, identity of classes is identity of membership, not identity of specifying conditions. This principle is known as the *principle of extensionality*. A class with no members, such as the class of Chinese popes, is said to be *null*. Since the membership of all such classes is the same, there is only one null class, which is therefore usually called *the* null class (or sometimes the empty class); it is symbolized by  $\Delta$  or  $\phi$ . The notation  $x = y$  is used for "x is identical with y" and  $\sim (x = y)$  is usually abbreviated to  $x \neq y$ . The expression  $x = \Delta$  therefore means that the class x has no members, and  $x \neq \Delta$  means that x has at least one member.

Interrelations  
of classes

A member of a class may itself be a class. The class of dogs, for example, is a member of the class of species of animals. An individual dog, however, though a member of the former class is not a member of the latter—because an individual dog is not a species of animal (if the number of dogs increases, the number of species of animals does not thereby increase). Class membership is therefore not a transitive relation. The relation of class inclusion, however (to be carefully distinguished from class-membership), is transitive. A class x is said to be *included* in a class y (written:  $x \subseteq y$ ) if and only if every member of x is also a member of y. (This is not meant to exclude the possibility that x and y may be identical.) If x is included in but is not identical with y—*i.e.*, if every member of x is a member of y but some members of y are not members of x—x is said to be *properly included* in y (written:  $x \subset y$ ).

It is perhaps natural to assume that for every storable condition there is a class (null or otherwise) of objects that satisfy that condition. This assumption is known as the *principle of comprehension*. In the unrestricted form just mentioned, however, this principle has been found to lead to inconsistencies and hence cannot be accepted as it stands. One storable condition, for example, is *non-self-membership*, *i.e.*, the property possessed by a class if and only if it is not a member of itself. This in fact appears to be a condition that most classes do fulfill; the class of

dogs, for example, is not itself a dog and hence is not a member of the class of dogs.

Let it now be assumed that the class of all classes that are not members of themselves can be formed and let this class be y. Then any class x will be a member of y if and only if it is not a member of itself; *i.e.*, for any class x,  $(x \in y) \equiv (x \notin x)$ . The question can then be asked whether y is a member of itself or not, with the following awkward result: If it is a member of itself, then it fails to fulfill the condition of membership of y; and hence it is not a member of y; *i.e.*, not a member of itself. On the other hand, if y is not a member of itself, then it does fulfill the required condition; and therefore it is a member of y—*i.e.*, of itself. Hence the equivalence  $(y \in y) \equiv (y \notin y)$  results, which is self-contradictory. This perplexing conclusion, which was pointed out by Bertrand Russell, is known as *Russell's paradox*. Russell's own solution to it and to other similar difficulties was to regard classes as forming a hierarchy of types and to posit that a class could only be regarded sensibly as a member, or a nonmember, of a class at the next higher level in the hierarchy. The effect of this theory is to make  $x \in x$ , and therefore  $x \notin x$ , ill-formed. Another kind of solution, however, is based upon the distinction made earlier between two kinds of classes, those that are sets and those that are not—a set being defined as a class that is itself a member of some class. The unrestricted *principle of comprehension* is then replaced by the weaker principle that for every condition there is a class the members of which are the individuals or *sets* that fulfill that condition. Other solutions have also been devised; but none has won universal acceptance, with the result that several different versions of set theory are found in the literature of the subject.

Formally, set theory can be derived by the addition of various special axioms to a rather modest form of LPC that contains no predicate variables and only a single primitive dyadic predicate constant ( $\in$ ) to represent membership. Sometimes LPC-with-identity is used and there are then two primitive dyadic predicate constants ( $\in$  and  $=$ ). In some versions the variables x, y, . . . are taken to range only over sets or classes; in other versions they range over individuals as well. The special axioms vary; but the basis normally includes the *principle of extensionality* and some restricted form of the *principle of comprehension*, or some elements from which these can be deduced.

A notation to express theorems about classes can be either defined in various ways (not detailed here) in terms of the primitives mentioned above, or else introduced independently. The main elements of one widely used notation are the following: if a is an expression containing some free occurrence of x, the expression  $\{x:a\}$  is used to stand for the class of objects fulfilling the condition expressed by a—*e.g.*,  $\{x : "x \text{ is a prime number}"\}$  represents the class of prime numbers;  $\{x\}$  represents the class the only member of which is x;  $\{x, y\}$  the class the only members of which are x and y; and so on.  $\langle x, y \rangle$  represents the class the members of which are x and y *in that order* (thus  $\{x, y\}$  and  $\{y, x\}$  are identical; but  $\langle x, y \rangle$  and  $\langle y, x \rangle$  are in general not identical). Let x and y be any classes, as (for example) those of the dots on the two arms of a stippled cross. The *intersection* of x and y, symbolized as  $x \cap y$ , is the class the members of which are the objects common to x and y—in this case the dots within the area where the arms cross—*i.e.*,  $\{z : z \in x \cdot z \in y\}$ . Similarly, the *union* of x and y, symbolized as  $x \cup y$ , is the class the members of which are the members of x together with those of y—in this case all of the dots on the cross—*i.e.*,  $\{z : z \in x \vee z \in y\}$ ; the *complement* of x, symbolized as  $\sim x$ , is the class the members of which are all those objects that are not members of x—*i.e.*,  $\{y : y \notin x\}$ ; the complement of y in x, symbolized as  $x - y$ , is the class of all objects that are members of x but not of y—*i.e.*,  $\{z : z \in x \cdot z \notin y\}$ ; the *universal* class, symbolized as  $\Delta$ , is the class of which everything is a member, definable as the complement of the null class—*i.e.*, as  $\sim \Delta$ .  $\Delta$  itself is sometimes taken as a primitive

Russell's  
paradox:  
theory of  
types

Notation,  
definitions,  
theorems

individual constant, sometimes defined as  $\{x : x \neq x\}$ —the class of objects that are not identical with themselves. Among the simpler theorems of set theory are:

$$(\forall x)(x \cap x = x); (\forall x)(\forall y)(x \cap y = y \cap x);$$

and corresponding theorems for  $\cup$ ;

$$(\forall x)(\forall y)(\forall z)[x \cap (y \cap z) = (x \cap y) \cap (x \cap z)];$$

$$(\forall x)(\forall y)[-(x \cap y) = -x \cup -y];$$

and corresponding theorems with  $\cap$  and  $\cup$  interchanged;

$$(\forall x)(-x = x); (\forall x)(\forall y)(x - y = x \cap -y);$$

$$(A x)(\Delta \subset x); (\forall x)(x \cap \Delta = \Delta); (\forall x)(x \cup \Delta = x).$$

In these theorems the variables range over classes. In several cases, there are obvious analogies to valid *wff*'s of PC. For an account of further developments, more advanced axioms, etc., see SET THEORY.

Apart from its own intrinsic interest, set theory has an importance for the foundations of mathematics in that it is widely held that the natural numbers can be adequately defined in set-theoretic terms. Moreover, given suitable axioms, standard postulates for natural-number arithmetic can be derived as theorems within set theory.

#### LOGICAL FOUNDATIONS OF MATHEMATICS

It is possible to develop arithmetic in the form of a logical system without recourse to set theory.

**Axiomatization of arithmetic.** Axiomatic bases for the arithmetic of the natural numbers (0, 1, 2, ...) can be constructed as extensions of LPC designed to have a direct numerical interpretation. One such basis, with the intended interpretation indicated, is the following: in addition to the usual operators and quantifiers, the symbols comprise (a) an infinite list of individual variables, the values of which are to be natural numbers; (b) one individual constant, 0, to represent zero; (c) one dyadic predicate constant, =, to represent equality; (d) three function constants: a monadic one, ', interpreted as "the successor of"; and two dyadic ones, + and ·, interpreted as "the sum of" and "the product of," respectively. In view of their intended interpretations, it is convenient to write ' after its argument, and =, +, and · between their arguments. The numeral 1 may be defined as 0', the numeral 2 as 1' (or 0''), and so on. Terms are defined as explained in III. *Extensions of LPC*; and since there are no predicate variables, an atomic *wff* will simply be any expression of the form  $(t_1 = t_2)$ , where  $t_1$  and  $t_2$  are terms. The following special axioms are added to the general axioms for LPC:

- (1)  $(x = y) \supset [(x = z) \supset (y = z)];$
- (2)  $(x = y) \supset (x' = y');$
- (3)  $0 \neq x';$
- (4)  $(x' = y') \supset (x = y);$
- (5)  $x + 0 = x;$
- (6)  $(x + y)' = (x + y)';$
- (7)  $x \cdot 0 = 0;$
- (8)  $x \cdot y' = (x \cdot y) + x.$

There is also the following special axiom schema:

(9) Let  $\alpha$  be any *wff* and  $a$  any individual variable; let  $\alpha(0)$  be  $\alpha$  but with 0 replacing every free occurrence of  $a$ , and  $\alpha(a')$  be  $\alpha$  but with free  $a'$  replacing every free occurrence of  $a$ : then

$$\alpha(0) \supset \{(\forall a) [\alpha \supset \alpha(a')] \supset (\forall \sim) \alpha\}$$

is an axiom.

The transformation rules are *modus ponens* and *universal generalization* as before. Axiom schema (9) expresses the principle of *mathematical induction*. It may be paraphrased by saying that if a property (i) belongs to 0 and (ii) belongs to the successor of any natural number to which it also belongs, then it belongs to every natural number whatsoever.

**Scope and limitations of axiomatized arithmetic.** In this system (which shall be called S), the axioms for identity given in III. *LPC-with-identity* are derivable as theorems. Since S contains no variables other than individual variables, every closed *wff*—i.e., every

*wff* containing no free individual variables—will (given the intended interpretation) express not a proposition form but a determinate proposition of natural-number arithmetic—possibly one containing no variables at all, such as  $3 + 5 = 8$ , or possibly one containing bound variables, such as

$$(\forall x)(\exists y)(4 + x = 3 + y) \text{ or}$$

$$(\forall x)(\forall y)(\forall z)[x \cdot (y + z) = (x \cdot y) + (x \cdot z)].$$

The range of arithmetical propositions expressible by *wff*'s of S is indeed much greater than might appear from the fact that its only primitive predicate is = and its only primitive function symbols are ', +, and ·, inasmuch as many relations and properties not so far explicitly mentioned, such as "is less than," "is divisible (without remainder) by," and "is prime," can be defined in terms of the primitives of S; e.g.,  $x < y$  can be defined as  $(\exists z)(x + z' = y)$ . Moreover, even if a given numerical function is not directly definable in terms of the primitives of S, it may still be possible to express propositions involving that function as *wff*'s of S, in a way that can be sufficiently explained for present purposes as follows: A numerical function is one that always has a natural number as its value when its arguments are natural numbers. Now let  $f(x)$  be such a function with one argument  $x$ . It may then be possible to find a *wff* of S,  $\alpha$ , containing two free variables,  $x$  and  $y$ , such that (i) all values of  $x$  and  $y$  that make  $f(x) = y$  true also turn  $\alpha$  into a theorem of S, and (ii) whenever  $\alpha'$  is formed from  $\alpha$  by uniformly replacing  $x$  by a numeral,  $(\exists! y)\alpha'$  is a theorem of S. In that case every true proposition of natural-number arithmetic involving only that function will be expressible as a *wff*, appropriately constructed from  $\alpha$ , that is a theorem of S; and  $\alpha$  is then said to *represent* that function in S. For functions with more than one argument, the above account can be extended in a straightforward way and, provided that a true natural-number proposition involves only functions that are representable in S, the *wff* that expresses it will be a theorem of S.

A numerical function is said to be *effectively computable* if there is an effective (mechanical and finite) method of calculating the value of the function in all cases when its arguments are given (e.g., the addition function  $x + y$  is effectively computable since, given any two numbers, it is possible to calculate their sum mechanically in a finite number of steps). Various attempts have been made to give a precise mathematical analysis of the conditions for effective computability, and it is widely held that a satisfactory analysis of this kind is provided in the theory of recursive functions; i.e., that the (intuitively defined) class of effectively computable functions coincides exactly with the (mathematically defined) class of recursive functions. An account of recursive functions will be found in the article MATHEMATICS, FOUNDATIONS OF: *The crisis in foundations following 1900: Logicism, formalism, and metamathematical method*, and is therefore omitted here. In the present context the essential point is that it can be proved that the numerical functions representable in S are precisely those that are recursive. And from this fact, given the assumption that effective computability and recursiveness do in fact coincide, it follows that every true proposition of natural-number arithmetic in which all of the functions are effectively computable can be expressed as a *wff* that is a *theorem* of S. In this sense, S is an adequate basis for natural-number arithmetic.

It would be natural to hope that S were also complete in the sense that every true arithmetical proposition whatever that can be expressed as a *wff* of S would be a theorem. It can be shown, however—at least if S is assumed to be consistent, which there seems no reason to doubt—that this hope is unfounded. That this is so is a direct consequence of the most important finding that has been made to date in this area, a finding that is known as *Gödel's incompleteness theorem*, after the mathematician and logician Kurt Gödel who formulated and proved it in 1931. An application of Gödel's argument to S shows how to construct a certain closed *wff* of S of

Effective  
comput-  
ability and complete-  
ness

Axiomatic  
basis and  
inter-  
pretations

Proposi-  
tions  
expressible  
in S

which it can be proved both that it expresses a true arithmetical proposition, and also that it is not a theorem of  $S$ , if  $S$  is a consistent system. Moreover, contrary to what one might expect, the incompleteness of  $S$  could not be overcome by adding extra axioms or rules to it; for, although it would be easy to strengthen the basis of  $S$  so as to obtain a system  $S'$  in which the *wff* in question is indeed a theorem, Gödel's reasoning would then enable one to construct another closed *wff* which would stand to  $S'$  exactly as the previous one does to  $S$ . The position in fact is that any consistent extension of  $S$  is bound also to be incomplete, and this fact is often expressed by saying that  $S$  is "essentially incomplete." Nor could one obtain a complete system for arithmetic by starting afresh with some other axioms and rules in place of those of  $S$ , for the upshot of Gödel's theorem is that any axiomatic system whatever that is sufficient for natural-number addition and multiplication is essentially incomplete; and as a result the otherwise natural ideal of giving a complete axiomatization of the whole, or even of some considerable part, of pure mathematics must be abandoned.

Sum-  
marizing  
distinctions

An important threefold distinction therefore exists among logical systems. There are those, like PC, that are both decidable and completely axiomatizable; there are those, like LPC, that are not decidable but are completely axiomatizable; and there are those, like natural-number arithmetic, that are neither decidable nor completely axiomatizable. The ability to draw this distinction with clarity and to demonstrate to which of the three groups a given system belongs is one of the most noteworthy achievements of contemporary logic.

Information about various theories of the nature of mathematical concepts and propositions and of the relation between logic and mathematics will be found in the articles MATHEMATICS, FOUNDATIONS OF; and METALOGIC.

APPLIED LOGIC

In a broad sense logic may be said to be applied when logical principles are used to test the validity of a particular inference or as a practical guide in discovering what conclusions one is or is not entitled to draw from a given set of premises. For this purpose lists of the forms of commonly encountered invalid inferences (logical fallacies) can be useful and are often given in textbooks, though the ways of going wrong, in reasoning as in other matters, are so multifarious that a fully systematic account of fallacies is perhaps a vain hope.

A logical system may, however, be an applied logic in the sense that it is meant to systematize the forms of sound reasoning, or to express a body of universal truths, in some relatively restricted field of thought or discourse. Typically such a system is constructed by setting up special constants (with specified interpretations) or new variables (with specified ranges of values) and extra axioms involving these and adding them to some "pure" logical system such as PC or LPC. (It has already been noted how this can be done in constructing extensions of LPC.) Some of the fields in which such applied logics have been constructed and investigated are noted briefly here. More detailed information will be found in the article LOGIC, APPLIED.

Various  
areas of  
application

1. Deontic logic is concerned with obligation, permissibility, and allied moral notions. Its simplest form involves adding two monadic operators, say  $O$  and  $P$ , to PC, with appropriate special axioms.  $Op$  is then understood to mean "It is obligatory that  $p$ " and  $Pp$  to mean "It is permissible that  $p$ ."  $O$  may be defined as  $\sim P\sim$  ("It is not permissible that not . . .") or  $P$  as  $\sim O\sim$ . More complex versions may involve the modal operators  $L$  and  $M$  (for necessity and possibility) as well, enabling formulas such as  $Op \supset Mp$  ("Whatever is obligatory is possible") to be constructed; and versions based on LPC may contain formulas such as  $O\phi xt$  to express "It is obligatory that  $x$  should  $\phi$  at time  $t$ ."

2. The logic of relative value can be somewhat analogously investigated. The dyadic operator  $B$  (for "is better than") could be thought of as having either propositions or names of individuals as its arguments; thus  $Bpq$  would

mean that it is better that  $p$  should be the case than that  $q$  should be the case, and  $Bxy$  would mean that object  $x$  is better than object  $y$ .

3. Epistemic logic is the logic of knowing and believing.  $Kxp$  can be used for "x knows that  $p$ " and  $Bxp$  for "x believes that  $p$ ."  $K$  and  $B$  would be unlike other operators so far considered in that one of their arguments would be the name of an individual and the other a proposition. Plausible theorems would be  $Kxp \supset p$  and  $Kxp \supset Bxp$ ; a more contentious one would be  $Bxp \supset \sim B\sim p$ —i.e., "If  $x$  believes that  $p$ , then  $x$  does not believe that not- $p$ ."

4. In systems designed to express the logic of temporal relations, propositions have usually been conceived as capable of changing their truth value with the passage of time. Thus "It is raining in London" may be both true on Tuesday and false on Wednesday. The way is thus opened for a logic of tenses. The simple  $p$  is taken to mean "It is (now) the case that  $p$ ,"  $Fp$  to mean "It will be the case that  $p$ ," and  $Pp$  to mean "It was the case that  $p$ ."  $PFp$  will then mean "It was the case that it would be the case that  $p$ ," and so forth. In this way a range of operators analogous to grammatical tenses can be built up and the logical relations between them systematized. Another development has been based on a reinterpretation of the modal necessity operator  $L$  so that  $Lp$  means "It is and always will be the case that  $p$ ."

5. Attempts have also been made to give a formal logic of various classes of conditional propositions that seem to resist analysis in terms of the implication relations (such as material or strict implication) that are expressed in the standard logical systems. Causal propositions of the form "If  $p$  then as a causal consequence  $q$ " comprise one such class; counterfactual conditionals—i.e., propositions of the form "If it were (had been) the case that  $p$ , then it would be (would have been) the case that  $q$ "—comprise another.

6. It should finally be mentioned that a certain amount of work—though not as yet a great deal—has been done toward constructing a formal logic of various non-propositional elements that play an important part in human discourse—elements such as questions, commands, exhortations, and expressions of intention.

V. Varieties of notation in symbolic logic

A wide variety of notations is found in works on formal logic. Sometimes in place of "literary" bracketing a system of dots is used, a larger group of dots having a wider scope than a smaller group; thus  $(p \supset q) \supset [q \supset (r \supset p)]$  may be written as  $p \supset q \cdot \supset : q \supset \cdot r \supset p$ . Or a combination of dots and brackets may be used. Conventions are often laid down for reducing the number of brackets; e.g., it may be stipulated that  $p \supset q \supset r$  is to be understood as  $(p \supset q) \supset r$ , not as  $p \supset (q \supset r)$ . But these conventions vary considerably from author to author. The negation  $\sim p$  is sometimes written as  $\bar{p}$  or as  $\bar{p}$ ;  $p \cdot q$  as  $p \wedge q$  or as  $p \& q$  or simply as  $pq$ ;  $p \supset q$  as  $p \rightarrow q$ ;  $p \equiv q$  as  $p \leftrightarrow q$  or as  $p \sim q$ . The symbol  $\forall$  is frequently omitted and universal quantifiers written as  $(x)$ , etc.  $\exists$  is sometimes written as  $E$ . In modal logic,  $M$  is often replaced by  $\diamond$ , and  $L$  by  $\square$  or less frequently by  $N$ . The choice of letters used as variables also varies considerably.

A more radically different symbolism is found in the so-called Polish notation, devised by Jan Łukasiewicz, in which all operators, dyadic as well as monadic, are written immediately before their arguments. In this notation  $\sim p$  becomes  $Np$ , and  $p \cdot q$ ,  $p \vee q$ ,  $p \supset q$ , and  $p \equiv q$  become respectively  $Kpq$ ,  $Apq$ ,  $Cpq$ , and  $Epq$ . In LPC,  $(\forall x)$  is written as  $\Pi x$ ,  $(\exists x)$  as  $\Sigma x$ , and  $x = y$  as  $Ixy$ . In syllogistic logic,  $a$ ,  $b$ , . . . are used as term variables and  $SaP$ ,  $SeP$ ,  $SiP$  and  $SoP$  are written as  $Aab$ ,  $Eab$ ,  $Iab$  and  $Oab$ , respectively. In modal logic,  $L$  and  $M$  are used as in this article, but  $p \rightarrow q$  is written as  $Cpq$  or as  $\mathcal{C}pq$ . In this notation no brackets of any kind are required, the distinctions made in other notations by bracketing being marked instead by the order of the symbols. Thus  $p \supset (q \vee r)$  is  $CpAqr$  but  $(p \supset q) \vee r$  is  $ACpqr$ .

BIBLIOGRAPHY. A great many books containing or consisting wholly of elementary introductions to modern formal logic are now available; thus the following list is bound to be

rather arbitrary. ALFRED TARSKI, *Elementy logiki matematycznej*, 2nd ed. (1958; Eng. trans., *Introduction to Logic and to the Methodology of Deductive Sciences*, 3rd ed. rev., 1965); W.V.O. QUINE, *Elementary Logic*, rev. ed. (1965); ALICE AMBROSE and MORRIS LAZEROWITZ, *Fundamentals of Symbolic Logic* (1948); IRVING M. COPI, *Symbolic Logic*, 3rd ed. (1967); JOHN A. FARIS, *Truth-Functional Logic* (1962), propositional calculus only, and *Quantification Theory* (1964), lower predicate calculus only; E.J. LEMMON, *Beginning Logic* (1965); GEORGE E. HUGHES and D.G. LONDEY, *The Elements of Formal Logic* (1965). All of these, except where noted, contain introductions to both the propositional and lower predicate calculi. The natural deduction rules given in this article are derived from the book by Lemmon. Also introductory, but more advanced in character, are: W.V.O. QUINE, *Methods of Logic* (1950); ARTHUR N. PRIOR, *Formal Logic*, 2nd ed. (1962); RUDOLF CARNAP, *Introduction to Symbolic Logic and Its Applications* (1958); and PATRICK C. SUPPES, *Introduction to Logic* (1957). The most influential work in the field is ALFRED NORTH WHITEHEAD and BERTRAND RUSSELL, *Principia Mathematica*, 3 vol. (1910-13). In *Principia Mathematica* to \*56 (1962), those parts of the original that are of most concern to logicians as distinct from mathematicians are reprinted. Another important and influential work is DAVID HILBERT and W. ACKERMANN, *Grundzüge der theoretischen Logik*, 2nd ed. (1938; Eng. trans., *Principles of Mathematical Logic*, 1950). Probably the most definitive account of the propositional and lower predicate calculi is presented in ALONZO CHURCH, *Introduction to Mathematical Logic*, vol. 1 (1956). For Syllogistic Logic, see JOHN N. KEYNES, *Studies and Exercises in Formal Logic* (1906), for a comprehensive traditional account; and JAN LUKASIEWICZ, *Aristotle's Syllogistic from the Standpoint of Modern Formal Logic*, 2nd ed. (1957); and OTTO A. BIRD, *Syllogistic and Its Extensions* (1964), for modern treatments. For Modal Logic, ROBERT FEYS, *Modal Logics* (1965), contains a comprehensive survey of axiomatic systems; GEORGE E. HUGHES and M.J. CRESSWELL, *An Introduction to Modal Logic* (1968), is a textbook and general survey. For brief introductions to set theory see P.R. HALMOS, *Naive Set Theory* (1960), and E.J. LEMMON, *Introduction to Axiomatic Set Theory* (1969); fuller accounts are given in PATRICK C. SUPPES, *Axiomatic Set Theory* (1960); and W.V.O. QUINE, *Set Theory and Its Logic* (1963). For an advanced treatment, see A.A. FRAENKEL, *Abstract Set Theory*, 3rd ed. (1965). For the logical foundations of mathematics (number theory and recursive functions), see ELLIOTT MENDELSON, *Introduction to Mathematical Logic* (1964); and J.W. ROBBIN, *Mathematical Logic: A First Course* (1969), though neither is easy reading. A standard advanced work in this field is S.C. KLEENE, *Introduction to Metamathematics* (1952). The most important journals in the field of formal logic are *The Journal of Symbolic Logic*, *Notre Dame Journal of Formal Logic*, *Logique et Analyse*, and *Zeitschrift für mathematische Logik und Grundlagen der Mathematik*.

(G.E.H.)

## Logic, History of

A survey of the development of logic may appropriately begin by delineating the boundaries of the discipline. Traditionally, logicians have distinguished between deductive logic, whose principles are used in drawing new propositions out of premises in which they lie latent, and inductive logic, which ventures conclusions from particular facts that appear to serve as evidence for them. But this division is obsolete, because the problems earlier subsumed under induction are now apportioned to the methodology of the natural sciences. Thus, in the present account, logic is taken to mean deductive logic with all of its ramifications.

### DEDUCTIVE LOGIC AS A DISCIPLINE

**Divisions and nature of deductive logic.** In its narrower sense deductive logic divides into (1) the logic of propositions (also called sentential logic) and (2) the logic of noun expressions. The logic of propositions or sentences is so named because, in it, propositions or sentences form the only basic semantic category (or part of speech). Some of them are simple and remain unanalyzed, others are compound and are analyzed into propositional connectives ("if . . . then," "and," "or," "it is not the case that," . . .) and their arguments, which themselves are propositions. In logical systems they are represented by  $p$ ,  $q$ ,  $r$ , . . . In the logic of noun expressions simple propositions are broken down into their parts, which comprise

a second basic semantic category; namely, the category of names ("Socrates," "the father of Socrates") or the category of common nouns ("philosopher," "Athenian citizen"). In simple propositions names often occur as arguments in concatenation with predicates; that is to say, verbs ("moves," "lives") or verblike expressions ("is wise," "is a philosopher"). The theory whose vocabulary comprises propositional connectives, names (represented by  $a$ ,  $b$ ,  $c$ , . . . or  $x$ ,  $y$ ,  $z$  . . .), predicates (represented by  $F$ ,  $G$ ,  $H$ , . . .), and the quantifiers ("for all . . ." and "for some . . .") is known as the logic of predicates or lower functional calculus or logic of quantification. Verbs or verblike expressions that require one name to form a proposition are called one-place predicates. There are also two-place predicates, three-place predicates, etc.; i.e., verbs or verblike expressions that require two or three or more names to form a proposition (" $a$  is bigger than  $b$ ," " $a$  gives  $b$  to  $c$ "). It is the task of the logic of relations, another part of the logic of noun expressions, to exhibit the use of such predicates. Neither the logic of predicates nor the logic of relations accommodates common nouns as a semantic category in its own right. Both treat common nouns as integral parts of predicates. Common nouns, however, can be given the status of a basic semantic category, as was, in fact, done in Aristotle's syllogistic and in that part of the logic of noun expressions that is known as the logic of classes.

In a wider sense, logic comprises, in addition to the above, various theories of language—such as logical syntax, the study of the various relationships that hold between the meaningful expressions of a natural or an artificial language; and semantics, the study of the various relationships that hold between the expressions in a language and some objects outside the language. Systems of the logic of propositions as well as systems of the logic of noun expressions can become, in turn, objects of special studies that are part of what is now known as metalogic or the methodology of deductive systems, a logic of logics, as it were. Theories of modalities—i.e., theories that are concerned with the notions of necessity, impossibility, possibility, and contingency—fall also within the scope of logic in its wider sense. Finally, in surveying the development of logic, the crucial role of logical fallacies and paradoxes cannot be overlooked.

As already mentioned, the principles or theses of the logic of propositions exhibit directly the use of such expressions as "if . . . then," "it is not the case that," "and," and "or," employed in concatenation with propositions,  $p$ ,  $q$ ,  $r$ . The principle of the hypothetical syllogism, which says that

$$\text{For all } p, q, r, \text{ if } [( \text{if } p \text{ then } q ) \text{ and } ( \text{if } q \text{ then } r ) ] \text{ then } ( \text{if } p \text{ then } r ),$$

is an example of a thesis belonging to the logic of propositions. The theses of the logic of noun expressions exhibit the use of such constant terms as "is the same object as," "is," "every . . . is," "some . . . is," "no . . . is," and "some . . . is not," to mention only a few. In concatenation with noun expressions,  $a$ ,  $b$ ,  $c$ , these terms form propositions. Examples of statements belonging to the predicate logic are the law that asserts the symmetry of statements of identity:

$$\text{For all } a \text{ and } b, \text{ if } a \text{ is the same object as } b \text{ then } b \text{ is the same object as } a$$

and the Aristotelian syllogism (called *Darii*):

$$\text{For all } a, b, \text{ and } c, \text{ if every } b \text{ is } c \text{ and some } a \text{ is } b \text{ then some } a \text{ is } c.$$

It should be noted that, in the theses of the logic of noun expressions, a vocabulary belonging primarily to the logic of propositions is employed, which reflects the fact that the logic of propositions is logically prior to that of noun expressions.

Some logicians have wondered whether there are any logical theories that involve the use of three or more basic semantic categories; and the answer is "yes," though so far such theories have not been worked out in detail.

**Alternative formats employed in presenting logical principles.** The foregoing examples of logical theses have been formulated with the aid of propositional variables,

Direct method: theses and expressions

Deductive and inductive logic

Logic of propositions and logic of noun expressions

Standard examples, metalogical terms, and schemata

$p$ ,  $q$ ,  $r$ , and with the aid of nominal variables,  $a$ ,  $b$ ,  $c$ , which stand for noun expressions. This formulation, first used by Aristotle, may be described as (1) the direct method of expressing logical principles. But Aristotle himself and many of his ancient and medieval followers often referred to logical principles also by means of (2) standard examples. For instance, the law of the hypothetical syllogism could be represented by the following example, adapted from a Greek commentator to Aristotle's *Analytica priora*:

If [(if a man exists then an animal exists) and (if an animal exists then a substance exists)] then (if a man exists then a substance exists).

Instead of expressing the law of the hypothetical syllogism directly or illustrating it with the aid of a standard example, it can be described in (3) metalogical terms:

For all  $a$ ,  $b$ , and  $c$ , if ( $a$  implies  $b$  and  $b$  implies  $c$ ) then  $a$  implies  $c$ . (Example: If [the universal affirmation ( $a$ ) implies the corresponding particular affirmation ( $b$ ), and the particular affirmation ( $b$ ) implies the negation of the corresponding universal denial ( $c$ )], then the universal affirmation ( $a$ ) implies the negation of the corresponding universal denial ( $c$ ). For terminology see below *Theory of opposition*.)

Here the variables  $a$ ,  $b$ , and  $c$  are nominal instead of propositional variables, and the term "implies"—which is not the same as the connective "if . . . then," because it requires noun expressions, and not propositions, as arguments—belongs to the vocabulary of metalogic. Many logical principles give rise to valid inferences, and some logicians have preferred using (4) schemata of valid inferences in presenting their systems of logic. The schema

If  $p$  then  $q$ ; but if  $q$  then  $r$ ; therefore if  $p$  then  $r$

gives the form of inferences the validity of which is guaranteed by the law of the hypothetical syllogism. A less abstract way of referring to logical principles consists in making use of (5) standard inferences. Thus, the inference

If a man exists then an animal exists; but if an animal exists then a substance exists; therefore if a man exists then a substance exists

if used in the context of a logical discussion, can be understood as representing the law of the hypothetical syllogism. Note that standard examples that illustrate logical principles are propositions, whereas standard inferences are sets of propositions. In an inference one proposition, usually indicated by the preceding "therefore," is the conclusion; the remaining propositions are called premises. These five different ways of referring to logical principles must be kept in mind when tracing their gradual emergence in the course of the development of logic.

#### ANCIENT LOGIC

**Precursors of ancient logic.** Though in theory the logic of propositions is logically prior to the logic of noun expressions, it was the latter that historically preceded the former. The first system of the logic of noun expressions was worked out by Aristotle in the 4th century BC. Aristotle was right when he claimed that in creating syllogistic, which is a part of the logic of noun expressions that can be formulated in terms of categorical propositions, he was a pioneer—though preparatory work of considerable extent and significance had been done for him already by earlier Greek mathematicians, rhetoricians, and philosophers. The Greeks were, in fact, almost unique in their practice, cultivation, and enjoyment of argument and proof; and without interest in the art of argumentation one cannot have an intellectual climate conducive to the development of logical theories. The ability, however, to produce valid inferences in the course of an argument does not necessarily presuppose any knowledge of logic. Indeed, the preserved speeches of ancient Attic orators and the dialogues of Plato contain numerous valid inferences, but the logical laws that account for their validity were unknown at the time.

It was mentioned earlier that in its wider sense logic comprises theories of language. In this field, preparatory work had been done by the Sophists, a class of private

tutors in ancient Greece who were the first to distinguish different types of sentences—affirmations, denials, questions, answers, and injunctions—and who were also interested in the study of synonyms. Further progress in theories of language was later made in the Academy, the school that Plato founded. In the *Sophist*, written in the 4th century BC, Plato remarked that neither a series of noun expressions alone nor a series of verbs alone can produce a proposition, a principle that is accepted even by logicians today, who have generalized it to read that no series of expressions belonging to one and the same semantic category can form a meaningful expression. More important for the development of logic, however, was Plato's conception of the axiomatic method, which lays down principles (usually self-evident) and deduces theorems from them, as an ideal means of systematizing knowledge. It was not until Aristotle and Euclid (c. 300 BC) that Plato's program was successfully turned into concrete achievement.

In discussing the prehistory of logic, mention should be made of fallacious arguments and paradoxes. These are arguments that, from premises that appear to be true, lead, by steps that appear to be valid, to a conclusion that appears to be false. The Sophists used to teach their pupils how to argue for and also against any propounded statement. This procedure, of course, gave occasion to fallacious arguments, which called for skillful refutation. In the 5th and 4th centuries BC, the interest in fallacious arguments was widespread, as is evidenced by Plato's *Euthydemus* and Aristotle's *De sophisticis elenchis*. The most famous of the early paradoxes was perhaps the "Achilles," invented by Zeno of Elea, an ancient Rationalist. Zeno argued that Achilles, reputed to be the fastest runner of all, could not overtake a tortoise in a race once the tortoise was allowed to get in front of him. For before overtaking the tortoise, Achilles would have to cover the distance that separated him from the tortoise at the time  $t_1$ . This he could accomplish at the time  $t_2$ ; but at that time the tortoise would have moved away and Achilles would still be separated from it. The argument can then be repeated for the distance between them at the time  $t_2$  and so on, pointing apparently to the conclusion that Achilles would never overtake the tortoise.

In a system of logic some of the theses are described as definitions. In introducing definitions, there are a number of conditions that must be carefully satisfied if they are to be used without endangering the consistency of the system. Though rules for thus introducing correct definitions into systems of logic are of recent origin, the credit for being the first to practice the art of definition should, according to Aristotle, be given to Socrates.

**Aristotle and the logic of noun expressions.** The collection of Aristotle's logical treatises is known as the *Organon*, a title invented probably by an ancient editor of his writings, which reflects the view that logic is a tool for sharpening thought. It consists of the *Categoriae*, the *De interpretatione*, the *Analytica priora* (two books), the *Analytica posteriora* (two books), the *Topica* (eight books), and the *De sophisticis elenchis*. The order of the treatises is supposed to be systematic; it does not seem to correspond to the chronological order, however. From the point of view of logic, the *De interpretatione* and the *Analytica priora* are by far the most important.

**Structure of language.** In Aristotle, the discussion of the syntactical and semantical features of language constituted a preamble to his syllogistic. Following Plato, he distinguished between nouns and verbs and regarded them as essential parts of a proposition; but he seemed to concentrate his attention on nouns and, in particular, on referential common nouns with limited generality. He did so because he believed that nonreferential or empty noun expressions, like "goat-stag," singular nouns, and the nouns of ultimate generality, such as "thing" or "object," are of lesser importance for scientific inquiries. Noun expressions, which in Aristotle included adjectives, are used for the purpose of constructing simple affirmations and denials of the following four types:

1. Singular: e.g., Socrates is white—Socrates is not white;
2. Universal: e.g., Every man is white—No man is white;

Theories of language of the Sophists and Plato

The *Organon*

3. Particular: *e.g.*, Some man is white—Some man is not white;  
 4. Indefinite: *e.g.*, Man is white—Man is not white.

In Aristotelian syllogistic, use is made of universal and particular propositions only. Called categorical propositions, these involve the following constant vocabulary: "Every . . . is," "No . . . is," "Some . . . is," and "Some . . . is not," which form propositions that were designated by medieval logicians as A, E, I, and O, respectively.

*Theory of opposition.* Syllogistic comprises (1) the theory of opposition, (2) the theory of conversion, and (3) the syllogistic proper. The theory of opposition, expounded in the *De interpretatione*, considers the logical relations that obtain between the four types of propositions formed by the affirmation and denial of universal and particular propositions. It stipulates that a universal affirmation, "Every *a* is *b*," and the corresponding particular denial, "Some *a* is not *b*," are contradictories; *i.e.*, that one of the pair must be true whereas the other must be false. A universal denial and the corresponding particular affirmation are also contradictories. A universal affirmation, "Every *a* is *b*," however, and the corresponding universal denial, "No *a* is *b*," form a pair of contrary propositions, which cannot both be true though they can both be false. A particular affirmation and the corresponding particular denial cannot both be false, though Aristotle did not state this fact. Finally, either of the two universal propositions implies the corresponding particular proposition (its "subaltern"), a fact that, judging from a passage in the *Topica*, was known to Aristotle. In the *De interpretatione*, the theory of opposition was stated in metalogical terms. Using the direct method, it is now possible to express the relevant logical principles as follows:

For all *a* and *b*, every *a* is *b* if and only if it is not the case that some *a* is not *b*.

For all *a* and *b*, no *a* is *b* if and only if it is not the case that some *a* is *b*.

For all *a* and *b*, if every *a* is *b*, then it is not the case that no *a* is *b*.

For all *a* and *b*, if it is not the case that some *a* is *b*, then some *a* is not *b*.

For all *a* and *b*, if every *a* is *b*, then some *a* is *b*.

For all *a* and *b*, if no *a* is *b*, then some *a* is not *b*.

*Theory of conversion.* Discussed in the *Analytica priora*, the theory of conversion considers the logical relationship that holds between a categorical proposition and its converse, obtained by reversing the order of the noun expressions *a* and *b*, and states in which cases such a converse can be inferred from the original proposition. The logical principles involved are not only described in metalogical terms and illustrated with the aid of standard examples but also are expressed directly. They are:

For all *a* and *b*, if every *a* is *b*, then some *b* is *a*.

For all *a* and *b*, if some *a* is *b*, then some *b* is *a*.

For all *a* and *b*, if no *a* is *b*, then no *b* is *a*.

For all *a* and *b*, if no *a* is *b*, then some *b* is not *a*.

This last principle, however, was not mentioned by Aristotle and has been disregarded by his successors.

*Syllogistic proper.* The *Analytica priora* contains also a systematic exposition of syllogistic proper. By a syllogism Aristotle understood a "propositional expression [*logos*] in which certain things having been laid down, something other than what has been laid down follows of necessity from their being so." This definition, however, is far too general; and it seems convenient for the present purposes to narrow it to apply to any inference for which the premises and conclusion are all categorical propositions—*i.e.*, simple propositions, rather than "if . . . then," "either . . . or," or "both . . . and" propositions—or to a logical principle that lends validity to such an inference. In Book I, chapters 4–7, Aristotle examined syllogisms with two premises. Such syllogisms, construed as logical principles, are all of the form

If  $\alpha$  and  $\beta$ , then  $\gamma$

in which the Greek letters alpha, beta, and gamma stand for categorical propositions with variable noun expressions called "terms." In syllogisms of this form, Aristotle distinguished: (1) the "major" term, which is the predicate in the conclusion and is assumed to occur in one of

the premises; (2) the "minor" term, which is the subject in the conclusion and is assumed to occur in the other premise; and (3) the "middle" term, which occurs in both premises but does not occur in the conclusion. Except for the definition of the middle term, which was employed by Aristotle, these definitions of the major and minor terms appear to have been introduced by John Philoponus, a 6th-century Christian theologian and Aristotelian commentator. In an Aristotelian syllogism the premises are also referred to as "the major" and "the minor," depending on which term (the major or the minor) they contain. Aristotle, in his exposition of syllogistic, was concerned to find out which pairs of categorical premises give rise to a valid syllogism. To systematize his search, he distinguished what he called the "three figures" of the syllogism, which he defined according to the placement of the middle term. First he examined those pairs of categorical propositions in which the middle term is the predicate in the minor premise and the subject in the major. Such combinations of premises are said to constitute the first syllogistic figure. Aristotle found that, in this figure, four different pairs of premises yield syllogistic principles. They are set out below together with their medieval names, the vowels of which indicate the kinds of propositions involved, whether A, E, I, or O (as earlier defined), and their sequence. The vowels of syllogism *Ferio*, for example, being EIO, indicate that the major (or first) premise is an E proposition ("No . . . is"), the minor (or second) premise is an I proposition ("Some . . . is"), and the conclusion is an O proposition ("Some . . . is not").

*Barbara:* For all *a*, *b*, and *c*, if every *b* is *c* and every *a* is *b*, then every *a* is *c*.

*Celarent:* For all *a*, *b*, and *c*, if no *b* is *c* and every *a* is *b*, then no *a* is *c*.

*Darii:* For all *a*, *b*, and *c*, if every *b* is *c* and some *a* is *b*, then some *a* is *c*.

*Ferio:* For all *a*, *b*, and *c*, if no *b* is *c* and some *a* is *b*, then some *a* is not *c*.

With the aid of appropriate counterexamples, Aristotle showed that the remaining combinations of premises in this figure do not yield valid syllogisms. The second figure is defined as the one in which the middle term occurs in the premises as the predicate. In this figure, too, four combinations of premises were found by Aristotle to give rise to syllogisms (*Cesare*, *Camestres*, *Festino*, *Baroco*). In the third figure, the middle term occurs in the premises as the subject. Here six combinations of premises prove to be syllogistic (*Darapti*, *Disamis*, *Datisi*, *Felapton*, *Bocardo*, *Ferison*). The syllogisms of the second and the third figures are not stated here explicitly since they can easily be reconstructed from their medieval names. As in the case of the first figure, the combinations of premises that, in the second and the third figures, do not produce valid syllogisms were shown by Aristotle to fail by means of counterexamples.

The most important features of Aristotle's presentation of syllogistic are the following: First, he gave his syllogisms the form of direct principles of logic and not the form of inferences or inference schemata. This he could do because, for the first time in the history of logic, he had thought of making use of variables, or letters that can stand for any noun expression. Second, he deduced his syllogisms of the second and the third figures from the syllogisms of the first figure, and by doing so he became the author of the first deductive system in the history of logic. In his deductions, Aristotle made explicit use of the theories of opposition and conversion. If his proofs were to be complete, however, he would have had to use a number of theses from the logic of propositions; but of this he was not aware.

In his syllogistic, Aristotle did not mention the combination of premises in which the major term is the subject and the minor is the predicate. Five such combinations yield valid syllogisms (*Bramantip*, *Camenes*, *Dimaris*, *Fesapo*, *Fresison*). They constitute a fourth figure, acknowledged by medieval logicians and the traditional logicians of modern times. To be sure, the syllogisms were known to Aristotle; but they were not included in his ac-

The three terms and three figures of the syllogism

Contradictories, contraries, and subalterns

Important features of Aristotle's syllogistic

count of syllogistic. This fault was rectified by his pupil Theophrastus, who redefined the first figure as the one in which the middle term occurs as the subject in one premise and as the predicate in the other, thus making it possible for the five syllogisms in question to be incorporated into the system. A further expansion of syllogistic was apparently effected by Ariston of Alexandria (1st century BC), a Peripatetic (member of Aristotle's school), who is said to have included in the system the "subaltern" syllogisms; *i.e.*, the syllogisms that result from taking a syllogism of a form already recognized and replacing the universal conclusion by the corresponding particular conclusion (*Barbari, Celaront, Cesaro, Camestrop, Camenop*).

**Modal logic.** In addition to constructing the first system, however modest, of the logic of noun expressions, Aristotle initiated the development of modal logic, which deals with the notions of necessity, impossibility, possibility, and contingency. Not only did he study their application to syllogistic, but he also arrived at some more general principles. He seems to have abandoned his earlier view that a necessary proposition cannot be said to be possible in favour of the following principles:

Relation of possibility to necessity

1. A proposition is necessary if and only if its negation is not possible;
2. A proposition is possible if and only if its negation is not necessary;
3. A proposition is contingent if and only if it is neither necessary nor impossible.

Aristotle's modal syllogistic contains, however, a number of controversial ideas, which were widely discussed in his school, the Lyceum. Unfortunately, the treatise *On the Disagreement Concerning Mixed Moods Between Aristotle and his Friends* by the expositor of Aristotle, Alexander of Aphrodisias (AD 200), which could have thrown light on the controversy, has not survived. Even today modal logic is a subject of controversy, logicians being divided on the fundamental issue of the nature of modal principles. Some include them within the logic of propositions; others assign them a place in metalogic.

Aristotle was not aware that his syllogistic presupposes a more general logical theory, *viz.*, the logic of propositions. To be sure, he mentioned "syllogisms from hypothesis," by which he may have meant some principles belonging to that logic; but he gave no details. As will be seen, there are firmer grounds for associating the origin of the logic of propositions with Theophrastus; with the Megarians, a 4th-century school of Socratic dialecticians and logicians; and with the Stoics.

**Theophrastus and the logic of noun expressions.** The writings of Theophrastus on logic are now lost; but evidence from secondary sources shows that he made creditable improvements in the systematization of syllogistic. He suggested, for instance, that the indefinite proposition, which asserts, for example, that "Man is white," should be treated as if it were particular (referring to "some men"), and he redefined the first figure and included in it five syllogisms originally omitted by Aristotle. Within the modal syllogistic he abandoned the notion of contingency. For the remaining modal notions, he introduced the principle of "the weaker premise," which regards a true proposition as weaker than a necessary one (since a proposition can be true, yet not necessary—but not vice versa) and a possible proposition as weaker than a true one, and demands that the conclusion in a valid syllogism should not be stronger, in respect of modality, than its weakest premise.

Prosleptic syllogisms

Theophrastus' theory of prosleptic syllogisms is perhaps his most interesting contribution to the logic of noun expressions. By prosleptic propositions he understood expressions of the form

For all  $x$ , if  $F(x)$  then  $G(x)$

in which both  $F(x)$  and  $G(x)$  stand for categorical propositions in each of which  $x$  occurs as one of the terms. (Example: "For all  $x$ , if every man is  $x$ , then every  $x$  is substance.") It should be noted that  $x$  is here a variable term bound by a universal quantifier, the expression "For all  $x$ ." It was described by Theophrastus as indefinite and called the middle term. Depending on the position of the middle term, conceived in this way, prosleptic propo-

sitions can be divided into three figures. In combination with an appropriate categorical premise, a prosleptic premise yields a prosleptic syllogism, as exemplified in the following inference schema:

For all  $x$ , if every  $x$  is  $a$ , then no  $x$  is  $b$ ;  
but every  $c$  is  $a$ ; therefore no  $c$  is  $b$ .

Some prosleptic propositions are equivalent to categorical propositions (Example: "For all  $x$ , if every  $x$  is  $a$ , then every  $x$  is  $b$ " is equivalent to "every  $a$  is  $b$ "), but this cannot be said about all of them, as Galen claimed that it could. For instance, no categorical proposition with  $a$  and  $b$  as arguments is equivalent to the prosleptic proposition which says that

For all  $x$ , if some  $a$  is not  $x$ , then every  $x$  is  $b$ .

It was Galen (died AD 199), however, one of the two greatest physicians of antiquity, who made the last major contribution to the logic of noun expressions in antiquity by developing a theory of compound syllogisms, occurring in four figures, in which two middle terms appear. Syllogisms of this sort can be illustrated by the following standard inference:

Every man is an animal; every man is rational; no irrational being is rational; therefore, some animal is not an irrational being.

Galen was of some importance as the transmitter of Greek logic to Arab scholars of the early Middle Ages. Their interest in Galen's writings on logic appears to have equalled that with which they read his medical works.

**Founding of the logic of propositions.** The earliest consideration of the logic of propositions occurred in the works of Theophrastus, of the Megarians, and of the Stoics. Theophrastus, according to Alexander of Aphrodisias, worked out a theory of totally hypothetical syllogisms, which, following the example of Aristotle, he neatly set out in three figures:

- |             |   |
|-------------|---|
| 1st figure, | If $p$ then $q$ ; if $q$ then $r$ ; therefore if $p$ then $r$ .           |
|             | or  |
|             | If $p$ then $q$ ; if $q$ then $r$ ; therefore if not- $r$ then not- $p$ . |
| 2nd figure, | If $p$ then $q$ ; if not- $p$ then $r$ ; therefore if not- $q$ then $r$ . |
|             | or  |
|             | If $p$ then $q$ ; if not- $p$ then $r$ ; therefore if not- $r$ then $q$ . |
| 3rd figure, | If $p$ then $r$ ; if $q$ then not- $r$ ; therefore if $p$ then not- $q$ . |
|             | or  |
|             | If $p$ then $r$ ; if $q$ then not- $r$ ; therefore if $q$ then not- $p$ . |

In these inference schemata, the letters  $p$ ,  $q$ , and  $r$  represent complete propositions; and for Theophrastus they probably represented categorical ones. But in fact, the nature of the propositions in this context is irrelevant to the validity of the inferences involved. By grouping the hypothetical syllogisms into three figures, Theophrastus tried to assimilate them to the Aristotelian categorical syllogisms of the predicate logic. He does not seem to have realized that hypothetical syllogisms belong to a different logical theory, to the logic of propositions and not to the logic of noun expressions. This fact, however, gradually became clear to the logicians in the Megarian school and in the Stoa (Stoic school).

The Megarian school was made famous by Eubulides (*c.* 4th century BC), a critic of Aristotle, by the dialectician Diodorus Cronus (died *c.* 307 BC), and by Philo of Megara, a pupil of Diodorus. To Eubulides logicians are indebted for certain paradoxes, including the celebrated "liar paradox" ("Does a man who says that he is now lying speak truly?"). Diodorus tried to connect modal notions, such as those of necessity and possibility, with the notions of past, present, and future; and Philo was the first to work out the truth-functional conception of implication; that is to say, of "if . . . then" propositions. (A compound proposition is said to be conceived truth-functionally if its truth or falsity is taken to depend exclusively on the truth or falsity of the propositions of which it is compounded.) Now, Philo argued, against Diodorus, that an implication is true if and only if its "if" proposition, known as the antecedent, is false or its "then" proposition, or consequent, is true; and that it is false if and only if its antecedent is true and its consequent is false.

The logic of Theophrastus and that of the Megarians

The inference schemata of Chrysippus

*Stoic logic.* It is not known whether the truth-functional interpretation of the rest of the vocabulary of the logic of propositions is also attributable to Philo; but it is known that implication, conjunction ("and" propositions), exclusive disjunction ("either . . . or" propositions), and negation ("it-is-not-the-case-that" propositions) were all interpreted truth-functionally by Chrysippus of Soli (died c. 207 BC), the second founder of the Stoa. The truth-functional vocabulary was used by Chrysippus to formulate various logical principles. As a rule, these principles were represented by means of standard inferences or by inference schemata. The following schemata are said to have been set out by Chrysippus as indemonstrable:

1. If the first then the second; but the first; therefore the second;
2. If the first then the second; but not the second; therefore not the first;
3. Not both the first and the second; but the first; therefore not the second;
4. Either the first or the second; but the first; therefore not the second;
5. Either the first or the second; but not the second; therefore the first.

Various other inference schemata can be derived from these five in accordance with certain rules or directives. Two such rules, which can be reconstructed from preserved fragments, can be stated in terms of variables as follows:

- A. For all  $a, b, c$ , and  $d$ , if  $b$  together with  $c$  implies  $d$  and  $a$  imply  $b$  then  $a$  together with  $c$  implies  $d$ .
- B. For all  $a, b$ , and  $c$ , if  $a$  together with  $b$  implies  $c$ , then  $a$  together with the negation of  $c$  implies the negation of  $b$ .

By applying rule A—which, incidentally, was known to the Peripatetics and used by them for the purpose of constructing compound syllogisms—the Stoics could derive the following inference schemata:

6. If the first then if the first then the second; but the first; therefore the second;
7. If the first and the second then the third; however, not the third; but the first; therefore not the second.

It is clear from a moment's inspection that, in an appropriate context, schema 7 could replace rule B; and it is interesting to note that, according to Alexander of Aphrodisias, rule B results from dividing a rule that, in fact, was the same as rule A. From the modern point of view, rules A and B belong to a branch of metalogic.

In matters of logic there was little collaboration between the Lyceum and the Stoa. There was even some effort on the part of both schools to create quite artificial differences; they developed, for instance, two different logical terminologies. For the Stoics, logic was a part of philosophy, whereas for the Peripatetics it was a tool. Aristotle presented his syllogisms in the form of direct logical principles, whereas the Stoics preferred to make use of inference schemata. The Stoics knew, however, that inferences owe their validity to direct logical principles, and they had a simple method of converting schemata into principles. Aristotle and his followers used letters as variables; the Stoics used numerals. In their logical practice, the Peripatetics allowed for a considerable amount of linguistic flexibility, whereas the Stoics became notorious for the formalistic approach, which demanded that expressions should have the same form if they were to have the same meaning. The most important difference, however, between the logics of the two schools is that the Peripatetic syllogistic is part of the logic of noun expressions, whereas the schemata of the Stoics represent principles that belong to the logic of propositions. In the time of Galen both of these logics became part of the syllabus for general philosophical education.

*Commentaries and compendiums.* After Theophrastus and Chrysippus, little creative work in logic was done in ancient times. To be sure, Galen wrote critical commentaries on the logical writings of Aristotle, Theophrastus, and Chrysippus; but those commentaries have not survived. After Galen there were only certain compendiums of logic, on the one hand, and scholarly commentaries on

Aristotle's logical treatises, on the other. Much of this literature has been lost, but the works of Alexander of Aphrodisias; of Porphyry (died c. 301), a pupil of Plotinus, the founder of Neoplatonism; of Ammonius Hermiae (5th century AD), a Neoplatonic mathematician and astronomer; and of the latter's pupil Simplicius have been preserved at least in part. Although these authors made, on occasion, improvements in the minutiae of the Aristotelian and Stoic logic, they can hardly be credited with any major contribution. Logicians are indebted to them, however, for salvaging numerous fragments from the lost writings of earlier logicians. The same can be said of certain Roman authors: of Cicero (died 43 BC); of Martianus Capella (5th century AD) and the senator Cassiodorus (died c. 582)—both of whom prepared compendiums of ancient learning; of the translator and commentator Boethius (died AD 524/5), whose influence dominated the early Middle Ages; and of others. These scholars worked out the Latin terminology for the field of logic and transmitted the achievements of the Greek logicians to the logicians of the Middle Ages.

#### MEDIEVAL LOGIC

*Development of medieval logic.* During the five centuries that followed the end of antiquity, little or nothing of any significance happened in the field of logic. As part of the basic curriculum (the trivium), logic was treated as a subsidiary subject providing useful training for students of law and theology. For the most part it was limited to discussing Porphyry's *Isagoge* and Aristotle's *Categoriae* and *De interpretatione* in a Latin translation by Boethius. Boethius' own logical writings were also read, along with some treatises by Gaius Marius Victorinus, a 4th-century African rhetorician, and the sections on logic to be found in the compendiums by Martianus Capella and Cassiodorus, and in the *Etymologiae* by the influential Spanish encyclopaedist Isidore of Seville (died c. 636). This sterility eventually began to change, however, because of the work of St. Anselm of Canterbury (died 1109), known for his ontological proof of the existence of God, and of Peter Abelard (died probably 1144), an eminent though controversial theologian and dialectician. During the 12th century, Latin translations of the remaining treatises of Aristotle's *Organon* were made, adding to the "old logic" a wealth of topics, then unfamiliar, that were given the name of the "new logic." In the 13th century logicians split: while some adhered to the Aristotelian orthodoxy and advocated the *logica antiqua*, others took a more liberal view and, in the faculties of arts of the newly established universities, propounded the *logica moderna*. The English logician William of Sherwood and his student Peter of Spain, later Pope John XXI, author of the most used textbook on logic for the next 300 years, seem to have been the most outstanding representatives of this new trend in logic. Among the logicians of the 14th century, mention should at least be made of the foremost philosopher of the century, William of Ockham; of Jean Buridan, also a scientist, who was the first to derive the laws of deduction deductively; and of his student and colleague Albert of Saxony. In the century that followed, Paul of Venice, an Augustinian theologian, produced a very comprehensive logic textbook under the descriptive title *Logica magna*. In the Greek world, the tradition of paraphrasing Aristotle's logical treatises and writing commentaries to them was continued by John Philoponus, by Stephanus of Alexandria, a 7th-century Neoplatonist, who transferred the tradition to Byzantium, and by others; and, in the 11th and 13th centuries, several logical compendiums were produced that deserve mention.

Logical studies were also cultivated by the Arabs. By the middle of the 9th century, Porphyry's *Isagoge* and Aristotle's *Categoriae*, *De interpretatione*, and *Analytica priora* had been translated first into Syriac and then into Arabic. The remaining parts of the *Organon* were similarly translated during the second half of the century. The works of Galen, too, attracted the attention of Arabic scholars, and it is through this channel that the logic of the Stoics percolated to Arab logicians. A more original work on the Aristotelian *Organon* was initiated in a school of

Arabic logic

Comparison of the Lyceum and the Stoa

logicians that flourished at Baghdad in the 10th century, of which the most famous representatives were the Nestorian Abū Bishr Mattā ibn Yūnus; Abū Naṣr al-Fārābī, who acquainted the Arabs with Plato and Aristotle; and a pupil of both of the foregoing, the Jacobite Yahyā ibn 'Adī. Unfortunately, their commentaries on Aristotle's logical writings and their own logical treatises, except for some commentaries by al-Fārābī, have been lost. In the view of the outstanding Persian philosopher Avicenna (died 1037), the school of Baghdad was too slavishly adherent to the Aristotelian tradition. He himself advocated a more independent line and gave expression to his concept of logic in his *Kitāb ash-shifā* ("The Book of Healing"). The tradition of the school of Baghdad, which in Islām was regarded as Western, was revived in Muslim Spain during the 11th and 12th centuries. It reached its climax in the works of Ibn Rūshd, known as Averroës, whose commentaries on the *Organon* played an important role in reviving the interest of Western scholars in Aristotle. In the 14th and 15th centuries, the logical studies by Arab scholars degenerated into the compiling of handbooks and the writing of explanatory notes to the handbooks bequeathed by earlier logicians.

The value of the Arabic contribution to the development of logic is not very great. Arab logicians kept interest in the *Organon* alive at a time when, in the West, only a small part of it was known to philosophers. They also preserved the Stoic tradition as transmitted by Galen; but so far, hardly any fresh light has been thrown on the logic of the Stoics from Arab sources. Of the three branches of medieval logic—the Byzantine, the Arabic, and the Scholastic—the latter appears to have been by far the most fruitful. Neither the Byzantine nor the Arab logicians seem to have achieved any lasting results. Even the hope that the writings of the Byzantine and Arab logicians might reveal important fragments of the logic of the ancient Greeks is not likely to be fulfilled.

**Theories of language.** As in antiquity, so also in the Middle Ages, the study of language played a significant part in the development of logic. Following Aristotle, the Scholastic logicians of the High Middle Ages distinguished between nouns and verbs; but this distinction was often replaced by the distinction between the subject and the predicate in a proposition. Expressions that could be used as subjects or as predicates were called *categoremata* (from Greek *katēgorein*, "to predicate") and distinguished from *syncategoremata* (from Greek *synkatēgorein*, "to predicate jointly"); i.e., from such parts of propositions as "every," "all," "no," "some," "only," and the like. Both *categoremata* and *syncategoremata* were meaningful expressions; but whereas a *categorematic* expression designated something outside of the language (i.e., had a referent), a *syncategorematic* expression was not capable of designation in the usual sense. By and large, *syncategorematic* expressions coincide with what is today described as logical vocabulary, and, indeed, some Scholastic texts implicitly suggested that logic should be construed as a theory of *syncategoremata*. According to Scholastic logicians, the function of a *syncategorematic* expression consists in changing or modifying the designation of *categorematic* expressions in a proposition—a problem connected with that of ambiguity in the use of *categoremata*. The Scholastics attempted to solve both of these problems with the aid of their theory of supposition, which is regarded as one of the original achievements of medieval logic. This theory appears to have originated in the 12th century; but it was Ockham and Albert of Saxony who gave it its traditional form. More than half a dozen different kinds of supposition can be distinguished. Supposition is a property of a term; i.e., of a *categorema*, as used in a proposition. Thus, for instance, in the proposition "Man is mortal" the term man is supposed to have formal supposition; but the same term is said to have material supposition in the proposition "Man is a noun." The terminology could perhaps be more illuminating, but the distinction at issue clearly corresponds to the present distinction between use and mention. In the proposition "Every man is mortal," the term man designates several men; hence, its supposition is common. But in the propo-

sition "This man is running," the term man designates exactly one man, and its supposition is described as discrete. This sort of distinction has special significance in the case of languages that, like Latin, have no articles. In such propositions as "Man is a species" and "Every animal apart from man is irrational," the term man has simple supposition. In application to the categorical propositions, the doctrine of supposition can be summarized, following Albert of Saxony, as follows: The subject in a singular proposition has discrete supposition, but in all indefinite or particular propositions it has determinate supposition. The supposition of the subject in a universal proposition is confused and distributive and so is the supposition of the predicate in a negative proposition. The supposition of the predicate in a particular affirmative proposition would be described, presumably, as determinate. The theory of supposition survives in traditional syllogistic as the theory of distributed terms, which asserts that in a given true proposition a term *a* is "distributed" if and only if, *a* having been replaced by a term *b* whose designata form a subclass of the designata of *a*, the proposition remains true.

**Formal logic.** Versions of the logics of noun expressions, of propositions, and of modal expressions can all be distinguished in the history of medieval logic.

**Logic of noun expressions.** In the Middle Ages the logic of noun expressions continued in the form of syllogistic. Medieval logicians abandoned the use of variables. Consequently, they had to illustrate logical principles with the aid of standard examples or describe them in metalogical terms; and they employed examples of inferences rather than of logical laws. One of the more important improvements in their syllogistic was the recognition of the fourth figure (in which the middle term is predicated of the major and the minor of the middle). To be sure, syllogisms constituting the fourth figure had been known to the Scholastics. But this figure was not recognized as such until the Averroistic Jewish philosopher Isaac Albalag did so in the 13th century. A great deal of ingenuity was devoted to the task of devising various mnemonics for the purpose of memorizing valid syllogisms and remembering the ways in which they can be "reduced" to syllogisms of the first figure (in which the middle term is predicated of the minor and the major of the middle).

**Logic of propositions.** The logic of propositions as developed by Theophrastus and the Stoics was transmitted to the Scholastics by Boethius. It seems not to have stimulated further development, however; it seems, instead, to have ossified in the early medieval compendiums; hence it had to be rediscovered. Its revival in the 13th century took the form of the theory of "consequences." At first its application was limited to syllogistic; but gradually it reached the level of abstraction at which the specific contents of the propositions involved lost their relevance, and the theory acquired the generality that it had possessed in the logic of the Stoics. The Scholastic consequences involved the use of conjunctions, inclusive disjunctions (i.e., alternations), and implications. All of these kinds of compound propositions were interpreted by the Scholastics truth-functionally. According to Pseudo-Scotus, the author of *In universam logicam quaestiones* ("Questions on Universal Logic") formerly attributed to John Duns Scotus, a consequence is a hypothetical proposition composed of an antecedent and a consequent joined by means of a conditional connective ("if") or, more often, by one expressing a reason ("therefore," "hence") and thus forming an inference. These, however, can be divided into material and formal inferences. A consequence that is valid for any terms, provided that their arrangement is preserved, is formal; and a consequence that does not fulfill this condition is material. A material consequence is valid if by adjoining a true proposition as premise it can be reduced to a formal consequence. (Example: "Socrates is a man; therefore, Socrates is mortal" is a valid material consequence because "Every man is mortal; Socrates is a man; therefore, Socrates is mortal" is a formal consequence.) In the medieval logic of propositions, logical principles were either described in metalogical terms or il-

The fourth figure and reduction to the first figure

*Categoremata* and *syncategoremata*; theory of supposition

New logical principles of the Scholastics

lustrated with the aid of standard examples. Among the principles that were known to the Scholastics, but not known to the ancient logicians, the following can be mentioned:

1. An alternation follows from each of its parts; *i.e.*,  
For all  $p$  and  $q$ , if  $p$  then  $(p \text{ or } q)$   
and  
For all  $p$  and  $q$ , if  $q$  then  $(p \text{ or } q)$ .
2. From a conjunction of contradictories there follows any other proposition; *i.e.*,  
For all  $p$  and  $q$ , if  $p$  and not- $p$  then  $q$ .
3. From a false proposition there follows any other proposition; *i.e.*,  
For all  $p$  and  $q$ , if not- $p$  then  $(\text{if } p \text{ then } q)$ .
4. Every true proposition follows from any other proposition; *i.e.*,  
For all  $p$  and  $q$ , if  $p$  then  $(\text{if } q \text{ then } p)$ .
5. An alternation for which the parts are contradictories of the corresponding parts of a conjunction is itself a contradictory of the conjunction; *i.e.*,  
For all  $p$  and  $q$ ,  $(p \text{ or } q)$  if and only if it is not the case that  $(\text{not-}p \text{ and not-}q)$   
and  
For all  $p$  and  $q$ ,  $(p \text{ and } q)$  if and only if it is not the case that  $(\text{not-}p \text{ or not-}q)$ .
6. If the opposite of the consequent is consistent with the antecedent, the consequence is not valid; *i.e.*,  
For all  $p$  and  $q$ , if  $p$  and not- $q$  then it is not the case that if  $p$  then  $q$ .
7. If the opposite of the consequent is not consistent with the antecedent, the consequence is valid; *i.e.*,  
For all  $p$  and  $q$ , if it is not the case that  $(p \text{ and not-}q)$  then if  $p$  then  $q$ .

*Logic of modal expressions.* In the Middle Ages, modal logic continued to be applied to syllogistic, but there is also some evidence of a more general development. Thus, the notions of truth, falsity, knowledge, opinion, doubt, appearance, will, and preference were added to the list of the traditional modal notions, and a number of modal theses were set up by Pseudo-Scotus, Ockham, Albert of Saxony, and Walter Burley, a 14th-century English Scholastic. The following theses can serve as examples of their modal principles:

1. The contingent does not follow from the necessary.
2. The impossible does not follow from the possible.
3. Anything whatsoever follows from the impossible.
4. The necessary follows from anything whatsoever.
5. Actuality (truth) can be validly inferred from necessity.
6. Possibility can be validly inferred from actuality (truth).
7. The possibility of negation can be validly inferred from the negation of necessity, and conversely.
8. The necessity of negation can be validly inferred from the negation of possibility, and conversely.

*Fallacies and paradoxes.* Aristotle's work *De sophisticis elenchis* attracted a great deal of attention from medieval logicians after it became available in the 12th century. Some of them regarded the study of sophisms as an essential part of an education in logic. As an exercise in clarifying the ambiguities of ordinary language, the inventing and solving of linguistic puzzles was not entirely fruitless; but of greater significance for logic was the discussion of the *insolubilia*. According to the polymath Scholastic St. Albertus Magnus (died 1280), teacher of St. Thomas, insoluble propositions are such that, whichever side of the contradictory is granted, the opposite also follows. (Example: If someone swears that he swears falsely, then, if he swears falsely, what he swears is not true—*i.e.*, he does not swear falsely; but if he does not swear falsely, then what he swears is true—*i.e.*, he swears falsely.) This is one of the many different and sometimes quite complicated versions of the ancient paradox of the liar. Various solutions of this paradox were discussed by logicians of the 14th and 15th centuries; in fact, Paul of Venice gave a list of 15 different attempts at explaining it. But the most interesting suggestions are to be found in an anonymous manuscript dating from the beginning of the 14th century. According to one doctrine, whoever says "What I am saying now is false" is in fact saying nothing; his utterance is simply meaningless. Another way of dealing with the difficulty consists in pointing out that the word false occurring in that statement cannot refer to the proposi-

tion of which it is a part. Both solutions have found advocates among contemporary logicians and philosophers.

#### LOGIC IN THE EAST

Judging from the outline of the development of logic given so far, it would appear that logic has been an exclusive product of Western culture. Some historians of the subject, however, have found this view parochial and sought to identify traces of logic in Indian and Chinese thought. But research in these two fields is beset with tremendous difficulties: most of the texts remain unpublished or untranslated; some of the monographs are unreliable; and scholars well trained both in logic and philology are extremely rare. Thus, a fair evaluation is, as yet, impossible.

**Indian logic.** Indian logic, which arose in the last centuries BC, when certain grammarians and religious thinkers became interested in methods of philosophical discussion, involved the study of texts called *sūtras* and of numerous commentaries on them written over centuries. Around each of these texts a school developed, which cultivated and defended its doctrines, of which the Mīmāṃsā, Vaiśeṣika, Nyāya, and New Nyāya schools of Hindu logic are of particular interest. Although Pāṇini and Patañjali, Indian grammarians, were active as early as the 5th and 2nd centuries BC, the first millennium AD was the classical period in the development of Indian logic. Among the most important Hindu logicians of this period were Kumārila (7th–8th centuries) of the Mīmāṃsā school, Praśastapāda (5th–6th centuries) of the Vaiśeṣika school, and Vātsyāyana (5th–6th centuries) of the Nyāya school. Several Buddhist logicians also flourished during the classical period, most notably Dignāga (5th century), Dharmakīrti (7th century), and Dharmottara (8th–9th centuries). The second half of the second millennium AD constituted a new chapter in Indian logic, represented by the New Nyāya, among the followers of which were Raghunātha (16th century), and Mathurānātha, Jaḡadīśa, and Annam Bhaṭṭa (all 16th and 17th centuries).

As the grammarians devised a special terminology for describing their language and formulating grammatical rules, they encountered problems similar to those of the modern distinction between language and metalanguage, as well as problems of definition, clarity, and economy in stating the rules of grammar.

In the *Vaiśeṣika-sūtra* (1st century AD), a doctrine was expounded that resembled Aristotle's theory of categories; *i.e.*, the theory of the kinds of entities that constitute the universe or of the generic terms that refer to them. The author distinguished (1) substances: earth, water, fire, air, ether, time, space, self, and mind; (2) attributes: colour, taste, smell, and touch, numbers, measures, separateness, conjunction and disjunction, priority and posteriority, understandings, pleasure and pain, desire and aversion, and volitions; and (3) actions: throwing upward, throwing downward, contraction, expansion, and motion. The remaining categories were (4) genus; (5) ultimate difference; and (6) inherence. To these, later texts added the category of (7) absence. It was no more clear, however, than it was in the case of Aristotle whether the list was meant to classify the meanings of words or the things denoted by words.

The *Nyāya-sūtra*, which was edited in the 2nd century AD, is regarded as the fundamental text of Indian logic. Its so-called five-member syllogism is usually illustrated by the following argument:

Proposition:	There is fire on the mountain.
Reason:	Because there is smoke on the mountain.
Example:	As in a kitchen—not as in a lake.
Application:	It is so ( <i>i.e.</i> , it is so in the present case).
Conclusion:	There is fire on the mountain.

The interpretation of the argument is not simple. In particular, the role of the example is obscure. If it is meant to remind one of instances in which smoke and fire are present and of instances in which they are absent, then the syllogism is an argument by analogy and has no validity in logic. On the other hand, the reason would im-

Leading Hindu and Buddhist logicians

The liar paradox

The *Nyāya-sūtra* and the five-member syllogism

ply the conclusion if the example could be interpreted as standing for a universal statement: "Where there is smoke there is fire." Development in this direction seems, in fact, to have taken place in Buddhist logic. Thus, according to Dignāga, the following three-membered rule holds: if (1) the presence of a definite mark in the subject has been stated, and if it is remembered that (2) the same mark is certainly in everything similar to the subject, but (3) absolutely absent in everything unlike it, then the result of the inference is certainly valid. Dharmakīrti, a commentator on Dignāga, used in fact a universal premise as the example. In the final form of the syllogism, as found in a textbook by Annam Bhaṭṭa of the New Nyāya school, the author distinguished between inference for oneself and inference for another. The inference for oneself consists of three steps such as:

1. Everywhere where there is smoke, there is fire.
2. There is smoke on this mountain.

From the combination there arises the knowledge:

3. There is fire on the mountain.

Inference for another involves five members and reads:

The mountain is fiery—that is the proposition. Because smoky—that is the reason. All that is smoky is fiery—that is the example. So here—that is the application. Therefore it is so—that is the conclusion.

The member that is described as the application raises a problem. Although modern commentators seem to regard it as mere restatement of the reason, which is the second member, it is tempting to view it as the application of the universal statement—*i.e.*, the third member—to the particular instance under consideration. If this were correct, then the expressions "It is so" and "So here" could be interpreted as abbreviations standing for "If there is smoke in the mountain then there is fire in the mountain" or "If the mountain is smoky then the mountain is fiery." Be that as it may, the five-member syllogism bears a close resemblance to the prosleptic syllogism of Theophrastus (see above *Theophrastus and the logic of noun expressions*).

An argument reminiscent of the Stoic inference schemata has been found in a Buddhist work, the *Kathāvattu*, which reads:

- If the soul be known in the sense of a real and ultimate fact, then indeed, good sir, you should also say, the soul is known in the same way as any other real and ultimate fact is known. (2) That which you say here is wrong, namely, that we ought to say, "The soul is known in the sense of a real and ultimate fact," but we ought not to say, the soul is known in the same way as any other real and ultimate fact is known. (3) If the latter statement cannot be admitted, then indeed the former statement should not be admitted. (4) In affirming the former statement, while denying the latter, you are wrong.

It is easy to say that this argument is an instance of the following schema:

- |            |                                 |
|------------|---------------------------------|
|            | (1) If $p$ then $q$ ;           |
| therefore, | (2) Not ( $p$ and not- $q$ );   |
| therefore, | (3) If not- $q$ then not- $p$ ; |
| therefore, | (4) Not-( $p$ and not- $q$ ).   |

All of these inferences are valid; but although another argument of similar form, with "not  $p$ " instead of " $p$ " and "not  $q$ " instead of " $q$ ," is found in the text, it would be too generous to credit the Buddhist logician with the discovery of the logic of propositions. In the *Kathāvattu*, the arguments are not used as standard examples to represent any argument whatsoever of the same form. They occur in a discussion on the knowability of the soul and belong to psychology rather than to logic. Discussions of this kind do appear, however, to follow very strict rules based probably on practice and tradition.

The notion of negation seems to have been of particular interest to Indian logicians. Thus, the followers of the Mīmāṃsā explored the ways in which an injunction could be negated. They distinguished "He shall-not look," "He shall not-look," and "Not-he shall look" as possible negations of "He shall look." Mathurānātha, of the New Nyāya school, wrote, "Wherever one perceives a pot, there one does not perceive constant absence of a

pot. . . . Accordingly, absence of constant absence of pot is essentially identical with pot." This statement looks like a double negation law expressed with the aid of a standard example. In the texts of the New Nyāya, the notion of negation often occurs in connection with abstract terms. Thus, instead of the simple proposition "The mountain is smoky," for instance, the cumbersome one "Not-mountain-ness qualifies the locus of not-being-smoky" is employed. This type of language invites comparison with the highly artificial Latin of the medieval logicians.

Compared with the logic of the ancient Greeks, Indian logic is not very impressive. It must be emphasized, however, that—unlike the logic of the Arabs—it developed independently of Greek thought. While it may be granted that the logic of propositions may have been anticipated by some Buddhist logicians, it does not seem that much progress was made. The logic of noun expressions asserted itself more firmly, as in the five-member syllogism and its variants, but it never reached the level of Aristotle's syllogistic. The development of Indian logic was severely handicapped by the failure of its logicians to make use of variables. As a result, no logical principles could be stated directly; they had to be illustrated by standard examples or described metalinguistically (*i.e.*, in talk about the language in which they might have been stated). Finally, in Indian thought, logical topics were not always separated from metaphysical and epistemological topics (on the nature of being and knowledge, respectively). It must be remembered, however, that present knowledge of the development of logic in India is incomplete and that it may have to be revised in the light of future research.

**Chinese logic.** For the most part, Chinese philosophy is concerned with practical and moral problems on the one hand and with mystical interpretations of life on the other. It has little room for the study of logic, which has remained neglected since the establishment of Neo-Confucianism in the 11th century AD. In the classical period of Chinese philosophy (5th to 3rd centuries BC), the controversies between the major philosophies of Confucianism, Taoism, and Moism gave rise to a kind of dialectic, which eventually was systematized to some extent by the Moists. They turned it into a weapon against the skepticism of the Taoists, who maintained that one point of view is as good as another because each is based upon different assumptions regarding the relations between names and objects. According to the Taoists, assumptions of this kind are entirely arbitrary. As dialecticians, the Moists were primarily interested in the study of names in relation to objects. They distinguished "unrestricted" names, which apply to every object; "private" names, which apply to one object each; and names like "horse," which apply to every object of a kind. (As noted earlier, a comparable classification of noun expressions had been worked out by Aristotle; see above *Aristotle and the logic of noun expressions: Structure of language*.) The Moists were also interested in defining the terms used in philosophical discussions and in listing various senses of ambiguous terms. Their definitions of "all" and "some" resemble the laws of obversion for the universal affirmative and particular affirmative propositions. They distinguished between absolute identity and relative identity (sameness in a specified respect). Gradually, the Moists developed an interest in the forms of propositions and in inferences from propositions of the same form; but, whereas Western logicians searched for the similarity of form in the structures of propositions with a view to establishing logical principles or schemata of valid inference, the Moists considered instances in which the similarity of form does not warrant any inference. "A white horse is a horse" implies "Riding white horses is riding horses"; but one may ask whether "A robber is a man" implies "Killing robbers is killing men." The Moists' answer was in the negative; and they supported it by pointing out that, although a robber is a man, abounding in robbers is not abounding in men, and disliking the abundance of robbers is not disliking the abundance of men. The purpose of this argument, however, does not seem to have been to elucidate any logical or linguistic

Evaluation of Indian logic

The Moist dialectic of names and objects

Nascent inference schemata

puzzle but to show that, contrary to the opponents of Moism, killing robbers was compatible with love for all men; it was not a point of logic that was at issue but a point of morals. Discussions of this sort could have led, in due course, to the investigation of logical problems, but as it happened, they did not do so. In developing logic, the Chinese thinkers did not advance beyond the stage of preliminaries, a stage that was reached in Greece by the Sophists in the 5th century BC.

#### MODERN LOGIC

**Logic in the Renaissance and in Humanism.** Returning to the West, the logical tradition of the Middle Ages survived for about three centuries after it had reached its maturity in the 14th century. The intellectual climate, however, that established itself in the West with the advent of the Renaissance and Humanism did not enhance logical studies. The Latin of the Roman writers Lucretius, Cicero, and Quintilian proved more attractive than the language of Boethius and the Scholastics; and rhetoric took precedence over logic. At the same time, the authority of Aristotle was gradually replaced by that of Plato and the Neoplatonist Plotinus. The rise of the natural sciences also contributed to the neglect of logic, which, as a deductive discipline, gave way to methodological investigations. These developments called for a new approach to logic; and in the mid-16th century such an approach was in fact taken by Petrus Ramus, an anti-Aristotelian logician and educational reformer. Ramus described logic as an "art of discussing" and distinguished it from grammar and rhetoric, which in his view were concerned with matters of style. Logic, according to Ramus, should treat of concepts, judgments, inferences, and proofs—in that order. Among inferences he counted syllogisms, both categorical and hypothetical. To the former he added syllogisms involving the use of singular propositions. In accordance with the spirit of the time, he used illustrations from classical literature. The divisions of logic suggested by Ramus were adopted by the authors of *La Logique: Ou l'art de penser* (1662; Eng. trans. in *The Port-Royal Logic*, 1851), which consisted of four parts. The discussion of concepts and judgments in parts I and II, respectively, seems to contain a few original observations, which belong, however, to epistemology rather than to logic. In part III, on reasoning, the validity of syllogisms is determined by giving rules for each of the figures and proving corollaries. Although some of these rules were known to the Scholastics, *The Port-Royal Logic* gives a systematic presentation of what later writers of textbooks developed into a metalogical theory of syllogistic. In part IV, on method, Euclid's *Elements* is recommended as a model of scientific method. Following René Descartes, the father of modern philosophy, they insisted that, in any scientific inquiry, obscure or equivocal terms should be defined; that only perfectly known terms should be used in definitions; that only self-evident truths should be used as axioms; and that all propositions that are not self-evident should be proved with the aid of axioms, definitions, and already proved propositions. Despite the competition of an entirely new conception of logic afforded by Gottfried Wilhelm Leibniz, a German Rationalist of widespread interests, the ideas expounded in *The Port-Royal Logic* continued to be popular to the mid-19th century.

**Rise of mathematical logic during the Enlightenment.** Modern logic began in the 17th century with Leibniz and developed in partnership with mathematics.

*Leibniz' characteristic universalis.* Leibniz influenced his contemporaries and successors through his ambitious program for logic, which for him had ceased to be "a scholar's diversion" and began to take the form of a "universal mathematics." His program envisaged a universal language based on an alphabet of thought, or *characteristica universalis*, a general calculus of reasoning, and a general methodology. In Leibniz' view, the universal language should be like algebra or like a version of the Chinese ideograms and consist of basic signs standing for simple unanalyzable notions. Complex notions would then be signified by appropriate constructions involving

the basic signs, which would thus reflect the structure of complex notions and, in the final analysis, that of reality. The use of numerals to represent unanalyzable notions would hopefully enable the truths of any science, when formulated in terms of the universal language, to be computed by arithmetical operations. Neither the idea of an artificial language nor that of reducing reasoning to computing was entirely new; it was owing to Leibniz' vision and confidence, however, that the two ideas came eventually to fruition—as witnessed by the arithmetization of logical languages by Kurt Gödel, a Moravian-U.S. mathematical logician, on the one hand, and by the emergence of contemporary computer science, on the other. Leibniz' more concrete contributions to the development of logic appear to be twofold: he successfully applied mathematical methods to the interpretation of the Aristotelian syllogistic, and in proposing a "calculus of real addition" he showed that parts of algebra are open to nonarithmetical interpretation.

In discussing Aristotle's syllogistic, Leibniz rightly insisted that each of the four categorical propositions has existential import (*i.e.*, its terms have instances), and that, consequently, there are six valid syllogisms in each of the four figures. He also correctly suggested that singular propositions could be treated as universal. But his most important finding consisted in a very ingenious arithmetical interpretation of syllogistic, which rests on the assumption that variables take ordered pairs of relatively prime numbers as their values. Leibniz showed how, on this assumption, the four categorical propositions should be interpreted, and he demonstrated that, when so interpreted, all valid syllogisms are verified and the rejected syllogisms falsified. Moreover, his interpretation has proved to be adequate even in relation to a very intricate rule of rejection proposed for syllogistic in the 1940s by the Polish logician Jerzy Słupecki of the Warsaw school of logic, later professor at the University of Wrocław (formerly Breslau). The problem of defining the four propositions in terms of identity, difference, logical product of noun expressions, and logical complement long exercised Leibniz' mind. Anticipating the use of quantifiers, Leibniz suggested the following definitions (slightly streamlined):

1. For all  $a$  and  $b$ , every  $a$  is  $b$  if and only if for all  $c$ , if  $c$  is  $a$  then for some  $d$ ,  $d$  is  $b$  and  $c$  is the same object as  $d$ .
2. For all  $a$  and  $b$ , some  $a$  is  $b$  if and only if for some  $c$ ,  $c$  is  $a$  and for some  $d$ ,  $d$  is  $b$  and  $c$  is the same object as  $d$ .
3. For all  $a$  and  $b$ , no  $a$  is  $b$  if and only if for all  $c$ , if  $c$  is  $a$  then for all  $d$ , if  $d$  is  $b$  then  $c$  is different from  $d$ .
4. For all  $a$  and  $b$ , some  $a$  is not  $b$  if and only if for some  $c$ ,  $c$  is  $a$  and for all  $d$ , if  $d$  is  $b$  then  $c$  is different from  $d$ .

Leibniz claimed that, given these definitions, one can prove all of the valid syllogisms with the aid of two principles: one of them states that "For all  $a$ ,  $b$ , and  $c$ , if  $a$  is the same object as  $b$  and  $b$  is the same object as  $c$ , then  $a$  is the same object as  $c$ "; and the other states that "For all  $a$ ,  $b$ , and  $c$ , if  $a$  is the same object as  $b$  and  $b$  is different from  $c$ , then  $a$  is different from  $c$ ." Actually, Leibniz was right, provided that one is entitled to assume that "For all  $a$  and  $b$ ,  $a$  is different from  $b$  if and only if it is not the case that  $a$  is the same object as  $b$ ," and that "For all  $a$ , for some  $b$ ,  $b$  is  $a$ ."

Leibniz' treatment of Aristotelian syllogistic reflects his interest in the notions of identity and difference. In one of his papers he stated that those terms are "the same" or "coincident" of which either can be substituted for the other wherever one pleases without loss of truth—*e.g.*, "triangular" and "trilateral." This informal definition expresses an idea that today would be expressed directly as the law of extensionality for noun expressions: "For all  $a$  and  $b$ ,  $a = b$  if and only if [for all  $F$ ,  $F(a)$  if and only if  $F(b)$ ],"  $F$  standing for any predicate (verblike expression). Here " $a = b$ " means that " $a$ 's are the same as  $b$ 's." Leibniz expanded his calculus of identity through the notions of "complement" and "real addition": In his symbolism, the "real sum" of the terms  $a$  and  $b$  is expressed as " $a \oplus b$ ," but the complement of  $a$  is simply expressed as "not- $a$ ." Leibniz' calculus of real addition has the form of a deductive system based on axioms and definitions.

Period of neglect and the new approach of Ramus

The Port-Royal Logic

Arithmetical interpretation of syllogistic

Calculus of identity

Given the theory of identity, the axiomatic foundations of this system can be condensed into the following simple proposition: "For all  $a, b$ , and  $c$ ,  $a = b \oplus c$  if and only if ( $a = c \oplus b$  or it is not the case that  $a = a \oplus a$ )." If one wishes to incorporate the notion of complement, however, then the single axiom would have to be replaced by the following: "For all  $a, b$ , and  $c$ ,  $a = b \oplus c$  if and only if it is not the case that [ $a = \text{not}(c \oplus b)$  and  $a = a \oplus a$ ]." Leibniz' logical papers remained for the most part unknown until *La Logique de Leibniz* was published by Louis Couturat, a French philosopher of mathematics, in 1901. Had these papers been published during the lifetime of Leibniz, the revival of logic, which in fact occurred in the mid-19th century, would have happened much earlier.

*Search for clarity and use of diagrams.* The new approach to syllogistic and the search for an algebra capable of nonarithmetical interpretation characterized the development of logic after Leibniz. At the end of the 17th century and during the 18th century, these two lines of research were followed mainly by mathematicians. Girolamo Saccheri, an Italian Jesuit, influenced by the Cartesian methodology, proceeded to apply to logic the standards of clarity expected in geometrical proofs. He was dissatisfied with Aristotle's use of extra-logical counterexamples in rejecting invalid syllogisms. Consequently, he proposed a different method of rejection, suggested by a certain kind of proof found in Euclid. It was the method of *reductio ad absurdum*, but a *reductio* with a difference. Saccheri used, for example, the premises

Saccheri's *reductio ad absurdum*

1. Every syllogism of the first figure with a universal major and an affirmative minor premise is a valid syllogism;

and

2. No AEE-syllogism (i.e., with A and E premises and an E conclusion) of the first figure is a syllogism with a universal major and an affirmative minor premise;

and concluded from them that

3. No AEE-syllogism of the first figure is a valid syllogism.

Actually, though the premises and the conclusion are true, the argument as it stands is not valid. A further premise, which Saccheri tacitly assumed, is needed, viz.,

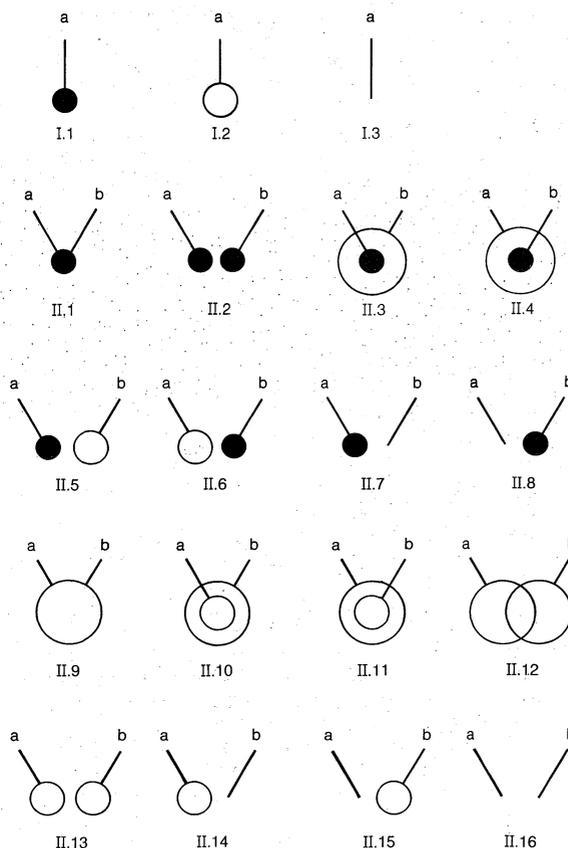

4. If some AEE-syllogism of the first figure is a valid syllogism, then for all  $a, b$ , and  $c$ , if every  $b$  is  $c$  and no  $a$  is  $b$  then no  $a$  is  $c$ .

With this addition, given the syllogistic laws of contradiction, the premises (1), (2), and (4) now imply (3) as a conclusion and enable the usual *reductio* to be applied; for if, contrary to the conclusion, it is additionally assumed that "Some AEE-syllogism of the first figure is a valid syllogism," then it can be easily shown that, even on this assumption, the conclusion holds—which means that the assumption is redundant. No extra-logical vocabulary has here been used, provided that logic is understood to include metalogic, and in particular metasyllogistic.

The practice of illustrating categorical propositions by geometrical diagrams was already in evidence in the 16th century. Though it was later used by Leibniz, and by Johann Heinrich Lambert and Gottfried Ploucquet—authors of two early formulations of logical calculi—it has come to be associated with the name of Leonhard Euler, an 18th-century Swiss mathematician.

If one wants to go further than Euler and distinguish between singular, general, and nonreferential noun expressions, then properties and relations that belong to or hold between extensions of singular, general, and nonreferential noun expressions can be determined with reference to diagrams tabulated as shown in the figure. A small shaded circle represents the extension of a singular noun expression and an unshaded circle that of a general noun expression. No circle is used in the case of a nonreferential noun expression. The diagrams I.1, I.2, and I.3 illustrate the following propositions: "There exists exactly one  $a$ ," "There exist more  $a$ 's than one," and "There exist no  $a$ 's." The spatial relations between the circles in diagrams II.1–II.16 correspond to the relations between the extensions of noun expressions represented by  $a$  and  $b$ . Some, but not all, of these relations are fairly familiar. Thus, for instance, diagrams II.1, II.2, and II.3 illustrate

Diagrams for relations between kinds of noun expressions

Properties and relations belonging to or holding between extensions of singular, general, and nonreferential noun expressions (see text).

From *Ratio* (1958); Blackwell, Oxford

the following propositions: "a is the same object as b," "a is different from b," and "a is one of many b's." And the proposition "No a's are b's" is illustrated by diagram II.13.

In Euler's *Lettres à une princesse d'Allemagne* (3 vol., 1768–72), he used diagrams II.10 and II.13 to illustrate the universal affirmative and the universal negative propositions and used II.12 to illustrate the two particular propositions. If the interpretation suggested by his diagrams is adhered to rigorously, however, it is found to fail for the syllogistic laws of identity, contradiction, subalternation, and subcontrariety, as well as for the syllogisms that depend on these laws.

**Development of mathematical logic in the 19th century.** During the 19th century, and especially during its last half, the foundations were being laid for the most remarkable developments in the history of logic.

*Expansions of syllogistic by Gergonne and Bentham.* More than 100 years after Euler, his idea of geometrical diagrams was elaborated systematically by the Frenchman Joseph Diez Gergonne, a mathematician and editor of a mathematical journal. Following the Aristotelian tradition, Gergonne disregarded both singular and nonreferential noun expressions, but his treatment of general noun expressions can be regarded as complete. He needed only five diagrams to determine the five simple relations between the extensions of two general referential noun expressions, viz.,  $a \mid b$ ,  $a \subset b$ ,  $a \supset b$ ,  $a \times b$ , and  $a \text{ H } b$  (in the foregoing table: II.9, II.10, II.11, II.12, and II.13). These simple relations can now be used to define the categorical propositions of syllogistic, as set out below:

- For all  $a$  and  $b$ , every  $a$  is  $b$  if and only if  $a \mid b$  or  $a \subset b$ ;
- For all  $a$  and  $b$ , no  $a$  is  $b$  if and only if  $a \text{ H } b$ ;
- For all  $a$  and  $b$ , some  $a$  is  $b$  if and only if  $a \mid b$  or  $a \subset b$  or  $a \supset b$  or  $a \times b$ ;
- For all  $a$  and  $b$ , some  $a$  is not  $b$  if and only if  $a \supset b$  or  $a \times b$  or  $a \text{ H } b$ .

Gergonne's relations can be defined, conversely, in terms of the syllogistic constants. Thus, Gergonne's innovation

Use of the diagrams by Euler and Gergonne

consisted, in fact, in expanding the vocabulary of syllogistic and proposing new kinds of inference based upon the expansion. He did not, however, axiomatize his system. This was done, instead, in the 20th century by John Acheson Faris, a Belfast logician.

From the point of view of logic, "every . . . is" (or "all . . . is") is treated as a single syntactically unanalyzable term, which in concatenation with two noun expressions forms a proposition. Traditionally, however, it had been held that "every" (or "all") modifies the way in which the subject should be construed. This suggested to logicians a similar modification of the predicate. The idea was not new, however; it had been discussed by Aristotle in the *De interpretatione*, only to be abandoned later. Some of Aristotle's ancient commentators determined that a modification of this sort would generate 16 different propositions. But the authority of Aristotle prevented them from enquiring more deeply into the problem. Because of the writings of Sir William Hamilton, an influential Scottish metaphysician, "the doctrine of the quantified predicate" became topical in the first half of the 19th century and led to a bitter controversy between him and Augustus De Morgan, an English mathematician and logician. Hamilton distinguished eight different forms of proposition that involved quantification of the predicate, but apparently he did not know that the same distinctions had already been made by George Bentham, an English botanist and systematist. Bentham was concerned with the relations of identity and exclusion (or outsidedness) as holding between both total and partial extensions of two noun expressions. In his system of notation, " $tX = pY$ " meant that the total extension of  $X$  is identical with a proper part of the extension of  $Y$ , and " $pX \parallel pY$ " meant that a proper part of the extension of  $X$  is entirely outside a proper part of the extension of  $Y$ . Hamilton used a symbolism of his own to express his eight forms of proposition, but he also expressed them in ordinary language. The table shown below gives, on the left hand side, propositions distinguished by Bentham, and, on the right hand side, their Hamiltonian versions:

- |                            |                            |
|----------------------------|----------------------------|
| a. $tX = pY$ . . .         | All $X$ is some $Y$ .      |
| b. $tX \parallel pY$ . . . | Any $X$ is not some $Y$ .  |
| c. $tX = tY$ . . .         | All $X$ is all $Y$ .       |
| d. $tX \parallel tY$ . . . | Any $X$ is not any $Y$ .   |
| e. $pX = pY$ . . .         | Some $X$ is some $Y$ .     |
| f. $pX \parallel pY$ . . . | Some $X$ is not some $Y$ . |
| g. $pX = tY$ . . .         | Some $X$ is all $Y$ .      |
| h. $pX \parallel tY$ . . . | Some $X$ is not any $Y$ .  |

Obviously, Bentham arrived at his list of propositions by permutating his symbols, but he was not very clear about their interpretation. Thus, he claimed, for instance, that propositions (b) and (d) both represent the E proposition. He thought that proposition (d) was rather useless and that the remaining propositions could be reduced to the four standard types. Hamilton, too, was somewhat confused about the meanings of his eight propositions. He identified propositions (a), (d), (e), and (h) with the A, E, I, and O propositions, but, following Euler, he illustrated each of these propositions with the aid of one set of circles. This means, in fact, that each of these propositions exhibits the use of a Gergonne constant. For the purpose of such an interpretation, however, "some" had to be understood as meaning "some but not all." On these assumptions, propositions (a), (c), (d), (e), and (g) can be regarded as exemplifying the Gergonne constants C, I, H, X, and O, respectively. Proposition (f) then turns out to be just another version of (e), whereas (b) and (h) can be taken to express compound relations between extensions: proposition (b) can be construed as equivalent to "All  $X$  is some  $Y$  or some  $X$  is some  $Y$ " and proposition (h) as equivalent to "Some  $X$  is all  $Y$  or some  $X$  is some  $Y$ ." Alternatively, one can accept Hamilton's identification of propositions (a), (d), (e), and (h) with the four categorical propositions and treat propositions (b), (c), (f), and (g) as expanding the vocabulary of syllogistic. This, in fact, is how Hamilton viewed his contribution, though he also claimed, wrongly, that his scheme was an improvement on Aristotelian logic. Using the new vocabulary, Hamilton and his fol-

lowers worked out a great number of additional syllogisms and tried to work out a simple criterion for testing their validity. At the root of the difficulties experienced by Hamilton was his pardonable failure to distinguish between "all" and "some" as integral parts, on the one hand, of the constants "all . . . are" and "some . . . are," and, as used, on the other hand, in "For all  $a$ , . . ." and "For some  $a$ , . . ." which are quantifiers in the sense accepted today. When expressed in a more sophisticated logical idiom, the conceptions of Bentham and Hamilton reveal an affinity to the Leibnizian definitions involving identity and difference.

*Expansion of syllogistic by De Morgan.* A more successful attempt at expanding syllogistic was made by Augustus De Morgan, who developed a logic of noun expressions in *Formal Logic* (1847), in his *Syllabus of a Proposed System of Logic* (1860), and also in a number of articles. Like Bentham and Hamilton, De Morgan was concerned with comparing the extensions of terms. In his symbolism, a parenthesis following the subject—as  $X$ —or preceding the predicate—as  $(Y)$ —indicates that the total extensions of  $X$  and  $Y$  are under consideration. If only part of the extension of a term is involved, the parenthesis is reversed—as  $X($  or  $)Y$ . By placing the predicate after the subject together with the respective parentheses, a proposition is formed that states the identity of the extensions as specified by the parentheses. For instance, " $X)Y$ " states that the total extension of  $X$  is identical with a part of the extension of  $Y$ —i.e., that "All  $X$  is  $Y$ "; and " $X()Y$ " states that a part of the extension of  $X$  is identical with a part of the extension of  $Y$ —i.e., that "Some  $X$  is  $Y$ ." To express exclusion between extensions instead of identity, a dot is placed between the parenthesis belonging to the subject and that belonging to the predicate. Thus, " $X) . (Y$ " means that "No  $X$  is  $Y$ ." De Morgan also made use of negated terms, introducing the notion of a logical complement. In his system negated terms are counted as primitive. They are symbolized by small letters; thus, " $x$ " means the same as "non- $X$ ," " $x$ " and " $X$ " forming a pair of contradictory terms. Given the use of negative terms, De Morgan examined systematically all of the forms of affirmative categorical propositions. They are:

- |                    |                              |
|--------------------|------------------------------|
| a. $X)Y$ . . .     | Every $X$ is $Y$ .           |
| b. $x)y$ . . .     | Every non- $X$ is non- $Y$ . |
| c. $X) . y$ . . .  | Every $X$ is non- $Y$ .      |
| d. $x)Y$ . . .     | Every non- $X$ is $Y$ .      |
| e. $X()Y$ . . .    | Some $X$ is $Y$ .            |
| f. $x()y$ . . .    | Some non- $X$ is non- $Y$ .  |
| g. $X() . y$ . . . | Some $X$ is non- $Y$ .       |
| h. $x()Y$ . . .    | Some non- $X$ is $Y$ .       |

De Morgan formulated a simple rule for generating propositions equivalent to those above; viz., replace one of the terms by its contradictory, turn its bracket the other way, and put a dot between the brackets—or if there is a dot already present, remove it. Thus, from each of the eight propositions one derives three other equivalent propositions. One now finds that to each proposition involving a negated term there is an equivalent in which both terms are positive. Thus, the original list can now be replaced by the following:

- |                   |                                    |
|-------------------|------------------------------------|
| a'. $X)Y$ . . .   | Every $X$ is $Y$ .                 |
| b'. $X((Y$ . . .  | Every $Y$ is $X$ .                 |
| c'. $X).(Y$ . . . | No $X$ is $Y$ .                    |
| d'. $X(.)Y$ . . . | Everything is either $X$ or $Y$ .  |
| e'. $X()Y$ . . .  | Some $X$ is $Y$ .                  |
| f'. $X)(Y$ . . .  | Something is neither $X$ nor $Y$ . |
| g'. $X).(Y$ . . . | Some $X$ is not $Y$ .              |
| h'. $X.)Y$ . . .  | Some $Y$ is not $X$ .              |

The meaning of (d') and that of its contradictory (f'), however, does not quite harmonize with the way in which the symbolism was to be interpreted originally. One would expect, for instance, that (f') should mean the same as "Only every  $X$  is  $Y$ ," thus expressing an identity of the extension of  $X$  and that of  $Y$ . But this would not be compatible with the meaning of (f).

De Morgan achieved a further extension of his syllogistic vocabulary with the aid of definitions. This extension gave rise to new kinds of inference, both direct (involving

The work of Hamilton and Bentham

Relations between the extensions of terms

New kinds of inference and the theory of relations

one premise) and indirect (involving two premises). Through this symbolism he was able to work out purely structural rules for transforming a premise or a pair of premises into a valid conclusion.

Inferences that appeared to illustrate principles belonging to the logic of noun expressions, but which could not be accommodated in syllogistic, had been known to logicians before De Morgan. It is to him, however, that credit should be given for initiating and developing a theory of relations. He invented a symbolism in which such notions as the contradictory, the converse, and the transitivity of a relation could be expressed, as well as the union of two relations (by which he meant their relative product). He also stated some logical principles, among them:

Contradictories of converses are themselves converses;  
 Converses of contradictories are contradictories;  
 The contradictory of the converse is the converse of the contradictory;  
 If a first relation is contained in a second, then the converse of the first is contained in the converse of the second, and the contradictory of the second is contained in the contradictory of the first;  
 A transitive relation has a transitive converse;  
 The contradictory of a transitive relation is not necessarily transitive.

De Morgan also set out, in four figures, various inference schemata analogous, in a sense, to those of syllogistic.

*Boole's algebra of logic.* Leibniz' pioneering attempts at constructing an algebraical calculus capable of nonarithmetical interpretation were continued by Ploucquet, Lambert, Jean Castillon, an Italian-born mathematician, and others, but the results achieved by them were not of lasting value. Real progress was made by George Boole (died 1864), a self-taught English mathematician who presented his new ideas on logic in the *Mathematical Analysis of Logic* (1847) and in *An Investigation into the Laws of Thought, on Which Are Founded the Mathematical Theories of Logic and Probabilities* (1854).

Notion of a "true calculus" and its laws of combination

In Boole's view, the notion of a "true calculus" rests on the employment of symbols in accordance with some general but well-determined laws of combination. Although the combining of symbols in this way should admit of a consistent interpretation, the interpretation should not prejudice the validity of what Boole called the process of analysis; *i.e.*, the process whereby interpretable combinations of symbols are obtained. Whereas Leibniz sought a calculus that admitted of a nonarithmetical interpretation, Boole was advocating a formal calculus that could accommodate a number of different interpretations—in particular, two: one relevant to relations among things, and the other to relations among facts as expressed by propositions. In other words, Boole appears to have been aware of the distinction between the logic of noun expressions and that of propositions, respectively. He did not, however, realize that the logic of noun expressions presupposes the logic of propositions.

Boole's calculus was not a deductive system but it is clear from the way in which it was developed that the following presuppositions were acceptable to him:

1. For all  $x$  and  $y$ ,  $xy = yx$ .
2. For all  $x$  and  $y$ ,  $x + y = y + x$ .
3. For all  $x$ ,  $y$ , and  $z$ ,  $x(y + z) = xy + xz$ .
4. For all  $x$ ,  $y$ , and  $z$ ,  $x(y - z) = xy - xz$ .
5. For all  $x$ ,  $y$ , and  $z$ , if  $x = y$  then  $xz = yz$ .
6. For all  $x$ ,  $y$ , and  $z$ , if  $x = y$  then  $x + z = y + z$ .
7. For all  $x$ ,  $y$ , and  $z$ , if  $x = y$  then  $x - z = y - z$ .
8. For all  $x$ ,  $x(1 - x) = 0$ .

Except for the last formula, the system of these presuppositions lends itself to ordinary numerical interpretations. If the values of the variables are restricted to 0 and 1, then the eight presuppositions become interpretable in such a restricted algebra. "The laws, the axioms, and the processes of such an algebra," Boole claimed, "will be identical in their whole extent with the laws, the axioms, and the processes of an algebra of logic." Boole had in mind the interpretation relevant to relations among things; *i.e.*, the class interpretation within the logic of noun expressions. Thus, " $x = y$ " means that the classes  $x$

and  $y$  have the same members; " $xy$ " represents the intersection of the classes  $x$  and  $y$  (*i.e.*, their common part); " $x + y$ " represents the class consisting of the members of  $x$  and the members of  $y$  when they have no members in common; " $x - y$ " represents the class of those members  $x$  that are not members of  $y$ ; and finally, "1" represents the universal class, of which everything is a member, and "0" the null class, of which nothing is a member.

Boole's calculus can also be interpreted within the logic of propositions. In this interpretation, the variables  $x$ ,  $y$ , and  $z$  become propositional variables, " $xy$ " becomes a conjunction of two propositions (read " $x$  and  $y$ "), " $x + y$ " is exclusive disjunction "Either  $x$  or  $y$  but not both," and " $-x$ " becomes "It is not the case that  $x$ ." The symbols 1 and 0 are now construed as the standard true and the standard false propositions, respectively. The sign of identity " $=$ " becomes that of equivalence "if and only if." Interpreted in this way, the calculus can be extended by adding to it

9. For all  $x$ , either  $x = 1$  or  $x = 0$ ,

which does not hold for the class interpretation.

*Refinements of the calculus.* Boolean algebra was subsequently improved by various researchers. William Stanley Jevons, a British economist and logician, rightly urged that all intermediate formulas involved in the process of algebraical transformations should lend themselves to the same interpretation as the initial and final formulas. A further improvement was the replacement of the exclusive by the inclusive disjunction: thus, within the logic of noun expressions, " $x + y$ " denoted all those objects each of which was either  $x$  but not  $y$ , or  $y$  but not  $x$ , or both  $x$  and  $y$ . Consequently, it was true to say that "For all  $x$ ,  $x + x = x$ ," and also that "For all  $x$ ,  $x + -x = 1$ ." Neither of these formulas obtains, however, in the arithmetical algebra.

For the purpose of computing the validity (or invalidity) of inferences, Jevons constructed a "logical piano," a forerunner of the modern computer.

Charles Sanders Peirce, a U.S. logician, engineer, and Pragmatist philosopher, also held that inclusive disjunction is more suitable for an algebra of logic than exclusive disjunction. In addition, he employed the notion of inclusion, for which he devised a special symbol:  $—<$ . Peirce interpreted " $a—<b$ " as meaning "Whatever is  $a$  is  $b$ " or "If  $a$  then  $b$ ." Thus believing, like Boole, that the logic of noun expressions and that of propositions are merely two different interpretations of one and the same algebra of logic, he assimilated propositions to terms expressing relations. Usually, such terms had been thought of as involving two arguments. According to Peirce, however, there is no reason for not assuming under the notion of relations terms that require three or more arguments ( $a, b, c, \dots$ ) as well as terms that require one argument (predicates), or no argument (propositions).

Peirce also set up, independently of Frege, an axiom system for the logic of propositions based on "if . . . then" and on the notion of a proposition that implies any proposition; and he systematically developed the truth-table method of defining constant terms within the algebra of logic. He calculated that, given two values  $T$  and  $F$  (obviously standing for "true" and "false"), there can be four different functors (or operators) for one argument, 16 for two arguments, and 256 for three. Apparently Peirce considered introducing more values than two and thus anticipated the 20th-century development of many-valued logics. Peirce introduced the notion of quantifiers, "For all  $a, \dots$ " and "For some  $a, \dots$ ," needed in elaborating his theory of relations. And finally, he was responsible for the idea of treating relations as classes of ordered pairs or, more generally, as classes of ordered  $n$ -tuples.

Boole's algebra of logic was given the form of a deductive system by Ernst Schröder, a German logician and mathematician, in his *Operationskreis des Logikkalküls* (1877; "The Operational Sphere of the Logical Calculus") and, more systematically, in his *Vorlesungen über die Algebra der Logik* (1890–1905; "Lectures

Refinements by Jevons and Peirce

Refinements by Schröder

on the Algebra of Logic”), which includes the theories of identity and of relations. The system that he had constructed, like that of Peirce, made use of the notion of inclusion, the meaning of which can be determined by reference to diagrams II.1, II.3, II.8, II.9, II.10, II.15, and II.16 in the figure. If inclusion is symbolized thus:  $\subset$ , then its axioms are:

1. For all  $a, a \subset a$ .
2. For all  $a, b$ , and  $c$ , if  $a \subset b$  and  $b \subset c$  then  $a \subset c$ .
3. For all  $a, 0 \subset a$ .
4. For all  $a, a \subset 1$ .
5. For all  $a, b$ , and  $c, c \subset ab$  if and only if ( $c \subset a$  and  $c \subset b$ ).
6. For all  $a, b$ , and  $c, a + b \subset c$  if and only if ( $a \subset c$  and  $b \subset c$ ).
7. For all  $a, b$  and  $c, a(b + c) = ab + ac$ .
8. For all  $a, a - a \subset 0$ .
9. For all  $a, 1 \subset a + -a$ .

Schröder's interpretation of  $+$  was in harmony with that of Jevons and Peirce. At the time of its publication, Schröder's *Vorlesungen* gave, and still gives, the fullest account of an algebra of logic and of its development.

One of the notions investigated by Schröder was that of being an individual, which he defined as follows:

10. For all  $a, a$  is an individual if and only if (it is not the case that  $a \subset 0$  and for all  $x, a \subset x$  or  $a \subset -x$ ).

In addition, he characterized the new notion with the aid of an axiom that states that: “A nonempty class contains at least one individual,” or more precisely

11. For all  $a$ , if it is not the case that  $a \subset 0$ , then for some  $x, x \subset a$  and  $x$  is an individual.

Whereas Schröder's conception of an algebra of logic emphasized the logical aspect of the theory, the inquiries of Alfred North Whitehead, who later became a leading process metaphysician, as presented in *A Treatise on Universal Algebra* (1898), were aimed at integrating the algebra of logic with other branches of mathematics. Extensive studies of the axiomatic foundations of the algebra of logic were successfully undertaken by Edward Vermilye Huntington, a Harvard University mathematician, and by Alfred Tarski, the founder of semantics as part of metalogic.

*Logic and the foundations of mathematics.* As mentioned earlier, Boolean algebra has interpretations within both the logic of propositions and the logic of noun expressions. Neither Boole nor Schröder, however, was concerned with the relationship between the two interpretations or the two logics. But this was not true of Gottlob Frege, an outstanding German mathematician and an original philosopher. Frege set for himself a new problem, the elucidation of the notion of numbers. He felt that the notion of natural number could be reduced to logical notions and that, consequently, arithmetic could be shown to be a part of logic. Frege therefore devised a symbolic language that, in proving logical or arithmetical theses, dispensed with ordinary usage. By applying axiomatic methods, he hoped to determine the meaning of the vocabulary of the logic of propositions. Thus, for Frege, the problem was to develop a calculus or an algebra for a given interpretation. This he did for “if . . . then” and “it is not the case that” (or simply “not,” construed as the negation of a proposition). In terms of ordinary usage, the axioms required for Frege's logic of propositions read as follows:

1. For all  $p$  and  $q$ , if  $p$  then if  $q$  then  $p$ .
2. For all  $p, q$ , and  $r$ , if (if  $p$  then if  $q$  then  $r$ ) then if (if  $p$  then  $q$ ) then (if  $p$  then  $r$ ).
3. For all  $p$  and  $q$ , if (if  $p$  then  $q$ ) then (if not- $q$  then not- $p$ ).
4. For all  $p$ , if not-(not- $p$ ) then  $p$ .
5. For all  $p$ , if  $p$  then not-(not- $p$ ).

In his *Begriffsschrift: Eine der arithmetischen nachgebildete Formelsprache des reinen Denkens* (1879; “Concept-Script: A Formal Language of Pure Thought on the Pattern of Arithmetic”), the foregoing axiom system is supplemented by the following propositions:

6. For all  $a, b$ , and  $F$ , if  $a$  is the same object as  $b$  then if  $F(a)$  then  $F(b)$ .
7. For all  $a, a$  is the same object as  $a$ .

8. For all  $a$  and  $F$ , if for all  $x, F(x)$  then  $F(a)$ .

Axioms 6–8 constitute the foundations of a system of the logic of noun expressions or, more precisely, of the logic of predicates.

In *Die Grundlagen der Arithmetik* (1884; Eng. trans., *The Foundations of Arithmetic*, 2nd rev. ed., 1953), Frege discussed, thoroughly but not formally, the notion of number. He first introduced the notion of equality or equinumerosity between concepts by positing that “The concept  $F$  is equal to concept  $G$  if and only if for some  $R, R$  correlates one to one the objects falling under  $F$  with the objects falling under  $G$ .” By the number that belongs to the concept  $F$ , Frege understands an extension of the concept “equal to the concept of  $F$ .” Thus, the following definition of number is formulated: “For all  $n, n$  is a number if and only if for some  $F, n$  is the number that belongs to  $F$ .”

A formal reduction of arithmetic to logic was given in Frege's *Grundgesetze der Arithmetik: Begriffsschriftlich abgeleitet* (1893 and 1903; “Basic Laws of Arithmetic: Conceptually Derived”). The axioms and rules of inference given in the *Grundgesetze* differ slightly from those laid down in the *Begriffsschrift*, and he also added rules for determining the correctness of definitions. Frege also introduced the device of binding variables by the universal quantifier. Finally, Frege made important contributions to the theory of language. His analyses of the notions of sense and reference as well as of object, concept, and function have contributed greatly to the interest in semantics and in theories of meaning.

Another trend in the study of logic and the foundations of mathematics began with the establishment, by the German mathematician and philosopher Georg Cantor (died 1918), of the theory of manifolds or sets as a new mathematical discipline. By a set, Cantor understood “a collection into one whole of definite, distinct objects of our perception or our thought, which are called the elements of the set.” Thus, the notion of set appears to have much in common with that of class. A set is uniquely defined by its elements. Sets with identical elements are themselves identical, and identical sets have identical elements. It would appear that set theory is just another version of the logic of noun expressions, similar to one of the interpretations of the algebra of logic. And indeed, a number of set-theoretical notions have their analogues in the algebra of logic and in systems such as that of Frege. Thus, whereas Frege talked about the number belonging to a concept, Cantor made use of the notion of the power or cardinal number of a set, a measure of its order of magnitude. He was especially interested in the cardinal numbers of nonfinite sets. His general theorem, to the effect that the cardinal number of a set is always smaller than that of the set of its subsets, gives rise to a series of transfinite numbers, each of which is the cardinal number of a nonfinite set. The smallest such number is the cardinal number of the set of natural numbers. Preoccupation with the notion of numerical infinity led Cantor to the idea of developing a general arithmetic of transfinite numbers within the framework of his theory of sets. Frege highly appreciated Cantor's *Grundlagen einer allgemeinen Mannigfaltigkeitslehre* (1883; “Foundations of a Universal Theory of Manifolds”), which on many counts differed from his own system, mainly in terminology. But, whereas Frege's findings were presented as a deductive system based on axioms and developed in accordance with explicit rules, Cantor's theory of sets was still in a pre-axiomatic stage.

Cantor eventually discovered a paradox in the theory of sets. If one considers the set  $U$  that comprises all sets, then its subsets must be among its elements; hence, the cardinal number of  $U$  cannot be smaller than that of the set of the subsets of  $U$ ; yet, in accordance with the general theorem mentioned above, the cardinal number of the set of the subsets of  $U$  should be greater than the cardinal number of  $U$ . The problem became acute when in 1902 Bertrand Russell, author (with A.N. Whitehead) of the monumental *Principia Mathematica*, discovered another paradox, this time in the system of Frege, involving the notion of the class  $C$  of all of those classes that are not

Cantor's development of set theory

Discovery of fundamental paradoxes

Frege's reduction of arithmetic to logic

elements of themselves. If the class  $C$  is an element of itself, then, like all of the elements of  $C$ , it is not an element of itself; but if  $C$  is not an element of itself, then it has the property that qualifies it for the membership of  $C$ ; i.e., it is an element of itself—hence the contradiction. Frege could not find a fault in Russell's reasoning. In a postscript to volume II of his *Grundgesetze*, Frege tried to remedy the situation by altering one of his axioms. It is now known, however, that the corrected system remains contradictory, and Frege himself was not at all confident that he had found the right solution. Nonetheless, the collapse of Frege's system did not prevent Russell from holding, unreservedly, that arithmetic can be derived from logic.

#### TWENTIETH-CENTURY LOGIC

**Logicism, intuitionism, and formalism.** When, early in the 20th century, Bertrand Russell set out to show that arithmetic is an extension of logic, he had the benefit of the earlier research of Giuseppe Peano, an Italian mathematician and logician. Peano had not been convinced that the primitive notions of arithmetic—of 0, of number, and of the successor of a number—could be reduced to the vocabulary of logic. He thought it desirable, however, to base arithmetic on axiomatic foundations. A proposal to this effect was first published in his *Arithmetices Principia Nova Methodo Exposita* (1889). In his *Formulaire de mathématiques*, 5 vol. in 3 (1895–1908), Peano made use of the following axiom system for arithmetic:

1. 0 is a number.
2. The successor of any number is a number.
3. No two numbers have the same successor.
4. 0 is not the successor of any number.
5. Any property that belongs to 0, and also to the successor of every number that has the property, belongs to all numbers.

Supplemented with appropriate definitions, these axioms yield all of the characteristic laws of arithmetic; but they fail to single out the progression of natural numbers from other progressions. It is this defect that Russell was anxious to remove by deriving arithmetic from logic. He first approached the problem informally in *The Principles of Mathematics* (1903). Then, in collaboration with Whitehead, he produced the monumental *Principia Mathematica*, 3 vol. (1910–13), which has become a classic of logic. The *Principia* marked a climax of the researches in logic and the foundations of mathematics that had been flourishing since the time of Leibniz. At the same time, it provided a starting point for the development of logic in the 20th century.

In addition to Cantor's paradox in his theory of sets and Russell's proof that Frege's system is contradictory, several other paradoxes were discovered during the 15 years prior to the *Principia* that cast doubt upon men's logical intuitions. Among them were those known as Burali-Forti's paradox of the greatest ordinal number, Berry's paradox of the least integer not nameable in fewer than 19 syllables, Richard's paradox of the class of all decimal numbers definable in a finite number of words, and Grelling's paradox of autological and heterological adjectives. The liar paradox of Eubulides, already known among the ancient Megarian logicians, can also be included in this list. (See ANTINOMY in the *Ready Reference and Index*.)

In the *Principia*, where the paradoxes are discussed at considerable length, Russell argued that they result from a "vicious circle" that consists in assuming illegitimate totalities. A totality is illegitimate when it is supposed to involve *all* of a collection but is itself *one* of the same collection. In the *Principia*, such totalities cannot be generated because of Russell's adoption of the theory of logical types. The theory of logical types demands that a functor or an operator should be regarded as belonging to a higher logical type than any of its arguments, or that a class belongs to a higher logical type than that to which its elements belong. (Similarly, a predicate belongs to a higher logical type than the object of which it is predicated.) Consequently, to say that a class is an element of itself is neither true nor false but simply meaningless. Although the theory of logical types obviated the paradox of the class of all classes not

members of themselves, it raised certain problems of its own. It was by no means clear whether the theory was a kind of ontology that classified extra-linguistic entities or a kind of grammar that classified expressions of a logical language. Moreover, some critics charged that it was an ad hoc palliative against paradoxes, and that the ramifications of its hierarchy of types were unduly complicated. Far-reaching suggestions for simplifying the theory were offered by Leon Chwistek, a Polish logician, and the short-lived Cambridge philosopher Frank Ramsey. And, clearly, the paradoxes called for more individual treatment.

Another theory proffered by Russell, of particular interest to philosophers, was his theory of definite descriptions (see ANALYTIC AND LINGUISTIC PHILOSOPHY: *Diversifying and unifying aspects of analytic philosophy*). The *Principia* is a work of impressive scope that, in addition to purely logical topics such as the logic of propositions, and the theories of quantification, of classes, and of relations, includes cardinal arithmetic and the theories of ordinals and of relation-numbers in general, of series, and of measurement.

The view that mathematics is a continuation of logic, with no sharp demarcation between them, has been called "logicism." Opposed to it are intuitionism and formalism. "Intuitionism" is associated with the names of L.E.J. Brouwer, a Dutch mathematician, and his pupil Arend Heyting, according to whom mathematics presupposes mental constructions, which, in turn, presuppose the set of natural numbers. The progression of natural numbers is somehow derived from the intuition of time and the awareness of separable moments of human experience. Thus, intuitionistic mathematics is an activity of thought, and the statement of universal logical laws is not necessary. In particular, intuitionists reject "the thoughtless application of the logical theorem of tertium exclusum," which states that there can be no middle (third) between two contradictories; and by doing so, they believe that they are rejecting, in fact, the principle that every mathematical problem is soluble. They also reject the elimination of double negation, which, in their view, allows its proponents erroneously to infer the provability of a proposition from the unprovability of its negation. Existential statements of the form "There exists an  $x$  such that . . ." are prohibited unless they are implied by statements of the form " $a$  is such that . . .," a restriction that harmonizes with the intuitionistic insistence on constructivism, the view that mathematical proofs must be constrained by the possibilities of finitistic mental constructions. Finally, intuitionists reject the notion of complete or actual infinity; there are no infinite sets other than denumerable sets, such as the set of natural numbers, which exemplifies potential infinity.

Whereas Frege regarded the truth of the axioms of a theory as evidence that the theory is consistent, a Göttingen mathematician, David Hilbert, the founder of modern formalism, maintained that freedom from contradiction in an arbitrarily posited axiom system is the guarantor of the truth of the axioms. Although the problem of whether the fundamental notions of mathematics could be defined in terms of logical notions did not interest Hilbert, he would have answered the question in the negative. He conceived of mathematics as a stock of formulas, which constitute the subject matter of a new mathematics, a "metamathematics," the task of which is to examine and secure the foundations of the former. Hilbert, like Frege, thought very highly of axiomatic methods; but, unlike Frege, he was less concerned with the meaning of the axioms. Within mathematics proper, he advocated a complete formalization with purely formal inferences without any reference to a possible interpretation of the formulas involved. In metamathematics, however, inferences are to have regard to the subject matter. The principal problem of metamathematics is the search for mathematical theories that can be proved to be consistent and complete. As a result of the extensive studies undertaken by Gödel, however, it is known that most interesting mathematical theories are incomplete because every theory that includes the arithmetic of natural numbers is

Brouwer's intuitionism

Hilbert's formalism

Russell's logicism and the theory of types

incomplete; and in order to prove the consistency of such theories, the consistency of stronger theories must be assumed.

**Logic of propositions.** As logics became more specialized, it was the logic of propositions that, largely because of its simplicity, attracted the attention of those logicians who favoured specialization. Propositional connectives other than "if . . . then," "or," and "it is not the case that" were examined for their suitability as primitive (or basic) terms in systems of propositional calculus. The method of truth tables that display the T-F values of compound propositions for all combinations of the T-F values of the component propositions was developed by Peirce, by the Polish logician Jan Łukasiewicz, by the U.S. logician Emil Post, a specialist in recursive unsolvability, by the Austrian-English logician and philosopher Ludwig Wittgenstein, and by other logicians to determine the meanings of propositional connectives and to evaluate expressions consisting of connectives and variables. The problem of the interdefinability of the connectives was examined and solved by Henry M. Sheffer, a Harvard logician, who proved that the joint denial "neither . . . nor" and the alternative denial "either it is not the case that . . . or it is not the case that . . ." are each so fundamental that all of the remaining propositional connectives can be defined in terms of it—a finding that had been anticipated by Peirce. J.-G.-P. Nicod, a French logician, found that a system of the calculus of propositions equivalent to that of the *Principia* could be based on a single axiom with the alternative denial as the only primitive notion. On the problem of simplifying the axiomatic foundations of this logic, considerable work was done by Łukasiewicz (died 1956) and by his collaborators in Warsaw and later in Dublin. Efforts to develop systems of the logic of propositions that dispense with certain dubious principles have been made, as in Hilbert's positive calculus, in the minimal calculus of the mathematician Ingebrigt Johansson of the University of Oslo, and in Heyting's intuitionistic system. Here, too, belong Wilhelm Ackermann, one of Hilbert's collaborators, and his system of rigorous implication, and the system of entailment constructed by Alan Ross Anderson of the University of Pittsburgh, a philosopher of mathematics and science, and N.D. Belnap, his associate.

Another line of development consisted in strengthening systems of the logic of propositions by employing internal quantifiers to bind propositional variables. A system extended in this way was set up by Łukasiewicz and Tarski. A still stronger system was envisaged by Stanisław Leśniewski (died 1939), one of the founders of the Warsaw school, who called it a system of "protothetic." It allowed for the use of functorial variables, such as those for which propositional connectives can be substituted. Axiomatic foundations can be obtained for protothetic by adjoining to the axioms of a classical system the law of extensionality for propositions; i.e., that "For all  $p$  and  $q$  ( $p$  if and only if  $q$ ) if and only if for all  $f$ ,  $f(p)$  if and only if  $f(q)$ ." In addition to employing the usual rules of inference, systems of protothetic are equipped with rules of quantification, definition, and extensionality. The rule of extensionality enables laws of extensionality to be introduced for any semantic category that may be brought into the system by means of definitions. Systems of protothetic are the richest as regards their vocabulary and syntactical variety, and the strongest as regards their deductive power.

In classical logic, a proposition of the form "If  $p$  then  $q$ " is considered to be true if and only if it is not the case that both  $p$  is true and  $q$  is false. This Philonian interpretation of "if . . . then," which was challenged in antiquity, was challenged again, soon after the publication of *Principia*, by Clarence Irving Lewis, a conceptual Pragmatist and author (with C.H. Langford) of *Symbolic Logic* (1932), a classic of modal logic. In this and an earlier work (1918), Lewis distinguished between the material implication of classical logic and strict implication, which he found preferable. Construed as an instance of strict impli-

cation, a proposition of the form "If  $p$  then  $q$ " is true if and only if it is not possible that  $p$  should be true and  $q$  false. Lewis's treatment of implication involves the modal notion of possibility and thus marks the beginning of new developments. Lewis suggested several different systems of strict implication ( $S_1$ – $S_5$ ), and many more have been constructed since. Among them, Gödel's system with necessity as a primitive notion deserves special mention, and so does the system with the notion of contingency, constructed by E.J. Lemmon, an Oxford logician. More recently, the logic of propositions has been enlarged to include deontic logic, the aim of which is to exhibit the use of such expressions as "it ought to be the case that," "it is permissible that," and "it is forbidden that" and to interrelate them with modal notions (see LOGIC, APPLIED: *Practical logic: Deontic logic*).

A different approach to extending the logic of propositions was taken by Łukasiewicz. His analysis of the modal notions in Aristotle and his resolve to justify indeterminism suggested the idea of a three-valued logic and of many-valued logics in general (see LOGIC, FORMAL: *Special systems of PC: Nonstandard versions of PC*). In these systems, Łukasiewicz employed the notions of implication, alternation, conjunction, and negation, but the meanings of the corresponding constants—"if . . . then," "or," "and," and "it is not the case that"—differ from their meanings in two-valued logic. Łukasiewicz determined their new meanings with the aid of many-valued truth tables, which, in addition to truth and falsity, allow for intermediate truth-values—such as possibility, for instance. Although Łukasiewicz suggested axiomatic foundations for three-valued and infinitely-many-valued logics, his systems were not complete. Nor was it possible to define, within their framework, all of the constants for which the meaning could be determined with the aid of appropriate truth tables. Many-valued systems that have no such defects have been developed by Bolesław Sobociński, a Notre Dame logician, and by the Polish logician Jerzy Śłupecki. Purely formal systems of many-valued logics have been constructed independently by Emil Post.

The most recent and, philosophically, by far the most exciting way of extending the logic of propositions consists in constructing systems of tense logic with a view to clarifying the conception of time (see LOGIC, APPLIED: *Logics of physical application: Temporal logic*). According to the British logician A.N. Prior, the characteristic constants of tense logic are "it has been the case that," "it is now the case that," and "it will be the case that." Several other constants can be introduced by means of appropriate definitions.

Modal logic, deontic logic, tense logic, and, of course, many-valued logics presuppose the abandonment of two-valued logic. In many cases, they also presuppose the rejection of the principle of extensionality. Some logicians, however, do not approve of these serious sacrifices and believe that alternative ways of solving these problems should be explored.

**Logic of noun expressions.** At the end of the 19th century, the logic of noun expressions had developed the following branches: Aristotle's syllogistic, Leibniz' theory of identity, Schröder's algebra of logic interpreted as a theory of classes and relations, Frege's theory of quantification, and Cantor's set theory. Although in the 20th century some of these branches have been growing on their own, the ideal of comprehensiveness, achieved by the authors of *Principia*, has not been abandoned altogether. As a result of Łukasiewicz' research, syllogistic has been given the form of a modern deductive theory. It has been axiomatized and proved to be consistent and decidable in the sense that every syllogistic or polysyllogistic expression can either be derived from the axioms or shown to be rejected. Other fragments of the logic of noun expressions have been distinguished by logicians and made objects of special studies—such as, for instance, the functional calculus of first order, functional calculi of higher orders, and the functional calculus of order omega ( $\omega$ ), often referred to as the simple theory of types.

Łukasiewicz' multi-valued logic

Leśniewski's protothetic and Lewis' systems of strict implication

Leśniewski's ontology and mereology

The tendency toward comprehensiveness found expression in the system of the logic of noun expressions constructed by Leśniewski, whose interest was aroused by Russell's paradox of the class of all those classes not elements of themselves. Although Leśniewski accepted the need for a theory of logical types, he did not believe that the paradox resulted from confusing types (or "semantic categories" as he called them) but from the failure to realize that class expressions often are used ambiguously. In order to explain this ambiguity, he constructed two theories, called ontology and mereology. Ontology, which is a system of the logic of noun expressions, is obtained by subjoining some ontological axioms to the protothetic, adapting its rules to them, and setting up a rule of ontological definition and a rule of ontological extensionality. In standard systems of ontology, the copula "is" is the only primitive ontological term. Diagrams II.1 and II.3 determine its meaning. In Schröder's algebra, it can be defined as follows: "For all  $a$  and  $b$ ,  $a$  is  $b$  if and only if both  $a \subset b$  and  $a$  is an individual." In ontology, it is characterized by the following single axiom: "For all  $a$  and  $b$ ,  $a$  is  $b$  if and only if (i) for some  $c$ ,  $c$  is  $a$ , (ii) for all  $c$  and  $d$ , if  $c$  is  $a$  and  $d$  is  $a$  then  $c$  is  $d$ , and (iii) for all  $c$ , if  $c$  is  $a$  then  $c$  is  $b$ ." As regards its contents, ontology comprises syllogistic, the theory of identity, a counterpart of the theory of classes, and counterparts of functional calculi of any orders. If required, ontology can be supplemented with the axioms of infinity and of choice. Whereas the logical language of the *Principia* presupposes the concept of proper name, that of ontology is based on common noun expressions, to which proper names are assimilated. The mere use of the language of ontology implies no existential assertions, which is not the case with the language of the *Principia*. Instead of a theory of logical types, Leśniewski had developed a theory of semantic categories, which was inspired by certain ideas of Edmund Husserl, the founder of Phenomenology, and was concerned with the grammar of logical language and not with any extralinguistic entities.

Mereology, which is the theory of part-whole relations, is obtained by subjoining mereological axioms to ontology and adapting the rules of ontology to them. Whereas ontology was meant to provide the foundations of arithmetic, mereology was to serve as the basis of geometry. Mereology, and *a fortiori* ontology, is consistent if protothetic is consistent. Theories of part-whole relations have also been worked out independently of Leśniewski's mereology by J.H. Woodger, author of an axiomatized biology, by the U.S. logician Henry Leonard, and Nelson Goodman, a U.S. philosopher.

The development of Cantor's theory of sets was greatly affected by the discovery of paradoxes. For, it soon became clear that more solid foundations were required if paradoxes were to be eliminated. With this aim in view, the German mathematician Ernst Zermelo axiomatized the theory and succeeded in avoiding the paradoxes without resort to the theory of types. The Israeli mathematician Abraham Fraenkel has informally set out Zermelo's axioms:

1. *Axiom of Extensionality*: Sets containing the same members are equal.
2. *Axiom of Pairing*: For any two different sets  $a$  and  $b$ , there exists a set  $c$  that contains just  $a$  and  $b$ .
3. *Axiom of Union*: For any set  $a$  that contains at least one member, there exists the set the members of which are just the members of the members of  $a$ .
4. *Axiom of Power-set*: For any set  $a$  there exists the set the members of which are just subsets of  $a$ .
5. *Axiom Schema of Singling-out*: For any set  $a$  and any monadic predicate  $P$ , there exists the set that contains just those members  $x$  of  $a$  that fulfill the condition  $P(x)$ .
6. *Axiom of Choice*: If  $a$  is a disjointed set that does not contain the null-set, the Cartesian product of the members of  $a$  is not empty (the Cartesian product of two sets is the set of all pairs having a member from each set).
7. *Axiom of Infinity*: There exists a set  $a$  such that the empty set is a member of  $a$  and for all  $b$ , if  $b$  is a member of  $a$  then the set of which the only member is  $b$  is also a member of  $a$ .

This axiom system is deductively strong enough to yield

a substantial part of Cantor's theory, but it does not imply the existence of certain special sets presupposed by Cantor. To accommodate these sets, Fraenkel suggested

8. *Axiom of Replacement*: If the domain of a single-valued function is a set, its counter-domain is also a set.

And in order to eliminate certain extraordinary sets, the Hungarian-U.S. mathematician John von Neumann, a pioneer in computer mathematics, proposed:

9. *Axiom of Foundation*: Every non-empty set  $a$  contains a member  $b$  such that  $a$  and  $b$  have no members in common.

Von Neumann also distinguished between sets, which can be members of other sets, and classes, which have no such property. Both sets and classes can have members, but the notion of membership in the case of sets is not the same as membership in the cases of classes.

More recently, the Swiss logician and mathematician Paul Bernays, Hilbert's collaborator, has made important contributions to the study of the axiomatic foundations of set theory.

So far, the theory based on the above-listed axioms has proved to be free from contradictions, but the axioms have scarcely made the notion of a set any clearer. If the axioms describe some aspects of reality, it is not known what these aspects are. Thus, the theory is becoming detached from any interpretation.

According to Cantor's "continuum hypothesis," if the cardinal number of a denumerable set is denoted by  $\aleph_0$  ("aleph-null") and that of the power-set (the set of all subsets) of a denumerable set by  $2\aleph_0$ , then there is no cardinal number between  $\aleph_0$  and  $2\aleph_0$ —which means that  $2\aleph_0 = \aleph_0$ . In its generalized form, the hypothesis says that "For any  $\alpha$  if  $\alpha$  is the cardinal number of an infinite well-ordered set then there is no cardinal number between  $\alpha$  and  $2^\alpha$ ."

In the systems of the logic of noun expressions developed by W.V.O. Quine, a Harvard University logician, the theory of logical types is replaced by the much simpler theory of stratification. A propositional formula is said to be stratified if it is possible to put numerals for the variables in such a way that  $\in$  occurs only in contexts of the form " $n \in (n + 1)$ ." Now, the rule of abstraction, which corresponds to the axiom schema of singling out, stipulates that the formula from which abstraction is made should be stratified. This sort of restriction enabled Quine to abandon the theory of types. His system, first published in 1937 and known as system NF, was subsequently developed into system ML, published in 1940 and revised in 1951.

**Metalogical studies.** Once systems of logic had been axiomatized, their development seemed to have slowed down. Instead of proving new theses within the framework of axiomatized systems, logicians began to examine the systems themselves and prove theses about them. This was the beginning of metalogic (*q.v.*), the development of which owes a great deal to Hilbert's conception of metamathematics and to his formalist philosophy of mathematics. The problems that are the concern of metalogic are many and various. In the first place, there are the problems of the consistency and completeness of deductive systems and their decidability (since for some systems one can construct intrinsically undecidable propositions) as well as the problem of the independence of the axioms and that of the definability of primitive terms within an axiom system.

For systems of the logic of propositions, methods have been developed for solving these problems. Thus, the consistency of the calculus of propositions was proved by Post and independently by Łukasiewicz. Methods of proving the completeness of the calculus were worked out by Łukasiewicz and others. Truth tables provided means of determining the decidability of systems and the mutual independence of their axioms. The Italian mathematician Alessandro Padoa (died 1938), a collaborator of Peano, found a method of proving the independence of primitive notions within an axiomatized theory.

Systems of the logic of noun expressions are more difficult objects for metalogical investigation, but here too there are several findings to be recorded. Because of Łu-

Zermelo's axiomatization of set theory

Quine's theory of stratification

Problems of consistency, completeness, and decidability

kasiewicz' and Ślupecki's researches, it is known that syllogistic, as axiomatized by Łukasiewicz, is consistent, decidable, and based upon independent axioms. The completeness of the first order functional calculus was proved by Gödel and its consistency by Hilbert. As Alonzo Church, an eminent U.S. logician, has shown, however, the decision problem for a pure functional calculus of first order is unsolvable, although there is a decision procedure for that part of the calculus that contains monadic functions only. The most interesting finding in this field of study was obtained by Gödel, who succeeded in proving that a system of logic that is deductively strong enough to yield the arithmetic of natural numbers, viz., the system of Russell's *Principia*, is not complete and cannot be made complete by extending its axiomatic foundations. Furthermore, Gödel proved that the consistency of systems that include the arithmetic of natural numbers can only be proved if one assumes the consistency of stronger systems. Other metalogical findings obtained by Gödel concern intuitionistic logic and the theory of sets. In the latter field, Gödel established the fact that the *axiom of choice* and the *generalized continuum hypothesis* are consistent with the remaining axioms provided that these axioms are consistent themselves. The independence of the *axiom of choice* and that of the *generalized continuum hypothesis* were proved, in 1963, by Paul J. Cohen, a Stanford University mathematician, thus opening a new chapter in the history of set theory. It has been proved that Quine's system *ML*, as revised, is consistent if system *NF* is consistent.

Another branch of metalogical studies is syntax, which is concerned with the language of logic and describes the purely formal aspects of that language. One of its tasks is to formulate the directives of a logical system; i.e., the rules of inference, of extensionality, and of definition. Among logicians whose contributions to syntax have been of lasting value are the German-U.S. philosopher Rudolf Carnap, once a member of the Vienna Circle, who defined a number of fundamental syntactical concepts applicable to languages of any form; Leśniewski, who stated the directives of his systems, including the rule of definition, in purely syntactical terms; Kazimierz Ajdukiewicz, a Polish methodologist and philosopher of science, who developed a system of categorial indices to identify syntactical categories of a language; and Gödel, who devised a method of arithmetizing syntax—i.e., of uniquely assigning a number to an expression of symbolic language.

Syntax must be distinguished from semantics, which is another metalogical discipline. Speaking generally, semantics studies the relationship between language and reality. Among semantical concepts are those of truth, denotation, satisfaction, and definition or rather determination. Semantics as a metalogical discipline was established by Tarski, whose paper "Der Wahrheitsbegriff in den formalisierten Sprachen" ("The Concept of Truth in the Formalized Languages"), in the *Studia Philosophica*, vol. I (1935), has become a classic. Tarski also laid the foundations for the theory of logical consequence, which provides a conceptual framework for the study of deductive systems in abstraction from the language in which they are formulated. Independently of Tarski's researches, a thorough study of the concept of logical deducibility was made by Karl Popper, an Austrian-British authority in scientific methodology.

An alternative to the method of expressing logical principles directly with the aid of variables consists in setting up schemata of valid inference. The method was developed by the German mathematician Gerhard Gentzen, who was for several years an assistant to Hilbert, and independently by Stanisław Jaśkowski, a logician of the Warsaw school. Both logicians tried to fashion their systems of logic to reflect the actual procedures of practicing mathematicians; they have therefore come to be known as systems of natural deduction. These systems are widely employed by logicians today.

#### ROLE OF LOGIC AS AN ELEMENT WITHIN A CULTURE

Both in the West and in the East, the origin of logic is associated with an interest in the grammar of language

and in the methodology of argument and discussion, be it in the context of law, religion, or philosophy. More is needed, however, for the successful development of logic: it appears that logic can thrive only in a culture that upholds the conviction that controversies should be settled by the force of reason rather than by the orthodoxy of a dogma or the tradition of a prejudice. This is why logic has made much greater progress in the West than in the East.

It has been acknowledged since the time of Aristotle that logic has a part to play in general education. Before embarking on the study of any science, one should, as Aristotle thought, receive some training in logic. Today logic is taught at almost every university, and for many courses it is a compulsory subject; it is gradually taking over the role that the study of classical languages used to play in general instruction. Indeed, for better understanding the working of one's native language, the study of logic is as helpful as the study of Latin grammar.

According to Plato, the axiomatic method is the best method to use in presenting and codifying knowledge, and for centuries Euclid's *Elements* has served as the paradigm of deductive theory. In the 17th century, when, because of the work of René Descartes, the ideals of clarity and precision were vindicated, it became the ambition of many scholars to present their disciplines *more geometrico*; today, however, it is logic and not geometry that sets the example of precision.

Bertrand Russell once wrote that there are two ways of researching in mathematics: one aims at expansion, the other at exploring the foundations. And the same is true of any other discipline. But it is in exploring the foundations of a science that one again encounters logic; for every science that claims to describe some aspect of reality and allows for proof makes use of logical vocabulary. This means that logic lies at the head of a ramified hierarchy of sciences and can be conceived of as the most abstract and most general description of reality. Viewed in this way, logic has a part to play in philosophy and, more precisely, in metaphysics.

## Logic, Philosophy of

The term logic comes from the Greek word *logos*. The variety of senses that *logos* possesses may suggest the difficulties to be encountered in characterizing the nature and scope of logic. Among the partial translations of *logos*, there are "sentence," "discourse," "reason," "rule," "ratio," "account" (especially the account of the meaning of an expression), "rational principle," and "definition." Not unlike this proliferation of meanings, the subject matter of logic has been said to be the "laws of thought," "the rules of right reasoning," "the principles of valid

Foundational function of logic in education

Carnap's studies in philosophical syntax and Tarski's in semantics

argumentation," "the use of certain words labelled 'logical constants'," "truths (true propositions) based solely on the meanings of the terms they contain," and so on.

#### LOGIC AS A DISCIPLINE

Valid argument and matters of fact

**Nature and varieties of logic.** It is relatively easy to discern some order in the above embarrassment of explanations. Some of the characterizations are in fact closely related to each other. When logic is said, for instance, to be the study of the laws of thought, these laws cannot be the empirical (or observable) regularities of actual human thinking as studied in psychology; they must be laws of correct reasoning, which are independent of the psychological idiosyncrasies of the thinker. Moreover, there is a parallelism between correct thinking and valid argumentation: valid argumentation may be thought of as an expression of correct thinking, and the latter as an internalization of the former. In the sense of this parallelism, laws of correct thought will match those of correct argumentation. The characteristic mark of the latter is, in turn, that they do not depend on any particular matters of fact. Whenever an argument that takes a reasoner from  $p$  to  $q$  is valid, it must hold independently of what he happens to know or believe about the subject matter of  $p$  and  $q$ . The only other source of the certainty of the connection between  $p$  and  $q$ , however, is presumably constituted by the meanings of the terms that the propositions  $p$  and  $q$  contain. These very same meanings will then also make the sentence "If  $p$ , then  $q$ " true irrespective of all contingent matters of fact. More generally, one can validly argue from  $p$  to  $q$  if and only if the implication "If  $p$ , then  $q$ " is logically true—*i.e.*, true in virtue of the meanings of words occurring in  $p$  and  $q$ , independently of any matter of fact.

Logic may thus be characterized as the study of truths based completely on the meanings of the terms they contain.

In order to accommodate certain traditional ideas within the scope of this formulation, the meanings in question may have to be understood as embodying insights into the essences of the entities denoted by the terms, not merely codifications of customary linguistic usage.

The following proposition (from Aristotle), for instance, is a simple truth of logic: "If sight is perception, the objects of sight are objects of perception." Its truth can be grasped without holding any opinions as to what, in fact, the relationship of sight to perception is. What is needed is merely an understanding of what is meant by such terms as "if-then," "is," and "are," and an understanding that "object of" expresses some sort of relation.

The logical truth of Aristotle's sample proposition is reflected by the fact that "The objects of sight are objects of perception" can validly be inferred from "Sight is perception."

The various branches of logic

Many questions nevertheless remain unanswered by this characterization. The contrast between matters of fact and relations between meanings that was relied on in the characterization has been challenged, together with the very notion of meaning. Even if both are accepted, there remains a considerable tension between a wider and a narrower conception of logic. According to the wider interpretation, all truths depending only on meanings belong to logic. It is in this sense that the word logic is to be taken in such designations as "epistemic logic" (logic of knowledge), "doxastic logic" (logic of belief), "deontic logic" (logic of norms), "the logic of science," "inductive logic," and so on. According to the narrower conception, logical truths obtain (or hold) in virtue of certain specific terms, often called logical constants. Whether they can be given an intrinsic characterization or whether they can be specified only by enumeration is a moot point. It is generally agreed, however, that they include (1) such propositional connectives as "not," "and," "or," and "if-then" and (2) the so-called quantifiers " $(\exists x)$ " (which may be read: "For at least one individual, call it  $x$ , it is true that") and " $(\forall x)$ " ("For each individual, call it  $x$ , it is true that"). The dummy letter  $x$  is here called a bound (individual) variable. Its values are supposed to be members of some fixed class of entities, called individuals, a

class that is variously known as the universe of discourse, the universe presupposed in an interpretation, or the domain of individuals. Its members are said to be quantified over in " $(\exists x)$ " or " $(\forall x)$ ." Furthermore, (3) the concept of identity (expressed by  $=$ ) and (4) some notion of predication (an individual's having a property or a relation's holding between several individuals) belong to logic. The forms that the study of these logical constants take are described in greater detail in the articles LOGIC, FORMAL; SYLLOGISTIC; METALOGIC; and LOGIC, APPLIED—in which the different kinds of logical notation are also explained. Here, only a delineation of the field of logic is given.

When the terms in (1) alone are studied, the field is called propositional logic. When (1), (2), and (4) are considered, the field is the central area of logic that is variously known as first-order logic, quantification theory, lower predicate calculus, lower functional calculus, or elementary logic. If the absence of (3) is stressed, the epithet "without identity" is added, in contrast to first-order logic with identity, in which (3) is also included.

Borderline cases between logical and nonlogical constants are the following (among others): (1) Higher order quantification, which means quantification not over the individuals belonging to a given universe of discourse, as in first-order logic, but also over sets of individuals and sets of  $n$ -tuples of individuals. (Alternatively, the properties and relations that specify these sets may be quantified over.) This gives rise to second-order logic. The process can be repeated. Quantification over sets of such sets (or of  $n$ -tuples of such sets or over properties and relations of such sets) as are considered in second-order logic gives rise to third-order logic; and all logics of finite order form together the (simple) theory of (finite) types. (2) The membership relation, expressed by " $\epsilon$ ," can be grafted on to first-order logic; it gives rise to set theory ( $q.v.$ ). (3) The concepts of (logical) necessity and (logical) possibility can be added.

This narrower sense of logic is related to the influential idea of logical form. In any given sentence, all of the nonlogical terms may be replaced by variables of the appropriate type, keeping only the logical constants intact. The result is a formula exhibiting the logical form of the sentence. If the formula results in a true sentence for any substitution of interpreted terms (of the appropriate logical type) for the variables, the formula and the sentence are said to be logically true (in the narrower sense of the expression).

**Features and problems of logic.** Three areas of general concern are the following.

**Logical semantics.** For the purpose of clarifying logical truth and hence the concept of logic itself, a tool that has turned out to be more important than the idea of logical form is logical semantics, sometimes also known as model theory (see METALOGIC: *Model Theory*). By this is meant a study of the relationships of linguistic expressions to those structures in which they may be interpreted and of which they can then convey information. The crucial idea in this theory is that of truth (absolutely or with respect to an interpretation). It was first analyzed in logical semantics around 1930 by the Polish-American logician Alfred Tarski. In its different variants, logical semantics is the central area in the philosophy of logic. It enables the logician to characterize the notion of logical truth irrespective of the supply of nonlogical constants that happen to be available to be substituted for variables, although this supply had to be used in the characterization that turned on the idea of logical form. It also enables him to identify logically true sentences with those that are true in every interpretation (in "every possible world").

The ideas on which logical semantics is based are not unproblematic, however. For one thing, a semantical approach presupposes that the language in question can be viewed "from the outside"; *i.e.*, considered as a calculus that can be variously interpreted and not as the all-encompassing medium in which all communication takes place (logic as calculus versus logic as language).

Furthermore, in most of the usual logical semantics the

Truth as defined in model theory

very relations that connect language with reality are left unanalyzed and static. Ludwig Wittgenstein, an Austrian-born philosopher, discussed informally the "language-games"—or rule-governed activities connecting a language with the world—that are supposed to give the expressions of language their meanings; but these games have scarcely been related to any systematic logical theory. Only a few other attempts to study the dynamics of the representative relationships between language and reality have been made. The simplest of these suggestions is perhaps that the semantics of first-order logic should be considered in terms of certain games (in the precise sense of game theory) that are, roughly speaking, attempts to verify a given first-order sentence. The truth of the sentence would then mean the existence of a winning strategy in such a game.

*Limitations of logic.* Many philosophers are distinctly uneasy about the wider sense of logic. Some of their apprehensions, voiced with special eloquence by a contemporary Harvard University logician, Willard Van Quine, are based on the claim that relations of synonymy cannot be fully determined by empirical means. Other apprehensions have to do with the fact that most extensions of first-order logic do not admit of a complete axiomatization; *i.e.*, their truths cannot all be derived from any finite—or recursive (see below)—set of axioms. This fact was shown by the important "incompleteness" theorems proved in 1931 by Kurt Gödel, an Austrian (later, American) logician, and their various consequences and extensions. (Gödel showed that any consistent axiomatic theory that comprises a certain amount of elementary arithmetic is incapable of being completely axiomatized.) Higher-order logics are in this sense incomplete and so are all reasonably powerful systems of set theory. Although a semantical theory can be built for them, they can scarcely be characterized any longer as giving actual rules—in any case complete rules—for right reasoning or for valid argumentation. Because of this shortcoming, several traditional definitions of logic seem to be inapplicable to these parts of logical studies.

These apprehensions do not arise in the case of modal logic, which may be defined, in the narrow sense, as the study of logical necessity and possibility; for even quantified modal logic admits of a complete axiomatization. Other, related problems nevertheless arise in this area. It is tempting to try to interpret such a notion as logical necessity as a syntactical predicate; *i.e.*, as a predicate the applicability of which depends only on the form of the sentence claimed to be necessary—rather like the applicability of formal rules of proof. It has been shown, however, by Richard Montague, an American logician, that this cannot be done for the usual systems of modal logic.

*Logic and computability.* These findings of Gödel and Montague are closely related to the general study of computability, which is usually known as recursive function theory (see MATHEMATICS, FOUNDATIONS OF: *The crisis in foundations following 1900: Logicism, formalism, and the metamathematical method*) and which is one of the most important branches of contemporary logic. In this part of logic, functions—or laws governing numerical or other precise one-to-one or many-to-one relationships—are studied with regard to the possibility of their being computed; *i.e.*, of being effectively—or mechanically—calculable. Functions that can be so calculated are called recursive. Several different and historically independent attempts have been made to define the class of all recursive functions, and these have turned out to coincide with each other. The claim that recursive functions exhaust the class of all functions that are effectively calculable (in some intuitive informal sense) is known as Church's thesis (named after the American logician Alonzo Church).

One of the definitions of recursive functions is that they are computable by a kind of idealized automaton known as a Turing machine (named after Alan Mathison Turing, a British mathematician and logician). Recursive function theory may therefore be considered a theory of these idealized automata. The main idealization

involved (as compared with actually realizable computers) is the availability of a potentially infinite tape.

The theory of computability prompts many philosophical questions, most of which have not so far been answered satisfactorily. It poses the question, for example, of the extent to which all thinking can be carried out mechanically. Since it quickly turns out that many functions employed in mathematics—including many in elementary number theory—are nonrecursive, one may wonder whether it follows that a mathematician's mind in thinking of such functions cannot be a mechanism and whether the possibly nonmechanical character of mathematical thinking may have consequences for the problems of determinism and free will. Further work is needed before definitive answers can be given to these important questions.

#### ISSUES AND DEVELOPMENTS IN THE PHILOSOPHY OF LOGIC

In addition to the problems and findings already discussed, the following topics may be mentioned.

**Meaning and truth.** Since 1950, the concept of analytical truth (logical truth in the wider sense) has been subjected to sharp criticism, especially by Quine. The main objections turned around the nonempirical character of analytical truth (arising from meanings only) and of the concepts in terms of which it could be defined—such as synonymy, meaning, and logical necessity. The critics usually do not contest the claim that logicians can capture synonymies and meanings by starting from first-order logic and adding suitable further assumptions, though definitional identities do not always suffice for this purpose. The crucial criticism is that the empirical meaning of such further "meaning postulates" is not clear.

*Logical semantics of modal concepts.* In this respect, logicians' prospects have been enhanced by the development of a semantical theory of modal logic, both in the narrower sense of modal logic, which is restricted to logical necessity and logical possibility, and in the wider sense, in which all concepts that exhibit similar logical behaviour are included. This development, initiated between 1957 and 1959 largely by Stig Kanger of Sweden and Saul Kripke of the U.S., has opened the door to applications in the logical analysis of many philosophically central concepts, such as knowledge, belief, perception, and obligation. Attempts have been made to analyze from the viewpoint of logical semantics such philosophical topics as sense-datum theories, knowledge by acquaintance, the paradox of saying and disbelieving propounded by the British philosopher G.E. Moore, and the traditional distinction between statements *de dicto* ("from saying") and statements *de re* ("from the thing"). These developments also provide a framework in which many of those meaning relations can be codified that go beyond first-order logic, and may perhaps even afford suggestions as to what their empirical content might be.

*Intensional logic.* Especially in the hands of Montague, the logical semantics of modal notions has blossomed into a general theory of intensional logic; *i.e.*, a theory of such notions as proposition, individual concept, and in general of all entities usually thought of as serving as the meanings of linguistic expressions. (Propositions are the meanings of sentences, individual concepts are those of singular terms, and so on.) A crucial role is here played by the notion of a possible world, which may be thought of as a variant of the logicians' older notion of model, now conceived of realistically as a serious alternative to the actual course of events in the world. In this analysis, for instance, propositions are functions that correlate possible worlds with truth-values. This correlation may be thought of as spelling out the older idea that to know the meaning of a sentence is to know under what circumstances (in which possible worlds) it would be true.

*Logic and information.* Even though none of the problems listed seems to affect the interest of logical semantics, its applications are often handicapped by the nature of many of its basic concepts. One may consider, for instance, the analysis of a proposition as a function that correlates possible worlds with truth-values. An arbitrary

truth-  
values

trary function of this sort can be thought of (as can functions in general) as an infinite class of pairs of correlated values of an independent variable and of the function, like the coordinate pairs  $(x, y)$  of points on a graph. Although propositions are supposed to be meanings of sentences, no one can grasp such an infinite class directly when understanding a sentence; he can do so only by means of some particular algorithm, or recipe (as it were), for computing the function in question. Such particular algorithms come closer in some respects to what is actually needed in the theory of meaning than the meaning entities of the usual intensional logic.

This observation is connected with the fact that, in the usual logical semantics, no finer distinctions are utilized in semantical discussions than logical equivalence. Hence the transition from one sentence to another logically equivalent one is disregarded for the purposes of meaning concepts. This disregard would be justifiable if one of the most famous theses of Logical Positivists were true in a sufficiently strong sense, viz., that logical truths are really tautologies (such as "It is either raining or not raining") in every interesting objective sense of the word. Many philosophers have been dissatisfied with the stronger forms of this thesis, but only recently have attempts been made to spell out the precise sense in which logical and mathematical truths are informative and not tautologous.

**Problems of ontology.** Among the ontological problems—problems concerning existence and existential assumptions—arising in logic are those of individuation and existence.

**Individuation.** Not all interesting interpretational problems are solved by possible-world semantics, as the developments earlier registered are sometimes called. The systematic use of the idea of possible worlds has raised, however, the subject of cross identification; i.e., of the principles according to which a member of one possible world is to be found identical or nonidentical with one of another. Since one can scarcely be said to have a concept of an individual if he cannot locate it in several possible situations, the problem of cross-identification is also one of the most important ingredients of the logical and philosophical problem of individuation. The criticisms that Quine has put forward concerning modal logic and analyticity (see above) can be deepened into questions concerning methods of cross identification. Although some such methods undoubtedly belong to everyone's normal unarticulated conceptual repertoire, it is not clear that they are defined or even definable widely enough to enable philosophers to make satisfactory sense of a quantified logic of logical necessity and logical possibility. The precise principles used in ordinary discourse—or even in the language of science—pose a subtle philosophical problem. The extent to which special "essential properties" are relied on in individuation and the role of spatio-temporal frameworks are moot points here. It has also been suggested that essentially different methods of cross identification are actually used together, some of them depending on impersonal descriptive principles and others on the perspective of a person.

**Existence and ontology.** Because one of the basic concepts of first-order logic is that of existence, as codified by the existential quantifier " $(\exists x)$ ," one might suppose that there is little room left for any separate philosophical problem of existence. Yet existence, in fact, does seem to pose a problem, as witnessed by the bulk of the relevant literature. Some issues are relatively easy to clarify. In the usual formulations of first-order logic, for instance, there are "existential presuppositions" present to the effect that none of the singular terms employed is without a bearer (as "Pegasus" is). It is a straightforward matter, however, to dispense with these presuppositions. Though this seems to involve the procedure, branded as inadmissible by many philosophers, of treating existence as a predicate, this can nonetheless be easily done on the formal level. Given certain assumptions, it may even be shown that this "predicate" will have to be " $(\exists x) (x = a)$ " (for "a exists"—literally, "There exists an  $x$  such that  $x$  is  $a$ ") or something equivalent. Furthermore, the

logical peculiarities of this predicate seem to explain amply philosophers' apparent denial of its reality.

The interest in the notion of existence is connected with the question of what entities a theory commits its holder to or what its "ontology" is. The "predicate of existence" just mentioned recalls Quine's criterion of ontological commitment: "To be is to be a value of a bound variable"—i.e., of the  $x$  in  $(\forall x)$  or in  $(\exists x)$ . According to Quine, a theory is committed to those and only those entities that in the last analysis serve as the values of its bound variables. Thus ordinary first-order theory commits one to an ontology only of individuals (particulars), whereas higher order logic commits one to the existence of sets—i.e., of collections of definite and distinct entities (or, alternatively, of properties and relations). Likewise, if bound first-order variables are assumed to range over sets (as they do in set theory), a commitment to the existence of these sets is incurred.

The doctrine that an ontology of individuals is all that is needed is known as (the modern version of) nominalism. The opposite view is known as (logical) realism. Even those philosophers who profess sympathy with nominalism find it hard, however, to maintain that mathematics could be built on a consistently nominalistic foundation.

The precise import of Quine's criterion of ontological commitment, however, is not completely clear. Nor is it clear in what other sense one is perhaps committed by a theory to those entities that are named or otherwise referred to in it but not quantified over in it. Questions can also be raised concerning the very distinction between what in modern logic are usually called individuals ("particulars" would be a more traditional designation) and such universals as their properties and relations; and these questions can be combined with others concerning the "tie" that binds particulars and universals together in predication.

An interesting approach to these problems is the distinction made by Gottlob Frege, a pioneer of mathematical logic in the late 19th century, between individuals—he called them objects—and what he called functions (which in his view include concepts) and his doctrine of the unsaturated character of the latter, according to which a function (as it were) contains a gap, which can be filled by an object. Another approach is the "picture theory of language" of Wittgenstein's *Tractatus Logico-Philosophicus*, according to which a simple sentence presents a person with an isomorphic representation (a "picture") of reality as it would be if the sentence were true. According to this view (which was later given up by Wittgenstein), "a sentence [or proposition, *Satz*] is a model of reality such as we think of it as being."

**Alternative logics.** The natures of most of the so-called nonclassical logics can be understood against the background of what has here been said. Some of them are simply extensions of the "classical" first-order logic—e.g., modal logics and many versions of intensional logic. The so-called free logics are simply first-order (or modal) logics without existential presuppositions.

One of the most important nonclassical logics is intuitionistic logic (see MATHEMATICS, FOUNDATION OF: *The crisis in foundations following 1900: Intuitionism*), first formalized by the Dutch mathematician Arend Heyting in 1930. It has been shown that this logic can be interpreted in terms of the same kind of modal logic serving as a system of epistemic logic. In the light of its purpose to consider only the known, this isomorphism is suggestive. The avowed purpose of the intuitionist is to consider only what can actually be established constructively in logic and in mathematics—i.e., what can actually be known. Thus, he refuses to consider, for example, "Either A or not-A" as a logical truth, for it does not actually help one in knowing whether A or not-A is the case. This does not close, however, the philosophical problem about intuitionism. Special problems arise from intuitionists' rejection (in effect) of the nonepistemic aspects of logic, as illustrated by the fact that only a part of epistemic logic is needed in this translation of intuitionistic logic into epistemic logic.

Other new logics are obtained by modifying the rules of

Entities  
to which a  
theory is  
committedIntuition-  
istic  
logic

those games that are involved in the game-theoretical interpretation of first-order logic mentioned above. The logician may reject, for instance, the assumption that he possesses perfect information, an assumption that characterizes classical first-order logic. One may also try to restrict the strategy sets of the players—to recursive strategies, for example.

Among the oldest kinds of alternative logics are many-valued logics. In them, more truth values than the usual true and false are assumed. The idea seems very natural when considered in abstraction from the actual use of logic. But a philosophically satisfactory interpretation of many-valued logics is not equally straightforward. The interest in finite-valued logics and the applicability of them are sometimes exaggerated. The idea, however, of using the elements of an arbitrary Boolean algebra—a generalized calculus of classes—as abstract truth-values has provided a powerful tool for systematic logical theory.

#### LOGIC AND OTHER DISCIPLINES

**Technical disciplines.** The relations of logic to mathematics, to computer technology, and to the empirical sciences are here considered.

**Mathematics.** It is usually said that all of mathematics can, in principle, be formulated in a sufficiently theorem-rich system of axiomatic set theory. What the axioms of a set theory that could accomplish this might be, however, and whether they are at all natural is not obvious in every case. (The recent development in abstract algebra known as category theory offers the most conspicuous examples of these problems.) The axioms of set theory may be presumed to hold in virtue of the meanings of the terms set, member of, and so on. Thus, in some loose sense all of pure mathematics falls within the scope of logic in the wider sense. This assertion is not very informative, however, as long as the logician has no ways of analyzing these meanings so as to be able to tell what assumptions (axioms of set theory) should be adopted. The definitions of basic mathematical concepts (such as “number”) in logical terms proposed by Gottlob Frege (in 1884), by Bertrand Russell (in 1903), and by their successors do not help in this enterprise. It is not clear that more recent insights in logic help very much, either, in the search for strong set-theoretical assumptions. The relationship of mathematics to logic on this level therefore remains ambiguous.

Notwithstanding these deep problems, virtually all normal mathematical argumentation is carried out in logical terms—mostly in first-order terms, but with a generous sprinkling of second-order reasoning and various principles of set theory. Historically speaking, most specific early examples of nontrivial logical reasoning were taken from mathematics.

Often these examples were set in contrast to logical arguments understood in a narrow traditional sense—in a sense narrower still than the idea of logic as being exhausted by quantification theory. According to this traditional view, logic is equated with syllogistic (*q.v.*); *i.e.*, with a part of that part of first-order logic that deals with properties and not with relations. Much of what earlier philosophers said of mathematical reasoning must, thus, be understood as applying to relational (first-order) reasoning. The present-day philosophy of logic is therefore as much an heir to traditional philosophy of mathematics as to traditional philosophy of logic.

Specific logical results are applicable in several parts of mathematics, especially in algebra, and various concepts and techniques used by logicians have often been borrowed from mathematics. (Thus one can even speak of “the mathematics of metamathematics.”)

**Computers.** It has already been indicated that recursive function theory is, in effect, the study of certain idealized automata (computers). It is, in fact, a matter of indifference whether this theory belongs to logic or to computer science. The idealized assumption of a potentially infinite computer tape, however, is not a trivial one: Turing machines typically need plenty of tape in their calculations. Hence the step from Turing machines to

finite automata (which are not assumed to have access to an infinite tape) is an important one.

This limitation does not dissociate computer science from logic, however, for other parts of logic are also relevant to computer science and are constantly employed there. Propositional logic may be thought of as the “logic” of certain simple types of switching circuits. There are also close connections between automata theory and the logical and algebraic study of formal languages. An interesting topic on the borderline of logic and computer science is mechanical theorem proving, which derives some of its interest from being a clear-cut instance of the problems of artificial intelligence, especially of the problems of realizing various heuristic modes of thinking on computers. In theoretical discussions in this area, it is nevertheless not always understood how much textbook logic is basically trivial and where the distinctively nontrivial truths of logic (including first-order logic) lie.

**Methodology of the empirical sciences.** The quest for theoretical self-awareness in the empirical sciences has led to interest in methodological and foundational problems as well as to attempts to axiomatize different empirical theories. Moreover, general methodological problems, such as the nature of scientific explanations, have been discussed intensively among philosophers of science. In all of these endeavours, logic plays an important role.

By and large, there are here three different lines of thought. (1) Often, only the simplest parts of logic—*e.g.*, propositional logic—are appealed to (over and above the mere use of logical notation). Sometimes, claims regarding the usefulness of logic in the methodology of the empirical sciences are, in effect, restricted to such rudimentary applications. This restriction is misleading, however, for most of the interesting and promising connections between methodology and logic lie on a higher level, especially in the area of model theory. In econometrics, for instance, a special case of the logicians’ problems of definability plays an important role under the title “identification problem.” On a more general level, logicians have been able to clarify the concept of a model as it is used in the empirical sciences.

In addition to those employing simple logic, two other contrasting types of theorists can be distinguished: (2) philosophers of science, who rely mostly on first-order formulations, and (3) methodologists (*e.g.*, Patrick Suppes, a U.S. philosopher and behavioral scientist), who want to use the full power of set theory and of the mathematics based on it. Both approaches have advantages. Usually realistic axiomatizations and other reconstructions of actual scientific theories are possible only in terms of set theoretical and other strong mathematical conceptualizations (theories conceived of as “set-theoretical predicates”). In spite of the oversimplification that first-order formulations often entail, however, they can yield theoretical insights because first-order logic (including its model theory) is mastered by logicians much more thoroughly than is set theory.

Many empirical sciences, especially the social sciences, use mathematical tools borrowed from probability theory and statistics, together with such outgrowths of these as decision theory, game theory, utility theory, and operations research. A modest but not uninteresting beginning in the study of their foundations has been made in modern inductive logic.

**Human disciplines.** The relations of logic to linguistics, psychology, law, and education are here considered.

**Linguistics.** The revival of interest in semantics among theoretical linguists in the late 1960s awakened their interest in the interrelations of logic and linguistic theory as well. It was also discovered that certain grammatical problems are closely related to logicians’ concepts and theories. A near-identity of linguistics and “natural logic” has been claimed by the U.S. linguist George Lakoff. Among the many conflicting and controversial developments in this area, special mention may perhaps be made of attempts by Jerrold J. Katz, a U.S. grammarian-philosopher, and others to give a linguistic characterization of such fundamental logical notions as analyticity; the

Many-valued logics

Turing machines and the infinite tape

Use of first-order versus set-theoretical formulations

sketch by Montague of a "universal grammar" based on his intensional logic; and the suggestion (by several logicians and linguists) that what linguists call "deep structure" is to be identified with logical form. Of a much less controversial nature is the extensive and fruitful use of recursive function theory and related areas of logic in formal grammars and in the formal models of language users.

**Psychology.** Although the "laws of thought" studied in logic are not the empirical generalizations of a psychologist, they can serve as a conceptual framework for psychological theorizing. Probably the best known recent example of such theorizing is the large-scale attempt made in the mid-20th century by Jean Piaget, a Swiss psychologist, to characterize the developmental stages of a child's thought by reference to the logical structures that he can master.

Elsewhere in psychology, logic is employed mostly as an ingredient of various models using mathematical ideas or ideas drawn from such areas as automata or information theory. Large-scale direct uses are rare, however, partly because of the problems mentioned above in the section on logic and information.

**Law.** Of the great variety of kinds of argumentation used in the law, some are persuasive rather than strictly logical, and others exemplify different procedures in applied logic rather than the formulas of pure logic. Examinations of "Lawiers Logike"—as the subject was called in 1588—have also uncovered a variety of arguments belonging to the various departments of logic mentioned above. Such inquiries do not seem to catch the most characteristic kinds of legal conceptualization, however—with one exception, *viz.*, a theory developed by Wesley Newcomb Hohfeld, a pre-World War I U.S. legal scholar, of what he called the fundamental legal conceptions. Although originally presented in informal terms, this theory is closely related to recent deontic logic (in some cases in combination with suitable causal notions). Even some of the apparent difficulties are shared by the two approaches: the deontic logician's notion of permission, for example, which is often thought of as being unduly weak, is to all practical purposes a generalization of Hohfeld's concept of privilege.

**Education.** After having been one of the main ingredients of the general school curriculum for centuries, logic virtually disappeared from liberal education during the first half of the 20th century. It has made major inroads back into school curricula, however, as a part of the new mathematical curriculum that came into fairly general use in the 1960s, which normally includes the elements of propositional logic and of set theory. Logic is also easily adapted to being taught by computers and has been used in experiments with computer-based education.

**BIBLIOGRAPHY.** W.V. QUINE, *Philosophy of Logic* (1970), is the best compact introductory exposition. HILARY PUTNAM, *Philosophy of Logic* (1971), is useful as a complement to Quine. Much of the important recent literature, however, is in the form of brief papers rather than monographs. The most successful anthologies of such papers are perhaps L.W. SUMNER and JOHN WOODS (eds.), *Necessary Truth* (1969), on logical truth and analyticity; and LEONARD LINSKY (ed.), *Reference and Modality* (1971), on modal concepts and intensional logic. RAYMOND KLIBANSKY (ed.), *Contemporary Philosophy*, vol. 1 (1968), contains several survey articles covering thoroughly the whole field. Still central are the classical writings of the great modern philosophers of logic: PETER GEACH and MAX BLACK (eds.), *Translations from the Philosophical writings of Gottlob Frege*, 2nd ed. (1960); BERTRAND RUSSELL, *Logic and Knowledge* (1956); LUDWIG WITTGENSTEIN, *Tractatus logico-philosophicus* (Eng. trans., 1922) and *Philosophical Investigations* (Eng. trans., 1953); ALFRED TARSKI, *Logic, Semantics, and Metamathematics* (1956); and RUDOLF CARNAP, *Meaning and Necessity* (1947). The period 1879–1931 is also covered in a magnificent volume by JEAN VAN HEIJENOORT (ed.), *From Frege to Gödel: A Source Book in Mathematical Logic, 1879–1931* (1967), which contains valuable introductions to the different selections and comments on them. Of recent literature, especially noteworthy are the writings of Strawson and Quine: P.F. STRAWSON, *Logico-Linguistic Papers* (1971); W.V. QUINE, *From a Logical Point of View* (1953), *Word and Object* (1960), and *Ontological Relativity and Other*

*Essays* (1969). Quine's ideas are discussed critically in DONALD DAVIDSON and JAAKKO HINTIKKA (eds.), *Words and Objections* (1969). A broad spectrum of new work on the borderline of philosophical logic and linguistics is represented in DONALD DAVIDSON and GILBERT HARMAN (eds.), *Semantics of Natural Language* (1972). Several problems mentioned above are discussed in JAAKKO HINTIKKA, *Logic, Language-Games, and Information* (1972); and in J.W. DAVIS, D.J. HOCKNEY, and W.K. WILSON (eds.), *Philosophical Logic* (1969).

(K.J.Hi.)

## Logistics Systems, Military

The word logistics stems from the Greek word *logistikos*, "the science of computation, or calculating." "Logista" was the title of administrative officials in the Roman and Byzantine armies. A cognate French word, *loger*, means the billeting of soldiers, and in the late 17th century the French staff officer responsible for the quartering and movement of troops was the *maréchal des logis*, or quartermaster general. His staff was linked with a branch of the French military engineers, the *ingénieurs géographes*, whose task was to make maps and draw up memoranda of operational areas for use in planning the movement and maintenance of armies. Baron Jomini, an early 19th-century authority on Napoleonic warfare, in his book *Précis de l'art de la guerre* (1836), defined logistics as "the practical art of moving armies" in which he included reconnaissance, engineer, and staff work. The purpose was to produce a logistical approach to battle and so to achieve strategic and tactical mobility and surprise.

Jomini's logistic theories had little impact on military thought in Europe and the term itself fell into disuse. It was revived in 1882 by then U.S. Captain (later Admiral) Alfred Thayer Mahan, who defined logistics as the support of armed forces by the economic and industrial mobilization of a nation.

From 1918 the U.S. armed forces increasingly used logistics to describe the activities of the Ordnance Department and Quartermaster Corps, embracing a wide range of staff duties including supply, transportation, construction, and medical service. The term was seldom used elsewhere until World War II. In the Royal Army, administration covered all activities connected with the interior economy of units in peace, and their supply, movement, and maintenance in war. Neither logistics nor administration was used by European armies. The French *intendance*, "management of supply," led to the title of *intendant general* for the officer in continental armies responsible for supply.

Logistics is today an official term in the military terminology of NATO (North Atlantic Treaty Organization) countries, and with the complexity of modern war it has acquired a wider meaning. It is concerned not only with the movement and maintenance of forces and the evacuation and hospitalization of personnel but also with the design, development, acquisition, storage, and distribution of material—in other words, the procurement of weapons, their associated systems, and all other materials of war. The term administration is increasingly used to denote personnel management and the day-to-day handling of men in matters affecting pay, discipline and morale. The distinction between the two terms remains blurred. The British, for instance, have recently created a chief of personnel and logistics in the Ministry of Defense. Where administration ends and logistics begins is a matter of importance only to the military pedant and writer of official terms.

The complexity of modern war imposes many strains on the logistic planners who must recognize the speed and depth of operations, the vulnerability of lines of communication to air and ground attack, and the vast organization needed for the maintenance of modern forces.

Military logistics is an inexact science. Its data vary between the precise and the problematical. Though experience can minimize the uncertain factors, it will never eliminate the need for common sense, imagination, anticipation, and preparation. Logistic planning is the intelligent forecasting of the requirements of an operation.

## The history and development of logistics systems

### EARLY WARS

The armies of ancient history lived off the country or were self-contained; that is, the supplies they needed were brought with them in their invading ships. This was the pattern of maintenance when the Persian army invaded Greece in 490 and 481 BC. The larger Greek armies of Xenophon, Epaminondas, and Alexander the Great, in the 4th century BC, needed more support. Supply bases were established. Elephants and camels were used in Alexander's march of 4,000 miles from Egypt through Persia to India. The Roman wars of the 3rd and 2nd centuries BC saw supply depots established and stocked from local sources of food and forage. Hannibal's march from Spain across the Alps into Italy was a masterpiece of logistic planning. Large numbers of elephants brought from Africa were used to carry supplies over the Alps. The Roman legions stationed throughout the provinces of the Empire were supplied from fortified depots at regular intervals of 16 miles, or one day's march, along the routes of march. In an emergency a legion could carry up to 30 days' supply of food. The legions' ability to march fast and far owed much to the excellent roads built by the army. The engineers, artificers, and armourers brought repair shops with them.

After the fall of the Roman Empire, the army of the Byzantine Empire (AD 600) achieved a degree of administrative efficiency surpassing all previous efforts. Belisarius organized the provinces of the empire into military districts, each of which provided a field force of one cavalry division, maintained in peace by tax levied on the provinces and administered by their governors. Each field division of the standing army had its own engineers, supply trains, and medical services and was on a permanent war footing, always ready for operations outside the empire.

The Mongolian cavalry armies of Genghis Khan and Sabutai that invaded China and Europe had no supply problem. By nature they lived frugally and moved quickly. Each man had three spare horses. One was a mare from which he drew kumiss, the mare's milk, and the other two were his spare chargers, which in extremity he ate.

When the Mongol army drew near its objective it left the spare horses behind and, dividing into separate columns, converged on the enemy rapidly from several directions. Using this method in his invasion of Hungary (1241), Sabutai covered 180 miles in three days, outmanoeuvring Polish, German, and Bohemian armies before surprising and annihilating the Hungarian army on the Danube.

### THE 17TH AND 18TH CENTURIES

The Thirty Years' War, 1618–48, devastated central Europe as essentially mercenary armies pillaged the countryside. Partly as a result, international laws on the conduct of war were introduced and pillage was prohibited. Armies became disciplined bodies of long-service professional soldiers restricted as to their conduct in peace and war. In 1650 the marquis de Louvois, war minister of Louis XIV of France, introduced a new system. The French Army was supplied by a regular commissariat service and a system of wagon trains based on magazines stocked from the home base or by purchase of local produce. This system contained the essential elements of a logistic organization and set the pattern for the supply and maintenance of armies for over a century. But the new system, instead of improving the mobility of armies, limited the speed and scope of military operations. Armies were restricted to the few roads, and even in the summer months movement was limited to seven marches from the nearest magazine and two from a field bakery. Defense or capture of the magazines, situated in fortresses or fortified towns, became the principal preoccupation of generalship. To force an enemy to consume his supplies was much; to compel him to supply his opponent was more; to take up winter quarters in his territory was victory. The supply and maintenance of armies had become the master of strategy instead of its servant.

Hannibal's march

The Duke of Marlborough broke away from these sterile theories in his march to the Danube and the victory of Blenheim, a masterpiece of logistic planning, in 1704. The commissary general ensured that provisions were ready at every halt of the 400-mile march down the Rhine. Credit for their payment was assured with German bankers. New boots were provided for the army of 40,000 men on its arrival in Bavaria. The good order of the men and the excellent condition of the horses was the result of Marlborough's genius in administrative planning and the meticulous detail of his preparations.

The French Revolutionary Wars (1792–99) brought about a change in the meaning of logistics. The *levée en masse* ("general conscription") placed France on a total war footing. Supplies, transport, and services were requisitioned from the civil authorities under penalty of imprisonment or fine. Payment was seldom made. Conscription was introduced; in the *levée en masse* young men were drafted into fighting units, older men into the forging of weapons and the transport of supplies, and women into tentmaking and hospital service.

The Napoleonic Wars (1800–15) saw another change in the meaning of logistics. The French Army was reorganized into permanent corps and divisions, which Napoleon used to increase the scope of strategic manoeuvre and to accelerate tactical operations. Logistics and strategy became virtually synonymous. The duties of the quartermaster general became those of a chief of staff through whom the commander in chief issued his orders. Marshal Louis-Alexandre Berthier, formerly *maréchal des logis* ("quartermaster general") under the revolutionary regime, was Napoleon's chief of staff. Similarly Sir Archibald Murray, Wellington's quartermaster general in Spain, was chief of staff, with duties including intelligence, map making, and the issue of orders for all types of movement, both on the field of battle and in rear areas.

The commissary general and the ordnance department were responsible for the maintenance of the Royal Army in Spain. The commissaries were civilians who combined the responsibilities of treasury officials, paymasters, and purveyors. They bought, stored, transported, and issued rations for men and animals and issued cash for the pay of officers and soldiers.

The requisition system of Napoleon's armies had many advantages. Troops lived on the country they occupied and could move wherever local supplies were available, without administrative preplanning. Requisition, however, aroused resistance against French armies in Spain, Germany, and elsewhere, especially in the case of a prolonged occupation of the same district. The concentration of a large force in one place was difficult unless depots were maintained.

Despite these problems, Napoleon's campaigns in Italy and Germany were logistic triumphs; the movement of his army from Boulogne to Austerlitz in the 1805 campaign, for example, involved intricate planning and transport arrangements to overcome the advantages the Austrians and Russians enjoyed by their proximity to bases. In 1812, however, Napoleon made the mistake of taking a large army deep into enemy country without sufficient logistic preparation; the scarcity of supplies, especially forage, in Russia and the poor roads combined to create a logistic catastrophe.

### THE 19TH CENTURY

**The impact of the Industrial Revolution on logistics systems.** The Industrial Revolution and the introduction of steam-driven machinery changed the nature of war. Logistics was affected by three major developments. First, by creating armaments of constantly increasing firepower, industry became the primary source of military power. Second, improved transport and communications permitted large increases in the size of armies. Third, medical science began the conquest of epidemic disease. Yet the production of new armaments lagged so far behind the pace of invention that in the Crimean War (1853–56) the British and French armies differed little from those of the Napoleonic Wars. In 1759 French inventor Nicolas Cugnot made the first steam-

Introduc-  
tion of  
conscrip-  
tion

Use of steam-traction engines

driven road vehicle, which he discussed in a paper "The Automobile in War," but the idea was to remain untested for over a hundred years. The Crimean War revived interest; a British-built machine fitted with revolving scythes was designed literally to mow down infantry, but was rejected by the government as unsuitable for civilized warfare. Steam-traction engines were, however, used in the Crimea to haul ammunition wagons from the magazines at Balaclava to the front. They were also used in the Franco-Prussian and Russo-Turkish wars a few years later. In 1899 the British War Office sent armoured steam-traction engines and wagons to the South African War, but they were not used forward of the bases.

A similar technical lag occurred in 19th-century naval logistics. Because the British Admiralty opposed the introduction of steamships, sailing ships transported and maintained the Royal Army in the Crimea. A decade later steamships played a major part in the U.S. Civil War, both as gunboats and as supply ships.

**The impact of railways.** The development of railways in the first half of the 19th century revolutionized military transportation by increasing the size of armies and speeding up deployment in the field. Prussia immediately recognized the importance of rail transportation. The ability to move troops rapidly from the centre of the country to its periphery was a greater advantage to it than to any other European power. In 1846 a Prussian Army Corps, 12,000 strong with horses and guns, made an experimental rail move. In the Austro-Prussian War of 1866 the Prussian general Moltke used the five available railways to deploy along a 250-mile front and to outmanoeuvre the Austrian army. In the Franco-Prussian War of 1870 the railways leading to the Rhine enabled him to encircle the French armies assembled in Alsace-Lorraine. In these and subsequent wars, armies depended on railways for their maintenance. Ease of supply encouraged commanders to swell their forces at the railheads. From these points men had to march, and supplies and ammunition had to be carried in animal-drawn transport. By the end of the 19th century the new magazine rifle and quick-firing artillery increased the demand for ammunition and expanded horse transport caused congestion on the roads, which were often unusable in winter. Railways thus were actually reducing mobility rather than increasing it. Although they gave strategy a speed of movement, they offered no logistic flexibility and were in addition vulnerable themselves to attack.

The U.S. Civil War was fought on and individual actions were fought for the new railways. Among the Confederacy's most effective military efforts throughout the war were raids on the railroads that maintained the large Union armies, especially in the western theatre. In 1864 the Confederacy was increasingly dependent on two railways that ran from the Mississippi to Richmond by way of Chattanooga and Atlanta. These railways carried grain and meat produced in the western states to the eastern seaboard. The capture of these two railway centres wrecked the Confederate supply system. These decisive operations foreshadowed the time when air and tank forces would sever supply lines.

In the South African War (1899-1902) the mounted Boer commandos repeatedly attacked the railways on which the Royal Army depended for its supply. Away from the railroads, a British division, with its 650 animal-drawn vehicles, including 200 heavy wagons each drawn by 16 oxen, moved less than two miles an hour. When Field Marshal Lord Roberts became commander in chief in 1900, he pooled the transport of the fighting units under the control of the Army Service Corps, sharply reduced baggage and tentage scales, and gave the Cavalry Division pack mules and carts. This reorganization of the army's transport contributed to the relief of the besieged towns of Kimberley and Ladysmith. The Boers then resorted to guerrilla warfare, forcing Major General Lord Kitchener, who became commander in chief in 1901, to build blockhouses a mile or so apart along the railways. Many infantry battalions were tied up in the static defense of railways instead of being available for offensive operations against the Boers.

Relief of Kimberley and Ladysmith

## THE 20TH CENTURY

**Pre-World War I.** *The impact of the internal-combustion engine.* By the beginning of the 20th century a network of rails covered Europe, and the invention of the internal-combustion engine offered a solution to the problem of supplying troops from the railhead. Motor trucks could carry from three to four times as much as horse-drawn vehicles occupying a similar space on the road and travelled six times as fast. They brought supplies from railheads, delivered them to fighting formations, and returned rapidly. An illustration of this is the comparison between the forces used in the Franco-Prussian War of 1870 and those deployed at the start of World War I. In the Franco-Prussian War Germany placed armies of about 380,000 men in the field; France opposed them with 275,000 men. In August 1914 Germany deployed 1,500,000 men against France, and Belgium and France opposed with armies numbering 1,000,000. The initial military effort of the two countries had, thus, increased fourfold and it continued to develop until armies numbered millions. Transportation had ceased to be a limiting factor in the size of armies.

*Medical science.* Before World War I epidemic diseases, chiefly enteric (typhoid) fever, typhus, and smallpox, were the scourge of armies. In the three years of the South African War 13,000 British soldiers died from enteric and nearly 64,000 cases were invalidated home.

Deaths in Various Wars

war	killed and died of wounds per thousand	died of disease per thousand	forces
Napoleonic Wars	35	270	French and British
Crimean	35	190	British and French
U.S. Civil War	20	71	Union and Confederate
South African	17	30	British

Deaths from enemy action were fewer than 8,000. Between 1902 and 1914 medical research and surgery advanced rapidly. Hygiene was improved, smallpox vaccination was introduced, and battle casualties were given aseptic surgical and hospital treatment. In World War I (1914-18) deaths from disease in the British and American armies fell to four per 1,000. Gangrene of wounds and trench fever were gradually controlled. Disease, instead of being a major, became a minor cause of loss, at least in western Europe where malaria was not endemic. In Macedonia and Salonika there were 126,000 malarial admissions to the hospital of whom 500 died. In this and other Middle East theatres of war dysentery became a problem but improved methods of hygiene kept it in check.

**World War I (1914-18).** Many wars lasted longer than World War I, but it was unique in two respects: the size of the opposing armies and their permanent contact. From the logistic point of view it is best seen as a siege. After the first few weeks of mobile warfare, the armies lay static, facing each other in a continuous line of trenches that stretched from Switzerland to the North Sea. Siege warfare required massive supplies of munitions. By the beginning of 1915 the Germans had increased their production of ammunition to 250,000 rounds per day; the French were producing 100,000 rounds; British production lagged at only 22,000 rounds per day.

Munitions production

*The problem of matériel.* Massive industrial mobilization took place in all the belligerent nations. As demands for war material continued to mount, shortages developed. Germany felt them in foodstuffs, textiles, metals, and oils. In Britain, too, shortages of food and raw materials became critical in the face of losses from U-boat sinkings. Food rationing was introduced in most warring countries. Transportation, too, was everywhere taken over by governments. Logistics thus became a universal concern, profoundly affecting all national life and introducing the concept of total war.

*Logistics on the Western Front.* The logistic services of the warring armies stood the test of the mobile operations

at the beginning of the war. Besides the roads and railways, the armies made use of canals in France and Belgium. Supplies arrived daily at railheads in packtrains loaded with the rations and ammunition of a division for the next 24 hours. Reserves were held at the base and only small balancing stocks were kept near the front line. The number and contents of ammunition trains arriving daily at railheads depended on expenditure, past or planned. The principle of ammunition resupply was based on the automatic replenishment of fighting units.

The Battle of Verdun in 1916 demonstrated the vulnerability of railways to shellfire, and the German offensive in the spring of 1918 aimed at disrupting the British lateral railway system. It stopped movement on the forward lateral rail line, and air attacks were bunched on the rear lateral. The danger was averted by the construction of new railways and bridges.

*Motor transport.* The French and British reorganized their motor transport in 1918, withdrawing trucks from units to form headquarters motor reserves. This pooling improved logistic mobility and flexibility. In the final Allied advances of 1918 military engineers concentrated on extending railways and roads behind the armies. Motor transport carried supplies forward from railheads. Yet it is worth noting that all the Western armies still used large amounts of horse-drawn transport throughout 1918.

The tendency in most armies in this war was to divide logistic responsibility into forward and rear areas. For example, for the French Army the forward zone, the "zone of advance," was controlled by a general staff officer, whereas the rear zone, or "zone of supply," was administered by the War Ministry in Paris. This system of supply and distribution was suitable for an army fighting in its own country. The U.S. Army had an assistant chief of staff at headquarters in control of logistic support for the fighting area and a general commanding the service of supply in the rear. Under the American system the heads of the various logistic corps were not at general headquarters but at their own headquarters.

*Medical services.* In World War I the adjutant general administered the British medical services. The French and American medical services were under the quartermaster general's branch of the staff. Collection, evacuation, and treatment of the wounded and sick were efficiently carried out in comparison with earlier wars. The test was severe. During the Somme battles British field ambulances collected 316,073 wounded between July 1 and November 30, 1916, including 26,675 in the first 24 hours; 305,285 were transferred to base hospitals, and on one day 10,112 arrived in hospital ships at Dover and Southampton.

*The Eastern theatre.* Railroads on the Eastern Front played a decisive logistic role, with horse-drawn transport almost universally used from the railheads. In the opening campaign of 1914 the limitations of the Russian railroad system in Poland and the effectiveness of the German system in East Prussia were largely responsible for a German victory at Tannenberg. But the difficulty the Germans experienced in turning their tactical successes of 1915 into meaningful strategic successes was also largely due to the shortcomings of the Russian railroad network.

*The Middle East theatre.* Allied amphibious landings at Gallipoli in 1915 were a triumph of naval improvisation with the army supplied over open beaches in the absence of a port facility. The campaign ended in failure, but not for logistic reasons.

The British campaign in Mesopotamia in 1916, on the other hand, suffered from poor logistic planning. Supplied aid administered from India, the army used the Tigris and Euphrates rivers for water and for lines of communication but did not bring along sufficient river transport. Land transport was similarly inadequate, and medical arrangements broke down, with hundreds of wounded dying from exhaustion and thirst in the desert sun. The object of the campaign, the relief of the garrison in Kūt al-Imāra, was not attained.

By way of contrast, the subsequent Palestine campaign (1916-18) was a masterpiece of careful logistic planning and execution. A 140-mile standard-gauge railway and

a 12-inch water pipeline were built from the Suez Canal across the Sinai Desert. Filtering machinery, pumping stations, and reservoirs were included. This modern technology was supplemented with an ancient means of transport; the water was carried from the pipe head at Beersheba to the army by 35,000 camels. The campaign foreshadowed some of the extraordinary logistic achievements of World War II.

*The interwar years.* During the years of peace from 1919 to 1939, scientific and mechanical invention mapped the pattern of logistics in a future war. Motor vehicles were improved in design and given a cross-country performance capacity. This led to the mechanization of armies and the gradual disappearance of horse-drawn transport. Mobility was restored to the battlefield. Supply and maintenance in the field were changed to meet this new requirement. Motor transport was organized to maintain armies with supplies and ammunition 100 miles from railheads. Mechanical earth-moving equipment, the bulldozer, was invented, and bridging equipment of improved design increased mobility and simplified military engineering.

An area of neglect was the logistic potential of aircraft, although the Germans developed transport aircraft for airborne and parachute forces. The logistic problems of amphibious warfare and seaborne operations were also insufficiently considered.

*World War II.* More than anything else, World War II (1939-45) was a war of logistics, this time on a global scale. Conventional and familiar logistics problems recurred on a much larger scale, as in the supply of the Soviet and German armies on the long Eastern Front through nearly four years of intensive war. This was essentially a railroad operation. The Russian rail network had been considerably improved since 1914-17. Movement of supplies from the railheads was chiefly by truck, though horse-drawn transport and tracked vehicles were both widely used.

The innovations in logistics in World War II grew largely out of the global commitments of the two major Western allies, particularly the United States. Even after the decision to give the defeat of Germany first priority, enormous questions remained in the realm of how to make the best use of available production, especially shipping. In the words of George C. Marshall, U.S. Army chief of staff, "the limitations in resources presented a most difficult and trying problem. Ocean tonnage, transport planes to fly supplies into China from India, an increase in the flow of troops into the United Kingdom for the invasion of Normandy, and landing craft for the Island campaigns in the southwest Pacific all had to be taken into consideration in the light of limitations in resources. Sacrifices would be required somewhere but if made at the wrong place would delay final victory." The extent to which these problems were overcome is the major part of the history of logistics in World War II.

*Shipping.* The largest single logistics problem on either side in the entire war was the Anglo-American shipping problem. Though other nations had shipping problems, the interior lines on which the Germans and Italians operated in the Mediterranean, and the Japanese in the western Pacific, made their problems small in comparison with those of the U.K. and U.S. planners. Throughout the war, cargo shipping and tanker shortages had a stranglehold effect, restricting the scope of Allied strategy and limiting the size of individual operations.

One aspect of the problem was submarine warfare in which twice as much Allied tonnage was sunk as was built in the first three months of 1943. The British merchant fleet was reduced from 17,000,000 tons to 13,500,000. The convoy system, tactically essential to defeat the U-boats, was logistically uneconomic. Convoys took time to assemble and had to sail at the speed of the slowest ship, thus reducing their rate of turnaround.

The loss of the Mediterranean and the unavailability of the Suez Canal aggravated the shipping shortage. Alternative routes from England to the Middle East, India, and beyond required going around South Africa. This was 9,000 miles longer, a voyage of two months instead

Persistence of horse-drawn transport

Neglected areas of logistics

Disadvantages of convoy system

of two weeks. A ship could make at most three round trips a year by the Cape as compared with ten through the Mediterranean.

To solve these difficulties, routes across Africa were developed. Those for stores and crated vehicles ran from the mouth of the Congo by river and rail to Egypt. Crated aircraft were shipped from America and the U.K. to Africa's Gold Coast, assembled at Takoradi (now Sekondi-Takoradi), and flown to the Middle East and India. The Congo route was designed to take 30,000 tons of stores and 800 crated vehicles a month. This was not fully operational when the Mediterranean was reopened to Allied shipping in the summer of 1943.

After the invasion of Russia by Germany in 1941, large tonnages of British and American munitions and supplies were shipped to Russia over one of two routes: south to the Persian Gulf and thence by rail and road through Iran to the Caspian; or north, around Norway to Murmansk. The northern route was open to German sea and air attack and involved nearly catastrophic losses; in June 1942, one convoy with a large naval escort lost 22 of its 33 merchant ships, and, as a result, the British Admiralty suspended northern convoys to Russia until the following winter, at the very moment the German Stalingrad offensive was developing.

Meantime, ship construction, though increasing in the U.S., was declining in the U.K. from the end of 1942. Desired Allied shipping requirements were never met, and less important requirements had to be cancelled. For example, 600,000 tons of British coastal shipping, much of it used to carry coal, were withdrawn for the invasion of Normandy in June 1944. In the following winter a nationwide fuel crisis threatened U.K. munitions production. The shortage of shipping was aggravated by other difficulties; the failure to capture enough ports in France made it necessary for 246 Allied ships to stand unable to dock; urgently required elsewhere, they became floating depots. The same problem occurred in the Pacific; during the attack on Okinawa in 1945, 100 ships lay helplessly off the island, some ultimately returning to Hawaii without unloading their cargoes.

*Landing craft.* Of all types of shipping, assault shipping was the most persistently in demand. Before the war, little attention had been given to this class of vessel. When the U.S. entered the war it was decided that British shipyards should concentrate on traditional naval craft, whereas American yards built landing craft and ships, including the landing ship tank, a large oceangoing assault ship carrying stores and heavy vehicles and capable of landing them directly on steep beaches. On flat beaches they discharged at low water or anchored offshore and unloaded into barges placed under the ramp.

This method of discharge was first used on a large scale in the Anglo-American invasion of Sicily in July 1943, a landmark in the history of amphibious warfare, which proved the practicability of prolonged maintenance over open beaches. In addition to 139 landing ship tanks, many smaller amphibious assault landing craft participated. The invasion of Normandy in 1944 required 236. Most of the landing ship tanks in the Mediterranean returned to the U.K., limiting the development of operations in Italy; the planned amphibious assault on Rangoon was cancelled, and allocations of new landing ship tanks for the Pacific were reduced.

*Transport aircraft.* Air transport was one of the most significant logistic developments of World War II. It sustained Resistance movements in Europe by dropping agents, arms, and demolition equipment by parachute. Transport aircraft, notably the American twin-engined C-47 (Dakota), resupplied the 1944-45 airborne assaults in Normandy, The Netherlands, and on the Rhine. Thousands of casualties were evacuated by air without loss, and hundreds of tons of stores a day were delivered. Air supply made possible the rapid advance of the Allied armies from the Rhine to the Baltic and the Danube. In April 1945, for example, U.S. Troop Carrier Command delivered 54,000 tons of stores and six field hospitals to American and French armies and flew out casualties, while British transport aircraft flew 8,000 tons of supplies

into north Germany and took out 6,000 casualties and 35,000 Allied former prisoners of war. The British Bomber Command also dropped food to the starving people of west Holland.

Air transport was essential for the development of Allied plans in Asia. Air supply solved the British logistic problem in Burma and was effectively used by the U.S. to sustain Chinese forces fighting the Japanese.

In 1943 it was decided to develop an air route over the Himalayan Mountains, to fly in 20,000 tons a month, from Assam, in northeast India, to Chung King, in central China. Twenty-four airfields were constructed in Assam for 600 U.S. cargo planes; the monthly capacity of the narrow-gauge railway from Calcutta to Assam was increased by about 250,000 tons, and 750 miles of gasoline pipeline were laid from Calcutta to the airfields. These remarkable logistic developments were completed by engineer and railway construction and operating units in less than 18 months.

Although air transport in World War II was an uneconomic method of movement compared with sea and land transport, it was of incalculable military value. As an air expert said, "Air transport was the best means to get supplies to many places, the only way to get supplies to some places and it proved to be the fastest way to get supplies to any place."

*The growth of logistics systems.* When the British expeditionary force crossed the English Channel in 1939 its passage and disembarkation were unopposed. Well-equipped French ports and railways handled the unloading and inland movement of 150,000 men, 25,000 vehicles and guns, and 140,000 tons of stores, in 24 days. In June 1944 the Allied expeditionary force that crossed the Channel assaulted a heavily defended coast, lacked a port of any significance, and had to be maintained over open beaches. During the first 24 days 900,000 men, 176,000 vehicles and guns, and 900,000 tons of stores were landed. The transformation in logistics thinking and capabilities was dramatically illustrated.

Before and after D day 1944, the Allies concentrated their air attack against the German supply system, the railways, and roads. After D day the Germans used the same policy in reverse. They attacked the Allied logistic buildup by destroying the ports. The repair and operation of the French ports and railways required large numbers of army engineers and transportation personnel and vast quantities of stores and bridging. Cherbourg was captured by July 1, 1944. The port and harbour were strewn with mines; deepwater quays were demolished and their cranes and elevators blown into the water. The port was reconditioned by Anglo-American naval and army units and two months later the port was handling 18,000 tons a day, double peacetime capacity.

Another area of growth in logistic requirements was the construction and maintenance of airfields, a major problem on all fronts. In northwest Europe alone British Army airfield construction units repaired over 100 forward airfields and built 50, each requiring 3,500 tons of material. Pierced steel track for runways was the largest item.

Large increases in motor transport in base areas and on the lines of communication were demanded by armies moving at rates in excess of 50 miles a day. Significantly, one of the largest categories of U.S. lend-lease aid to the U.S.S.R. was in trucks. In France a high-priority, high-speed truck transport system known as the Red Ball Express between Normandy and Reims used some 100 truck companies to operate fast convoys to General Patton's U.S. Third Army in the period August to October 1944. Results were excellent in spite of wastage from accident and breakdown. Such huge motor-transport and air-transport operations in support of mechanized warfare required extensive chains of ordnance depots, repair workshops, and maintenance facilities on airfields. Each aircraft had to be supported by a ground crew of about 35 officers and men. These increases in logistic systems are reflected in the organization of Allied forces, which show a large increase in logistic overhead in the rear echelons. For every combat division ashore (about 16,000 men),

an additional 24,000 troops and 4,000 air force personnel were required in the theatre. This combined figure of 40,000 army personnel was known, for logistic planning purposes, as a divisional slice. Sometimes this slice was larger. It amounted to 68,000 in the Allied invasion of North Africa in 1942 and rose to 92,000 in Burma, owing to the long and difficult line of communications from Calcutta.

Daily maintenance tonnages and reserves also increased. The following figures show the daily quantities of gasoline and engineer stores required by a divisional slice in 1944:

Factor	Tons
Supplies (5.6 lb per man)	97
Ordnance	74
Gasoline (50 miles per vehicle)	194
Engineering stores	180
Ammunition (average expenditure)	130
	<hr/> 675

This excludes air force maintenance tonnages.

Two inventions alleviated the logistic burdens; an artificial harbour Mulberry and Pluto (pipeline under the ocean), the undersea gasoline pipelines that stretched from England to France. The plan for the invasion of Normandy included the early capture of the port of Cherbourg. But it was foreseen that demolitions might prevent its use for many weeks. The two Mulberry artificial harbours, each the size of Dover Harbour, were considered essential for the discharge of cargo over open beaches in the crucial early stages of the campaign. These harbours, it was hoped, would nullify the hazards of tide and weather. The gales that threatened the invasion of Europe with disaster continued to hamper the buildup, and culminated in a great storm. The British Mulberry with its breakwaters of concrete caissons and sunken ships protected the transport vessels and landing craft, and, though the American Mulberry broke up and had to be abandoned, the landing was secured. The Allied margin of maintenance was at times so perilously slight that the contribution of the Mulberries was a major one. Although heavy seas reduced the effectiveness of such things as so-called Rhino ferries (strings of pontoons towed by powered craft), small amphibious craft, and landing craft, the buildup went on. The millionth man stepped ashore 28 days after the invasion and 1,000,000 tons of stores and 300,000 vehicles had been landed by the 38th day.

*The modification of supply systems.* The German blitzkrieg of 1940 in France and Flanders demonstrated that the World War I system based on the daily arrival of supply and ammunition trains at railheads no longer worked. The system had to be altered to meet the needs of mechanized armies and fast-moving warfare. Demands for gasoline, ammunition, engineer, and ordnance stores varied frequently according to operations planned or in progress. The switching of a formation from one army or corps to another was normal operational practice. It became impossible to communicate orders for supplies with accuracy or in time for their movement up a long line of communication. The punctual arrival of road convoys was not predictable. The supply system had to be modified to give an army's staff closer control over the logistic services. Forward maintenance areas were formed to hold reserves against interruptions in the supply chain and to overcome inaccuracy in forward planning. Despite many improvements, formations outran their supplies in the rapid advance of the Allied armies from Normandy to the Rhine in 1944 and had to be halted for want of gasoline.

The supply of gasoline to the European continent was a major problem. A pipeline laid from Liverpool to the south coast of England and continued by undersea pipelines in the Channel saved shipping and also ensured against bad weather. Two types of submarine pipe were used. The first lines were submarine cable with the core removed, laid from the Isle of Wight to Cherbourg. The second were specially made and laid from Dungeness in Kent to Boulogne. In all, 16 lines delivered about 3,500 tons of gasoline (over 1,000,000 gallons) a day. Later in

the campaign pipelines on the Continent were laid from Boulogne and Antwerp to east of the Rhine. The maintenance of the Allied forces in their final drive into Germany would have been impossible without these. By 1945 pipelines on the Continent were delivering 10,000 tons a day to forward maintenance areas.

*The mechanization of armies.* The mechanization of armies in World War II gave new emphasis to the importance of roads and bridges. For the Allied crossing of the Rhine in 1945, 16 floating bridges were built; and between the Rhine and the Elbe 508 bridges had to be built.

*Medical services.* New medical techniques were developed to meet the needs of mobile warfare. A major problem was to provide rapid surgical treatment for the wounded in fast-moving and wide-ranging battle in desert, jungle, and mountain terrain and in amphibious operations. Mobile field surgical and blood transfusion teams were attached to casualty-clearing stations behind the forward troops. These units and the quick evacuation of casualties by air, hospital carrier, or landing ship tank to base hospitals saved many lives.

In the Pacific, malaria was conquered by spraying mosquito-infested areas with DDT, by strict hygiene discipline, and by the daily use of paludrine and other suppressive drugs. At Okinawa, notoriously malarial, there were only two cases in one four-month period.

*Lend-lease.* One of the outstanding innovations of World War II, not itself in the realm of logistics, but with vast logistic consequences, was the U.S. lend-lease program. Lend-lease enabled America to act as "the arsenal of democracy" and permitted a degree of inter-Allied production planning. Thus, by ordering certain types of equipment from the U.S., such as jeeps and trucks, the Russians could concentrate on production of tanks. Cooperation between the U.S. and the U.K. was even more effective. A combined Munitions Board was set up in Washington and London.

In spite of the difficulties of coordination, the flow of supplies from the U.S. to British forces grew throughout 1943 and reached its peak before the invasion of Europe in June of 1944. In return, the British provided accommodations for 1,350,000 American troops, their rail movement, and their supplies within England all as part of the buildup of U.S. forces in the U.K.

*Logistics problems of Germany.* German munitions production stood the strain of war until the late summer of 1944. Three years of strategic bombing directed against its factories and cities were less crippling than Allied air attacks on the land and sea communications of its armed forces (Wehrmacht).

Gen. Alfred Jodl, chief of operations at Hitler's headquarters, recognized the Wehrmacht's dependence on supply and maintenance for its strategic and logistic flexibility. In December 1943 he pointed out the impossibility of defending the Atlantic coast along a front of over 3,000 kilometres, meanwhile maintaining large armies in the Soviet Union and the northern Mediterranean countries at the end of long and inadequate lines of communications. He advised reducing the defensive perimeter to provide a strong central reserve in Germany that could readily be moved to whatever area the Western powers chose to assault. Only thus could Germany continue to exploit the logistic advantage of fighting on interior lines and make full use of its excellent east-west railways and roads. Hitler, however, refused to give up a yard of ground.

Inside Germany there was no strategic reserve. Industrial statistics supported Hitler's belief that he could hold the fronts in the Soviet Union and Italy and repulse the cross-channel invasion. In spite of the Allied bombing of German war industries, the rate of munitions production, under the energetic direction of Albert Speer, was rising steadily.

Even this rise in munitions production was not enough to support long intensive operations on more than one front. From the summer of 1944 until the end of the war the Wehrmacht fought on three fronts with ever-decreasing air support. By June 1944 the Allies had virtual air supremacy. Rail traffic between Germany and Norman-

dy was disrupted; the invasion area was sealed off from large-scale German reinforcement; and, later, as the front moved eastward, the railways and canals extending into Germany were attacked. Bombers flying from the airfields at Foggia in Italy attacked the Romanian oil fields at Ploesti and damaged war industry in southern Germany—up to then outside the range of air attack.

By October 1944 rail traffic in western Germany was paralyzed. This had a catastrophic effect on the distribution of coal from the Ruhr to munitions factories. The synthetic oil plants were also attacked. This dealt a serious blow to the production of aviation fuel, explosives, and synthetic rubber. If these targets had been attacked at an earlier stage in the war, the industrial capacity of Germany and the mobility of its armed forces might have been seriously weakened. As it turned out, the German Army retained a remarkable degree of tactical mobility and logistic flexibility until the final weeks of the war. This was a feat of high military competence in an adverse air situation.

*Logistics problems of Japan.* As was the case with Germany, the early victories of Japan spread its forces too far for logistic stability. They became dangerously dispersed and susceptible to defeat. But unlike Germany, Japan's economic and logistic position was unsound from the start. Its economic potential was only 10 percent of that of the United States, and its acreage of arable land not more than three percent; yet this land had to support a population over half as large as that of the U.S. The High Command failed to provide the army with the logistic support required for land and amphibious warfare against Western armies. The early tide of Japanese conquest extended from the Indo-Burmese border in the west to the Solomon and Midway islands in the Pacific. This over-dispersion resulted in defeats. Admiral Mitsumasa Yonai, navy minister, was alone in realizing that the destruction of the Japanese navy by the American Third and Seventh fleets in the Battle of Leyte Gulf, October 1944, sealed the fate of Japan. The merchant shipping on which Japan depended for the import of most of its raw materials and much of its food was now at the mercy of submarine attack. Such attacks accounted for some 55 percent of the 9,000,000 tons of Japanese merchant shipping sunk during the war.

By the end of 1944, if not before, Japan faced economic defeat. Its conquests in Southeast Asia were a liability; and it could no longer depend on essential imports of grain and minerals from Manchuria and Korea.

*Logistics problems of the Soviet Union.* Hitler's invasion of the U.S.S.R. tends to take its place in a historical niche beside Napoleon's, as a hopeless gamble doomed to failure from the start. No such conclusion emerges from a study of the campaign. The Soviet Union only survived by a narrow margin until its epic victory at Stalingrad in January 1943. The German offensives of 1941 and 1942 destroyed much of its army and air force. It was touch-and-go whether Stalin could scrape together new armies to halt Hitler and prevent the capture of the Caucasian oil fields and its resources up to the Volga.

In January 1943 the hinge of fate turned at Stalingrad, where Field Marshal von Paulus surrendered the remnants of his army. The German conquest had reached its high-water mark. A number of logistic factors enabled the Soviet Union to survive the German invasion, to turn to the offensive in the spring of 1943, and two years later to capture Berlin. As in Napoleon's defeat, the Soviet Union's reserves of manpower remained firm. Equally, the size of the country and the rigours of the winter were natural allies. In spite of Anglo-American supplies, the logistics of the Red Army were primitive, but the Soviet soldier was tough and could endure severe hardships. He was commanded by generals who combined the will to fight with a talent for logistic improvisation. Never perhaps in the history of war have fewer supplies been put to more effective use than by the Soviets during these years. Last, the Soviets excelled at making weapons the outstanding characteristics of which were their ruggedness of construction and ease of maintenance.

The Soviets concentrated on the mass production of one or two types of each weapon. Their crudeness was outweighed by the advantage of rapid output. Priority was given to the equipment of the tank arm. The mass-produced T-34 medium and Stalin heavy tanks were superior to comparable German types.

After Stalingrad the armoured divisions were the most efficient part of the Soviet army. Their mobility was improved by American trucks. The ordinary infantry divisions had to scrape along with a makeshift collection of transport—much of it horse drawn. Most of the 400,000 American trucks supplied under lend-lease were allotted to the armoured divisions and the rear logistic services.

The capacity of the Soviet soldier for logistic improvisation was illustrated by the fact that until late in the war the Soviet army lacked specialized river-crossing equipment, yet assaulted and crossed the broad rivers of the U.S.S.R. and Poland astonishingly quickly. The engineers felled trees near the riverbank and turned them into well-built wooden bridges. Some of these bridges were built under water to avoid detection by German aircraft.

The Soviet Union fought World War II with its own native skills. The Red Army's weapons and logistic support were rough and ready but proved remarkably effective in battle.

## Logistics problems in the nuclear age

### WEAPON DEVELOPMENT

**Procurement.** Modern logistics systems must meet the requirements of (1) limited war without the threat of nuclear attack, (2) limited war with a nuclear threat, and (3) nuclear war on a global scale.

The procurement of weapons for such a wide range of threats is complicated. The most vital and also the most difficult calculation involves the time factor between the development and testing of a new weapon and its actual production. This reflects difficulties in the methods by which defense policy is decided: the central control of programs, budgeting, and expenditure; the construction of a framework of strategic policy against which the requirements for new weapons can be assessed; and the machinery to control the competing demands of rival services for expensive weapon systems.

It takes from seven to ten years to develop a weapon system from drawing board to operational use. If the weapon's useful life is another ten or more years, then the defense planner has to assess values about 20 years ahead against the uncertain background of technical progress and economic, defense, and foreign policies. Critics argue that this time scale makes errors of judgment inevitable because the weapon can be outdated before it is operational. The best answer available is careful scrutiny of projects to ensure their operational need and cost effectiveness, but despite all precautions wrong decisions can be made. After the Korean War (1950-53), for example, the U.S. and U.K. planned weapon systems to maintain a global military presence and a nuclear delivery system, but the time and cost taken to develop these new weapons were underestimated. By 1961 research and development costs represented a third of a complex weapon system. The cost of military research and development in the U.K. was four-fifths of the nation's total research allocation. The arms race increased costs by making weapons obsolete even before they became operational. Changes in operational requirement and design led to delays in production and cancellation of major projects. The cancellation of the British Blue Streak nuclear missile and the costly argument between the U.S. Army and Air Force over two similar ballistic missile systems, Thor and Jupiter, show the difficulties.

By 1960 problems of cost dominated the whole field of weapon procurement. Smaller nations could not find the money to design and produce sophisticated weapon systems; yet they could not ignore the advance of technology, and affluent America could hardly afford to continue its mistakes of the past decade. Uncertainties in strategic planning aggravated the problem of allocation of re-

sources. In the U.S. and the U.K. the defense departments assumed mandatory powers over all stages of weapon procurement.

Feasibility studies

When the need for a new weapon has been established, the concerned service normally makes a "feasibility study" that gives a detailed description of the weapon, its required operational performance, and the anticipated cost in time, resources, and money. If this report is accepted, a "project study" normally follows to establish certain cost and development criteria. If the study shows that these conditions cannot be met the project can be abandoned without wasting more than 5 percent of the total estimated cost. Though such feasibility and project studies may take from 18 months to two years to complete, they are assumed to avoid much waste.

One U.S. secretary of defense in the 1960s encouraged U.S. universities and other institutions to study strategic threats and force requirements. These studies are called systems analysis. They seek to define, for example, whether in a nuclear war most lives would be saved by a full civil defense organization, an active missile defense, or a powerful nuclear delivery system with a counterforce capability. The techniques of cost effectiveness and quantitative analysis are applied to weapon systems—*i.e.*, to intercontinental ballistic missiles on the one hand, and airlift and air support requirements in limited war on the other.

In the Soviet Union the period from about 1953 to 1967 was marked by the evolution of military aircraft from the transonic to supersonic speed ranges and the replacement of centrifugal with axial turbojets. Since 1967 the emphasis has been on short takeoff and landing capabilities and the construction of such advanced, multipurpose aircraft as the MiG-23 high-altitude interceptor and strike aircraft.

All these aircraft were made from competitive prototypes designed and developed by civilian engineer teams—*i.e.*, MiG and Yak. These teams work apart from the aircraft industry, which is tooled for rapid mass production of completed aircraft. There is little indication that this costly method of procurement is more effective than Western methods. The information the Soviet designer learns at the competitive prototype stage emerges with greater certainty from the Western system of research and development.

The Soviet system probably reflects a comparative lack of wind tunnel and other technical aids to design. The development of new aircraft systems by competitive test flying is regarded as an essential step in technological progress.

The Soviet air force tends to base its procurement on proved advances in aerodynamic and engine technology, whereas in the West the emphasis is more on converting the theories of applied science to prototype design. Thus, as the Soviets think in terms of adequate aircraft, easy to maintain and operate in extreme cold, Western air forces and their designers think more in terms of technological perfection.

**Research and development.** A weapon is developed in four stages: technical development; operational research; the testing of prototypes; and trials of production models under operational conditions. Technical development is primarily concerned with applied research into the components of the weapon system. It does not consider cost or operational effectiveness.

Operational research

Operational research (or operational analysis) seeks to suggest more effective ways of using weapons (see also OPERATIONS RESEARCH). It provides data on which the practical problems and cost of new weapons can be assessed. It was first developed by the British in World War II. A notable example of its use was in a study of depth-charge patterns by antisubmarine aircraft. Operational research is largely a matter for the individual services, their technical staffs, and scientific advisers. Production engineers and management experts are consulted. The study of nuclear, bacteriological, and chemical warfare requires experts in physics, chemistry, physiology, and other branches of medicine. Computers and data analysis machines are used to solve complicated development

problems. The operational analysis of a new weapon system starts with a definition of the strategic and tactical background. This study must define the situation ten or more years in the future in terms of the strength, composition, deployment, strategy, and tactics of enemy and friendly forces. Some miscalculation is inevitable in assessing these due to uncertainty as to the comparative rates of technical development. The "scenario" is used to measure the operational effectiveness and cost of a weapon system with the technological possibilities. The task of a weapon must be precisely defined so that inherent weaknesses exploitable by the enemy may be discovered.

For example, a recent U.K. operational analysis of an airborne early warning system for fighter aircraft and surface-to-air missiles established that two surface-to-air missile weapon systems were required, one to meet attack by medium- and high-flying aircraft and the other to meet low-level attack by subsonic and supersonic aircraft.

The research, development, and manufacturing costs of producing a reliable high-performance weapon with low maintenance and repair costs are large. Reliability is the product of precision in manufacture and the prolonged testing of prototype and production models. Delays in large-scale delivery must be accepted.

It may be necessary to study the cost of inserting new weapons into existing combat forces. If, for example, the partial re-equipment of an air defense fighter force with surface-to-air missiles is planned, such study might relate reductions in total expenditure to the cost of each spare fighter aircraft. This is the "opportunity cost." These aircraft can be used in four ways: they can be sold at secondhand value; they can be given another role—for example, to reinforce an existing ground attack force; they may be used to reduce the procurement of new ground attack aircraft; finally, they may be placed in reserve and used to prolong the life of the fighter force, thus delaying expenditure on new fighter aircraft.

Operational analysis may also be used to study the ratio of increased cost of diminishing effectiveness—the law of diminishing returns. A study of targets for ballistic missiles, for example, may show that there are 100 potential targets, and operational analysis may prove that the theoretical chance of destroying any one target is, for example, not more than 50 percent. The first 100 missiles should therefore destroy 50 targets, and 200 missiles destroy a progressively smaller number of targets, the last 100 probably destroying three only.

Operational analysis is not a precise science. It can, however, identify problems and reduce the uncertainties of long-term weapons requirements. It provides the defense planner with an impartial investigation, based on a number of possible alternatives, from which he must draw his own common sense conclusions.

**Programs and budgets.** The final decision on the choice of weapon systems depends on political and economic factors. Research and development are therefore inseparable from programs and budgets. The object is to improve cost effectiveness. Defense costs are analyzed under functional heads and their requirements projected ten years ahead to allow for the time lag in weapon production. Estimates for the early years are firm; those for later years contain elements of guesswork. For this reason these forecasts are reviewed annually. Inevitably, difficulties occur: service programs require more money than governments are prepared to make available. Long-term functional cost assessments do not eliminate arbitrary decisions or do away with interservice disputes; but it can reduce them and provide a yardstick of information to settle misjudgments when they occur.

**The problem of unification.** The system of a single weapons procurement agency has been adopted in some countries. Areas of common use in modern weapon systems are growing; for example, the Royal Navy provides electronic components for all three services and the Army supplies all the guns, ammunition, and mechanical vehicles. Canada has adopted the pattern of one combat force.

**The problem of reliability.** A weapon must be easy to operate and maintain. Complete reliability can of course

Missile  
reliability

never be attained. The larger the number of components the greater the chances of failure. A weapon system of 1,000 components, each with a failure rate of one in 1,000,000, has a failure rate of one in 1,000. A missile of 30,000 to 40,000 components, each with a failure rate of one in 100,000, has a theoretical misfire rate of one missile in three. These facts are unwelcome equally to the service staffs who decide operational requirements and to the scientists who encourage the staffs to press their requirements to the frontiers of technology. Design and development time and money for an advanced aircraft engine may amount to 500 times the production cost of one engine. Well-designed equipment stands up to long periods of overoperation and stress and to long periods without servicing. Less well-designed equipment can be kept serviceable only by frequent inspection, maintenance, and repair, during which it is nonoperational.

The prolonged testing of prototypes, followed by field and troop trials of early production models, plays an essential part in the search for reliability. Tests reveal defects in performance that can be rectified before large-scale production starts. Development does not end with these trials. The services and their design staffs strive to improve the breed of a weapon system. The original production model, a Mark I, is followed by further Marks and usually rather quickly by Mark II. Thereafter, the gap between sequential Marks tends to grow. The multiplication of minor modifications is often a sign that the weapon suffers from basic faults in design.

**Maintenance and repair.** Although advanced techniques in the design and production of weapon systems must be accepted, it is necessary to achieve simplicity in operation and easy diagnosis of failure, maintenance, and repair. Experience shows that some of the best ways of achieving these ends are by the standardization of equipment, the use of commercial components, and overhaul by the replacement of complete assemblies. The maintenance problems of the different services illustrate these points. The servicing and repair at sea of naval machinery is made more difficult by high steam pressures and speeds and confined machinery spaces. Complex automatic controls change the duties of the engine-room staff from operators to diagnosticians and maintainers. The upkeep of the electrical and mechanical equipment for the ship's armament and domestic purposes increases the maintenance load. A standard range of engines in a minimum number of sizes meeting a practical range of horsepower has improved the reliability of naval machinery. Limitations on the exact speeds required for full power or cruising endurance are accepted. Every effort is made to use machinery with a wider market. Diesel generators and a large range of auxiliary machinery can be adapted for naval use.

Use of  
multirole  
aircraft

The gradual replacement of bomber and fighter aircraft by guided missiles concentrates development on fewer types of multirole combat aircraft for tactical strike, reconnaissance, and close support. The decision of the U.K., Italy, and West Germany to develop such aircraft is an example of European cooperation in defense procurement and standardization. The increasing use of helicopters and short takeoff and landing (STOL) and vertical takeoff and landing (VTOL) aircraft poses the problem of their servicing in forward fighting areas. There are four categories of military aircraft servicing. Scheduled and unscheduled servicing both follow civil aircraft practice and are based on flying hours and the immediate repair of minor faults. Flexible servicing is used when the aircraft is grounded for operational or weather reasons. A fourth, contingency servicing, is used only when operations require an exceptional rate of aircraft utilization. It is confined to the minimum necessary to success because of the difficulties of servicing in forward areas.

The mechanization of armies in World War II applied not only to wheeled transport vehicles but also to fighting vehicles, including artillery of many calibres and tracked vehicles of many types. The modern repair techniques that were largely developed then are based on the optimum compromise between military and technical engineering requirements. Repairs are carried out as far for-

ward as possible in order to reduce both the time that equipment is out of action and the recovery and movement to field workshops of heavy equipment casualties such as tanks. The technical efficiency of army repair facilities in forward areas is limited. When operational conditions make forward repair essential, repair teams are sent up from workshops to repair vehicles on the spot. Repair is usually the fitting of a complete new or reconditioned assembly. Generally, a repair team can remove and replace a tank engine in six to eight hours.

Experience shows that in war a tank needs a major replacement assembly every 700-800 miles. It is not possible, however, to forecast with accuracy which of the six major assemblies in a tank will be needed. The engine alone weighs about 1½ tons. Producing the right assembly at the time and place is difficult and the extent to which forward repair will prove practicable in future war is subject to doubt. It is likely that the speed and dispersion of modern land fighting will result in greater scrapping of equipment damaged beyond the means of economic recovery and repair. Armies are now equipped with standard ranges of load carriers adapted from civil use; the all-purpose main battle tank has replaced the medium and heavy World War II tanks of many types. The complexity of modern equipment has, however, increased greatly; amphibious ability, sophisticated weapon guidance, night-fighting aids, additional radio and radar all increase the repair and maintenance load. To this must now be added guided weapon systems. A missile system consists of a large number of components that must be brought together, assembled, and tested before the system is operational. This presents little difficulty in the case of a small missile with solid propellant and a conventional warhead. A large missile with its ground handling, guidance, and other supporting equipment is a more difficult problem. A tactical missile system must be moved to its firing site and assembled and tested in time for its operational task. Nuclear warheads are stored and maintained by special units in guarded areas. Their movement by air or ground to missile firing sites requires special security and traffic-control arrangements.

**The control of ordnance stores.** Ordnance stores include all types of weapons, ammunition and vehicles, radar and other technical equipment, aircraft, and a vast range of spare parts. The latter may amount to 600,000 to 1,000,000 separate items, the demand for each of which is relatively small and predictable only in general terms. Normal practice is to stock a small range of common-user items in forward depots and to hold larger and less frequently required items in central depots in base and support areas. The efficient stocking and issue of stores requires (1) accurate requisitions, or orders, rapidly transmitted from the user to the depot; (2) quick identification and location of the item by the depot staff; (3) secure and protective storage and packing, particularly in tropical climates; (4) mechanical handling equipment; (5) quick delivery of stores to users; and (6) regular reviews of scales and stocks to ensure they meet changes in requirement. Improvements in these methods give greater economy in manpower and costs. Automatic data-processing machines have revolutionized the management of ordnance depots and similar establishments. Depots are linked, irrespective of their distances apart, by computers that store the data and give the requisite information, thus rationalizing the storage and flow of supplies and spare parts and eliminating paper work. Computers are invaluable in control of an establishment such as the U.S. early warning system of 150 stations and depots containing 400,000 items. Before the Six-day War of 1967 the Israeli army installed a computer to change their ordnance store holdings, in which there were critical shortages, from a peace to a war footing. It processed all requisitions and supply issues, ensuring sufficiency for operations. After the war it analyzed the cannibalization of captured equipment.

machines

#### LOGISTIC PROBLEMS IN LIMITED WAR OPERATIONS

It is impossible to predict how and where limited war situations will emerge or the form they will take. They

may include military aid by large powers to warring factions, antiradical and antiguerrilla operations, or local war between minor powers armed with conventional weapons. The essential requirement in meeting the problems posed by limited war situations of the 1950s and 1960s was a capacity to act swiftly. A small force on the spot quickly can achieve more than a large one later. The logistic plan for limited war must be capable of achieving a quick concentration of effort in the area of violence and of maintaining it there. Science and technology have made and continue to make significant contributions to the strategic and tactical mobility of air, land, and amphibious forces.

**Logistics and mobility.** The range and speed of aircraft, coupled with air refuelling, make most parts of the world accessible to land and air forces within a few days. There are few countries without civil airfields, but if air reinforcements are to provide more than a token force some prestocking of aircraft spare parts and fuel may be necessary. Political "air barriers" restricting the movement of military aircraft, as in the Middle East, can be circumvented. In the early 1970s new giant transport aircraft made possible lifting troops, with their heavy equipment, tanks, and guns, at a speed of 400 knots, for a distance of 5,800 miles from an 8,000-foot unpaved airstrip. In the future large aircraft may be propelled by nuclear power, providing unlimited flexibility. Short and vertical takeoff transport aircraft can supply combat troops in action. The extensive use of helicopters by the U.S. Army in Vietnam is one of the more notable logistic developments of recent years. Rear-door transport aircraft, parachutes, and cargo pallets of improved design simplify the airdrop of supplies, weapons, and equipment. Pallets can be skidded onto the ground from low-flying aircraft.

The sea endurance of naval forces has improved through nuclear power and techniques for replenishment of warships at sea. The mobility and logistic self-sufficiency of amphibious forces have also increased. Commando and assault ships, supported by fast logistic ships and improved landing ship tanks, achieve the rapid deployment of assault forces over long distances. Logistic ships are equipped with derricks of up to 120 tons capacity. Vehicles can also be carried in M.T. (motor transport) ships and roll-off-roll-through vehicle ferries. Dock landing ships (landing platform docks) can be beached or discharge their cargo from deep water by pontoons into powered lighters. The hovercraft provides mobility and support in otherwise impossible conditions—swamps, cataracts, and ice floes. Another development with logistic possibilities is the amphibious hydrofoil, a surface-skimming vehicle designed to carry cargo between ship and shore at a maximum speed of 35 knots. Although the threat of nuclear retaliation makes very large-scale amphibious operations most improbable, smaller seaborne landings and raids may well be practicable; certainly the logistic ability to mount them has improved greatly.

Nuclear-powered supertanker and bulk freight submarines for the commercial movement of crude oil and iron ore under the ice of Arctic waters are now a technical possibility. This invention has military application for the movement of supplies in war. A submarine freighter would open up new and shorter sea routes—e.g., to the Pacific beneath the polar ice cap and through the Bering Strait—and a craft with a designed speed of 30 knots could reach Australia from Europe in two weeks.

To this concept of cargo submarines must be added the technical possibility of underwater bases anchored to the seabed. This is an adaptation of a floating bases project considered for the planned invasion of Japan in 1945. On land, armoured personnel carriers and large cargo vehicles cross rough country and sail across rivers and flooded areas. Better engines, improved suspensions, and lightweight armour provide protected vehicles for the movement of combat troops and their support on the battlefield. Cost, however, is a major factor in producing these new methods of transportation. Compared with an army truck carrying 1,500 pounds (680 kilograms), a helicopter with the same capacity costs 200 times as much; a

hovercraft with about eight times the lift costs 1,000 times as much. Thus, there seems little immediate prospect that older, cheaper methods of transport will be more than partially superseded by advanced vehicles.

**Supply and maintenance in limited war.** Limited war operations are most likely to occur in areas remote from strategic bases. The country may be undeveloped and with few communications. Airfields and ports could be poor and roads little more than tracks; communications may be by river or across waterless desert. There may be no military stockpiles in the country so that maintenance requirements must be met from overseas. On the other hand, local stocks of gasoline and basic engineer materials may be available, and buildings can be improvised for military use. Full use must be made of all local resources to achieve a rapid buildup of forces. These conditions pose peculiar logistic problems.

The initial entry in a future limited war will probably be by air using long-range transport aircraft. If lack of airfields makes the early landing of troops impracticable, a proportion of the force can be dropped by parachute or flown in by seaborne helicopters. The initial fly-in will include engineer and air force personnel with airfield construction equipment. The air-transported force may be followed by an amphibious force carried in commando, assault landing ships, or landing ship tanks supported by logistic ships loaded with heavy equipment. Logistic support within the area of operations will probably continue to be by air, except for bulk fuel supplies that must be moved by road. If the area of operations is large, a forward airhead maintenance area may be established for the use of medium- and short-range transport aircraft.

The coordination of sea, land, air, and civil agencies of supply and maintenance will involve joint plans and implementation. Items required by more than one service will be provided by the service best equipped to do so. The army may construct airstrips and landing pads for helicopters and light aircraft and the air force construct airfields for its tactical aircraft. The construction of larger airstrips for long- and medium-range transport aircraft may be a joint responsibility. The provision or repair of bulk gasoline storage and the distribution of gasoline by pipeline is the army's responsibility.

Troops may have to move rapidly from temperate to extreme climates and go into action on arrival. The best preparation is physical fitness. Experience shows that it compensates for the lack of a natural acclimatization period, about six weeks, provided there is a high standard of hygiene at unit level.

#### LOGISTICS AND THE NUCLEAR THREAT

In the circumstance imposed by nuclear war it is impossible to visualize land forces supported by conventional logistic systems with depots of supplies behind the shield of forward troops. The requirement is for a method of maintaining forces without the whole system collapsing if one part of it is destroyed. The efficient handling of logistic support will depend on conditions in rear areas that cannot be predicted with accuracy.

Dispersion is the main safeguard against the loss of installations and stores, though it is difficult to control and expensive in manpower, time, and stocks. Logistic dispersion is easier when fighting on interior or overland lines of communication. It is less practicable with exterior lines passing through ports, beaches, and airfields. These and their associated base complexes are vulnerable to nuclear attack. A partial solution may be to hold more reserve stocks in forward areas, thus making combat formations and units more self-reliant. Maximum use must be made of air maintenance. The extent to which it can be used depends on the air situation and weather. Neither may be entirely favourable. Air maintenance is therefore best superimposed on land links of supply.

These considerations suggest a reorganization of rear and forward maintenance areas. The proportion of stores held in the rear should be reduced while increasing those in the forward area. The proportions depend on a number of factors including the operational and air situations, terrain, distances, and the type of commodity.

Use of  
helicopters  
in Vietnam

Nuclear-  
powered  
ships and  
submarines

The  
significance  
of  
dispersion  
in a  
nuclear  
war

The number of forward maintenance areas will vary with the size of the force. Groups will be dispersed over wide areas, with medium-range transport aircraft delivering supplies, perhaps by airdrop. Short-range fixed-wing transport aircraft and helicopters can be used to supply combat formations. Large, high-speed helicopters may provide armoured forces with vital logistic support in fast-moving operations. Combat units will be dispersed over a far wider area than in the past, and will need to carry a large reserve of gasoline and ammunition.

No one knows, however, if such methods of supply and maintenance in the field would remain effective in the face of nuclear attack. There appears to be certain limitations to which a solution is not immediately clear. The most important are: (1) the extent to which continuous operations can be sustained by day and night; (2) the limited fuel carried by an armoured fighting vehicle and the difficulties of bulk resupply of gasoline to ensure full mobility; (3) the vulnerability of helicopters against a sophisticated enemy; (4) the problems of logistic command and control in large-scale dispersed and mobile operations. Such traditional logistic calculations as the daily movement of large tonnages would be out of the question. In fact it is difficult to think of logistic systems as a rational military term in large-scale nuclear war. Only sea, amphibious, air, and airborne forces would be capable of offensive action after the first shock.

#### THE PEACEFUL USES OF MILITARY LOGISTICS

War, with its potential for total destruction, can be averted, and the prevention of war may become the main purpose of armed forces. Within this concept the task of military logistics still remains the orderly deployment of armed force. The threshold of intervention must be lowered to avert and cure the discontents that produce violence.

The development of remote and less developed areas is now recognized as a major goal of the more affluent nations. The logistic services of an army are suited for these tasks.

The U.S. Army Corps of Engineers has a long and distinguished record of large-scale development at home and abroad. It has planned and constructed engineering schemes, including flood control of large rivers, irrigation of arid areas, canals, communications systems, and hydroelectric projects. The Australian army has been employed on similar projects in the development of the Snowy Mountains hydroelectric and irrigation project.

The logistic capacity of army engineer corps in terms of air and sea transportation, supply, repair, and medical facilities makes them more capable of quick deployment and self-maintenance in disaster areas than civilian rescue organizations. A good example is the mobilizing of Royal Army aid after the hurricane that struck Glasgow in 1968. Within 24 hours 600 army engineers were working on the roofs. Tarpaulins were flown in from army depots, and soldiers skilled as slaters, bricklayers, and scaffolders were employed.

There is a growing demand in some Western countries for an international rescue service. Such a service would, it has been suggested, solve the problem of closing the gap between willing donors and needful recipients. Aid could be stockpiled in advance of emergencies. Anonymity would then protect both the donor and the eventual recipient. But world stockpiles of relief supplies would serve no useful purpose unless they could be moved quickly and distributed within disaster areas. In large disasters only the military logistic forces of nation-states have the means to do this. The alternative is for the United Nations to have its own logistic contingency planning staff and permanent rescue service. Under certain conditions this might also be a peace-keeping force. In future years this concept might provide the nucleus around which the peaceful uses of military logistic systems could be built.

A change in the nature of military logistics is slowly developing. The movement of the military away from the civil is gradually being reversed. There are many reasons for this. Business methods of management and adminis-

tration are increasingly used to improve the efficiency of military establishments. The same techniques of planning and management are used by civil and military logisticians. The same equipment and machinery are used in civil and military engineering and construction projects. A civilian qualification, or at least skills of value in civil life, is the ideal for every serviceman. Technical skills acquired in the armed forces increasingly fit military personnel for employment in civilian life.

## Loire River

France's longest and, perhaps, most beautiful river, the Loire flows some 630 miles (over 1,000 kilometres) from its source, near the uptilted southern edge of the Massif Central in the Cévennes near the Mediterranean coast, to the Atlantic Ocean, which it enters south of the Bretagne (Brittany) peninsula. For half its length it flows in a northerly direction and is oriented toward the centre of the Paris Basin, but then it swings in a great curve past Orléans and flows westward to the sea by its long estuary at Nantes. Its catchment basin covers more than 45,000 square miles (117,000 square kilometres), and the château-dotted scenery of its valley is among the nation's finest.

*The course of the Loire.* The river rises at about 4,500 feet above sea level, at the foot of the Gerbier de Jonc in the Cévennes. In its upper course it flows through a succession of downfaulted, flat-floored basins—Le Puy, Forez, and Roanne—inset in the crystalline highlands of the Massif Central, in crossing which its valley narrows to gorges. At Le Bec d'Allier, 560 feet above sea level,

Uncertainties

The notion of an international rescue service

just downstream from Nevers, it receives on its left bank its major tributary, the Allier, which has pursued a roughly parallel course in draining the Monts d'Auvergne farther west. The greatly enlarged stream then traverses the limestone platform of Berry, and its valley is only a slight groove in low platforms of sedimentary rocks until in Anjou it finally breaks across the old rocks of the southern part of the Massif Armoricaïn in the lowest part of its course. Apart from the scarped hills of Sancerrois and La Puisaye, which its valley breaches below Cosne, the platforms that flank its middle course show few accidents of relief. They represent the bevelling of only slightly tilted sedimentary rocks that have been over-spread in places with extensive sheets of unconsolidated sands and clays, brought down from the crystalline rocks of the Massif Central, and elsewhere with residual debris, the product of intense weathering under humid, tropical climatic conditions that have obtained in the past. This has resulted in the decalcification of impure limestones and chalk. Much of these extensive tracts of overburden, differing from the bedrock below, yield only poor, siliceous soils that are responsible, for example, for the *gâtinés* (tracts of degraded woodland and heath) of Touraine and the ill-drained surface of Sologne within the great curve of the river south of Orléans. In Touraine the main stream is joined by further important left-bank tributaries, the Cher, Indre, and Vienne; and below the Val d'Anjou, where it finally engages in the crystalline rocks of the Bois d'Anjou, it is entered by its major right-bank tributary, the Maine, which is the product of the confluence a little to the north, near Angers, of the Loir, Sarthe, and Mayenne.

Diversion  
of the  
river by  
structural  
forces

The upper course of the Loire in the Massif Central and as far as Cosne seems directed toward the centre of the Paris Basin, and its diversion west toward the Atlantic Ocean is the presumed result of geologically recent Earth movements that tilted the floor of the southwestern part of the Paris Basin and let in a gulf of the sea as far as Blois. The vigorous ancestor of the Lower Loire was thus able to extend its catchment at the expense of the Seine system, capturing the Upper Loire and diverting its drainage into the present generally westward course to the ocean.

*The Loire Basin.* The Loire Basin now experiences a temperate maritime climate, with no consistent dry season and with heavy precipitation, including winter snow-fall, in the highlands that occupy its upper basin. The area of its headwaters is also subject to violent autumn storms from the Mediterranean. The river suffers from a somewhat irregular and notably capricious regime. At the end of summer its bed in the middle course is usually a long streak occupied mostly by pale sand rather than by water; in very dry years, such as 1949, the stream dwindles to such a degree that there was virtually no flow of water at Orléans. The river there is usually highest in late winter, but there is no reliable rule; and floods may occur in any month, except perhaps July and August. The worst recorded were in October 1846, May–June 1856, and September 1966, when the river rose 23 feet above normal at Tours.

The shallow but steep-sided groove occupied by the river in its middle course is successively called the Val de Loire, Val d'Orléans, Val de Blois, Val de Touraine, and Val d'Anjou. In this wide *val*, the river's position is usually eccentric. Its once-marshy floodplain is protected from flooding by *levées* ("embankments") built progressively from the 12th to the 19th centuries. Effective agricultural reclamation did not begin until the 14th century but was stimulated by the presence of the French court in the 15th and 16th centuries, when the Middle Loire Valley became a strip of intensive cultivation of money crops. In the 18th century, before the French Revolution, it reached the peak of its prosperity. The river was the great highway for movement of goods, and the cities on its banks were busy ports. River navigation by flat-bottomed vessels remained active until 1860, since when it has greatly declined with the coming of railways. During the period of developing river traffic in the 17th and 18th centuries, canal links were built connecting the Loire nav-

Economic  
aspects

igation with the Seine system of navigable waterways by way of the Canal de Briare (1642) and the Canal d'Orléans (1692). These links allowed products such as wine to be carried to Paris. Later the Canal du Centre (1794) across the Loire–Saône watershed linked the Loire with the Rhône navigation and played an important part in the early development of the small coalfield it traverses. These connecting canals are too narrow for modern vessels, and the Loire navigation itself is a mere shadow of its former importance. The long estuary below Nantes is obstructed by islands and sandbanks; but a channel, dredged to a depth of 26 feet, is maintained as far as Nantes, which was once so important as a colonial port. The modern, deepwater outport at Saint-Nazaire has important shipbuilding and repair yards.

Left aside by modern developments, the Loire countryside today remains profoundly rural, Old World, and little affected by modern industry. With its numerous châteaux and parks, it abounds in monuments to its illustrious past, recalling the faded glory of the life and landscape of two centuries ago.

**BIBLIOGRAPHY.** ROGER DION, *Le Val de Loire: étude de géographie régionale* (1934), is one of the most important and typical works in the tradition of French geographical writing. It studies the physical and human aspects of the Loire Valley, from Decize to Nantes, and includes numerous references to the history of the area since the 15th century. JACQUES GRAS, *Le Bassin de Paris méridional: étude morphologique* (1963), is a recent and comprehensive work on the physical geography. Additional information, in English, may be found in HILDA ORMSBY, *France*, 2nd ed. rev. (1962).

(A.E.Sm.)

## Lomonosov, Mikhail Vasilyevich

Mikhail Vasilyevich Lomonosov was a leading figure in Russian literature and science. His poetry brought new forms of expression to Russian poetic composition, and his *Ritorika* ("Rhetoric") and *Rossiyskaya grammatika* ("Russian Grammar") made him the foremost theoretician of his language. He made substantial contributions to the natural sciences, reorganized the St. Petersburg Imperial Academy of Sciences, established in Moscow the university that today bears his name, and created the first coloured glass mosaics in Russia.

Lomonosov was born on November 19 (November 8, old style), 1711, on an island in the Dvina River, near Kholmogory, and 50 miles (80 kilometres) from Arkhan-

Photo Larousse

Early  
struggles  
and  
achievements

gelsk, where, at the age of ten, he began the life of a fisherman. When the few books he was able to obtain could no longer satisfy his growing thirst for knowledge, in December 1730, he left his native village, penniless and on foot, for Moscow. His ambition was to educate himself to join the learned men on whom the tsar Peter I the Great was calling to transform Russia into a modern nation.

The clergy and the nobility, attached to their privileges and fearing the spread of education and science, actively opposed the reforms of which Lomonosov was a lifelong champion. His bitter struggle began as soon as he arrived in Moscow. In order to be admitted to the Slavonic-Greek-Latin Academy he had to conceal his humble origin; the sons of nobles jeered at him, and he had scarcely enough money for food and clothes. But his robust health and exceptional intelligence enabled him in five years to assimilate the eight-year course of study; during this time he taught himself Greek and read the philosophical works of antiquity.

Noticed at last by his instructors, in January 1736 Lomonosov became a student at the St. Petersburg Academy. Seven months later he left for Germany to study at the University of Marburg, where he led the turbulent life of the German student. His work did not suffer, however, for within three years he had surveyed the main achievements of Western philosophy and science. His mind, freed from all preconception, rebelled at the narrowness of the empiricism in which the disciples of Isaac Newton had bound the natural sciences; in dissertations sent to St. Petersburg, he attacked the problem of the structure of matter.

In 1739, in Freiberg, Lomonosov studied firsthand the technologies of mining, metallurgy, and glassmaking. Also friendly with the poets of the time, he freely indulged the love of verse that had arisen during his childhood with the reading of Psalms. The "Ode," dedicated to the Empress, and the *Pismo o pravilakh rossiyskogo stikhovorstva* ("Letter Concerning the Rules of Russian Versification") made a considerable impression at court.

Important  
publications

After breaking with one of his masters, the chemist Johann Henckel, and many other mishaps, among which his marriage at Marburg must be included, Lomonosov returned in July 1741 to St. Petersburg. The Academy, which was directed by foreigners and incompetent nobles, gave the young scholar no precise assignment, and the injustice aroused him. His violent temper and great strength sometimes led him to go beyond the rules of propriety, and in May 1743 he was placed under arrest. Two odes sent to the empress Elizabeth won him his liberation in January 1744, as well as a certain poetic prestige at the Academy.

While in prison he worked out the plan of work that he had already developed in Marburg. The 276 *zametok po fizike i korpuskulyarnoy filosofii* ("276 Notes on Corpuscular Philosophy and Physics") set forth the dominant ideas of his scientific work. Appointed a professor by the Academy in 1745, he translated Christian Wolff's *Institutiones philosophiae experimentalis* ("Studies in experimental philosophy") into Russian and wrote, in Latin, important works on the *Meditationes de Caloris et Frigoris Causa* (1747; "Cause of Heat and Cold"); the *Tentamen Theoriae de vi Aëris Elastica* (1748; "Elastic Force of Air"); and the *Theoria Electricitatis* (1756; "Theory of Electricity"). His friend, the celebrated German mathematician Leonhard Euler, recognized the creative originality of his articles, which were, on Euler's advice, published by the Russian Academy in the *Novye kommentari*.

In 1748 the laboratory that Lomonosov had been requesting since 1745 was granted him; it then began a prodigious amount of activity. He passionately undertook many tasks and, courageously facing ill will and hostility, recorded in three years more than 4,000 experiments in his *Zhurnal laboratorii*, the results of which enabled him to set up a coloured glass works and to make mosaics with these glasses. *Slovo o polze khimi* (1751; "Discourse on the Usefulness of Chemistry"), the *Pismo k I.I. Shuvalovu o polze stekla* (1752; "Letter to I.I. Shuva-

lov Concerning the Usefulness of Glass"), and the "Ode" to Elizabeth celebrated his fruitful union of abstract and applied science. Anxious to train students, he wrote in 1752 an introduction to the physical chemistry course that he was to set up in his laboratory. The theories on the unity of natural phenomena and the structure of matter that he set forth in the discussion on the *Slovo o proiskhozhdenii sveta* (1756; "Origin of Light and Colours") and in his theoretical works on electricity in 1753 and 1756 also matured in this laboratory.

Encouraged by the success of his experiments in 1760 Lomonosov inserted in the *Meditationes de Solido et Fluido* ("Reflections on the Solidity and Fluidity of bodies") the "universal law of nature"—that is, the law of conservation of matter and energy, which, with the corpuscular theory, constitutes the dominant thread in all his research.

To these achievements were added the composition of *Rossiyskaya grammatika* and of *Kratkoy rossiyskoy letopisets* ("Short Russian Chronicle"), ordered by the Empress, and all the work of reorganizing education, to which Lomonosov accorded much importance.

From 1755 he followed very closely the development of Moscow University, for which he had drawn up the plans. Appointed a councillor by the Academy in 1757, he undertook reforms to make the university an intellectual centre closely linked with the life of the country. To that end, he wrote important works on the *Rassuzhdeniye o bolshey tochnosti morskogo puti* (1759; "Precision of the Maritime Route"); the *Rassuzhdeniye o proiskhozhdenii ledyanikh gor v severnykh moryakh* (1760; "Precision of the Formation of Icebergs in the Northern Seas"); the *Kratkoye opisaniye raznykh puteshestvy po severnym moryam* ("Northern Maritime Routes"); and the *O sloyakh zemnykh* ("Of the Layers of the Earth"), which constituted an important contribution both to science and to the development of commerce and the exploitation of mineral wealth.

Despite the honours that came to him, he continued to lead a laborious and simple life, surrounded by his family and a few friends. He left his house and the laboratory erected in his garden only to go to the Academy. His prestige was considerable in Russia, and his scientific works and his role in the Academy were known abroad. He was a member of the Royal Swedish Academy of Sciences and of that of Bologna. His theories concerning heat and the constitution of matter were opposed by the empiricist scientists of Germany, although they were analyzed with interest in European scientific journals, such as the *Journal encyclopédique* and the *Annales typographiques*.

The persecutions he suffered, particularly after the empress Elizabeth's death, exhausted him physically, and he died on April 15 (April 4, old style), 1765, in St. Petersburg. The empress Catherine II the Great had the patriotic scholar buried with great ceremony, but she confiscated all the notes in which were outlined the great humanitarian ideas he had developed. Publications of his works were purged of the material that constituted a menace to the system of serfdom, particularly that concerned with materialist and humanist ideas. Efforts were made to view him as a court poet and an upholder of monarchy and religion rather than as an enemy of superstition and champion of popular education. The authorities did not succeed in quenching the influence of his work, however. The complete publication of his *Polnoye Sobraniye sochineniy* ("Works") in 1950-57 by Soviet scholars has revealed the full contributions of Lomonosov, who has long been misunderstood by historians of science.

**BIBLIOGRAPHY.** Lomonosov's complete works, *Полное собрание сочинений*, 10 vol., Latin and Russian texts with notes, have been published by the Russian Academy of Sciences (1950-59). BORIS N. MENSHTUTKIN, *Russia's Lomonosov* (1952), is a translation of Menshutkin's 1937 biography. LUCE LANGEVIN, *Lomonossov* (1967), contains a biography and extracts from Lomonosov's works and summarizes recent evaluations by U.S.S.R. historians of science (in French). See also HENRY M. LEICESTER (trans.), *Mikhail Vasil'evich Lomonosov on the Corpuscular Theory* (1970).

## London

Capital city of the United Kingdom and the industrial, commercial, and political centre of a once vast empire, London lies astride the Thames in southeast England, 40 miles from the estuary on the North Sea. Its population of almost 7,400,000 persons places it among the six largest cities of the world: many would assert that it is the most hospitable of all. Urban tensions are moderated by a traditional sense of civic responsibility and by the relatively human proportions of a cityscape rich in greenery and open spaces. Although, like all of the other massive cities of the world, London has failed to come to terms with the late 20th century, it has at least managed to conserve many of the virtues of centuries past.

On a map, the outline of Greater London is a ragged oval that might be compared with a squashed tomato. Central London is an irregular blotch in the middle, about a sixth of the whole and containing 12 of the 32 boroughs and the historic core region (now associated with financial institutions) known as the City. An aerial view reveals surprisingly few skyscrapers and a preponderance of one-family houses. Despite the great density of population (almost 12,000 persons per square mile [4,600 per square kilometre]), there is considerable open space: hundreds of garden squares, hundreds of parks and playing fields (20,000 acres [8,000 hectares] in Greater London), scores of churchyards, and many former village commons. Of all London's parklands, the most celebrated are the six Royal Parks (5,900 acres), which sweep through the West End of Central London. The whole is surrounded by the Green Belt, established in 1935 and covering in 1972 about 967 square miles (2,505 square kilometres) with further extensions totaling 320 square miles planned for the early 1970s. The river itself, one of the largest continuous open spaces in the area, is characterized in a Greater London Council (GLC) report on the environment as "perhaps the greatest of London's assets." Seen from above, London is relatively unscarred by high-speed multilane highways and their ground-gobbling interchanges, but this condition is not likely to endure in the face of a Greater London Plan, offered in 1970, proposing a network of roads based on three concentric rings of motorway with connecting radials, to be completed by the late 1990s.

Although new major roads would alter the appearance of London and affect city living as drastically as did the introduction of rail lines in the 19th century, they are not the biggest changes in store. During the decade 1974-84, notable portions of Central London are expected to be radically altered.

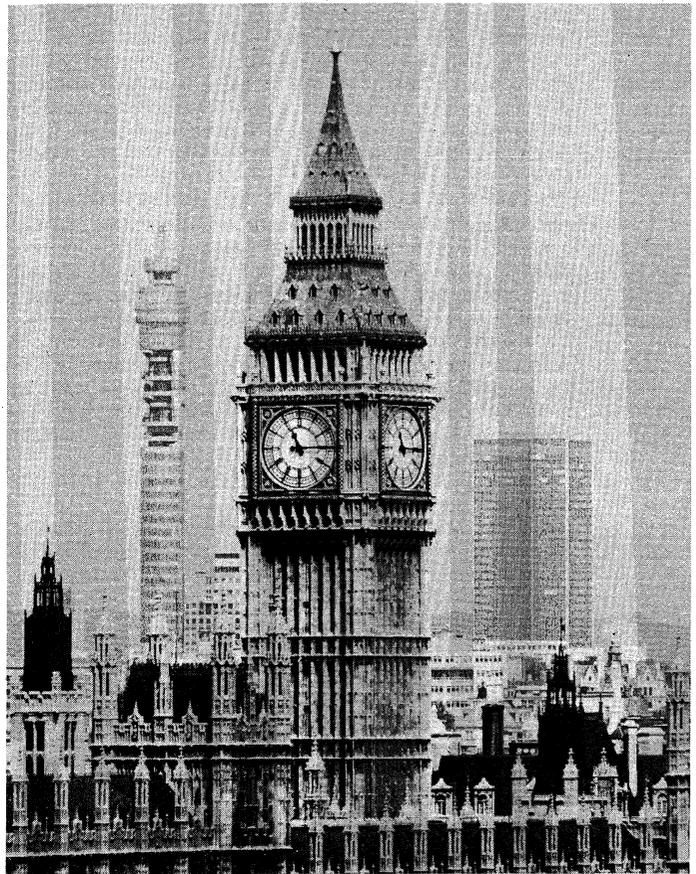

This new cast to the face of London will express, as have the major changes of the past, a new phase in British history. The 25 years following World War II constituted the period of dissolution of empire and withdrawal from world power; the point of view and the sense of national mission that had been shaped over three centuries suddenly no longer pertained. Once the war damage had been repaired (a massive enterprise that included the erection of low-rent housing groups still models of their kind), there ensued a terrible sense of battle fatigue. The lights had gone on again, as had been promised in wartime song and speech, but the hopes of a bright new world were stupefyingly frustrated. The famous British "muddling through" was supposedly replaced by scientific planning, and "talented amateurism" was ostensibly supplanted by technocratic professionalism; nevertheless, error and fumbling persisted. The two decades of bewilderment, imitation, and vigorous half measures between 1950 and 1970 can be read in the stones of the city. By the 1970s, however, a new period had begun, one that saw a reaffirmation of London's ancient virtues of self-confidence, imagination, and courage. A growing humanism became manifest; the measure for governmental action seemed increasingly to be the living community rather than the statistical category.

### THE HISTORY OF LONDON

**The city takes shape.** The history of London begins effectively with the Roman period. Gracechurch Street,

The character of the city

The new initiatives of the 1970s

Majestically dominating the London skyline are Big Ben, the Post Office Tower (left), and the Thorn Electric Building (right).  
Fox Photos—Pictorial Parade

which leads from London Bridge up to Cornhill, led from the bridge in Roman times to the hub of Londinium, where the Romans built a basilica. Seventeen years after the Romans had installed themselves, Icenian tribesmen under Queen Boudicca revolted and sacked the city. From traces of the fires they set, it can be determined that the settlement had already begun to spread westward across Walbrook toward the hill where St. Paul's Cathedral would later be built. After the sack, a bigger basilica was built: an aisled hall 500 feet (150 metres) long. On the same spot today stands Leadenhall Market, an 1881 effusion of cast iron and glass. To protect the city, Cripplegate Fort was constructed at the northwestern edge, but walls were not built until the end of the 2nd century AD. Remains of the wall can still be seen at the edge of Barbican (the street is called London Wall) and in a small park on Tower Hill. In medieval times the walls were rebuilt and extended, necessitating construction of additional gates but retaining the Roman gates: Aldgate, Aldersgate, Bishopsgate, Cripplegate, Ludgate, and Newgate. The legions were recalled to Rome early in the 5th century, and what happened to the city in the next two centuries is a matter of conjecture, though the Roman street pattern was not obliterated. (Cheapside and Cannon Street were the medieval successors to Roman east-west roads.)

No records tell how or when London fell into Saxon hands, but it was still, or had once again become, a city of importance by AD 597, the year that Pope Gregory I the Great sent St. Augustine there from Rome. Aethelberht, king of Kent, founded St. Paul's Cathedral, and Mellitus was installed as bishop there in 604. In the following century the Venerable Bede described London as a mart of many people arriving by land and by sea. After that the city vanished from Anglo-Saxon chronicles for more than a century, until the time of Alfred the Great (died 899) and the wars with the Danes.

The  
importance  
of the  
Tower of  
London

**Medieval London.** The city's future importance as a financial and military—and therefore political—power was made clear at the time of the Norman Conquest (1066). One of the first acts of William I the Conqueror was to accord a charter promising the citizens that they should enjoy the same laws as under King Edward I and that he would suffer no man to do them wrong. It was a further mark of respect for the city's latent puissance that he planted just outside its walls the intimidating Norman keep, the White Tower, central stronghold of the fortress-castle known as the Tower of London. A roughly square (118 by 107 feet) structure 90 feet high, it has towers at each corner of the walls, which are 15 feet thick at the base and 11 feet thick at the battlemented top. King Richard I returned from the Crusades with a new concept of fortification and began surrounding the keep with concentric systems of curtain walls with towers at intervals, a work completed by Henry III. Each reign since then has added its bit, and the Tower incorporates almost every period of English architecture. A royal residence until James I, it has also housed the Royal Mint, the Royal Menagerie, the public records, an observatory, and an arsenal. The history of its executions is long and tenebrous, and it has always served as a prison for state offenders. The first prisoner was the Bishop of Durham in 1101, and the last was the deputy party leader of Nazi Germany, Rudolph Hess, during World War II. The Crown Jewels are on display there, as is a superb collection of English arms and armour.

When Henry I died in 1135, Londoners, exercising their "right" to elect the king of England, chose Stephen, who was crowned three weeks later at Westminster Abbey. About 1136 a major fire destroyed many of the city's wooden houses and St. Paul's itself. In the rebuilding, houses of stone and tile began to appear, and streets were paved and at least partially cleansed by open sewers and conduits. By the end of the 12th century, the large colony of Danish merchants was outnumbered by the Germans, who had their own three-acre (1.2-hectare) trading enclave, the Steelyard on the riverfront, until 1598. Other important trading groups were the Gascons, the Flemish, and the northern Italians. When the last named were firmly established as bankers, the Jews (in 1290) were despoiled, imprisoned, and then banished, not to return for centuries.

By astute purchase from needy monarchs, the guilds—110 of them by 1400—were able to buy increasing freedom from royal intrusion in their affairs and further their self-government. The first mayor of London, Henry Fitzailwin, probably took office in 1192. The first evidence of a Common Council dates from 1332. Since disorder in the realm provoked unrest in the City, London usually supported strong, orderly government, especially in such crises as the deposition of Edward II (1327) and Richard II (1399), the English Peasants' Revolt in 1381, and the rebellion headed by Jack Cade (1450).

**Elizabethan London.** Toward the middle of the 16th century, London experienced a startling growth of trade and population. From 1530 to 1600 the number of Londoners trebled. The excess population at first found living space in the grounds of the religious institutions seized during the Reformation by Henry VIII. To fill the void left by the cessation of the religious charities, the city organized poor relief in 1547, providing grain in times of scarcity and instigating the foundation or reconstitution of the five royal hospitals: St. Bartholomew's, Christ's, Bethlehem (the madhouse known as Bedlam), St. Thomas's, and Bridewell. Many of the private charities founded at this time still function. Trade was further promoted by the establishment of monopolies such as those held by the Muscovy Company (1555), the Turkey (later Levant) Company (1581), and the East India Company (1600).

By 1605 the City population had reached an incredible 75,000, and, despite laws that attempted to restrain its size, a further 150,000 lived outside the walls. Southwark, at the far end of the original London Bridge, became the City's 26th ward. New industries, including silk weaving and the production of glass and majolica pottery, were established, often outside the gates and thus outside the

Eliza-  
bethan  
charitable  
and  
trading  
founda-  
tions

restrictive regulations of the livery companies. The establishment of Henry VIII's naval dockyard at Deptford on the south bank was accompanied by a straggle of waterfront hovels on the north bank at Wapping.

When Henry VIII in 1529 began to convert Cardinal Wolsey's York Place into the royal palace of Whitehall and to build St. James's Palace across the fields, the City of Westminster began to take more definite shape around the court. Between Westminster and the City the great houses of nobles began to appear, with gardens down to the river and each with its own water gate. Along the Strand opposite these houses were distinguished lodgings for gentlemen who were in town during legal sittings. The name London was before long to embrace both the City of London and the City of Westminster and the built-up land between them.

The reign of Elizabeth I (1558–1603) marked the apogee of the City's domination of England. The Queen based her strength on its militia, its money, and its love. It provided one quarter of the men for service abroad in 1585 and 1589 and formed its armed "trainbands" to defend against the threatened Spanish invasion.

**Caroline London.** The trainbands remained a force to be reckoned with, and Charles I, who had damaged the City's trading interests and flouted its privileges as cavalierly as he had Parliament's, was deterred from attacking London in 1642 by their presence at Turnham Green. Hostility toward the King made the fortified City the core of parliamentary support, and Parliament's success in the Civil War was due in good part to City allegiance.

In 1664–65, the Plague, a frequent invader since the Black Death of 1348, killed 75,000 Londoners. The following year the Great Fire burned from September 2 to September 5 and consumed four-fifths of the City. From the unscorched corners in the northeast and extreme west, the rebuilding began. A rational street plan was rejected, but streets along the old traces were wider and a bit straighter. Between 1667 and 1671 most of the new houses (brick—no more half-timbering was allowed) were rebuilt. Many of the tiny parishes were combined, and a few churches had escaped the fire, so only 50 were rebuilt, in addition to a new St. Paul's. Sir Christopher Wren, mathematician, astronomer, physicist, and engineer (but not architect), was given the formidable task of designing them and supervising their construction.

There is a Wren inscription in St. Paul's Cathedral, *Lector, si monumentum requiris, circumspice* ("Reader, if you seek a memorial, look about you"). The whole City is in fact Wren's memorial. His churches, ranging from the homely Dutch to the Gothic but mostly in his own expression of the classical style, are all touched with the same felicity and springing vigour, a series of virtuoso variations on basic architectural concepts. St. Paul's dome is one of the most perfect in the world and, like the rest of the cathedral, is classical in theme with Baroque grace notes. The memorial column for the Great Fire was adapted from a Wren design and erected near Pudding Lane, where the fire had started in the house of the king's baker. Wren constructed four other churches outside the City, built the Royal Hospital located in Chelsea, parts of Kensington Palace, Greenwich Hospital, the Royal Observatory of Greenwich, and Hampton Court Palace.

Under Charles II royal abrogation of City rights was resumed, and although James II restored forfeited City charters before his flight in 1688, it was in Guildhall under protection of the trainbands that the lords spiritual and temporal met to declare allegiance to William, prince of Orange (henceforth known as William III of Great Britain).

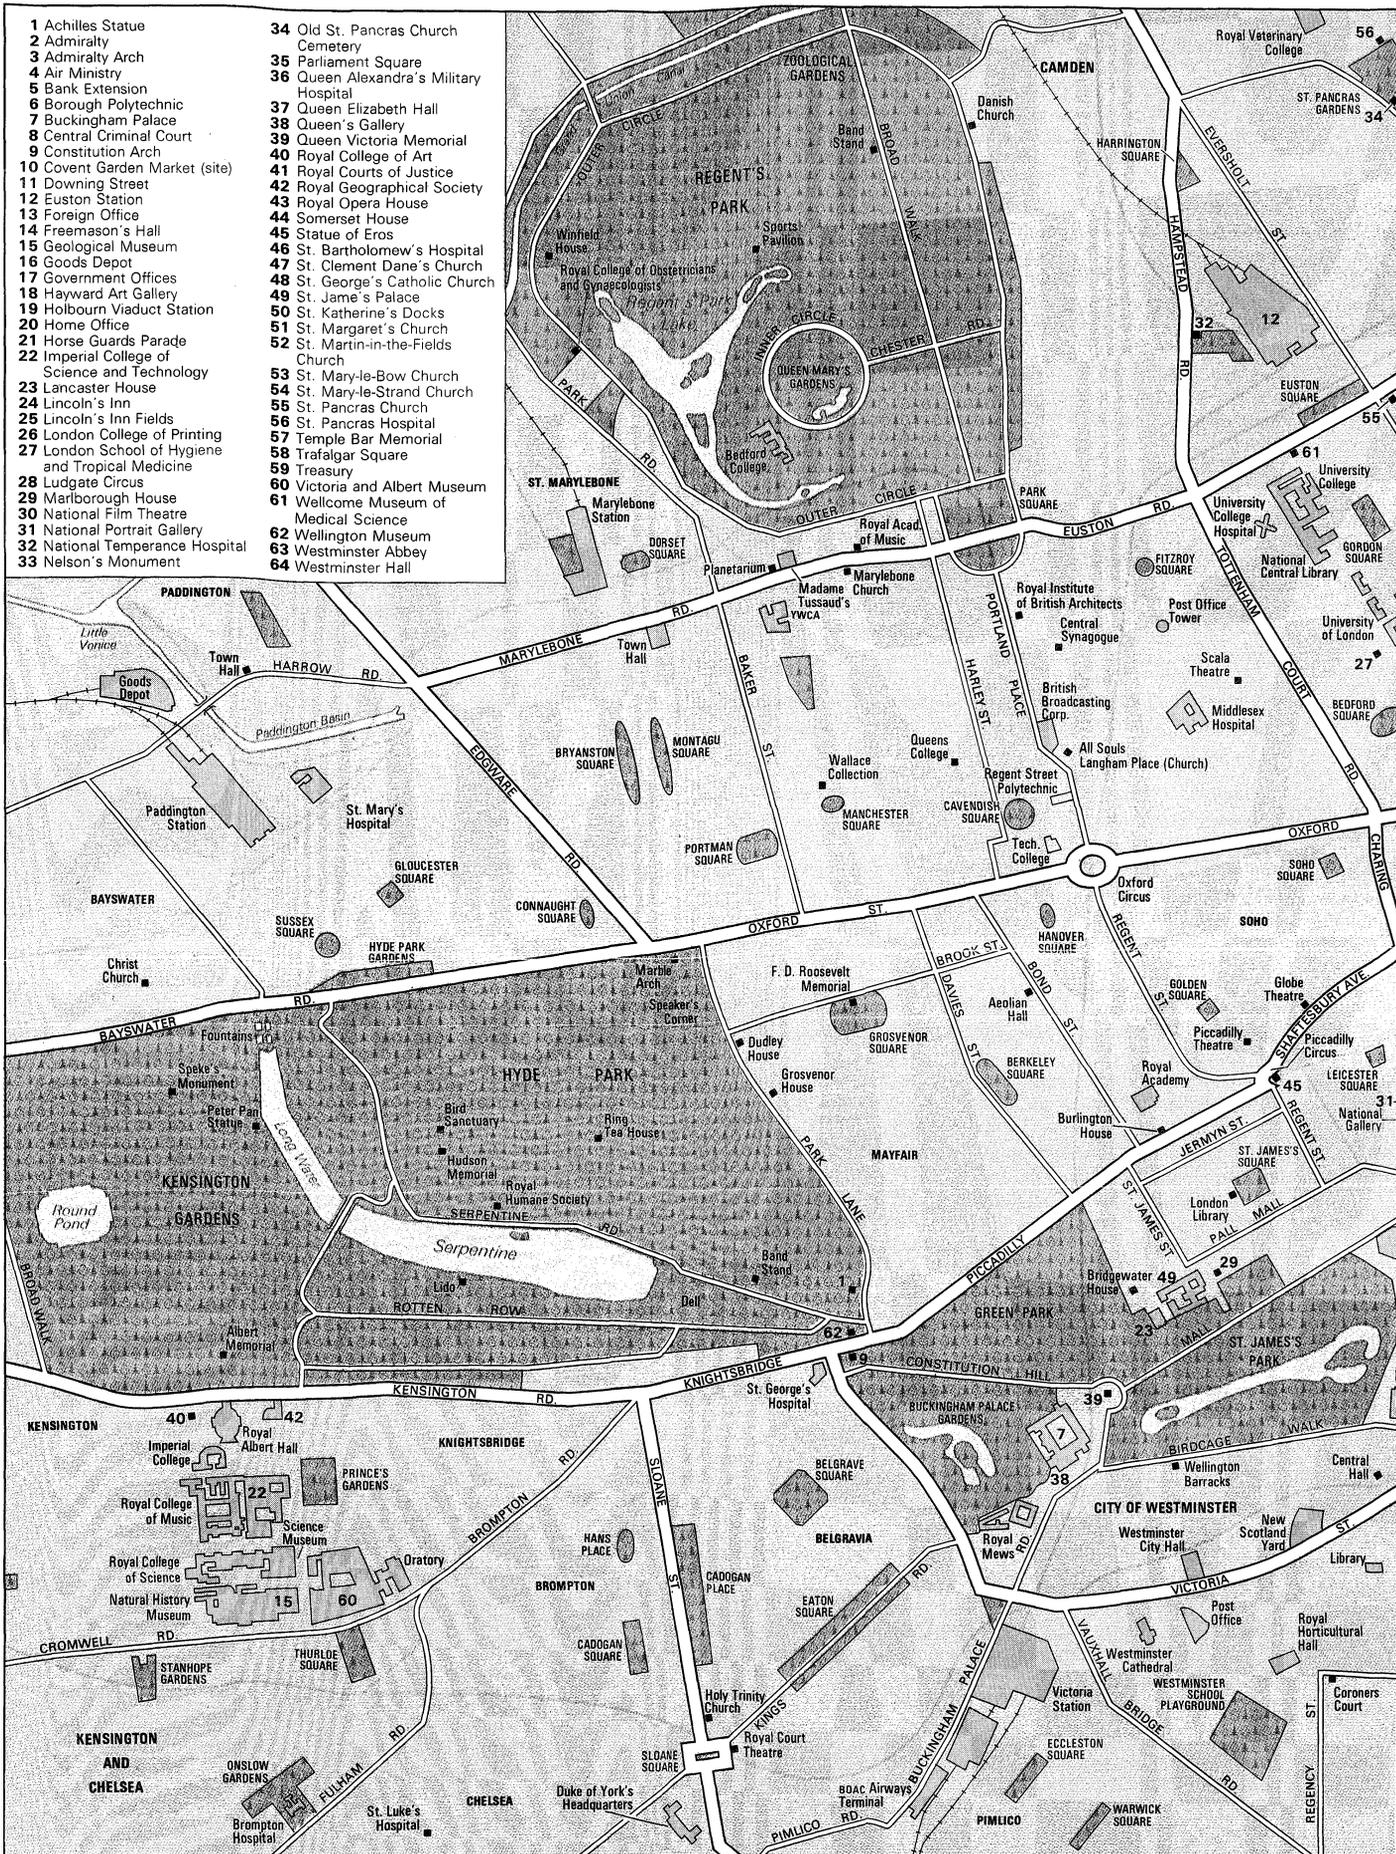

To support the war against France in 1694, 40 City merchants formed the Bank of England, and thenceforth the City's money market became a prime factor in the affairs of state. Another aspect of the City's power in the nation was the centring of the national press in Fleet Street (*The Times*, founded in 1785 off Blackfriars Lane, has never budged).

**19th- and 20th-century London.** By 1820, when George IV succeeded to the throne, the whole character of Lon-

Central London and (inset) the Greater London metropolitan area.

don had changed. Its population had increased to more than 1,100,000. Villages and hamlets that in 1666 had been the objects of summer outings from the heart of the city had become part of the built-up area. Some of the building had been well-planned works of great landowners; some, however, the sorry work of the small and greedy. The Bedford, Portman, and Foundling estates produced streets and squares that embellished the town. On the other hand, to the east, parts of Stepney and Bethnal Green were constructed with ill-built cottage terraces. Agar Town, which lay near the modern King's Cross and St. Pancras railway stations, was a scandal.

The changes brought by the years 1689–1820 had followed no conscious plan. Inside the City its government was in full control and reasonably active. Beyond its boundaries, unchanged since the Middle Ages, government services and communications for the new areas came piecemeal. The important developers obtained local acts of Parliament enabling them to levy rates out of which to finance paving, lighting, cleansing, and the watch (a group of persons charged with protecting life and property). The popularity of the developers' streets depended in part on such services, and they were usually adequately administered. Lesser men left a legacy of slums and neglect for later generations to clear.

Socially, commercially, and financially, London was the hub of the kingdom. As a corollary to its great wealth, fed by the profits of the East and West Indies' trade and by trade with most of the known world, it reigned supreme in England in matters of the theatre, literature, and the arts. It was the London of David Garrick, Oliver Goldsmith, Samuel Johnson, and Sir Joshua Reynolds, of the great furniture makers and silversmiths, and of the world-famous foreign musicians. But its size brought increasing problems.

*Organization, innovation, and reform.* Although new dispensaries and new or enlarged hospitals were reducing mortality, the former riverside town required new forms of government, of communications, and of sanitation if it was to continue to grow. These were slowly and painfully evolved in the London of 1820–1914. Against a background of statistics that showed the population of the built-up area rising from 1,225,694 (1821) to 6,586,269 (1901), the innovations came piecemeal. In 1829 a centralized Metropolitan Police Force was provided, under the ultimate control of the home secretary, in place of the uncoordinated watchmen and parish constables. The lighting of streets by feeble oil lamps was revolutionized by the introduction of gas, and soon the Gas Light and Coke Company (1812) was followed by similar companies scattered throughout London. Omnibuses (1829) began a revolution in road transport, and carriage by rail came less than 10 years later. The year 1845 saw a great inquiry into public health, with the exposure of London's worst deficiencies, followed by legislation in 1852 ensuring a purer water supply. A statute in 1855 (the Metropolitan Management Act) combined a number of the smaller units of local government and replaced the medley of franchises with a straightforward system of votes by all ratepayers. Major works, such as main drainage, were put in the hands of a Metropolitan Board of Works.

The momentum of these changes, established by such diverse reformers as Bishop C.J. Blomfield, Sir Robert Peel, Edwin (later Sir Edwin) Chadwick, and the Earl of Shaftesbury, continued throughout the century. New churches, new schools, better law and order, main drainage, and care for the outcasts were some of the reformers' legacy; Trafalgar Square, the Embankment, and roads, such as Shaftesbury Avenue and Charing Cross Road, driven through the worst of the slums are their most obvious monuments. The changes in government continued, if not so drastically. The London County Council superseded the Metropolitan Board of Works in 1888, the vestries were transformed into metropolitan boroughs by the London Government Act (1899), and the various water companies combined in 1902 into a publicly owned Metropolitan Water Board.

Public and private works continued to transform the face of London. The opening of the Metropolitan, a

steam railway, in 1863 and the making of Holborn Viaduct in 1869 were accompanied by the building of new Thames bridges and the rebuilding of Battersea, Westminster, Blackfriars, and London bridges. After years of discussion and agitation, the road bridges outside the City passed into public ownership, and the tollgates disappeared. All the main railways carried their lines northward across the Thames into London, to the Victoria, Charing Cross, Blackfriars, and Cannon Street stations. It was an era in which an abundance of initiative and of capital was joined to abundant labour to make the widest use of new skills, cheap transport, and copious raw materials.

Technical progress continued gradually to alter the lives of Londoners and the face of the town. Cheap suburban trains enabled the skilled artisan to live farther and farther from his work. The London School Board, established under the Education Act of 1870, set about the task of providing elementary education for all. Trains or streetcars (horse-drawn), after an unsuccessful beginning in 1861, became important in the 1870s and a major factor in metropolitan transport as their electrification developed in the first years of the 20th century. By then electricity was being used as the motive power for traffic below ground, the Prince of Wales opening the world's first electric underground railway, from King William Street to Stockwell, on November 4, 1890. With the arrival, before 1914, of the gasoline-driven omnibus, the outline of transport in modern London was complete and the way opened for still faster development of suburbia.

Inevitably this was accompanied by rising land values in the central zone, by the construction of ever larger offices, factories, and warehouses in place of small houses, and by a continuous outlay of public and private funds on better housing and street improvements. World War I, in which air raids inflicted 2,632 casualties on London, brought only a temporary pause, and peace saw resumed development on a mounting scale. As a national and in some respects a world capital, London required institutions capable of meeting its needs. An era of amalgamation and expansion ensued. From banks to hospitals, and from telephone exchanges to power stations, almost all was expanded. Street congestion, well-known in the 1850s, was worse in the 1930s, despite the rationalization of traffic authorities. By 1939 the population of the Greater London conurbation exceeded 8,000,000.

*Reconstruction after World War II.* World War II, with evacuation and heavy damage by air raids, brought the greatest setback in the history of modern London. Air attacks killed more than 30,000, injured more than 50,000, damaged most public buildings, and, in such areas as the City and Stepney, obliterated whole sections of the street system. Westminster Abbey and the Houses of Parliament were damaged but saved, as were St. Paul's and Guildhall in the City. Ordinary houses and the docks suffered severely.

The end of hostilities brought a gradual return of many evacuees and a housing shortage made worse by the ravages of dry rot. Reconstruction, hampered by the shortage of most materials, began at once—and with the advantage of plans and surveys already put forward. The Town and Country Planning Act (1944), followed by acts of 1947, 1954, 1959, and 1968, gave unprecedented powers of purchase, direction, and control. The urgency of the Festival of Britain (1951) produced Lansbury (a redevelopment in Poplar) and the Royal Festival Hall, but the most significant postwar features have been the vast investment in new houses, the restoration of services and the Port of London, the general acceptance of a planned urban economy, and the sustained effort to divert industries to new or expanded towns outside London.

#### THE CONTEMPORARY CITY

**Site and environment.** The oval chalk basin through which the Thames meanders from west to east is filled with great thicknesses of younger sediments, including solid rock from the Eocene Epoch of the Tertiary Period, sands, clays, terraces of pebble gravels, and Thames alluvium. Central London has up to 20 feet of "made

Innovations in transport in the 19th century

The Victorian era

ground" accumulated in historic times. The earliest settlements were built on the well-watered gravel hills, and the clay produced bricks for building the city for many centuries.

The significance of the Clean Air Act

The climate of the basin is typical of the eastern edge of the British Isles. St. James's Park, in the middle of Central London, receives 23.4 inches of rain a year, but, over the rest of the basin, the rainfall is irregular from year to year, with extremes of 70 to 130 percent of the average. Temperatures are mild (43°–64° F [5°–18° C] January–July mean) and vary little, although it is warmer in the city than in the suburbs. Since the passage of the Clean Air Act of 1956, there is as much sunshine in the city as in the nearby countryside: average visibility in winter has increased from one mile to four miles, and the amount of smoke in the air has been reduced to between 33 and 25 percent of that measured in 1964. Since the act went into effect, there has been no smog in London, and the celebrated pea-soup fogs have become much rarer.

**Vegetation and animal life.** London is of special interest to naturalists for the plants and animals that thrive there in close association with man.

In the centre, wild plants are found in the parks, squares, and private gardens, on building sites, railway banks, neglected gutters, and broken walls. Many of the most common ones have wind-borne fruits, so that they quickly colonize any soil available. Oxford ragwort, rosebay willow herb, bracken, the shrub *Buddleja davidii* (butterfly bush), and Canadian fleabane were the five most abundant plants growing on bombed sites during and after World War II, when 269 species were found in the "square mile" of the City.

In the suburbs the number of species is much greater. Wimbledon, Mitcham, and Barnes commons, Hampstead Heath, and Epping Forest have a good representation of wild plants. Within 20 miles of St. Paul's Cathedral, 1,835 species of flowering plants and ferns, 221 mosses, and 68 liverworts have been recorded since 1900.

Four kinds of birds have learned to live in great numbers in close association with man. Feral domestic pigeons have been a feature of London birdlife for at least 600 years and are familiar to visitors to Trafalgar Square, St. Paul's Cathedral, Victoria Station, and other places. House sparrows abound in Central London, and white-headed gulls have been regular winter visitors since 1895 and are seen in large numbers by the Thames and elsewhere. Immense numbers of starlings roost on buildings in Central London; the numbers are increased by immigrants from Europe in the winter. The mute swans on the Thames are the property of the crown and are marked by the Vintners and Dyers livery companies, which have a royalty. An ancient ceremony known as swan-upping takes place each July to mark the birds, and then congregations of 100 or more may sometimes be seen on the Thames in Central London. The ravens at the Tower of London are semidomesticated birds introduced from Wales.

In inner London 160 species of birds are recorded, and 37 of these species have bred. St. James's Park and Kew Gardens have good collections of waterfowl. Within 20 miles of St. Paul's 245 species have been recorded since 1900 in a wide range of habitats. Of these species, 100 are believed to nest annually.

The brown rat is a serious pest, and the black rat is found in the upper parts of buildings over a large area, including the West End. The house mouse is common, hedgehogs are frequent in the suburbs, and several species of bats occur.

Butterflies are often seen, and some species, such as the migrant red admiral, congregate around the flowers of buddleia and Michaelmas daisies. Many moths occur in Central London, where the lime hawk, eyed hawk, and poplar hawk (*Laotoë populi*) are among the larger species. The trend toward melanism is less general in moths in London than in other industrial cities but is shown in a few species.

**Administration.** As defined by the Registrar-General for England and Wales, Greater London covers 610

square miles, but there are, administratively speaking, a dozen different Londons. For electricity and gas supplies and hospital services, Greater London is only a portion of an administrative area for four electricity boards, three gas boards, and four metropolitan regional hospital boards. The City of London, which is independent of the Greater London Council, with its own police force and its own government headed by the lord mayor, is commonly thought to be one square mile in area (really larger, 677 acres [274 hectares]). The three great dock systems and 90 miles of river are controlled by the Port of London Authority. The London school area is only 117 square miles, the responsibility of the Inner London Education Authority; the 20 outer London boroughs have their individual school systems. The London postal area is 570 square miles. The Metropolitan Police district, which does not serve the City of London, covers 786 square miles. The area serviced by the London Transport Board is 900 square miles, and that serviced by the Metropolitan Water Board is 570 square miles. The area administered by the Greater London Council (GLC) is 610 square miles (1,580 square kilometres). Replacing the London County Council, which had taken over from the Metropolitan Board of Works as the city's government in 1889, the GLC came into being in 1964.

At the same time, the 90 separate local authorities were abolished, and 32 London borough councils (plus the City of London) were set up as the primary units of local government, little "cities" of 150,000 to 340,000 in population. The elected borough councils fix the annual rate payable on local property and have charge of such activities as housing, local parks, public libraries, refuse collection, street cleaning, and borough planning. The GLC is responsible for—among other things—overall planning, traffic control, roads, ambulance and fire brigades, education (in inner London), sewers, courts, historic buildings and public monuments, and disposal of the garbage collected by the boroughs.

**Population.** Within the Greater London conurbation a decline in population has occurred in the City of London since 1851, in inner London since 1901, and in outer London since 1951. Encircling the conurbation area is a broad fringe up to 30 miles wide of almost continuous population increase (more than 1,000,000 since 1951) that embraces satellite towns beyond the Green Belt areas and extends along every major road and rail route from London. The entire London and South East region had a population of more than 17,000,000 in the early 1970s, more than one-half of which was outside the Greater London conurbation.

Population of London

	City of London	inner London*	outer London†	Greater London conurbation‡
1801	128,269	959,310	157,980	1,117,290

\*Comprising the County of London after 1888 and the inner boroughs after 1965. †After 1965 the outer London boroughs. ‡Area reduced in 1965 when it became coterminous with that of the Greater London Council plus the City of London. §Preliminary 1971 census figures.

As hundreds of thousands of people move out annually, a smaller number of "new Londoners" move into those city neighbourhoods that had often lost their "village" character to bombs or urban renewal. New building, especially of hotels and offices, has gnawed into residential districts. Most enduring of all has been a change in the outlook of the mass of the population: the working class has been emancipated from belief in its own inferiority. Better housing, improved education, a complete scheme of health care, and social security have done much to terminate mute acceptance of the old social system.

The class system persists, the "old boy net" of former public (private) school students still aids its mem-

Administrative overlap and its effects

Erosion of the "working class mentality"

bers, but the society—if perhaps still only lacking the easy egalitarianism of Australian or North American cities—is more open, and the traditional “good family, good school, good regiment” endorsements are not essential to a career. Great tracts of Central London still belong to ducal families, and the most important corporations still decorate their boards of directors with the nobility. At the opposite end of the scale, inhabiting the last of the substandard houses and finding the least desirable employment, are the most recent bloc of unabsorbed immigrants, mostly non-whites from former colonies. Legislation now protects them against the worst effects of racial discrimination, and in the 1970s special efforts were being made to accelerate their integration into London life.

#### TRADITIONAL NEIGHBOURHOODS

**The Thames and its environs.** The central historical fact of London is the Thames. In the classic pattern, at the spot where a road crossed the stream, foreign invaders (the Claudian conquest of AD 43) displaced the natives and built a bridge and a city (Londinium). In those days the river was broader and shallower. Two small streams, the Walbrook and the Fleet, both of which still flow into the Thames but now through underground conduits, enabled the Romans to bring boats inside their fortified city. After the departure of the Romans, the foreign commerce they had established continued, even through the historically dim Anglo-Saxon period, and made the city rich and therefore powerful.

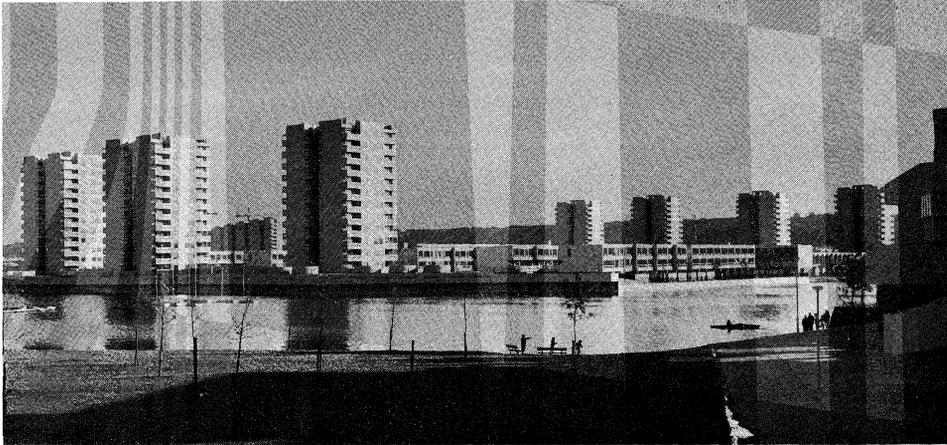

Two miles upstream at the Westminster river crossing, where there had been a small Roman settlement, a religious community in Saxon times, and a royal palace in the 11th century, the City of Westminster grew. Between the commercial city and the royal city the town houses of nobles and bishops were built, each with its own water

gate, and eventually a road (the Strand) ran from Charing Cross to Temple Bar, one of the City of London's 10 gates. Well into the 18th century it was the river rather than the road that served as the main highway.

All the bridges spanning the Thames from London to Southwark were wooden until, between 1176 and 1209, a single stone bridge was finally built. The tidal waters roared tumultuously through its 19 arches, and until 1831 “shooting the bridge” in a small boat was one of the thrills of London. A chapel was built on the bridge to St. Thomas à Becket, martyred in 1170. Soon after, shops lined both sides of the roadway between the fortified gates at either end, and then houses were built above the shops, 138 of them in 1350. In Queen Elizabeth I's time water mills were installed that added to the uproar. The houses were removed in 1760, the year the City gates were dismantled, but the bridge continued to serve for another 71 years, a total lifetime of 622 years. Its replacement was in its turn replaced piecemeal between 1969 and 1972. Tower Bridge, one-half mile downstream, built between 1886 and 1894 by Sir Horace Jones, who had previously designed Billingsgate, Smithfield, and Leadenhall markets, has twin Gothic towers and a central drawbridge and is a good deal more quaint and “Olde” English than London Bridge or the two other spans owned and maintained by the City, Blackfriars (originally constructed 1756–69) and Southwark (first built 1813–19).

After the Norman Conquest the port's foreign trade increased, and embankment of the river on the seaward side of London Bridge began in the 12th century and was completed in the 14th, reclaiming from the water 42½ square miles (110 square kilometres) of marshland at Rotherhithe and Deptford on the south bank and the Isle of Dogs on the north. Still boggy centuries later, this land was easily excavated for dock building.

The role  
of London  
Bridge

Thamesmead, a model city under development approximately nine miles east of Central London on the south bank of the River Thames.

Alan Hutchinson—Camera Press, London

Further embankment of the river was not achieved until the 19th century, when at last London stopped dumping its wastes into the Thames and constructed main sewers. From 1864 to 1870 the mains were laid along the north bank behind stone retaining walls and roadways laid over them from Blackfriars Bridge to Westminster. About 37½ acres (15 hectares) of mudbank were reclaimed and converted into parkland (Victoria Embankment Gardens between Waterloo Bridge and the Hungerford Railway Bridge). In 1874 Chelsea Embankment, also laid over new sewer mains, was completed. The embankment system, interrupted briefly at the Houses of Parliament, is four and a half miles (seven kilometres) long. On the riverside opposite Parliament, Albert Embankment was built in 1869 as a flood-control installation, extended—for pedestrian traffic only—in front of London's County Hall, downstream of Westminster Bridge, in 1910. The last of the embankments was made in 1951, when the South Bank cultural complex was started on a bombed site between London's County Hall (the headquarters of the GLC) and Waterloo Bridge.

Flood protection

Straightening the shoreline and jacketing the river with stone walls moved the tidal limit from London Bridge 19 miles (31 kilometres) upstream to Teddington Weir. The average high tide at London Bridge is rising at the rate of about three feet each century, as London sinks about one foot in the same period. High tide at London Bridge is four feet higher than it is downstream at Southend on the broad estuary 43 miles away. London's embankments were raised an additional one and a half feet in 1971 to guard against floods that might come when a wavelike surge mounts the river from the North Sea. This was provisional protection pending the construction of a movable barrier at Silvertown, in the Woolwich Reach section of the Thames, eight miles downstream from London Bridge, scheduled for completion by the late 1970s.

*Development of the docks.* During the reign of Queen Elizabeth I, "legal quays" were established on the north bank of the Thames between London Bridge and the Tower as the only place where ships could land dutiable goods legally. The traffic soon grew too great for the quays, and in 1663 Parliament allowed the establishment of alternative "sufferance wharves" on both banks. Port activity doubled between 1700 and 1770, and, by the end of that time, the Upper Pool (that part of the river that stretches a little less than a mile below London Bridge) held as many as 1,775 ships in a space allocated to 600. Unloaded into the 3,500 lighters that carried goods from ship to wharf, cargoes sometimes remained caught in the maritime traffic jam for weeks at a time, subject to pilfering and to raids by river pirates. To enable ships to discharge directly into guarded quays, where goods could be stored in secure warehouses, the West India Dock was opened in 1802 at the northern end of the Isle of Dogs, a marshy river peninsula opposite Greenwich Hospital. In 1805 the London Dock opened in Wapping, and downstream from the Isle of Dogs the East India Dock was

inaugurated in 1806. In 1807 the existing Greenland Dock (where whale blubber was rendered) and Howland Wet Dock in Rotherhithe on the south bank were combined, later to be enlarged as the Surrey Commercial Docks, covering 410 acres, a tract bigger than Hyde Park. St. Katherine's Docks were built under the lee of the Tower in 1828. Except for the West India, all of these and the dock at the entrance to Regent's Canal are closed. The Port of London operates from three large dock systems: West India, Millwall (1868), and Poplar, on the Isle of Dogs; Royal Victoria (1855), Royal Albert (1880), and King George V (1921), six miles farther downstream; and Tilbury Docks (1886), 26 miles from London Bridge. In 1909 the Port of London Authority (PLA) was created to take over ownership of all existing docks and control of the river and the port.

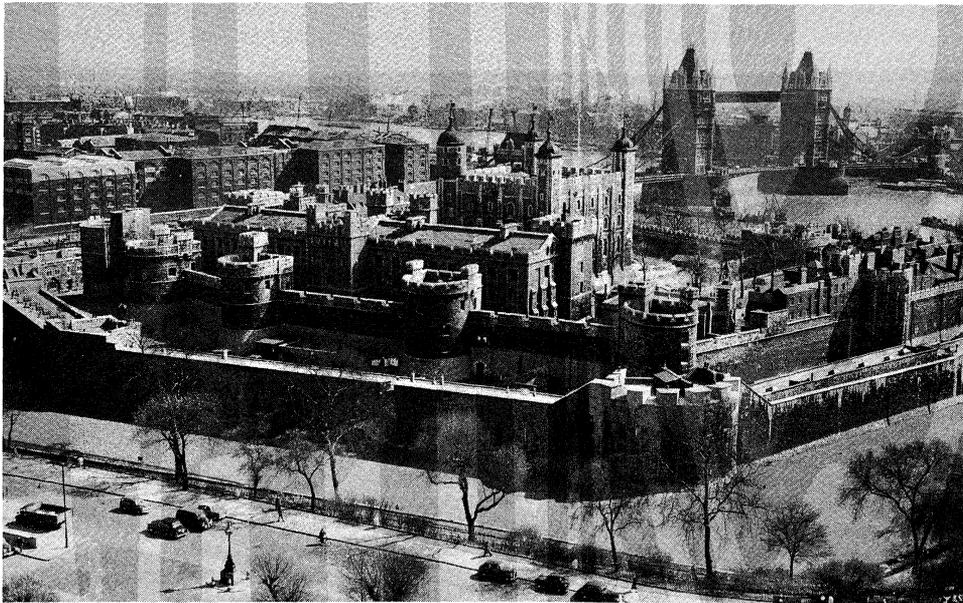

*Waterfront development.* Having closed down the upstream docks in the 1960s, riverfront properties covering 850 acres, the PLA decided to sell, providing a historic opportunity to remake a rich portion of London. In 1969 the GLC bought the first parcel, St. Katherine's Docks (25 acres, 10 of them water), for £60,000 an acre; three years later, it was worth £250,000 an acre. Some of the original majestic warehouses were retained, and a theatre, hotel, cinema, yachting marina, restaurants, and pubs were built as part of a village for 2,000 residents occupying houses, flats, and studios with extraordinary river views at a wide variety of rents. At the same time, the GLC began construction of Thamesmead, 1,450 acres on the site of the 300-year-old Royal Arsenal of Woolwich. Designed to be a model town of social and architectural balance, it should have a population of 60,000 by 1986. Simultaneously, in the disused Royal Victorian Victualling Yards, Deptford, the GLC brilliantly converted the interiors of the 1795 rum warehouses into 65 flats, a sailing school, and yachting centre.

The originality and habitability of these projects generated a new enthusiasm for long-ignored areas. Private developers bought and restored "forgotten" squares and terraces in waterfront neighbourhoods. The 12 miles of waterfront from Waterloo to Woolwich, formerly declining docks, factories, and decayed housing, became the subject for frantic bidding and fevered planning that ranged from the utopian to the crassly exploitative. The borough councils, the GLC, and those ministries that might be concerned pondered all the proposals that would eventually return a vast tract of the city to the living community.

The river about which all this excitement was concentrated was until recently foul-smelling and almost black with pollutants. Since the late 1960s it has become cleaner each year, thanks to strenuous antipollution policing; fish are returning in increasing numbers, and birds, not seen for many years, are nesting along the less clamorous portions of the river.

**The City of London.** One and five-eighths miles at its longest and seven-eighths of a mile at its widest, the City

Originality in urban renewal plans

The Tower of London and Tower Bridge.  
*The Times*, London—Pictorial Parade

is a marvelous *mélange* of ancient elegance and modern efficiency, of outdated practices and newfangled irritations, a place where for 1,000 years tradition has been honoured and innovation has been essential. Thus, while the messengers ("waiters") of the Bank of England are dressed in top hats and pink tailcoats and a detachment of the Brigade of Guards has been reporting nightly to repel mobs ever since the Gordon Riots of 1780, the bank employs computers and other contemporary aids to expedite its labours.

The City is one of the world's great financial centres despite the deliberate dismantling of the sterling bloc. It also remains a pivotal point for world trade in commodities in spite of the fact that raw goods no longer originate in British possessions and that few of the commodities dealt with by the 14 exchanges are actually physically handled at the Port of London.

The City's institutions are as varied as they are ancient. Five "wise men" set the world price of bullion in the opulent Gold Room of N.M. Rothschild & Sons, St. Swithin's Lane, at 10:30 each morning, but, before these gentlemen are out of bed, the gentlemen from the Fishmongers Guild, their boots silvered with fish scales, are exercising their immemorial functions down by the river at Billingsgate, London's fish market. On the other side of the City, predawn buyers eye hook-hung carcasses at Smithfield, the world's largest dressed-meat market. Nearby, nurses begin to prepare patients for surgery at St. Bartholomew's ("Bart's"), London's first hospital (founded in 1123) and the place where, in the 17th century, William Harvey first demonstrated the circulation of the blood. Closer to St. Paul's Cathedral, the vans begin to deliver prisoners whose cases will be heard that day at Old Bailey, as the Central Criminal Court is known, where most of Britain's sensational murder trials have been held.

As the daylight broadens, the first of the 400,000 commuters begin their daily invasion, descending from five main railway stations, from buses, from the underground railway, and from the other side of the river across London Bridge in what seems to be a solid mass of pedestrians. The bankers, the insurance underwriters from Lloyd's, the Stock Exchange members, and the commodity exchange brokers arrive a little later than their employees, some by underground and others in their limousines.

*The Barbican scheme.* Since 1973, there have been some City men who arrive at their desks after a short stroll from their homes in Barbican, a City redevelopment on 45 acres of World War II bomb craters around the 16th-century church of St. Giles Cripplegate. The

modern buildings accord with the hues of the old church stones and bricks, and the whole is planned to bring inhabitants back to the City, where the nighttime population was just over 4,000 in 1971. Barbican will house 6,500 additional citizens in 2,113 flats and maisonnettes. There are private patios and terraces, an artificial lake, a greenery, and subsurface service roads and parking for 2,500 cars. In addition to offices, shops, and restaurants, there is the new building for the old City of London School for Girls (boys resolutely some distance away at Blackfriars on the site of Henry VII's Baynard's Castle, which stood at the river edge from 1487 to the Great Fire). Also at Blackfriars are found an art gallery, cinema, library, exposition hall, new quarters for the famed City-run Guildhall School of Music and Drama, a theatre for the Royal Shakespeare Company, and a 2,000-seat concert hall for the new headquarters of the London Symphony Orchestra.

*The hub of the City.* The central spot in the City is an open space from which eight streets radiate. On the south side is Mansion House, which was designed in the mid-18th century by George Dance as the lord mayor's residence, office, and court (he is first magistrate) and which is still so employed by each lord mayor during his one-year term. Clockwise from Mansion House is Lombard Street, the traditional banking street; on each of its establishments hang the fanciful signboards contrived in earlier centuries. Between Cornhill and Threadneedle Street sits the third restoration of Sir Thomas Gresham's 1567 Royal Exchange. Across the street, the original 18th-century ground-floor screen hides the four-acre Bank of England headquarters, which was built in the period 1921 to 1937 to replace Sir John Soane's 1782-1802 masterpiece, some believe the worst loss to the nation ever caused by the bank. Across a narrow lane east of the bank rises the 28-story Stock Exchange (1968), and a short distance to the northeast stands the twice-restored Guildhall, originally built in the period 1425-45, seat of the Corporation of London.

The Corporation of London operates without a charter of incorporation, the only one in the nation to do so. Some 14,000 voters of the 25 wards elect 159 common councilmen and 26 aldermen (one of whom is chosen as lord mayor by the aldermen from two candidates nominated annually by the 15,000 liverymen of the guilds). Voters are enfranchised by residence in the City or by tenancy or ownership of property of annual gross value of £10. Members of livery companies must be freemen of the City; freedom of the City, acquired through completion of guild apprenticeship, through inheritance or through purchase, was until the mid-19th century a pre-

The daily flood of commuters

The Corporation of London, the guilds and livery companies

requisite for trading or working at a craft in the City. Today 84 livery companies exist, successors of religious or social fraternities of the 11th century, and continue to multiply, the most recently granted livery being that of the Scientific Instrument Makers, 1964.

Some guilds—the Apothecaries, Goldsmiths, Fishmongers, Spectacle Makers, for example—still exercise a controlling influence in their trades, especially in the maintenance of high standards of quality. Livery companies conduct training schools or provide scholarships and grants for research and education in schools and universities.

*The Inns of Court.* The Temple, with an entrance off Fleet Street, represents another segment of the City's power machinery. Originally the British headquarters of the Knights Templar, after dissolution of the order it eventually became the first of the Inns of Court, where barristers had their chambers and where they trained (and still do train) the coming generation of trial lawyers. Middle Temple, Inner Temple, Lincoln's Inn, and Gray's Inn, the latter two just north of the borders of the City, are oases of calm, civility, and continuity. The Inns of Court were rebuilt almost entirely in the 18th century, but the Temple retains its much-rebuilt, round Norman church with a 13th-century addition. Near the entrance stood the most recently built of the City gates, Temple Bar.

Just across Fleet Street, Chancery Lane begins, with the Royal Courts of Justice on the west and the Public Record Office to the east. The Law Courts, as the Royal Courts of Justice are usually called, were designed by G.E. Street in the mid-19th century, a chill, gloomy Victorian Gothic mass. It is here that the Lord Mayor's Show comes to an end on the second Saturday of November, when the new lord mayor alights from his State Coach (a brewery lends the six horses) to pledge fealty to the monarch, represented by the lord chief justice. Until 1838 the show was waterborne, and the lord mayor went up river to Westminster in his State Barge.

**The City of Westminster.** Once the court stopped following the sovereign whenever he moved and settled itself in Westminster, executive departments such as the Chancery and Exchequer were able to develop. By the 16th century Parliament became institutionalized. Dukes of the realm and princes of the church found it expedient to maintain palaces close to the source of preferment.

The Strand, link between the City of London and the City of Westminster, became more thickly built upon as time went on, but in Danish times there had already been a parish church outside the Roman wall, St. Clement Dane's. Its "twin" further west in the Strand, St. Mary-le-Strand, was first mentioned in 1147. Today both stand on tiny islands of land in the middle of the roadway, St. Clement's rebuilt around its 15th-century tower by Wren in 1680 and St. Mary's rebuilt (1714–17) by James Gibbs, in a handsome blend of Italian and English Baroque. St. Clement's was rebuilt again in 1958 after World War II bombing. Between the two churches, but back from the Strand, long stood the town houses of the ill-fated Earl of Essex and that of the Duke of Norfolk, who still owns the land.

On the south side of the Strand is Somerset House, constructed in 1776, possibly the first building in modern times specifically built for government offices. Designed by Sir William Chambers, it is most widely known for its archives of wills and birth and death records. Wings were added in the 19th century, and King's College (now part of London University) was installed in one in 1835. In 1970 two late-17th-century houses were removed from the Strand to permit construction of the college's architecturally flat-footed laboratories.

North and west of this part of the Strand, a parallelogram about three-quarters of a mile long and not quite half a mile wide would enclose 33 of London's 40 theatres and most of its first-run cinemas. Until almost the middle of the 19th century, the Strand was London's smartest theatre, hotel, and shopping street.

In 1972 construction of a new garden square—a hardy private venture—began just south of the Strand, only the

second to be built in inner London since World War I. No amount of gracious building in this area can make good the loss of Robert and James Adam's magnificent 18th-century urban set piece, Adelphi. Red brick and Palladian, massive in total bulk but delicate in detail and proportion, it rose on arches above the riverbank in 1768 (completed 10 years later). In 1936 it was razed to clear space for more profitable development. In three narrow streets named for the brothers, nine of their houses survive, wistful reminders of a regrettably departed glory.

Today the City of Westminster, doubled in size (to 8.3 square miles) when the boroughs were reorganized under the 1963 local government act, is the wealthiest of any borough in the kingdom with a ratable value of £112,417,000. It stretches along the Thames from the Temple to Chelsea Bridge and north through the titillations of Soho and the consultations of Harley Street to the Grand Union Canal. It includes some of the most strenuously desired residential pockets in the kingdom and some of the least coveted slums. It owns more than 16,000 low-rent dwellings, and it plans new ones at an average of 750 a year, with an active renovation program for historically and aesthetically valuable old housing.

It contains Westminster Abbey (Anglican) and Westminster Cathedral (Roman Catholic), Buckingham, Westminster, and St. James's palaces, the principal government offices, the most important shopping districts of the country, New Scotland Yard, most of London's luxury hotels, Madame Tussaud's waxworks museum, and four museums of art, two of them of world rank. The National Gallery, Trafalgar Square, has a superb collection of masterpieces of Western painting. The Tate Gallery, on the river near Vauxhall Bridge, has a collection of 4,000 British paintings, more than 300 modern foreign works, and 360 pieces of sculpture. Named after donor Sir Henry Tate, it was built in the period 1893–97, and a new extension was to be completed in 1975.

**Shopping districts and markets.** The most important retail shopping concentration in the United Kingdom is Oxford Street, where its first palatial department store building was constructed in 1909 by Gordon Selfridge, a "retired" Chicago retail merchant. The heavy shopping activity flows southward along Regent Street to Piccadilly Circus, turns right along Piccadilly, with northward branches along Sackville Street and Savile Row, where eminent tailors still make some of the world's finest men's clothing. Just alongside the Royal Academy is one of retailing's most charming and luxurious shopping streets, the 600-foot-long Burlington Arcade. With 72 tiny shops under a glass-roofed promenade, it was built in 1815 at the same time that John Nash built his Royal Opera Arcade. Parallel and a little farther west, Bond Street is still a magnet for lavish spenders from around the world. South of Piccadilly, and parallel to it, Jermyn Street is studded with long-established makers of costly shirts, hats, and other male accoutrements.

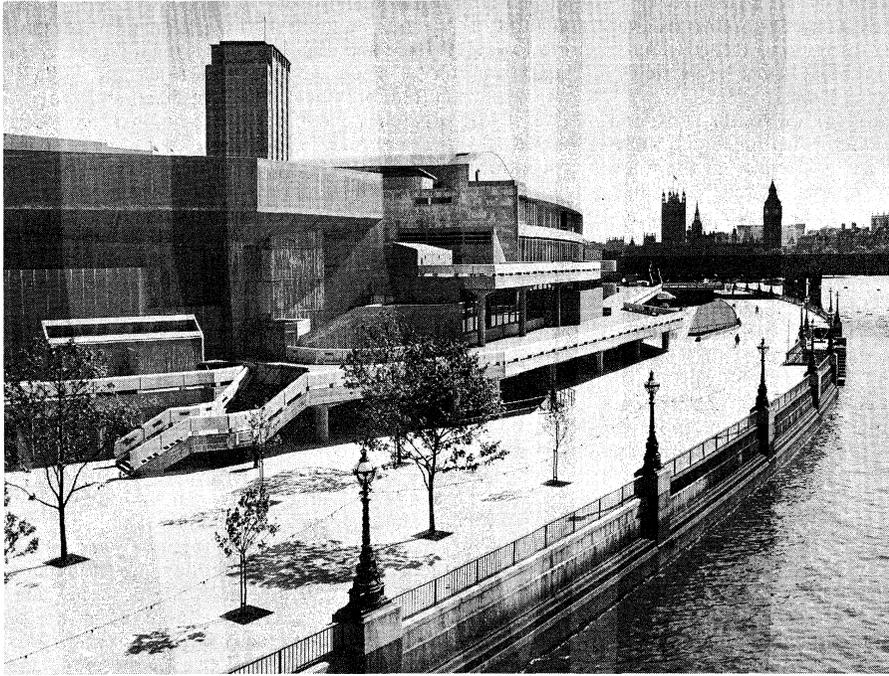

Several streets east of Piccadilly Circus, an area along and around Charing Cross Road, is one of the world's great gleaning grounds for secondhand books, a treasure hunt for the collector and a university for the curious.

Kensington High Street and Knightsbridge are two other heavily patronized shopping districts that attract clients from all over. Kensington High Street is just south and west of Kensington Gardens, with several traditional department stores and a flurry of modish clothing and accessory shops that in the 1960s came to be called "boutiques."

About a mile to the west, the Knightsbridge shops cluster where Knightsbridge, Belgravia, and the stuffer parts of Chelsea convene haughtily south of Hyde Park. West along Brompton Road and then south down Sloane Street the shops progress toward King's Road in Chelsea. Traced from St. James's Palace to Hampton Court Palace across farmland and through several hamlets, the King's Road was, until Victoria's accession, reserved to court traffic. Aside from a few antique shops and a large department store in Sloane Square, it was a typical London "village high street" until the 1960s, when it was invaded by fashion shops, private dancing and drinking clubs, and

Oxford Street, Regent Street, and the Burlington Arcade

The Strand

FPG

The character of Chelsea

coffee bars. From the mid-19th century Chelsea had been a heavily working class district with a few elegant old streets, the homes of some celebrated writers, the studios of noted painters, and a fringe of arty-crafty aspirants, but after World War II it became increasingly fashionable and expensive. The effect spread westward by the end of the 1960s, raising rents and the decibel count in neighbouring Fulham.

There are still at least 16 outdoor markets in Central London, most of them selling only fruit and vegetables but some offering a very general assortment of merchandise. Two of the best known general markets are on Petticoat Lane (really Middlesex Street), in the East End, and on Portobello Road, off Notting Hill Gate.

**The East End.** Beyond the easternmost City gate down to the River Lea is London's East End. The neighbourhood names persist: Aldgate, Spitalfields, Whitechapel, Mile End, Bethnal Green, Wapping, Shadwell, Stepney, Limehouse, Poplar, and Isle of Dogs, but officially they comprise the borough of Tower Hamlets.

In the Middle Ages, the East End was part of vast Stepney Parish based on the Saxon church of St. Dunstan's, and, by the early 17th century, it was already a place to which the poor gravitated. With the development of the docks in the 19th century, offering casual employment, and the growth of the clothing and furniture industries, which batted on sweated labour, the increasing number of poor people competed for an intermittent pittance.

Among the overcrowded houses there was no drainage, and, despite the early foundation of hospitals and charities, the average age of death in Bethnal Green in 1840 was 16 years, 50 percent of all deaths among the labouring classes being children under five. Through the latter half of the century, there were continuing waves of immigrant groups, to whose poverty the onus of racial, religious, and anti-foreign prejudice was added. This was the London of Jack the Ripper, where life and gin were equally cheap.

The East End was the most savagely bombed and burned part of London in World War II. The rebuilding reflected far lower population densities, and many families accepted new homes and jobs in the New Towns started at this period; thus the population in 1960 was less than half that of 1901. Industry as well as population continued to drain away from Tower Hamlets, causing a decline in the borough tax revenues, from which local improvements are largely financed. The housing con-

struction program continues, with Spitalfields and Stepney-Poplar being two of the areas of concentration. Spitalfields, which has the borough's highest density of population, has been a receiving station for immigrants since the Huguenot silk weavers fled France at the end of the 17th century. The most recent immigrants have been Indian and Pakistani, mingling with an earlier wave of West Indians and little settlements left over from the turn-of-the-century Irish and east European Jewish arrivals, spreading down into Whitechapel. The whole district, after consultation with the residents, was to be remade in the 1970s. The Stepney-Poplar district, old Cockney territory, is to emerge as a "New Town" for 100,000 people. The new redevelopment of the dock areas has led to the private purchase and restoration of Georgian buildings by Londoners of a socio-economic category that last inhabited the district 200 years ago. The GLC has plans for a "green corridor" of open space from Victoria Park through Bethnal Green, Mile End, and Stepney down to the river at Limehouse and Shadwell. When the Fleet Line of the Underground is completed in 1976, it will attach more solidly to Central London the further reaches of the East End and accelerate the rehabilitation of the area.

**South London.** The inner London boroughs of Greenwich, Lewisham, Southwark, Lambeth, and Wandsworth occupy the south bank of the Thames as far as six miles (10 kilometres) inland, but the term South Bank refers above all to the music and arts complex begun in 1951 for the Festival of Britain. It begins just downstream from London County Hall, GLC headquarters. The first permanent building on the South Bank site was the 3,000-seat Royal Festival Hall, which presents the world's great orchestras and ballet troupes in about 450 performances a year. The 1,000-seat Queen Elizabeth Hall (1967) and its chamber-music auditorium, the 370-seat Purcell Room, offer about 400 and 300 performances, respectively, each year. Many of the musical groups appearing in these halls receive grants from the GLC. The Hayward Art Gallery, opened in 1968, is leased for token rent by the GLC to the Arts Council of Great Britain, which stages major art exhibitions there. The National Film Theatre, tucked into a corner, shows classic films from all nations. The National Theatre, which was lodged for years at the Old Vic Theatre (built 1816), behind Waterloo Station, was to be moved into its new home just east of Waterloo Bridge on the South Bank in 1975. Next to it, on space originally designated for residential use, are the studios and offices

The South Bank Complex

of an independent television station. The riverside promenade for pedestrians that starts opposite the Houses of Parliament continues now all the way along the South Bank to Blackfriars Bridge, from which point waterfront redevelopment was planned to stretch more than 10 miles down to Woolwich.

Bankside, as the riverfront between Blackfriars and London bridges is called, is where Shakespeare's Globe Theatre and its rivals stood and where the palace of the bishop of Winchester neighbored the 13th-century Southwark Cathedral (largely rebuilt in the 19th century). Around this end of London Bridge, coaching inns, mentioned by Chaucer in the 14th century and by Shakespeare in the 17th, once clustered. One such inn, the George, rebuilt after the Southwark fire of 1667 and truncated by the railroad in 1889, continues to operate in an atmosphere of bustling bonhomie. The railway also displaced St. Thomas's Hospital, which had stood by the bridge since 1213. The hospital was removed to its present riverside site between Westminster and Lambeth bridges in 1871, and its medical school is just across the street from the much-restored 13th-century Lambeth Palace of the archbishop of Canterbury. Southwark still has a famed teaching hospital, Guy's, founded in 1721.

Southwark and Lambeth were both heavily bombed during World War II, and many popular proletarian resorts, Elephant & Castle and Lambeth Walk, for example, were later rebuilt out of all recognition. Lambeth, one of the most densely populated of the boroughs, has just over 300,000 persons jammed into little more than 6,700 acres. The Brixton district, where much of South London's shopping is still done, houses one of the city's principal West Indian concentrations. The borough programs called for demolition and replacement of 10 percent of its housing by 1977, but some of its old squares have been renovated rather than razed and have been brought back to life.

Upstream, the adjacent borough of Wandsworth shares its waterfront in part with the somewhat seedy Battersea Park, which contains a children's zoo and a fun fair that was erected for the Festival of Britain. The riverfront west of the Albert Bridge, an endearing iron suspension bridge of the cuckoo-clock school of design, is now taken up with factories, but a private development plan proposed a new neighbourhood of apartment housing in a park setting behind a public riverside walk.

**London's squares and parks.** Although almost nothing remains in London of the works of the architect Inigo Jones (1573–1652), his mark is stamped probably forever on the town. He came back from an Italian tour with a new architectural idol, Andrea Palladio. The two great examples of Jones's buildings, the Queen's House at Greenwich (designed 1616) and the Banqueting House of Whitehall Palace (1619–23), show that he did not swallow Palladio's classicism whole and spit it out again: he was no mere imitator but the personal interpreter of a concept and a style. His great contribution to London was not Palladian Venetian but Medicin Tuscan: the city square. Derived from Cosimo I de' Medici's Piazza d'Arme built in Livorno in 1571, which had already inspired Henry IV's Place des Vosges (1603) in Paris, the city square was to set the pattern of London city building for the next 200 years, sometimes fashioned into ellipses and crescents but always enhancing the variety and surprise of the urban composition.

Jones's Covent Garden Piazza (1630) was surrounded on three sides by tall houses with an arcaded street floor, filled on the west by the low, solemn-porticoed St. Paul's Church. When it had stood there 50 years, Charles II gave permission for a vegetable market (Covent Garden Market) to operate in the square "forever," which turned out in fact to mean until 1974, when the Nine Elms market across the river was expected to replace it. The year before its departure, market traders in the 96 acres centring on the piazza handled £64,000,000 worth of fruit and vegetables and £11,000,000 worth of flowers.

Not long after the Jones square was completed, a cock-fighting hangar was opened in adjacent Drury Lane and was converted into a theatre in 1662. It was destroyed by

fire several times, and the present building dates from 1812, with later external additions. For 115 years it was the only licensed theatre in London, until the opening of the Covent Garden theatre, where Handel's *Messiah* was first heard in 1742 and where all his succeeding oratorios were introduced. The present Royal Opera House, built by E.M. Barry in 1858, is the home of the Royal Ballet as well as the Royal Opera.

Some experts contend that Lindsey House on Lincoln's Inn Fields, the largest square in Central London, was built following a Jones design. With its rusticated lower floor and giant pilasters supporting the entablature, it was the prototype for a whole race of London town houses. Charles I gave a direct license in 1641 for the development of Lincoln's Inn Fields as a city square, but work was halted by an appeal to the House of Commons from the society of Lincoln's Inn (this Inn of Court, founded in the 14th century, still contains some 15th-century buildings), and so the square was not completed until 1656. Within the Inn's conclave is New Square, an elegant oblong of red-brick houses unchanged—except for the effects of German bombing in 1941—since it was built in 1685.

New Square, like Covent Garden and other West End squares, was built as a private speculation. Some of the loveliest portions of London—entire cherished neighbourhoods—were conceived for the benefit of (usually) noble and sometimes royal landlords. The Earl of Southampton in 1660 built Bloomsbury Square, the first to bear the word square in its name. The district was passed by marriage to the dukes of Bedford, who built a splendid series of garden squares, of which Bedford Square (1775) is one of London's handsomest and Russell Square (1800) one of the largest. The whole atmosphere of Bloomsbury, distinguished and intimate, was for long enhanced by the presence of teachers and scholars, painters, actors, and writers. In the area are the University of London and its University College and Birkbeck College, the London School of Hygiene and Tropical Medicine, the Royal Academy of Dramatic Art, the Slade School of Art, the Wellcome Museum of Medical Science, and the Courtauld Institute Galleries.

**The British Museum.** The jewel in this cultural crown is the British Museum, founded here in 1753, its present building constructed in the period 1823–47. Its library, which is entitled to receive a copy of every book printed in the United Kingdom, has more than 6,000,000 volumes and has been cramped for space for 100 years. The Reading Room, in which Karl Marx wrote *Das Kapital*, was formed by roofing over the central courtyard. The museum's print room is justly famed, as is the manuscript collection, which ranges from Aristotle's *Constitution of Athens* to modern British classics. The museum collections are extraordinarily varied, especially in antiquities of Egypt, western Asia, the Orient, Greece, Rome, and Britain.

To the west of Bloomsbury, Cavendish Square was laid out in 1717 by the Duke of Newcastle, whose daughter married Edward Harley, 1st earl of Oxford, and whose granddaughter married the Duke of Portland. Oxford Street is named after the Earl, whose family name was given to one of the world's most celebrated concentrations of medical specialists, Harley Street.

The south side of Oxford Street belongs to the single largest private landowner in London, the Duke of Westminster (the Church of England, the crown, and the boroughs of London are the three biggest landlords). The lands stretch from Oxford Street through Mayfair, across Hyde Park Corner through Belgravia and Pimlico right down to the Thames. Originally Westminster Abbey property, by 1677 it was the dowry of Mary Davies when she wed Sir Thomas Grosvenor—Grosvenor being the family name of the dukes of Westminster. Grosvenor Square was built about 1700 (on the neighbouring estate to the east, Berkeley Square was built about the same time, Bond, Dover, and Stafford streets having been built up some 30 years earlier by Sir Thomas Bond and the earls of Dover and Stafford), and Mayfair became a fashionable district, as it remains today. The gardens

The atmosphere of Bloomsbury

Inigo Jones's contribution to the city layout

Tourist-filled Trafalgar Square, with Nelson's Monument and the National Gallery.  
Pictorial Parade

around which Grosvenor Square was built were given to the nation in 1946 as a memorial to U.S. president Franklin D. Roosevelt by the 2nd Duke. Park Lane, where the town houses of the Grosvenors and other wealthy Londoners stood, has become a street of hotels and offices.

The last Grosvenor land to be developed, before the Grosvenors became the dukes of Westminster in 1847, included Belgravia and Pimlico. The original layout, made in 1815, was somewhat altered by the three builders, who took long leases on sections of the property and began construction in 1824. The owners wanted a mixed development—thus, the palatial mansions of Belgrave Square (now mostly embassies and institutions), the tall Parisian town houses of Eaton Square (still one of London's more chic addresses), the middle class residences in Chester and Wilton streets, and the more modest houses in Bourne Street, Graham Terrace, and Caroline Terrace. This imposing piece of town planning remains largely intact. Pimlico (by the Thames), until the 1970s ill-served by public transport, sloughed into slum by World War II, but those parts that survived the severe bombing were subsequently restored to something close to their original dignity.

Originally all the squares in all the developments, planted as gardens or parks on private property, were closed to all save house owners with keys to the gate. Leicester Square, a common grazing ground usurped by the Earl of Leicester to grace his town house, was surrounded by houses by 1680 but became public only in 1870, and Lincoln's Inn Fields remained private until 1894. The majority of the gardens are still fenced and available only to key holders from surrounding buildings. Among the buildings surrounding the garden in St. James's Square (built by Henry Jermyn, earl of St. Albans, 1664) are Chatham House (home of three British prime ministers, present headquarters of the Royal Institute for International Affairs), the London Library (a private subscription library with 600,000 volumes), several private clubs, and some discreet corporation headquarters. There are some modern intrusions, but most of the houses are 17th and 18th century. Fiscally, physically, and psychically, the square and its environs continue to constitute the conservatory of the "British Establishment," that astonishingly hardy perennial of island ecology.

*Trafalgar Square.* Possibly the most famous of all, Trafalgar Square, has always been public and has no garden. Seven major arteries pump automobiles around

the great paved space, in which stands a statue (17 feet, 4½ inches) of the hero of the Battle of Trafalgar (1805), Horatio Nelson, on a victory column (167 feet, 6½ inches). Two fountains, stone lions, live pigeons, and assorted memorial military statuary keep him company. The openness of the space attracts numbers of mass meetings every year and is a favourite resting place for tired sight-seeing visitors.

The name Trafalgar Square was bestowed on the site in 1832, after which hundreds of hovels were cleared from the area. Grading began 10 years later, and the column was erected in 1842. The National Gallery (into which architect William Wilkins in 1838 was obliged to incorporate the colonnade from the regent's razed palace, Carlton House) occupies most of the north side of the square, with the National Portrait Gallery next to it. To the east of the galleries is the church of St. Martin-in-the-Fields (1722–26) by James Gibbs, replacing a 1544 church on a site where a house of worship was first mentioned in 1222. The site shows off the church superbly. Just below, the Strand runs off to the City, one-half mile east, where it changes its name to Fleet Street.

South of Nelson's monument is a statue of Charles I, erected on the site of Charing Cross where the funeral cortege of Eleanor of Castile, wife of Edward I, rested in 1290. Several of the Cromwell supporters who voted the execution of Charles I were burned here after the Restoration, after which the rediscovered 1633 statue was erected. To the west is the 1910 Admiralty Arch, which frames the entrance to the pink-surfaced Mall, which leads to Buckingham Palace.

*Whitehall.* Directly south from Trafalgar Square—Charing Cross runs a street that was once the power centre of the world, Whitehall. Today it remains the seat of the government's executive branch. Interspersed among Victorian and post-World War II pachyderms are several graceful 18th-century buildings still in government service. On the east side is Inigo Jones's calm, lovely Palladian Banqueting House (1619–23), the only important part of Whitehall Palace to survive intact the fire of 1698. Across the street is the Horse Guards Parade, a 1760 replacement of an earlier headquarters. Every day the plumed troopers of the Household Cavalry ride in on black horses from their 35-story Knightsbridge Barracks (1970, Sir Basil Spence) to post guards at 11:00 AM.

Farther south is the Old Treasury, built around the remains of Henry VIII's tennis court after the fire, now

The seat of government

used as Cabinet offices, connected by a corridor to the Cabinet Room at 10 Downing Street. Sir George Downing built this very short street of houses as a speculation between 1663 and 1682, and behind the simple brick facades are 200 rooms reconstructed in the 1960s. The prime minister lives at No. 10, his chancellor of the exchequer at No. 11, and his party's chief whip at No. 12. Past the Foreign and Commonwealth offices, the Home Office, and the all-powerful Treasury is Parliament Square, which has a small central garden with benches and statues. It leads on to two of the most important buildings in Britain, the Houses of Parliament and Westminster Abbey.

*Parliament.* Parliament dates its beginnings from 1265, when Henry III had to accept the Parliament called by Simon de Montfort. Meetings on fixed dates began under Henry VIII, and in Tudor times the Commons evolved its basic rules of procedure. Early meetings were held in the Abbey's Chapter House, which was then, from 1547, in the deconsecrated chapel of St. Stephen of the Palace of Westminster. The House of Lords met in the palace Chamber of Requests in Old Palace Yard. Originally built for Edward the Confessor (reigned 1042-66), the palace served Parliament until destroyed by fire in 1834. The crypt of St. Stephen, a section of 1526 cloister, and the medieval Westminster Hall are all that remain today. The hall, completed in 1097, received its magnificent hammer-beam roof during 14th-century modifications. Damaged by incendiary bombs in May 1941, the roof was later restored.

After the 19th-century fire, a competition for a new Palace of Westminster was won by Charles Barry, who was knighted for his work, and Augustus Welby Northmore Pugin, an ardent medievalist, who died mad. Full of variety and movement that lighten its massiveness, the prize-winning design functioned well for the Parliament of its day and became almost instantly a symbol of that institution's power and solidity. The Clock Tower at the eastern end houses among its bells Big Ben, which sounds the hours and is marked "13 tons 3 cwt 3 qtrs 15 lbs."

Big Ben

*Westminster Abbey.* Built by Edward the Confessor, Westminster Abbey was consecrated in 1065. To honour Edward, Henry III undertook to build a more magnificent church in 1245, in Gothic, leaving of the original building only the Norman Undercroft, the Dark Cloister, and the Chapel of the Pyx, all of which still exist. After 25 years the work stopped, not to be resumed until more than a century later, but in perfect imitation of the style in which it had begun. The octagonal Chapter House is one of the identifiable portions built in the mid-13th century. Henry VIII completed the fan-vaulted and richly carved chapel begun in 1503 by his father at the eastern end of the abbey. The restorations and additions of the 18th and 19th centuries were drastic; the twin towers on the west front are from 1735-40, designed by Hawksmoor. The church is styled a Royal Peculiar, with Dean and Chapter (its officials) depending directly on the monarch, head of the Church of England. Nearly all British rulers since Harold II (who lost to William I the Conqueror in 1066) have been anointed and crowned here, and until 1760 they were buried here as well. National heroes of politics, literature, and war are interred here, although some of the most heroic (Shakespeare, Milton, Marlborough, Nelson, Churchill, for example) lie elsewhere.

The abbey, its boys' school (Westminster, one of the nation's most distinguished), and its neighbour, the medieval Gothic church of St. Margaret's (parish church of the Commons), form a placid precinct on the edge of Victoria Street, cut through slums in 1851 to Victoria Station. Much of the bold Victorian architecture along the street was replaced in the 1960s with indifferent contemporary buildings, including a 22-story glass box, the Westminster City Hall, and just off Victoria Street, in a building of the same mock-courageous cut, is the New Scotland Yard, 1964 headquarters of the Metropolitan Police. Scotland Yard, the 1891 Scottish baronial castle of convict-quarried granite, is half a mile east on Victoria Embankment.

*St. James's Park.* Behind Whitehall's ministries and Downing Street, westward toward Buckingham Palace, lies St. James's Park, the oldest and most romantic of the six central Royal Parks that give the West End of London a heritage of beauty, repose, and sense of continuity.

The swampy ground belonging to the Sisters of St. James-in-the-Field was taken in 1532 by Henry VIII, who built the red-brick toy-soldier castle toward the western end. To the court at this St. James's Palace the credentials of foreign diplomats are still addressed. The Stuarts admitted the public to the park, which Charles II had done up in the formal Versailles manner. The first Georges cut off one end of the ornamental water to form the Horse Guards Parade, where in early June the sovereign's official birthday is celebrated with the Trooping the Colour by the Brigade of Guards, to the music of the brigade's massed bands.

Horse  
Guards  
Parade

George IV had the park re-designed in its present seductive form by John Nash in 1828. The formal "canal" was changed into a long, irregular lake graced with a small bridge from which the Whitehall buildings, topped with pinnacles and pennants, form a rather "Arabian nights" silhouette. The weeping willows around the lake also lend an Oriental touch to what is an archetypal (and extremely artful) English landscape. The flower beds are the best in Central London. Among the many species of waterfowl to be seen are the pelicans originally introduced by Charles II. The northern border of the park is the half-mile-long, arrow-straight Mall, a splendid ceremonial way that terminates at the bulky Queen Victoria Memorial, around which are planted each spring 40,000 tulips, succeeded by 14,000 geraniums.

*Buckingham Palace.* The memorial stands before Buckingham Palace, built in 1703 by the Duke of Buckingham and bought by George III in 1762. When Nash reshaped the park, he enlarged and remodelled the palace and designed Marble Arch, which served as the entryway until 1851, when it was removed to the northeast corner of Hyde Park. The Mall facade of the palace was redesigned again in 1913. When the monarch is in residence, the flag flies from the roof and the guard is changed in the forecourt every morning. Victoria made Buckingham Palace the monarch's London residence, relegating St. James's to purely ceremonial use.

*Green Park.* Green Park, close by, is an unpretentious knoll of especially thick, rich grass and luxuriant stands of trees, the plainest of the Royal Parks. It is bordered on the east by the once-private homes that clustered around St. James's Palace: 19th-century Lancaster House, about which Queen Victoria remarked to the Duchess of Sutherland, "I have come from my house to your palace," now a government conference building; Bridgewater House, a 19th-century Florentine palazzo and one of the 280 buildings that are on the Grade I list of protected historic buildings; mid-18th-century Spencer House, which, like Bridgewater House, is now functioning as business offices.

Despite the increasing number of modern buildings, the district embraced by St. James's Street and Pall Mall still retains its great distinction. More than a dozen of the most illustrious gentlemen's clubs are located in this corner. There are also shops, some of which have been in St. James's for more than 200 years.

The part of Piccadilly that runs along the top of the park was from the 18th century the site of great town houses, some few of which survive today as clubs. No. 1 Piccadilly, once known simply as "No. 1, London," was the town house of the dukes of Wellington from 1815 until it was given to the nation in 1947 as the Wellington Museum. This mansion was built as Apsley House by Robert Adam in 1778, and the 1st Duke had the red brick clad in stone and added a big Corinthian portico. Constitution Arch, which stands at the highest point of Green Park opposite the house, was built as a memorial to Wellington.

*Hyde Park and Kensington Gardens.* Across the traffic of Hyde Park Corner is another work by the same architect, Decimus Burton, the triple-arched Ionic screen that was the original entrance to Hyde Park, for which he also

Marble  
Arch and  
Speakers'  
Corner

designed the lodges at the other gates. From this corner a once-celebrated riding track, Rotten Row, starts westward under the arching boughs. Once the central part of Henry VIII's great forest hunting preserve watered by the West Bourne and Tyburn, Hyde Park and Kensington Gardens together have an area of 615 acres. The Tyburn Tree, a 12-foot-high triangular gibbet with room for eight malefactors on each arm, stood at the northeast corner of Hyde Park until 1783. Marble Arch, which gave its name to the adjacent crossroads, and Speakers' Corner, the traditional open-air, open-question forum, occupy this northeast corner of the park today. From there to the southwest corner of Kensington Gardens is a two-mile walk across meadows and through groves of fine old trees. Only in very rare spots is the public requested to keep off the grass, under which, on the violated eastern border of the park, is a 1963 parking garage for 11,000 cars.

From an Italianate water garden in Kensington Gardens flows the Long Water, which, once it enters Hyde Park, becomes the Serpentine, where there is boating and ice-skating and, at a strand called the Lido, swimming. William III nipped 26 acres off the western end of Hyde Park in 1689 to make a garden for Kensington Palace, enlarged by further acquisitions by succeeding reigns. Kensington Gardens was not opened to the general public until the mid-19th century and still retains some feeling of elevated separateness, one of the last repairs of nanny-tended prams, with expensive model boats being sailed in the Round Pond and hearty gentlemen fulfilling childhood dreams by flying magnificent kites. The traditions of Hyde Park have always been—aside from the vanished magnificence of Rotten Row—more popular, from public hanging to public swimming. The Great Exhibition of 1851 was held in the Crystal Palace, Paxton's remarkable iron-trussed glass building. The palace was erected in Hyde Park, almost, but not quite, in Kensington Gardens. It was destroyed by fire in 1936.

Unpretentious, domestic, red-brick Kensington Palace was the Earl of Nottingham's 1661 country house, enlarged by Wren for William III in 1689 and again by William Kent for George I. About 1700, Kensington Square to the south was built for those who wished to be near the court. When she succeeded to the throne (June 1837), the 18-year-old Victoria was living in Kensington Palace with her mother. It is still inhabited by members of the royal family, and its staterooms are open to the public.

In front of the palace runs a private road constructed in 1843 and lined with grandiose mansions of which a dozen are now embassies and some others are diplomatic residences. The southern end leads to lofty Kensington, and the northern end to sleazy Notting Hill, both parts of the Royal Borough of Kensington and Chelsea. Although the borough has the smallest percentage of public-housing tenants (about 5 percent) of any in London, it has one of the most troubled—and troubling—slum districts of the city.

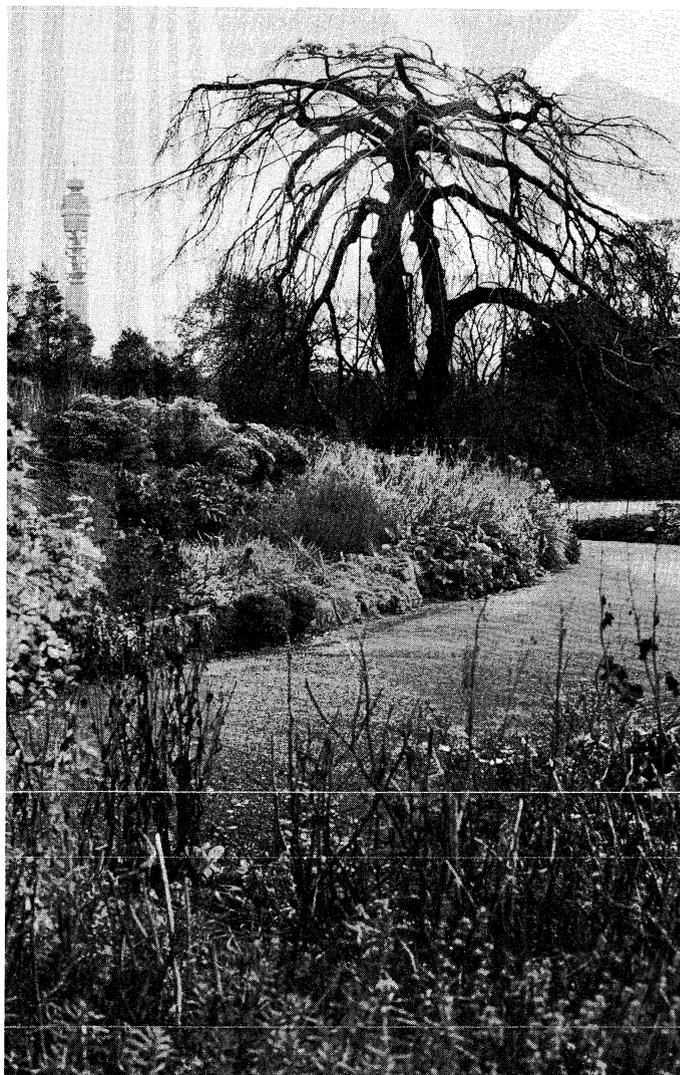

Albert  
Memorial  
and Royal  
Albert Hall

Kensington Gardens accommodates one of London's more remarkable monuments, the Albert Memorial, 175 feet high, graced with 175 sculpted figures somewhat larger than life. This Victorian Gothic improbability was concocted in 1863–71 by Sir George Gilbert Scott, who, at the same time (1868–74), wrought even more fanciful gothic conceits at St. Pancras Station, fortunately preserved. Out of the park and across the street is the domed, elliptical, 7,000-seat Royal Albert Hall, part of an 80-acre cultural centre for which the ground was bought with profits from the 1851 exhibition. There are five colleges and four museums: the Royal College of Organists, the Royal College of Music, the Royal College of Science and the Imperial College of Science and Technology (the Royal College of Art was moved there from Exhibition Road in 1962); the Science Museum, the Geological Museum, the Natural History Museum, and the Victoria and Albert Museum.

*Regent's Park.* Regent's Park, with Primrose Hill abutting (472 acres in all), is about a quarter of an hour's walk north from Marble Arch. This parkland, too, was

part of Henry VIII's hunting preserve. The elongated lake was made by damming the Tyburn. It was opened to the public in 1815, the culminating point of John Nash's Triumphal Way, which started from St. James's Park. Starting in 1811 and working until 1830, he built Water-

J. Allan Cash

Regent's Park.

loo Place (the column to the Duke of York was erected later), then lower Regent Street to Piccadilly. From there he was unable to continue Regent Street on a straight line, but he did obtain a right-of-way in a quarter-mile curving arc. To join this curve to the straight, he contrived the city's first traffic roundabout—Piccadilly Circus. Along the curved section, known as the Quadrant, he swung twin lines of arcaded buildings. (The arcades were ripped out before Nash was dead a dozen years.) He thrust on until he came to the jog where his street would join Portland Place, already lined with buildings by Robert Adam (little of that work is left, either). There he constructed a church, All Souls Langham Place, with a circular portico, gently concealing the bad join between the two streets.

John  
Nash's  
Triumphal  
Way

The effect was ruined later in the century, when the curlicued Langham Hotel was erected, and the ruin was completed in 1931, when the British Broadcasting Company planted its Broadcasting House there.

Having already put Regent's Park in order, Nash massed around three sides of it one of London's most magnificent architectural showpieces, a series of terrace houses. The facades of the individual houses in each terrace, based on a continuous ground-floor arcade, were

composed to form one grand entity with column-supported pediments and a unifying lattice of balcony across the front, so that each tenant seemed to occupy a portion of a palace. War damage and dry rot made the future of these terraces uncertain for years after 1945, but by 1970 they had been restored and put to educational, charitable, and residential uses.

The park is a series of romantic vales and has the amenities offered by most of the others, but two of its endowments are unique: the Zoological Gardens (very superior middle-sized city zoo; London's big zoo is at Whipsnade) and the Regent's (Grand Union) Canal. The GLC (Greater London Council) is clearing footpaths along the canal, and Westminster Council is encouraging home building on old factory and warehouse sites. The western end of the canal is a district of richly maintained large houses called Little Venice.

Nash's Piccadilly Circus was no longer circular after 1877, when Shaftesbury Avenue was started there and hacked through the rookeries (slums) of Soho and St. Giles, eventually becoming the principal theatrical street of the West End. The Soho district has been the special resort of foreign colonies since Frenchmen found refuge there from the 16th-century wars of religion, followed in turn by Greeks in 1677 and, in the 19th century, the Italians.

These three groups with their ethnically flavoured restaurants and grocery shops still thrive in Soho amid the grimy nightclubs and the remnants of between-wars Bohemia. They have been joined by a growing number of Chinese from Hong Kong. The old Chinatown in Limehouse in dockland was virtually deserted after World War II. A sizable Greek community flourishes in Bayswater near the Greek cathedral of Hagia Sophia.

Piccadilly Circus, a seedy traffic chute by day and a neon-loud gathering place by night, still attracts visitors from all over the world. The youth of all nations sprawl on the steps of its stone island, which is crowned by the 1893 aluminum statue of Eros (in reality, the Angel of Christian Charity, a memorial to the reformer, the 7th Earl of Shaftesbury).

*The outer parks.* Outside London and Westminster there are four other Royal Parks: Greenwich, Richmond, Hampton Court, and Bushy. Richmond Park, 2,358 acres, has changed little since it was first enclosed in 1637 for the grounds of the vanished Richmond Palace. The ponds abound in fish, and the centuries-old oaks shelter 600 deer. The Royal Ballet School occupies White Lodge in the middle of the park, which comes near to the Thames 15 miles upstream from Westminster Bridge. To the east are Wimbledon Common, Wimbledon Park, and Putney Heath, which together make an open space of 1,700 acres. On the edge of the park is Alton West Estate, Roehampton, a low-rent housing group built by the LCC (London County Council). In a garden setting, which includes some preserved 18th-century country houses, is a population of 9,600 served by its own schools, shops, and library.

Further upstream past the tidal head at Teddington are Hampton Court and Bushy parks. Hampton Court was built in 1514 by Cardinal Wolsey and was presented, along with its contents, to Henry VIII two years later in a futile effort to stave off disgrace. The house, an imposing red-brick building with white-stone accents and typically Tudor twisted chimneys, was enlarged for Henry and, in the 17th century, enlarged further for William and Mary by Sir Christopher Wren, who planted the avenue of flowering chestnut trees that grow today in Bushy Park, an 1,100-acre tract inhabited by deer, by horses belonging to the Royal Household, by the director of the National Physical Laboratory (in 18th-century Bushy House), and by the Admiralty Research Laboratory, in Charles II's Upper Lodge.

On the way back downstream is Kew Gardens, one mile below Richmond Park. Although it contains a former royal palace (1631), Kew is not a royal park. It is the site of the Royal Botanic Gardens, with four museums, a research and training centre, and gardens of trees and plants from all over the world.

Greenwich Park is 21 miles farther downstream, five miles below London Bridge. The 185-acre (81-hectare) park was first enclosed by Humphrey, duke of Gloucester, in 1433. He built a castle on the hill, which Henry VIII enlarged and which Charles II demolished in 1675, to make way for Wren's Royal Observatory, whence issued Greenwich Mean Time. The Duke also built a palace, Placentia, on the riverbank, where Henry VIII and his daughters Mary and Elizabeth were born. On the rise behind the palace, Charles I had Inigo Jones build for Henrietta Maria the Queen's House, now the National Maritime Museum. Charles II tore down Placentia and had John Webb start a new one. William and Mary made the building into a naval hospital and had Wren design further buildings. Nicholas Hawksmoor and Sir John Vanbrugh were architects for later additions. The English Baroque group, best seen from the river, is one of the best sided and finely balanced architectural compositions in London.

The park that rises behind them is graced with Spanish elms set out in the mid-17th century. Like the other Royal Parks, it is spacious, soothing, and deceptively "natural." Just to the south lies historic Blackheath (270.5 acres), where rebel armies gathered on several occasions down the centuries, where James I introduced the Scottish game of golf to England, and where highway robbers lurked in the 18th century.

Far to the opposite side of the city is another open space much prized by Londoners, the 800-acre Hampstead Heath. The residents of the wealthy and picturesque village of Hampstead, on the highest hill in London, organized into a protective society and fought in the courts from 1856 to 1872 to assure free access to an integrally preserved natural open space. The heath, the citizens' group, and a good many village aspects still prevail in Hampstead today.

Highgate Wood, just north of the heath, belongs to the City of London, as do Queen's Wood and West Ham Park. Farther out, City-sustained greenery includes Epping Forest (6,000 acres) in Essex, Coudson Commons (423 acres) in Surrey, and Burnham Beeches in Buckinghamshire. Hainault Forest (1,108 acres), in Essex, belongs to the GLC, which maintains there and at Her-sham and Stoke D'Abernon, in Surrey, tree banks (54,000 young, transplantable trees) to supply the streets and parks of London.

Most parks in and around Central London provide entertainment (band and symphony concerts, poetry readings, ballet, opera) and facilities for sports from bowling on the green to motor racing. Coaching is given in lawn tennis and skiing, and championships open to all Londoners are held every year in seven different sports. On Sunday mornings in the season, Hackney Marshes park offers the spectacle of 2,500 footballers at play.

BELL, *History of the London County Council, 1889-1939* (1939), a knowledgeable study of the development of the London County Council and its services; *Report of the Royal Commission on Local Government in Greater London*, 2 vol. (1960), a clearly-written study of the development of Greater London as influenced by social and economic factors—treats the nature and purpose of local government and planning; SYDNEY K. RUCK, *London Government and the Welfare Services* (1963), an account of the scope and variety of the services available, also includes a description of the reorganization of the services in the new London boroughs; P.G. HALL, *London 2000* (1963), on the town-planning problems of the London region, including a program for regional development and urban restructuring (thoroughly documented); SYDNEY K. RUCK and GERALD RHODES, *The Government of Greater London* (1970), an account of the workings of the new system of governing Greater London that went into effect on April 1, 1965, which traces the background of this modification and interprets its significance.

**Commerce and industry:** P.G. HALL, *The Industries of London Since 1861* (1961), a study of the locations of various industries in London and how these change, with an investigation of the new industries in the metropolis; JAMES BIRD, *The Geography of the Port of London* (1957), an analysis of the port, its docks and adjacent industrial development, and a study of the river traffic, markets, and trade; J.G. BROODBANK, *History of the Port of London*, 2 vol. (1921), based partly on Port of London Authority records; HENRY MAYHEW, *London Labour and the London Poor* (1851; 4 vol., 1861-62, reprinted 1969), a classic report; CHARLES BOOTH, *Life and Labour of the People of London*, 9 vol. (1892-97), a description of London life during a period of momentous changes—a pioneer work in the field of social investigation; LONDON SCHOOL OF ECONOMICS, *The New Survey of London Life and Labour*, 9 vol. (1930-39), a con-

tinuation along the lines of the Booth work, with the investigated region widened to take in all of Greater London; CENTRE FOR URBAN STUDIES, *London: Aspects of Change* (1964), views of historians and sociologists on the changing communities of the metropolis; DONALD L. FOLEY, *Controlling London's Growth* (1963), a study of planning for London since World War II and its results; MARY CATHCART BORER, *The City of London: Its History, Institutions, and Commercial Activities* (1962), on the commodity markets, Baltic Exchange, Stock Exchange, and other aspects of mercantile London.

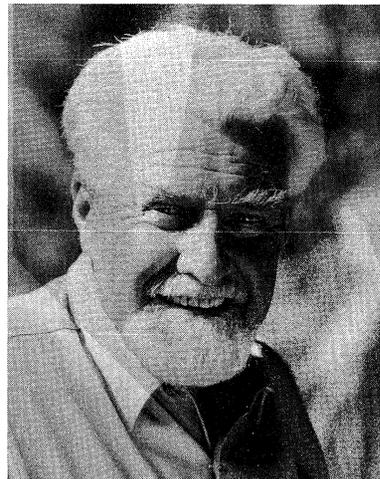

**Transport:** IVAN MARGARY, *Roman Roads in Britain*, rev. ed. (1967), a study of these roads, most of them leading out of London; VERNON SOMMERFIELD, *London Transport* (1934), a record and a survey of the system, including a history of the events leading up to the creation of the London Passenger Transport Board that unified services and evolved into London Transport; and (ed.), *London's Buses* (1933), a brief but informative account of their 100-year history, with many illustrations; HOWARD LINECAR, *British Electric Trains*, 2nd ed. (1949), includes a study of the building of London's early tubes and the development of the London Transport lines; E.A. COURSE, *London Railways* (1962), a history of the development of the railways that provides insight into London's growth in the 19th century; H.P. WHITE, *A Regional History of the Railways of Great Britain*, vol. 3, *Greater London* (1963), investigates the reasons for placement of the railways and studies their relationship to the economic and social life of London.

(B.E.)

## Lorenz, Konrad

Konrad Lorenz, an Austrian zoologist, is the founder of modern ethology, the study of animal and human behaviour by means of comparative zoological methods. His ideas contributed to an understanding of how behavioral patterns may be traced to an evolutionary past, and his later work on the roots of aggression reached a growing audience because of its possible application to understanding social violence in urban populations and, on a larger scale, to the prevention of war.

Hermann Kacher

Lorenz.

Lorenz was born in Vienna on November 7, 1903, the son of an orthopedic surgeon. He showed an interest in animals at an early age. Receiving considerable encouragement from his parents, he kept animals of various species—fish, birds, monkeys, dogs, cats, and rabbits—many of which he brought home from his boyhood excursions. While Lorenz was still young, he provided nursing care for sick animals from the nearby Schönbrunner Zoo. He also kept detailed records of bird behaviour in the form of diaries.

In 1922, after graduating from secondary school, he followed his father's wishes that he study medicine and spent two semesters at Columbia University, in New York City. He then returned to Vienna to study. In 1927 he married Margarethe Gebhardt, by whom he had two daughters and a son.

During his medical studies Lorenz continued to make

Medical studies

detailed observations of animal behaviour; a diary of a jackdaw that he kept was published in 1927 in the prestigious *Journal für Ornithologie*. He received the M.D. degree in Vienna in 1928. He then studied comparative anatomy and was awarded the Ph.D. degree in zoology in 1933. Encouraged by the positive response to his scientific work, Lorenz established colonies of birds, such as the jackdaw and greylag goose, published a series of research papers on what he observed, and soon gained an international reputation. In 1935 Lorenz described learning behaviour in young ducklings and goslings. At a certain critical stage soon after hatching, they learn to follow real or foster parents. The process, which is called imprinting, involves visual and auditory stimuli from the parent object; these elicit a following response in the young that affects their subsequent adult behaviour.

In 1936 the German Society for Animal Psychology was founded. The following year Lorenz became co-editor in chief of the new *Zeitschrift für Tierpsychologie* (a post he has held since then), which became a leading journal for ethology. Also in 1937, he was appointed lecturer in comparative anatomy and animal psychology at the University of Vienna. From 1940 to 1942 he was professor and head of the department of general psychology at the Albertus University at Königsberg.

From 1942 to 1944 he served as a physician in the German Army and was captured as a prisoner of war in Russia. He was returned to Austria in 1948 and headed the Institute of Comparative Ethology at Altenberg from 1949 to 1951. In 1950 he established a comparative ethology department in the Max Planck Institute of Buldern, Westphalia, becoming co-director of the Institute in 1954. He has been at the Max Planck Institute for Behaviour Physiology, in Seewiesen, since 1958 and its director since 1961.

Lorenz' early contributions dealt with the nature of instinctive behavioral acts, particularly how such acts come about and the source of nervous energy for their performance. He has also investigated how behaviour may result from two or more basic drives that are activated simultaneously in an animal. Working with Niko Tinbergen of The Netherlands, Lorenz showed that different forms of behaviour are harmonized in a single action sequence.

His concepts have advanced the understanding of how behavioral patterns evolved in a species, particularly with respect to the role of ecological factors and the adaptive value of behaviour for species survival. He has proposed that animal species are genetically constructed to learn specific kinds of information that are important for the survival of the species. His ideas have also cast light on how behavioral patterns develop and mature in the life of an individual organism. In recent years, his ideas have been applied to the behaviour of humans as members of a social species, an application with controversial philosophical and sociological implications. In a popular book, *On Aggression* (1966), he argued that fighting and warlike behaviour in man have an inborn basis but can be environmentally modified by the proper understanding and provision for the basic instinctual needs of man. Fighting in lower animals has a positive survival function, he observed, such as the dispersion of competitors and the maintenance of territory. Warlike tendencies in man may likewise be ritualized into socially useful behaviour patterns.

Lorenz has received honorary degrees from Yale, Loyola, Leeds, Basel, and Oxford universities, as well as numerous prizes and honours.

*Works: Er redete mit dem Vieh, den Vögeln und den Fischen* (1949; Eng. trans., *King Solomon's Ring*, 1952); and *So kam der Mensch auf den Hund* (1950; Eng. trans., *Man Meets Dog*, 1954), entertaining semipopular accounts of Lorenz's experiences with animals and his views on animal behaviour; "Phylogenetische Anpassung und adaptive Modifikation des Verhaltens," *Z. Tierpsychol.*, 18:139-187 (1961; Eng. trans., *Evolution and Modification of Behavior*, 1965), a scientific theoretical discussion on the dual sources of behaviour in evolution and individual experience; *Das sogenannte Böse* (1963; Eng. trans., *On Aggression*, 1966), a de-

scription of the phenomena of aggression in animal species, the ethological findings and interpretations of aggression, and the significance of these for the understanding of human behaviour; *Über Tierisches und Menschliches Verhalten* (1965; Eng. trans., *Studies in Animal and Human Behaviour*, 2 vol., 1970-71), contain several papers written by Lorenz during his career and document in detail his scientific methods in studying animal behaviour.

Lorenz's life and his general approach to the study of behaviour are well described in: O. KOEHLER, "Konrad Lorenz 60 Jahre," *Z. Tierpsychol.*, 20:385-401 (1963); and in J. AL-SOP, "Profiles: A Condition of Enormous Improbability," *New Yorker*, 45:39-42 (1969).

(E.H.H.)

## Los Angeles

A semitropical Southern California metropolis of palm trees and oil derricks, television studios and aerospace factories, Los Angeles is the third largest city in the United States, with a 1970 population in excess of 2,800,000. It has paid for its spectacular growth by acquiring such contemporary urban attributes as smog-filled skies, a polluted harbour, clogged freeways, explosive ghettos, overcrowded schools, and annual budgets teetering on the brink of bankruptcy. In the early 1970s, however, Los Angeles was still growing, whereas most major American cities, caught up in the same conditions, were shrinking.

The city sprawls across some 464 square miles (1,202 square kilometres) of a broad coastal plain agreeably situated between the San Gabriel Mountains and the Pacific Ocean. Its hallmark is a network of freeways that provide moving parking places for the county's 4,000,000 cars and trucks. Angelenos commute, shop, bank, and breed by automobile. The vehicle so dominates life in this uniquely mobile community that a visiting English architectural critic, taking his cue from intellectuals who study Italian in order to read Dante, is said to have learned to drive a car so he could "read Los Angeles in the original."

The city is the seat of Los Angeles County, which contains 76 other incorporated cities—including Beverly Hills, Pasadena, and Long Beach—within its 4,083.2 square miles. The county also encompasses two channel islands, Santa Catalina and San Clemente, a mountain peak—Mt. San Antonio, familiarly known as Old Baldy, 10,081 feet (3,073 metres) high—more than 900 square miles of desert, and 74 miles of seacoast. Only eight states in the U.S. exceed the county's population, more than 7,000,000 in 1970. Since city and county are so intertwined physically and spiritually, any consideration of Los Angeles must move back and forth between the two entities. (For information on related topics, see the article CALIFORNIA.)

#### THE GROWTH OF THE METROPOLIS

**The Spanish-Mexican town and city.** On August 2, 1769, the day after celebrating a jubilee mass for Our Lady of the Angels of Porciúncula, a Spanish expedition headed by Gaspar de Portolá, searching for mission sites, camped near a river they named the Porciúncula. The expedition leaders exchanged gifts with the peaceful, Shoshonean-speaking Indians of the nearby village of Yang-na and left on the following morning. Despite three earthquakes during his overnight stay, Father Juan Crespi noted in his diary that "this delightful place among the trees on the river" had "all the requisites for a large settlement."

Two years later the Mission San Gabriel Arcangel was established about nine miles northeast of the campsite. A decade went by before Gov. Felipe de Neve succeeded in colonizing the fertile river basin with 44 recruits from Mexico, half of them children and most of them of Indian and African blood. The illiterate settlers assembled on the west bank of what is now the Los Angeles River on September 4, 1781, to claim the land they had been promised. Little is known about the events of that momentous day, but mythmakers have cloaked the city's founding in a ceremonial splendour worthy of its destiny and its high-sounding name, El Pueblo de Nuestra Señora la

The essence of the city

The early settlers

Work at the Max Planck Institute

Reina de Los Angeles (The Town of Our Lady the Queen of the Angels).

El Pueblo, as it was commonly called, remained so isolated from the United States during its formative years that Joseph Chapman, the first Yankee to become an Angeleno, was thought of as an Englishman ("El Inglés"). An engaging pirate from Boston, Chapman landed in 1818 with a black fellow privateer, Thomas Fisher. Both men took a liking to the place and stayed on. The first outsider to arrive by way of the arduous overland route was a fur trapper, Jedediah Smith, who turned up in 1826, four years after an independent Mexico had hoisted its flag above El Pueblo.

Los Angeles, with a population of nearly 1,250, had become a *ciudad* (city) in 1835 when the future writer Richard Henry Dana looked in on it. "In the hands of an enterprising people," he mused in *Two Years Before the Mast* (1840), "what a country this might be." By the time war broke out between the U.S. and Mexico in 1846, the California capital was so overrun with enterprising people that Gov. Pío Pico felt helpless against "the hordes of Yankee immigrants." When American forces under Capt. John C. Frémont and Commodore Robert F. Stockton entered the city on August 13, 1846, not a shot was fired. A revolt was put down the following January, and on July 4, 1847, Los Angeles celebrated its first Independence Day.

**The American city.** Los Angeles was incorporated on April 4, 1850, and designated the seat of Los Angeles County, which the state legislature had established as one of California's original 27 counties. According to the first United States census, the new county had a population of about 3,500, which included 13 physicians, six lawyers, 11 blacksmiths, 19 carpenters, one painter, 138 farmers, and two Angelenos listed merely as "Gentlemen." There were no schools, and 1,115 of the 1,734 adults were illiterate. The city comprised 28 square miles.

The lawless, adobe cow town—"gambling, drinking and whoring are the only occupations," grumbled a pioneer physician in 1849—prospered in the wake of the Gold Rush when hungry miners in San Francisco and Sacramento gorged on beef from Southern California. A catastrophic drought (1862-65) following several years of declining cattle prices brought an end to the era of the ranchos, with their hospitable adobe haciendas, dark-eyed señoritas, and hard-riding cowboys known as vaqueros. Vast Spanish and Mexican land grants, mortgaged and bankrupt, their owners ignorant of *Yanqui* laws and *Yanqui* interest rates, were broken up, fenced, and planted by a new breed of Angeleno. By 1860 the city had become so Americanized that it had banned bullfighting and formed a baseball club.

With the coming of the railroads (the Southern Pacific in 1876, the Santa Fe in 1885), Los Angeles began to ship its oranges back east and, by means of a massive advertising campaign, to lure immigrants westward to the New Eden. Aided by a railroad rate war, the boom of the 1880s more than quadrupled the city's population, from 11,183 in 1880 to 50,395 in 1890. Father Crespi's campsite was overrun by shrewd, aggressive Yankee boosters determined to build a city in their own image and requiring only two things denied them by a bountiful providence: a harbour and an adequate water supply.

Unlike San Francisco and San Diego, Los Angeles has no natural harbour. A narrow, artfully gerrymandered "shoestring strip" connects the inland city with its port, 23 miles south of City Hall. Los Angeles acquired its two harbour communities, San Pedro and Wilmington, by consolidation in 1909 following an epic struggle between the powerful Southern Pacific Railroad interests and the Free Harbour League. Work began on the harbour in 1899 and the first municipal wharf was ready in 1914.

Now one of the world's largest man-made harbours, the "cargo capital of the West" handles more tonnage than any other Pacific Coast harbour and accommodates the largest commercial fishing fleet and fish-canning enterprise in the U.S.

In 1904, casting about for new sources of water to sustain the city's relentless growth, William Mulholland, wa-

ter-bureau superintendent, explored the Owens Valley some 250 miles northeast of Los Angeles and returned with a bold plan for a long aqueduct to carry melted snow from the southern slopes of the Sierra Nevada to Los Angeles faucets. The plan outraged Owens Valley ranchers, enriched two syndicates of Los Angeles speculators, and gave rise to rumours of wrongdoing that historians have never quite managed to silence.

"There it is; take it," Mulholland told the thousands of Angelenos who assembled on November 5, 1913, to watch the Owens River water come cascading into a San Fernando Valley spillway at the rate of 26,000,000 gallons a day. The 233-mile-long aqueduct, with 142 separate tunnels totalling 52 miles in length, has been supplemented by a conduit. Together they supply 525,000,000 gallons a day, 80% of the city's present water needs. The remainder comes from local wells, the underground basin of the Los Angeles River, and the Colorado River (8%). Water from Northern California, carried south over a 450-mile-long aqueduct, is expected to meet the city's requirements for the foreseeable future.

**The 20th-century city.** In the first decade of the 20th century, while San Francisco tidied up the rubble of its 1906 earthquake, Los Angeles tripled its population, from about 100,000 to nearly 320,000. One local entrepreneur opened the first motion-picture theatre in the United States, in 1902, and another built the city's first garage to accommodate its growing number of automobiles, but the parasol-shaded girls from the red-plush brothels run by Pearl Morton and Cora Phillips still drove about in open carriages, much to the distress of the retired druggists, dentists, and wheat farmers from the Middle West who kept streaming into Los Angeles.

"Virtue has become virulent," reported Willard Huntington Wright, who later took to writing mystery stories under the pseudonym S.S. Van Dine. He depicted the city in 1913 as "an overgrown village" swarming with "spiritualists, mediums, astrologists, phrenologists, palmists and all other breeds of esoteric wind-jammers." Successive waves of migratory writers, taking much the same tack, have stereotyped the city as an open-air institution for the elderly and the insane, where, according to *The Saturday Evening Post* (1945), "you can drink in a drive-in saloon, eat in a café shaped like a toad, and when you die, they will bury you in a 'Happy Cemetery.'"

In recent years the city's more perceptive critics have echoed the note Wright sounded toward the end of his prescient article in *Smart Set* (March 1913): "Great problems are being worked out there. The city reeks with promise." Since then, the problems have magnified; the promise has become more difficult to redeem. Smog is no laughing matter in New York, London, or Tokyo and traffic congestion no source of amusement to motorists in Paris and Rome. Los Angeles has been called the "Prototype of Supercity" and the "Ultimate City."

More than half of the city's residents live in single-family homes, walled off from one another by their disparate life-styles. The surf-fishermen at Malibu, the Sunday sailors at Marina del Rey (described by county officials as "the world's largest man-made, shallow-draft, pleasure boat harbour"), the equestrian set in Calabasas, and the cliff dwellers in the Hollywood Hills all go their own way, surfing, yachting, riding, hiking, skiing, playing golf and tennis. Nowhere is the pursuit of happiness more unabashedly materialistic, and perhaps no city in modern times has been so universally envied, ridiculed, and, because of what it may portend, feared.

#### THE CONTEMPORARY CITY

**Physical layout.** The city is grotesquely shaped, like a charred scrap of paper, with independent municipalities such as Beverly Hills and Culver City as well as unincorporated county land lying within its 315-mile boundaries. Elevation averages about 275 feet, ranging from sea level to 5,082 feet at Elsie Peak. The Santa Monica Mountains, covering an area of 92 square miles and reaching heights of 3,000 feet, bisect the city, separating Hollywood, Beverly Hills, and Pacific Palisades from the southern boundary of the San Fernando Valley, a 219.6-square-mile area

Emergence of the bizarre in the city

The search for a port and water

The city of Los Angeles and vicinity.

Hollywood and the "Sunset Strip"

in which nearly 1,000,000 Angelenos made their home in the early 1970s.

Hollywood, eight miles northwest of the central city, was laid out in 1887 by Horace Wilcox, a Prohibitionist, who intended his subdivision to be a sober, God-fearing community. It was gobbled up by Los Angeles in 1910 when its water supply ran low. The following year Blondeau Tavern at the corner of Sunset Boulevard and Gower Street was turned into Hollywood's first motion-picture studio—to be abandoned 60 years later when Columbia Pictures moved to Burbank. By then the stars had long since left Hollywood, many of them moving into secluded hillside mansions above Beverly Hills, the most famous of which is Pickfair, built by Douglas Fairbanks for Mary Pickford in 1919.

Sunset Boulevard meanders 21 miles west from the state park, which encompasses the city's birthplace, to the sea.

A one-mile section of the boulevard becomes the "Sunset Strip," or simply the "Strip," as it cuts through county land on the eastern border of Beverly Hills. It is one of the few places where Angelenos stroll and take the sun at sidewalk cafés. During the Prohibition era of the 1920s, the Strip served as an oasis for the thirsty film colony. Forty years later the promenade had been taken over by the marijuana-smoking subculture of the young, whose discothèques and psychedelic shops stood cheek by jowl with expensive boutiques and restaurants.

**Natural phenomena.** *Climate.* Nothing is predictable in this unpredictable land, least of all the weather, which is usually described as unusual. Coastal mountain ranges to the north and east act as buffers against extremes of summer heat and winter cold. Even in the hottest months the humidity tends to be mercifully low and the nights cool. "Night and morning low clouds" is

the most common summer forecast, with the sun breaking through in the afternoon. Pronounced climatic differences occur in different sections of the city. The San Fernando Valley is generally several degrees cooler in winter and warmer in summer than communities on the opposite side of the Santa Monica Mountains. The city's mean temperature is about 64° F (18° C). The record high was 110° F (43° C) on September 1, 1955, the record low 27.9° F (-2.3° C) on January 4, 1949. The average annual rainfall is nearly 15 inches (380 millimetres) with nearly 85% of it falling in the winter months.

**Smog.** When Juan Cabrillo spotted a dark-brown pall hovering over the hunting grounds of Southern California Indians in 1542, he gave the name Bahía de los Fumos (Bay of Smokes) to what is now the city's harbour. Four centuries later, in September 1943, Angelenos got their first massive doses of air pollution. Their highly publicized sunshine literally was cooking the noxious vapours rising from the stacks of their wartime factories, from their oil refineries, and, most important, from their automobiles to produce photochemical smog.

By the early 1970s the county was discharging a daily average of 26,200,000 pounds of pollutants into the atmosphere, 1,100,000 more than in 1955. Although concentrations had not increased, carbon monoxide, which hastens the death of cardiac patients, had gone up from 17,500,000 pounds a day to 18,200,000. Oxides of nitrogen, which damage the lungs and cause constriction and irritation of the bronchial tubes, had shot up from 1,100,000 pounds a day to 2,100,000. The county's crop losses due to smog were estimated at \$2,900,000 in 1970.

**Earthquakes.** The great San Andreas Fault is 33 miles from downtown Los Angeles at its closest point, but more than 40 known lesser faults crisscross the metropolitan area. No earthquakes of major intensity—*i.e.*, higher than 7 on the Richter scale of 10—have hit Southern California since the 1850s, but aside from the periodic minor jolts that Angelenos take for granted, destructive temblors have struck Santa Barbara (1925), Long Beach-Compton (1933), and the San Fernando Valley (1971).

**Winds.** The city is occasionally buffeted by a Santa Ana, a hot, dry wind named for the canyon through which it often blows. Santa Anas occur when air rushes down from the high inland plateaus and is heated by compression as much as 5.5° F (3° C) for every 1,000 feet of descent. The natives are noticeably restless during a Santa Ana, and the mystery-story writer Raymond Chandler once wrote, "Meek little wives feel the edge of the carving knife and study their husbands' necks."

**Fires.** Dry winds whipping through narrow canyons on hot days heighten the ever-present danger of fire in the city's brush-covered mountains. On November 6, 1961, during the driest season in Los Angeles history, a fire in the affluent Bel Air district was quickly spread by 50-mile-per-hour gusts of wind. No lives were lost, but 484 homes were destroyed. Property damage was estimated at \$25,000,000, making it the fifth-costliest fire in the U.S. and the worst in California since the fire that followed the great San Francisco earthquake.

**The Angelenos.** *The making of the mix.* Around the turn of the 20th century, as might be expected in a country still predominantly rural and agrarian, most of the newcomers to Los Angeles from other states were from small farming communities. A generation later, the annual Iowa picnics were still drawing crowds of 100,000 persons. After World War II, as elderly Iowans died off, the city swarmed with young former soldiers who had passed through Los Angeles on their way to the South Pacific and had returned to make it their home. In 1950, while the veterans waged war on crabgrass in San Fernando Valley backyards, the Iowans mustered only 50,000 for their summer picnic; and by 1970 the *Los Angeles Times* no longer bothered to cover the event.

Angelenos have always been a mixed lot. In the 1850 census, 33 of the county's 3,500 residents had been born in England, 30 in Germany, 27 in Ireland, 18 in France, and one in the Sandwich Islands (Hawaii). In 1930, non-whites composed about 14% of its population, compared with about 6% in San Francisco and nearly 5% in New

York. The county now has about 100,000 Japanese-Americans and a sizable number of Chinese, Filipinos, Cubans, and Puerto Ricans. According to 1970 census data, Angelenos are getting younger, and their impoverished black neighbourhoods tend to be considerably younger than their affluent white enclaves. While the city's overall median age dropped during the 1960s from 33.2 to 30.5 years, the median age in Watts (91% black) was about 17.18; in Bel Air (97% white) it was nearly 40.

**The blacks.** Although 26 of the city's 44 founders were of African ancestry and the granddaughter of a black tailor ended up owning the land now occupied by Beverly Hills, the city's blacks in 1930 numbered only 38,894, 3% of the total population. Forty years later, streams of black immigrants, mostly from the rural South, had swelled the figure to 503,606, nearly 18%. They live and go to school in the separate and unequal world of *de facto* segregation. Only about 6% of the city's 155,000 black public-school children were attending predominantly white schools at the start of the 1970-71 term, whereas in Mississippi the comparable figure was over 26%, in South Carolina, nearly 45%.

Watts, the 2.5-square-mile core of the city's south central black ghetto, exploded on the hot summer night of August 11, 1965. The flames of Charcoal Alley gave whites a glimpse of the misery and anger of rural blacks trapped in an urban slum. After six days of looting and burning, 34 persons were dead, 1,032 wounded, and 3,952 had been arrested. Property damage was estimated at \$40,000,000. Six years later the black community's unemployment rate had increased to three times the national average, and, while the people of the San Fernando Valley (96% white) drove to work on multimillion-dollar freeways, Watts was still dependent on an overburdened, outmoded bus system in a city in which to be without a car is to be crippled.

**The Mexican-Americans.** In the simmering barrios (neighbourhoods) of East Los Angeles, young Mexican-American activists calling themselves Chicanos began to take to the streets in the early 1970s, protesting conditions that in some respects were worse than those in Watts. The Chicano not only was born to a world in which jobs were scarce, housing substandard, schools overcrowded, streets drug infested, and welfare checks inadequate, but also he had the handicap of speaking an alien tongue in the land of his forefathers. Chicanos were likely to drop out of school two years ahead of their black neighbours and roam the same dead-end streets.

Adding further injury, the more than 500,000 Mexican-Americans in East Los Angeles had been gerrymandered into political impotence. The barrios have not been represented on the city council since 1963, when their one councilman was elected to Congress. In the same election, blacks captured and have since held three of its 15 seats.

**The Japanese-Americans.** Before World War II, during which some 40,000 Southern Californians of Japanese ancestry were placed in isolated detention camps by the federal government, 85% had been farmers. Twenty years after their release in 1945, only 10% were farming. The first-generation, the Nisei, and their children, the Sansei, had gone into the professions. Whereas in 1950 only one out of 22 Japanese-Americans could be found in a professional field, in 1961 the figure was one out of six. By the end of the 1960s, young Sansei intellectuals were prepared to fight for the justice and equity their elders had meekly done without.

**The city's economy.** Once a land of vineyards, orange groves, and dairy farms, the Los Angeles area is now dominated by banks, savings and loan associations, insurance companies, steel plants, research and development facilities, oil refineries, and factories turning out everything from toy rockets and patio furniture to spacecraft and sportswear.

**Agriculture.** Los Angeles County, between 1950 and 1965, lost 31,000 acres of orange groves. While its population was shooting up nearly 50% in the 1950s, it sacrificed 3,000 acres a day to the bulldozer (freeways alone consume about 40 acres per mile), and it ceased to be the nation's wealthiest agricultural county, a position it

The ethnic  
minorities

had held since 1910. It remains the largest flower market and ranks second in the slaughtering of cattle.

**Manufacturing.** Before World War I, San Francisco was the state's manufacturing hub, but since the 1920s it has been far outstripped by Los Angeles. Manufacturing accounts for well over one-fourth of the county's more than 3,000,000 jobs. Major products include aerospace equipment, petroleum and refining, processed food, electronics, pharmaceuticals, glass, rubber, and cement.

**Aviation.** The first international air meet in the Western Hemisphere was held near Los Angeles in 1910. On opening day Glenn H. Curtiss achieved the Pacific Coast's first flight in a heavier-than-air craft. A dozen years later Donald W. Douglas was turning out an airplane a week in his Santa Monica plant. One-third of the nation's World War II military aircraft were built in the Los Angeles area. During the 1950s and 1960s, industrial emphasis shifted to aerospace, electronics, and such research and development "think tanks" as those operated by the Rand Corporation in Santa Monica, Hughes Aircraft on a hillside in Malibu, and the Aerospace Corporation just south of the city's International Airport.

**Motion pictures.** Weekly motion-picture attendance in the U.S. dropped from 85,000,000 in the mid-1940s to 17,300,000 in 1970. Faced with dwindling profits and soaring production costs, some studios began disposing of their valuable real estate holdings. The backlot of 20th Century-Fox Film Corporation was converted to Century City, a multimillion-dollar complex of office buildings, apartments, shops, and restaurants. Universal Pictures & Television made a tourist attraction of its film-making activities. Meanwhile, many producers had taken to shooting their pictures in foreign countries in which production facilities are available at lower cost. Despite this "runaway production," however, Los Angeles remains the nation's film capital and continues to play a leading role in the radio, television, and recording industries.

**Oil.** Los Angeles sits on one of its major resources, as Edward L. Doheny demonstrated in 1892 when he started selling local crude oil for industrial fuel. In 1921, after the automobile had created a ravenous appetite for petroleum products, the world's richest deposit in terms of barrels per acre turned up on Signal Hill. In its first half-century its 2,400 wells produced 859,000,000 barrels of oil.

**Tourism.** Nearly 8,500,000 vacationers visit Southern California in the course of a year and spend around \$1,500,000,000. A 30-year campaign by the city's business interests to attract still more visitors culminated in 1971 with the dedication of a large, multimillion-dollar convention and exhibition centre.

**The communications media.** The city's first newspaper, the *Star*, began weekly publication in 1851. Thirty years later the *Los Angeles Times* published its first issue. Acquired the following year by Gen. Harrison Gray Otis, it became the bible for the city's boosters, conservative Republicans, and antilabour forces. Its plant was dynamited in the early morning hours of October 1, 1910, and 21 men were killed. When it passed into the hands of General Otis' grandson, Otis Chandler, in the 1960s, the paper took a more liberal editorial stance and enlarged its foreign coverage. A breakfast-table institution, its daily circulation passed the 1,000,000 mark in 1971. Evening newspapers, such as the *Daily News* and the *Mirror-News*, have faded into history, leaving only the *Herald-Examiner*. More than 70 radio stations slake the Angelenos' taste for news, sports events, music, and talk. They also have nine television stations, including one for the Spanish-speaking community.

**Transportation.** Half of California's 20,000,000 residents live in the four southern counties served by the state's Rapid Transit District, but fewer than one in ten ride its buses. Ironically, much of the city's astonishing growth in the early 1900s was due to the superb interurban transit service provided by the big red electric cars of railroad tycoon-art collector Henry E. Huntington. The system became a freeway casualty in the early 1940s, and Los Angeles found itself committed to a state master plan designed to put a freeway within four miles of

every home in the metropolitan area. A generation later state, county, and city officials were generally agreed on the urgent need for a rapid transit system, but not on what form it should take or how it was to be financed.

During World War II as many as 5,000,000 travellers a year moved through the city's Union Passenger Terminal, but by the end of the 1960s it was virtually deserted. In that same decade, the number of passengers getting in and out of planes each year at Los Angeles International Airport rose from about 7,000,000 to nearly 21,000,000, and Ontario International Airport was handling more than 800,000 passengers by 1970. Projections for the main airport indicated 34,000,000 passengers by 1979, 7,000,000 for Ontario.

**Administration. Government.** The city's mayor and its 15 councilmen are elected to four-year terms, along with the city attorney, controller, and the seven-member board of education. The county, operating on an annual budget of more than \$2,000,000,000, is run by a five-man board of supervisors serving four-year terms, each of them representing a constituency of more than 1,000,000 Angelenos. No ethnic minority has won a seat on the board, but in 1969 and 1971 the city council chose one of its three black members as president pro tempore.

Angelenos live in a jurisdictional jungle of overlapping city-county agencies. In downtown Los Angeles there are two crime laboratories, one run by the city, the other by the county; the city taxpayer supports both. He also supports two fire departments, and, in some border areas, his home may be the responsibility of a city engine company that is farther away than a fire station in county territory.

Some city departments—airports, harbour, water, and power (the last, the largest municipally owned electric utility in the U.S.)—are virtually autonomous, and all are under the control of five-member commissions appointed by the mayor with the approval of the council. Various studies of overlapping services and jurisdictions have produced reports recommending clearer lines of authority.

**Politics.** In the November 1968 election, registered Democrats outnumbered Republicans by wide margins in both the county and the city. Richard Nixon, a native son running for president on the Republican ticket, carried the county narrowly but lost the city by a large majority.

The city administration traditionally has been Democratic, but in the eyes of many observers it had become under Sam Yorty, mayor since 1961, more closely aligned with the conservative wing of the Republican Party. In his 1969 mayoralty campaign against black councilman Thomas Bradley, Yorty warned that a black mayor would form a racial coalition with left-wingers, and he strongly emphasized a "law and order" platform. He was re-elected.

**Law enforcement.** At the time of the Watts disorders in 1965, Police Chief William Parker had become something of a folk hero to white, middle class Angelenos. Technically, his department was considered to be one of the best in the world; blacks and Mexican-Americans conceded the point, but both communities complained that in its dealings with ethnic minorities it was bigoted and brutal. Parker's successors initiated corrective measures, including an improved recruitment program, but skeptical critics argued that emphasis was placed on public relations rather than community relations. Of the nation's six largest cities, however, none has so few policemen per 1,000 residents.

**Education.** At the start of the 1970s, nearly 650,000 young Angelenos were enrolled in the city's public schools; one-half of them white, one-quarter black, and about one-fifth with Spanish surnames. There are 20 junior colleges in the county and five state colleges with a combined enrollment of some 270,000. The area's two oldest institutions of higher learning are the University of Southern California (usc; 1880) and Occidental College (1887). USC is noted especially for its schools of law, medicine, dentistry, engineering, and performing arts. The state-supported University of California at Los Angeles (UCLA; 1919) is the largest, with around 27,000 students. It has a wide range of undergraduate and gradu-

ate offerings, with a particularly heavy commitment to the life and geophysical sciences and the arts. California Institute of Technology, founded in 1891 as Throop Polytechnic Institute, moved to its present location in Pasadena in 1910. Telemetric commands from its Jet Propulsion Laboratory controlled the movements of the first robot spacecraft to soft land on the moon, in 1966.

**Recreational and cultural activity.** *Public and commercial parks.* When the Portolá-Crespi party broke camp on the Porciúncula River during their 1769 visit, they headed west toward the sea along what is now Wilshire Boulevard. They stopped to marvel at the black, bubbling lakes on their right, which excavations between 1906 and 1913 revealed to be a unique repository of fossilized skulls and bones of long-extinct mammals trapped in the seepage of *brea*, or "tar," that was scooped up by early-day Angelenos to waterproof their roofs. The 23-acre site of the Rancho La Brea pits was given to the county in 1916 by G. Allan Hancock, an oil tycoon for whom the park is named. It features life-size figures of such creatures as the imperial mammoth, the American mastodon, the sabre-toothed tiger, the ground sloth, and the short-faced bear.

Griffith Park is spread across 4,064 rugged mountainous acres, an area larger than Beverly Hills. Mule deer wander down from the park's hillsides to peer at some of the 3,000 more exotic creatures in the city's zoo. The ranches of humorist Will Rogers in Pacific Palisades and silent film cowboy-actor William S. Hart in Newhall have been preserved as public parks. Within easy reach of the city by freeway are such commercial ventures as Disneyland, Japanese Village and Deer Park, Knott's Berry Farm and Ghost Town, Marineland of the Pacific, and Magic Mountain.

*Sports.* Intercollegiate athletics is highlighted by the intense USC-UCLA rivalry. The annual New Year's Day Rose Bowl football game is played in Pasadena. Angelenos also support professional major league teams in baseball, football, basketball, and ice hockey. There is horse racing at Santa Anita and Hollywood Park.

*Historic landmarks.* Angelenos have held onto little of their Spanish-Mexican past, but through the efforts of Charles F. Lummis, a colourful turn of the century editor and writer, the missions of San Gabriel (1771) and San Fernando (1797) have been preserved. Olvera Street, a narrow, block-long string of Mexican shops, cafés, and

the Ávila family's adobe townhouse (c. 1818), has been a popular tourist attraction since its opening in 1930. It is now part of El Pueblo de Los Angeles State Historical Monument, a 40-acre area that includes the plaza where the city got its start and the first church its residents managed to build (dedicated in 1822, rebuilt in 1861-62).

The three Watts Towers (99, 97, and 55 feet high) in the Watts section were built of broken tiles, dishes, bottles, and seashells over a 33-year period by Simon Rodia, an unschooled Italian immigrant who later explained, "I had in mind to do something big, and I did." When his work was completed in 1954, he gave the property to a neighbour and left, never to return. The towers have been hailed by art critics around the world as a major achievement of 20th century American folk art. One of the astonishing delights of downtown Los Angeles is the Bradbury Building (1893). Sunlight warms and illuminates the five-story inner court with its delicate French ironwork, Belgian marble, and Mexican tile.

*The living and preserved arts.* Los Angeles from time to time has sheltered such distinguished architects, composers, and writers as Frank Lloyd Wright, Igor Stravinsky, Arnold Schoenberg, Thomas Mann, F. Scott Fitzgerald, and Aldous Huxley. The city has been the subject of innumerable novels, the most durable of which appear to be those by Raymond Chandler, Fitzgerald's *Last Tycoon* (1941), Huxley's *After Many a Summer Dies the Swan* (1940), Evelyn Waugh's *Loved One* (1948), and Nathanael West's *Day of the Locust* (1939).

Los Angeles has developed a lively marketplace for works of art. Many of its leading galleries are scattered along La Cienega Boulevard, a popular promenade between Hollywood and Beverly Hills noted for its restaurants and its rare-book shops. The city draws primarily on New York City for its opera and on London, Copenhagen, and Moscow for its ballet, but it supports its own philharmonic orchestra, and chamber music is plentiful.

Other performing arts are magnificently housed in the Music Center of Los Angeles County, which includes a 3,250-seat pavilion for symphony and opera; a 2,100-seat theatre for plays, musical comedy, and light opera; and a 750-seat forum for experimental stage productions, chamber music, and intimate opera. The Hollywood Bowl, a natural amphitheatre in the Hollywood Hills, offered its first production, *Julius Caesar*, on May 19, 1916, and initiated its programs known as Symphonies Under

The performing arts

the Stars in 1922. The out-of-doors Greek Theatre (1930) in Griffith Park provides a wide range of summer entertainment, mostly musical. Small, innovative theatres continue to spring up around the city as such old standbys as the Pasadena Playhouse darken their stages.

Among other exhibits, the county's Museum of Natural History in Exposition Park displays artifacts of Hollywood's early days and skeletons of Hancock Park's prehistoric predators. The Southwest Museum in Highland Park contains a superb collection of American Indian materials. The observatory in Griffith Park has a planetarium and a twin refracting telescope available for public use. The Mount Wilson Observatory is north of Pasadena; it has the world's first 100-inch telescope, completed in 1917.

Museums,  
galleries,  
and  
libraries

The county's \$12,000,000 Museum of Art (1965) seems to float in a black pool next door to the tar pits in Hancock Park. The Municipal Art Gallery in Barnsdall Park occupies Hollyhock House (1918-20), designed by Frank Lloyd Wright. The J. Paul Getty Museum, in Malibu, features Greek and Roman statuary and rare paintings and tapestries by Dutch and Italian masters. Tourists often overlook the charming sculpture garden on the UCLA campus, with works by Jacques Lipchitz, Henri Matisse, Henry Moore, and Auguste Rodin, but they have beaten a path to nearby San Marino to see Thomas Gainsborough's "The Blue Boy" and Sir Thomas Lawrence's "Pinkie" at the Henry E. Huntington Library and Art Gallery.

Other treasures at the Huntington, a centre for scholarly research, include a Gutenberg Bible, the Ellesmere Chaucer, and the original manuscript of Benjamin Franklin's autobiography. The city's central library (1926) was the last building designed by Bertram Goodhue. The county's law library is unequalled in the American West. One of the world's finest collections of the works of Leonardo da Vinci is at UCLA's research library, 13th in size among the nation's academic libraries. Its William Andrews Clark Memorial Library has major collections covering English cultural history between 1650 and 1750.

#### THE CHANGING FACE OF THE CITY

*Building and rebuilding.* The 28-story city hall (1928) dominated the Los Angeles skyline until 1957, when the municipal building code's 13-story (150 feet) height limit was lifted. Towering structures began to spring up in the central city and spread westward along Wilshire and Sunset boulevards. By 1970 there were 17 buildings in Los Angeles exceeding 300 feet in height.

Bunker Hill, a fashionable residential area at the turn of the century, had become a downtown slum in the 1940s when Raymond Chandler wrote of the pensioners holed up in its dilapidated Gothic mansions: "On the wide cool front porches, reaching their cracked shoes into the sun, and staring at nothing, sit the old men with faces like lost battles." Now brisk, successful lawyers, stockbrokers, and government officials live in skyscraper apartments on the levelled hill, within walking distance of the county courthouse, the local bourse, and a massive civic centre described as "the greatest concentration of government buildings outside of Washington, D.C."

*Environmental ravages.* Los Angeles had 130 professional planners on its payroll in the early 1970s, more than any other city in the U.S., but it still had no general plan. A prisoner of its past, the city remained a captive of the promoters, moneylenders, builders, and speculators who continued to shape its growth. With the blessing of a city council and city-planning officials generally sympathetic to what Angelenos have been reared to regard as "progress," the developers were busy mutilating the Santa Monica Mountains, flinging up high-rise buildings at random, and converting the softly rounded hills of the San Fernando Valley into a monotonous expanse of subdivisions and shopping centres.

Although their automobiles account for 80% of their smog, Angelenos refuse to press for a modern mass-rapid-transit system. Pollution follows them when they go deep-sea fishing. The city pours 340,000,000 gallons

(1,000,000 cubic metres) of sewage into the ocean on an average day, two-thirds of which has received only primary treatment. In the course of a year Angelenos discard 145,000 tons of newspaper and cardboard, the equivalent of nearly 2,500,000 trees.

"We cannot continue as if growth can go on forever," the mayor's council on environmental management reported in 1971, shortly after the planning department had suggested that the city's population in the next 50 years might be held to 5,000,000 rather than swell to the projected 10,000,000, a figure that some officials viewed with equanimity, others with alarm. The environmental advisers called on city fathers to "accept the fact that there is a limit to how many people this basin can support." The city faces "the most crucial period in its history," the report warned, echoing a plea Aldous Huxley made to a magazine writer in 1962: "You must tell people they don't have much time."

**BIBLIOGRAPHY.** There is no single comprehensive book on Los Angeles. Three standard works, although dated, are still indispensable: J.M. GUINN, *A History of California and an Extended History of Los Angeles and Environs*, 3 vol. (1915); CAREY MCWILLIAMS, *Southern California Country: An Island on the Land* (1946); and FEDERAL WRITERS' PROGRAM, *Los Angeles: A Guide to the City and Its Environs*, 2nd ed. rev. (1951). The first 40 years as a city are covered in two classic studies: ROBERT GLASS CLELAND, *The Cattle on a Thousand Hills: Southern California, 1850-1880*, 2nd ed. (1951); and GLENN S. DUMKE, *The Boom of the Eighties in Southern California* (1944); and in two recent works: LEONARD PITT, *The Decline of the Californios: A Social History of the Spanish-Speaking Californians, 1846-1890* (1966); and ROBERT M. FOGELSON, *The Fragmented Metropolis: Los Angeles, 1850-1930* (1967).

Three early-day Angelenos have left invaluable recollections: HORACE BELL, whose *Reminiscences of a Ranger* (1881) should be read with caution; HARRIS NEWMARK, *Sixty Years in Southern California, 1853-1913*, 4th ed. rev. (1970); and BOYLE WORKMAN, *The City That Grew* (1936). One of the most useful and captivating records of pioneer days is to be found in J. ALBERT WILSON'S compendium, *Reproduction of Thompson and West's History of Los Angeles County, California* (1880, reprinted 1959). Recent works include: RICHARD G. LILLARD, *Eden in Jeopardy; Man's Prodigal Meddling with His Environment: The Southern California Experience* (1966); REMI A. NADEAU, *Los Angeles: From Mission to Modern City* (1960); CHRISTOPHER RAND, *Los Angeles, the Ultimate City* (1967); W.W. ROBINSON, *Los Angeles: A Profile* (1968); WERNER Z. HIRSCH (ed.), *Los Angeles: Viability and Prospects for Metropolitan Leadership* (1971).

(J.D.W.)

## Lottery

A lottery is a scheme or procedure for distributing something (usually money or prizes) among a group of people by lot or chance. The type of lottery that is the subject of this article is a form of gambling in which a usually large number of people purchase chances, called lottery tickets, and the winning tickets are drawn from a pool composed of all tickets sold (sweepstakes) or offered for sale. The value of the prizes is the amount remaining after expenses—including the profits for the promoter, the costs of promotion, and the taxes or other revenues—are deducted from the pool; in most large-scale lotteries a very large prize is offered along with many smaller ones. Lotteries have a very wide appeal as a means for raising money; they are simple to organize, easy to play, and, in general, popular but controversial.

**History of lotteries.** The practice of determining the distribution of property by lot is traceable to ancient times. Dozens of references can be found in the Bible to the practice. In one example from the Old Testament (Num. 26:55-56), the Lord instructed Moses to take a census of the people of Israel and to divide the land among them by lot. The Roman emperors Nero and Augustus used lotteries to give away property and slaves during Saturnalian feasts and other entertainments. (See also references to the casting of lots in the article GAMBLING.) Modern lotteries of a similar type include those used for military conscription, commercial promotions in which property is given away by a random procedure, and the selection of jury members from lists of

registered voters. Under the strict definition of a gambling type of lottery, however, payment of a consideration (property, work, or money) must be made for a chance of receiving the prize.

*Early Europe.* The first European records of such lotteries are from 15th-century Burgundy and Belgium and reveal that towns attempted to raise money for such purposes as fortifying their defenses or aiding the poor. Francis I of France permitted the establishment of lotteries for private and public profit in several cities between 1520 and 1539. The first public lottery to have paid money as prizes is believed to be *La Lotto de Firenze* in Florence in 1530. This was such a successful enterprise that the practice quickly spread to other Italian cities. When the Italian nation was united, the first national lottery was created in 1863, with regular (weekly) drawings organized for the purpose of providing income for the state. *Lotto*, the Italian National Lottery, is regarded as the basis for such modern games as Policy, the Numbers Game, Lotto, Keno, and Bingo.

Queen Elizabeth I chartered a general lottery in England in 1566 for the purposes of raising money for repairing harbours (of the Cinque Ports) and other public purposes. In 1612 the Virginia Company obtained permission from James I for a lottery to help in financing the settlement of Jamestown in the New World. While several lotteries organized by the company did not erase a desperate need for funds and although businessmen in some English towns complained of difficulties related to them, they were nevertheless thought to be the "first and most certain" way to obtain funds. Lotteries accounted for almost half of the yearly income of the company by 1621 when, as a result of bitter dissension within the company itself, the company's lotteries were finally prohibited by the House of Commons. In 1627 a series of lotteries was licensed to raise money for the building of an aqueduct for London, and, in fact, except for a ban from 1699 to 1709, lotteries were held in England until 1826.

*Problems and abuses.* Some important problems developed in the manner of conducting lotteries in England in the 17th and 18th centuries. These were to affect public opinion and official attitudes in Britain and America to the present day. For most of that period lotteries were the only form of organized gambling available to the people; they were intensively advertised by such promotions as torchlight processions in the streets; contractors would often manage to purchase tickets at less than the standard prices for subsequent resale at excessive markups; and a type of side bet was popularized called insurance—a small wager that a ticket would or would not be drawn in the regular lottery. The state could not derive revenues from either of the latter two practices, but dishonest private operators could. Also, it was claimed that lotteries encouraged mass gambling and that drawings were fraudulent. Their abuses strengthened the arguments of those in opposition to lotteries and weakened their defenders, but before they were outlawed in 1826, the government and licensed promoters had used lotteries for all or portions of the financing of such projects as the building of the British Museum and the repair of bridges, plus many projects in the American colonies, such as supplying a battery of guns for the defense of Philadelphia, rebuilding Faneuil Hall in Boston, and, in a lottery managed by George Washington, the building of the road over the Cumberland Mountains.

*Lotteries in America.* It was natural for the Continental Congress in 1776 to vote to establish a lottery to try to raise funds for the American Revolution. The scheme was abandoned, but over the next 30 years the practice continued of holding smaller public lotteries, which were seen as mechanisms for obtaining "voluntary taxes" and helped build several American universities: Harvard, Dartmouth, Yale, King's College (now Columbia), William and Mary, Union, and Brown. Privately organized lotteries also were common in England and America as means for merchandisers to sell products or properties for more money than could be obtained from a regular sale. By 1832 lotteries had become very popular indeed;

the *Boston Mercantile Journal* reported that 420 had been held the previous year in eight states.

Abuses by private organizers continued, however, and once again voices of opposition began to dominate. In 1827 postmasters and their assistants were barred from selling lottery tickets. Most of the states began legislating antilottery laws. In 1868 Congress declared it unlawful to use the mail for letters or circulars concerning lotteries ". . . or other similar enterprises on any pretext whatever." This prohibition included a very strict definition of what could be allowed to travel through the mails, and the restriction was supported by an opinion of the Supreme Court in 1878 that held lotteries to have "a demoralizing influence upon the people."

The postal rules did not have an immediate effect in eliminating lotteries, for the most successful one in America was organized in Louisiana in 1869 and ran continuously for 25 years. Agents for the Louisiana Lottery were located in every city in the United States; the total sales per month were \$2,000,000 at its peak; monthly drawings generated prizes up to \$250,000, and twice-yearly prizes could go as high as \$600,000. In 1890 Pres. Benjamin Harrison and Congress agreed in condemning lotteries as "swindling and demoralizing agencies" and prohibited the interstate transportation of lottery tickets. The Louisiana Lottery, the last state lottery in America until 1963 (New Hampshire), was killed, but not until it had acquired both enormous profits for its (private) promoters and a reputation for bribery and corruption.

*France and Ireland.* The history of lotteries in several European countries was roughly similar to those of England and America but not to that of Italy. In France, lotteries became increasingly popular after their introduction by Francis I in the 1500s. Their general appeal lasted until the 17th century, when Louis XIV and several members of his court managed to win the top prizes in a drawing—an event that seems to have generated some suspicion and resulted in the King's returning the money for redistribution. Perhaps this occasion was a turning point for French lotteries; in any event, they were abolished in 1836. Almost a century later (1933) a new *Loterie nationale* was established, closed just before World War II (probably because the state was receiving only 1.4 percent of the turnover), and later reopened. The state in the early 1970s was receiving 32 percent.

In the 1930s also, the Irish Hospitals' Sweepstake was established and a pattern set for the modern, highly organized lotteries of the 20th century. Yet the pattern of the sweepstakes was not very different from the state lotteries of Georgian England or 19th-century Europe.

*Modern lottery operations.* The basic elements of lotteries are usually quite simple. First, there must be some means of recording the identities of the bettors, the amounts staked by each, and the number or other symbol on which the money is bet. The bettor may write his name on a ticket that is deposited with the lottery organization for subsequent shuffling and possible selection in the drawing. Or the bettor may buy a numbered receipt, in the knowledge that this number will be entered into a pool of numbers, the bettor having the responsibility of determining later if his ticket was among the winners. Another procedure requires only that the bettor inform a representative of the lottery which number, usually up to three digits, he guesses will be drawn, and the representative is trusted to appear later with the prize, if any is won. This is the usual procedure in the Numbers Game, which has been popular for several decades in several large American cities.

The Numbers Game is defined in state laws as an illegal lottery. Hence for it to be carried on, other illegal practices, especially bribery of the police, must accompany it; it is often referred to as a racket.

A second element of all lotteries is the drawing, a procedure for determining winning numbers. This may take the form of a pool or collection of tickets or their counterfoils from which the winners are extracted. The tickets must first be thoroughly mixed by some mechanical means as shaking or tossing. This is a randomizing procedure designed to insure, in an honest lottery, that chance and

First

winners

only chance determines the selection of winners. Computers have come increasingly into use for this purpose, because of their capacity for storing information about large numbers of tickets and also for generating random numbers for identifying the winners. The Numbers Game follows special procedures for identifying winners that are both random and public. Under one method the amounts paid by winning horses in two or three races at a nearby racetrack are added together to produce the winning number. Under other methods, the "number" may be three digits from the total volume of stock-exchange transactions, from daily bank clearances, or from United States Treasury balances, or from other published figures.

Policy, similar to numbers, differs in that the winning numbers are determined by a drawing of pellets numbered 1 to 78 that have been whirled in a drum-shaped wheel (the "Policy Wheel"). Twelve of the pellets are drawn, and bets are made that three, four, or five particular numbers will be drawn. Bolita, a lottery similar to Policy, is played in Puerto Rico and, in the United States, among Cuban and Puerto Rican groups. The drawing is of one numbered ball from a sack of balls numbered 1 to 100.

Promoters of public, especially of large-scale, lotteries may exploit the opportunity to make the drawing and mixing process as colourful and dramatic as possible. Drawings such as those held by the Irish Sweepstakes may be combined with horse racing in which two drawings are held, one to identify winning numbers and another to associate those numbers with the names of horses entered in a major race; the success of the individual horses then determines the final order of the prizes.

A third element is the existence of a mechanism for collecting and pooling all the money placed as stakes. This is usually accomplished by a hierarchy of sales agents who pass money paid for the tickets up through the organization until it is "banked." A practice common in many national lotteries is to divide tickets into fractions, usually tenths. Each fraction if and when it is sold separately costs slightly more than its share of the total cost of an entire ticket. Many people then buy whole tickets, in effect at a premium or discounted price, for marketing in the streets where customers can place relatively small stakes on the fractions. In a large-scale lottery, the use of the regular mail system is desirable for communicating information and transporting tickets and stakes. In the United States and some other countries, however (see above), postal rules prohibit use of the mails. Postal prohibitions apply also to international mailings of lotteries. Though post-office authorities are diligent, it is clear that much smuggling and other violation of interstate and international regulations occurs.

A fourth requirement is a set of rules determining the frequencies and sizes of the prizes. Costs of organizing and promoting the lotteries must be deducted from the pool, and a percentage normally goes as revenues and profits to the state or sponsor. Of the remainder available for the winners, a decision must be made on whether to pay few large prizes or many smaller ones. Potential bettors seem to be attracted to lotteries that offer very large prizes, but in some cultures they also demand a chance to win smaller ones (which, typically, are wagered again in the next round). Authorities on lotteries disagree about which of these choices is better for the welfare of the people and the economic success of the lottery. The amount of the pool returned to the bettors tends to be between 50 percent and 60 percent. The Numbers Game usually returns 54 percent to winners.

**Distribution of modern lotteries.** The list of countries that have state lotteries or license large-scale private ones is long and not limited by religious restrictions or geographical location. It includes many African and Near Eastern states, most European countries, all the Communist countries of eastern Europe and the Soviet Union itself, most Latin American countries, Japan, Australia, and several countries on the Asian mainland, but not the People's Republic of China and India (which permits "small" lotteries). It also includes three states of the United States—New Hampshire, New York, and New Jersey. Although religious traditions may have delayed

the establishment of lotteries in many countries, it is clear they no longer suppress them entirely. Communist countries attempted for a few decades to reject public gambling institutions as decadent and anti-Marxist, but now only privately organized gambling appears to be in disfavour.

Australia, however, has been called the real home of the state lottery. There, all the states except South Australia conduct lotteries for financing public programs and projects. New South Wales, which had lotteries as early as 1849, has the largest, with sales of more than 1,000,000 tickets a week; it has financed, among other things, the spectacular Sydney Opera House (completed in the early 1970s). New South Wales also raffles houses, cars, and similar prizes on a scale unequalled anywhere in the world.

**Resistance to lotteries.** In view of the worldwide adoption of lotteries, the resistance offered by England and most of the United States seems anachronistic. Both may be given a closer look.

*England.* Repeatedly in the recent past, Parliament and the London County Council have debated bills to institute national or county lotteries. These bills have always been rejected, but not easily. Perhaps of most relevance is the fact that many other gambling activities flourish in England. Indeed, so much gambling had been successfully promoted by 1967 that the Home Secretary complained that England had "become a gambler's paradise more wide open than any comparable country." Moreover, many forms of gambling played by Britishers are themselves either variations of ordinary lotteries or closely resemble them, including Bingo, which is extremely popular among a very large percentage of the British working class, and football (soccer) pools, which are ordinarily played in such a manner that they resemble lotteries in that they depend entirely on chance to identify several draws (tries) out of all the professional soccer games to be played on a given Saturday. A large percentage of Britain's adults play the pools weekly. The premium bonds also are in fact a special variety of national lottery. Purchasers of premium bonds do not collect regular interest, but, instead, raffles are held each month to distribute prizes—all of the interest that would ordinarily be evenly distributed—among a small percentage of the bond holders.

With all these forms of gambling activities, in addition to the fact that horse racing and many other forms of gambling have long been popular, it is not surprising that prolottery bills have failed to pass.

*United States.* American legislators have also feared that legalizing new forms of gambling would only increase the total amount rather than compete with less desirable forms. American public opinion has been sharply divided on the desirability of lotteries. The combination of America's Puritan heritage, its history of cheating and criminal involvement in gambling, and its distrust of foreign practices all appear to be important factors.

Readers are directed to the bibliography for analyses of arguments for and against lotteries.

## Louis I the Pious, Emperor

It was the destiny of Louis I, who inherited the undivided Frankish empire from his illustrious father, Charlemagne, to preside over the Frankish domains during a turbulent period that was decisive in the eventual breakup of the empire. Louis was born in 778 at Chasseneuil, near Poitiers, Aquitaine, the fifth child of Charlemagne's second

payoffs

wife, Hildegard the Swabian. From 781 until 814 Louis ruled Aquitaine with some success, though largely through counsellors. When Charlemagne died at Aachen in 814 and was succeeded by Louis, by then his only surviving legitimate son, Louis was well experienced in warfare; he was 36, married to Irmengard of Hesbaye, and was the father of three young sons, Lothair, Pepin, and Louis (later, Louis the German); he had inherited vast lands, which seemed to be under reasonable control; there was no other claimant to the throne; and on September 11, 813, shortly before his father's death, Louis had been crowned in Aachen as heir and co-emperor.

By courtesy of the Österreichische Nationalbibliothek, Vienna

Louis I the Pious, portrait from *Hrabanus Maurus*, manuscript of the Fulda School, 831–840. In the Österreichische Nationalbibliothek, Vienna (Codex 652).

Louis' first task was to carry out the terms of Charlemagne's will. According to the Frankish chronicler Einhard, Louis did this with great scrupulousness, although other contemporary sources tell a different story.

Louis next began to allocate parts of the empire to the various members of his family, and here began the difficulties and disasters that were to beset him for the remainder of his life. In August 814 he made Lothair and Pepin nominal kings of Bavaria and Aquitaine. He also confirmed Bernard, the son of his dead brother Pepin, as king of Italy, which position Charlemagne had allowed him to inherit in 813. But when Bernard revolted in 817, Louis had him blinded, and he died as a result of it. Louis sent his sisters and half sisters to nunneries and later put his three illegitimate half brothers—Drogo, Hugo, and Theodoric—into monasteries.

At the assembly of Aachen in July 817, he confirmed Pepin in the possession of Aquitaine and gave Bavaria to Louis the German; Lothair he made his co-emperor and heir. Charlemagne had been in his 70s and within a few months of death before naming his heir, and for Louis to give such premature expectations to a youth of 22 was to ask for trouble. Moreover, Louis did not anticipate that he would become father of another child: the empress Irmengard died in 818; and four months later Louis married Judith of Bavaria, who, in June 823, bore him a son, Charles (Charles the Bald), to whom the Emperor gave Alemannia in 829.

Backed by his two brothers, Lothair rose in revolt and deposed his father. The assembly of Nijmegen in October 830, however, restored Louis to the throne; and, the following February, at the Assembly of Aachen, in a second partition, Lothair was given Italy. In 832 Louis took Aquitaine away from Pepin and gave it to Charles. The three brothers revolted a second time, with the support of Pope Gregory IV, and at a meeting near Sigolsheim, in Alsace, once more deposed their father. In March 834 Louis was again restored to the throne and made peace with Pepin and with Louis the German. Later in 834,

Lothair rose again, but alone; Lothair retreated into Italy. Encouraged by his success, Louis made over more territories to his son Charles at the assemblies of Aachen and Nijmegen (837–838)—a move the three brothers accepted, but with bad grace. In 839 Louis the German revolted but was driven back into Bavaria.

Meanwhile, Pepin had died (December 838), and, at the assembly of Worms (May 30, 839), a fourth partition was made, the empire being divided between Lothair and Charles, with Bavaria left in the hands of Louis the German. Toward the end of 839 Louis the German marched his troops for the last time against his father, who once more drove him back. The Emperor called an assembly at Worms on July 1, 840. Before it could meet, however, Louis the Pious died at Petersaue, an island in the Rhine near Ingelheim (June 20, 840). He was 62 and had ruled for nearly 27 years. He was buried in the Church of St. Arnulf in Metz by Bishop Drogo, his half brother.

The empire he had inherited in peace, Louis left in disarray. He had engaged in no serious external conflict, although the Danes and others had continued to make inroads into the empire. From 829 his four sons had been a constant source of disruption; the quarrels among Lothair, Louis the German, and Charles the Bald were to continue for decades after his death. In many ways Louis seems to have been an estimable person. He was presumably given the epithet the Pious because of his devoutness, his liberality to the church, his interest in ecclesiastical affairs, and the good education he had received. Contemporary historians vary little in their judgment: the Astronomer of Limousin stresses his continued courage in the face of adversity; Thegan, bishop of Trier, gives a long and admiring description of his person, his talents, his Christian charity, his devoutness, and his skill as a hunter; and the poem of Ermoldus Nigellus is full of adulation.

Like his father Charlemagne, Louis the Pious is depicted in several of the chansons de geste of the 12th century, notably the *Chanson de Guillaume*, the *Couronnement de Louis*, and the *Charroi de Nîmes*: he appears as a kindly ruler, but a weak and vacillating one.

**BIBLIOGRAPHY.** An excellent study of Louis the Pious in English is that of RENE POUPARDIN in the *Cambridge Medieval History*, vol. 3, ch. 1 (1922), with bibliography.

(L.T.)

## Louis IV, Emperor

Louis IV the Bavarian, Holy Roman emperor of the House of Wittelsbach from 1328, was duke of Bavaria for 46 years and king of Germany for 32. His rule marks the end of the rivalry between emperor and pope as universal authorities and heralds the change from universal domain to the power state.

Louis was born in 1283(?), probably in Munich. As the younger son of Louis II, count Palatine and duke in Upper Bavaria, Louis had no claim to the crown by birth. On his father's death in 1294, the 11-year-old boy was made a ward of his brother Rudolf, who was then 20, and of his mother, Mechthild, a Habsburg and a daughter of King Rudolf I. Louis immediately found himself involved in high politics; his brother took the side of King Adolf of Nassau and his mother that of her brother, Albert I of Austria, who was attempting to depose Adolf. Keeping her son out of Munich, she sent him to her brother's court in Vienna, where he was reared, together with his Habsburg cousins, Frederick and Leopold. This circumstance no doubt had a lasting effect on Louis, though he never let political decisions be influenced by family ties. Albert's victory over Adolf of Nassau at Göllheim (July 2, 1298) allowed Louis to assume the share in the government that was his by law but that his older brother had hitherto withheld from him. The rivalry between the brothers, which had flared up again after the assassination of King Albert (1308), ended in 1310 with a partition of territories, which Louis was able to impose on the strength of being the guardian of his Lower Bavarian cousins. But the traditionally anti-Austrian attitude of Lower Bavaria led to a quarrel with the Habsburgs. Having assured himself of his brother's goodwill by means of a compromise (June

21, 1313), Louis gained a decisive victory over the Habsburgs at Gammelsdorf (November 9), while the succession to the German crown, fallen vacant with the emperor Henry VII's unexpected death on August 24, was still the subject of negotiations.

The empire had become an elective monarchy, but counts no longer figured among the candidates. The houses of Habsburg and Luxembourg (Luxemburg), risen to the rank of major German powers as a result of acquiring Austria (1282) and Bohemia (1310), respectively, contended for the throne; had it not been divided into warring lines, the House of Wittelsbach might have been a third contender. On the strength of his victory, Louis, in 1314, became the candidate of the Luxembourgs, who had failed to gain the crown for John of Bohemia, the late emperor's son. The Habsburgs, however, would not acknowledge Louis, though he was grandson of King Rudolf; in the double election of October 19–20, 1314, Louis gained little advantage from the fact that his claims were rather more substantial than those of the anti-king, Frederick III of Austria, crowned on the same day, November 25. Military successes enabled Louis to wrest exclusive control over Upper Bavaria and the Rhenish Palatinate from his brother, who had voted against him; but a permanent settlement with the latter's descendants could be made only after the death of Rudolf, his widow Mathilde of Nassau, and his oldest son, Adolf. The dynastic Compact of Pavia (1329), dividing the House of Wittelsbach into a Bavarian and a Palatinate line, enabled Louis to gain the latter line's support in matters of imperial policy. He failed, however, to achieve a lasting understanding with his Lower Bavarian cousins; that conflict was not settled until this line became extinct in 1340.

Louis' struggle with the Habsburgs

Louis' most pressing problem was the struggle with the Habsburgs. The decisive battle was fought on September 28, 1322, at Mühlendorf, where Louis gained victory, taking prisoner King Frederick with his brothers. By April 1323 he could risk investing his oldest son, Louis, still a minor, with the Margravate of Brandenburg, which had been in abeyance since 1319. Territorial aspirations motivated the conclusion of a hereditary alliance with the House of Wettin as well as Louis' second marriage, to Margaret of Holland (1324), which in 1345 led to the accession of Holland and its dependencies. These successes did not sit well with John of Bohemia, who refused to be pacified either by the donation of Upper Lusatia in 1320 or by the marriage of Duke Henry the Elder of Lower Bavaria with a Luxembourg the following year, or by the acquisition, by way of collateral, of the Egerland. Luxembourg finally allied itself with France, and this move, in turn, led to an increased hostility toward Louis on the part of the Pope, who was wholly under French influence.

Pope John XXII had taken advantage of the contest for the crown of Germany to appoint Robert of Naples imperial vicar in Italy *vacante imperio* (in the absence of a Holy Roman emperor) and to threaten the Italian Ghibellines with heresy proceedings. When Louis' own imperial vicar forced the Pope and Robert to raise the siege of Milan, the heresy proceedings were extended to Louis himself, who was excommunicated in March 1324. This interdiction, never lifted, exposed Louis' adherents to a conflict of conscience while providing his enemies with a convenient excuse for disobedience. In the eyes of the Curia and of his other enemies, he was thenceforth merely Ludovicus Bavarus, Louis the Bavarian, by which name he lives on in history.

Louis hit back with several proclamations of his own, notably, the so-called Sachsenhausen Appellation of May 22, 1324, in which the charge of heresy was turned against the Pope. The argumentation ill-advisedly dealt with constitutional problems touching on the empire as well as with doctrinal points. Louis quickly acknowledged this as a mistake and softened its effect, but at this time the Austrians also joined the alliance of France and Luxembourg (July 27, 1324). Louis broke up the hostile combination by agreeing to share the rule with his prisoner Frederick; even so, he overcame Duke Leopold's objections only by further agreeing (January 7,

1326) to abdicate altogether, provided that the Pope gave his approbation to Frederick's sole rule. There was little likelihood of that because the Curia was interested in perpetuating the rivalry for the German crown. Its reaction proved to Frederick that he had been callously used; he now became a loyal co-ruler with Louis.

When Duke Leopold died in February 1326, Louis boldly opposed the Pope in Italy itself. Supported by the Ghibellines, he accepted the iron crown of Lombardy in Milan (May 31, 1327) and the imperial crown in Rome (January 11, 1328), offered by the representatives of the Roman populace. This unusual move could be considered an emergency measure because the Pope had refused to crown the designated emperor, declaring him a heretic on purely political grounds.

Acceptance of the imperial crown

Louis let himself be persuaded to depose the Pope formally by a decree of April 18, 1328, and to countenance the appointment of an antipope whose incompetence furnished John XXII with an easy triumph. Moreover, Louis' forces were insufficient to subjugate Robert of Naples or to institute a stable order in Italy, for which he lacked the necessary prerequisite of a firm hold on Germany. Turning to the north again, he celebrated Christmas of 1329 in Trent, whence he had departed for Italy in February 1327.

King Frederick died on January 13, 1330. The problem of shared rule was thus solved. Yet Louis' German enemies had not been idle. John of Bohemia had arranged the marriage of his younger son, John Henry, with Margaret, the heiress of Carinthia-Tirol, in 1330. This caused Louis to enter into a secret covenant with the Habsburgs regarding the partition of this strategically important inheritance (May 31, 1331). He thus encircled John of Bohemia, forcing him to withdraw from Italy, where he had ensconced himself in the guise of an imperial vicar. In order to confuse his enemies, Louis issued a new decree of abdication, hedged with countless provisos, on November 19, 1333; this time he proposed to renounce the throne in favour of his Lower Bavarian cousin Henry. The death of Duke Henry of Carinthia-Tirol in 1335 compelled Louis to invest the Habsburgs with Carinthia, by way of carrying out his part of the secret compact; he also granted them southern Tirol in order to save at least the northern part for himself. But the Habsburgs, in their eagerness to secure Carinthia, concluded an agreement behind his back with Luxembourg, which thus acquired the whole of the Tirol. As a result, the influential Archbishop of Mayence came over to Louis' side (June 29, 1337), and Edward III of England made a treaty with him (August 26), thus proving that Louis was a desirable ally on the international plane.

The Germans, tired of the incessant quarrels over the crown, were disconcerted by the Pope's intransigence. Through their city magistrates and other representatives, they pressed for legitimization of Louis' rule and the rejection of papal interference. When Louis issued a statement of principle regarding the accession to the imperial throne before the Frankfurt Diet (*Fidem catholicam* of May 17, 1338), he had the support not only of the cities but also of the empire's ecclesiastical lords. He used this support in promulgating a basic electoral law (*Licet juris*) in Frankfurt (August 3) and again in Coblenz, where he met the King of England and bestowed on him an imperial vicarate on the Lower Rhine. The promulgation, however, remained an empty gesture because the electoral princes, while assembled at Rhens on July 16, had rejected the Pope's claims without declaring themselves in favour of Louis and withheld their approval. The conflict over the crown and the charge of heresy thus continued to smolder. By isolating John of Bohemia and issuing a formal waiver of his own claims to the Tirol, Louis managed nonetheless to force John to renounce all claims to Italy, to declare himself a vassal, and to acknowledge Louis emperor in 1339.

Seeing that the entire clergy of the empire, except for the border bishoprics of Liège and Cambrai, had submitted to his rule and that the English held out the prospect of subsidies, Louis had reason to hope that he could confront the French in battle and thereby make the Pope

yield. When Edward III declared war on France on September 1, 1339, and had himself acknowledged as king of France in Ghent on January 27, 1340, Louis was in a position to arbitrate between England and France. But the Tirolean question spoiled everything. In November 1341 Margaret expelled her Luxembourg husband; whereupon Louis, declaring that the marriage had not been consummated and was therefore void, married her with ill-considered haste to his widowed son, Louis of Brandenburg, on February 10, 1342. This created an unfavourable impression throughout the empire. Worse, it led to the final rupture with Luxembourg and to Charles of Moravia declaring himself a candidate for the imperial crown now that the King of France, at war with England, was eliminated as a pretender. Louis vainly attempted to propitiate the Luxembourgs by the cession of Lower Lusatia and by the offer of one of his daughters in marriage. They negotiated with him but at the same time encouraged the new, intensely nationalistic French pope to renew the heresy proceedings against him and to demand a new election (August 1343). Once more Louis countered by offering to abdicate, this time in favour of his son, Louis of Brandenburg-Tirol (September 1343). The Luxembourgs maintained the negotiations until Charles of Moravia, who had granted excessive concessions to the Pope, gained all electoral votes except the two of the House of Wittelsbach and thus was elected king (July 1346). Preparing himself for the war that had become inevitable, Louis died of a heart attack while bear hunting near Munich on October 11, 1347.

Louis had wanted to raise his family to royal status, such as the houses of Habsburg and Luxembourg. But he failed to achieve the major prerequisite—the wedding of his family into a uniform body motivated by a single political will. He strove for this unity with all the diplomatic and juridical means at his disposal, and the Upper Bavarian law code of 1346 (first formulated about 1335) remains a monument to these efforts. For, while Charles IV did what he could to erase Louis' memory within the empire, Charles' famous edict, the Golden Bull of 1356, represents only the final codification of fundamental imperial laws that had actually evolved under Louis. This codification enabled the empire to stand up to the juridically minded church of Avignon.

Louis possessed courage and tenacity without being rigid. He won men over by a jovial and chivalrous demeanour; and his suppleness, coupled with diplomatic skill, charmed them even as a certain mercurial quality made him appear unfathomable. He was a political man, whose guiding principle remained the *honor imperii*. Even in his darkest hours he brooked no interference with the imperial rights. It would be unfair to judge him solely by the yardstick of success. It was Louis' fate to come up repeatedly against adversaries who were talented and powerful.

**BIBLIOGRAPHY.** The documentary sources on Louis IV are extensive but have not yet been completely inventoried. Important summaries reflecting the current state of research are given by HERBERT GRUNDMANN, "Der Kampf um das Reichsrecht unter Ludwig dem Bayern," in BRUNO GEBHARDT, *Handbuch der deutschen Geschichte*, 9th ed., vol. 1, pp. 518-554 (1970); and on Louis IV as ruler, in articles by MAX SPINDLER and HEINZ ANGERMEIER in the *Handbuch der bayerischen Geschichte*, ed. by Spindler, vol. 2, pp. 104-137, 144-181 (1969), both with bibliographies. Important modern works include RUDOLF MOST, "Der Reichsgedanke des Ludwig d.B.," *Deutschen Archivs für Erforschung des Mittelalters*, vol. 4 (1941); CARL MUELLER, *Der Kampf Ludwigs des Baiern mit der römischen Curie*, 2 vol. (1879-80), fundamental for Louis' struggle with the Papal Curia, although partly out of date; H. LIEBERICH, "Kaiser Ludwig der Baier als Gesetzgeber," *Zeitschrift der Savigny-stiftung für Rechtsgeschichte, Germanistische*, 76: 173-245 (1959), on Louis as a legislator; and, in English, W.T. WAUGH, "Lewis the Bavarian," *Cambridge Medieval History*, vol. 7, ch. 4 (1932).

## Louis IX of France

Louis IX, or St. Louis, king of France from 1226 to 1270, remains the most popular of the Capetian monarchs, his

reign marking the high point of the ideal of kingship in the Middle Ages in Europe. His love of peace, his reputation for piety, and his concern for the poor made him one of the most celebrated figures of French history.

Giraudon

Saint Louis carrying the hand of justice, detail from the *Ordonnances de l'Hotel du Roi*, late 13th century. In the Archives Nationales, Paris.

Louis was born April 25, 1214, at Poissy in the modern *département* of Forêt des Yvelines. He was the fourth child of King Louis VIII and Queen Blanche of Castile, but, since the first three died at an early age, Louis, who was to have seven more brothers and sisters, became heir to the throne. He was raised with particular care by his parents, especially his mother.

Experienced horsemen taught him riding and the fine points of hunting. Tutors taught him biblical history, geography, and ancient literature. His mother instructed him in religion herself and educated him as a sincere, unbogoted Christian. Louis was a boisterous adolescent, occasionally seized by fits of temper, which he made efforts to control.

When his father, who succeeded Philip II Augustus, ascended the throne in 1223, the long struggle between the Capetian dynasty and the Plantagenets of England (who still had vast holdings in France) was still not settled, but there was a temporary lull, since the English king, Henry III, was in no position to resume the war. In the south of France the Albigensian heretics, who were in revolt against both church and state, had not been brought under control. Finally, there was ferment and the threat of revolt among the great nobles, who had been kept in line by the firm hand of Philip Augustus.

Louis VIII managed to bring these external and internal conflicts to an end. In 1226 Louis VIII turned his attention to quelling the Albigensian revolt, but he unfortunately died at Montpensier, November 8, 1226, on returning from a victorious expedition. Louis IX, who was not yet 13, became king, under the regency of the redoubtable Blanche of Castile.

**Accession to the throne.** The Queen Mother's first concern was to take Louis to Reims to be crowned. Many of the most powerful nobles refrained from participating in the ceremony, but Blanche was not a woman to be discouraged by adversity. While continuing her son's education she vigorously attacked the rebellious barons, particularly Hugh of Lusignan and Peter of Dreux (Pierre Mauclerc), duke of Brittany. Without support from King Henry III of England the baronial coalition collapsed, and the Treaty of Vendôme gave Blanche a brief respite.

She took advantage of it to put an end to the Albigensian revolt. Louis's troops were sent into Languedoc, where they forced Raymond VII, count of Toulouse, to concede defeat. On April 11, 1229, the King imposed the

The  
Tirolean  
question

Education

Treaty of Paris on Raymond, in accordance with the terms of which Raymond's daughter was to marry the King's brother Alphonse, and, after their deaths, all of Languedoc would revert to the royal domain. As a political debut it was a magnificent success. When the students at the University of Paris revolted for a trivial reason, Louis, on his mother's advice, closed the university and ordered the students and professors to disperse, thereby strengthening the royal authority.

The problem of the Plantagenet holdings in France remained. Supported by Peter of Dreux, Henry III attempted an expedition in the west of France and landed in Brittany. Louis IX, though only 15, personally commanded the troops. He ordered the château at Angers to be rebuilt and pushed toward Nantes, where Henry III was based. There was not even a battle, for, after a futile ride to Bordeaux, Henry withdrew. Truces were renewed, and Peter of Dreux submitted to Louis's authority.

When Blanche laid down the reins of government in 1234, the kingdom was temporarily at peace. Louis IX could now think about marriage. He was a splendid knight, tall and well-made, whose kindness and engaging manner made him popular. And he was a just king: although he exacted what was due him, he had no wish to wrong anyone, from the lowest peasant to the richest vassal. He often administered justice personally, either in the great hall of the Palais de la Cité, which he later endowed with a magnificent chapel, or in his Vincennes manor, where he assembled his subjects at the foot of an oak, a scene often recalled by his biographer Jean de Joinville, the good seneschal of Champagne. He was also a pious king, the protector of the church and friend of those in holy orders. In 1228 he founded the noted Abbey of Royaumont. Although respectful of the pope, he staunchly resisted unreasonable papal demands and protected his clergy.

Marriage

Blanche of Castile had selected Margaret, daughter of Raymond Berenger IV, the count of Provence, as Louis's wife. The marriage was celebrated at Sens, May 29, 1234, and Louis showed himself to be an eager and ardent husband, which made Blanche intensely jealous of her daughter-in-law. Louis and Margaret had 11 children.

After subduing Thibaut of Champagne, Louis IX had to set out again on the road for Aquitaine. This time the rebel was Hugh of Lusignan, who had married John's widow, the mother of Henry III. Once again Henry descended on the Continent, this time at Royan, with a powerful force. The majority of the nobles in the west of France united with him. An almost bloodless encounter at the bridge of Taillebourg in 1242 resulted in defeat for the English, and Henry returned to London. With each truce slightly more progress was made toward gaining a peace that would put a permanent end to this first hundred-year war between France and England.

**Leadership of the Sixth Crusade.** After his victory over the English, Louis IX fell seriously ill with a form of malaria at Pontoise-lés-Noyon. It was then, in December 1244, that he decided to take up the cross and go to free the Holy Land, despite the lack of enthusiasm among his barons and his entourage. The situation in the Holy Land was critical; Jerusalem had fallen into infidel hands on August 23, 1244, and the armies of the Sultan of Egypt had seized Damascus. If aid from the West was not forthcoming, the Christian kingdom of the east would soon collapse. In Europe the times had never been more propitious for a Crusade. There was a respite in the great struggle between the Holy Roman Empire and the papacy; moreover, Louis IX's forceful attitude toward the Holy Roman emperor, Frederick II, had dampened the latter's enthusiasm for war. The kingdom of France was at peace, and the barons agreed to accompany their sovereign in the Sixth Crusade.

Objective of the Crusade

The preparations were long and complex. After entrusting the regency to his mother, Louis IX finally embarked from Aigues-Mortes on August 25, 1248. He took his wife and children with him, since he preferred not to leave the mother and daughter-in-law alone together. His fleet was comprised of about 100 ships carrying 35,000 men. Louis' objective was simple: he intended to land in

Egypt, seize the principal towns of the country, and use them as hostages to be exchanged for Syrian cities.

The beginning was promising. After wintering in Cyprus, the expedition landed near Damietta, Egypt, in June 1249. The King was one of the first to leap onto land, where he planted the oriflamme of St. Denis on Muslim territory. The town and port of Damietta were strongly fortified, but on June 6 Louis IX was able to enter the city. He then pushed on toward Cairo, but the rain-swollen waters of the Nile and its canals stopped him for several months. It was necessary to capture the citadel of al-Manşūrah. After several attempts, a pontoon bridge was finally built, and the battle took place on February 8, 1250. The outcome of the struggle was for a long time undecided, and the King's brother Robert of Artois was killed. Louis finally gained control of the situation through his energy and self-possession.

But the army was exhausted. The Nile carried thousands of corpses away from al-Manşūrah, and plague struck the survivors. The King had to issue orders for the agonizing retreat toward Damietta. Louis IX, stricken in turn, dragged himself along in the rear guard of his disintegrating force. The Egyptians harassed the fleeing army and finally captured it on April 7, 1250.

Retreat and capture

After long negotiations, the King and his principal barons were freed for a high ransom, and Louis rejoined Margaret of Provence at Acre. The crusaders would have preferred to return to France, but the King decided instead to remain. In four years he was to transform a military defeat into a diplomatic success, conclude advantageous alliances, and fortify the Christian cities of Syria (see also CRUSADES). He returned to his kingdom only upon learning of his mother's death.

**Achievement of peace and administrative reforms.** The saintly Louis enjoyed immense prestige throughout western Christendom. He took advantage of this to open negotiations for a lasting peace with the English king, Henry III, who had become his brother-in-law. The discussions extended over several years, but the treaty was finally signed in Paris May 28, 1258. The terms of the treaty were generous with regard to the Plantagenets. Although Louis could have stripped Henry III of all his continental holdings, he left him Aquitaine and some neighbouring territories. In return, the King of England acknowledged himself to be Louis's vassal. In Louis's eyes this was the most important point, for in the 13th century the power of a sovereign was measured less by the extent of his possessions than by the number and importance of his vassals. A just and equitable ruler, Louis also wanted to create goodwill between his children and those of the Plantagenets. The King's reputation for impartiality was so great that he was often called upon to arbitrate disputes outside France, as he once did in a violent dispute between Henry III and his barons.

He took advantage of his authority to reorganize the administration of his kingdom. Some of his officials, profiting by his absence, had abused their power. Louis IX appointed royal investigators charged with correcting abuses on sight and with hearing complaints. Two well-known ordinances, in 1254 and 1256, carefully outlined the duties and responsibilities of officials in the royal domain, and Louis closely supervised their activities. Royal officials were forbidden to frequent taverns or to gamble; and business activities such as the purchase of land or the marriage of their daughters could be carried out only with the King's consent. Further ordinances forbade prostitution, judicial duels, and ordeal by battle. The King imposed strict penalties on counterfeiting, stabilized the currency, and compelled the circulation of royal coinage. In general, his measures strengthened royal justice and administration and provided a firm base for French commercial growth.

Louis should not, however, be portrayed as a stained-glass figure. Like all men he had faults. He was quick-tempered and sometimes violent, and he had to struggle against his gluttony. He made his decisions alone but knew how to choose wise counsellors, and his sincere piety did not prevent him from curbing the abuses of the clergy, sometimes brutally.

The King devoted attention to the arts and to literature. He directed the construction of several buildings in Paris, Vincennes, Saint-Germain, and Corbeil (to house relics of the "True Cross"). He encouraged Vincent of Beauvais, his chaplain, to write the first great encyclopaedia, *Speculum majus*. During his reign foreign students and scholars flocked to the University of Paris.

The King was very high-spirited. Nothing would be more inaccurate than to imagine him entirely steeped in piety. After meals he gladly descended into his gardens, surrounded by his intimates, and discussed diverse topics with them. There, each one indulged in quodlibet, or in talking about anything that pleased him.

**Death and canonization.** But throughout the latter part of his reign he was obsessed by the memory of the Holy Land, the territory of which was rapidly shrinking before the Muslim advance. In 1269 he decided once again to go to Africa. Perhaps encouraged by his brother Charles of Anjou, he chose Tunisia as the place from which to cut the Islāmic world in half. It was a serious mistake for which he must take responsibility, and he eventually had to bear the consequences of it. Ill and weak, he knew that he risked dying there.

The expedition landed near Tunis at the beginning of July 1270 and at first won a succession of easy victories. Carthage was taken. But once again plague struck the army, and Louis IX could not withstand it. After having entrusted the future of the kingdom of France to his son Philip, to whom he gave excellent instructions (*enseignements*), asking him especially to protect and assist the poor, who were the humblest of his subjects, he died in the afternoon of August 25, 1270.

The Crusade dissolved, and his body was brought back to France. All along the way, through Italy, the Alps, Lyons, and Cluny, crowds gathered and knelt as the procession passed. It reached Paris on the eve of Pentecost, 1271. The funeral rites were solemnly performed at Notre-Dame de Paris, and the coffin went to rest in the Abbey of Saint-Denis, the tomb of the kings of France.

Without awaiting the judgment of the Roman Catholic Church, the people considered Louis IX to be a saint and prayed at his tomb. Pope Boniface VIII canonized Louis IX, the only king of France to be numbered by the Roman Catholic Church among its saints, on August 11, 1297. His feast day is celebrated on August 25.

**BIBLIOGRAPHY.** Among contemporary sources are JEAN DE JOINVILLE, who lived close to the king for 25 years and wrote down his recollections between 1305 and 1309; and Queen Margaret of Provence's confessor, GUILLAUME DE SAINT-PATHUS, *Vie de Saint Louis*, written in 1302-03. All of the chroniclers have been published in the *Recueil des Historiens des Gaules et de la France*, new ed., vol. 20 (1894).

Modern works include HENRI WALLON, *Saint Louis et son temps*, 2 vol. (1875), old but still useful. JACQUES LEVON, *Saint Louis; ou, l'apogée du Moyen Age* (1969), is a good recent study with an extensive bibliography. A number of books were published on the 700th anniversary of Louis IX's death. The most valuable of them, ed. by REGINE PERNOUD, is a collection of articles by about 30 French and foreign historians: *Le siècle de Saint Louis* (1970).

(J.L.e.)

## Louis XI of France

King of France from 1461 to 1483, Louis XI suppressed the rebellions of his semi-sovereign vassals, centralized the administration with the help of bourgeois officials, and continued the unending struggle with Burgundy, which he finally added to the domain of France.

Louis was born at Bourges on July 3, 1423, the son of Charles VII of France by his consort Mary of Anjou. When Louis was born, the English were ruling a large part of France, and he spent most of his childhood at the Loches in Touraine. Ugly and fat, Louis grew up in austere seclusion to become secretive, ruthless, and superstitious; yet, he was also devout, intelligent, and well-informed, a cunning diplomat and a bold warrior who was able to command loyalty. Known as the universal spider, he could still claim to personify the French national consciousness; as he was later to say to his rebellious vassals, "I am France."

Louis XI of France, limestone sculptured head from Toul, France. In the Art Institute of Chicago.

Louis was married to Margaret, daughter of James I of Scotland, in 1436—an unhappy union formed solely for political reasons. In 1439 the King sent him to superintend the defense of Languedoc against the English and then to act as royal lieutenant in Poitou. Louis, however, was impatient to reign and was induced by malcontent princes to put himself at their head in 1440 during the revolt known as the Praguerie, named after a contemporary disturbance in Bohemia. Charles VII pardoned his rebellion and installed him as ruler of the Dauphiné.

Louis took part in his father's campaigns of 1440-43 against the English, and in 1443 he forced the English to raise their siege of Dieppe. When the Anglo-French truce of 1444 left numbers of mercenary troops unemployed, he led a large body of them to attack Basel, in ostensible support of the German king Frederick V (later Holy Roman emperor as Frederick III) in his quarrel with the Swiss confederacy. Failing to take Basel, Louis attacked the Habsburg possessions in Alsace since Frederick would not grant him the promised winter quarters. Meanwhile, Charles VII had invaded Lorraine and was holding court at Nancy. When Louis rejoined him there, Charles was completely under the influence of Agnès Sorel and Pierre de Brézé. Father and son became wholly estranged after the death (1445) of the dauphine Margaret, to whom his father had been attached. Detected in a plot against Brézé, Louis was exiled to Dauphiné. He was never to see his father again.

In Dauphiné, Louis served his apprenticeship as a ruler. He set up a central chancellery, reconstituted the local administration, founded the University of Valence, instituted a parlement, reduced the nobles to obedience, and confirmed the privileges of the towns. He also started to exploit the country's mines and forests and to promote its trade. Exercising full sovereignty, he pursued a foreign policy sometimes at variance with his father's. After concluding a secret alliance with Savoy for a partition of the duchy of Milan, Louis, recently widowed, married Charlotte, daughter of Duke Louis of Savoy, despite Charles VII's prohibition (1451). Subsequently, however, Louis fell out with Savoy; and in 1456, when Charles approached Louis' frontiers with an army and summoned him to his presence, he fled to the Netherlands to the court of Philip the Good, duke of Burgundy.

Installed as Philip's guest, Louis could acquaint himself thoroughly with the working of the great Burgundian state, the ruin of which he was later to seek. (Charles VII remarked that Philip was feeding the fox that would eat his hens.) At the same time, Louis kept himself posted by spies with every detail of his father's illness, thus laying himself open to the unsubstantiated accusation that he had hastened his death by poison. At last, after five years of impatient exile, Louis became king of France when Charles died in 1461.

His first act was to strike at Charles VII's ministers.

Dauphin,  
rebel,  
and exile

Last  
Crusade

Pierre de Brézé and Antoine de Chabannes were imprisoned, but they and some of their more serviceable colleagues were subsequently reinstated. Relying largely on men drawn from the lower nobility or from the middle class, Louis formed a circle of loyal advisers who helped him to impose his authority, to enlarge the royal domain, and to develop the wealth of the kingdom.

Louis XI's major preoccupation was with the princes and great vassals of the kingdom, who were ready to form alliances with each other or with England against him. Former officers of Charles VII stirred up hostility against the King's new men; Jean II, duc de Bourbon, and Francis II of Brittany emerged as the leaders of the malcontent nobility; Philip the Good's son and future successor, Charles the Bold of Burgundy, supported the King's enemies; and the King's own brother, Charles de France, at first duc de Berry, became a tool of the rebels.

In 1465 the malcontent princes formed the League of the Public Weal to make war against Louis. All France seemed on the verge of anarchy, but the lesser gentry refused to rise against the King and the bourgeoisie rallied to him. After some fighting, the league was brought to an end by treaties with the Burgundians and with Brittany, but Louis had to yield much: the Somme towns were given back to the Burgundians, and Normandy was granted, in exchange for Berry, to Charles de France, so that all northern France, from Brittany to Burgundian Artois, was linked in the hands of the former rebels. In 1466, however, the King reoccupied Normandy.

Charles the Bold, having become duke of Burgundy on Philip the Good's death (1467), allied himself with Francis of Brittany and with Edward IV of England; but in 1468 Louis invaded Brittany and detached Francis from the alliance. He then went to his disastrous interview with Charles the Bold at Péronne (October 1468). During the negotiations Charles learned of an insurrection in Liège, fomented by the French king's agents. Furious, he put Louis under house arrest, forced him to make far-reaching concessions, and finally took him to Liège to witness the suppression of the revolt.

After his humiliation at Péronne, Louis attempted to nullify the Anglo-Burgundian alliance by assisting the ousted House of Lancaster against Edward IV, but the final defeat of the Lancastrians (May 1471) put an end to his hope. Having already attacked Burgundy, Louis found himself facing a new host of enemies, comprising not only Charles the Bold, Edward IV, and Francis of Brittany but also, in the southwest, Charles de France, to whom Louis had granted the duchy of Guyenne in 1469, Jean V d'Armagnac, and John II of Aragon, who hoped to recover Roussillon. But, after Charles de France died in 1472, both Charles the Bold and Francis of Brittany signed truces; the royal army overran Armagnac, and France and Aragon agreed to suspend hostilities in Roussillon. Charles the Bold then began scheming for a partition of France between Burgundy, England, and other states, but Louis soon concluded truces with or bought off Charles's allies.

After 1475 it remained for Louis to destroy the power of Burgundy. He subsidized the Swiss confederates and René II of Lorraine in their war against Charles the Bold, and Charles was defeated and killed in battle at Nancy on January 5, 1477. Louis thereupon proceeded to dismember the Burgundian state, eager to reunite its French fiefs to the royal domain and to take as much else as he could. Charles's daughter Mary, however, married the Austrian archduke Maximilian, who defended her inheritance against Louis. Finally, by the Treaty of Arras (1482), Louis retained full sovereignty over the Duchy of Burgundy, Picardy, and Boulonnais and possession of Franche-Comté and Artois as the dowry of Margaret of Austria, daughter of Mary and Maximilian, fiancée of his infant son and heir, the future Charles VIII.

Louis regarded war as a precarious enterprise and made it only with reluctance, though he maintained the standing army that Charles VII had instituted. Diplomacy and inheritance were the means that he preferred for extending the royal domain. Even so, Louis pursued an active policy in Spain and in Italy. After Charles the Bold's

death there was no one to prevent Louis from exercising a virtual protectorate over Savoy, where his sister Yolande was regent; and he made himself the arbiter of the affairs of northern Italy.

In France itself, having broken the resistance of the princes, Louis could impose his authority everywhere. Louis XI, in referring to the abstract concept of the crown, expressed a modern idea of the state. He reaffirmed tradition by making the feast of "Saint" Charlemagne a holiday and by founding the knightly Order of Saint Michael. Yet, in his time, the subordination of subject to sovereign definitely replaced the feudal ties of personal fidelity. Centralization developed. A section of the royal council administered the justice formerly "reserved" by a lord. The role of the administrative departments was expanded and the officers of the king, owning their offices, began to constitute an influential class. A network of messengers allowed Louis XI to be abreast of all developments, and he frequently travelled throughout his kingdom. A new concordat with the Pope, concluded in 1472, allowed him to control the appointment of bishops. He augmented the royal revenues by raising taxes on his own authority. The meetings of notables and the assemblies of the estates had only a consultative role. Nevertheless, Louis XI sought the support of the bourgeoisie, some of whom were among his most trusted advisers. Considering wealth to be an element of power, he encouraged the guilds and promulgated numerous ordinances for industry. He encouraged the exploitation of mines, introduced the silk industry to Lyons and Tours, established printing at the Sorbonne (1470), stimulated Rouen's commerce with England and the Hanseatic towns, and promoted the fairs of Lyons. He also planned to create a company for the spice trade in the Mediterranean.

Of delicate health, Louis XI was a tireless worker, and overwork may have precipitated the cerebral arteriosclerosis that finally affected him. For his last two or three years he lived in seclusion at Plessis-les-Tours, in Touraine, where he died on August 30, 1483.

## Louis XIV of France

The glory and prestige of Louis XIV earned him the name the Sun King. He ruled France in one of its most brilliant periods and remains the symbol of absolute monarchy and of the classic age. He inspired a style and way of living embraced by all of Europe after his death. The object of the extremes of adoration and hatred, his history is filled with great achievements and terrible mistakes, with victories won and defeats suffered. After dominating Europe, he left his country weakened and impoverished, but under his rule France acquired several provinces and became the model of civilization.

He was born September 5, 1638, the son of Louis XIII and his Spanish queen, Anne of Austria. He succeeded his father on May 14, 1643. At four years and eight months he was, according to the laws of the kingdom, not only the master but the owner of the bodies and property of 19,000,000 men. Though saluted as "a visible divinity," he was, nonetheless, a neglected child given over to the care of servants. He narrowly escaped drowning in a pond because no one was watching him. Anne of Austria, who was to blame for this negligence, inspired him with a lasting fear of "crimes committed against God."

Louis was nine years old when the nobles and the Paris Parlement (a powerful law court), driven by hatred of the prime minister Cardinal Jules Mazarin, rose against

the crown in 1648. This marked the beginning of the long civil war known as the Fronde, in the course of which Louis suffered poverty, misfortune, fear, humiliation, cold, and hunger. These trials shaped the future character, behaviour, and mode of thought of the young King. He would never forgive either Paris, the nobles, or the common people.

In 1653 Mazarin was victorious over the rebels and then proceeded to construct an extraordinary administrative apparatus with Louis as his pupil. The young King also acquired Mazarin's partiality for the arts, elegance, and display. Although he had been proclaimed of age, the King did not dream of disputing the Cardinal's absolute power.

The war begun in 1635 between France and Spain was then entering its last phase. The outcome of the war would transfer European hegemony from the Habsburgs to the Bourbons. A French king had to be a soldier, and so Louis served his apprenticeship on the battlefield.

In 1658 Louis faced the great conflict between love and duty, a familiar one for princes of that period. He struggled with himself for two years over his love for Mazarin's niece, Marie Mancini. He finally submitted to the exigencies of politics and in 1660 married Marie-Thérèse of Austria, daughter of the King of Spain, in order to ratify peace between their two countries.

The childhood of Louis XIV was at an end, but no one believed him capable of seizing the reins of power. No one suspected his thoughts. He wrote in his *Mémoires*:

In my heart I prefer fame above all else, even life itself . . . Love of glory has the same subtleties as the most tender passions . . . In exercising a totally divine function here on earth, we must appear incapable of turmoils which could debase it.

**The young King.** Mazarin died on March 9, 1661. The dramatic blow came on March 10. The King informed his astonished ministers that he intended to assume all responsibility for ruling the kingdom. This had not occurred since the reign of Henry IV. It cannot be overemphasized that Louis XIV's action was not in accordance with tradition; his concept of a dictatorship by divine right was his own. In genuine faith, Louis viewed himself as God's representative on earth and considered all disobedience and rebellion to be sinful. From this conviction he gained not only a dangerous feeling of infallibility but also considerable serenity and moderation.

He was backed up first by the great ministers Jean-Baptiste Colbert, the Marquis de Louvois, and Hugues de Lionne, among whom he fostered dissension, and later by

men of lesser capacity. For 54 years, Louis devoted himself to his task eight hours a day; not the smallest detail escaped his attention. He wanted to control everything from court etiquette to troop movements, from road building to theological disputes. He succeeded because he faithfully reflected the mood of a France overflowing with youth and vigour and enamoured of grandeur.

Despite the use of pensions and punishments, the monarchy had been unable to subdue the nobles, who had started 11 civil wars in 40 years. Louis lured them to his court, corrupted them with gambling, exhausted them with dissipation, and made their destinies dependent on their capacity to please him. Etiquette became a means of governing. From that time, the nobility ceased to be an important factor in French politics, which in some respects weakened the nation.

Louis's great fortune was in having among his subjects an extraordinary group of men in every area of activity. He knew well how to make use of them. He was the protector of writers, notably Molière and Jean Racine, whom he ordered to sing his praises, and he imposed his own visions of beauty and nature on artists. France's appearance and way of life were changed; the great towns underwent a metamorphosis, the landscape was altered, and monuments arose everywhere. The King energetically devoted himself to building new residences. Little remains of his splendid palaces at Saint-Germain and Marly, but Versailles—cursed as extravagant even as it was under construction and accused of having ruined the nation—still stands. Versailles was approximately the price of a modern airport; it was an object of universal admiration and enhanced French prestige. All the power of the government was brought to bear in the construction of Versailles. Louis XIV was not wrong, as some have claimed, to remove himself from unhealthy and tumultuous Paris, but he erred in breaking with the wandering tradition of his ancestors. The monarchy became increasingly isolated from the people and thus assumed a mythical quality.

While Louis watched his buildings going up, Colbert, who supervised the construction, obtained from him the means to carry out an economic revolution aimed at making France economically self-sufficient while maximizing exports. Manufacturers, the navy and merchant marine, a modern police organization, roads, ports, and canals all emerged at about the same time. Louis attended to every detail, while at the same time giving dazzling entertainment and carrying on a tumultuous love affair with Louise de La Vallière.

In 1667 he invaded the Spanish Netherlands, which he regarded as his wife's inheritance, thus beginning a series of wars that lasted for a good part of his reign. Louis himself on his deathbed said, "I have loved war too much," but his subjects, who often complained of his prudence and moderation, would not have understood had he not used force to strengthen the frontiers of France. After a brilliant campaign, the King had to retreat (1668) in the face of English and especially Dutch pressure. He never forgave the Dutch and swore to destroy their Protestant mercantile republic. To this end he allied himself with his cousin Charles II of England and invaded the Netherlands in 1672. The long war that ensued ended in 1678, in the first treaty of Nijmegen with Louis triumphant.

**Zenith and decline.** The Sun King was at his zenith. Almost alone he had defeated a formidable coalition (Spain and the Holy Roman Emperor had joined the Dutch against him) and dictated terms to the enemy. He had extended the frontier of France in the north by annexing part of Flanders and in the east by seizing Lorraine and the Franche-Comté. His fleet equalled those of England and Holland. Paris called him "the Great." In his court he was an object of adoration, and as he approached the age of 40 he could view himself as far surpassing all other men.

At the same time, great changes were occurring in his private life. In 1680 the Marquise de Montespan, who had replaced Madame de La Vallière as Louis's mistress in 1667, was implicated in the Affair of the Poisons, a

Patron of  
the arts

Early wars

Marriage

scandal in which a number of prominent people were accused of sorcery and murder. Fearful for his reputation, the King dismissed Madame de Montespan and imposed piety on his entourage. The ostentation, gambling, and entertainments did not disappear, but the court, subjected to an outward display of propriety, became suffused with boredom. Hypocrisy became the rule.

The King had openly renounced pleasure, but the sacrifice was made easier for him by his new favourite, the very pious Madame de Maintenon. She was the widow of the satirist Paul Scarron and the former governess of the King's illegitimate children.

In 1682 the seat of government was transferred to Versailles. The following year marked a turning point in the life and reign of Louis XIV. The Queen died, and the King secretly married Madame de Maintenon, who imperceptibly gained in political influence. He remained devoted to her; even at the age of 70 she was being exhorted by her confessor to continue to fulfill her conjugal duties, according to letters still extant.

Colbert also died, leaving the way free for the bellicose Louvois. The repulse of a Turkish invasion of his Austrian domains left the Emperor free to oppose France in the West. In 1688–89 the fall of the Stuarts and William of Orange's accession to the throne of England further reversed the situation to the detriment of France.

Revocation  
of the  
Edict of  
Nantes

To his traditional enemies Louis now added the entire Protestant world. His mother had inculcated in him a narrow and simplistic religion, and he understood nothing of the Reformation. He viewed French Protestants as potential rebels. After having tried to convert them by force, he revoked the Edict of Nantes, which had guaranteed their freedom of worship, in 1685. The revocation, which was accompanied by a pitiless persecution, drove many artisans from France and caused endless misfortune.

Thus began the decline.

England, the Dutch, and the Emperor united in the Grand Alliance to resist Louis's expansionism. The resulting war lasted from 1688 to 1697. Despite many victories, Louis gave up part of his territorial acquisitions when he signed the Treaty of Rijswijk, for which the public judged him harshly. He reconciled himself to another painful sacrifice when he recognized William of Orange as William III of England, in violation of his belief in the divine right of the Stuart king James II to William's throne.

Three years later, in 1700, Charles II, the last Habsburg king of Spain, died, bequeathing his kingdoms to Louis's grandson, Philip of Anjou (Philip V). Louis, who desired nothing more than peace, hesitated but finally accepted the inheritance. He has been strongly criticized for his decision, but he had no alternative. With England against him, he had to try to prevent Spain from falling into the hands of the equally hostile Holy Roman Emperor Leopold I, who disputed Philip's claim.

Final years

In the War of the Spanish Succession (1701–14) the anti-French alliance was reactivated by William of Orange before his death. The disasters of the war were so great that, in 1709, France came close to losing all the advantages gained over the preceding century. Private griefs were added to Louis's public calamities. Almost simultaneously he lost his son, the Grand Dauphin, two of his grandsons, the ducs de Bourgogne and Berry, his great grandson, the Duc de Bretagne, and the Duchesse de Bourgogne, who had been the consolation of his declining years.

An excess of flattery from within and an excess of malediction from without had created an artificial image of the King. He was viewed as an idol who would collapse under the blows of ill fortune, but the opposite occurred. Having first been the embodiment of a triumphant nation, Louis surpassed himself by bearing his own suffering and that of his people with unceasing resolution.

Finally, a palace revolution in London, bringing the pacific Tories to power, and a French victory over the imperial forces at the Battle of Denain combined to end the war. The treaties of Utrecht, Rastatt, and Baden, signed in 1713–14, cost France its hegemony but left it

territorially intact. It retained its recent conquests in Flanders and on the Rhine, which were so much in the order of things that neither later defeats nor revolutions would cause it to lose them.

Louis XIV died on September 1, 1715, at the age of 77. His body was borne, amid the jeers of the populace, to the Saint-Denis basilica.

His heir, the last son of the Duc de Bourgogne, was a five-year-old child who was not expected to live. Louis had distrusted his nephew, the Duc d'Orléans, and wanted to leave actual power in the hands of the Duc du Maine, his son by Madame de Montespan. In attempting to accomplish this, he had drawn up a will that was to help destroy the monarchy. The Parlement of Paris, convened to nullify the will after his death, rediscovered a political power that it used to prevent all reforms during the ensuing reigns, thus making the Revolution inevitable.

**Evaluation.** During his lifetime, Louis was flattered ceaselessly by his subjects, while foreign journals compared him to a bloodthirsty tiger. Voltaire portrayed his grandeur in his *Age of Louis XIV*. The Duc de Saint-Simon, a member of his court whose *Mémoires* show equal proportions of literary genius and insincerity, dealt with him quite harshly, without denying his admiration for him. Later judgments of Louis varied according to the author's political views.

Louis XIV was the foremost example of the monarchy that brought France to its pinnacle. He has been accused of having dug the grave of that monarchy, particularly through his religious policy, his last will, and his isolation of the court from the people. These mistakes could have been corrected. His irremediable error was to have concentrated all the machinery of the state in his own person, thus making of the monarchy a burden beyond human strength.

Louis XIV  
and the  
French  
monarchy

His reign, compared by Voltaire to that of the Roman emperor Augustus, had both its strong and its weak points. Despite his victories and conquests, France lost her primacy under him. Yet the brilliance of his reign made up for his military policies. The aristocracy of Europe adopted the language and customs of the France where the Sun King had shone, although resentments lingered for a long time.

The King identified with his office to such an extent that it is difficult to find the individual. His harshness and courage, despotism and stoicism, prodigious pride and passion for order, megalomania and religion, intolerance and love of beauty can be understood only as a function of the exigencies of governing. He wanted France to be powerful, prosperous, and magnificent but was not overly concerned with the well-being of the French people. His armies committed atrocities, but the horrors of today have eclipsed them, and under his reign one did not see whole nations reduced to slavery, mass deportations, and genocide. When an Italian chemist offered him the first bacteriological weapon, he gave him a pension on condition that he never divulge his invention.

Louis was sometimes a tyrant, but in the words of Voltaire: "His name can never be pronounced without respect and without summoning the image of an eternally memorable age."

**BIBLIOGRAPHY.** LOUIS XIV, *Mémoires* (Eng. trans., *Memoirs of Lewis the Fourteenth, Written by Himself and Addressed to His Son*, 2 vol., 1806), is very important for an understanding of the psychology of Louis XIV. There are many French editions of this work. Contemporary accounts include: the DUCHESS D'ORLEANS (Madame Palatine), *Correspondance complète*, 2 vol. (1857); *Mémoires of the Duc de SAINT-SIMON*; the *Journal of DANGEAU*; reports of the Venetian ambassadors and of the marquis de Saint Maurice, ambassador from Savoy; and EZECHIEL SPANHEIM, *Relation de la cour de France en 1690* (1704; Eng. trans., *Account of the Court of France*, 1900). VOLTAIRE, *La Siècle de Louis XIV*, 2 vol. (1751; Eng. trans., *The Age of Louis XIV*), an admirably written and well-documented study, remains an important source. JACQUES ROUJON, *Louis XIV* (1943), is a very objective and complete work. Two of the best books written on this period in the past century are PHILIPPE ERLANGER, *Louis XIV* (1965; Eng. trans., 1970); and JOHN B. WOLF, *Louis XIV* (1968).

(P.Er.)

## Louis XVI of France

The last monarch in the line of French kings preceding the Revolution of 1789, Louis XVI (reigned 1774–92) was unfitted by temperament and education for the duties of kingship. Weak-willed and incapable of decision, he was unable to forestall by reform the French Revolution of 1789, and once the Revolution had begun, missed the opportunity to be its leader. He never responded to, because he never understood, the liberal and democratic forces of his age. He feebly attempted first to resist and then to betray the Revolution that might well have consolidated his royal authority.

Louis XVI, portrait by J.-S. Duplessis (1725–1802). In the Château de Versailles.

Louis was born at Versailles on August 23, 1754, the third son of the dauphin Louis and his consort Maria Josepha of Saxony. At first known as the duc de Berry, he became the heir to the throne on his father's death in 1765. His education was entrusted to the duc de La Vauguyon (Antoine de Quélen de Caussade), who made little effort to ensure that he should be properly trained for his responsibilities. Louis nevertheless possessed an excellent memory, acquired a sound knowledge of Latin and English, and took an interest in history and geography. In 1770 he married the Austrian archduchess Marie Antoinette, daughter of Maria Theresa and the Holy Roman emperor Francis I.

On the death of his grandfather Louis XV, Louis succeeded to the French throne on May 10, 1774. At that time he was still immature, lacking in self-confidence, austere in manner, and, because of a physical defect (later remedied by an operation), frigid in his relations with his young wife. Well-disposed toward his subjects and interested in the conduct of foreign policy, Louis had not sufficient strength of character or power of decision to combat the influence of court factions or to give the necessary support to reforming ministers, such as Anne-Robert-Jacques Turgot or Jacques Necker (*qq.v.*), in their efforts to give great stability to the tottering finances of the *ancien régime*. The prestige of the monarchy was also compromised early in his reign by the decision in August 1774 to restore the powers of the Parlements (judicial bodies supporting the interests of the aristocracy) whose political authority had been withdrawn in 1771. Louis XVI's reign before 1789 coincided with the increasing strength of the aristocratic reaction. It was aristocratic

opposition to the fiscal, economic, and administrative reforms of the controller general of finance, Charles-Alexandre de Calonne, in 1787 that forced the King, in July 1788, to summon the Estates-General, the representatives of the clergy, nobility, and commoners, for the following year and thus set in motion the Revolution.

After 1789 Louis XVI's incapacity to rule, his irresolution, and his surrender to reactionary influences at court were partially responsible for the failure to establish in France the forms of a limited constitutional monarchy. Louis had at first rightly regarded the Revolution as the product of aristocratic intransigence and should, therefore, have grasped the opportunity of forming an alliance between the crown and the middle-class reformers. Instead he allowed himself, in the spring of 1789, to be dominated by the reactionary court faction surrounding his younger brother Charles, comte d'Artois (later King Charles X) and to be converted to the policy of defending the privileges of the clergy and nobility in the Estates-General. He continued to believe, even after the increasingly radical trend of popular movements in Paris and the provinces during the summer had demonstrated the futility of such hopes, that the Revolution would burn itself out.

By this time the fundamental weakness of the King's character had become evident: lethargic in temperament, lacking political insight and therefore incapable of appreciating the need to compromise, Louis continued to divert himself by hunting and with his personal hobbies of making locks and doing masonry. He dismissed Necker in early July 1789 and showed his reluctance to sanction the achievements of the National Assembly (as the Estates-General was now called) such as the Declaration of the Rights of Man and of the Citizen and the "destruction" of the feudal regime in August. His resistance to popular demands was one of the causes of the forcible transfer of the royal family from Versailles to the Tuileries Palace in Paris on October 6. Yet he made still more mistakes, refusing to follow the secret advice tendered to him after May 1790 by the royalist deputy, the comte de Mirabeau (*q.v.*), abdicating his responsibilities, and acquiescing in the disastrous attempt to escape from the capital to the eastern frontier on June 20, 1791. Caught at Varennes and brought back to Paris, he lost credibility as a constitutional monarch. Thenceforward he seems to have been completely dominated by the Queen, who must bear the chief blame for the court's subsequent political duplicity.

From the autumn of 1791 the King tied his hopes of political salvation to the dubious prospects of foreign intervention. At the same time he encouraged the Girondin faction in the Legislative Assembly in their policy of war with Austria, in the expectation that French military disaster would pave the way for the restoration of his authority. Prompted by Marie Antoinette, Louis rejected the advice of the moderate constitutionalists, led by Antoine Barnave, to implement faithfully the constitution of 1791, which he had sworn to maintain, and committed himself to a policy of subterfuge and deception. The outbreak of the war with Austria in April 1792, the suspected machinations of the Queen's "Austrian committee," and the publication of the manifesto by the Austrian commander, the duke of Brunswick, threatening the destruction of Paris if the safety of the royal family were again endangered, led to the capture of the Tuileries by the people of Paris and provincial militia on August 10, 1792. It also led to the temporary suspension of the King's powers by the Legislative Assembly and the proclamation of the first French republic on September 21. In November proof of Louis XVI's secret dealings with Mirabeau and of his counterrevolutionary intrigues with the foreigners was found in a secret cupboard in the Tuileries. On December 3 it was decided that Louis, who together with his family had been imprisoned since August, should be brought to trial for treason. He himself appeared twice before the Convention (December 11 and 23). Despite the last-minute efforts of the Girondins to save him, Citizen Capet, as he was then called, was found guilty by the Convention and condemned to death on January 18, 1793, by 387 votes (including 26 in favour of a debate on the

Louis's reaction to the Revolution

Attempt to flee the country

Con-  
demned to  
death

possibility of postponing execution) against 334 (including 13 for a death sentence with the proviso that it should be suspended). When a final decision on the question of a respite was taken on January 19, Louis was condemned to death by 380 votes against 310. He was guillotined in the Place de la Révolution in Paris on January 21, 1793. Louis XVI's courage on June 20, 1792, when the royal palace was invaded by the Paris mob after his dismissal of the Girondin ministry, and his dignified bearing during his trial and at the moment of execution, did something to redeem, but did not re-establish, his reputation.

**BIBLIOGRAPHY.** S.K. PADOVER, *Life and Death of Louis XVI* (1939; new ed., 1963), is virtually the only serious biography available in English. J. DROZ, *Histoire du règne de Louis XVI*, 3 vol. (1858), though old-fashioned and written from an exclusively political angle, is still worth consultation on the attempts of the central government to reform the ancien régime. It has been superseded in that respect by D. DAKIN, *Turgot and the Ancien Régime in France* (1939); G. LEFEBVRE, *Quatre-vingt-neuf* (1939; Eng. trans., *The Coming of the French Revolution, 1789, 1947*); and J. EGRET, *La Pré-Révolution Française, 1787-1788* (1962). The most recent scholarly studies of royal policy after the flight to Varennes are: J. CHAUMIE, *La Réseau d'Antraigues et la Contre-Révolution, 1791-1793* (1965), which throws an entirely new light on the royal web of counterrevolutionary intrigue; A. SOBOUL, *Le Procès de Louis XVI* (1966), which gives a succinct analysis of the issues raised by the king's trial and execution, along with documentary material from the French archives; and M. REINHARD, *La Chute de la Royauté* (1969), which is likely to remain the definitive account of the final overthrow of the Bourbon monarchy.

(A.I.G.)

## Louisiana

With parts of its land lying farther south than any portion of the continental United States except for south Texas and the Florida peninsula, and with New Orleans, its largest city, lying on the same parallel as Cairo, Delhi, and Shanghai, Louisiana owes much of its complex personality to its geographical position.

The state commands a once strategically vital region where the waters of the great Mississippi-Missouri River System, draining the continental interior of North America, sweep out into the warm, northward-curving crescent of the Gulf of Mexico. It is not surprising that the flags of seven nations have flown over its territories since 1682, when the explorer La Salle placed a wooden cross in the ground and claimed the territory for France's Louis XIV. The consequent varieties of cultural heritage run like bright threads through many aspects—social, political, and artistic—of the state's life.

The subtropical climate of the state has provided the magnificent, brooding scenery of the coastal bayous, and the lush dank vegetation of its shores conceals a rich mineral wealth in the form of oil. The fertile soils covering much of its terrain made it the richest agricultural portion of the Union by 1860, with sugarcane and cotton plantations flourishing. A lumbering boom ushered in the 20th century, which was to see a rapid industrialization after World War II. Mineral output exceeded \$3,000,000,000 annually by the 1970s, and the state ranked second only to Texas in petroleum production.

But progress has not been without its tragic and turbulent aspects: bitter territorial disputes, succeeded by violent internal struggles for political power, impeded the social and economic development of the state and crippled many of its political institutions. The wealth of the plantations was accumulated through the extensive use of slaves, whose descendants still comprise almost one-third of the population, and whose culture has contributed much to the social fabric of the state. Racism and racial conflict have marred the development of the state from the Civil War period, through Reconstruction and the ensuing reaction, marked by the activities of the Ku Klux Klan, down to the civil rights conflicts of the 1960s and beyond. Louisiana's Deep South heritage is a complex one.

The state is delineated from its neighbours by four natural and three man-made boundaries: Texas, Arkansas, and Mississippi. Over 3,000 square miles of its 48,523

square miles (125,675 square kilometres) consist of inland waters. (For further details see NEW ORLEANS; MISSISSIPPI RIVER; NORTH AMERICA; UNITED STATES; and UNITED STATES, HISTORY OF THE.)

### THE HISTORY OF LOUISIANA

**Early settlement.** At least 16,000 years before European exploration, Indians were present in what was to become Louisiana. At least seven archaeological sites have been excavated, notably the so-called Poverty Point sites (dated at approximately 700 BC), and the Marksville site (dated AD 100 to 550). Most Louisiana Indians lived in hunting and gathering camps in the uplands and coastal prairies, though there were farming villages in the rich, low-lying areas known as bottoms. It is estimated that there were 15,000 Indians in the area when settlement by Europeans began in the 1700s. Only about one-fifth as many Indians can be identified as such today. Their heritage remains in the many place-names that lend colour to the state's map.

While the Spanish were first to discover the area, it was the French who colonized it. Serious colonization by France began in 1699, when Pierre Le Moyne, sieur d'Iberville, together with his brother Jean-Baptiste Le Moyne, sieur de Bienville, explored the area and struggled to found permanent colonies. The city of New Orleans was established by Bienville in 1718. Royal charters covering the area had been granted, first to Antoine Crozat, in 1712, and then, in 1717, to the Scottish businessman, John Law, whose Company of the West failed in 1720. When Louisiana became a French crown colony in 1731, its population had grown from less than 1,000 to nearly 8,000, including slaves. In addition to the Frenchmen, many thousand Germans arrived, settling on the river just above New Orleans on what became known as the German Coast. Colonization was significantly increased in the 1760s with the arrival of the French-speaking Acadians, who had been expelled from Nova Scotia by the British.

In 1762, Louisiana and New Orleans were ceded to Spain by a secret treaty that was to establish nearly four decades of Spanish rule and influence. In 1779, the Spanish first wrested Baton Rouge from the British, and then took all West Florida, which then extended from the peninsula westwards across the Gulf Coast to the Mississippi. In 1800 the Spanish re-ceded Louisiana to France, and in 1803 the United States concluded the famous Louisiana Purchase.

**The 19th century.** Louisiana was subsequently divided into the Territory of Orleans, which consisted essentially of the present boundaries of the state, and the Territory of Louisiana, which included all the vast area drained by the Mississippi and Missouri rivers. In 1810 the Territory of Orleans consisted of 77,000 people, and statehood proposals were beginning to be heard. When, in 1812, the territory petitioned to enter the Union, the eastern region now called the Florida Parishes—where the people had rebelled against the Spanish and established the Republic of West Florida—was included.

An economic boom, generated by the slave labour from Africa now toiling on the flourishing sugarcane and cotton plantations, existed by the 1830s and sets of natural cleavages were asserting themselves in the political affairs of the state as first French-American, and later planter-farmer, interests clashed in the political process. While the yeoman farmer held the suffrage, representation rested in the hands of a plantation aristocracy that overcame one-man, one-vote principles by counting slaves in the determination of district units. Under this circumstance, and with the breakdown of the two-party system in the 1850s, sentiment in the state divided when the issue of secession from the union arose. The pro-secession group prevailed in the convention of 1861, even though later research had made it appear that a majority of the state's citizens wanted to stay in the Union.

Separation was short lived in south Louisiana, for by May 1, 1862, New Orleans was occupied. Louisiana was readmitted into the Union in 1868 and the state experienced a most severe Reconstruction period. Political

Initial  
coloniza-  
tion

The Civil  
War and  
its  
aftermath

conflict occurred between the federal Republicans located in New Orleans and the former Confederates in the rural parishes. After 1876, Democrat contested with Republican as the freed black man, whose vote represented the balance of power, became the pawn in the electoral struggle.

The plantation economy continued to prevail as the farmer class, white and black alike, was squeezed from farm ownership into sharecropping or tenancy. Subsequent agrarian protests that emerged in the 1880s and 1890s produced the Populist (People's) Party and what seemed at the time to be a chance to overthrow the planter-merchant-lawyer rule. Louisiana entered the 20th century, however, under a restrictive rule, as the elite was able to defeat the reform movement of the farmers in the gubernatorial election of 1896 and to enact the Constitution of 1898. As a result of this triumph of reaction nearly all blacks were legally denied the right to vote, while many whites lost the will to do so. The state was now firmly in the Deep South, with all the tragic historical connotations of that term.

**The 20th century.** Extensive lumbering operations attracted large corporations to Louisiana for three decades after 1890, and the discovery of oil and gas reserves in this period helped to increase industrial development. While these trends may have laid the foundations for the eventual development of the Louisiana economy, the early decades of the 20th century witnessed a political leadership that was not ready to take advantage of these developments in terms of increased tax revenues and services to the people. Louisiana remained a backward, segregated, and agrarian society.

Part of the rise of the demagogic and populist Huey P. Long to the governorship in the late 1920s may well be attributed to the seriously arrested socioeconomic development of the state. With the support of the rural areas and the emerging working class, Long substituted a realism for the romance perpetuated by the conservative leadership. Under his administration, welfare benefits and educational services were extended, and bridges and roads and hospitals were constructed, not on the old pay-as-you-go basis of the past but through the floating of bonded indebtedness. Since the rise of Longism, and its perpetuation under Huey's brother, Earl K. Long (governor in 1948 and 1956), no political administration has seen fit to turn back the series of public benefits financed by increased taxation.

During and after World War II, Louisiana underwent further economic development until, by 1960, industrial plants had begun to line the Mississippi between Baton Rouge and New Orleans. Such developments did not ordain more moderate politics, however, as, in the decade beginning in 1960, national policies began to take up where the state itself had lacked impetus, demanding school desegregation and the re-enfranchising of the black third of Louisiana's citizenry. Conflicts over race and religion broke the bridge the Longs had built between north and south Louisiana, and in the presidential election of 1968, the state, perhaps symbolically, gave its vote to Southern conservative segregationist George C. Wallace.

#### THE LANDSCAPE

**The natural environment.** *Physiography.* Louisiana shares the general physiographic characteristics common to the Gulf Coast states of the southern United States, with the vital exception of the Mississippi River, which flows through the state and extends its delta far into the Gulf of Mexico. The changing course of this great North American river has created the huge Atchafalaya Basin and has dumped tons of sediment along the coast. It has been estimated that the quite beachless coastline of Louisiana is eroding at a rate of about 16 square miles per year as the system of levees, or embankments, constructed by the federal government keeps the Mississippi in a central channel.

Three types of natural regions are found in Louisiana: lowlands, terraces, and hills. The lowlands consist of the coastal marshes and the Mississippi flood plain with its

natural levees and moderate relief. Similarly, the Red River Valley has a low elevation relief but with many raft lakes, built up by impounding water from a number of log jams, and red soils in association with its alluvial plain. The terraces include much of the so-called Florida Parishes above and to the northeast of the Mississippi, as well as the prairies of southwest Louisiana. On either side of the Red River Valley and in the northern portion of the Florida Parishes are found upland hills; the state's highest elevation, in northwest Louisiana, is only 535 feet (160 metres) above sea level.

The soils of Louisiana have been one of the state's priceless resources; nearly one-third of the total land area is covered by the rich alluvium deposited by the overflowing of its rivers and bayous. Muck and peat soils are found within the coastal marshes, while the bottoms hold rich alluvial soils: the lighter and coarser bottom soils of the Mississippi and Red River valleys and older alluvium and loessial, or windblown soils. Finally, within the uplands, or hills, there are more mature soils that do not sustain such a high degree of fertility.

*Climate.* Louisiana's climate is subtropical, a natural result of its location on the Gulf of Mexico. As it also lies at the mouth of the vast Mississippi-Missouri River Valley, halfway between the Atlantic and the Pacific oceans, the state is also affected by continental weather patterns. Hot, humid summers, tempered by the frequent afternoon thunder showers maintained by high pressure areas located to the east, alternate with mild winters periodically affected by an influx of Arctic air as high pressure settles down across the midcontinent. Louisiana is subject to tropical storms and the hurricane season extends fully six months from June through November. Average annual temperatures range from 64° F (18° C) in the extreme north of the state, to 71° F (21° C) at the mouth of the Mississippi River. The highest monthly average is 83° F (28° C) in August, and the lowest is 46° F (8° C) in January. Summer averages do not extend above the low 80s Fahrenheit, and it is the humidity, rather than the heat, that is one of the more marked characteristics of the state's subtropical climate. The frost season begins between November 1 in northern Louisiana and December 14 in the extreme southeast. The average growing season ranges from 220 to 320 days and the average precipitation from just below 48 inches near Shreveport to over 64 inches between New Orleans and Baton Rouge.

*Plant and animal life.* Natural vegetation is found in three major divisions: the first consists of forest, upland pines and hardwoods, bottomland hardwoods, and bald cypress, the second of prairie or dry grassland, and the third of marshland or wet grassland. In the southern half of the state, along a zone running west from Baton Rouge, the live oak with its characteristic drapings of Spanish moss predominates, providing a memorable element in the state's landscape. The magnolia, whose blossom is the state flower, grows throughout the state.

Muskrats and other fur-bearing rodents, together with the alligator, have been trapped in the marshes of south Louisiana. There is a great variety of birds, native and migrant, but the once-frequent brown pelican (the state bird), the ivory-billed woodpecker, and the wild turkey are nearly extinct. The grey squirrel, deer, and dove are plentiful. Fish, shrimp, crayfish, crabs, and oysters are a source of food and of income in the coastal and swamp areas.

**Natural regions.** North Louisiana forms a natural region including the northeast Louisiana Delta, the Red River Valley, together with the north Louisiana hills. South Louisiana, which may be said to be composed of the parish of Avoyelles together with all the parishes that lie beneath the 31st parallel, has three major subregions: (1) the Florida Parishes, (2) southwest Louisiana—which contains many Anglo-Saxon Protestants but at the same time an important French minority—and (3) in between, a region variously known as the Cajun, or the river and bayou country, or the sugar bowl.

**Settlement patterns.** The earliest settlements in the river and bayou parishes were "line" villages, where farm-

Subtropical characteristics

Civil rights in the 1960s

Variety  
of land  
divisions

steads were built at the river front of a long and narrow lot, with the stream itself serving as a highway. This line village pattern contrasted with the irregular pattern stemming from the ancient land division system of metes and bounds used by the Anglo-Saxons of the Florida Parishes. Where the natural levee was wide enough, a further element, that of plantations, appeared. In north Louisiana, in the period before the Civil War, the uplands were peopled from the eastern states through the medium of isolated farmsteads amongst the pine woods. Southwest Louisiana was developed after 1880, and the prairies of this region given over to the cultivation of rice. The form of settlement here resembled the geometrical pattern—based on a grid system of land division—found throughout the interior of the United States.

#### THE LOUISIANIANS

**Ethnic origins.** If a diversity of landscapes and forms of settlement characterizes the state, its peoples and its cultures also make for many Louisianians. The earliest European settlers were French or Spanish, and only later were the Floridas region and the northern part of the state settled by *les Américains*. Each area of settlement managed to preserve a cultural heritage strongly marked by adherence to either the Catholic or Protestant faith. The Louisiana French, particularly the descendants of the Acadians, came to dominate much of south Louisiana: indeed many of those who have arrived to live among them have been assimilated to the Cajun way of life. The French language is still heard in many parishes, and throughout south Louisiana one may hear English spoken with a French accent. In addition, several cultural islands exist in both regions of the state. These are made up of Italian, Spanish (*Isleños*), Hungarians, Germans, and Dalmatian-Slavonian communities. There are, as well, several racially mixed settlements.

The peoples of Louisiana exhibit a greater variety than those in other Deep South states not only because of the patterns of historical settlement but also because of the migration to and through New Orleans from Europe and Latin America and, more recently, from Cuba. Of the state's nearly 124,000 foreign-born residents recorded in the 1960 census, slightly over half resided in New Orleans and adjacent Jefferson Parish and of these almost one-third were Italians. The vast majority of foreign-born residents are found within the most urbanized parishes of the state. The 1960 census showed, nevertheless, that over 80 percent of the total population was comprised of native-born Louisianians. The proportion of whites so born was 77 percent while the nonwhite ratio was even higher, at 90 percent.

The black  
contribution

From the earliest days of the state, blacks have played a significant role in it. By 1970, only two states had higher proportions of nonwhites than Louisiana, whose 30.2 percent nonwhite contrasted sharply with the 12.6 percent in the nation as a whole. Historically, the Negro population was concentrated in those areas containing the plantations sustained by their labour, initially under slavery. In the early decades of the 20th century a large out-of-state migration took place, supplemented, after World War II, by a black migration to the state's urban areas. Although Louisiana's black population has been denied many of the traditional avenues leading to social and economic power, the black experience has nevertheless contributed to the life and character of the state, and of New Orleans, its major city.

**Demographic trends.** South Louisiana contains 70 percent of the state's population. The 1970 census figures reveal that about 34 percent of the people in both north and south Louisiana reside in their three most populated parishes. A predominantly urban population was achieved for the first time in 1950, and the proportion of the population residing in urban places had risen to 66.1 percent by 1970. New Orleans has always been the dominant urban settlement, and, since 1810, the population of the city has been about 20 percent of the total state population. The farm population, which constituted 36 percent of the total in 1940, had decreased to a proportion of barely 7 percent by the 1960s.

Louisiana has a young population. Fully 32 percent were under 15 years of age in 1970 while, on the other hand, only 8.4 percent were 65 years and over (the national figures were 28.5 percent and 9.9 percent, respectively). The parishes with greater than average numbers of young are found in south Louisiana, where the predominantly Catholic population sustains a higher birth rate and immigration is high. The heavier emigration of north Louisiana gives the area's population a higher average age.

The 1970 census showed a total Louisiana population of 3,641,306. The rate of growth between 1960 and 1970 was 11.9 percent, slightly below the national average, and resulted in a net gain of some 386,000 over the decade, mostly as a result of the excess of births over deaths. Death rates are slightly lower than the national average and the state's birth rate is slightly higher. The white population increased by 328,000 over the same period, while the black population increased by almost 50,000. This trend is expected to continue, with high rates of net immigration in the urbanized areas and with net out-migration affecting the rural regions. Demographers expect south Louisiana, at least, to join the whole coastal region from South Carolina to south Texas as one of the fastest growing areas in the nation.

Migratory  
trends

#### THE STATE'S ECONOMY

Louisiana has shared the general condition afflicting Southern states: economic underdevelopment. As late as 1940 nearly one-third of the labour force was employed in the primary, raw-material-oriented industries while only one-fifth worked in the secondary sector of mining, building, and manufacturing. Such an imbalance had the effect of depressing total personal income per capita, which, as late as 1929, was but slightly more than half of the national figure.

World War II hastened the industrial growth of Louisiana to the extent that the proportion of the labour force engaged in manufacturing alone increased from 13 percent to nearly 16 percent in the 20-year period ending 1960. The most important development was that of a chemical industry, based on the fortuitous local combination of oil, sulfur, salt, and water. An investment boom occurred from 1947 to 1957 when the first big move to offshore petroleum production was made. Though the trend subsequently fluctuated, the state may be expected to continue to experience industrial expansion as its program of offering inducement to industrial investment is maintained.

**Resources.** Petroleum resources are found in all areas of the state, but the main oil fields have been developed between Shreveport and Monroe, and throughout most of south Louisiana. In recent years, drilling has moved out into the open Gulf. Natural gas resources have also been utilized. Oil in Louisiana is often found in association with the more than 100 known salt domes, blister-like intrusions in the bedrock, and sulfur lies in the caprock overlying the salt. Conservation efforts have capitalized on the resources of soil and climate, and there is, as a result, extensive "tree farming." The natural gas resources of the state have been an important source of industrial power and the abundant mineral fuels which are available have been used to develop electrical power for the state. Louisiana also possesses a prime asset in its water resources.

**Industry and agriculture.** The total value added by manufacture in the state averaged over \$2,000,000,000 annually by the late 1960s. Petroleum and chemical products, food processing, transportation equipment, and paper products were the leading items concerned. Cotton is no longer king in the agricultural domain: it was still first in cash farm receipts in 1960, but by 1969 beef cattle had become the leading agricultural product followed by rice, soybeans, dairying, sugarcane, with cotton reduced to sixth in importance. While the state has become much less dependent upon farming, it is estimated that the farm and farm-oriented business together constitute some 10 percent of the employment structure of the state. New Orleans remains the country's second-ranked port while

The  
decline  
of cotton

Baton Rouge, at the head of deep channel navigation on the Mississippi, is important for shipping of petroleum and chemical products, including aluminum, and grain.

The growth in Louisiana's per capita personal income from 1960 to 1970 was 85 percent, although, with a figure of \$3,065 (78.4 percent of the national average), the state still ranked only 41st among the U.S. states.

**The public sector.** In the public sector, state revenue is characterized by a high proportion—approaching 30 percent—of federal grants and a high degree of fiscal concentration on the level of state government. Louisiana's per capita state general revenue amounted to \$280 in 1968, giving it sixth rank among the states, but this figure is somewhat misleading, as over one-third of all the state's revenues excluding federal funds came from taxes on oil and gas production, rather than from taxes paid directly by the people.

The state budget topped \$1,000,000,000 for the first time in 1965: the bulk of tax revenues goes for expenditures for education, highways, and public welfare. Public welfare receives support above the national average, while education receives below average support. The state government has not been unwilling to initiate expenditures, although no major new source has been taxed since 1948, and the problem of balancing the budget has, in consequence, become increasingly difficult.

Many political leaders believe the state's current fiscal woes can be resolved if the "tidelands" oil controversy with the Federal government can be settled, as millions of dollars are now tied up in escrow awaiting the outcome. The major question involved remains that of the location of the seaward boundary of the state. State officials contest the federal government's claim to offshore leases beyond the three-mile limit until the question is settled as to what is the actual shoreline along the marshy, beachless edges of the state.

The labour movement has failed to gain a strong foothold in the state, though union leaders have become effective lobbyists in the state legislature. The percentage of nonagricultural employees who belonged to unions is, at some 18 percent, barely two-thirds of the corresponding national figure.

#### TRANSPORTATION

Louisiana waterways have never ceased to be an important means of transportation. By the 1970s, the state's 4,800–7,500 miles of navigable waterways included the intracoastal canal. This—Louisiana's only east–west waterway and canal system—runs some 400 miles from Mississippi Sound to the Sabine River and gives the important ports of Baton Rouge, New Orleans, and Lake Charles, access to the Mississippi River.

Railroads became common after the 1830s, initially as feeders to the steamboat traffic, with the Clinton and Port Hudson line being the state's first. Railroading reached its peak in the early 20th century in connection with a feverish lumbering boom and there are currently almost 4,000 miles of track in Louisiana. There are 53,000 miles of highway in the state. Louisiana has at least 65 airports and New Orleans International Airport, a leading continental link, is a major point of connection with Latin America.

Since the beginning of the 20th century, pipelines have existed to carry crude oil to refineries, or natural gas to provide energy for home or industry in state and distant markets. Many miles of electric power lines likewise crisscross the state.

#### ADMINISTRATION AND SOCIAL CONDITIONS

**The constitutional framework.** A constitution adopted in 1921 was the tenth in 108 years. It has managed to remain in force over the ensuing half-century, a period during which the state witnessed more fundamental change than had occurred in all the preceding 11 decades of experience with statehood.

The earliest document (1812) secured the political power of the planters and business classes and gave great appointive powers to the governor: the antebellum documents of 1845 and 1852 extended the suffrage and made

every government office, including the judiciary, elective. Representation, based on total population, continued legislative domination by the planter masters. The Constitution of 1861, which substituted the phrase "Confederate States" for "United States," and its successors of 1864 and 1868, which extended the suffrage to all males, black as well as white, may be called the Civil War documents. The Constitution of 1879, marking the end of the Reconstruction period, sought to restrict the action of the legislature and granted executive powers rivalling those of 1812, while the Constitution of 1898 disenfranchised the black citizens of the state. The Constitutions of 1913 and 1921 were written by delegates of conventions called to grapple with the problems of the 20th century: in many respects, they failed, not least because of the shadows of the past that hung over them.

The governor remains the most powerful official, not only from the weight of tradition (and personal performance) but also because of the extent of his patronage among the more than 250 executive agencies in the state.

**Local government.** Local self-government in Louisiana followed the Virginia system of county government. The parish (county), together with municipality and special district, are the units of local government. There are 64 parishes with land areas and population varying from the 205 square miles and 593,471 people in Orleans to 1,441 square miles and 8,194 people in Cameron Parish. The name of the parish governing board, "the police jury," is unique.

The 265 incorporated municipalities in Louisiana are state units and exercise narrowly construed powers. The charter of incorporation detailed by law recognizes three classes of municipalities based upon population: city (5,000); town, (1,000–4,999); and village, (150–999).

Special districts established by the legislature provide for the administration of new or expanding functions of local government. There are about 630 units of local government of which just over 300 are special districts, nearly 70 of them being school districts.

**Political life.** The closed primary system is used in the nomination of congressmen, state legislators, and all other state, district, and parish officers. Usually a runoff is necessary, since nomination requires a majority of the votes cast. Democratic nomination has been tantamount to victory but, recently the Republicans have made the general election important again.

The State Central Committee, the governing body of both the Democratic and Republican parties, is presently entitled to 105 members elected every four years, although, since they are not organized in each parish, the Republicans actually have a smaller number. These committees determine the procedures for the selection of presidential electors.

The conduct of elections at the lowest level has been the responsibility of election commissioners. Since 1954, the use of voting machines has been mandatory in all elections.

While many whites continue to indicate a determination to maintain the ways of a segregated society, utilizing either their votes or more direct racist methods, the traditional barriers are nevertheless coming down. At polling booths, in schools, on public conveyances, in stores and plants, and even at some churches, desegregation of the races is taking place, although it must be admitted that this has come about not so much from voluntary choice on the part of the white power structure, as from the insistence of federal laws. A civil rights movement has been active in Louisiana, where the National Association for the Advancement of Colored People has, perhaps, been the most effective among various vehicles catering for the establishment of black rights and the organization of protests. From the 1950s on, communities have established varieties of biracial human relations councils. Their activities were supplemented in the 1960s by federal monies from the Office of Economic Opportunity, which sustained various organizations designed for community advancement. Through efforts beginning in New Orleans in the 1940s and extending to south Louisiana rural parishes and other urban areas in the 1950s,

The  
tidelands  
contro-  
versy

The parish  
system

about 300,000 blacks, or about 60 percent of the potential total, have become registered voters.

**The legal system.** Louisiana's legal system is distinguished from that of the other 49 states in that it is based not on the common law but on civil law, which is code, or written, law. In this, the state draws upon her colonial inheritance, whereby she adopted a code based upon the Code Napoléon of France and further influenced by Spanish laws, each of which, in turn, had a common source in Roman law. The civil law consists of broad principles drafted by authorities in various fields of law. In Louisiana it is enacted in the constitution, which vests authority to make law in the legislature, whereas the functions of the courts are limited to the application of the law to given sets of facts, not bound by previous decisions. It governs all personal and property rights and has been extended to civil and criminal procedures.

**Services.** Close to 1,000,000 children are enrolled in the schools of Louisiana, approximately 15 percent of them in nonpublic parochial schools located primarily in south Louisiana. Public elementary and secondary education is administered by an elected state board of education and the state department of education, whose superintendent is also elected. The schools are locally administered by 64 parish school boards and three independent city school boards. The state board also administers nine colleges and universities, while the Louisiana State University system, with five campuses, two medical centres, and widespread agricultural activities, is administered by its own 15-member board of supervisors. Louisiana compares poorly with the national averages in educational attainment, with median school years completed by adults 25 years of age and over standing at 8.8 years, compared to 10.6 years for the nation. Part of this gap is the consequence of segregation practices. The comparable figures for whites was 10.5 years and for nonwhites 6.0 years.

The Department of Highways is responsible for 53,000 miles of roads, 14,000 miles of which are state roads, 27,000 miles are parish, and 11,000 miles are city streets. It is administered by a board, which appoints a director to administer the department. Each parish governing board is responsible for its own road system.

The legislature has established programs to provide a system of economic security and social welfare for various categories of citizens including persons 65 years of age and over; aid and welfare to mothers and children; care and treatment of crippled children; and aid to the needy blind. Various state departments provide some aspects of welfare aid but by far the most important is the Department of Public Welfare.

The so-called Charity Hospital system supported and administered by the state is almost unique among the 50 states. The Charity Hospital of Louisiana in New Orleans has received some public support since 1811. Three kinds of charity hospitals were maintained in the early 1970s, ten general hospitals, three for the mentally ill, and three for the treatment of tuberculosis.

The Louisiana Department of Health provides health services to Louisiana citizens through a central office in New Orleans and local health units in 62 parishes.

Five penal and correctional institutions operated by the state are administered under the general authority of the Louisiana Board of Institutions. The penal system has suffered from an excess of political interference.

#### CULTURAL LIFE AND INSTITUTIONS

The extensive power of the Roman Catholic Church in south Louisiana and the domination of Baptists in north Louisiana and among the black population remain important influences on social and cultural life. New Orleans and many smaller communities have been able to support the arts and philanthropic institutions. The Creoles (descendants of French or Spanish settlers) developed a distinctive architecture, art, and cuisine centred on New Orleans. American planters emulated the Creoles, and to this day, the people of the alluvial parishes of north Louisiana are more cosmopolitan in outlook than the more sober-minded people of the uplands.

In any estimate of the state of the arts and of folk

culture, it must be concluded that Louisiana more than holds her own. This is very much so in the realm of music, whether it be in Negro folk songs, including the celebrated rural blues; the Cajun bands at *fais-dodos*, country dances held in south Louisiana; the community hymn singings of north Louisiana; the jazz that New Orleans migrants took to Chicago and elsewhere; or the renaissance in dixieland music played by bands at New Orleans' Preservation Hall in the 1960s.

New Orleans, with its opéra, theatre, and painters, was one of the major "culture" centres in 19th-century America. Its French Quarter attracted such artists as John J. Audubon, the great wildlife painter, and George Catlin, noted for his portrayals of the American West, together with writers such as Walt Whitman, Sherwood Anderson, and William Faulkner. Since the 1930s other cities, notably Shreveport, Monroe, Baton Rouge, and Lafayette, have evolved their own museums and galleries, orchestras, choruses, and little theatres.

Tourism has developed as an important industry using the appeal, to some, of the antebellum past and the attraction of Creole cuisine, an exquisite blend of French, Spanish, Negro, and Indian dishes. A series of parades and balls culminating in the main celebration of Mardi Gras (Shrove Tuesday) has become a national attraction in New Orleans. Many parks and gardens are set aside for public use and display throughout the state. The state is advertised as a "sportsman's paradise" for hunting and fishing, and it is also football country, where junior and senior high school players prepare for big-time college and professional careers.

The literate Creole culture provided the state with a long press tradition with the first newspaper, *Le Moniteur de la Louisiane*, appearing in 1794. Eight others were published in New Orleans at the turn of the 19th century, and the rural parishes likewise published their own papers. In the 1970s the leading newspapers have been concentrated in the urban parishes. There are around two dozen dailies with a combined circulation of 764,000, ten Sunday papers and nearly 110 weeklies. The first radio stations appeared in New Orleans in 1922, and there are now 140 stations: of the 16 television stations, only one is an educational channel.

#### PROSPECTS

The Louisiana of the early 1970s has managed, as yet, to avoid much of the violence accompanying the contemporary national crisis in race relations. In part, this has been due to the leadership of the governor who, in 1965, established the Louisiana Commission on Human Relations, Rights and Responsibilities, a biracial body whose functions have been to advise the governor in all areas of human relations and to cooperate in efforts to avert and solve racial problems in the state. The state of Louisiana entered the 1970s with nearly all its school districts under court injunctions to integrate and with leadership on many levels trying to maintain a peaceful process of desegregation.

The quadrennial gubernatorial elections of 1971-72 brought many of the state's unresolved problems into focus. The credibility of state government remained unresolved. Most important, perhaps, are signs of a move to rewrite the state's outmoded constitution with its over 250,000 words and well over 500 amendments. In any event, Louisiana's long traditions, coupled with richer than average resources and a new social and political awakening, make the elusive promise of maturity a much more realistic challenge for the 1970s and beyond.

## Louvois, François-Michel Le Tellier, Marquis de

François-Michel Le Tellier, Marquis de Louvois, French secretary of state for war under Louis XIV, was Louis's most influential minister in the period 1683–91.

Born in Paris and baptized on January 18, 1639, he was the son of one of the wealthiest and most powerful officials in France, Michel Le Tellier, secretary for war and a creature of Jules, cardinal Mazarin, Louis XIV's chief minister. Indeed, after the Cardinal's death many observers thought that Le Tellier would succeed his patron as first minister. Le Tellier, however, realizing that the King wanted no ambitious man to challenge his authority, subtly effaced himself while grooming his son as his replacement. His method was simple: he personally directed Louvois's education while planting the suggestion in the King's mind that the monarch deserved the credit for recognizing his son's administrative talents. The task was no easy one; Louvois was not a brilliant scholar, and he received no more than a superficial education at the Jesuit college of Clermont. He was, moreover, dissolute and seemed well on the road to becoming a wastrel in his father's eyes. If the secretaryship was to remain in the family—Louvois had acquired no more than the right of succession in 1655—he had to be reformed. Consequently, his father brought him into the war department and subjected him to an iron discipline that led the youth to the point of rebellion. Yet he emerged hardworking, supremely confident of his own ability, and with extensive experience in military administration.

As his knowledge increased, so did his position: in 1662 he obtained the right to exercise his father's functions in the latter's absence or incapacity. The same year he improved his social position by marrying Anne de Souvré,

Giraudon

Louvois, portrait by Pierre Mignard (1612–95). in the Musée des Beaux-Arts, Reims, France.

daughter of Marquis de Courtenvaux. In 1665 the King granted Louvois the right to handle all the duties of Le Tellier's office and to sign all papers, but only in his father's presence. His first important test came in the War of Devolution (1667–68) between France and Spain over Louis XIV's claim to the Spanish Netherlands, when Louvois accompanied the King into battle. Although this campaign revealed a disturbing lack of supplies, Louvois learned his lessons well, and his competence became unquestioned. Nevertheless Le Tellier continued to guide his son until 1677, when the father accepted the position of chancellor of France. Until this date, Louis XIV had in fact two secretaries of war, father and son, who cooperated closely. Indeed, the son consulted his father until the latter's death in 1685.

Louvois's successful career was tarnished by two acts: the dragonnades leading up to the revocation in 1685 of the Edict of Nantes, which had granted French Protestants certain liberties, and the destruction of the Palatinate. Historians have accused Louvois of originating the dragonnades, the quartering of troops in Protestant households with the intention of forcing conversion to Catholicism. Recent research, however, has demonstrated that Louvois was not responsible for this measure. Instead, the dragonnades were the result of ambitious subordinates, who saw that overstepping the letter of the law led to royal favour. Yet, although Louvois had no strong religious feelings himself, he was guilty of complicity. As an astute politician, he recognized Louis XIV's interest in religious unity and went along with the King's wishes. Personally, he disliked the methods of the dragonnades, for they encouraged a lack of discipline among the troops.

Louvois bore much more responsibility for the destruction of the Palatinate (1688), to which Louis XIV laid claim, thus leading to the War of the League of Augsburg. Louvois had never been afraid of using force in enemy territory, and now military necessity seemed to demand the destruction of the Rhineland to prevent it from being used as a base for the invasion of France. He encouraged the destruction of the major cities of the Palatinate: Worms, Speyer, Mannheim, and Heidelberg. Yet Louvois alone cannot bear the entire blame; the King also approved the measure.

Louvois's relationship with the King was often strained, particularly during the last years of the Minister's life. Louis XIV had always tried to play off his officials against each other, preventing any servant from becoming too powerful. With the death of Colbert in 1683, however, Louvois increasingly dominated affairs of state. War seemed to perpetuate itself, and every campaign made the War Minister indispensable, while Louis XIV's resentment grew as Louvois asserted himself. Finally, during the difficult years of the War of the League of Augsburg (1689–97), rumours circulated at court of Louvois's imminent disgrace, and, according to contemporaries, only the sudden death of Louvois at Versailles, on July 16, 1691, saved him from imprisonment in the Bastille. Most historians, however, reject this theory. Certainly, Louis XIV valued Louvois's military talents too highly to remove him in the middle of a war. Louvois, "this man who had served me well," was no more, and the King had reason to mourn his servant's loss, for Louvois's son and successor, the Marquis de Barbezieux, had little skill in military administration.

Most historians have allotted to Louvois all the glory for perfecting the French military machine. In reality, Le Tellier was the innovator; Louvois was only the brilliant administrator who brought his father's reforms to fruition. Memoir writers have pictured Louvois as a hard-working, aggressive, and exceedingly ruthless man: in his memoirs the Duc de Saint-Simon spoke of him as "brutal, inflated with his own authority"; Louis XIV's sister-in-law called him "horribly cruel and quite incapable of feeling any pity." Both, however, had personal reasons for disliking Louvois; one regarded him as an upstart who threatened the traditional aristocracy; the other disliked him for his role in the destruction of the Palatinate, her homeland. Louvois was, however, a loving

Louvois's involvement in the dragonnades and the destruction of the Palatinate

Assessment

son and a devoted friend. Some historians have mistakenly portrayed him as a war hawk and his rival Jean-Baptiste Colbert, Louis XIV's chief adviser after Mazarin's death, as a dove, but in reality both had surprisingly similar personalities. Each was harsh and egocentric with a sometimes violent temperament, bent on safeguarding his own interests and increasing his influence. Yet, beyond furthering his career, Louvois had done his work well. After his death the French army remained one of the most formidable in Europe.

**BIBLIOGRAPHY.** Standard works include CAMILLE ROUSSET, *Histoire de Louvois et de son administration politique et militaire*, 3rd ed., 4 vol. (1863–1865); and particularly LOUIS ANDRÉ, *Michel Le Tellier et Louvois* (1942). See also André's earlier work, *Michel Le Tellier et l'organisation de l'armée monarchique* (1906). JACQUES ROUJON, *Louvois et son maître* (1934), is a popular and less satisfactory study; while L.L. BERNARD's specialized article, "Foucault, Louvois, and the Revocation of the Edict of Nantes," *Church History*, 25:27–40 (1956), is a more recent scholarly effort.

(D.C.B.)

## Lovell, Sir Bernard

The founder and director of England's Jodrell Bank Experimental Station (Nuffield Radio Astronomy Laboratories) and one of the foremost pioneers in this relatively new science, Alfred Charles Bernard Lovell has made significant contributions to man's knowledge of the universe and his exploration of space. Moreover, as a popularizer of science through his writings and lectures, Lovell shared with lay audiences his enthusiasm and concerns for space research while providing a better understanding of the importance of such efforts.

Born at Oldland Common, Gloucestershire, near Bristol, England, on August 31, 1913, Lovell attended grammar school in Bristol as well as the University of Bristol, from which he received the Ph.D. degree in 1936. After a year as an assistant lecturer in physics at the University of Manchester, he became a member of the cosmic-ray research team at that institution, working in this capacity until the outbreak of World War II in 1939. Meanwhile, in 1937 he married Mary Joyce Chesterman, who subsequently bore him five children. In 1939 he published his first book, *Science and Civilization*. During World War II, Lovell worked for the Air Ministry, doing valuable research in the use of radar for detection and navigation purposes for which he was awarded the Order of the British Empire in 1946.

On returning to the University of Manchester in 1945 as a lecturer in physics, Lovell acquired a surplus army radar set for use in his research on cosmic rays. Because interference from the surrounding city hampered his efforts, he moved the equipment, which included a searchlight base, to Jodrell Bank, an open field located about 20 miles south of Manchester. Shortly thereafter,

authorities at the university agreed to provide him with a permanent establishment at the site, which already belonged to the university's botany department, and to sponsor the construction of his first radio telescope, for which he used the searchlight base as a mounting.

Lovell's initial investigations with the instrument involved the study of meteors. About 15 years earlier, when radio waves had been bounced off meteors during certain meteor showers, some astronomers had noted that the number of meteors observed visually was much smaller than the number of radio echoes received, an indication that the showers actually consisted of more meteors than could be seen. To determine if the echoes were meteoric in origin, Lovell used his new radio telescope to observe a particularly intense meteor shower on the night of October 9–10, 1946. As the shower first increased and later decreased in intensity, radio signals from the instrument's transmitter were directed toward the shower. Throughout the evening, not only did the number of optical sightings coincide with the number of radio echoes being received, but the timing of the two rates was also as predicted, thereby conclusively proving that the echoes were caused by the meteors. Having established this fact, Lovell could now apply radio techniques to meteor showers previously unknown because they occurred during daylight hours. Further experiments with the radio telescope in 1947 and 1948 also determined that orbits of meteors are elliptical, thus confirming the belief that these bodies are members of the solar system and are not of interstellar origin.

In recognition of his work and growing reputation, Lovell was appointed by the University of Manchester to the position of senior lecturer in 1947 and reader in 1949; in 1951 he became the first professor of radio astronomy at the university. During this time, he had already begun planning and building a bigger and more sophisticated radio telescope, which, when it was completed in 1957, was the world's largest of its kind, with a diameter of 250 feet. The structure rotates horizontally at 20° per minute, and the reflector itself moves vertically at 24° per minute. Lovell described the instrument and the problems associated with its construction in *The Story of Jodrell Bank* (1968). While work on the telescope was in progress, Lovell also wrote three other books: *Radio Astronomy* (1952), *Meteor Astronomy* (1954), and *The Exploration of Space by Radio* (1957).

Lovell frankly admits that it was mainly the prospect of using the new radio telescope to track the first Sputnik, scheduled for launch by the Soviet Union on October 4, 1957, that spurred his efforts to complete the instrument by that time. By supplying a much-needed boost to the prestige of the project at a time when its financial viability was being seriously threatened by rapidly rising costs, this completely unforeseen application of the instrument guaranteed its success and Lovell's personal fame. Ever since, the giant radio telescope at Jodrell Bank has been a vital tool for pinpointing the exact locations of Earth satellites, space probes, and manned space flights, as well as for collecting data transmitted by instruments in some of these vehicles.

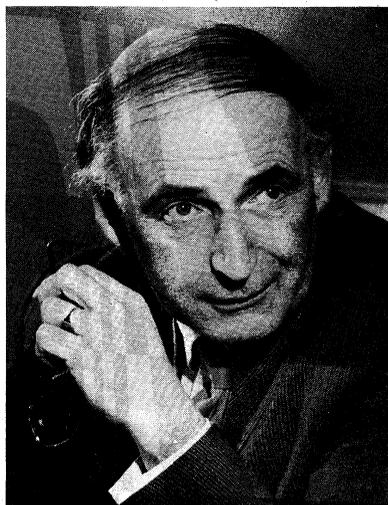

Because of the widespread publicity given to Jodrell Bank and its director, coupled with the latter's reputation as a popularizer of science, the British Broadcasting Corporation in 1958 invited Lovell to give a series of radio talks, known as the Reith Lectures, which were published in 1959 as *The Individual and the Universe*. When Lovell was knighted in 1961 for his pioneering work in radio astronomy, 20 investigations—mostly on radio emissions originating thousands of millions of light years away—were in progress at Jodrell Bank. Some of this work is discussed in his book *The Exploration of Outer Space* (1962). His research has since been concerned mainly with radio emissions from outer space, including those from pulsars (discovered in 1968), and measuring the angular diameters of distant quasars.

In addition to honorary degrees bestowed upon him by various academic institutions, Lovell was elected a fellow of the Royal Society in 1955, receiving its Royal Medal in 1960; he is also an honorary member of several foreign

Lovell, 1964.

academies and professional organizations. Other honours include the Physical Society's Duddell Medal (1954), the Daniel and Florence Guggenheim International Astronautics Award (1961), the French Order of Merit (1962), and the Society of Engineers' Churchill Gold Medal (1964). From 1969 to 1971, he was president of the Royal Astronomical Society.

**BIBLIOGRAPHY.** The best summary of Lovell's scientific work is given in the biographical article in the 1966 edition of *McGraw-Hill Modern Men of Science*. The building of the Jodrell Bank telescope is described in full by Lovell himself in his *Story of Jodrell Bank* (1968).

(M.A.H.)

## Low Countries, History of

A treatment of the medieval history of the Low Countries (the Netherlands) runs up against a considerable problem in that the area did not form a self-contained political unit; it was a part of a greater whole. Neither did it form a cultural or ethnic unit. A geographical limit to the area to be discussed must, therefore, be chosen somewhat arbitrarily. For the purposes of the present article, the term the Netherlands includes the area covered by the medieval duchy of Lower Lorraine, belonging to the Holy Roman Empire, and the county of Flanders, which was principally part of the Kingdom of France, but a small part of which also belonged to the Holy Roman Empire. It corresponds roughly to the area now covered by the states of The Netherlands, Belgium, and Luxembourg and by a small part of northern France (Artois). This article contains the following sections:

- I. The Netherlands to c. 1600
  - Ancient and early medieval times (to 925)
    - The Roman period
    - Frankish rule
  - Late medieval and early modern times, 925–1579
    - The development of the territorial principalities and the rise of the towns (925–c. 1350)
    - Burgundian and Habsburg rule (1384–1579)
    - The revolt and the formation of the republic (1567–79)
- II. The Netherlands since 1579
  - Political and constitutional developments, 1579–1609
    - The Union of Utrecht
    - Foreign intervention
    - The formation of the new government
  - Ascendancy of the Dutch economy
  - Political developments, 1609–1713
    - The Twelve Years' Truce
    - War with Spain, 1621–48
    - The first stadholderless period
    - William III
  - Dutch civilization in the Golden Age (1609–1713)
    - The economy
    - Society
    - Religion
    - Culture
  - The 18th century
    - Economic and political stagnation
    - The Patriotic movement
  - The period of French rule, 1795–1813
    - The Batavian Republic, 1795–1806
    - The Kingdom of Holland and the French Empire, 1806–13
  - The Kingdom of The Netherlands (1814–1918)
    - King William I
    - William II and William III
    - Queen Wilhelmina and World War I
  - The Netherlands since 1918
    - World War II
    - The postwar period
- III. The southern Netherlands, Belgium and Luxembourg (1579 to present)
  - The period of foreign rule
    - The Spanish regime
    - The Austrian regime (1713–95)
    - French and Dutch rule
  - Belgium and Luxembourg (1831 to present)
    - Independent Belgium
    - The Grand Duchy of Luxembourg

### I. The Netherlands to c. 1600

#### ANCIENT AND EARLY MEDIEVAL TIMES (TO 925)

**The Roman period.** At the time of the Roman conquest (1st century BC), the Low Countries were inhabited

by a number of Celtic tribes to the south and west of the Rhine and by a number of Germanic tribes to the north. Cultural and ethnic influences in both directions, however, make it difficult to draw the line between Celtic and Germanic peoples. On the coast of northern France and in Flanders lived the Morini; to the north of them, between the Scheldt and the sea, the Menapii; in Artois, the Nervii; between the Scheldt and the Rhine, the Eburones and the Aduatuci; and, in what is now Luxembourg, the Treveri. North of the Rhine, the Frisii (Frisians) were the principal inhabitants, although the arrival of the Romans brought about a number of movements: the Batavi came to the area of the lower reaches of the Rhine, the Canninefates to the western coastal area of the mouth of the Rhine, the Marsaci to the islands of Zeeland, the Toxandri to the Campine (Kempenland), the Cugerni to the Xanten district, and the Tungri to part of the area originally inhabited by the Eburones (who were wiped out by Julius Caesar).

The Roman conquest of Gaul, which was completed by Caesar in 59–52 BC, stopped short at the Rhine. The emperor Augustus' attempt to extend Roman military power over the Elbe failed, and the area occupied by the Frisians, north of the Rhine, was therefore never under Roman rule. In the Rhine delta and to the south and west of the Rhine, the Romans set up the same administrative organizations as those found in other parts of Gaul. The Low Countries formed part of the provinces of Belgica and Germania Inferior (later Belgica Secunda and Germania Secunda), which themselves were subdivided into *civitates*: in Belgica, those of the Morini, Menapii, Treveri, Tungri, and possibly the Toxandri; in Germania Inferior, those of the Batavi, Canninefates, and Cugerni. Because of the later adoption by the church of the division into *civitates*, a number of centres of the *civitates* have become the seats of bishoprics; among these are Théroutanne, Tournai, Tongres, and Trier (Trèves).

In the northern regions, fishing and cattle raising were the principal means of support, while to the south of the Rhine it was possible, with Roman protection, to engage in farming in the Gallo-Roman fashion, using villas as centres. There must also have been a certain amount of trading and other traffic, even if only to provision the Roman military and civil services.

In the mid-3rd century, Roman power in the Low Countries began to weaken, and the forts were abandoned. This was the result not only of a resurgence of the Germanic tribes but also probably of the encroachment of the sea, which probably brought about a drastic change in the area's economy. A temporary recovery began at the end of the 3rd century. In particular, Julian, caesar of Gaul, waged several wars in the Low Countries between 355 and 360 and was able to put new strength, for a time, into the Rhine border. A great invasion by Germanic tribes in 406–407, however, ended the Roman occupation of the Low Countries. The Romans had already tolerated the Germanic penetration of their territory and had given some tribes the task of protecting the borders of the empire. The Franks, who had settled in Toxandria, in Brabant, were given the job of defending the border areas, which they continued to do until the middle of the 5th century.

The Franks were probably influenced considerably by Roman culture, becoming familiar with the Roman world and way of life, although the expansion of their own race and their growing self-confidence were barriers to complete romanization. Around 450 they moved southward, founding a new Frankish kingdom centred on the region between the Somme and the Loire. The number of Franks in this Merovingian-Frankish kingdom has been vigorously debated: French and Belgian scholars believe that only a small number of ruling families made the move; German scholars claim a mass migration of the whole tribe. It is certain, however, that the Franks never achieved a majority in the population of the kingdom but probably settled in the conquered area as colonists and farmers. Their cultural influence was too slight to oust the Romance languages; thus, the linguistic frontier between the Romance and Germanic languages has re-

Decline of  
Roman  
power

mained the same as the limit of Roman culture in the north—crossing the Low Countries, in particular the later principalities of Flanders, Brabant, and Liège, in an east-west line.

**Frankish rule.** The first kings of the Merovingian Franks—Childeric (d. 481/482) and Clovis (ruled 481/482–511)—ruled the regions of Tournai and Cambrai before the great conquest of Gaul had even begun. Despite this, however, the Low Countries originally formed a border region in which the might of the Frankish state was hardly felt. The area occupied by the Frisians in the north was completely outside the Frankish sphere of influence, but the Rhine delta and even what is now Noord-Brabant also appear to have retained the virtually independent status they had possessed during the Roman era. It is possible, though not certain, that Nimwegen (Nijmegen) was a Merovingian outpost.

The area occupied by the Frisians was part of a North Sea culture that formed a distinct foil to Frankish power. The Frisians played an important role in trade, which sought routes along the Rhine and the Meuse and across the North Sea. Industrial products were imported from northern France, the Meuse plain, and the Rhineland, where Merovingian power was more firmly established and where centres of commerce (e.g., Dinant, Namur, Huy, and Liège) developed. The more or less independent area on the North Sea coast, however, found itself threatened during the 7th century by the rise of the Frankish nobles. In particular, the family of the Pepins, who came from the centre of Austrasia (the Ardennes and upper Meuse), was able to secure land in Limburg. Moreover, encouraged by the Frankish king Dagobert (ruled 623–639), the Frankish church began an offensive that led to the foundation of the bishopric of Thérouanne (the *civitas* of the Morini) and of several monasteries.

This collaboration between church and nobles prepared the way for an expansion of political power to the north, which was carried out under the leadership of the Pepins, who as “mayors of the palace” in Austrasia had virtually taken over power from the weakened Merovingian kings. After defeating the mayor of the palace of Neustria (the western part of the Frankish Merovingian kingdom) at Tertry (687), Pepin II turned to the north, where he won a victory over the Frisian king Radbod near Dorestad (689). The Anglo-Saxon Willibrord was then ordained archbishop of the Frisians in Rome and, with Pepin’s help, was given Utrecht as see of the bishopric and centre for his missionary activities. Even so, Frankish power expanded northward only gradually, making use of such bases as Utrecht and several former Roman forts. Charles Martel, a bastard son of Pepin II, who managed after several years’ fighting (714–719) to grasp supreme power over the whole Frankish Empire, succeeded in 734 in forcing his way through to the northern centres of the Frisians and gaining a victory near the River Boorne. His victory was later consolidated by Pepin III (who in 751 became King Pepin I) and Charlemagne (ruled 768–814), his son. The whole area of the Low Countries thus effectively formed part of the Frankish Empire, which was then ruled by the Pepin, or Carolingian, dynasty.

**Government.** The administrative organization of the Low Countries during this period was basically the same as that of the rest of the Frankish Empire. Supreme authority was held by the king, who, aided by servants of the palace, toured the country incessantly. The Carolingian kings naturally made several visits to the Low Countries, where they had old palaces or built new ones (Herstal, Meerssen, Nijmegen, Aix-la-Chapelle) and where they also possessed extensive crown estates. Their authority (*bannus*) was delegated to counts who had control of counties, or *gauen* (*pagi*), some of which corresponded to Roman *civitates*. Among these counties in the Low Countries were the *pagus* Taruanensis (centred on Thérouanne), *pagus* Mempiscus, *pagus* Flandrensis (around Bruges), *pagus* Turnacensis (around Tournai), *pagus* Gandensis (Ghent), *pagus* Bracbatensis (between the Scheldt and the Dijle), *pagus* Toxandrie (modern Noord-Brabant), and, north of the great rivers, Marssum, Lake et Isla, Teisterbant, Circa oras Rheni, Kin-

nem, Westflinge, Texla, Salon, Hamaland, and Twente. In the north, however, it is frequently not possible to determine with certainty whether the word *gau* in fact denoted a region controlled by a count who exercised the king’s authority or indicated simply a region of land without reference to its government. Smaller administrative units were the *centenae*, or hundreds, and districts called *ambachten*. These last were mainly in what are now the provinces of Vlaanderen, Zeeland, and Holland.

**Religion.** The conversion to Christianity of the southern Low Countries, which took place largely during the 7th century, led to the foundation of further bishoprics at Artois, Tournai, and Cambrai, which were part of the ecclesiastical province of Rheims (the former Roman province of Belgica Secunda). Germania Secunda contained the ecclesiastical province of Cologne, in which the *civitas* of Tongres seems to have had an uninterrupted existence as a bishopric since Roman times; the centre of this bishopric was moved for a time to Maastricht (6th and 7th centuries) until, in about 720, Liège became the seat of the bishopric. Christianity was brought to the north of the Low Countries mainly by Anglo-Saxon preachers, by Frisians influenced by them, and by Franks. This Anglo-Saxon Christianity was particularly important in the missionary bishopric of Utrecht, which at first, because of its missionary character, had no precisely defined borders. True, the city of Utrecht had been named as the see of the bishopric, but, as in England, the monasteries played an important part in the missionary work; among these was the monastery of Echternach in Luxembourg. The country between the Meuse and the Waal and the area around Nijmegen belonged to the bishopric of Cologne, while certain districts in the north and east were part of the bishopric of Münster (founded by Charlemagne). The bishoprics were subdivided into relatively large parishes, about the foundation of which only scanty information exists. With an increase in population during the 10th, 11th, and 12th centuries, the parishes were split into smaller ones, based on small chapels that at first had only limited rights. In the north and, above all, in Friesland, the initiative for founding parishes often came from the faithful themselves, who built a church and provided it with the necessary income in the form of estates (*dos*). The influence of laymen and, in particular, of the aristocracy was often extremely strong; and they usually collected the tithes and other revenues. On the other hand, this system of proprietary churches formed a distinct stimulus for the conversion of the country areas.

**Justice.** The administration of justice was the duty of the king and his appointed counts. They pronounced judgment principally in important cases (*causae majores*) or in cases involving prominent people: theirs was known as the higher court of justice. To fulfill this task, Charlemagne appointed groups of permanent judges, called *scabini* (French *échevins*), who under the direction of the count “found” the law and applied it as a verdict. At lower levels, it seems that justice must have been administered in the smaller legal units of hundreds and *ambachten*. Only to a small extent is the content of the law included in the codes of Germanic law, such as the *Lex Salica*, which consist largely of criminal law (robbery, theft, homicide, and rape) and property law (land and cattle). On Charlemagne’s initiative, a large part of Frisian law was put down in writing as the *Lex Frisionum*, as well as the *ewa quae se ad Amorem habet*, “the law that exists on the Amor” (Amor being the name of an unidentified river, probably in the Waal and Meuse district). Charlemagne amplified the *Lex Salica* and *Lex Saxonum* in various of his *capitularia* (ordinances). The law was thus materially diverse, while formally the situation was complicated even further by the immunity that was frequently granted to churches or monasteries, which put their property beyond the reach of the legal and administrative powers of the count and his subordinates. The secular jurisdiction that in this way became the prerogative of bishops or abbots was the basis of later, more extensive secular powers, which in the Low Countries, more than anywhere else, were to play an important role in the foundation of the ecclesiastical territorial principalities.

the Franks

The people

*Social classes.* The social structure of the Low Countries in the Frankish era included a number of classes. At the top was an elite that probably already operated on a hereditary system and of which the members were bound to the king as vassals and rewarded by fiefs (*beneficia*). Next were the freemen (*liberi, ingenui*), bound to the king by an oath of allegiance and traditionally under an obligation to serve in the army and in the law courts. A freeman's *Wergeld*—the sum that had to be paid to his family if he was killed—was in principle 200 shillings (*solidi*); but the *ingenui Franci*, or *homines Franci* (found in the region of the great rivers; probably descended from native nobles who had early placed themselves in the service of the Franks in their policy of conquest), had a much higher *Wergeld*. At the bottom of the ladder were the bondsmen, who were closely dependent on a lord (often an important landowner), in whose service they stood, in most cases working on his estates. It may be supposed that the position of the bondsmen was relatively favourable in the coastal areas of Holland and Friesland, where there were no large estates and, moreover, where the struggle against the sea required as much manpower as the community was able to offer.

*Economy.* Economically, the structure of the Low Countries in the Frankish period was principally agrarian. Particularly in the south and east, it was common practice to exploit the land from a central farmhouse (*villa* or *curtis*), using the services of dependent subjects (bondsmen), who were duty bound to work on the domain of the lord and to this end received small farms from him. The nature of the land in the west and north, however, probably to a large extent precluded this classical type of exploitation of the domains; there was scattered, even fragmentary, ownership of land, and the *curtis* was no more than a gathering place to which the bondsmen had to take a part of their produce. In Holland and Friesland, fishing and the raising and selling of cattle were of importance. This Frisian trade, of which Dorestat was a centre, was greatly stimulated by absorption into the Frankish Empire, and it reached its zenith under Charlemagne and Louis the Pious (ruled 814–840). Moreover, by virtue of its becoming part of the Frankish Empire, Friesland obtained an important hinterland in the southern regions of the Meuse and Rhine and was thus in a position to develop export and through trade to Denmark, Norway, and the Baltic countries. The importance of Frisian trade may be seen in the Carolingian coins found in Dorestat, where there was a toll and a royal mint. This trade was supplied by the southern Low Countries. Thus the cloths that were sold as Frisian cloths were produced in the area of the Scheldt (later called Flanders). Quentovic, at the mouth of the Canche, was another trading centre; it too had a toll and a mint. Smaller trade settlements (*portus*, or *vicus*) emerged at Tournai, Ghent, Bruges, Antwerp, Dinant, Namur, Huy, Liège, and Maastricht—a clear indication of the commercial importance of the Scheldt and the Meuse.

*Decline of the Frankish Empire.* The great Carolingian Empire passed into a decline as early as the reign of Louis the Pious, and the process was accelerated after his death, in 840. Repeated wars broke out under his sons, leading eventually to the partition of the empire: by the Treaty of Verdun (843), the empire was divided into an eastern, western, and an extensive middle kingdom. The last of these, allotted to Louis's eldest son, Lothair, who also wore the imperial crown, was, after his death, further divided into three parts—the northern part, stretching from the Jura Mountains to the North Sea, falling to his son Lothair II, after whom it was named. After it had belonged alternately to the western and eastern Frankish kingdoms, Lorraine eventually (925) became part of the eastern kingdom, by then the German kingdom, because there were no longer any ruling Carolingians. The nobles of Lorraine had themselves taken an important part in this changing political game. Gisibert, a member of one of the most noble families, had turned the scales in favour of joining the German kingdom, for which service King Henry I presented him with what then became the duchy of Lorraine.

Partition of the empire

The dissolution of the Carolingian Empire had also been helped by Viking, Magyar, and Saracen attacks—the Viking attacks being of greatest import for the Low Countries. The attacks had begun immediately after the death of Charlemagne (814) in the form of plundering raids, the magnitude and danger of which soon increased. (Dorestat, for example, was destroyed four times between 834 and 837.) Churches and monasteries, with their rich treasures, were the principal targets for the Vikings, who soon took to spending the winter in the Low Countries. In order to ward off the danger, attempts were made to throw up walls around towns and monasteries or even to drive off the Vikings by fierce counterattacks—a procedure that enjoyed some success, so that the counts of Flanders, for example, were able to lay a firm foundation for their own power. Another method of defense was to admit the Vikings on the condition that they defend the areas given them against other Vikings. The danger diminished after 900, though it was not until about 920 that Bishop Balderic risked the journey from Deventer to Utrecht, whence his predecessor had fled.

## LATE MEDIEVAL AND EARLY MODERN TIMES, 925–1579

**The development of the territorial principalities and the rise of the towns (925–c. 1350).** Politically speaking, the period between 925 and about 1350 is characterized by the emergence, growth, and eventual independence of secular and ecclesiastical territorial principalities. The rulers of these principalities—both secular and spiritual—had a feudal relationship with the German king (the Holy Roman emperor), with the exception of the count of Flanders, who held his land principally as the vassal of the French king, with only the northern part of his county, Imperial Flanders, being held in fealty to the German king. While the secular principalities came into being as a result of individual initiative on the part of local rulers and of their taking the law into their own hands, to the detriment of the king's authority, the development of the spiritual princes' authority was systematically furthered and supported from above by the king himself. The secular principalities that arose in the Low Countries and whose borders were more or less fixed at the end of the 13th century were the counties of Flanders and Hainaut, the duchies of Brabant and Limburg (after 1288 joined in personal union), the county of Namur, the county of Loon (which was, however, to a large degree dependent on the bishopric of Liège), the county of Holland and Zeeland, and the county (after 1339, duchy) of Guelders. The Frisian areas (approximately corresponding to the modern provinces of Friesland and Groningen, excluding, however, the city of Groningen itself) had no sovereign authority. The spiritual principalities were Liège and Utrecht. The secular authority of the bishop of Utrecht was exercised over two separate areas: the Nedersticht (what is now the province of Utrecht) and the Oversticht (what are now the provinces of Overijssel and Drenthe and the city of Groningen).

Origin of the principalities

This article will sketch the emergence of these principalities, their relations with one another, their dissociation from the German king, and the increasing influence upon them of France and England. It must be noted that, although these principalities displayed common characteristics in their economies, social structures, and cultures, it was a pure coincidence—the intrusion of the Burgundian dynasty—that brought about a certain degree of political unity, which in turn furthered economic, social, and cultural unity and even led to the beginnings of a common national feeling (which was nevertheless too weak to prevent partition in 1579).

*The secular principalities.* The foundations upon which the secular princes built up their power were basically the following: In the first place, the count still exercised the rights that had for centuries been attached to the Carolingian office of count, denoted by the term *comitatus*. They included the administration of justice, various military powers, and the right to levy fines and tolls. To these rights fiefs were attached, which during the passage of time were expanded by the counts, who eventually owned such large estates that they were by far the great-

est landowners in their territories. Soon the term *comitatus* covered not only the office, or duty, but also the whole area over which that office was exercised; thus it could be said that the count held his county in fief of the king. An important element of the count's authority was supervision over the county's religious foundations, especially the monasteries. In the 10th century, the counts sometimes even assumed the function of abbot (lay abbot); but they later contented themselves with the control of appointments to ecclesiastical offices, through which they often had great influence over the monasteries and profited from the income from monastic land. Thus, monasteries such as St. Vaast (near Arras), St. Amand (on the Scarpe), St. Bertin (near St. Omer), and St. Bavon and St. Pieter (in Ghent) became centres of the power and authority of the counts of Flanders; Nivelles and Gembloux, of the dukes of Brabant; and Egmond and Rijnsburg, of the counts of Holland.

Expansion  
of counts'  
power

At the end of the 9th and in the 10th centuries, during the Viking attacks and while connections with the empire were loosening, the local counts built up their power by joining a number of *pagi* together and building forts to ensure their safety. The counts of Flanders amalgamated the *pagi* Flandrensis, Rodanensis, Gandensis, Courtracensis, Iserae, and Mempiscus, the whole being thenceforth called Flanders; they fortified this area of their power with new or surviving Roman citadels. In the northern coastal regions, the Viking Gerulf was granted in about 885 the rights over a number of counties between the Meuse and the Vlie (Masalant, Kinnem, Texla, Westflinge, and a district known as Circa oras Rheni, which was, as the name implies, on both sides of the Rhine); his descendants consolidated their power there as counts of west Frisia and, after 1100, took the title of counts of Holland. In Brabant and Guelders, the amalgamation of fragmentary and dispersed estates took place later than in Flanders and Holland.

These secular princes were bound by a feudal relationship to the German or French kings, and they in turn used a similar relationship to bind the nobles to them. As supreme lords, they stood at the head of their vassals, who were duty bound to carry out services of *auxilium* and *consilium* (to serve in the army and at court). These services were rewarded with fiefs, and in most of the principalities a powerful feudal nobility emerged, to which the prince had to give the fullest consideration. At first, in the 10th and 11th centuries, the prince and his subjects had no direct link, and the princes had no specific duties to carry out, as bearers of authority, toward their subjects. On the contrary, the princes' activities during this period were almost exclusively motivated by greed for power and money.

During the 10th and 11th centuries, the German kings of the Saxon and Salian dynasties—particularly Otto I (ruled 936–973), Henry II (ruled 1002–24), Conrad II (ruled 1024–39), Henry III (ruled 1039–56), and Henry IV (ruled 1056–1106)—attempted to impose their authority on the increasingly powerful secular principalities by the appointment of dukes. In Lorraine, a duke was appointed to exercise imperial power over the local counts; but the plan failed, except for a short period (953–965) during the reign of Otto I, when the king's brother Bruno held the position (Bruno's success was largely due to the fact that he was also archbishop of Cologne). Taken all in all, the dukes of Lorraine had too little authority and no effective means to exercise their power to subdue the local counts. Lorraine was soon split into two dukedoms—Upper and Lower Lorraine. In Lower Lorraine, the title of duke was given to the counts of Louvain and the counts of Limburg—the former at first called themselves dukes of Lorraine but soon assumed the title of dukes of Brabant; the latter were known as the dukes of Limburg.

*The spiritual principalities.* That the German kings failed to integrate Lorraine into the Holy Roman Empire as a duchy ruled by a viceroy may be attributed to the fact that the kings soon developed another way to strengthen their power, not only in Lorraine but throughout the empire, by systematically investing bishops and abbots

with secular powers and making them pillars of authority. This procedure, developed by Otto I and reaching its summit under Henry III, was carried out in phases and led eventually to the establishment of the Imperial Church (Reichskirche), in which the spiritual and secular principalities played an important part. The most important ecclesiastical principalities in the Low Countries were the bishoprics of Liège, Utrecht, and, to a lesser degree, Cambrai, which, though within the Holy Roman Empire, belonged to the French church province of Rheims. The secular powers enjoyed by these bishoprics were based on the right of immunity that their churches exercised over their properties and that meant that, within the areas of their properties, the counts and their subordinates had little or no opportunity to carry out their functions. This situation, which had existed during the Carolingian and Merovingian periods, enabled the bishops to exercise jurisdictional and military powers in these areas, helped by lay officials known as advocates (*advocati*), whom they themselves appointed. The German kings strengthened this immunity and put it to their own service by enlarging its jurisdictional powers, while at the same time investing the bishops' advocates with the *bannus* (public authority), so that they formed a link between the king and the immunities. Next, the kings gave certain bishops jurisdictional authority in areas outside their own property, such as in the towns where they resided; at the same time, the bishops' properties were extended by gifts of crown land, which were then also covered by the powers of immunity. Further, the kings transferred such regal powers (*regalia*) to the bishops as the right to found markets, raise tolls, and strike coins. Through the exercise of these regalia, the bishops became for the first time bearers of royal authority and, thus, of the public authority; and they also derived from these rights a considerable personal income. The last phase in the bishops' growth occurred when the kings decided to transfer to the bishops the powers of counts in certain areas that were not covered by immunity (the power thus acquired is referred to as *ban-immunity*). Certain bishops, such as those of Liège and Utrecht, were able to combine their rights of immunity, certain jurisdictional powers, regalia, and *ban-immunities* into a unified secular authority, thus forming a secular principality which was called a *Sticht* (as distinct from the diocese) or—where the power structure was very large and complex, as in the case of the bishop of Liège—a prince-bishopric. As princes, the bishops were vassals of the king, having to fulfill military and advisory duties in the same way as their secular colleagues. The advantage of this system to the kings lay in the fact that the bishops could not start a dynasty that might begin to work for its own ends, and its smooth running stood and fell with the authority of the kings to nominate their own bishops—an authority that they maintained firmly.

Thus the spiritual-territorial principalities of the bishops of Liège and Utrecht emerged—the prince-bishopric of Liège and the *Sticht* of Utrecht. In Liège this development was completed in 972–1008 under the guidance of Bishop Notker, appointed by Otto I. As early as 985 he was granted the rights of the count of Huy, and the German kings made use of the bishopric of Liège to try to strengthen their positions in Lorraine. Utrecht, which lay more on the periphery of the empire, developed somewhat later; although the foundations of this power had already been laid in the 10th century, it was principally the kings Henry II, Conrad II, and Henry III who strengthened the secular power of the bishops through privileges and gifts of land.

*Struggle for independence.* Thus, the Low Countries during the 10th and 11th centuries saw the development of the pattern of a number of more or less independent feudal states, both secular and ecclesiastical, each of which was struggling for more freedom from the king's authority, the enlargement of its sphere of influence, and the strengthening of its internal power. Flanders led the way. In the 10th and 11th centuries it needed to pay only scant attention to the weak French kings of the Capetian dynasty and was thus soon able to exercise its power

Rise of  
bishops  
and abbots

farther south—in Artois—and was even able to play an important part in a political power struggle around the French crown. In 1066 the Count of Flanders lent his support to the expedition to England of his son-in-law, William, duke of Normandy. The counts of Flanders built up a strong administrative apparatus—the *curia comitis*, based on central officials and on local rulers called burgraves or castellans (*castellani*), who were in charge of districts known as castellanies, where they had extensive military and administrative powers. The reclamation of land from the sea and from marsh and wasteland in the coastal area, which began in the 11th century, enlarged the estates and the income of the counts and brought about the need for a rational administrative system. The nobles were a power to be reckoned with, but Count Robert I (ruled 1071–93) and his successors were able to find support and a balancing force in such developing towns as Bruges, Ghent, Ypres, Courtrai, and Cassel. The murder by a family of former bondsmen of the powerful and highly respected Count Charles the Good (ruled 1119–27), who was childless, plunged Flanders into a crisis that involved not only the nobles and the towns but also, for the first time, the French king.

Decline of  
the  
German  
kings

Around 1100 such other territories as Brabant, Hainaut, Namur, and Holland began to expand and form principalities, helped by the weakening of the German crown during the Investiture Contest (a struggle between civil and church rulers over the right to invest bishops and abbots). The Concordat of Worms (1122) ruled that bishops were to be chosen by the chapter of canons of the cathedral; thus, the German king was obliged to transfer the secular powers to an *electus*, who was then usually ordained bishop by the metropolitan. Although the king still exercised some influence over the elections, the local counts were able to make their voices heard the loudest in the chapter, so that Utrecht, for example, soon had bishops from the families of the counts of Holland and Guelders. This was the end of the strong influence that German imperial power exercised through the bishops in the Low Countries. Thenceforth, the spiritual and secular princes stood together, although the death of a bishop still tended to plunge the principality into a crisis—a fact that did nothing to maintain the stability of government.

*French and English influence.* With the decline of the German kings, emperors could do little more than involve themselves almost incidentally in the affairs and many conflicts of the Low Countries. The German decline went hand in hand with the increasing influence of the French and English kings, particularly after 1200; this applied especially to French power in Flanders. A struggle for the throne that broke out in Germany at the death of Henry VI (1197) found the two powerful factions—the Ghibellines and Guelfs—on opposite sides; in the Low Countries, a game of political chance developed for the territorial princes, in which the Duke of Brabant (Henry I) played an important role, alternately supporting both parties. The French king Philip Augustus and his bitter opponent, King John of England, both interfered in the conflict, which polarized into an Anglo-Guelf and a Franco-Ghibelline coalition, each looking for allies in the Low Countries. A decisive victory won by the French king at the Battle of Bouvines, east of Lille (1214), put the Count of Flanders at his mercy.

Throughout the 13th century, the French kings increased their influence in Flanders, which was joined to Hainaut by personal union; by 1300, the annexation of Flanders was almost complete. Resistance by Count Guy, which was supported by the crafts in the towns, culminated in a resounding victory by the Flemish army (which consisted largely of citizens of the towns fighting on foot) over the French knights at Courtrai (the Battle of the Spurs, 1302) and prevented total annexation. French power in Flanders remained very strong, however, until the outbreak of the Hundred Years' War (1337). French political influence in Brabant was less powerful; an attempt at political infiltration was foiled by a coalition of the Duke of Brabant and the Count of Hainaut-Holland. English influence and money kept the balance of power in the Low Countries from passing into French hands; En-

gland had a strong commercial interest in relations in the Low Countries, particularly in the important ports and shipping of the coastal areas of Flanders, Zeeland, and Holland.

*Social and economic structure.* To obtain some insight into the social structure of the Low Countries between 900 and 1350, it is important to realize that, although the territorial princes wielded supreme power, the people were in fact directly dependent on an elite that, by virtue of owning land and possessing certain powers of jurisdiction and administration, had formed seigneuries, in which they held considerable effective power. These lords could control their dependents by demanding agricultural services, exercising certain rights over dependents' inheritances, levying monies in return for granting permission to marry, and forcing them to make use of the lords' mills, ovens, breweries, and stud animals. In the main, the owners of these seigneuries were treated as nobles and were often, though not always, bound to the territorial prince by feudal ties. A separated class was formed by the knights, who in the 12th century were usually *ministeriales* (servants who had originally been bondsmen) and were used by their lords for cavalry service or for higher administrative duties, for which they received a fief. It was not until the 13th century and, in many places, even later that the feudal nobility and ministerial knights became unified in a single aristocracy. Apart from these nobles, there were also freemen who owned their own land (*allodium*), but little is known about them; they were present, however, in large numbers in the cattle breeding regions of Flanders, Zeeland, Holland, and Friesland, where the numerous rivers and streams must have split up the land into many small farms. The descendants of noble families who were no longer able to live as richly as the nobles and who were known as *hommes de lignage* (in Brabant), *hommes de loi* (Namur), or *welgeborenen* (Holland), must have been very close in status to the freemen. In the agricultural areas of Hainaut, Brabant, Guelders, and the Oversticht were dependents whose legal status is difficult to determine, though they may be classed as bondsmen because of their being liable for various services and payments.

Social  
classes

A factor of great, if not decisive, importance for social and economic relations, not only in the Low Countries but in all of western Europe, was the growth of the population, about which there is no direct statistical information but only a certain amount of indirect knowledge—after about 1050, it can be seen in the internal colonization (in the form of reclamation of such waste ground as woods and bogs), in the building of dikes and polders, in the expansion of agricultural land, and in the growth of the villages (new parishes) and towns.

Expansion  
of the land

The opening up of extensive areas of wood and heathland led to the foundation of new settlements (known in the French-speaking areas as *villes neuves*), to which colonists were attracted by offers of advantageous conditions—which were also intended to benefit the original estates. Many of these colonists were younger sons who had no share in the inheritance of their fathers' farms. The Cistercian and Premonstratensian monks, whose rules prescribed that they must work the land themselves, played an important part in this exploitation of new land. In the coastal regions of Flanders, Zeeland, and Friesland, they were very active in the struggle against the sea, building dikes both inland and on the coast itself. At first these dikes were purely defensive, but later they took on an offensive character and wrested considerable areas of land from the sea.

Especially important was the reclamation of marshland in the peat-bog areas of Holland and Utrecht and in the coastal regions of Flanders and Friesland. The Frisians had specialized in this work as early as the 11th century; Flemings and Hollanders soon adopted their methods, even applying them in the Elbe plain in Germany. The system, which consisted of digging drainage ditches, lowered the water table, leaving the ground dry enough for cattle grazing and later even for arable farming. The colonists, who were freemen, were given the right to cut drainage ditches as far back from the common water-

course as they wished. Certain restrictions were later imposed by the lords, however, who regarded themselves as the owners of these waste areas and demanded tribute money as compensation. Reclamation work was organized by a contractor (*locator*), who was responsible to the count and often carried out the function of local judge.

Formation  
of water  
authorities

Thus, in the 12th and 13th centuries, a large area of land in the Holland-Utrecht peat-bog plain was made available for agriculture, facilitating the rise of nonagricultural communities (*i.e.*, the towns). In Flanders, Zeeland, Holland, and Utrecht, this struggle against the sea and the inland water was particularly noteworthy in that it led to the foundation of water boards, which in the 13th and 14th centuries were amalgamated to form higher water authorities (the *hoogheemraadschappen*). Mastery over the water had to be carried out on a large scale and in an organized fashion; the building of dikes required a higher authority and coordinated labour. Thus, various organizations emerged, acting independently in the field of canal and dike building and maintenance and responsible only to the government itself. These were *communitates*, with their own servants and their own managements (dike reeves and *heemraden*) and empowered to take necessary measures to maintain the waterworks, administer justice, and issue proclamations. The *hoogheemraadschappen* of Rijnland, Delfland, and Schieland were all in the county of Holland; the dike reeves at the head of these organizations were also the count's bailiffs and were delegated by the count the duties of supreme judge and administrator within their bailiwicks.

The increase in the population and the reclamation of land from the sea and marshes, as well as the fight to keep the sea out, all helped change the social and economic structures of the Low Countries. For centuries, the southern and eastern areas had been agricultural, often making use of the domain system. Fishing and cattle raising had also been important, especially in the water-rich areas of Flanders, Zeeland, Holland, and Friesland (Frisian trade, with Dorestat as its centre, had not been weakened by the Viking invasions). The increasing population and the growing importance of such regions as Flanders and Holland-Zeeland, together with increases in agricultural production, stimulated trade further, though new routes had to be found.

Dorestat itself fell into decay not so much as a result of Viking raids (it was rebuilt after each one) as of a change in the course of the river upon whose banks the town was situated. Dorestat's leading position in trade was then taken over by Tiel, Deventer, Zaltbommel, Heerwaarden, and the city of Utrecht. Wheat was imported from the Rhine plain, salt from Friesland, and iron ore from Saxony, and, before long, wine, textiles, and metal goods were brought along the Meuse and Rhine from the south. The IJssel in Guelders also began to carry trading traffic through Deventer, Zutphen, and Kampen and, on the coast of the Zuiderzee (now IJsselmeer), through Harderwijk, Elburg, and Stavoren.

Growth of  
Flanders

In the south, Flanders became a second important trading and industrial area. For centuries, sheep farming had produced the wool needed in the cloth industry; but to meet an increased demand wool was imported from England, for which purpose merchants from various Flemish towns joined together in the Flemish Hanse in London. To a large extent, Flanders became economically dependent on England, a fact that must have had considerable political repercussions, particularly because it presented Flanders with the dilemma of having to choose which side to support in conflicts between France and England—on one hand, Flanders owed allegiance to its lord, the king of France, and, on the other, its economic interests were best served by taking the English side. These difficulties led to a reduction in Flemish commercial activity in England. Many Flemish craftsmen emigrated to England, while the English themselves took over the transport of wool. Nevertheless, Flemish cloth remained a high-quality product sold in large quantities at the fairs in the Champagne district and on the banks of the Rhine, to which it was transported by the people of Ghent.

On the whole, however, Flemish trade took on an ever more passive character. Although Flemish ships still sailed to Spain, Portugal, and Bordeaux to buy wine, the merchants of Bruges limited themselves to allowing colleagues from abroad to trade in the city. In this way, Bruges became the centre of trade with the Baltic countries, England, Spain, Portugal, the south of France, and—through the Champagne fairs—Italy. Grain, wood, tar, pitch, and furs were all brought from the east by the merchants of the German Hanse, who had formed a colony of their own in Bruges, where they bought Flemish cloth, wine from France and the Rhineland, and salt from France. Around 1300, the large Italian banking and trading houses set up branches in Bruges and began to send their fleets through the Strait of Gibraltar to Flanders; also, the English kings often sent their wool exports to Bruges, and the city became an international centre of trade and finance.

For the cloth industry itself, Ghent and Ypres were the most important towns. In Ghent, the production process was run by drapers (*drapiers*), who bought the raw material, had it treated by spinners, weavers, fullers, and dyers, and eventually sold the final product. A drop in wool imports from England could therefore cause immediate social and political upheavals in the city, particularly from the large weavers' quarter.

The area of the Meuse also carried on considerable trade and industry; merchants from Liège, Huy, Namur, and Dinant are named in 11th-century toll tariffs from London and Coblenz. This trade was supplied mainly by the textile industry of Maastricht, Huy, and Nivelles and by the metal industry of Liège and Dinant. Trade in Brabant, actively supported by the dukes, used the road, or system of tracks (medieval road systems were not advanced), that ran from Cologne through Aix-la-Chapelle, Maastricht, Tongres, Louvain, and Brussels to Ghent and Bruges. The counts of Brabant wanted to control as much of this trade route as possible by expanding eastward, though there was also considerable north-south trade along the Dijle.

Since prehistoric times, fishing, particularly for herring, had been important in the coastal regions of Zeeland and Flanders. This fishing industry was given added stimulus by the shift of the herring shoals from the coast of Schonen (Sweden) to the North Sea. The ships, however, were increasingly placed at the disposal of general trade and, in particular, of the wool trade with England. The merchants of the German Hanse also turned their attention to Holland, where Dordrecht became the most important centre. Because of its central position in the rivers area, this town offered the counts the chance to raise tolls on all traffic in the neighbourhood; moreover, all cargoes had to be unloaded and offered for sale—wine, coal, millstones, metal products, fruit, spices, fish, salt, grain, and wood—an arrangement that led to further economic expansion of Dordrecht. Not until the 14th and 15th centuries did trade in other towns begin to catch up with that of Dordrecht. Among these were Delft, Rotterdam, and Amsterdam, while Leiden had been one of the first towns with a textile industry; none of them, however, outstripped Dordrecht itself.

*The towns.* The towns gave the Low Countries a special character of their own. Apart from some towns that had existed even in Roman times, such as Maastricht and Nimwegen, most towns arose in the 9th century; in the 11th and 12th centuries, they expanded and developed considerably. The emergence of the towns went hand in hand with the population increase and the extension of cultivable land, which made possible higher production. The population centres that emerged were not primarily agrarian but specialized in industry and trade.

The oldest towns were in the regions of the Scheldt and Meuse. Near existing counts' castles or walled monasteries, merchants formed settlements (*portus*, or *vicus*). These gradually merged with the original settlements to form units that both economically and in their constitutions took on their own characters with respect to the surrounding country, characters that were later manifested by defensive ramparts and walls. In this connection,

Industrial  
and trade  
centres

mention must be made of Valenciennes, Bruges, Ghent, and Ypres (around the Scheldt) and of Dinant, Namur, Huy, Liège, Maastricht, Nivelles, and Gembloux (around the Meuse). A later group (though not much later) was formed by the northern towns of Deventer and Tiel, while Utrecht had long been a town in the sense of a commercial centre. Zutphen, Zwolle, Kampen, Harderwijk, Elburg, and Stavoren are other examples of early towns. Much younger (13th century) are the towns of Holland—Dordrecht, Leiden, Haarlem, Alkmaar, and Delft.

All the towns formed a new, nonfeudal element in the existing social structure, and from the beginning merchants played an important role. The merchants often organized into guilds, the origins of which may be traced back as far as the Carolingian era. From a manuscript dated about 1020, it appears that the merchants of Tiel met regularly for a drinking bout, had a common treasury, and could clear themselves of a charge by the simple expedient of swearing an oath of innocence (a privilege they claimed to have been granted by the emperor). Thus, there and elsewhere, the merchants constituted a horizontal community formed by an oath of cooperation and with the maintenance of law and order as its goal.

In contrast, therefore, to the vertical bonds in the feudal world and within the manors, horizontal bonds emerged between individuals who were naturally aiming at independence and autonomy. The extent to which autonomy was achieved varied greatly and depended on the power exercised by the territorial prince. Autonomy often developed spontaneously, and its evolution might have been accepted either tacitly or orally by the prince, so that no documentary evidence of it remains. Sometimes, however, certain freedoms were granted in writing, such as that granted by the Bishop of Liège to Huy as early as 1066. Such town charters often included the record of a ruling that had been the subject of demands or conflicts; they frequently dealt with a special form of criminal or contract law, the satisfactory regulation of which was of utmost importance to the town involved. Indeed, the first step a town took on the road to autonomy was to receive its own law and judicial system, dissociated from that of the surrounding countryside; a natural consequence of this was that the town then had its own governing authority and judiciary in the form of a board whose members were called *échevins*, headed by an *écoute* (*scultetus*, *major*, *villicus*). The *écoute* was appointed by the territorial prince and had the prince's interests at heart. The *échevins* also had to take an oath before the prince, but they were always recruited from the inhabitants of the town itself and therefore more often favoured autonomy than did the *écoute*. As the towns grew, the work of the board of *échevins* gained in importance, and functionaries appeared who had to look after the town's finances and its fortifications. They were often called *burgomasters* (*burgimagistri*).

The development of a town's autonomy sometimes advanced somewhat spasmodically as a result of violent conflicts with the prince. The citizens then united, forming *conjuraciones* (sometimes called *communes*)—fighting groups bound together by an oath—as happened during a Flemish crisis in 1127–28 in Ghent and Bruges and in Utrecht in 1159. The counts of Flanders from the house of Alsace (Thierry, ruled 1128–68, and Philip, 1168–91) kept careful watch, supporting and aiding the towns in their economic development but otherwise keeping the process in check.

In their struggle for autonomy the towns had to fight for financial freedom, such as for the lessening or abolition of the taxes and tolls they had to pay to the prince but also and principally for the right to impose their own taxes, usually in the form of indirect taxation (*e.g.*, excise duties), in order to raise money for necessary public works. Especially important to them was the right to frame their own laws; this legislative right (the *keurrecht*) was in most towns originally restricted to the control of prices and standards in the markets and shops but was gradually extended to cover civil and criminal law. The extent of a man's obligation to serve in the prince's

armed forces was often fixed or limited or both (sometimes by the provision for payment in lieu, sometimes by a legal definition of the number of foot soldiers or manned ships to be made available).

Thus, the town in the Low Countries became a *communitas* (sometimes called *corporatio* or *universitas*)—a community that was legally a corporate body, could enter into alliances and ratify them with its own seal, could sometimes even make commercial or military contracts with other towns, and could negotiate directly with the prince. Land within the town's boundaries usually became its property, and the town's inhabitants were usually exempt from any dependent relationship with outsiders.

The size of the population naturally varied considerably from town to town, but, in general, a normal town in the northern Low Countries had a population of between 2,000 and 6,000; Dordrecht, with 10,000 inhabitants, was a very large town for the region, surpassed only by Utrecht. In comparison, the Flemish towns were exceptionally large: in the mid-14th century, the population of Ghent was about 56,000; that of Bruges, 35,000. On the other hand, Antwerp, which belonged to Brabant, had at that time only 5,000 inhabitants.

A town's population usually had a distinct social structure. The merchants, the oldest and leading group, soon emerged as a separate class (the patriciate); they generally managed to gain control of the offices of *échevin* and burgomaster and thus controlled the town's finances. Sometimes the *homines novi*, a new class of up-and-coming merchants, tried to become part of the patriciate, as in Dordrecht and Utrecht. Beneath the patriciate a lower class formed, called the *gemeen* ("common," in the strict sense of the word), which embraced the artisans and organized into crafts such as tradesmen as butchers, bakers, tailors, carpenters, masons, weavers, fullers, shearers, and coppersmiths. These crafts originally developed out of charitable organizations of people in the same profession and had to adhere to regulations laid down by the authorities. Gradually, however, they tried to obtain their independence, exercise influence in politics, cut themselves off from outsiders by means of compulsory membership, and introduce their own regulations regarding prices, working hours, quality of products, apprentices, journeymen, and masters. Early tension between crafts and patriciate developed in the Flemish towns and in Liège, Utrecht, and Dordrecht. In Ghent, Bruges, and other Flemish towns, the crafts were able, with the help of the count, to gain a victory over the French and their patriciate sympathizers.

In Flanders and in the bishopric of Liège, the towns rapidly attained such power that they constituted a threat to the territorial prince, which hindered stable development in these principalities and often resulted in violent conflicts. In contrast to this, relations between the prince and the towns of Brabant were extremely harmonious; the political interests of the prince and the economic interests of the towns usually coincided. In Holland, however, the towns did not really develop until as late as the 13th century, when they were deliberately helped by the counts William II (ruled 1234–56) and Florent V (ruled 1256–96), who granted them charters that included extensive rights.

During this period, foundations were laid for the dominant role the towns later played in the Low Countries in political, social, economic, and cultural fields. A decisive change also took place in the authority of the territorial prince. Originally he regarded his powers mainly as a means of increasing his income and of extending the area over which he could exercise power. He felt little duty toward his subjects or desire to further the welfare of the community as a whole. At best there were religious as well as material motives in his dealings with the churches and monasteries. There were no direct relations between the prince and all his subjects, for he was primarily lord of his vassals. The political, social, and economic developments discussed above, however, brought a change in this situation. In the first place, the prince's increasing independence meant that he himself began to

Size of towns

Relations between towns and territorial princes

The struggle for autonomy

behave like a king or sovereign lord. His authority was then referred to as *potestas publica* ("public authority"), and it was believed granted by God (*a Deo tradita*). The area over which he ruled was described as his *regnum* or *patria*. This implied not only the duty of a lord toward his vassals but also that of a prince (*princeps*) toward his subjects. This duty included as its first priority the maintenance of law and order (*defensio pacis*) by means of laws and their administration. He had further to protect the church (*defensio* or *advocatio ecclesiae*), while his involvement in land reclamation and in the building of dikes and with the development of the towns brought him into direct contact with the nonfeudal elements of the population, with whom his relations were no longer those of a lord toward his vassals but took on a more modern aspect—that of a sovereign toward his trusted subjects. He became, according to the 14th-century lawyer Philip of Leiden, the *procurator rei publicae* ("he who looks after the matters of the people"). Contact with his subjects was through the representatives of the *communitates* of the water boards and *heemraadschappen* and through the towns and nonurban communities, which were legally corporate bodies not only in dealings with outsiders but also with the prince. Sometimes the towns expressly placed themselves under the protection of the prince and declared themselves committed to loyalty to him. Such a town was Dordrecht, which, in a document dated 1266, expressed its loyalty and at the same time described the count of Holland as *dominus terrae* ("lord of the land"). These new notions of a sovereign lord and sovereign power point to a more modern conception of a state, to a growing awareness of territoriality, and to new possibilities of collaboration between prince and subjects.

**Burgundian and Habsburg rule (1384–1579).** Among the many territorial principalities of the Low Countries, Flanders, Brabant, Hainaut-Holland, and Guelders in the mid-14th century had a dominating military and diplomatic position. Flanders had already arrested the course of French domination, and its feeling of territoriality was strengthened by this and by many minor wars between the principalities. The feeling found expression when the prince's subjects increasingly set themselves up against him as organized estates—those of the clergy or nobles and those of the towns. In the 14th century, this led almost everywhere to the formation of permanent organs that consisted of representatives of the estates. These organs represented the common interests of the estates against or, sometimes, in agreement with those of the territorial prince. At the same time, committees and law courts were set up to keep a watch on the prince's officials.

**Constitutional developments.** In Brabant, the close cooperation between duke and towns resulted in the harmonious growth of estates, though this was also due to the continuing lack of financial resources from which the dukes suffered and which gradually made them more and more dependent on the increasingly powerful and rich towns. The towns, therefore, set the pace, especially during periods of regency, when a ruler was below the age of majority. Between 1248 and 1356, the towns of Brabant developed cooperation between estates, culminating in the Joyeuse Entrée, in which this cooperation was defined and laid down in a constitution, the unity of Brabant and Limburg was declared indivisible, and the prince was obliged to choose his officials exclusively from among the people of Brabant and to win the approval of the towns and of his county before embarking on a war.

In Flanders, the power of the three towns of Ghent, Bruges, and Ypres was too great to enable smooth cooperation with the prince and the two other estates—those of the clergy and the nobles. The count succeeded only in making the Franc of Bruges—the countryside surrounding the town—a fourth estate, but there was no question of a constitution, written or otherwise.

Better results were obtained in Holland, although only after a political conflict between two political factions—Kabeljauwen ("codfish") and Hoeksens ("hooks")—in which the Kabeljauwen advocated cooperation between the estates and the prince but had too few noble families

among their supporters. Guelders, however, was late in its development, partly because the powerful Duke Willem (ruled 1379–1402) had his own financial resources as a result of his military activities in the service of the English and, later, French kings; under Willem's successors, however, the knights and the towns became more powerful and finally gained permanent representation as estates. In Utrecht, too, there was cooperation between the prince (the bishop) and the estates; and the clergy, particularly the collegiate churches of the town of Utrecht, played an important part: the Land Charter of Bishop Arnold in 1375 is comparable to the Joyeuse Entrée of Brabant. In the prince-bishopric of Liège, cooperation between prince and estates had to be won by violent conflicts between the towns and the bishop and, within the towns, between the patriciate and the crafts. It was mainly to these territorial estates that the princes had to turn for financial help, which was often voted to them only on limiting conditions.

**The Burgundians.** In the second half of the 14th century, the dukes of Burgundy (princes of the French royal house of Valois) began to penetrate these territorial principalities in the Low Countries, whose feelings of territoriality made them regard the dukes with suspicion. The marriage in 1369 of Philip of Burgundy (Philip the Bold) to the heiress of the Count of Flanders (Margaret) signified the beginning of this Burgundian infiltration, which was repeatedly furthered by such tricks of fate as marriages and inheritances.

Through his marriage Philip gained possession, after the death of his father-in-law in 1384, of the counties of Flanders, Artois, and Rethel and also of the county of Nevers and the free county of Burgundy (Franche-Comté), the last of which was within the Holy Roman Empire. He thus not only gained a large and powerful part of the Low Countries but was also able to extend his Burgundian property. Though it seemed at first that French power might again become the dominant force in the Low Countries, it soon became clear that the Burgundian dukes, while happy to continue taking part in French politics, were extremely independent and more interested in forging a single powerful empire out of the Low Countries and Burgundy. Duke John the Fearless succeeded to all his father's lands in 1404, while his younger brother Anthony was given Brabant, where the childless Duchess Joanna had named him as her successor, which was accepted by the estates. Anthony's branch of the Burgundians died out as early as 1430, so that Brabant fell to the other branch under Philip the Good (ruled 1419–67), who also gained possession—through war, family relations, and purchase—of Hainaut-Holland, Namur, and Luxembourg. This Burgundian power structure was not a state but was founded on a personal union among the various principalities, each of which jealously guarded its own freedom and institutions. The Burgundian dukes did, however, attempt to set up central organizations to bridge the differences among the principalities and to keep the various regions under stricter control by appointing viceroys (stadholders); but this ambition ran aground on the forced and overly hasty centralization and expansion of power carried out by Charles the Bold (ruled 1467–77), who was able, nevertheless, to annex Guelders. Charles imposed increasingly high financial demands, which were put before the States General—an assembly that united the delegates from the various states at meetings called by the duke and held at regular intervals; he introduced a central law court (the Parliament of Malines) and a central exchequer and did all he could to gain the status and title of king. After his death, a movement for regional independence arose and won a series of privileges from his daughter Mary (ruled 1477–82) that virtually nullified the previous centralization. Moreover, the duchy of Burgundy itself was taken over by the French crown, so that the Burgundian union became a union without Burgundy. An important point was that both the States General and the territorial states demanded and were given the right to meet on their own initiative.

After Mary's position had become more firmly estab-

lished by her marriage to Maximilian of Habsburg (the son and future successor to the Holy Roman emperor), the States General, because of its internal particularism, proved unable to provide a lasting administration. Gradually, a restoration took place, at first under the regency of Maximilian after Mary's death in 1482, but principally later, after their son Philip the Handsome took over the government. Philip resumed the centralization process by refounding the central law court (then known as the Great Council of Malines) and by setting up within the duke's council permanent commissions to discuss important political and financial questions.

*The Habsburgs.* The fate of the Low Countries was already closely bound up with that of Austria by virtue of the Habsburg marriage; in 1504, this situation was intensified when Philip and his wife, Joanna, inherited the Spanish crown. From then on, the Low Countries were merely a part of a greater whole, and their fate was principally decided by the struggle of this Spanish-Austrian empire for European hegemony. They repeatedly had to make sacrifices for the many wars waged against France, particularly under Emperor Charles V, who in 1519 had added the German imperial crown to his many possessions. The Emperor, who was almost always out of the country, placed the Low Countries under the rule of governesses—first his aunt Margaret and later his sister Mary, who retained control and worked toward further centralization even when he was in the country.

The States General could do little more than offer passive resistance, principally by providing financial obstructions to centralization. As a meeting place for the regional deputies, the States General did have a certain influence and, by its opposition, strengthened a sort of negative feeling of unity. That the Emperor himself also saw the Low Countries as a unit can be seen in his measures to separate them (but not entirely) from the empire as "Burgundian Kreis" (1548) and in the Pragmatic Sanction (1549), which stated that succession would be regulated in identical fashion in all the regions of the Low Countries that he had included in his empire (among these were Utrecht, Guelders, Groningen, and Friesland). The Low Countries were thus prevented from being split up.

In the meantime, the process of centralization had reached a decisive phase with the foundation of the collateral councils (1531), which were separate from the Great Council. They were the Council of Finance, which had in effect already existed for some time; the Council of State, in which members of the high nobility could advise the governess; and the Secret Council, in which permanent officials dealt with everyday administration and composed ordinances without having to wait for advice. All the government organs, except for the central law court in Malines, were in Brussels, which may thus be considered the capital of the Low Countries. The States General and territorial states were no longer allowed to sit whenever they wished; the territorial states were still a stumbling block in the acquisition of financial resources, so that Charles V was never able to provide himself with a standing army.

Under Charles's son Philip II, who in 1555–56 succeeded as king of Spain and prince of the Netherlands, the policy of centralization was continued. It culminated in the introduction of a new ecclesiastical hierarchy. The Low Countries (by then the Netherlands), which formerly had been, ecclesiastically speaking, merely an extension of the archbishoprics of Cologne and Rheims, became by virtue of a papal bull of 1559 a directly governed region of the church under three archbishops and 15 bishops. Resistance to this was fierce by the high nobles, who saw the high positions in the church slip from their grasp; by the abbots, who feared the incorporation of their monasteries; and by a number of territories, which were afraid of greater centralization activities under new bishops. The high nobles, who were often excluded from the activities of the Secret Council, led the resistance under the capable Prince William of Orange (1533–84) and the popular Count of Egmont. Resistance increased when the Burgundian Granvelle, who was bishop of Artois and

virtually Margaret of Parma's prime minister, was appointed cardinal and then archbishop of Malines and primate of the Netherlands. The government gave way, and Granvelle was forced to leave the country, yet the high nobles themselves hardly knew how to run affairs; the initiative was thus transferred to the low nobility, who in 1565 united by bond of oath in the Compromise and in 1566 presented to the Governess a petition requesting the relaxation of edicts and ordinances against the Calvinists and other Protestants. At the same time, they adopted the name *Geuzen* (*gueux*, "beggars"), originally a term of abuse.

The resistance grew stronger, the Calvinists became more confident, and fanatics started a violent campaign against churches—the "breaking of the images" (August 1566)—against which the governess took powerful measures and in the first few months of 1567 managed to restore peace. The King, however, whose information concerning these events was somewhat out of date because of slow communications and who was uneasy because of the "breaking of the images," decided to take stern measures. He sent his trusted general, the Duke of Alba, to the Netherlands. Alba's strict regime precipitated a revolt that eventually led to the partition of the Netherlands.

*Economic structure.* The economic structure of the country underwent far-reaching changes in the 14th–16th centuries. The growth in population, which in western Europe had begun in the 10th century, ceased with relative suddenness after 1300. Moreover, Europe in the mid-14th century was afflicted by wars, famines, and epidemics, which also affected the Low Countries. The Black Death of 1347–51 spared the Low Countries to a certain extent, but the cut in the population of the other European countries must have reduced the market for the Low Countries' trade and industry. The economy, relatively free in previous centuries, was now more limited and regulated, especially where the crafts had come to power, as in Flanders and Liège. The cloth industry of the large towns in Flanders and Brabant suffered a severe setback. Nevertheless, the economy during the 14th and, especially, during the 15th and 16th centuries sought and developed new areas for expansion. This led to a remarkable contrast between the apparent flourishing of trade and industry and the visible poverty of the mass of the people. The most noticeable development was the decline of trade in Bruges and its growth in Antwerp, which became the economic centre of the Netherlands in the late 15th century.

Antwerp, which as early as the 13th century had attained some importance, had attracted an increasingly large proportion of the English cloth imports during the 14th and 15th centuries. Conservative rule in Bruges and the insecurity created by the disturbances in Flanders caused many foreign merchants to move their business to Antwerp. The Portuguese, in particular, took their spices from the Indies to Antwerp, where they traded them for copper and silver brought by German merchants. Thus, Antwerp developed into an international port, where foreign merchants organized themselves into "nations" and where not only German but also Italian banking and trading houses had branches. New methods of trading and international finance developed in Antwerp, such as buying from samples and transferring money by means of bills of exchange. Even princes contracted loans in Antwerp.

A commercial capitalism was developing that stimulated the entire economy of the Netherlands. Although the cloth industry declined in the towns, it flourished in the villages and began to specialize in lighter cloths of coarser quality (principally in the country districts of Flanders, with Hondschoote as its centre).

The towns battled these rural industries in vain, though in 1531 Holland issued an edict to restrict them throughout the county, but it had little success. Moreover, Holland itself began to play an increasingly important economic role—Leiden boasted a growing textile industry, Delft and Haarlem had export breweries, and in the area of the River Zaan shipbuilding developed; nevertheless, fishing, shipping, and trade were its main means of

Commer-  
cial  
capitalismResistance  
to a new  
ecclesiastical  
hierarchy

support apart from arable farming and cattle breeding. Dordrecht was rivalled by Rotterdam and Gorinchem and, by the 16th century, was even outstripped by Amsterdam, which cornered an increasing proportion of Baltic trade, as may be seen from the lists of the toll in the Sound (between Sweden and Denmark).

The regions along the Meuse and IJssel also maintained their commercial activity. In the bishopric of Liège there was even a metal industry with blast furnaces, paid for by capital raised by traders. Coal mining in the area between the Meuse and the Sambre was also organized according to modern capitalist methods.

The cultivation of commercially exploitable crops also developed in country areas—hemp for rope making, hops and barley for brewing, flax for the manufacture of linen. But all this was at the expense of wheat farming. Grain had to be imported in increasingly large quantities, and, whenever grain imports fell off, the people, particularly the lower classes, went hungry. The economic apparatus had become more versatile and brought greater prosperity, but at the same time, precisely because of this specialization, it had become more vulnerable. The distribution of prosperity was variable; the great mass of the people in the towns suffered the consequences and bore the main burden of the rise in prices occasioned by inflation. It is estimated that, of the total population of Brabant, Flanders, and Holland, between a third and a half lived in the towns, where the opportunities for earning a living were still greater than in the country and where charitable institutions concerned themselves with the lot of the poor.

*Culture.* The Netherlands played an important part in the artistic, scientific, and religious life of Europe. In the late Middle Ages, when prosperity was increasing and the princely houses, particularly that of the Burgundians, as well as the middle classes in the towns, were encouraging progress, the Netherlands began to make an independent contribution to cultural life. In the southern Netherlands, this was already the case with mysticism, which reached its zenith in the 13th and 14th centuries in the poems of Sister Hadewych and in the prose of the prior Joannes Ruusbroec (Jan van Ruysbroeck). Ruusbroec's writings were founded on a considerable knowledge of theology; it is not certain whether his work had a direct influence on the founding of the religious movement along the IJssel—the modern devotion (*devotio moderna*)—or whether mysticism merely created the intellectual climate in which the new school of thought could develop. The modern devotion was inspired by Geert Grote (Gerard Groote, 1340–84) of Deventer, who preached, as did many others, the ascetic and pious life and resistance to the secularization of the church. His message was well received, and many lay people found in themselves a desire to live in communities devoted to the service of God; these were the Brethren and Sisters of the Common Life, who later organized themselves into the Windesheim monasteries and convents, which followed Augustinian rules. Their communities were extremely important for both education and religion; they were industrious copyists and brought a simple piety to the lower classes. Their work, like that of the mendicant orders, was a typical product of life in the towns. The movement reached its peak in Thomas à Kempis, from Zwolle, whose *Imitatio Christi* (*The Imitation of Christ*) became quite widely read.

Within the modern devotion, where great importance was attached to good teaching, Dutch Humanism was able to develop freely. Of importance was the foundation in 1517 of the Collegium Trilingue in Louvain, where Latin, Greek, and Hebrew were taught. The greatest Dutch Humanist was Desiderius Erasmus (1469–1536), whose fame spread throughout the world and who had been taught in the schools of the Brethren of the Common Life. He drew his inspiration, as did many other Humanists, from antiquity and was famed for his pure Latin. He was in touch with the greatest minds of his time, visited England (Cambridge) and Italy, and worked for some years in Basel and in Freiburg. Erasmus' greatest achievement was to turn the science of theology, which had degenerated into meaningless Neoscho-

lastic disputes, back to the study of sources by philological criticism and by publishing a new edition of the Greek New Testament. Although he vociferously criticized the church and even the princes, he avoided out of conviction a break with the church and pleaded for a religious tolerance that can be seen under many rulers of the later republic.

The Humanists were principally intellectuals, however, expressing themselves in literary and scientific treatises and having little impact on the broad masses of the people. Many of them, like Erasmus, desired no break with the church and did not accept that break when it became a fact by the appearance of Martin Luther. Instead, they wanted reformation within the church. It was otherwise for the reforming movements that brought turmoil to the Netherlands in the first half of the 16th century. Even Lutheranism had few followers, despite its early appearance in the Netherlands (Luther's dogmas were condemned by the University of Louvain as early as 1520). There was a Lutheran community in Antwerp; but otherwise, support for Lutheranism was limited to individual priests and intellectuals. It was precisely over the question of the Eucharist that the Sacramentarians differed with Luther; they denied the consubstantiation of Christ in the Eucharist. Although the Sacramentarians enjoyed little support from the people, their questioning of the value of consubstantiation was of considerable significance and their teaching was propagated in heretical Bible translations and even in rhetoric competitions.

Uproar was caused by the Anabaptists (so called because they rejected the baptism of infants and therefore had themselves rebaptized as adults), who refused to swear the oath of allegiance to the prince or to serve in the armed forces or in government per se and who believed in a *lumen internum* ("inner light"). This baptist movement won great popularity in the Netherlands after 1530; from the very beginning there were two branches—the social revolutionaries and the "quiet baptists." The first of these was characterized by a lively enthusiasm and a willingness, once the external trappings of the church had been rejected, to organize itself into communities, which soon formed close ties with each other. Prophecies by the social-revolutionary branch of the imminent coming of Christ and of a New Jerusalem fascinated the masses, while their fanaticism and readiness to sacrifice themselves made a deep impression on a population suffering poverty and misery. In 1534 a section of the Anabaptists moved to Münster in Westphalia, where they supposed that the New Jerusalem would be built; and in 1535 an abortive attempt was made to take over the town hall in Amsterdam. After a long siege, the Bishop of Münster succeeded in reconquering his town, and the Anabaptists suffered terrible vengeance. Only the "quiet baptists" were able to continue, under the leadership of the Frisian pastor Menno Simons (these Mennonites are even today strongly represented in the provinces of Groningen, Friesland, and North Holland).

The future of the movement for reformation in the Netherlands was assured, however, not by the biblical Humanists nor by the Anabaptists but by a movement less intellectual than the first and more realistic than the second—Calvinism.

The theology of John Calvin (1509–64) was radical, strict, logical, and consistent. Its central theme was the absolute might and greatness of God, which made man a sinful creature of no significance who hoped merely to win God's grace by honouring him in daily hard work. Calvinism found its way to the Netherlands by way of France, though there may have been some direct influence from Geneva, Calvin's town. Calvinist writings were known in Antwerp as early as 1545, while the first translation into Dutch of his *Christianae religionis institutio* is dated 1560, which was also the year in which support for him spread in the Netherlands, largely because the Calvinists preached their creed in public and held open-air services.

Calvinist teaching appealed not only to the lower classes but also to the intellectual and middle classes because of its glorification of work, its discipline, its organization

and  
religious  
contribu-  
tions

Reforming  
movements

Calvinism

into communities, and its communal singing of the psalms. The government saw the movement as a threat to its plans of unity and centralization, and it took stern measures against Calvinism. Calvinists forcibly removed their coreligionists from prisons and occasionally even attacked monasteries, and their rejection of icons, paintings, statues, and valuables in churches sometimes led them to remove them and hand them over to the town magistrates. But this idealism became corrupted, the leaders were unable to retain control of the movement, and it degenerated into the "breaking of the images" (1566), mentioned above. The nobility, and especially the lower nobility, which had been sympathetic to Calvinism, discarded the movement; the government besieged and captured the Calvinist centre, Valenciennes, by defeating a Calvinist army at Oosterweel, near Antwerp. The result was a great exodus of Calvinists. Nevertheless, Calvin's ideas had penetrated deeply, and his supporters, who had emigrated to England, East Friesland, and the Pfalz of Germany, were able to maintain their unity, which had been threatened by friction between the *rekkelijken* ("liberals") and the *preciezen* ("rigids"), and to support their coreligionists in the Netherlands. The Calvinists were to become the driving force behind the revolt against Spanish rule.

**The revolt and the formation of the republic (1567–79).** The forcible measures taken by the central government against the "breaking of the images" were followed by a brief period of peace. Ferdinand Álvarez de Toledo, duke of Alba (who became governor after the departure of Margaret of Parma on the last day of 1567), introduced stern measures at the express command of the King. These provoked a resistance to the government (often referred to as the "revolt") that triggered off the Eighty Years' War (1568–1648). The "breaking of the images" itself, which had raged across the country like a storm, had already shown a deep-rooted resistance that had many causes and was brought to a head by Alba's measures.

It is impossible to label any of the causes of the revolt as the decisive factor. An important one, however, was a religious motive. Criticism of the structure of the church and the riches and worldly way of life of its prelates and the accompanying desire for reform had always been strong in the Netherlands; and Protestantism, through the teaching of Luther, the Sacramentarians, the Anabaptists, and, above all, the Calvinists, had gained a firm foothold. The measures taken against the resistance—harsh edicts, prison sentences, torture, and death sentences, carried out with great cruelty—fanned the flames all the more and among all classes. Social and economic causes, however, also lay behind the resistance, especially among the lower classes—the wars with France, the epidemics, poor harvests, hard winters, floods, and a frightening inflation and consequent rise in prices all combined to cause despair and misery among the masses and made them susceptible to radical ideas. At the same time, in the upper classes of the nobility and the urban patriciate, there was a sharply felt reaction against the absolutist centralization policy of the King, who lived far away in Spain and yet whose wish was law in the Netherlands. Towns felt their privileges being threatened, and the nobles found their independent status being undermined, by the ever-increasing activities of the secret council. The mercenaries, who were often stationed in a town as a garrison and acted as occupying forces, also aroused hostility. The fact that the resistance did not present a united front may be ascribed to the particularism among the territories—Holland, with its commercial interests, could hardly be expected to be enthusiastic on behalf of typically agrarian feudal provinces such as Hainaut or Artois.

It is clear, however, that the terror organized by Alba burst like a bombshell in this political, social, economic, and religious climate. The Prince of Orange, with sharp political insight, had decided not to wait for Alba's arrival; he had managed to escape in time to his birthplace in Nassau-Dillenburg, leaving behind all his possessions, which were promptly confiscated. His son, Philip William, was taken prisoner to Spain. Alba sent his troops to

the principal towns and set up the Council of Troubles (or Council of Blood), which imposed severe penalties, often including the death sentence or confiscation of property, sparing nothing and nobody, not even the most powerful—the counts of Egmont and Hoorn were publicly beheaded in Brussels in June 1568.

Alba also rushed through installation of the new ecclesiastical hierarchy, which had not been completed. Furthermore, he attempted to make the central government independent of the provincial states by means of new taxes on property, on the sale of land or building, and on the sale of goods. This met with violent resistance because the taxes were to be general and permanent, so that the separate states would no longer have the means to make conditions for the furnishing of taxes (although they themselves already levied taxes on the sale of goods) and, more important, because a permanent tax system would make the king independent of his subjects, so that the taxes were the final link in the policy of absolutism and centralization, which would lead to a unified state controlled by a prince with unlimited power.

The severity with which Alba ruled was not able to prevent the immediate appearance of resistance. The Geuzen conducted pillaging raids in the country and piracy at sea, for which they had "authority" in the form of letters of marque issued by William of Orange in his capacity as sovereign of the principality of Orange. Attacks took place as early as 1568. A small force led by Louis of Nassau, William's brother, enjoyed a modest victory over the Spaniards at Heiligerlee (in the province of Groningen), considered the beginning of the Eighty Years' War; but shortly afterward Louis was defeated near Jengum in East Friesland. A greater setback, however, was the complete failure, due to lack of funds, of a campaign led by William himself in the south of the country. During the sombre years of 1568–72 the "Wilhelmus" was written—a song of faith, hope, and trust that was to become the Dutch national anthem. Other songs written by the Geuzen kept up the spirits of the people during this period and in later years.

During these years, William negotiated for help from Germany, England, and, above all, the French Huguenots. A large-scale attack was planned for the summer of 1572. Before William could carry it out, the Geuzen seized the port of Briel (April 1, 1572), west of Rotterdam. This was a move of considerable strategic importance because the port controlled the mouth of both Meuse and Waal, and the Prince immediately supported the movement. The Geuzen then took Flushing, Veere, and Enkhuizen, so that William had useful bases in Holland and Zeeland. The help that the Geuzen received from the Calvinists in these towns was striking—the Calvinists, a radical minority, were again and again able to force the more conservative town magistrates either to cooperate or resign. Oudewater, Gouda, Dordrecht, Leiden, Hoorn, and Haarlem followed, only Amsterdam keeping the Geuzen out. The purposeful activities of the Calvinists also led to their gaining churches, often the principal church of a town, for their services; they closed monasteries, and Catholic services were soon forbidden.

The revolt was at first successful only in Holland because of its unique position. As a commercially oriented province, it had been more inclined to look after its own interests than to cooperate with other provinces. Trade had been seriously threatened by the Geuzen but was now free again. Moreover, the province lay in a strategically favourable position—difficult to reach from the central government in Brussels and almost inaccessible to the Spanish armies by virtue of its many rivers, lakes, drains, and bogs.

To give the revolt a legal basis, the fiction was invented that it had been a revolt not against the King but against his evil advisers, particularly the Governor. By their own authority, in July 1572 the states of Holland foregathered in Dordrecht, where William of Orange was proclaimed stadholder of Holland and Zeeland. The Prince himself went to Holland and, realizing that the Calvinists had been the driving force behind the revolt, became a mem-

New taxes

The revolt

Legal basis

ber of the Calvinist church. But he repeatedly expressly avowed his ideal of the United Netherlands, in which there would be room for Catholics and Calvinists alike.

Alba, disappointed by his failure to push through the tax reforms and about to return to Spain, learned of the fall of Briel and decided to stay and start a counteroffensive. The south was immediately brought under control with the occupation and plundering of Malines; then Zutphen and Naarden in the north were taken and likewise plundered. This provoked stronger resistance, and Haarlem was retaken only after a very long siege, which not only demoralized and decimated Alba's troops but also strengthened the other towns in their decision to offer resistance (1573). Thus, the Spaniards were unable to take Alkmaar, their fleet suffered a heavy defeat in the Zuiderzee, and a long siege of Leiden was relieved by flooding the surrounding country (1574). (As a reward, the town later was given a university, where Calvinistic theology was to be the principal subject for study.) Spanish troops were never again to force their way into Holland—a heavy blow for the most powerful monarchy in the world.

Alba left on December 18, 1573, and his successor, Don Luis de Requesens, was unable to prevent further secessions in the north. Even the south, which had been loyal to Spain until then, but where active Calvinist movements existed (especially in Ghent), became amenable to William's ambition for a united resistance to the Spanish regime. There were considerable problems involved, and one of the greatest points of difference was the question of religion—the more radical north demanded the total abolition of Catholicism in Holland and Zeeland and the acceptance of Calvinism by the southern provinces, though William was diplomatic enough not to make this demand. It was finally agreed that the States General would deal with the question later, and until such time the Calvinists would be masters only of their own house in Holland and Zeeland. A new governor (Requesens died in March 1576) was to be accepted only if he approved the pacification and sent away the foreign troops, who, because they had received no pay, were beginning to mutiny and plunder and were becoming an increasing nuisance. Another condition of his acceptance was that he govern with native officials and in close consultation with the states. On this basis, delegates from all the provinces came to an agreement, and on November 8, 1576, they signed the Pacification of Ghent. Their sense of unity was further strengthened by the news that on November 4 Antwerp had been invaded by mutinying Spanish troops, who had slaughtered 7,000 citizens in what came to be known as the "Spanish Fury."

William's idealism, his desire for unity, and his tolerant ideas had apparently triumphed. Unity of thought, however, did not last long; and within three years signs of a split appeared between the northern and southern provinces (which later became a permanent split). It was immediately obvious that within the United Netherlands there were opposing powers of radicalism and reaction. For various reasons, they could not maintain equilibrium; the reactionaries tried to force their ideas on the country with the help of the new governor, Don Juan de Austria, a half-brother of the King, and the Calvinists continued their radical program to make theirs the official and only religion. Many factors caused these conflicts—deep-running religious differences between north and south, a deeply rooted particularism that hindered cooperation, structural and economic differences between Holland and Zeeland on the one hand (commerce and industry) and Hainaut and Artois on the other (agrarian economy and feudal possession of land). It is impossible to point to any one decisive factor. William did his utmost to save the Pacification, and he found support for his ideas of tolerance among the rich burghers; yet he was unable to bridge the differences between rich and poor, Catholics and Calvinists. Moreover, Don Juan died in 1578 and was succeeded by Alessandro Farnese (duke of Parma and son of the earlier governess Margaret), who was conspicuous for his military and diplomatic gifts, which made him a worthy opponent for William

and to which may be ascribed the bringing back of the southern provinces to loyalty to the king.

Notable, too, was the appearance in the north and south of movements in the direction of "limited unions," which within the whole of the United Netherlands were to bring about greater community of interests between certain provinces. On January 6, 1579, the Union of Arras (Artois) was formed in the south among Artois, Hainaut, and the town of Douay, based on the Pacification of Ghent but retaining the Catholic religion, loyalty to the king, and the privileges of the estates. Although William himself did not at first reject the idea of a northern union and expressly stated that it must be open to all provinces, matters subsequently developed in a direction not to his liking. (C.v.d.K.)

## II. The Netherlands since 1579

### POLITICAL AND CONSTITUTIONAL

#### DEVELOPMENTS, 1579-1609

**The Union of Utrecht.** On January 23, 1579, an agreement was concluded at Utrecht forming a "closer union" within the larger union of the Low Countries led by the States-General sitting in Brussels. Included in the Union were the provinces and cities committed to carrying on resistance to Spanish rule: Holland, Zeeland, Utrecht, Gelderland (Guelders), and Zutphen (a part of Overijssel) as the first signatories, followed in the next year by the whole of Overijssel and most of Friesland, and by Groningen, all in the north; and in the south, by the cities of Antwerp and Breda in Brabant, and Ghent, Bruges, and Ypres in Flanders. Designed to establish a league for conduct of the war of independence and ultimately to strengthen the central government in Brussels, the "Union of Utrecht" became in fact the foundation of a separate state and a distinct nation in the northern Netherlands. The new state was named the United Provinces of the Netherlands, or more briefly, the "Dutch Republic," and was known in the international community as the "States-General." The people of the northern Netherlands began to be distinguished from the inhabitants of the south (to whom the name of Flemings continued to cling) by the appellation Hollanders (French *Hollandais*, Italian *Olandese*, German *Holländer*, etc.), after their principal province. The English, however, came to apply exclusively to the Hollanders the name of Dutch, which previously they had applied to all German speakers (from German *Deutsch*, Dutch *Duits*). The name *Netherlanders*, which remained in use in the Low Countries for both the inhabitants of the United Provinces specifically and for all those, north or south, who spoke Dutch (*Nederlands*), passed out of currency in most foreign countries or came to be restricted to the northerners. The transformation had a price: the erosion of the bond of historical identity between northerners and southerners, Dutchmen and Belgians as they would be called in the 19th and 20th centuries.

The treaty that formed the basis of the new northern union established a military league to resist the Spaniards, but on a "perpetual" basis; and it provided for closer political arrangements among the provinces than those of "allies" in the ordinary sense. The provinces united, "for all time as if they were a single province"; each remained sovereign in its internal affairs, but all acted as a body in foreign policy. Decisions on war and peace and on taxation could be made only unanimously. The Union did not throw off the formal sovereignty of the king of Spain, but it confirmed the effective powers of the provincial stadholders (formally the "lieutenants," or governors, of the king) as their political leaders (there was no "stadholder of the United Provinces," as foreigners often assumed). The Union moved away from the religious settlement embodied in the Pacification of Ghent of two years before (see above) and toward a predominance of the Calvinists and their monopoly of public practice of religion in the key provinces of Holland and Zeeland.

The immediate political significance of the Union was that it dovetailed with the Union of Artois, concluded earlier in the month, which began the reconciliation of

the southerners with Philip II. The two "unions," parallel but opposite, thus undermined William's policy of collaboration between Catholics and Calvinists throughout the Low Countries in resistance to the Spanish domination, which required mutual toleration among the religions. But it took some time before the "general union," with its base in the States-General at Brussels, fell apart irrevocably. For another half decade the Prince struggled to keep intact the broader union and at the same time to assure its military and political support from abroad. Although Archduke Matthias of Habsburg, named governor general by the States-General in 1577 after the deposition of Don Juan, remained the formal head of state until 1581, the Prince continued to exercise his leadership. That the Prince was the head and heart of the rebellion was recognized by Philip II in 1580 when he put him under the ban of outlawry. William's *Apology* in defense of his conduct was followed in 1581 by the Act of Abjuration (literally, "Act of Abandonment," *Akte van Verlaten*) by which the States-General declared that Philip had forfeited his sovereignty over the provinces by his persistent tyranny. This was a declaration of independence for the whole of the Low Countries, but the military and political events of the next decade limited its permanent effect to the northern provinces, under the "closer union" of Utrecht.

Declara-  
tion of  
inde-  
pendence

**Foreign intervention.** Yet independence did not become William's objective even after the proclamation of the Act of Abjuration. Archduke Matthias returned home in 1581 after Orange turned to the Duc d'Anjou, who agreed to take over the "lordship" of the Low Countries in 1580. The Prince hoped for assistance from the Duc's brother, King Henry III of France, and considered the "lordship" of Anjou as only a kind of limited, constitutional "sovereignty" like that which the rebels had hoped to impose on Philip II at the beginning of their rising. Anjou, however, saw the lordship as a means to total dominion over the Netherlands. Irritated by restraints upon his authority, he even attempted the seizure of power by military force, resulting in the so-called French Fury of January 17, 1583, when his troops tried to capture Antwerp. The coup misfired, but Orange managed to keep Anjou (who returned to France) in his post despite the outraged feelings of the Netherlanders. Holland and Zeeland were on the verge of offering the title of count to William when he was assassinated on July 10, 1584, at Delft, by Balthasar Gerards, a fanatical young Catholic from Franche-Comté, spurred by the promises of the ban of Philip II. William's death did not end the rebellion, as Philip had hoped, but it did result in the almost unnoticed disappearance of the central government in Brussels. The States-General, which now met at The Hague in Holland, represented only the provinces in the Union of Utrecht. With the Spaniards steadily overrunning Flanders and Brabant, the Dutch in their plight did not immediately abandon William's policy of seeking foreign assistance. But after Henry III of France and Elizabeth of England both refused sovereignty over the country, the States-General in 1586 named as governor general Robert Dudley, earl of Leicester, whom Elizabeth had sent to command Dutch and English auxiliary forces against the Spaniards after the fall of Antwerp. Leicester, like Anjou before him, endeavoured to make himself absolute master of the country, relying on the support of popular Calvinism and of the outlying provinces that were jealous of Holland to create a strong centralized government under his authority. Holland thwarted Leicester's efforts, which culminated in an attempted invasion of Holland from Utrecht in 1587. With Leicester's departure, the United Provinces put aside all efforts to obtain a foreign protectorate and stood forth as an independent state.

**The formation of the new government.** Although derived from historical institutions, the government of the United Provinces was in practice largely a new set of institutions, not created, but confirmed, by the Union of Utrecht. Their primary force lay in the provinces, seven in number (Holland, Zeeland, Utrecht, Gelderland, Overijssel, Friesland, and Groningen), which were ruled by assemblies of provincial States representing the towns

and the landed nobility. Although the stadholders (who after a few years came to be drawn exclusively from the House of Orange) were elected by the States of the provinces, they at the same time possessed important prerogatives in the selection of members of the town governments from which the provincial assemblies ultimately derived their authority, and they were the acknowledged military leaders of the republic. Central government passed from the Council of State to the States-General, which was more explicitly subordinated to provincial authority. Although it conducted the military and diplomatic work of the republic, the States-General failed to obtain effective rights of direct taxation (except for import and export duties assigned to the admiralties), and its major decisions were taken under the rule of unanimity. In practice the province of Holland, by far the wealthiest province in the Union, and the contributor of more than half of the revenues of the central government, became the preponderant political force in the country, along with the stadholders of the House of Orange. The relationship between Holland and Orange governed the republic's politics for the two centuries of its existence. As collaborators, Holland and the princes of Orange could make the clumsy governmental system work with surprising effectiveness; as rivals, they imperilled its potency as a state, at least until one or the other emerged a temporary victor: but neither force was able to rule permanently without the other.

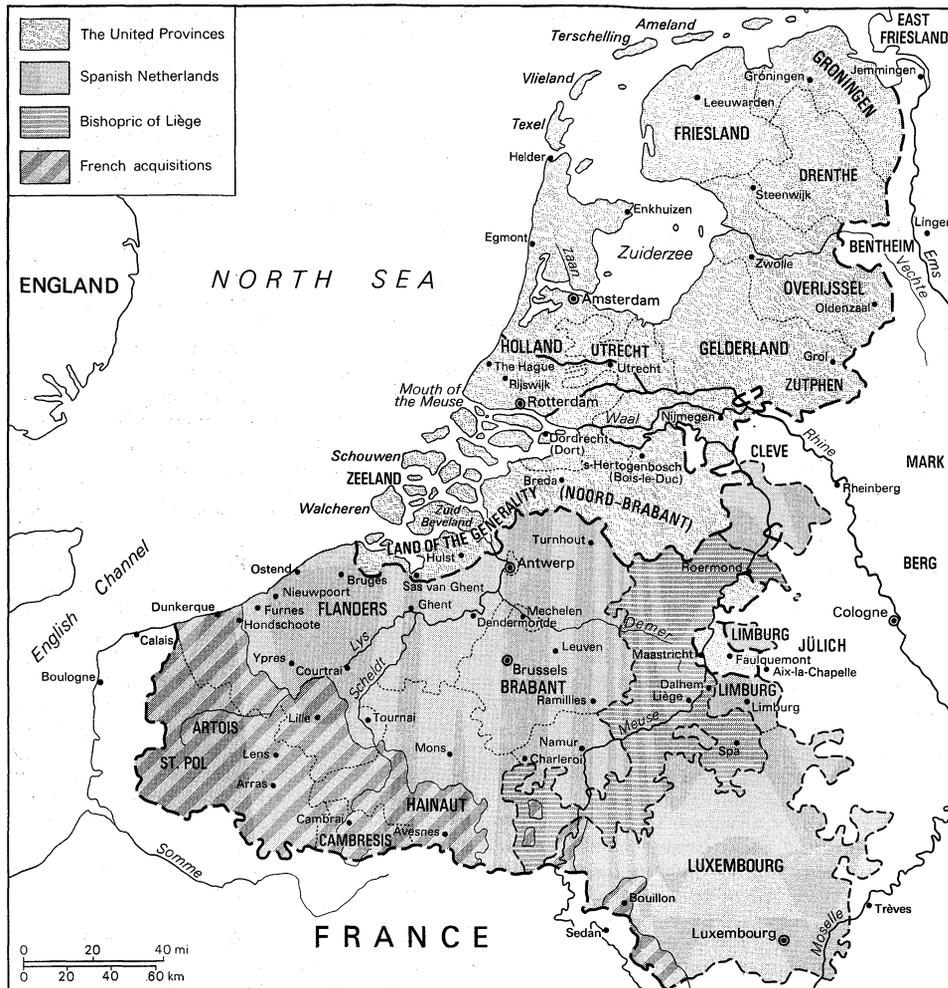

The decades immediately after 1587 were marked by close collaboration between Johan van Oldenbarnevelt, "advocate" of Holland (the legal and executive secretary of the provincial States), and Maurice of Nassau, William the Silent's second son (the first, Philip William, became prince of Orange and remained loyal to Spain), who was named stadholder of Holland and Zeeland and became the commander of the republic's armies. The result was a series of military triumphs over the Spanish forces under Parma. Maurice recaptured the Dutch territories north of the great rivers and extended them southward into much of Brabant and enough of Flanders to cut off Antwerp from the sea. These victories are recorded in the historical memory of the Dutch as "the closing of the garden," the territory that became the republic of the United Provinces and then (with a few additions) the modern Kingdom of The Netherlands. These victories were accompanied by the emergence of the States-General diplomatically recognized by England and France as an independent state.

#### ASCENDANCY OF THE DUTCH ECONOMY

The military prowess of the fledgling republic rested upon the wealth of Holland—which managed in wartime to maintain and extend its trade to all of Europe and, after the turn of the century, even to the Far East. Amsterdam replaced Antwerp, the great port on the Scheldt River, as the principal warehouse and trading centre for all Europe, even while Holland maintained the leadership in shipping it had already garnered during the 16th century. The foundation of Dutch economic prosperity lay in the fishing and shipping industries. Even during the period of Antwerp's ascendancy, ships from Holland and Zeeland had carried a large portion of the goods that passed through the Scheldt, and now that Amsterdam had taken over from Antwerp, Dutch shipping only expanded its predominance. Dutch fishermen had harvested the North Sea for centuries, and the salted cargoes were sold widely through western and central Europe. Dutch trade benefited, as had that of Flanders, from the location of the country at the nexuses of the great north-south and east-west trade routes of Europe. To these were added the route to the East Indies early in the 17th century. Amsterdam and the lesser ports of Holland and Zeeland became the principal European suppliers of grain and naval stores from the Baltic, to which they shipped manufactured goods and wines from the south. Germany's principal exports were now shipped down the Rhine, as Dutch ports replaced the Hanseatic towns of northern Germany. The bulk of French exports were carried in Dutch ships, and even Spain and Portugal depended on the Dutch for grain and naval stores (thereby enabling the

## Banking

Dutch to finance their war of independence). During the 17th century the Dutch also assumed a major role in supplying grain and other northern commodities to the countries of the Mediterranean and also became the principal importer of spices and other luxury goods from the East. Even England relied to a great extent upon Dutch shipping. The Dutch advantages lay not only in their situation but also in the efficient design of their bulky flyboats (*fluiten*), manned by small crews at lesser cost than any of their competitors. Modern banking institutions developed to meet the needs of the vastly expanding trade. Amsterdam's "exchange bank" was instituted in 1609 to provide monetary exchange at established rates, but it soon became a deposit bank for the safe settling of accounts. Unlike the Bank of England, established almost a century later, it neither managed the national currency nor acted as a lending institution (except to the government in emergencies). Private bankers met the need for credit, as well as acting as brokers in financial transactions. The need for commercial exports, as well as a growing population at home, spurred industry in many towns. Although the shipbuilders on the Zaan, northwest of Amsterdam, and the sugar refiners in particular developed large-scale operations, sometimes including machinery, Dutch industry generally remained at the level of handicraft production. Dutch agriculture also responded to the new needs. Grain production was encouraged in the inland provinces, while the polderland of the delta islands and along the coast was drained and diked, providing pastureland for a flourishing dairy industry.

### POLITICAL DEVELOPMENTS, 1609-1713

**The Twelve Years' Truce.** The Twelve Years' Truce that began in 1609 arose out of political controversies

that were to dominate the republic for the next two centuries. The collaboration between the House of Orange and the leaders of the province of Holland, which had thwarted Spain in its reconquest of the Netherlands north of the great rivers, was replaced by an intermittent, but often fierce, rivalry between them, in which the other tensions of Dutch political life were reflected and incorporated: the jealousy among the lesser provinces of a Holland that they considered too wealthy, too mighty, and too arrogant, but which they knew they needed for their own defense; the misunderstanding between maritime and landward provinces; the annoyance of landed noblemen that they were dependent upon the goodwill of burghers in Holland (they preferred the prince of Orange, whom they saw as one of themselves); the resentment of the popular classes, men of small property and of none, toward the town regents, against whom they looked to the princes of Orange to protect them; and the antipathy of the Reformed clergy toward the regents, who obstructed their desire to make the state serve the church. The debate over whether or not to conclude a peace with Spain mingled these various interests with that of the House of Orange, partly because Maurice opposed peace, partly because it involved making some compromise with Spain, and partly because it would mean a reduction of his influence in the state; but the province of Holland in particular, under Oldenbarnevelt's leadership, felt that the independence and security of the United Provinces had been sufficiently assured to permit a reduction of the immense expenditures for the war. When Spain reduced its immediate proposal to a truce rather than permanent peace, agreed to treat the United Provinces as independent and sovereign, which was just short of outright recognition, and put aside efforts to win guarantees for

Dutch Catholics, the pressure for conclusion of a truce could not be withstood.

Gomarists  
versus  
Arminians

But the Twelve Years' Truce did not end internal controversy within the republic; if anything, it only sharpened Maurice of Nassau's opposition to Holland and Oldenbarnevelt. The staunch Calvinists endeavoured to hold the Reformed Church to the strict orthodoxy expounded by Gomarus, a Leiden professor of theology, against the broader, less rigorous tenets upheld by his colleague Arminius. The Gomarists demanded the government uphold their principles because the Reformed Church was the only true church, but they reserved for themselves the right to declare what the correct doctrines were; and they vigorously asserted that other religious groups, Catholic, Protestant, and Jewish alike, should be suppressed or at least penalized and restricted. On the other hand, the Arminians had the support of the leaders of Holland and a majority of its towns, who felt that what was in effect the state church had to be under the authority of the government. Both out of principle and out of a desire not to hamper trade with men of all religions, they favoured a broadly inclusive Reformed Church and toleration for those outside its ranks. The efforts of Gomarists to seize churches for their own use in defiance of town authorities led to incipient civil war. Maurice broke openly with the dominant party in Holland when it attempted to set up little provincial armies in Holland and Utrecht. In 1618, he acted under the authority of the States-General, in which the majority of provinces favoured the Gomarists (now called the Contra-Remonstrants because they had opposed an Arminian petition) over the Remonstrants (Arminians) to crush the resistance of Oldenbarnevelt's party. Oldenbarnevelt, together with two of his chief supporters in Holland (including the great jurist Grotius) and an ally in Utrecht, was arrested and tried for treason by a special court instituted by the States-General. The defendants affirmed that they were subject only to the authority of the sovereign province which they served. The sentence, which to foes of the House of Orange over the centuries became an act of judicial murder, sent Oldenbarnevelt, then 71 years old, with almost four decades of service as Holland's leader, to his death by beheading in May 1619. Grotius and another defendant (the third had committed suicide) were sentenced to life imprisonment, although Grotius escaped, sensationally, a few years later. During these fateful months, the Reformed Church held a national synod at Dordrecht. Dominated by the Contra-Remonstrants, the synod expelled the Remonstrants, reaffirmed the doctrines of the church along Gomarist lines, and ordered the preparation of a new translation of the Bible (the famous States Bible that consolidated the Dutch language much as the contemporary King James Version consolidated English). The triumph of Maurice and the Contra-Remonstrants meant that war with Spain would be a virtual certainty upon the expiration of the Twelve Years' Truce in 1621—all the more because the Spanish authorities in the southern Netherlands insisted upon including rights for Dutch Catholics in a permanent treaty and even sought an acknowledgment by the States-General of the nominal overlordship of the king of Spain. Maurice did not use his new uncontested power to reform the complicated incoherence of the Dutch constitution; the structure of government and the distribution of formal power remained the same. Maurice was not a politically minded ruler and was satisfied as long as he had his way in military matters. The United Provinces continued essentially republican in character.

Execution  
of  
Oldenbar-  
nevelt

**War with Spain, 1621–48.** The war resumed in 1621 under Maurice's leadership. But his touch of victory was gone, and the republic appeared in danger when the great fortress of Breda on the southern frontier fell to the Spaniards in 1625. Only a few weeks before, Maurice had died. The danger was all the greater because the Austrian Habsburgs, in alliance with their Spanish cousins, were waging a successful struggle against their Protestant foes in Germany, in the first stages of the Thirty Years' War (*q.v.*). But Maurice's half-brother, Frederick Henry, who succeeded him as prince of Orange, stadholder, and

commander in chief, resumed the course of victory. He completed the recapture of the towns recently gained by the Spaniards and extended the territory under the States-General to the key fortress of Maastricht on the Maas (Meuse) well to the south. At the same time, the Dutch navy won a series of victories over the Spaniards, including Piet Hein's celebrated capture of their silver fleet off the coast of Cuba (1628) and the destruction of a Spanish fleet in the Downs, off the English coast, by Maarten Tromp in 1639.

Victories  
under  
Frederick  
Henry

Frederick Henry turned out to be a more subtle and purposeful politician than Maurice. On the one hand, he ended the suppression of the Remonstrants, with whose religious views he sympathized, without exasperating the Contra-Remonstrants beyond repair. On the other hand, he established a firm grip over the policies of the republic, notably by establishing a close alliance with France aimed at the joint conquest of the Spanish Netherlands. Frederick Henry's political predominance within the republic was based upon his control of the lesser provinces, which had a majority in the States-General and which could outweigh the influence of Holland. Gradually Holland turned against him, especially after he arranged the marriage of his young son William to Princess Mary Stuart, daughter of Charles I of England, on the eve of the English Civil War (1642–51). This fateful dynastic bond tied the interests of the House of Orange to the royal families of England, first to the Stuarts and later to the Hanoverians. The position of the House of Orange, however, was elevated by the connection: the French monarchy granted Frederick Henry the honorary address of "His Highness," normally restricted to royalty; and the debate over the function of the princes of Orange in Dutch politics began to be conducted as a controversy over monarchy. A quasi-royal court rose up around Frederick Henry, and this in turn only clarified and strengthened the republicanism of his opponents, especially in Holland, who feared that the political leadership of the princes of Orange would be turned into an explicit monarchy. During the 1640s, however, Frederick Henry lost his physical and intellectual powers and was unable to prevent Holland from reasserting its predominance over the republic's policies. The States-General entered into peace negotiations with Spain at Münster in Westphalia. Frederick Henry died in 1647 before the conclusion of the talks, but his son, William II, could not prevent the signing and ratification of the treaty in January 1648. Spain now formally acknowledged the independence of the Dutch, and indeed even urged its friendship upon the United Provinces, warning of the threat to both the Dutch and the Spanish from the rising power of France.

Peace of  
Westphalia

Prince William was not ready to accept a permanent peace, and he negotiated secretly with the French for a resumption of the war, not only against Spain but also against republican England, which had executed his father-in-law, King Charles I, in January 1649. Needing a powerful army to meet the anticipated war, William bitterly fought the efforts of Holland to reduce the standing army and thereby to permit more rapid payment of the huge debt accumulated over the eighty years' struggle for independence. Efforts at compromise broke down during the spring of 1650, as the Hollanders and William each sought to compel the other to concede political inferiority. William decided to make use of his preponderance in the States-General, and he led a delegation from that body to the towns of Holland to seek a change of their vote in the States of Holland; such a delegation was a direct violation of what Holland saw as its provincial sovereignty. Rebuffed by a number of town governments, most importantly by those of Amsterdam and Dordrecht, William decided to cut through the resistance by force. At The Hague, on July 30, 1650, he arrested six of the States' deputies from the recalcitrant towns and sent them to the castle of Loevestein (where Grotius had been imprisoned) on charges of having resisted lawful orders of the States-General. At that same time he sent an army to seize Amsterdam but it was thwarted by delays on its march and by the determined resistance of the municipal

Arrest  
of the  
deputies

authorities, supported by the common people. Amsterdam, however, faced a siege that might gravely imperil its trade, while the besiegers themselves ran the danger of being drowned should Amsterdam open the dikes. A compromise was soon worked out whereby William's opponents were released but were required to withdraw from government. William had cleared the way for his policies but at the price of arousing deep fears among the Dutch people—most of all in the powerful province of Holland—of military dictatorship, monarchical rule, and renewed involvement of the nation in war. But before he could carry out his plans, William II died of smallpox in early November. A posthumous son, William III, was born a week later.

**The first stadholderless period.** Fate thus intervened to give Holland's leaders, now intensely distrustful of Orangist influence, a chance to take over the country from the leaderless party of their antagonists. They governed the country for a little more than two decades, during what is known as the "first stadholderless period" (1650–72) because the five leading provinces did not appoint a successor to William II. (William II's cousin, William Frederick, of the junior branch of Orange-Nassau, continued to govern Friesland as well as Groningen, which also elected him as stadholder.) During the early months of 1651, a "Great Assembly" of the States-General, with expanded delegations from all the provinces, met at The Hague to consider the new situation. Holland was satisfied to consolidate the leadership it had so unexpectedly regained and conciliated the lesser provinces by leaving undisturbed the religious settlement of 1619 and by granting amnesty to those who had supported William II in 1650. But Holland's fears of the increased powers of the central government had been so stiffened that it depended upon its own preponderance, rather than upon constitutional reforms, to achieve effective government.

*Anglo-Dutch war.* Yet efficiency of rule, so difficult to obtain when the powers to make and apply policy were so widely scattered, became all the more necessary when the republic became embroiled in war with the English Commonwealth in 1652. That conflict arose out of a medley of causes: first, the English republicans, after their successes against the royalists, took up the cause of defending English commercial interests against the Dutch and passed the Navigation Act of 1651 forbidding Dutch ships from acting as middlemen in English trade both in Europe and overseas; second, the English sought to bring the Dutch into a political union directed primarily against the Stuarts and their Orange cousins. But the Dutch, whatever resentment the Hollanders bore against the Orange dynasty, were unwilling either to court civil war or to abandon their dearly won independence in a union that would make them junior partners to the English. An accidental clash between the Dutch and English fleets led to full-scale war in which a greatly improved English navy won the upper hand. By 1654 the Dutch were compelled to accept peace on English terms, including a secret promise by Holland ("Act of Seclusion") to exclude forever the prince of Orange from the stadholderate or the supreme command.

The decision to accept a humiliating peace as the only way to terminate a disastrous war had been taken at the insistence of the young Johan de Witt, who had taken office in 1653 as councillor pensionary of Holland (the same office once held by Oldenbarnevelt). With the return of peace, de Witt became the brilliant leader of the republic's foreign and domestic policy. He rebuilt the Dutch navy, reduced indebtedness, improved the financial condition of both the States-General and the States of Holland, and restored the republic's prestige in Europe. Carefully averting any renewal of strife with England, he was able not only to compel France to back down in a naval dispute but also to send a powerful Dutch fleet to save Denmark from Swedish conquest in the first Northern War (1657–60). When the exiled English king Charles II was restored to his throne in 1660, de Witt continued his policy of staying on good terms with England no matter who ruled there; this policy, however, founded on the same two issues—commercial rivalry and the status of

the House of Orange—that had brought about the war of 1652–54. Charles not only accepted the renewal of the Navigation Act of 1651 but intensified the rivalry with the Dutch by demanding forcefully that they acknowledge his sovereignty over the adjacent seas, pay tribute for the right to fish in the North Sea, and open the Dutch East Indies to English traders. When naval warfare resumed in 1664 off Africa, followed by war in Europe the next year, Charles took up the cause of the young Prince of Orange. By persuading the Orangists that his price for peace was restoration of William III to the offices of his forefathers, the English monarch built up a friendly party in the United Provinces that urged acceptance of his terms and even fostered a conspiracy to overthrow the government of de Witt and his friends. But de Witt managed to meet the new threat. When Charles had demanded too high a price for Dutch friendship in 1660–62, de Witt had negotiated an alliance with the French, who feared that the restoration of the Prince of Orange would create a hostile Anglo-Dutch coalition. Furthermore, the fighting at sea increasingly went to the newly rebuilt Dutch navy. In 1667 the Dutch fleet sailed up the Thames and the Medway to Chatham, destroying the English shipyards and burning the fleet at its moorings. An Orangist plot in Holland was uncovered and put down. In that same year, however, the French, under Louis XIV, who had only belatedly sent naval and land forces to aid the Dutch, began an invasion of the Spanish Netherlands in the War of Devolution. As French conquest of the southern Low Countries constituted a threat to both the Dutch Republic and Britain, the belligerents came to terms in the stand-off Peace of Breda (July 31, 1667), followed in January by an Anglo-Dutch alliance compelling France to make peace with Spain. This Triple Alliance (so-called because Sweden became a third partner) proved to be de Witt's undoing, although he had no effective diplomatic strategy to put in its place. Louis XIV, balked in his aim of conquest, considered that the Dutch had betrayed their alliance and turned to Charles II with proposals for a joint war against the United Provinces. Charles, bitterly resentful at his humiliating defeat, accepted the French offer of a richly subsidized alliance. Even as the threat from France emerged more clearly, the Orangists imagined that the Dutch could still win over Charles by the restoration of William III, but they were able to obtain only the Prince's appointment as commander in chief, early in 1672. Charles joined the French in open war in the spring of 1672, counting upon William to accept rule of a rump Dutch Republic after France and Britain had taken away important territories for themselves. But William, who was given full power, including the stadholdership, during a storm of riots and near rebellion that swept the country in June and July, after the French invasion penetrated to its heart, took over the leadership of the Dutch defense from de Witt, who was lynched by a mob in The Hague in August. With his support, the States-General rejected the Anglo-French terms.

**William III.** The tide of war now turned against the aggressors. The Dutch navy under Admiral de Ruyter repeatedly defeated the allied fleets off the coast of the republic, while the Dutch armies held on behind the flooded polders of the "water line." When other powers—Spain, at first as an auxiliary, then as a full participant, the Emperor, and Brandenburg—joined the Dutch side, the French armies withdrew from the republic. During six years of bitter war, William III was able to bring about the withdrawal of England (1674) and the defeat of all French war aims against the Dutch; yet his Grand Alliance was unable to bring Louis XIV to his knees, although Spain paid the price of a peace negotiated at Nijmegen in 1678. But during these years in which his political control of the republic, while strong, was not absolute, William was no more interested in constitutional reform than de Witt, his predecessor in the leadership of the country, had been. He was satisfied to expel adversaries from office and dominate the decisions taken by men who represented the same groups and the same social principles as those whom they replaced; but Holland,

The  
Triple  
Alliance

navigation  
acts

whose wealth ultimately was the basis for all Dutch power, political and military, slipped from under his thumb and asserted its autonomy of judgment and decision. The transformation of the republic, which had been from its origins an aristocracy dominated by mercantile wealth, into an oligarchy of inherited power, continued unimpeded by William: he had used the violence of the urban citizenry during the crisis of 1672 to unseat his opponents, but he was no more sympathetic than they had been to the vague democratic aspirations that were expressed here and there. During the decade after the conclusion of the Peace of Nijmegen, the tension between William and Holland (particularly Amsterdam) worsened because the Prince was fixed upon a policy of renewed resistance to Louis XIV, while the Hollanders preferred peace at any reasonable price. But the upsurge of the threat from France in the late 1680s—the French incursions into western Germany and the threat of French domination of England under James II, a stalwart Catholic and a pensioner of Louis XIV—brought William and Holland into agreement upon the need to support the Prince's expedition to England in 1688, which resulted in his acceptance of the English throne, jointly with his wife Mary Stuart, early the next year. William, as king-stadholder, had to give primacy to English interests because England was the more powerful partner in the alliance. He therefore approved the arrangement whereby England concentrated her efforts against France on the sea, while the Dutch did so on land; the result was neglect of the Dutch navy. Ironically, the final triumph of the English over the Dutch in their commercial rivalry was a consequence of their alliance, not their enmity.

William  
accepts the  
English  
throne

The war begun in 1689 ended with a stalemate peace in 1697, followed by two treaties between the maritime powers and France for partition of the Spanish monarchy. In 1700, however, Louis XIV accepted the bequest of the Spanish throne for his grandson, Philippe d'Anjou, and war was resumed the next year.

William died, childless, in 1702. When Holland again took the initiative for government without a stadholder, it was followed by the other provinces with much greater alacrity than had been true in 1650–51. Resentment had built up against the harshness with which the Prince had governed the country for three decades, and the absence of an adult heir meant that there was no effective opposition to the new course. Leadership of the Dutch state for the next 45 years came from the councillor pensionaries of Holland, who were often able men but either unwilling or unable to do more than conduct current business, without attempting the delicate and explosive task of restructuring the government. On the contrary, constitutional rigidity became the credo not only of Dutch republicans but also of the Orangist party, with the only point in contention between them whether or not the Prince of Orange-Nassau, who was stadholder of Friesland, should be elected to the same office in the other provinces. William IV, who followed his father in Friesland in 1711, was chosen stadholder in Groningen in 1718 and in Gelderland (and the district of Drenthe) in 1722. Even without a stadholder in the principal provinces, Dutch subordination to English interests remained intact during the War of the Spanish Succession (1701–13) and the succeeding years of peace.

#### DUTCH CIVILIZATION IN THE GOLDEN AGE (1609–1713)

The century from the conclusion of the Twelve Years' Truce in 1609 until either the death of Prince William III in 1702 or the conclusion of the Peace of Utrecht in 1713 is known in Dutch history as the "Golden Age." It was a unique era of political, economic, and cultural greatness during which the little nation on the North Sea ranked among the most powerful and influential in Europe and the world.

**The economy.** It was a grandeur that rested upon the economic expansion that continued with scarcely an interruption until 1648, at the end of the Thirty Years' War. The half century that followed was marked by consolidation rather than continued expansion, under the impact of the revived competition from the other nations,

notably England and France, whose policies of mercantilism were in large degree directed against the near monopoly of the Dutch over the trade and shipping of Europe. Although the Dutch tenaciously resisted the new competition, the long-distance trading system of Europe was transformed from one largely conducted through the Netherlands, with the Dutch as universal buyer-seller and shipper, to one of multiple routes and fierce competitiveness. Nonetheless, the wealth earned during a long century of prosperity made the United Provinces a land of great riches, with more capital by far than could find outlet in investment. Yet the economic burden of repeated wars caused the Dutch to become one of the most heavily taxed people in Europe. Because the role of agriculture was secondary, taxes were to some extent imposed on the transit trade in and out of the country. But as mercantile competition became stiffer, the rate of such taxation could not be safely increased, and the burden therefore fell increasingly on the consumer. Excise and other indirect taxes made the Dutch cost of living one of the highest in Europe.

Dutch prosperity was built not only upon the "mother trades"—to the Baltic and to France and the Iberian lands—but also upon the overseas trades with Africa, Asia, and America. The attempt of the Spanish monarchs (who also ruled Portugal and its possessions from 1580 to 1640) to exclude Dutch merchants and shippers from the lucrative colonial commerce with the Far East led the Dutch to trade directly with the East Indies. Individual companies were organized for each venture, but the companies were united by command of the States-General in 1602 in order to reduce the costs and increase the security of such perilous and complex undertakings; the resulting United East India Company established bases throughout the Indian Ocean, notably Ceylon, mainland India, and the Indonesian archipelago. The Dutch East India Company, like its rival English counterpart, was a trading company granted quasi-sovereign powers in the lands under its dominion. Although the East India fleets that returned annually with cargoes of spices and other valuables provided huge profits for the shareholders, the East India trade of the 17th and 18th centuries never provided more than a modest fraction of Dutch earnings from European trade. The West India Company, established in 1621, was built upon shakier economic foundations; trade in commodities was less important than the trade in slaves, in which the Dutch were pre-eminent in the 17th century, and privateering, which operated primarily out of Zeeland ports and preyed upon Spanish (and other) shipping. The West India Company had to be reorganized several times during its precarious existence, while the East India Company survived until the end of the 18th century.

**Society.** The social structure that evolved with the economic transformation of Dutch life was complex and marked by the predominance of the business classes that later centuries called the bourgeoisie, although with some significant differences. It was an unabashedly "aristocratic" country, socially and politically. The social "betters" of Dutch aristocracy were only to a limited extent landed noblemen, most of whom lived in the economically less advanced inland provinces. Most of the Dutch elite were wealthy townsmen whose fortunes were made as merchants and financiers, but they frequently shifted their activities to government, becoming what the Dutch called regents, members of the ruling bodies of town and province, and drawing most of their incomes from these posts and from investments in government bonds and real estate. The common people comprised both a numerous class of artisans and small businessmen whose prosperity provided the base for the generally high Dutch standard of living and a very large class of sailors, shipbuilders, fishermen, and other workers. Dutch workers were in general well paid, but they were also burdened by unusually high taxes. The farmers, producing chiefly cash crops, prospered in a country that needed large amounts of food and raw materials for its urban (and seagoing) population. The quality of life was marked by less disparity between classes than prevailed elsewhere, although the

regents

difference between a great merchant's home on the Herengracht in Amsterdam and a dock worker's hovel was too obvious to be remarked. What was striking was the comparative simplicity even of the wealthy classes and the sense of status and dignity among the ordinary people, although the exuberance that had earlier marked the society was toned down or even eliminated by the strict Calvinist morality preached and to some extent enforced by the official church. There was, too, a good deal of mingling between the burgher regents who possessed great wealth and political power and the landed gentry and lesser nobility who formed the traditional elite.

Religious  
"columns"

**Religion.** One of the characteristic aspects of modern Dutch society began to evolve in this period—the vertical separation of society into “columns” identified with the different Dutch religions. Calvinist Protestantism became the officially recognized religion of the country, politically favoured and economically supported by government. But the Reformed preachers were thwarted in their efforts to oppress or drive out other religions, to which a far-reaching toleration was extended. Mass conversion to Calvinism had been confined mainly to the earlier decades of the Eighty Years' War, when Catholics still frequently bore the burden of their preference for the rule of the Catholic monarchs in the southern Netherlands. Sizable islands of Catholicism remained in most of the United Provinces except Zeeland, while Gelderland and the northern parts of Brabant and Flanders conquered by the States-General were overwhelmingly Catholic, as they remain today. Although public practice of Catholicism was forbidden, interference with private worship was rare, even if Catholics sometimes bought their security with bribes to local Protestant authorities. Catholics lost the traditional form of church government by bishops, whose place was taken by a papal vicar directly dependent upon Rome and supervising what was in effect a mission; the political authorities were generally tolerant of secular priests, but not of Jesuits, who were vigorous proselytizers and linked to Spanish interests. Protestants included, along with the predominant Calvinists of the Reformed Church, both Lutherans in small numbers and Mennonites (Anabaptists), who were politically passive but often prospered in business. In addition, the Remonstrants, who were driven out of the Reformed Church after the Synod of Dort (Dordrecht; 1618–19), continued as a small sect with considerable influence among the regents. There were also other sects emphasizing mystical experiences or rationalist theologies, notably the Collegiants among the latter. Jews settled in the Netherlands to escape persecution; the Sefardic Jews from Spain and Portugal were more influential in economic, social, and intellectual life, while the Ashkenazim from eastern Europe formed a stratum of impoverished workers, especially in Amsterdam. Despite unusually open contacts with the Christian society about them, Dutch Jews continued to live in their own communities under their own laws and rabbinic leadership. Successful though some Jews were in business, they were by no means the central force in the rise and expansion of Dutch capitalism, as has sometimes been maintained. Indeed, no clear pattern can be detected of religious affiliation affecting the growth of the Dutch business community; if anything, it was the official Dutch Reformed Church that fulminated most angrily against capitalist attitudes and practices, while the merely tolerated faiths often saw their adherents, to whom economic but not political careers were open, prospering and even amassing fortunes.

The Jews

**Culture.** The economic prosperity of the Dutch Republic in this “golden century” was matched by an extraordinary flowering of cultural achievement, which drew from the nation's prosperity not only the direct resources of financial nourishment but also a driving and sustaining sense of purpose and vigour. This was reflected in the first instance by a notable series of historical works: from the contemporary chronicles of the revolt by Pieter Bor and Emanuel van Meteren; through the highly polished account by Pieter Corneliszoon Hooft, a masterpiece of narration and judgment in the spirit of

Tacitus; to the heavily factual chronicle of Lieuwe van Aitzema, with its interspersed commentary of skeptical wisdom, Abraham de Wicquefort's history of the republic (principally under the first stadholderless administration), and the histories and biographies by Geeraert Brandt. These were works in which a proud new nation took account of its birthpangs and its growth to greatness. Only in the latter part of the century did Dutch historians begin to express a sense that political grandeur may be transient. Political theorists shared the same concerns, although the effort to fit new experience and ideas into the traditional categories derived from Aristotle and Roman law created an air of unreality about their work, perhaps even more than was true of political thinkers elsewhere in Europe. Theorists such as the Gouda official Vrancken in the days of the foundation of the republic and Hugo Grotius in the early 17th century portrayed the republic as essentially unchanged since the early Middle Ages or even since antiquity—a country where sovereignty resided in provincial and town assemblies, which had partly lost their control to counts and kings before regaining it in the revolt against Philip II. The next surge of political debate came after midcentury, when for a little over two decades the country was governed without a prince of Orange as stadholder. The controversy over whether the young Prince William had any right by birth to the offices of his forefathers probed the fundamental character of the republic, for even a quasi-hereditary stadholdership created an incipient monarchy within the traditional structure of aristocratic republicanism. The debate involved the issue not so much of centralization versus provincialism as where the leadership of the republic properly lay, whether in the House of Orange or in the province of Holland and notably its greatest city, Amsterdam. Only the celebrated philosopher Benedict de Spinoza, an outsider by origin and character, elevated these political questions to the level of universality.

Two of the greatest philosophers of the 17th century resided in the Dutch Republic, but both were to some extent outsiders. The Frenchman René Descartes found there a freedom from intellectual inquisitions and personal involvements and lived in the Netherlands for two decades while engaged in the studies that helped transform modern thought. The second was Spinoza, a Jew by birth and upbringing but a key figure in the history of all modern Western philosophy. He was more than just Descartes' greatest exponent, for he was an independent thinker of the first order. Scientific activity in the United Provinces reached a high level. The physicist Christiaan Huygens approached Newton himself in power of mind and importance of scientific contribution. The engineer and mathematician Simon Stevin and the microscopists Antonie van Leeuwenhoek and Jan Swammerdam rank in the front of their fields.

Dutch literature, which knew great creativity during the “golden age,” remained the possession of the relatively small number of those who spoke and read Dutch. Figures like the historian P.C. Hooft or the poets Constantijn Huygens and Joost van den Vondel, who was also a distinguished playwright, wrote with a power and a purity worthy of the best that France and England produced at that time. Music was hampered by the Calvinists' antipathy to what they saw as frivolity. Organ music was barred from services in Reformed Churches, although town authorities frequently continued its performance at other times. The great organist-composer J.P. Sweelinck was more influential in encouraging the creative wave in Germany than among his own countrymen. The art whose achievements rank at the very top was painting, which rested upon the broad patronage of a prosperous population. Group portraits of regents and other influential citizens adorned town halls and charitable establishments, while still lifes and anecdotal paintings of popular life hung in profusion in private homes. Some of the greatest work, from the brushes of such painters as Hals, Steen, and Vermeer, were painted for these markets, but the greatest of Dutch painters, Rembrandt van Rijn, broke through the boundaries of the group portrait to create works with his own extraordinary mood and inward

Political  
theory

Painting

meaning. The landscape painters, notably Ruysdael, captured the distinctive Dutch flat land, broad skies with massed clouds, and muted light. Architecture remained at a lesser level, merging with some success the native traditions of brick buildings and gable roofs and fashionable Renaissance styles. Sculpture remained a largely foreign art.

#### THE 18TH CENTURY

**Economic and political stagnation.** Once the Dutch fleet had declined, Dutch mercantile interests became heavily dependent upon English goodwill; yet the rulers of the country were more concerned to reduce the monumental debt that weighed heavily upon the country. During the 18th century Dutch trade and shipping were able to maintain the level of activity reached at the end of the 17th century, but they did not match the dramatic expansion of French and especially English competitors. The Dutch near monopoly was now only a memory. Holland remained rich in accumulated capital, although much of it could find no outlet for investment in business. Some went into the purchase of landed estates, but a great deal was used to buy bonds of foreign governments; the bankers of Amsterdam were among the most important in Europe, rivalling those of London and Geneva. Dutch culture failed to hold its eminence; a medical scientist like Hermann Boerhaave or a jurist like Cornelis van Bynkershoek was highly respected, but they were not the shapers and shakers of European thought. Dutch artists were no longer of the first order, and literature largely followed English or French models without matching their achievements. The quality of life changed: instead of the seething activity of the 17th century, the 18th century was one of calm and easeful pleasantness, at least for men of property. The middling classes in town and countryside also knew continuing prosperity; conditions for the labouring classes continued to be hard, although foreign visitors thought the workers lived better than elsewhere. The poor as such were not labourers but a residual class of unemployed who subsisted on the charity of town governments and private foundations. Religious life was more relaxed, particularly among Protestants. Catholics, still without political rights, but facing milder restrictions, fell into a quarrel between adherents of Jansenism, which denied free will, and supporters of Rome; the former split off to form the Old Catholic Church, a small denomination that still exists. The educated classes widely accepted the principles and attitudes of the Enlightenment, although without the sharp hostility to religion that characterized the French Philosophes.

During the second stadholderless period of Dutch government (1702–47), the republican system became an immobile oligarchy. The “liberty” defended by the regents as soundly republican was in practice the rule of hereditary patricians, responsible to neither the citizenry below nor a stadholder above. Although William IV yearned for restoration to the offices held by the princes of Orange before him in the provinces to the south, he accepted, with no less admiration and commitment than the regents, the perfection and immutability of the Dutch constitutional system, with the single difference that he envisioned it including the stadholderate for all the provinces. It was not until the War of the Austrian Succession (1740–48) that the power of the regents began to crumble. As in 1672, disaster on the battlefield proved the Achilles’ heel of a regime that had not built up a broad popular political base. The regents had not been able to overcome the traditional commitment of the people to the House of Orange as their natural leader and saviour. French and Prussian armies swarmed over the Austrian (southern) Netherlands and were poised for invasion of the United Provinces, which were linked by alliance with England although they had remained formally neutral. When the French forces crossed into Dutch territory, rioting reminiscent of 1672, although less widespread and violent, led to the fall of the second purely republican government and the election of William IV as hereditary stadholder of all the provinces. Otherwise there was little change; some regents were compelled to step down from

their posts, and leadership in the hands of the Prince of Orange was uncontested. William rebuffed the efforts of burghers in Amsterdam and other towns who had supported his restoration in order to achieve democratic reforms, in which participation in government would be extended to men of modest property who had been completely disfranchised (although not to wageworkers or to paupers).

**The Patriotic movement.** During the next decades, in the face of the rigid conservatism of the princes of Orange (William V succeeded his father in 1751 and assumed personal government in 1759) and under the influence of the French Enlightenment, an essentially new political force began to take shape. Known as the Patriot movement after an old party term used by both republicans and Orangists, it applied fundamental criticism to the established government. Although the Patriot movement was representative of the new democratic and Enlightenment ideals, it had strong roots in native Dutch traditions. From the beginning, the United Provinces had rejected specifically democratic institutions in favour of frankly aristocratic government (in the Aristotelian sense), but the notion that the regents had a duty to serve not their own private interests but those of the country and the people had persisted in theory and in mood. When the aristocracy ceased to recruit new members from below and thus became an enclosed caste, the discrepancy between its claim of service to the general welfare and the reality of its practice became evident. The Patriot movement took in a wide range of supporters: discontented noblemen like the Gelderland baron Joan Capellen tot den Pol; wealthy bankers and businessmen without a voice in government; artisans and shopkeepers, traditionally Orangist in sympathy, who were dismayed to find their claims to an effective role in the politics of their towns rebuffed by the princes; and intellectuals committed to the new Enlightenment rejection of arbitrary power. The Patriots included in their ranks many Protestant dissenters and Catholics, but the Jews continued to look to the prince of Orange as their protector. Some regents, holding firm to the republicanism of their ancestors and resenting the return of the stadholderate, found a new base for their ideas in the Patriot movement. Most regents, however, saw more peril in the new movement for broader popular government than in the stolid conservatism of the princes of Orange; a reconciliation between the camps of the patrician republicans and the Orangists began to take shape under the impact of a common threat from below.

Again the events of war imperilled the established regime. Although the diplomacy of William V was firmly based upon the alliance with England, London became exasperated with the Dutch during the United States War of Independence (1775–83), when they attempted to continue and expand their profitable trade with the new American nation as well as with France. Dutch flirtations with the Russian-sponsored League of Armed Neutrality resisting British searches of neutral vessels and indications of Dutch negotiations for an alliance with the Americans only worsened relations. Finally open hostilities erupted in the fourth Anglo-Dutch War (1780–84). The Dutch navy, sorely neglected for more than a half century, was utterly unprepared to battle the powerful British fleet, and the Dutch fleet’s attempts to convoy their merchantmen brought only disaster. The onus of defeat fell upon the Stadholder. He was unable to stand firm against the increased agitation of the Patriots, who forced their way into governments of town after town in Holland and other provinces. Holland began organizing its own army, distinct from that under the Prince’s command, and civil war seemed in the offing. William V fled to Gelderland with his wife, Wilhelmina, the sister of the Prussian king Frederick II. Holland declared him deposed. It was the strong-willed Wilhelmina, rather than her hesitant and rather docile husband, who took the lead in the restoration of the stadholderate. Dutch politics had now become a concern of the great powers. France sided with the Patriots, not out of sympathy with their principles but because they opposed the

Revolution

Stadholder, who had fallen back into dependence upon English and Prussian support. As long as Frederick II ruled in Prussia, Wilhelmina's pleas for armed intervention fell on deaf ears, but when the throne passed to his nephew Frederick William II in 1786, the way opened for action. The Patriots counted upon the support of the French, but the government at Versailles, then entering the final financial and political crisis of the monarchy that erupted in the Revolution of 1789, could give no more than verbal encouragement. Wilhelmina, working closely with the English ambassador, arranged to create a crisis by seeking to return to Holland; her detention at the provincial border was taken by Prussia as justification to send an army into the United Provinces. The Prussians quickly swept away the makeshift militias of Holland and Utrecht and restored the Stadholder to his offices. A period of repression of Patriots followed; many went into exile, first in the Austrian Netherlands and then in France. The outbreak of the French Revolution in 1789 gave new hope to the exiles and their friends at home. They looked now for more effective French assistance and at the same time found in the French Revolutionary experience practical ideas for the reorganization of the government at home, notably the principle of a single, indivisible republic. The Patriots' hopes rose when French Revolutionary armies swept over the Austrian Netherlands (which had had a brief interlude of independence in 1789-90) in 1792, but the French forces retreated the next year. It was not until 1794 that they returned to Belgium (as it now became customary to call the southern Netherlands), driving up to and then across the frontier of the United Provinces. The moment for which the Dutch Patriots had long been waiting was at hand: French power would more than outweigh the English and Prussian strength upon which the stadholder relied (Prussia made a separate peace with France in 1795), and a democratic revolution, thwarted in 1787, would be possible. The freezing of the great rivers during the winter permitted the French forces to cross into the Dutch heartland, but even before they arrived the Patriots seized the reins of state from helpless William V, who abandoned office and fled to England.

#### THE PERIOD OF FRENCH RULE, 1795-1813

The old republic was replaced by the Batavian Republic, and the political modernization of the Netherlands began—a process that would take more than half a century and pass through many vicissitudes; yet it was one marked by an extraordinary lack of violence. For all its flaws and inconsistencies, the old regime of the United Provinces had enjoyed many of the institutions and practices that other countries had to create in the fire of revolution: the sovereignty of parliamentary assemblies; wide-ranging political and religious toleration; equality of all citizens before the law; and an unusually broad distribution of the benefits of economic prosperity, however far the social system was from equality. Even the sense of nationhood had put down deep roots, although the awareness of differences of religion remained powerful. In a word, the Dutch had already achieved a large measure of the “liberty, equality and fraternity” that had become the slogan of the French Revolutionaries. The task that confronted the Batavian and the successor regimes was to adapt old institutions and create new ones that could meet the needs of a new era. But the Dutch statesmen had to operate within the confines of a small power shorn of most of its military and naval strength, and yet more dependent than most other countries upon its trading and shipping.

**The Batavian Republic, 1795-1806.** The Batavian Republic lasted 11 years, during which it proclaimed the sovereignty of the people but was in fact a protectorate of France. The organization of government had to be approved not only by the Dutch people but also by whatever government happened to be in control in France. The constitutions therefore reflected not only Dutch conditions and ideas but also the arrangements in effect in Paris; nonetheless, they did create a political system of the new type, a new regime, in the Netherlands. After

much debate, the ancient historic provinces—so unequal in wealth, population, and influence—were replaced by a unitary republic divided into departments and electoral constituencies that were roughly equal in population, if not in wealth. The representatives elected to the National Assembly (which replaced the historic States-General) were not delegates of provincial assemblies by whose decisions they were bound but deputies with full independence of judgment. The ancient system of government, with its medley of assemblies and boards with imperfectly differentiated functions, was replaced by a modern system of separate and explicitly defined legislative, executive, and judicial branches; functionally organized ministries directed the work of foreign affairs, internal affairs, war, and navy. The full legal equality of all citizens in all parts of the country was proclaimed; the residents of North Brabant, Zeeland-Flanders, Limburg, and Drenthe gained the same rights as all other citizens of the republic, just as their districts, once excluded from the States-General, now participated in the national government equally with all others. The Reformed Church lost its standing as the sole official, protected church, supported out of state revenues; equal status was accorded to all religious denominations, including Catholics and Jews. Yet full separation of church and state was not proclaimed, and their relationship was to continue as one of the central factors in Dutch politics for more than a century. The historic privileges of class and locality were abolished; the liberty of each and all under the law and before the courts replaced the diverse “liberties” of town and province, noble and regent. Where, before, town governments had co-opted their members, deputies to the National Assembly were now elected; but the franchise was limited to property holders, and these did not choose their representatives directly, but through electors named by primary assemblies. Most of these institutional changes were permanent, though the republican form of government was replaced by a kingdom in 1806 and never re-established.

While these momentous changes were being debated and adopted, the ordinary work of state and nation had to continue amid conditions of almost unprecedented difficulty. England reacted to the French occupation of the Netherlands and the flight and overthrow of the Stadholder by a declaration of war and a blockade. Dutch overseas trade and fishing, the country's most essential occupations, were brought to a near standstill, while most of the Dutch colonies were seized by the English on behalf of William V. The French, however, remained relentless in their own exploitation of the occupied “fraternal republic.” The Dutch government, which took over the whole accumulated burden of national and provincial indebtedness, had also to bear the costs of the French occupying forces and to pay immense sums in tribute to the Paris government; indeed, the forced circulation of vastly inflated French assignats (paper currency) at face value was a scarcely disguised and very effective form of French taxation directly upon the Dutch people. Nor did the successive French governments—republican, consular, or imperial—grant the Dutch any greater freedom of trade with France or other countries under its control in compensation for the lost overseas business. As trade declined and industry languished, the Netherlands began to change in economic character toward a primarily agricultural country. The venturesome spirit for which Dutch businessmen had been so famed a century or two before seemed to be lost, replaced by what the Dutch themselves called a “jansalie” (stick-in-the-mud) attitude; once-bustling cities dwindled to mere market towns; even Amsterdam lost much of its population. As a result, it became difficult to consolidate the new government. A multiple executive modelled on the French Directory and lacking a firm base in established political institutions and practices reflected the intrigues of individuals rather than the programs of clearly delineated parties. The victors quarrelled among themselves and looked to Paris to decide among them, or at least passively accepted its dictum, given by coups d'état organized or approved by the French army command. In 1805, Napoleon gave quasi-dicta-

torial powers to R.J. Schimmelpenninck. Schimmelpenninck, called Councillor Pensionary after the fashion of the old provincial leaders, was actually an uncrowned and nearly absolute monarch (although, ultimately, power continued in Napoleon's hands); he nonetheless carried into practice many of the reforms that had been proposed but not adopted. But Napoleon decided the next year to incorporate the Dutch state directly into his "Grand Empire" of vassal states.

**The Kingdom of Holland and the French Empire, 1806–13.** Renamed the Kingdom of Holland, the Netherlands received as its monarch Napoleon's younger brother Louis. The four years of his kingship were one of the strangest episodes in Dutch history. Louis Bonaparte was a stranger in the land, yet he took its interests to heart, evading his brother's commands and winning the respect, if not quite the affection, of his subjects. The reconciliation of former Orangists, republicans, and Patriots began under his rule, for, in the face of the apparent permanence of the Napoleonic empire, they entered his government and worked together. Nonetheless the brute fact remained that, for Napoleon, Holland was the kingpin of the "continental system," which he hoped would bring England to its knees by cutting off its continental exports. French officials enforced the vigorous suppression of the smuggling of English and colonial goods to the Continent through Holland that had sprung up over the past decade with London's connivance. King Louis's resistance to his brother's efforts and his refusal to put French interests ahead of Dutch led to the Emperor's decision to oust his brother from his throne in 1810 and to incorporate Holland into the French Empire.

Little changed, however; the same officials—some Dutch, some French—continued to do the work of government in the country, which remained outside the French tariff system. As long as the Napoleonic empire seemed firmly based and permanent, Dutchmen served the new sovereign as they had King Louis, all the more readily because the exiled Prince of Orange gave permission for such collaboration. Dutch soldiers continued to fight in Napoleon's campaigns, losing heavily in the Russian invasion of 1812. But as it became increasingly obvious, after the failure of the Russian and Spanish campaigns, that the Napoleonic empire was collapsing, influential Dutchmen began to prepare for the creation of a new and independent regime; it was taken for granted that its head would be the Prince of Orange—the son of William V, who had died in 1806—and that it was desirable that it be established by the Dutch people rather than imposed by the eventual allied victors. The movement for restoration was led by a remarkable figure, Gijsbert Karel van Hogendorp, a man of firm political principle who had refused to serve any of the governments that ruled in Holland after 1795, yet accepted the necessity for a re-established prince of Orange to govern the country as a limited constitutional sovereign.

During the autumn of 1813, Hogendorp secretly planned a take-over of government from the French, which became possible without bloodshed during November, as French troops withdrew to their homeland. On November 30, the hereditary stadholder, at the invitation of Hogendorp's provisional authority, returned from England to proclaim his reign as hereditary prince. In 1814, he granted a charter establishing a constitutional monarchy, with restricted powers for a Parliament elected by a narrow property suffrage. At the insistence of the victorious powers meeting at the Congress of Vienna, he took the title of king of The Netherlands and was given sovereignty over the southern Netherlands, which included both Belgium and Luxembourg. During the campaign against Napoleon after his return from Elba in 1815, Dutch troops played a major role in his defeat at Waterloo.

#### THE KINGDOM OF THE NETHERLANDS (1814–1918)

**King William I.** The reign of King William I, as the restored Prince of Orange was now called, was one of the most critical periods in the history of The Netherlands. During this quarter-century the adaptation of the country

to the conditions and requirements of modernity moved in a complex and even contradictory way, guided by a monarch who in his economic policy was far more forward-looking than most of his countrymen but who in politics resisted the expansion of Parliament and the introduction of liberal principles. He was a 19th-century version of the "enlightened despot," a man intent upon power, although not so much for its own sake as in order to serve the welfare of his country as he saw it. The role of the States-General—which continued to represent a general electorate of tax-paying citizenry—was strictly limited to the enactment of laws proposed by the government and to approval of a long-term budget; it was in no sense the representative of a sovereign people. The ministers of state were the agents of the king and responsible to him, not to the States-General. Yet the basic structure of modern government had been created in The Netherlands; constitutional debate would be concerned with redistributing powers and responsibilities among existing institutions.

William I was at his best in confronting the problem of reviving the economic life of the country after the shattering impact of the long French occupation. He put the support of both the government and his own private fortune behind encouragement of commerce and, to a lesser extent, of industry. He sponsored the formation of The Netherlands Trading Society, a nominally private firm which undertook the important but costly and risky enterprise of reorganizing Dutch long-distance trade and shipping, particularly to the Netherlands East Indies, that were returned to Dutch sovereignty by England as part of the peace settlement. With the reopening of trade between the European continent and the wider world, the advantages of the Dutch position at the mouth of the great rivers favoured the revival of the traditional branches of Dutch enterprise; but competition from the ports of other countries, notably from Hamburg and Bremen, as well as from Britain, remained strong. Only in the Netherlands East Indies did the Dutch have a clear advantage over their rivals, despite the abandonment of the monopoly formerly maintained under the East India Company.

The most difficult problem faced by the new regime in The Netherlands was the relations between Holland (which now became the everyday name for all the northern Netherlands, in Dutch as well as foreign usage) and Belgium. The King was passionately devoted to the preservation of a single state encompassing all the Low Countries, a unity lost in the revolt against Spain more than two centuries before; but the sense of common nationhood, cultural and political, was quite weak among the people. The Belgians resented assuming a share of the burden of debt inherited by Holland; they were oriented toward industry, Hollanders toward trade; French was the language of the leading classes in the south, and the use of Dutch as the official language was bitterly opposed even by Flemings, who resented the Dutch version of the common Dutch-Flemish language. Most Flemings, as devout Catholics, were hostile to the predominantly Protestant Hollanders. William's efforts to assume the control that Napoleon had possessed over the Belgian Catholic Church met fierce resistance. At the same time the authoritarian character of William's government, particularly the sharp censorship of the press in Belgium, aroused the antipathy of liberals to the regime. The result was the outbreak of the Belgian Revolution of 1830 and the proclamation of Belgian independence. William, supported by a majority of Dutchmen, who were angered by what they saw as Belgian ingratitude, was able to defeat the hastily organized Belgian army; but the European powers intervened to secure Belgian independence, although it was not until 1839 that a final settlement was reached and the last Dutch troops withdrew from Belgian soil. William, deeply despondent, abdicated the next year, leaving to his son, King William II, the task of coming to terms with the new situation.

**William II and William III.** The new king was not a man of clear ideas or strong will, but he was able to do what his father dared not even envisage—to oversee the

franchise

transformation of The Netherlands into a parliamentary, liberal state. When the crisis of the 1848 revolutions broke, first in France and then in central Europe, William II turned to the leading liberal thinker, J.R. Thorbecke, to guide the change. A new constitution was written, largely modelled on the British (and Belgian) pattern, which gave effective supremacy to the States-General and made the monarch a servant and not the master of government. The King died the next year, and the work of transformation continued under his son, William III (1849–90), who named Thorbecke prime minister. The constitutional monarchy was consolidated, even though Thorbecke stepped down in 1853 because of Protestant rioting against the re-establishment of a Roman Catholic archbishop at Utrecht. Gradually, over the next century, the scope of Dutch democracy was extended to include ever broader sections of the Dutch population in the franchise; universal male suffrage was achieved during World War I, and suffrage was extended to women after World War II. During this period, political parties of the modern type took shape, organized along religious and ideological lines; to the original Liberal, Protestant, and Catholic parties were eventually added Socialist, Conservative-Protestant, Communist, and minor parties. As no single party was able to emerge with a majority, coalition politics became inevitable. The central issue of political controversy became the “school conflict” (*schoolstrijd*), which pitted the liberal (and later socialist) advocates of public schools against the combined Protestant and Catholic parties, which demanded that the state support private (“special”) schools equally with the public schools. For several decades, the liberals remained generally in control and made few concessions on the school issue. But when the Protestant leader Abraham Kuyper formed a coalition with the Catholics in 1888, the religious parties were able to gain power and to favour the special over the public schools. Their policy was assailed by the secular parties, the traditional liberals, the progressives, and the socialists. The liberals, however, were at odds with the other anti-clerical parties on other issues, notably economic policies and the extension of the suffrage. The liberals tended to be the most conservative party on economic issues and favoured a restricted electorate; the progressives were vigorously democratic in outlook, as were the socialists, who also favoured universal suffrage, protection of the right to strike, labour legislation, and other welfare measures. The other major issue of the latter half of the 19th century was the role of the Dutch East Indies. The income received by the Dutch treasury from Indonesian taxes helped balance the national budget; yet the revelations of harsh conditions in the distant archipelago made it impossible to maintain the “culture system,” which had been introduced to force the production of certain crops for export, while the long Achin war drained the treasury.

The Dutch  
in the  
Indies

**Queen Wilhelmina and World War I.** During the first half of the reign of Queen Wilhelmina (1890–1948), the political situation remained fundamentally unchanged. The major parties came to recognize that the school struggle interfered with the solution of other problems. An agreement in principle was reached on the eve of World War I, by which the secular parties accepted state support for religious schools on a basis of equal funds in exchange for enactment of universal male suffrage. When war broke out in 1914, Holland, which had declared its neutrality, put aside the proposed reforms in order to concentrate on the immediate problem of maintaining the country’s livelihood in the face of blockades. The “Pacification,” as the compromise was called, was adopted in 1917 and put into effect after the return of peace. The war years saw almost all political controversies set aside, while the government took unprecedented action in maintaining trade and guiding economic life. Although spared the horrors of combat, the Dutch had to maintain a large standing army, and mutinies broke out among the soldiers in 1918.

Economic  
transformation

The century from the restoration of Dutch independence in 1813 until World War I saw fundamental transformations of Dutch life. The economic base was mod-

ernized; the role of agriculture fell off, with most Dutch farmers producing dairy and meat products for the market; trade and shipping were revived in the face of fiercely competitive conditions. But most important was the rise of industry—first textiles in the eastern provinces, then coal in the southeast in Limburg, and finally modern manufactures, notably the great Philips electrical products factories at Eindhoven. Rotterdam became one of the world’s busiest ports and the centre of chemical and other industries. These changes were paralleled in society by the gradual extinction of pauperism, the domination of the middle class business and professional men, and the improvement of the conditions of working people and farmers, especially after the mid-19th century. Although religious freedom was generally as great as anywhere in Europe, Protestant conservatives faced major difficulties, especially during the first half of the century, when they protested the modernizing ideas of the Reformed (*Herformde*) Church; their efforts to create independent religious communities met with sharp resistance from the government, which did not interfere in non-Protestant religions. Some of the Gereformeerden (the older name for “Reformed” used by the conservatives) emigrated, many of them to the United States; but by the latter half of the century, persecution ceased. The cultural life of Holland remained very largely confined within national boundaries; Dutch thinkers, writers, and artists responded strongly to influences from Germany, France, and England but themselves had little impact abroad. Dutch scientists maintained a respected position for their country; Hugo de Vries was one of the principal founders of the science of genetics, while physicist Hendrik Antoon Lorentz contributed greatly to Einstein’s theories of relativity. Dutch artists were generally imitative, although the “Hague school” of Impressionists displayed great gifts; only Vincent van Gogh, who spent most of his active life in France, achieved world reputation. Dutch literature ran parallel to main currents abroad; the Réveil early in the century was a movement of intensely religious romanticism with strongly conservative ideas, while Eduard Douwes Dekker (pseudonym Multatuli) in mid-century expressed the moods of social criticism with great power; the movement of “Men of the ‘Eighties” (*Tachtigers*) brought to the fore a stress upon aesthetic values and spirituality; and early in the 20th century a literature of social protest re-emerged.

19th-  
century  
literature

#### THE NETHERLANDS SINCE 1918

The movement of The Netherlands into modernity was accelerated after 1918. Although the country became a member of the League of Nations, it reaffirmed its neutrality, which seemed to have obtained the respect of the powers and which was symbolized by the presence of the International Court of Justice at The Hague. There was considerable harshness in relations with Belgium, which not only abandoned its neutrality for a close alliance with France but demanded territorial cessions from Holland. The Dutch government, although humiliated by a demand that it present its case before the peace conference at Versailles, successfully resisted any amputation of its territory. The Dutch, for their part, refrained from giving any official support to the Flemish nationalist movement in Belgium, although a “Great Netherlands” movement, principally among intellectuals, emphasized the underlying unity of Dutchmen and Flemings. Domestic politics continued in the same course, with the Protestant political parties continuing to provide leadership for generally conservative policies, especially after the onset of the world depression in the 1930s. Although their small country was particularly dependent for its livelihood upon intercourse with other nations, the Dutch were compelled to introduce tariff measures in order to counter the protectionist policies of other lands.

**World War II.** At the outbreak of World War II in 1939, the Dutch sedulously maintained their neutrality, although their sympathies lay overwhelmingly with the Western powers. Nonetheless, when Nazi Germany undertook the campaign against France in the spring of 1940, its forces struck not only against Belgium in order

to outflank the French defenses but also against Holland. The aerial destruction of the ancient heart of Rotterdam was the most dramatic episode of the brief campaign, in which the Dutch land armies were overwhelmed in less than a week. The government, accompanied by Queen Wilhelmina and the royal family, withdrew to England, where they formed a government in exile. The Netherlands suffered the next five years of war under German occupation. The work of public administration was continued by Dutch organs of state, which attempted to buffer German political repression, deportation of Jews, and forced employment of Dutch labour in Germany. A resistance movement sprang up, which, with the exception of a few Dutch Nazi collaborators, spanned all groups from the conservatives to the Communists. The Germans retaliated by executing Dutch hostages for such measures of resistance as the strike of Amsterdam dock workers against the seizure and deportation of Dutch Jews to extermination camps in Germany. Some Jews were able to "dive under" (go into hiding) with the assistance of friends, but the large majority were taken away to their deaths, almost eliminating from Dutch life a small but vigorous part of the population, who for more than three centuries had contributed colour, intelligence, and sensitivity to Dutch society. In the final phases of the war, particularly after the failure of Allied airborne attempts to capture bridgeheads across the great rivers at Nijmegen and Arnhem, the Dutch suffered from severe food shortages, and during the last months before liberation (May 1945) they were on the verge of famine.

**The postwar period.** After the war many aspects of Dutch life changed dramatically. Wilhelmina and her government returned from exile to re-establish a government more strongly democratic than ever, with both universal suffrage and proportional representation in elections. Anticipating the characteristic difficulties of postwar reconstruction, the government, industry, and labour agreed upon a plan for industrial and commercial expansion, with avoidance of the rapid expansion of prices or wages that would bring a threat of inflation. The plan worked effectively for more than two decades, so that the Dutch were able to avoid drastic inflation until the introduction of a new taxation system in the late 1960s. Dutch industrialization moved forward with speed and depth, expanding to include the large-scale production of steel, electronics, and petrochemicals. Holland, putting aside the policy of neutrality as a failure, entered vigorously into the postwar Western alliances, including the North Atlantic Treaty Organization (NATO), and the various organizations of European unity (the Common Market); but its influence was limited, even though it joined with Belgium and Luxembourg in a closer union ("Benelux"). Indonesia, where Dutch authority was re-established after wartime Japanese occupation, with the expectation that it would be a kind of self-governing dominion in a Dutch community of nations, soon became the scene of a nationalist revolution. After some hesitation and bitterness, the Dutch granted it full independence and later gave economic aid and technological assistance at the request of the Indonesian government. The Netherlands Antilles and Surinam remained part of the Dutch kingdom, although no longer under the authority of the government at The Hague. Dutch political alignments shifted somewhat under postwar conditions. The Socialist Party reorganized itself as the Party of Labour without the traditional Marxist commitments, while the Catholics, who had split politically in the interwar period, united into the Catholic People's Party. The first postwar governments were dominated by an alliance of the Labour and Catholic parties, which continued until the early '60s. When this coalition broke up, the Catholics—who, as the consistently largest single party at the polls, provided all the prime ministers from the late 1950s to the early 1970s—turned to the Protestants and the Liberals, renamed People's Party for Freedom and Democracy. The general policy of the government was not, however, greatly modified. During the '60s, the generally peaceful mood of Dutch public life was broken by rioting of youth and labour groups, especially in Amsterdam. The

The  
resistance  
movement

Abandon-  
ment of  
neutrality

most difficult crisis affected the royal family. The marriage (1966) of Princess Beatrix, the heiress to Queen Juliana (who had succeeded Wilhelmina on her abdication in 1948), to a German diplomat aroused bitter debate and imperilled the position of the House of Orange as a national symbol above partisanship. The marriage of Princess Irene to a Spanish Carlist prince had already come as a shock even to the Catholics but was less difficult politically because she lost her right of succession.

Dutch politics, like Dutch society in general, continued to practice what was called pillarization (*verzuiling*)—the organization not only of political parties but of labour unions, businessmen's organizations, social and sport clubs, and many professional groups on the basis of membership in a religious-ideological "pillar," either Catholic, Protestant, or Humanist (the latter including liberals and socialists). Pillarization had received official confirmation in the Pacification of 1917 and removed most of the tinder from Dutch politics; but it also kept ordinary Dutchmen separated from each other, by religion, to a greater degree than in any other Western country. Yet, because the leaders of the pillar organizations worked well with each other and the right of each pillar to exist and function was unquestioned, public life generally ran smoothly. A quarter-century after the end of World War II, there were signs of disquiet over the system, however, and efforts were being made to form new political parties on a comprehensive basis. (H.R.o.)

zation

### III. The southern Netherlands, Belgium and Luxembourg (1579 to present)

#### THE PERIOD OF FOREIGN RULE

**The Spanish regime.** After 1579 Alessandro Farnese, supported by the Union of Arras, re-established Spanish authority in the predominantly Catholic southern Netherlands. This territory initially included what is now Belgium and Luxembourg, plus part of northern France and what later became the southernmost part of the United Provinces. In practice, its existence as a separate entity dates from Farnese's reconquest of Flanders in 1585, though Spain did not give up hope of resubjugating the north as well. With this end in view, Philip II granted the sovereignty of the Netherlands to his daughter Isabella and her husband, Archduke Albert, in 1598.

But the northern provinces were never recovered, and Spain allowed only a nominal independence to the south. In 1609 Albert was forced to make a 12-year truce with the United Provinces. He died in 1621, the same year the war was resumed, and Isabella was, from that time on, nothing more than a governor general. During the course of the war with the United Provinces, northern Brabant, as well as the region to the east of the Meuse, and Zeeland, were lost (1621–48). In addition, France, which was allied to the United Provinces, seized Artois (1640). Philip IV agreed to the new northern boundary of the Spanish Netherlands in the Peace of Münster (January 30, 1648), which also confirmed the closing of the Scheldt River to foreign shipping, destroying the commercial importance of Antwerp. Hostilities between Spain and France continued during most of the latter part of the 17th century. The treaties that interrupted this conflict were marked, in almost every instance, by new losses of territory to the southern Netherlands. The Peace of the Pyrenees (1659) confirmed the loss of Artois and provided for a series of French fortifications to be built along the border of what is now Belgium. By the peace of Aix-la-Chapelle (1668), France occupied part of Flanders. In 1700 the Spanish Habsburg dynasty died out with Charles II, who had turned his holdings over to Philippe d'Anjou, grandson of Louis XIV of France. The Spanish Netherlands was thereafter under French rule until it was occupied by the British and Dutch in 1706. By the Treaty of Utrecht (1713), ending the War of the Spanish Succession, the territory comprising present day Belgium and Luxembourg passed under the sovereignty of the Holy Roman emperor Charles VI, head of the Austrian branch of the House of Habsburg.

Territorial  
losses

**Administration.** The government of the Spanish Netherlands, though not independent, was characterized by a

large degree of autonomy. The king was represented in Brussels by a governor general who was, more often than not, a prince of the Spanish royal family. The three councils that assisted the governor (the Council of State, the Privy Council, and the Council of Finances) were composed almost entirely of local leaders, though the Council of State did include a certain number of Spanish nominees. The president of the Privy Council became a sort of first minister. During the 17th century the principal presidents were Pieter Roose (1632–53) and Charles de Hoyvne (1653–71). These men did not hesitate to show independence of Madrid in order to protect their interests, but they were essentially supporters of absolutism and regularly tried to assert the authority of the royal government at the expense of regional and local rights. After 1664 the Council of Finances, under its chief official, the treasurer general, began to act as a sort of ministry of economic affairs.

#### Internal autonomy

These councils gained considerable autonomy in internal affairs, but, with respect to foreign policy, they were controlled less by the governor general than by a Spanish official in Brussels called the secretary of state and war. In Madrid, there was a council of state for the Netherlands, the members of which were natives of the Belgian provinces. In this delicately balanced administration, divided between Brussels and Madrid, the Spanish element tended to predominate, especially in the field of foreign affairs.

There were representative bodies in the Spanish Netherlands. The most important were the provincial estates (assemblies) whose power lay in their authority to levy and collect taxes. This authority enabled them to see that a considerable portion of the revenue was spent within the country. A permanent deputation drawn from the estates supervised public works.

Before and during the revolt against Spain, the States-General, composed of delegates from all the provincial estates, had enjoyed great influence. When the country returned to Spanish rule, the role of the States-General was diminished; after 1632 it no longer met.

During the 16th century regionalism was deep-rooted in the provinces, but in the 17th century a wider feeling of unity developed. The nobles, angered by the government's centralizing policies, revolted in 1631–34; the aristocratic provincial governors involved in this revolt were forced to flee the country because the towns did not support them. Some were not replaced, and by 1700 only Hainaut, Luxembourg, Namur, Limburg, and south Gelderland, all of which had proved their loyalty, still had provincial governors.

In judicial matters, the supreme authority was still the Great Council of Malines, founded in 1504; but it had to defend its jurisdiction against the encroachments of the Privy Council. The provincial courts of justice were the councils of Flanders, Brabant, Namur, Luxembourg, south Gelderland, Hainaut, and (until 1659) Artois. The most important of these was the Council of Brabant, to which the king had originally granted autonomy in conformity with the provincial liberties of Brabant. Nevertheless, after 1603, he was represented in Brabant by financial officials under a procurer general. These magistrates, in accordance with a practice common at that time, had, in addition to their judicial duties, administrative functions that increased during the 17th century.

In the 17th century, the administration of the country was made difficult by constant warfare. Government finances, weakened by the loss of revenues from the northern provinces and the loans contracted during the 16th century, suffered further because of increased military expenses. Sale of public offices became a common practice.

#### Taxation

At the end of the 16th and the beginning of the 17th centuries, import and export duties provided a new source of revenue. Prior to this, the shipping of goods was taxed only as *tonlieu* (goods transported within the country). This tax remained but only supplied regional or local finances. Taxes on foreign trade originated from permits allowing trade with the rebellious northern provinces. At first these were sold to individuals, but they were

later replaced with fixed duties which, by 1654, had become customs tariffs. After that, there were customs houses, not only at the frontiers but in Brabant and Flanders as well.

In the country's military organization, the fortresses of Antwerp, Ghent, Ostend, and Charleroi were manned by Spanish troops; other armed forces were raised locally.

The principality of Liège (in present eastern Belgium) was ruled as a separate territory by its bishops, as it had been since the Middle Ages. During the revolt against Spain, it maintained a strict neutrality and continued to do so during most of the 17th century. Its institutional development was, in the main, parallel to that of the Spanish Netherlands.

*Economy.* The economy of the country had, of course, suffered greatly during the struggle against Philip II, but recent research has shown that economic recovery was more rapid and more far-reaching than had previously been thought.

The fortunes of the important linen industry can be traced by studying tax fluctuations. In the region of Oudenaarde, excise taxes almost doubled between 1570 and 1579. The figure for 1579 represents the highest point of the century; the low point occurred in 1589. Slightly earlier, a similar pattern occurred in Courtrai. Thus the decade 1570–80 was a favourable one for the linen industry. A period of crisis followed, but after 1590 there was a marked recovery. In 1600, Oudenaarde again reached the standard of 1561, while Courtrai surpassed that of the preceding century. The 17th century, formerly thought to have been a time of unrelieved calamity, now appears to have known considerable prosperity. Between 1609 and 1610 production doubled in Courtrai; in 1642 it was eight times that of the best years of the 16th century.

A similar situation existed in other branches of the textile industry. In the sayette (serge) mills at Hondschoote, the ten years following 1570 were still a period of great prosperity; the crisis did not begin until about 1580. In this instance the lowest point also occurs between 1580 and 1590. Historians formerly believed that there was a massive emigration of Flemish weavers to the northern Low Countries during the period of turmoil. Recent research has shown that this emigration was on a much smaller scale than had previously been thought and that in 1588 Hondschoote, Bruges, and Ypres were again very active.

The economic crisis in Flanders, the most advanced region in the southern Netherlands, was so short-lived that its existence was not generally realized. It coincides with the reconquest of Alessandro Farnese, in 1585. When this is understood, evidences of prosperity in the 17th century become more comprehensible. After 1600, the war between Spain and the United Provinces and repeated invasions by the French did cause havoc, but the basis of the economy was not seriously threatened until the War of the League of Augsburg (1689–97) and the War of the Spanish Succession (1701–13). In the second half of the century, despite the fact that the Dutch were able to close Antwerp to sea traffic, commerce was kept alive by transporting goods overland from the ports of Holland and Zeeland. Other goods entered the country by the ports of Ostend, Nieuwpoort, and Dunkirk. The digging of new canals facilitated internal transport, and overland trade with France, Germany, and Italy remained active.

The populations of the important cities steadily increased during the 17th century and declined after 1700. In the small towns and the countryside, the rate of expansion continued into the 18th century. The development of the rural linen industry is significant in this connection. The increase in urban population during the 17th century can be explained by the prosperity of the export trade, mostly in the various branches of the textile industry. In Ghent, silks, velvets, and blended weaves of wool, flax, silk, and cotton were all produced in increasing quantities. In Bruges, serge and fustian (a cotton-linen weave) were manufactured; Ghent specialized in luxury fabrics, Bruges in cloth for everyday use. The products of these

Ghent's  
textile  
industries

towns had an important place in the European and Spanish-American markets.

Linen dyers were especially numerous in Ghent. They processed large quantities of linen, which were shipped mainly to Spain and England. The majority of looms belonged to a restricted number of manufacturers. This concentration of the means of production in the hands of a few large entrepreneurs was increased by the mid-18th century to a point that presages the beginning of the Industrial Revolution. For a time Ghent rivalled Antwerp and Brussels as a centre of tapestry manufacture and trade, mainly because of the immigration of merchant entrepreneurs from Oudenaarde. In 1687 one manufacturer employed 200 labourers. In addition to simple floral designs, Ghent tapestries featured religious, mythological, and historic subjects, in the tradition of the great tapestry centres of Flanders. These goods were exported to France, Germany, Denmark, and the United Provinces.

Bruges in the mid-17th century had a population of about 35,000; some 1,500 adult labourers were employed there in the textile industry as weavers and in related jobs. If the wool combers and spinners living in the villages around Bruges are also counted, the total comes to more than 10,000.

The prosperity evident in the Flemish textile industry was not equalled in other areas of the economy, although metallurgy and mining in the principality of Liège were of considerable importance. Agricultural production was high enough to avert famine but increased too slowly to provide a base for much industrial expansion.

At Antwerp, the economic recovery that marked the end of Philip II's reign continued until at least the middle of the 17th century. The town had 42,000 inhabitants in 1589; 57,338 in 1644; and 65,711 in 1698. Although it lost much of its maritime commerce to other cities, Antwerp continued to prosper as an industrial centre. Goods made from Italian silk were exported to France, England, and Holland; ribbon and thread went to Spain and other parts of western Europe. English cloth continued to be distributed through Antwerp, thanks to a certain number of local entrepreneurs and to English merchants settled there. The city produced a great deal of lace for export; during the second half of the century a single lace manufacturer employed 300 persons. This lace was, for the most part, sent to Spain and Latin America. Antwerp was also a centre for the distribution of artworks throughout Europe and America. The paintings of Flemish artists were sent everywhere, and those of Italian masters were often distributed throughout western and central Europe via Antwerp. The same was true in printing and the book trade. Printers were important and numerous; the firm of Moretus was the largest industrial concern in Antwerp and one of the principal firms in Europe. The diamond industry and trade had an impressive development. Antwerp had 104 diamond cutters in 1608; by 1674 their number was 200. People came there from Frankfurt, Hamburg, London, and Paris to perfect their craft. The highly speculative diamond trade—the value of diamonds being contingent on their scarcity—was well suited to a city that dealt mainly in foreign commerce. Commercial firms of international importance were still centred in Antwerp. A recent estimate lists 46 of these in the period 1620–40, some Flemish and some foreign, a number of them controlling large amounts of capital. One of these firms, newly established and moderately prosperous, had commercial ties with Rouen, Calais, Lille, London, Dover, Canterbury, Amsterdam, Leiden, and Hamburg. It sold sugar and other colonial products, Spanish wool, and textiles. Within 30 years this company passed from ordinary trade to banking. It is clear, then, that the economic depression formerly attributed to the 17th century did not really begin until the latter part of that century and the beginning of the 18th.

The relative prosperity of the southern Netherlands, and particularly of Antwerp, no doubt partly explains its flourishing artistic life during this period. This was chiefly evident in the works of the Flemish School of 17th-century painters—among them Peter Paul Rubens, Anthony Van Dyck, and Jacob Jordaensz. Rubens (1577–1640),

court painter to Isabella and Archduke Albert, made Antwerp one of the cultural capitals of Europe. In the area of scholarship, the "Bollandists," a group of Antwerp Jesuits, made valuable contributions to historical methodology.

**The Austrian regime (1713–95).** Under the Austrian, as under the Spanish, Habsburgs, the southern Netherlands enjoyed political autonomy. But its prosperity had been ruined by the wars of the late 17th and early 18th centuries, and discontent was widespread. By 1719 there was opposition in Brussels to taxes levied by the new government. The emperor Charles VI attempted to relieve the economic distress of his new possession by founding the Ostend Company to trade with India (1722), but Britain and the United Provinces, wishing to avoid unwelcome competition, forced him to abandon the company in 1727.

At the death of Charles VI (October 20, 1740), the southern Netherlands passed to his daughter Maria Theresa without opposition. The War of the Austrian Succession, however, led to a new French occupation in 1744. Austrian rule was restored by the Treaty of Aix-la-Chapelle in 1748.

Maria Theresa's regime enjoyed popularity as the economic situation began to improve again toward the middle of the 18th century. As in contemporary England, an increase in agricultural productivity stimulated a population increase, especially in rural areas. This, in turn, spurred the development of various industries. The agricultural transformation occurred mainly on the small farms of Flanders; one of its main features was the spread of potato cultivation, which added an important element to the diet of the rural population. In addition, in the French-speaking part of the country, a number of landed proprietors invested in mining enterprises, notably in the area between the Sambre and the Meuse rivers, which belonged to the principality of Liège. In the southern Netherlands, urban merchants and manufacturers had more in common with the rural landowning class than was usual in continental European countries in the 18th century. As in the case of Britain, this created an atmosphere favourable to the development of industrial capitalism. During this period, Ghent, Antwerp, and Tournai had factories with more than 100 workers; wages, however, were poor. Verviers, in the principality of Liège, was an important center for woollen manufactures, Ghent for cotton goods.

Under the influence of the Enlightenment, the Austrian regime sponsored a number of reforms in the Netherlands. An academy was founded in 1772 and, when the Jesuits were suppressed in 1773, the government replaced their colleges with secular institutions. The government was not inclined to support the remnants of feudal privilege that caused so much discontent in 18th-century France.

Not all of its innovations were popular, however. The emperor Joseph II (reigned 1780–90) suppressed 163 religious houses, granted freedom of worship by his Edict of Toleration (1781), and closed the episcopal seminaries, replacing them with two state seminaries (1786). These measures alienated the Roman Catholic clergy. In 1787 the administration was modernized by replacing the traditional provinces with districts (*cercles*) governed by intendants. This caused dissatisfaction among the groups that controlled the provincial estates. The discontent of the privileged classes was increased by the suppression of the traditional councils and courts of justice, which, like the estates, were looked upon as safeguards of provincial autonomy.

Joseph's sister, Maria Christina, duchess of Saxony-Teschen, who was governor general, was reluctant to implement the unpopular edicts abolishing these traditional bodies. But other members of the administration, including Ferdinand von Trauttmansdorff, the Emperor's minister plenipotentiary, and Gen. Richard d'Alton, commander of the troops, insisted upon their enforcement. The estates of Hainaut and Brabant reacted by refusing to pay taxes (November 1788). In the following year, influenced by the outbreak of revolution in neighbour-

The  
Brabant  
Revolution

ing France, conservatives led by Henri Van Der Noot and progressives led by Jean-François Vonck united in opposition to the Emperor. Raising a corps of volunteers, Vonck defeated an Austrian force at Turnhout (October 24–27, 1789). Nervous because of the situation in France, the Austrians retreated to Luxembourg, and Van Der Noot made a triumphant entry into Brussels, where he and his "Statists," were supported by the Estates of Brabant, this time not only against the Emperor but also in opposition to the progressive Vonck, who favoured the convening of a national assembly. They successfully incited the people of Brussels against Vonck, who had to take refuge in Lille.

This "Brabant Revolution" (so called because most of its leaders came from Brabant) had widespread support in the towns; but the peasants, having little in common with the middle class revolutionaries, generally supported the Austrians. This was particularly evident among that segment of the rural population that lived, at least in part, by domestic work for the new manufacturers in the towns. Thus, in Hainaut, the province where the estates had first rebelled, the peasants of the countryside of Chimay rose up in favour of the Emperor and against the Statists.

Thus, when Joseph II died, and his successor, Leopold II, decided to re-establish imperial authority, he encountered no opposition from the mass of people. On December 2, 1790, Brussels was reoccupied by Austrian troops. Nevertheless, in order not to provoke the Statists, the Emperor did not reintroduce his predecessor's reforms. The discontented now looked to revolutionary France for support. When the French general C.F. Dumouriez occupied the Austrian Netherlands after his victory at the Battle of Jemappes (November 6, 1792), he was very well received. Enthusiasm languished, however, when it became clear that France was not going to allow the Netherlands to be independent. Austrian rule was briefly restored in 1793–94; but France's victory at Fleurus, on June 26, 1794, was the prelude to French annexation. This proved more of a jolt for the Austrian Netherlands itself than for the principality of Liège, where a revolution against the prince-bishop had prepared the country for assimilation into the French Republic.

**French and Dutch rule.** On October 1, 1795, the French National Convention voted to annex Belgium and Luxembourg. Under French rule, there was no autonomy as there had been under the Spanish and Austrian regimes; the reforms of Joseph II were revived, although in a more radical form. The administration was centralized and the territory divided into departments. Aristocratic privileges were abolished and the church persecuted. Military conscription, introduced in September 1798, provoked a peasants' revolt in the same areas that had opposed the conservative Statists during the Revolution of 1789. Repression was extremely harsh.

Under the Napoleonic Consulate and Empire (1799–1814), the French civil code and the decimal metric system were introduced, and the position of the clergy was regulated by Napoleon's concordat with the papacy. A politically united Europe offered vast outlets for expanding Belgian industry.

The beginning of industrialization

The period of the Napoleonic Empire, recent research has revealed, may be considered the "take-off" stage of the Industrial Revolution in Belgium. The Belgian departments produced almost half the empire's coal; the department of Jemappes (the former county of Hainaut) alone accounted for 30 percent. The blast furnaces and forges of the Belgian departments provided 25 percent of the empire's iron production. In relation to its population, Belgium produced 450 kilograms (992 pounds) of coal per capita. At the same time the corresponding total in France was 40 kilograms (88 pounds). That this was the beginning of the Industrial Revolution may be seen by a comparison with contemporary England, where this revolution was in progress, and with France, where it had not begun. The 450 kilograms (992 pounds) of coal per capita are comparable to the English 500 (1,100 pounds), but not to French production, which was one-tenth that amount. Figures for iron production were simi-

lar: 11 kilograms (24 pounds) per capita in Belgium, 20 (44 pounds) in England, and 4 (9 pounds) in France. The Verviers textile industry was second in the empire. In Flanders, linen and cotton occupied an important place; the same was true for paper, leather, and glass. Thus, Belgium was the first country on the Continent to go through the process of industrialization. However, during the later years of French rule, it became evident in Belgium, as it had to all the people subjugated by Napoleon, that military domination had had its day. The allied occupation of Belgium in 1814 was welcomed.

The allied forces decided to unite the former United Provinces with Belgium to form a Kingdom of The Netherlands. The people were not consulted, but Prince William of Orange-Nassau ascended the throne on March 16, 1815, and the existence of the kingdom was confirmed by the Congress of Vienna the following June.

Thus the northern and southern Netherlands, which had been one country until the 16th century, were reunited. But in the two intervening centuries they had developed in markedly different ways. The north was commercial, the south increasingly industrial; the north Protestant, the south Catholic. Under the Dutch House of Orange, the north was to be predominant; the fundamental law of the new kingdom gave Belgium and Holland the same number of representatives in the States-General despite the fact that the population of Belgium was 3,500,000 and that of the former United Provinces 2,000,000. Belgian representatives rejected the constitution, but it was promulgated by the King over their objections.

In the beginning, the economic situation continued to be favourable. The textile industries of Ghent and Verviers continued their progress, while the coal mines and forges of Liège and Hainaut prospered. King William I created three state universities: Ghent and Liège, which were new, and Louvain, which he put under state control to remove it from Catholic influence. In secondary education, the secular *athénées* were established, and schools controlled by the Church were subject to state inspection. An attempt to interfere with the training of priests (1825) brought clerical dissatisfaction with the government to its height.

After 1820 the conflicting interests of north and south also created an economic split. The commercial north, with little industry, desired free trade; the south needed tariff protection to allow its industry to compete against British prices. This gave the middle classes a grievance against the government. Progressives and clericals joined forces in 1828; the programs were different, but the enemy was the same: the Dutch regime. Following the July Revolution in Paris (1830), rioting broke out among the workers in Brussels on August 25. The bourgeoisie armed themselves, and when the working class uprising was put down, they turned their arms against the Dutch troops. The Dutch, led by the Prince of Orange, were expelled from Brussels on September 3 and tried unsuccessfully to reoccupy it on September 23. Two days later a provisional Belgian government was established. This revolutionary government proclaimed the country's independence on October 4. Meanwhile, the Belgians occupied Antwerp; Dutch troops, besieged in the citadel, bombarded the city on October 27, further increasing ill-feeling among the Belgians.

A National Congress was elected and met on November 10. It reaffirmed Belgian independence on the 18th and on the 24th voted to exclude the House of Orange from the Belgian throne. William I prepared for war, but on December 20 the great powers intervened, imposing an armistice on both sides. On January 20, 1831, a conference in London recognized Belgium as an independent, neutral state; its neutrality to be guaranteed by the powers.

#### BELGIUM AND LUXEMBOURG (1831 TO PRESENT)

**Independent Belgium.** *The formation of the kingdom.* The National Congress had decided that Belgium should be a monarchy, but finding a king proved difficult. On February 3, 1831, the congress elected Louis, duc de Nemours, son of the new French king Louis-Phi-

Dissatisfaction with Dutch rule

Conflict with The Netherlands

lippe, but the British, fearing French expansionism, opposed this, and Louis declined. The next choice was Prince Leopold of Saxe-Coburg, who was related to the British royal family. Since Leopold married Louis-Philippe's daughter shortly afterward, he was acceptable to the French also. On July 21, 1831, he promised to support the constitution drawn up by the National Congress, which gave the greater part of the governing power to a Parliament elected by property owners. Some days later, the Dutch army invaded Belgium. The Belgians, who had no regular army, were defeated, but the London Conference agreed to intervention by the French army, which forced the Dutch to retire. The conference then decided (November 15, 1831) to divide the provinces of Limburg and Luxembourg, awarding part to Belgium and part to The Netherlands. William I, to the surprise of the powers, refused to accept this settlement, although he did conclude an armistice. The Belgians, therefore, continued to occupy Dutch Limburg and the future Grand Duchy of Luxembourg until William finally relented in 1838. He then became the first grand duke of Luxembourg. The western half of Luxembourg became a Belgian province. The new Belgian king Leopold I tried to increase his role in the government by asking Parliament for the right to appoint and dismiss the members of the provincial and local administrations. The Parliament, however, rejected this proposal in 1836.

The economy continued to develop. The first railroad, between Brussels and Malines, was inaugurated in 1836. Capital investments rose from 37 million francs in 1834 to 145 million in 1836. One of the most powerful corporations was the Société Générale, which now controlled a number of industries. At the same time, the traditional Flemish textile industry, which was slow to mechanize, was undergoing a severe crisis. But by 1848, the decisive leap to industrialization was made in this area also.

After Dutch recognition of Belgium in 1839, the coalition that had backed the independence movement showed signs of breaking up. Disputes arose between the liberals (middle class anticlericals) and the Catholics, and a separate Liberal Party was formed in 1846. Between 1847 and 1857, Catholics and Liberals alternated in office; the period 1857-1870 was one of Liberal rule.

Leopold I proved to be a prudent ruler, and when revolution spread across Europe in 1848, Belgium remained peaceful. But the downfall of Louis-Philippe and, to an even greater extent, the creation of the Second French Empire under Napoleon III (1852) eventually caused problems. French republicans sought refuge from political persecution in Belgium, where they spread propaganda against Napoleon. This caused the French government to adopt a hostile attitude toward Belgium; in 1853, Leopold asked that Parliament allow Antwerp to be fortified and the nation prepared to meet a possible invasion, which, however, failed to materialize.

Further economic progress

In the economic sphere, industrial development allowed the gradual introduction of a free-trade policy beginning in 1849. A national bank having the right to issue currency was created in 1850. Municipal tolls on the entrance of foodstuffs into the cities were abolished in 1860. Finally, in 1863, the prosperity of the country permitted the redemption of The Netherlands' right to levy charges on shipping entering the Scheldt River. After more than two centuries, Antwerp was a free port again. Leopold I died on December 10, 1865, leaving Belgium a strong and united country.

*The reign of Leopold II.* Leopold II (reigned 1865-1909) found himself immediately faced with serious problems in foreign affairs. Prussia had become the dominant power in Germany, and Napoleon III wished to extend French control over Belgium and Luxembourg in compensation. A French rail company, with government support, attempted to acquire the railways of the province of Luxembourg in 1868; in 1869, the Belgian chamber reacted by forbidding the sale of railways. Only British support permitted the liberal ministry of Walther Frère-Orban to avoid hostilities with France.

When the Franco-German War broke out in 1870, Belgium remained neutral. Napoleon III's defeat momentar-

ily removed the French threat, but a unified Germany posed an equally serious problem on the eastern frontier. The subsequent rivalry between France and Germany in the period 1871-1914 constituted a continual danger to Belgium. In 1887 Leopold II asked Parliament for authority to erect two new fortifications, one to the east, at Liège, and the other to the south, at Namur.

Meanwhile, the process of industrialization continued. Coal and iron production increased; Belgium's population was the densest in Europe and, because there was no labour movement before 1870, labour was cheap. The Société Générale, one of the most powerful economic organizations in continental Europe, played an increasing role in financing industry.

The Belgian bourgeoisie increased both in number and wealth, and electoral property qualifications favoured their predominance. This class was the backbone of the Liberal Party. A Catholic reaction materialized in 1869, with the formation of a Catholic party opposed to the liberal Catholic deputies who, until then, had represented Catholic opinion in Parliament and in the government. The new party represented a militant and conservative position; in order to achieve its goals, it favoured eliminating property qualifications for voting, a measure also favoured by the more advanced Liberals. Socialism gained some adherents in Belgium after 1848, and the formation of the First Socialist (Marxist) International in 1867 increased its influence among industrial workers. Belgian socialism remained fragmented until the foundation of the Belgian Workers' Party (POB), the ancestor of the later Belgian Socialist Party (PSB), in 1885.

The opposition between Catholics and Liberals became acute in 1879, when the Liberal Frère-Orban ministry sponsored a law removing religion entirely from primary education. Controversy over this issue was extremely violent and even divided families. The church's opposition to the law led to a break in relations with the Vatican. In 1884 the Catholics won a majority in both chambers, and the Catholic party remained in power without interruption until 1914. Aside from the education controversy, the biggest factor in the Liberals' defeat was probably their advocacy of free trade, which was favoured by manufacturers but exposed farmers to ruinous foreign competition. In the early 1880s the Belgian market was flooded by American grain; the Catholic party became the champion of the rural classes by promising to protect agriculture. It also espoused the cause of the nascent "Flemish" movement that sought to expand opportunities for Dutch-speaking Belgians in a country until then dominated by a French-speaking upper bourgeoisie.

The working class did not have the right to vote because of the system of electoral property qualifications. The last years of the 19th century and the first of the 20th were years of violent social tension. In 1886 there was a disturbance among workers in Liège, followed by unrest in other industrial areas. The Catholic government of Auguste Beernaert suppressed this movement harshly, but beginning in 1889, a series of laws were passed regulating workers' housing, limiting labour by women and children, and providing workmen's compensation. The legislature revised the constitution in 1890, and, in 1893, universal suffrage was adopted for men 21 and over. Though this measure was modified by giving a plural vote to electors fulfilling certain conditions of income, age, and education and to heads of families, it resulted in the election of the first Socialist deputies to the legislature. Belgian industry, dominated by powerful financial groups, began to assume worldwide importance and was active in Asia and Latin America, as well as in Europe. In Africa, King Leopold II acquired the state of the Congo as a personal possession in 1885, but his subjects showed little interest in the area, leaving him to mismanage it until 1898, when the Matadi-Léopoldville railroad was completed, facilitating access to the interior of the Congo Basin. Then Belgian banks began to push for annexation, which eventually came in 1908. In 1909 the army recruitment system, which until then had favoured the wealthy by allowing them to hire substitutes for military service, was finally reformed.

Church-state conflict

Annexation of the Congo

*Belgium since 1909.* In 1909, Leopold II died, and was succeeded by his nephew Albert, who became king as Albert I (December 23). Social unrest, which had distinguished the last years of Leopold's reign, continued at the beginning of Albert's, but a general strike in 1913 caused no change in the parliamentary majority.

The international situation became increasingly tense at the end of July 1914, on the eve of World War I. The neutrality of Belgium and Luxembourg had been guaranteed by the great powers under the treaties of 1839. On July 30 the British government demanded assurance from France and Germany that Belgian neutrality would be respected in the event of the outbreak of war. Germany, after refusing to respond to the English request, invaded Luxembourg on August 2 and sent an ultimatum to Belgium demanding free passage of troops. Belgium refused and was invaded on the morning of August 4. Liège fell on August 16, Namur on August 23. The Germans occupied Brussels on August 20, but Antwerp, which was not attacked by the Germans advancing into France along the Marne, was not evacuated until October 6. The Belgian Army then retired behind the IJser in the west of Flanders and held this position until 1918.

During the war, the Belgian government sat at Le Havre, France, while the King, as commander-in-chief of the army, remained with his troops in unoccupied Belgium. After the invasion, the Catholic government named both a Liberal and a Socialist minister of state, and during the war, ministry offices were assigned to Liberals and Socialists.

Upon their return to Brussels, the King and Prime Minister announced the introduction of absolute universal suffrage (that is, the abandonment of plural votes). The elections of 1919 brought to power a government composed of Catholics, Liberals, and Socialists, which voted an eight-hour day, progressive taxes, and old-age insurance. The question of schools, which had divided Liberals and Catholics so strongly during Leopold II's reign, gave rise to a compromise whereby subsidies were granted to Catholic institutions.

The  
Flemish  
movement

Flemish nationalism had gained ground, and, in 1898, the Dutch language was finally recognized along with French as an official language of the country. Henceforth, the movement also took on an economic and social character, owing to the fact that in the coal-rich Walloon provinces, industrialization was very advanced. In contrast, economic development had been quite slow in the Flemish region after the Industrial Revolution. But, until 1914, the principal goal of the Flemish movement had been the creation of a university in which instruction would be given in Dutch. During World War I, Germany attempted to profit from Flemish-Walloon antagonism and supported the Activists—partisans of Flemish autonomy. Most Flemings, however, were resolutely hostile to collaboration with the enemy and refused to recognize either the Council of Flanders or the Flemish university, both founded during the occupation. Shortly after the liberation of the territory, the Belgian government made the University of Ghent, first partially, then completely, Flemish.

The Treaty of Versailles (1919) abolished Belgium's obligatory neutrality and returned the cantons of Eupen and Malmédy to its territory. In 1920 a treaty of military assistance was signed with France, and in 1921 an economic union was concluded with Luxembourg. The eastern frontier was guaranteed by the Pact of Locarno (1925). In Africa, Belgium received the mandates for Ruanda and Burundi, former German colonies that Belgian colonial forces had occupied during the conflict.

Post-war  
coalitions

The decade following the Peace of Versailles was distinguished by a considerable increase in industrial and commercial wealth and by prosperity among the workers and peasants. The middle classes, caught between these two forces, lost much of their wealth and political influence. The result was the retreat of the Liberal Party and the aggrandizement of the Catholic and Socialist parties. The three-party government born of the war did not survive the end of 1921; it was followed by a coalition of Catholics and Liberals that lasted until 1925, when the Social-

ists allied themselves with the Christian Democrats, then becoming the most important wing of the Catholic party.

In 1930, when the effects of the Great Depression were beginning to be felt, Parliament voted a series of laws transforming Belgium into two linguistic areas with different administrations. Henceforth, the Flemish provinces were administered solely in Dutch, the Walloon solely in French. In the face of the Depression the Socialist Party advocated a program of economic planning in accordance with the ideas of the socialist theorist Hendrik de Man. At the same time there emerged two Belgian fascist parties: a strictly Flemish party that enjoyed little success and the broader-based Rexists under the leadership of Léon Degrelle. The latter party won 21 seats, more than 10 percent of the chamber, in the elections of 1936. Strikes broke out in the same year and led the tripartite government of Paul van Zeeland to establish paid holidays for workers and a 40-hour week for miners.

Meanwhile King Leopold III, who succeeded his father Albert I, in 1934, faced an increasingly tense international situation. Leopold advocated a policy of independent neutrality that aimed at keeping Belgium removed from the seemingly inevitable conflict. This policy was approved by Parliament, but Belgium reasserted its determination to resist all aggression. Consequently, a line of defense from Namur to Antwerp was constructed facing Hitler's Germany.

On May 10, 1940, Hitler invaded Belgium along with Holland and Luxembourg. Holland capitulated after six days, Belgium after 18. France, which along with Britain had sent troops to Belgium, had to lay down arms three weeks later. The British troops, covered by the Belgian army, retreated from Dunkirk in particularly dramatic circumstances.

The four years of ensuing Nazi occupation were distinguished by a growing resistance organization. When the Allied forces reached Belgium on September 3, 1944, the Belgian underground army was able to prevent the destruction of the port of Antwerp, which served as a provisioning point for Allied troops for the remainder of the war.

While the economy recovered rapidly after the war, political stability deteriorated, notably over the "royal question." The King had been taken by the Germans and confined to his palace at Laeken; the government, on the other hand, had taken refuge in London. In 1944, at the time of the Allied offensive, the Germans transferred the King to Austria, where he was kept until 1945. The government, upon returning to Brussels, conferred the regency on the King's brother, Prince Charles. Opinion was divided between Leopold's opponents and supporters. Roughly, the Flemish were the King's partisans and the Walloons his opponents and the Catholics for, the Socialists and Liberals against, his return. In 1950 a referendum showed 57 percent of the voters to be in favour of the return of the sovereign, but the King's return signalled near civil war in the Walloon country. Leopold abdicated in favour of his eldest son, Baudouin I, who on August 11, 1950, took an oath of loyalty to the constitution. Because he was not yet of age, he took the title of prince royal until he became king on July 17, 1951. The composition of the government continued to fluctuate, although the Catholics achieved an absolute majority owing to the enfranchisement of women in 1949. The government was frequently composed of a leftist alliance of the Socialists and Liberals until the two most important parties, the Catholics and Socialists, formed a coalition that was frequently in power.

The  
"royal  
question"

In 1947, Belgium joined with The Netherlands and Luxembourg in the economic union of Benelux, and in 1949 the country became one of 12 signatories of the North Atlantic Treaty Organization (NATO); on July 1, 1960, independence was given to the Congo, where unrest had earlier broken out.

In the '50s and '60s Belgian political parties underwent a marked change. The Catholic party became the Social Christian Party, supported by the middle classes and the peasants. Its Christian-Democratic wing was predominant. The Liberal Party became more conservative and

is presently called the Party of Liberty and Progress (PLP). The Socialist Party has become moderate and has almost eliminated the Communist Party.

Belgium's main domestic difficulty is still the linguistic problem. As the numerical majority of Flemings has become increasingly apparent, it is not surprising that discontent has become manifest among the Walloons. Until World War II, heavy industry was concentrated in Walloon territory, but since then a displacement to the north of the country has begun. The Walloon syndicalist, André Renard, created, at the time of the strikes of December 1960–January 1961, the Walloon Popular Movement (MPW), which espouses protection for the Walloon economy and federalism. Reaction in the Flemish areas was at first negligible, but a struggle over the division of the University of Louvain into two universities, one Flemish and the other French, soon involved them. The Flemish Catholics demanded that the French university be established in the Walloon area and, thus, caused a split in the Demo-Christian party along linguistic lines. The Flemings have laid claim to Brussels, which is situated in Flemish territory but inhabited mainly by French-speakers, both native and immigrant. But the communal elections of October 11, 1970, indicated that Brussels wished to remain removed from the federalism that was shaping Belgium. That city, which is the seat of the European Common Market, appeared determined to preserve a position separate from the two linguistic regions of the country.

**The Grand Duchy of Luxembourg.** In 1839, by accepting the Treaty of 24 Articles, King William I of Holland also became grand duke of Luxembourg. The grand duchy, separated from Belgian Luxembourg, henceforth, was independent, but subject to personal union with the Low Countries. On October 7, 1840, the king-grand duke abdicated in favour of his son William II, under whose rule Luxembourg joined the German customs union (Zollverein). Under Grand Duke William III, who succeeded to the throne in 1849, the opposition of liberal industrialists favouring constitutional government gained support, and finally, in 1867, a constitution was promulgated. In the same year, Napoleon III wished to annex Luxembourg, but the Treaty of London (May 11, 1867) had made it a neutral state under the protection of the powers, as was also the case with Belgium. Prussian troops that occupied the citadel of Luxembourg in the name of the German Confederation withdrew as the Confederation was dissolved at the end of the 1866 war with Austria.

Shortly afterwards, Luxembourg experienced a powerful economic upsurge owing to the adoption of the Thomas and Gilchrist process for the dephosphorization of iron ore. The ore production increased from 1,000,000 tons in 1872 to 7,500,000 in 1907, the production of iron from 250,000 tons in 1875 to 2,500,000 in 1913.

The death of King-Grand Duke William III (1890) signified the end of the personal union with the Low Countries. Owing to a pact of succession concluded in 1783 between the Dutch and German branches of the House of Orange-Nassau, the throne reverted to Adolf of Nassau (1890–1905). His successor, William IV (reigned 1905–12), died without male issue and was succeeded by his eldest daughter, Maria Adelaide. The latter followed a reactionary policy and, after the German occupation of 1914–18, was forced to abdicate early in 1919. Under the government of her sister, Grand Duchess Charlotte (1919–64), Luxembourg concluded an economic union with Belgium in 1921 and joined the League of Nations. When it was invaded once again, on May 10, 1940, the grand-ducal family took refuge in England, but Nazi Germany annexed Luxembourg. Freed on September 10, 1944, by Allied troops, the grand duchy regained its independence; it joined the Benelux Union in 1947, abandoned its neutral stance in 1948, joined the North Atlantic Pact in 1949, and participated in the European Common Market. As of 1971, the country was governed by Grand Duke Jean, the son of Duchess Charlotte and Prince Félix of Bourbon. The ministry was composed of Christian-Socialists and Liberals. (J.C.V.)

## BIBLIOGRAPHY

*General works:* J.A. VAN HOUTTE *et al.* (eds.), *Algemene Geschiedenis der Nederlanden*, 12 vol. (1949–58), an extensive history of both the northern and southern Low Countries, with detailed bibliographies; G. EDMUNDSON, *History of Holland* (1922), still the best general history in English, although better for the republican than the modern period; P.J. BLOK, *Geschiedenis van het Nederlandsche Volk*, 4 vol. (1892–99; Eng. trans., *History of the People of the Netherlands*, 5 vol., 1898–1912), a classic history of the northern territories, now outdated, particularly so on the history of the Middle Ages; HENRI PIRENNE, *Histoire de Belgique*, 7 vol. (1900–32, with many revised editions), a brilliantly written history by the famous Belgian historian, covering for the period of the Middle Ages the southern as well as the northern parts of the Low Countries, although emphasis is on the south; I. SCHOFFER, *A Short History of the Netherlands* (Eng. trans. 1956), a brilliantly written and very useful survey of the history of the northern Netherlands up till the present time.

*History of the Netherlands to 1579:* S.J. DE LAET, *The Low Countries* (1958), a thorough survey of the Low Countries in prehistoric times; I.H. GOSSES and R.R. POST, *Handboek tot de staatkundige geschiedenis der Nederlanden*, vol. 1, *De Middeleeuwen* (1959), an accurate handbook of the political history, limited, however, to the Dutch-speaking territories; H.P.H. JANSEN, *Middeleeuwse geschiedenis der Nederlanden* (1965), a fairly thorough compendium of the medieval history of the Low Countries, with attention given to the political as well as to the social, economic, and cultural aspects; W. JAPPE ALBERTS and H.P.H. JANSEN, *Welvaart in wording: Sociaal-economische geschiedenis van Nederland van de vroegste tijden tot het einde van de Middeleeuwen* (1964), a social and economic history of the northern Netherlands during the Middle Ages, with emphasis on the economic aspects (the chapters on the Frisian trade and the trade of the 10th till the 13th century, written by J.F. NIEMEYER, belong to the best parts of the book); E. DE MOREAU, *Histoire de l'Église en Belgique*, 5 vol. with a suppl. vol. containing maps (1945–52), an extensive classic handbook of the church history of the southern Netherlands, containing exhaustive bibliographies; R.R. POST, *Kerkgeschiedenis van Nederland in de Middeleeuwen*, 2 vol. (1957), an extensive handbook of the church history of the northern Netherlands; D.P. BLOK, *De Franken (in Nederland), hun optreden in het licht der historie* (1968), a brilliant synthesis of the early history of the northern Netherlands; P.C.J.A. BOELES, *Friesland tot de elfde eeuw: Zijn vóór- en vroege geschiedenis*, 2nd ed. (1951; with an index by H.T. OBREEN, 1962), an authoritative work on the early Frisian history, with an English summary, pp. 559–598; D. JELLEMA, "Frisian Trade in the Dark Ages," *Speculum*, 30:15–36 (1955), a careful survey of Frisian trade and its background in the Merovingian period, drawing especially on archaeological and numismatic evidence; F.L. GANSHOF, *La Flandre sous les premiers comtes* (1948), a solid account of the history of the important principality of Flanders, tracing its origins and ending with the eventful crisis of 1127–28; H.S. LUCAS, *The Low Countries and the Hundred Years' War, 1326–1347* (1929), a very reliable and richly documented account of political events; R. VAUGHAN, *Philip the Bold: The Formation of the Burgundian State* (1962), *John the Fearless: The Growth of Burgundian Power* (1966), and *Philip the Good: The Apogee of Burgundy* (1970), well-documented studies of the Burgundian dukes and the growth of their political power; J. HUIZINGA, *Herfsttij der Middeleeuwen* (1921; Eng. trans., *The Waning of the Middle Ages: A Study in the Forms of Life, Thought and Art in France and the Netherlands in the 14th and 15th Centuries*, 1924), a classical work of cultural historical value; R.R. POST, *The Modern Devotion: Confrontation with Reformation and Humanism* (1968), the most recent and exhaustive work, based on old and new sources, with emphasis on the relationship between Modern Devotion and Humanism and the Reformation; G.N. CLARK, "The Birth of the Dutch Republic," in *Studies in History*, pp. 112–144 (1966), written with solid knowledge about the subject; *Geschiedkundige Atlas van Nederland*, 3 vol. of maps and 15 vol. of text (1911–38).

*The Netherlands since 1579:* H. DE BUCK, *Bibliografie der Geschiedenis van Nederland* (1968), the standard guide to the historical literature, primarily of the northern Low Countries; J.L. MOTLEY, *The Rise of the Dutch Republic*, 3 vol. (1856) and *History of the United Netherlands from the Death of William the Silent to The Twelve Years' Truce, 1609*, 4 vol. (1860–67), brilliantly written histories, rich with information, although highly partisan; P. GEYL, *Geschiedenis van de Nederlandsche Stam*, 2nd ed., 2 vol. (1948–49; rev. ed., 6 vol., 1961–62; Eng. trans., *The Revolt of the Netherlands Against Spain, 1555–1609*, 2nd ed., 1958; and *The Netherlands in the Seven-*

teenth Century, rev. ed., 2vol., 1961–64), partial English translations of Geyl's monumental work in which the linguistic-ethnic unity of the Dutch-speaking Low Countries is emphasized; and *History of the Low Countries: Episodes and Problems* (1964), a series of lectures carrying Geyl's analysis to the period after World War II; J. HUIZINGA, *Nederland's Beschaving in de Zeventiende Eeuw* (1941; Eng. trans., *Dutch Civilization in the Seventeenth Century, and Other Essays*, 1941 and 1969), a masterpiece of condensation and illumination; C.R. BOXER, *The Dutch Sea-Borne Empire, 1600–1800* (1965), a vigorously written and well-informed account; C.H. WILSON, *The Dutch Republic and the Civilization of the Seventeenth Century* (1968) and *Profit and Power: A Study of England and the Dutch Wars* (1957), by the outstanding English historian of The Netherlands; A. COBBAN, *Ambassadors and Secret Agents: The Diplomacy of The First Earl of Malmesbury at the Hague* (1954), on the counterrevolution of 1787; A.J. BARNOUW, *Holland Under Queen Wilhelmina* (1923); A. LIJPHART, *The Politics of Accommodation: Pluralism and Democracy in the Netherlands* (1968), a sociological study of "pillarization," fundamental for the contemporary period.

*Southern Netherlands, Belgium, and Luxembourg—1579 to the present*: C. ## Low-Temperature Phenomena

The term low-temperature phenomena refers to the behaviour of matter at temperatures below the boiling point of liquid nitrogen, about  $-196^{\circ}\text{C}$  ( $-321^{\circ}\text{F}$ ). At temperatures close to absolute zero ( $-273.2^{\circ}\text{C}$  [ $-459.7^{\circ}\text{F}$ ]) the thermal, electric, and magnetic properties of many substances undergo great change, and, indeed, the behaviour of matter may seem strange when compared to that at room temperature. Superconductivity and superfluidity can be cited as two such phenomena that occur below certain critical temperatures; in the former, many metals and alloys show no resistance whatsoever to the flow of electricity, and, in the latter, liquid helium can flow through tiny holes impervious to any other liquid.

Although the phenomena displayed by matter at low temperatures are many and diverse, they constitute a coherent body of study by virtue of the second law of thermodynamics (see THERMODYNAMICS, PRINCIPLES OF), which introduces the concept of entropy and provides a criterion for the direction of spontaneous change to a final equilibrium condition for any system at fixed absolute temperature,  $T$ . A system may be thought of as an isolated assemblage of a large number of particles; i.e., a group of atoms, molecules, subatomic particles, or some combination of them. The macro (large scale) state of a system as a whole can be described by a few thermodynamic (i.e., macro) variables such as pressure, volume, energy, entropy, and temperature. These few constraints can usually be satisfied by a tremendous number of arrangements (micro ways) of the modes of motion of the constituent particles in the system. Entropy is a measure of this number of detailed, different possible micro states open to the macro system, and it increases as this number increases.

The only changes a system can undergo at constant temperature to reach a final equilibrium macro state at that temperature are those for which the expression  $\Delta U - T\Delta S$  is negative. The symbol  $\Delta U$  means the magnitude of  $U$  after the change, less the magnitude of  $U$  before the change, and similarly for  $\Delta S$ .  $T\Delta S$  signifies temperature times change in entropy. The symbol  $U$  denotes the energy of the system or a closely related quantity, depending on what additional constraints beyond that of constant temperature (such as constant pressure or constant volume) are imposed on the system. The symbol  $S$  denotes the entropy of the system. As the temperature goes toward absolute zero ( $T = 0$ ), the second term in the expression becomes of smaller and smaller magnitude, such that the only processes that can finally occur are those with  $\Delta U$  negative, meaning only those processes that decrease the energy of the system. This significant unifying principle can be applied to all low-temperature phenomena.

Extremely tiny energy differences, the effects of which are not observable at ordinary temperatures, can be of great importance in arriving at a final observable low-temperature configuration—that is, physical arrangement—of the particles of a system. For physical science, the low-temperature region is an important field of study, because only within its confines can there be experimental elucidation of the nature of the interactions leading to the above-mentioned tiny energy differences. The effects manifested are often novel and unique, and in the case of superconductivity (see below *Superconductivity*) they are also of great technological importance.

Finally, there is a fundamental reason behind the fact that many phenomena not peculiar to the low-temperature region are best studied at low temperatures. The atomicity of the surroundings causes irregular fluctuations or noise in any measurable physical variable of a system such that the mean square fluctuation in any observable at equilibrium is directly proportional to the absolute temperature. Working at low temperatures thus means an enhanced sensitivity for all instruments in distinguishing real physical phenomena from background thermal noise.

### GENERAL LOW-TEMPERATURE PHYSICAL PHENOMENA

**The third law of thermodynamics.** In addition to a deduction from the second law of thermodynamics, that a system will assume its lowest energy value as the temperature goes to zero, there is a deduction from the third law of thermodynamics, that in most cases the entropy change ( $\Delta S$ ) itself in the above expression goes to zero at the absolute zero. This rule in turn suggests that for all systems the entropies converge to the same constant value (conventionally zero) at the absolute zero irrespective of state, or phase, of aggregation (solid, liquid, or gas) or chemical nature of the substance. This rule further means that, for an entropy of zero, the minimum energy states reached must be ones of complete order; i.e., that the constituent particles can be arranged in only one way, even from the point of view of microscopic modes of motion. The third law is best understood on the basis of the quantum-mechanical result that particles acquire or lose energy in quantized amounts and not in a continuous manner, as was assumed in classical, Newtonian mechanics, and that the number of particles having an energy, symbolized by the Greek letter epsilon,  $\epsilon$ , greater than the minimum energy is proportional to an exponential value of minus the energy difference divided by a universal constant of nature ( $k$ ) times absolute temperature ( $T$ ); i.e.,  $e^{-\epsilon/kT}$ . Unless the product  $kT$  is numerically as large as  $\epsilon$ , the number of particles in excited states (any state having more energy than the minimum) is small, and for zero temperature the number of particles is zero. Hence, at low temperature almost all particles will be in the configuration of lowest energy that can be arrived at only in one way, such that their entropy is zero. The third law as formulated above is not always observed to hold experimentally; this fact is believed to be not a failure of the principle but a result of the slow rates of transformation in the solid phase from higher to lower energy configurations, leaving the former unchanged for some substances.

Because of the uncertainty principle of quantum physics

Quantized  
energy  
states

Entropy

—i.e., that it is fundamentally impossible to determine simultaneously both the location and momentum of a particle—even at absolute zero there is not a complete cessation of particle motion, as would be predicted from the classical view that temperature is directly proportional to the average kinetic energy of the particles. There remains an ineradicable zero-point vibratory motion of particles about the lattice sites in a solid (i.e., positions that atoms would assume when at rest in a crystal structure) and a kinetic zero-point motion in a fluid. Indeed, the latter condition explains the fact that the two isotopes (atoms of the same element that have a difference in mass) of helium, helium-3 and helium-4, both remain liquid under their own vapour pressure when the temperature is reduced to absolute zero and can be solidified only by the application of an external mechanical pressure. The kinetic zero-point energy is inversely proportional to the particle mass and so is greatest for small masses. Although hydrogen molecules are lighter than helium atoms, hydrogen is solid for all pressures at absolute zero, because the attractive potential energy between two hydrogen molecules is much greater than the attraction between helium atoms, thus preventing the motion that characterizes liquids. The same argument shows that all other particles (atomic and subatomic) except electrons will also be in solid form at absolute zero. For electrons the Coulomb attractive force (the force between a negative and a positive charge) operative in their parent atoms or molecules serves to hold them localized in small regions of space except for metals, in which one or more electrons per atom are released into an electronic cloud that permeates the entire metallic volume. These metallic electrons are free to move at the lowest temperatures and can undergo an ordering process into the superconducting state if the electronic and lattice structure of the ions (charged molecules or atoms) is appropriate.

**Heat capacity.** The loss of entropy in a substance as its temperature is reduced can be followed experimentally in detail by measuring its heat capacity under defined conditions as a function of temperature. Operationally, the heat capacity,  $C$ , is obtained by dividing a known heat-energy input to a system by its observed resulting tempera-

ture change. Theoretically, the heat capacity is equal to the temperature times the rate of change of entropy with temperature. Whenever there is a large entropy change in a small temperature interval, the change will show up as a peak in the heat-capacity,  $C$ , curve (see the Figure, top). In some cases these peaks may even represent an infinite heat-capacity value at one specific temperature, although this condition can never be strictly checked experimentally. It can be shown that the contribution to the heat capacity of masses vibrating about the lattice sites of a solid (the lattice contribution) can never give a peak in the heat-capacity curve. All such peaks are caused by the very or moderately sudden onset of an ordering process among other than the vibrational set of energy levels (energy states visualized as a series of levels) as the temperature is lowered. Some of the different physical systems exhibiting this behaviour may be described.

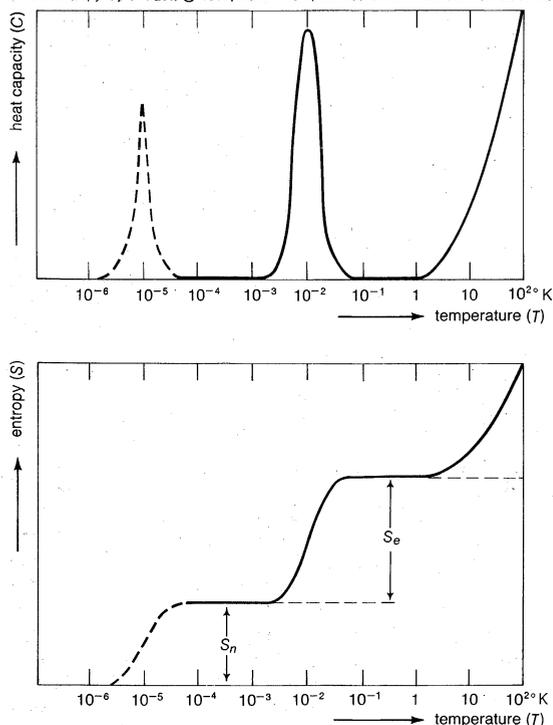

Vibrational and rotational energies

For solids with polyatomic molecules or ions on the lattice sites, there are, in addition to the vibration of the centre of mass, free rotational modes of motion of the group about the mass centre. These rotational modes have quantized energy states (expressed in finite increments) differing very slightly in energy; and, effectively, all such states will be equally occupied (i.e., equally probable), giving rise to a relatively high entropy contribution. As the temperature drops and the fixed small energy differences become large compared to the product of the universal constant ( $k$ ) and the absolute temperature ( $T$ ),  $kT$ , only the lowest states will tend to be occupied, the entropy will drop, and the previously free rotation will turn into a hindered type scarcely different from a vibratory mode. The change from free to hindered rotation can be of avalanche proportions, resulting in a heat-capacity peak, because the behaviour at neighbouring lattice sites is correlated; this condition comes about because when one group quits its free rotation it is easier for adjoining groups to quit also. This is a typical cooperative phenomenon.

**Magnetism and conductivity.** Every electron has the property of spin, or rotation about its own axis, which results in a mechanical property called angular momentum (a measure of momentum around an axis) and an associated magnetic dipole moment (a measure of the resistance to twisting in a magnetic field). For molecules and ions in solids at low temperatures, the coupling (combining effect) of the spin angular momenta determines the total magnetic moment of the groups as a whole. These magnetic moments at different sites can be aligned in an external magnetic field, giving rise to a magnetic property called paramagnetism (capacity to be weakly magnetized). Another magnetic property, ferromagnetism (capacity to be strongly magnetized), occurs when there is a spontaneous preferential parallel alignment of the magnetic moments in the absence of an external field; but ferromagnetism cannot be the result of a direct interaction of neighbouring magnetic moments; otherwise, contrary to experiment, all paramagnetic substances would become ferromagnetic at sufficiently low temperatures. The interaction responsible for ferromagnetism arises from the change in electronic spatial charge distribution between neighbours that, by the laws of quantum mechanics, inevitably accompanies the change of relative direction (i.e., the axis of rotation) of neighbouring spins. Below a certain temperature at which there is a sharp peak in the heat capacity, called, for a 19th-century French physicist, Pierre Curie, the Curie temperature, the preferential parallel spin alignment can maintain itself against the randomizing influence of thermal motion. In some materials there can occur a preferentially ordered anti-parallel arrangement of neighbouring spins below a certain temperature (Néel temperature, after a French physicist, Louis-Eugène-Félix Néel). This is the case of antiferromagnetism. Whereas most Curie temperatures are higher than the boiling point of nitrogen, many Néel temperatures occur in the low-temperature region as defined by this article.

The behaviour of mixtures as the temperature is lowered also exhibits several interesting methods of entropy reduction. In certain stoichiometric alloys (i.e., alloys in

Order-disorder  
heat  
capacity

which the relative number of various atoms is given by the ratio of small integers, 1:1, 1:2, etc.) below an ordering temperature, a single solid phase consisting of two interpenetrating lattices with only one species of atom on each lattice becomes favoured. This condition is manifested by a heat-capacity peak called order-disorder type. For non-stoichiometric alloys, several different ordered phases of different composition can result. In other cases below a critical point a first-order phase separation (see PHASE CHANGES AND EQUILIBRIA) may occur such that at the absolute zero two phases, possibly but not necessarily both pure, should exist physically separated from each other. This last behaviour is usually masked by the freezing in of nonequilibrium configurations. Helium-3-helium-4 mixtures, however, remain liquid to lowest temperatures, and these do separate into a pure helium-3 component and a mixture of the two isotopes.

In metals the released electrons can move coherently (in unison) under the influence of an external electric field, thus giving rise to the characteristic high conductivity of metals. The moving electrons are impeded by the vibrational motion of the lattice ions; and, because this motion is reduced as the temperature is lowered, the conductivity is greatly improved thereby. Defects in the lattice and impurities, or both, play a large role in the final low-temperature conductivity, and the study of these defects constitutes an important part of modern solid-state physics. On the other hand, the conductivity of semiconductors (substances the conductivity of which is increased at high temperatures) is greatly decreased as the temperature is lowered because the electrons in these substances are not free to move until they surmount a fixed energy barrier, and the lower the temperature, the fewer electrons there are with energy enough to break free.

#### SPECIAL PHYSICAL PHENOMENA AT VERY LOW TEMPERATURES

The lack of spatial order for electrons in metals and for helium atoms in liquid helium, even at absolute zero, permits the most striking macroscopic effects of quantum mechanics known to science, because these systems lose their entropy by various means of momentum ordering. The momentum of a particle is its mass times velocity, and a momentum ordering in a system of like particles implies the possible generation of a stable, coherent, flowing mass of electrons or helium atoms.

**Superconductivity.** The existence of superconductivity (*q.v.*) exemplifies the above considerations in the case of electrons. All superconductors have the fundamental property of suddenly losing all their electrical resistance below a critical temperature,  $T_c$ , characteristic of each. Superconductors may be divided into Type I, mainly pure elements with  $T_c$  less than  $10^\circ$  K (and the majority with  $T_c$  less than  $5^\circ$  K), and Type II, usually alloys or compounds with  $T_c$  values generally higher than those of Type I, although none are yet known with  $T_c$  above  $21^\circ$  K ( $0^\circ$  K equals about  $-273^\circ$  C [ $-460^\circ$  F]). The ordinary electrical resistance of Type I superconductors may be restored on application of a magnetic field,  $H_c$ , that depends on temperature, being zero at the critical temperatures and tending to a maximum field,  $H_0$  measured in oersteds, never much above  $10^3$  and often below  $10^2$ ) as the temperature goes to zero. In the superconducting state, Type I specimens are perfect diamagnetic materials; that is, they expel all magnetic flux (*i.e.*, are devoid of a magnetic field) from their interior. Type II superconductors below the critical temperature may be driven into a mixed state along a lower critical-field curve,  $H_{c1}$ . The mixed state can contain normal regions open to magnetic flux but remains superconducting below a much higher upper critical-field curve,  $H_{c2}$ .

A generally successful microscopic theory of superconductivity (introduced in 1957 by United States physicists John Bardeen, John Cooper, and John Schrieffer and often referred to as the BCS theory) showed that, below the critical temperature, pairs of electrons with equal but opposite momenta and opposed spins (thus being diamagnetic entities) could maintain themselves against thermal excitation in a state of lower energy than that of

a randomly chosen pair with uncorrelated momenta. Their proposed mechanism leading to this attractive interaction was an indirect one involving an initial encounter of the first electron with a vibrating ion of the metallic lattice and a subsequent encounter of its partner with the same vibrating mode. The members of a pair are not spatially close to one another and may be separated by distances equal to several thousand times the distance between two adjacent lattice sites. The paired electrons, having a perfectly definite total momentum (zero if no net current is flowing or some common finite value if a current has been started), by the uncertainty principle of quantum mechanics cannot have their centre of mass localized in any particular region of the metallic volume. They can be said to move without momentum change (*i.e.*, without meeting resistance) through the entire macroscopic specimen, just as on the microscopic level electrons in a single atom or molecule move coherently in their respective orbitals. It has become evident since the original theory was set forth that other mechanisms than the electron-vibrating-ion interaction do lead to bound electron pairs and thus to superconductivity. The elucidation of the nature of these interactions is a current field of active research.

**Superfluidity.** The superfluid properties of liquid helium-4 are heralded by a seemingly infinite lambda- ( $\lambda$ -) shaped heat-capacity peak at a temperature  $T_\lambda = 2.2^\circ$  K as the liquid is cooled under its own vapour pressure (see NOBLE GASES AND THEIR COMPOUNDS). Below the lambda temperature the liquid has a thermal conductivity some 3,000,000 times that of the liquid just above the lambda temperature, and it can flow or, at least, a part of it can flow without friction and without entropy transport through tiny capillaries and through leaks that just above  $T_\lambda$  are impassable not only to liquid but to gaseous helium-4. Many other strange phenomena have been investigated.

Early contributions to a theoretical understanding of liquid helium-4 behaviour by two physicists, Polish-born Fritz London and Lev Landau of the Soviet Union, were originally believed to exclude one another, but, with the later work of Richard Feynman and Chen Ning Yang, United States physicists, and a Norwegian chemist, Lars Onsager, their approaches have been seen to be complementary. Following London's interpretation, stress is put on the fact that helium-4 atoms are bosons; *i.e.*, that they contain an even number of elementary particles (electrons, protons, neutrons) and as such any number of them can occupy the same quantum state of momentum. Fermions, on the other hand, of which helium-3 is an example, contain an odd number of elementary particles, and no more than a few (only two if they have minimum nuclear or electronic spin values) can occupy the same momentum quantum state. It is assumed that below the lambda temperature a finite fraction of the helium-4 atoms are condensed into the zero momentum state with zero entropy and that these constitute a superfluid component in the liquid. This component is not spatially condensed but distributed uniformly through the liquid in a way not unlike the paired electrons of superconductivity theory. In fact a pair of electrons is a boson.

Liquid helium-3 does not exhibit the superfluid properties of liquid helium-4, thus strengthening the belief that these properties are a result of a boson momentum ordering. Whether or not the helium-3 atoms as fermions will undergo a momentum ordering analogous to that of superconducting electrons is an open question, and no firm experimental evidence of it had been found by the early 1970s down to a temperature of  $5 \times 10^{-3}^\circ$  K.

#### SPECIAL METHODS FOR OBTAINING LOW TEMPERATURES

**Adiabatic cooling.** When changes are made in a closed or isolated system without gain or loss of heat, the phenomenon is adiabatic. For example, an expanding gas that neither gains nor loses heat is expanding adiabatically. Primary gas thermometry depends on the variation in pressure of a gas with temperature and as such provides a temperature scale independent of the properties of any particular substance. The relation of this scale ( $T^\circ$  K) to

the Celsius scale ( $t^\circ \text{C}$ ) is  $T = t + 273.15$ , such that absolute zero is  $-273.15^\circ \text{C}$ . A convenient way of experimentally determining low temperature is to measure the vapour pressure of a sample of liquefied gas in thermal equilibrium with the sample the temperature of which is desired. This measurement requires use of tables of temperature as a function of the vapour pressure. To prepare these tables a few primary gas thermometric measurements must be made, which are supplemented at intermediate temperatures by simultaneously measuring the vapour pressure and one or more physical properties of an inserted probe that can be related to the temperature by means of empirical equations. These equations must express the probe property as a function of temperature and of a few constants the values of which are known by direct measurement of the probe property and the temperature at a few points. Use of the electrical resistance of certain pure metals or of carbon and the magnetic susceptibility of certain paramagnetic salts is common. Vapour-pressure thermometry with liquid helium-4 can be carried down to about  $1^\circ \text{K}$  and with liquid helium-3 to about  $0.3^\circ \text{K}$ .

By the third law of thermodynamics it is impossible to reduce the temperature of any sample precisely to zero, but in practice temperatures as low as  $10^{-5}^\circ \text{K}$  have been attained. Various liquefied gases boiling off under reduced pressure can serve admirably to cool samples down to about  $1^\circ \text{K}$ . To liquefy these gases they may be compressed to high pressure at a constant temperature (the heat generated by the compression being transferred via an exchange gas in an intermediate chamber to a liquid that can vaporize at constant temperature) and then isolated thermally (*i.e.*, heat is not allowed to flow in or out of the system) and allowed to expand to low pressure. In the expansion, work is done by the gas, and thus it cools. A series of such steps may be needed until the gas is cooled below its critical temperature and a portion of it liquefies. Alternatively, a process based on the Joule-Thomson phenomenon of adiabatic stationary flow can be made use of. In this process, when a gas flows through a porous plug or expansion valve from a constant high pressure to a constant low pressure, it undergoes a temperature change that depends in sign and magnitude on a balance between the cooling effect of increasing the separation of the molecules and the heating effect of work being done on the gas in pushing it through the valve. At low enough initial temperature and pressure, the effect is a cooling one. An initial expansion technique is quite often used to cool a gas until it is ready for a final Joule-Thomson liquefaction.

Spin  
ordering

To cool a substance below  $T_0 = 1^\circ \text{K}$  there must exist one or more sets of energy levels with spacings still smaller than  $kT_0$ , the entropy of which can be manipulated by varying an external parameter (quantity). In practice there are two such sets of energy levels available: states of net electron-spin-magnetic-dipole orientations associated with paramagnetic atoms and states of nuclear-spin-magnetic-dipole orientations associated with some atomic nuclei. It was suggested in 1926-27, independently by the Dutch physicist Peter Debye and the American William Giauque, that, if electron spins could be isothermally (*i.e.*, without change in temperature) ordered at about  $1^\circ \text{K}$  in an external magnetic field, thus removing much of their entropy by evolving heat that could be conducted away, then a subsequent adiabatic demagnetization (being practically a constant entropy process in which energy is lost; *i.e.*, work is done by the spin system as the field is turned off) would result in a much lowered temperature for the spin system. This loss would then result in a lowered temperature for the paramagnetic salt, and any sample in contact with it, as these would have a negligible heat capacity compared with that of the spins. Temperatures as low as  $10^{-2}^\circ$  to  $10^{-8}^\circ \text{K}$  have been obtained with this widely used technique. The curves in the Figure (bottom) show the usual heat-capacity peaks corresponding to rapid entropy decreases, as first the electronic spins settle into their lowest orientational state determined by the interactions that exist in the crystal, even in the absence of an external

Adiabatic  
demagnetization

field, and then at still lower temperature as the nuclear spins are ordered. The energy exchanges leading to the final low temperature are controlled by the hump in the electronic heat capacity; the minimum reached will always be in the neighbourhood of the temperature of that peak for the paramagnetic salt used. To reach temperatures in the region of the peak of the nuclear-spin heat capacity, extremely high magnetic fields are needed to order the spins, even starting from temperatures of  $10^{-2}^\circ \text{K}$  attained by an initial salt demagnetization. Thus this method, first carried out in 1956 by a Hungarian physicist, Nicholas Kurti, when a temperature of about  $10^{-5}^\circ \text{K}$  was attained in the nuclear spin system but not in the sample as a whole, is seldom used.

Temperature measurement below  $1^\circ \text{K}$  is carried out by measurement of the magnetic susceptibility of a paramagnetic salt and then relating this property to the absolute-temperature scale. This last procedure must be done separately for each salt, by determining the susceptibility change for known heat inputs and for known entropy changes arising from demagnetization experiments from known liquid-helium temperatures. (For a general survey of low-temperature applications, see CRYOGENICS, APPLICATIONS OF.)

**Adiabatic dilution.** Another technique to obtain temperatures to about  $10^{-2}^\circ \text{K}$ , originally suggested by German physicist Heinz London in 1951 but only experimentally realized since 1965, is the adiabatic dilution of liquid helium-3 by liquid helium-4. It is difficult to explain without mathematical formulation, and only a brief reference to the principles can be made here. Below  $0.1^\circ \text{K}$  there is a small, nearly constant limiting solubility of helium-3 in concentrated helium-4 that persists to absolute zero. At the starting temperatures of about  $0.5^\circ \text{K}$  reached in ordinary liquid helium-3, helium-4 is entirely superfluid with zero entropy, providing a noninteracting inert background for the helium-3, which in concentrated solutions behaves like a pseudo-one-component liquid and in dilute solutions like a pseudo-one-component gas. The crucial step for cooling, which is a dilution of a concentrated helium-3 solution across the two-phase region to the dilute side, is thus analogous to an ordinary adiabatic evaporation of a liquid. Continuous-refrigeration devices based on this technique have been developed.

## Lo-yang

Lo-yang (in Pin-yin romanization also Lo-yang; formerly Honan-fu and commonly called Honan), a city in north-west Honan Province, China, on the Lunghai Railway (joining Soochow with Sian), was important in Chinese

history as the capital for several ruling dynasties and as a Buddhist centre. Lo-yang is a busy commercial hub and the site of a tractor plant important to the whole Chinese economy.

Lo-yang's position on the north bank of the Lo River, between the Ch'an and Chien rivers, is comparatively high and formerly was held to be so defensible that "one man could resist ten thousand." Lo-yang is divided into an east town and a west town, about one mile (two kilometres) apart. The smaller west town has an airfield and a military parade ground.

Historical  
begin-  
nings

At the beginning of the Chou dynasty (late 12th century BC) the "royal city of Chou" was founded at Lo-i, thought to be near the present west town of Lo-yang, while the Chou capital remained at Hao Ching, near Ch'ang-an, in Shensi. In 771 BC King P'ing of Chou built a new capital on a site thought to be near Chien-hsi-ch'ih, just west of the present city of Lo-yang. The 11 succeeding Chou kings ruled there. King Ching (ruled 519-476 BC) moved the capital to a site about seven miles (11.5 kilometres) northeast of the present east town; it was named Lo-yang because it was north (*yang*) of the River Lo, and its ruins are now distinguished as the ancient city (*ku-ch'eng*) of Lo-yang.

The city of the Han period (206 BC-AD 220), west of the present town, was approximately on the site of the ancient Lo-i but was called Lo-yang. This name alternated with the name Honan-fu until modern times. Lo-yang did not become the Han capital until the 1st century AD, at the beginning of the Eastern Han period, though its economic importance had been recognized earlier. In AD 68 the Pai-ma-ssu, or "White Horse Temple," one of the earliest Buddhist foundations in China, was built about nine miles (14 kilometres) east of the modern east town. As capital of the Western Chin dynasty (AD 265-317), Lo-yang had walls measuring about 4.5 miles (7.5 kilometres) from east to west and about 3.6 miles from north to south and had a population of some scores of thousands.

During the 4th century Lo-yang changed hands several times between the rulers of Eastern Chin, Later Chao, and Yen, and it did not prosper again until 494. In that year the emperor Hsiao Wen of the Toba (Turkic) state of Northern Wei decided to move from near Ta-t'ung in Shansi to the more southerly Lo-yang, in order to take advantage of its strategic position to exercise his power over the whole of North China. Much of Lo-yang had been destroyed by war, and Hsiao Wen and his successors aimed at restoring the splendours of the Han metropolis. The city was rapidly expanded to include 333 sections, craftsmen and traders were attracted, three markets were organized, and the residential quarter of merchants and artisans vied with the great houses of the nobles and officials. Lo-yang's population rose to 40,000. The city became noted for its money lenders, musicians, workers in precious metals, its pleasures and fine wine, and the elegance of its funeral furnishings. Its trade went forth in every direction.

Expansion  
of the city

At Lung-men (properly I-ch'üeh Lung-men, the "Dragon Gates of the I Peaks"), about nine miles (14 kilometres) south of Lo-yang, the Northern Wei emperors saw to the excavation of cave temples in limestone cliffs facing each other across the east-west I River. This inaugurated one of the greatest centres of Chinese Buddhism, the surviving sculptures of which are of prime importance to the history of Chinese art. The style in the Ku-yang cave, begun in 495, marks a decided shift from earlier styles toward a more characteristic Chinese manner. The sculpture style of the Pin-yang triple cave, begun in 505, takes a further step in adaptation to native taste. Both caves reflect the growing ascendancy of Chinese interpretations of Buddhist doctrine. Further caves were excavated before the end of Northern Wei rule in 535 (notably the Lien-hua and Wei-tzu caves); but thereafter work ceased until 570, when the Yao-fang cave was begun. The latest group of caves was begun, and all were mostly completed, in the reign of the T'ang emperor Kao Tsung (ruled 649-683).

In the T'ang period (618-907) Lo-yang was expanded

to unprecedented size, and the part now constituting the east town was created, evidently to make Lo-yang the chief city in the national economy; Lo-yang was designated the eastern T'ang capital (Ch'ang-an in Shensi being the capital proper). Three markets that had been established in the Sui period (581-618) were reorganized, the streets were redivided into several hundred sections, and workers were separated according to their trades. But after a rebellion in the mid-8th century, Lo-yang fell into an economic decline, which lasted until recent times. From the later T'ang period economic primacy passed to the southern provinces around the lower Yangtze River.

With a population approaching 500,000 in the 1970s, Lo-yang was one of the leading industrial towns of China's interior; it was an important trade centre and a processor of cotton, wheat, and other crops grown in the region. The Khaikov tractor works in Moscow trained 173 management personnel and technical cadres for the No. 1 Tractor Plant, which was established in Lo-yang in November 1959. Also built were a plant for mining machinery and a thermoelectric plant to take advantage of the deposits of hard coal in the vicinity.

Excavations recently carried out at Chung-chou-lu on the supposed site of Lo-i discovered tombs ranging in date from the 9th-8th centuries BC to the 2nd century AD. Tombs of the Han period were excavated on the edge of the modern city at Shao-kou.

**BIBLIOGRAPHY.** An important early account of the city is *Lo-yang chia-lan chi* by YANG HSUAN, a description of the temples of Lo-yang, written in the early 6th century. For the role of Lo-yang in Buddhist art, see the standard work by L.C. SICKMAN and A. SOPER, *The Art and Architecture of China*, 3rd ed. (1968). References to Lo-yang are to be found in general histories, such as W. EBERHARD, *Chinas Geschichte* (1948; Eng. trans., *A History of China*, 1950); and C.P. FITZGERALD, *China: A Short Cultural History*, 3rd ed. rev. (1961). W.C. WHITE, *Tombs of Old Lo-yang* (1934), is the only specialized account in a Western language of archaeological finds made at the site of the ancient city. For the contemporary scene, see references in E. STUART KIRBY (ed.), *Contemporary China*, vol. 6 (1968); and J. WILSON LEWIS (ed.), *The City in Communist China* (1971).

(W.W.)

## Loyola, Saint Ignatius of

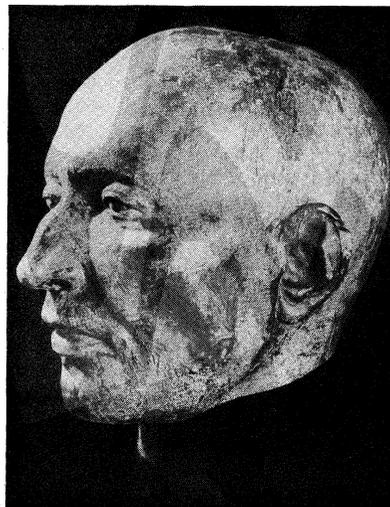

St. Ignatius of Loyola, the founder of the Society of Jesus (Jesuits), was one of the most influential figures of the Catholic Reformation of the 16th century.

**Early life.** He was born in the ancestral castle of the Loyolas in the Basque province of Guipúzcoa, Spain, in 1491. The youngest son of a noble and wealthy family, Ignatius became, in 1506, a page in the service of a relative, Juan Velázquez de Cuéllar, treasurer of the kingdom of Castile. In 1517 Ignatius passed as a knight into the service of another relative, Antonio Manrique de Lara, duke of Nájera and viceroy of Navarre, who em-

ployed him in military undertakings and on a diplomatic mission. While defending the citadel of Pamplona against the French, Ignatius was hit by a cannonball on May 20, 1521, sustaining a bad fracture of his right leg and damage to his left. This event closed the first period of his life, during which he was, on his own admission, "a man given to the vanities of the world, whose chief delight consisted in martial exercises, with a great and vain desire to win renown" (*Autobiography*, 1). Although his morals were far from stainless, Ignatius was in his early years a proud rather than sensual man. He stood just under five feet two inches in height and had in his youth an abundance of hair of a reddish tint. He delighted in music, especially sacred hymns.

**Period of reorientation.** It is the second period of Ignatius' life, in which he turned toward a saintly life, that is the better known. After treatment at Pamplona, he was transported to Loyola in June 1521. There his condition became so serious that for a time it was thought he would die. When out of danger, he chose to undergo painful surgery to correct blunders made when the bone was first set. The result was a convalescence of many weeks, during which he read a life of Christ and a book on the lives of the saints, the only reading matter the castle afforded. He also passed time in recalling tales of martial valour and in thinking of a great lady whom he admired. In the early stages of this enforced reading, his attention was centred on the saints. The version of the lives of the saints he was reading contained prologues to the various lives by a Cistercian monk who conceived the service of God as a holy chivalry. This view of life profoundly moved and attracted Ignatius. After much reflection, he resolved to imitate the holy austerities of the saints in order to do penance for his sins.

In February 1522 Ignatius bade farewell to his family and went to Montserrat, a place of pilgrimage in north-eastern Spain. He spent three days in confessing the sins of his whole life, hung his sword and dagger near the statue of the Virgin Mary as symbols of his abandoned ambitions, and, clothed in sackcloth, spent the night of March 24 in prayer. The next day he went to Manresa, a town 30 miles from Barcelona, to pass the decisive months of his career, from March 25, 1522, to mid-February 1523. He lived as a beggar, ate and drank sparingly, scourged himself, and for a time neither combed nor trimmed his hair and did not cut his nails. Daily he attended mass and spent seven hours in prayer, often in a cave outside Manresa.

The sojourn at Manresa was marked by spiritual trials as well as by joy and interior light. While sitting one day on the banks of Cardoner River, "the eyes of his understanding began to open and, without seeing any vision, he understood and knew many things, as well spiritual things as things of the faith" (*Autobiography*, 30). At Manresa, he sketched the fundamentals of his little book *The Spiritual Exercises*. Until the close of his studies at Paris (1535), he continued to make some additions to it. Thereafter there were only minor changes until Pope Paul III approved it in 1548. *The Spiritual Exercises* is a manual of spiritual arms containing a vital and dynamic system of spirituality. During his lifetime, Ignatius used it to give spiritual retreats to others, especially to his followers. The booklet is indeed an adaptation of the Gospels for such retreats.

The remainder of the decisive period was devoted to a pilgrimage to Jerusalem. Ignatius left Barcelona in March 1523 and, travelling by way of Rome, Venice, and Cyprus, reached Jerusalem on September 4. He would have liked to have settled there permanently, but the Franciscan custodians of the shrines of the Latin church would not listen to this plan. After visiting Bethany, the Mount of Olives, Bethlehem, the Jordan, and Mount of Temptation, Ignatius left Palestine on October 3 and, passing through Cyprus and Venice, reached Barcelona in March 1524.

**Period of study.** "After the pilgrim had learned that it was God's will that he should not stay in Jerusalem, he pondered in his heart what he should do and finally decided to study for a time in order to be able to help souls"

(*Autobiography*, 50). So Ignatius, who in his *Autobiography* refers to himself as the "pilgrim," describes his decision to acquire as good an education as the circumstances permitted. He probably could have reached the priesthood in a few years. He chose to defer this goal for more than 12 years and to undergo the drudgery of the classroom at an age when most men have long since finished their training. Perhaps his military career had taught him the value of careful preparation. At any rate, he was convinced that a well-trained man would accomplish in a short time what one without training would never accomplish.

Ignatius studied at Barcelona for nearly two years. In 1526 he transferred to Alcalá. By this time he had acquired followers, and the little group had assumed a distinctive garb; but Ignatius soon fell under suspicion of heresy, was imprisoned and tried. Although found innocent, he left Alcalá for Salamanca. There not only was he imprisoned but his companions were also apprehended. Again he won acquittal but was forbidden to teach until he had finished his studies. This prohibition induced Ignatius to leave his disciples and Spain.

He arrived in Paris on Feb. 2, 1528, and remained there as a student until 1535. He lived on alms and in 1528 and 1529 he went to Flanders to beg from Spanish merchants. In 1530 he went to England for the same purpose. In Paris, Ignatius soon had another group of disciples whose manner of living caused such a stir that he had to explain himself to the religious authorities. This episode finally convinced him that he must abstain from public religious endeavour until he reached the priesthood.

During his long stay in the French capital, Ignatius won the coveted M.A. of the famous university. He also gathered the companions who were to be cofounders with him of the Society of Jesus, among them Francis Xavier, who became one of the order's greatest missionaries. On Aug. 15, 1534, he led the little band to nearby Montmartre, where they bound themselves by vows of poverty, chastity, and obedience, though as yet without the express purpose of founding a religious order.

Early in 1535, before the completion of his theological studies, Ignatius left Paris for reasons of health. He spent more than six months in Spain and then went to Bologna and Venice where he studied privately. On Jan. 8, 1537, his Parisian companions joined him in Venice. All were eager to make the pilgrimage to Jerusalem, but war between Venice and the Turkish Empire rendered this impossible. Ignatius and most of his companions were ordained on June 24, 1537. There followed 18 months during which they acquired experience in the ministry while also devoting much time to prayer. During these months, although he did not as yet say mass, Ignatius had one of the decisive experiences of his life. He related to his companions that on a certain day, while in prayer, he seemed to see Christ with the cross on his shoulder and beside him the Eternal Father, who said, "I wish you to take this man for your servant," and Jesus took him and said, "My will is that you should serve us." On Christmas Day 1538 Ignatius said his first mass at the Church of St. Mary Major in Rome. This ends the third period of his life, that of his studies, which were far from a formality. Diego Laínez, a cofounder of the Society of Jesus and an intelligent observer, judged that despite handicaps Ignatius had as great diligence as any of his fellow students. He certainly became in the difficult field of ascetic and mystical theology one of the surest of Catholic guides.

**Founding of the Jesuit order.** The final period of Loyola's life was spent in Rome or its vicinity. In 1539 the companions decided to form a permanent union, adding a vow of obedience to a superior elected by themselves to the vows of poverty, chastity, and obedience to the Roman pontiff that they had already taken. In 1540 Pope Paul III approved the plan of the new order. Loyola was the choice of his companions for the office of general.

The Society of Jesus developed rapidly under his hand. When he died there were about 1,000 Jesuits divided into 12 administrative units, called provinces. Three of these were in Italy, a like number in Spain, two in Germany one in France, one in Portugal and two overseas in India and

Society of  
Jesus  
cofounders

Brazil. Loyola was, in his last years, much occupied with Germany and India, to which he sent his famous followers Peter Canisius and Francis Xavier. He also dispatched missionaries to the Congo and to Ethiopia. In 1546 Loyola secretly received into the society Francis Borgia, duke of Gandía and viceroy of Catalonia. When knowledge of this became public four years later it created a sensation. Borgia organized the Spanish provinces of the order and became third general.

Emphasis  
on  
education

Loyola left his mark on Rome. He founded the Roman College, embryo of the Gregorian University, and the Germanicum, a seminary for German candidates for the priesthood. He also established a home for fallen women and one for converted Jews.

Although at first Loyola had been somewhat opposed to placing his companions in colleges as educators of youth, he came in the course of time to recognize the value of the educational apostolate and in his last years was busily engaged in laying the foundations of the system of schools that was to stamp his order as largely a teaching order.

Probably the most important work of his later years was the composition of the *Constitutions* of the Society of Jesus. In them he decreed that his followers were to abandon some of the traditional forms of the religious life, such as chanting the divine office, physical punishments, and penitential garb, in favour of greater adaptability and mobility; they also renounced chapter government by the members of the order in favour of a more authoritative regime; and their vows were generally of such a nature that separation from the order was easier than had been usual in similar Catholic groups. The Society of Jesus was to be above all an order of apostles "ready to live in any part of the world where there was hope of God's greater glory and the good of souls." Loyola insisted on long and thorough training of his followers. Convinced that women are better ruled by women than by men, after some hesitation he resolutely excluded a female branch of the order. The special vow of obedience to the pope was called by Loyola "the cause and principal foundation" of his society.

Vow of  
obedience  
to the pope

Loyola and his work were much admired during his lifetime. But he also met with opposition in the church and outside it. His innovations in the religious life were criticized and, while Protestant leaders early came to look on him as one of their principal opponents, some Catholics accused him and his followers of being secret Protestants.

While general of the order, Loyola was frequently sick. In January 1551 he became so ill that he begged his associates, though to no purpose, to accept his resignation as superior. Despite his condition he continued to direct the order until his death on July 31, 1556. Since his days at Manresa, Loyola had practiced a form of prayer that was later published in *The Spiritual Exercises* and appears to have rivalled that of the greatest mystics.

**Canonization.** Ignatius Loyola was beatified by Pope Paul V in 1609 and canonized by Pope Gregory XV in 1622; his feast day is July 31. In 1922 he was declared patron of all spiritual retreats by Pope Pius XI. His enemies no less than his friends agree that Ignatius Loyola was a maker of history. Scores of books could be cited in proof of this statement. The spirit of Loyola lives on in the Society of Jesus and in the Jesuit *Constitutions*, which still regulate the lives and aspirations of over 30,000 Jesuits, scattered through most countries of the world. *The Spiritual Exercises* molded 27 canonized saints, three of them, Francis Xavier, Peter Canisius, and Francis Borgia, intimates of Loyola. His achievements and those of his followers form a chapter in the history of the Roman Catholic Church that cannot be neglected by those who desire to understand that institution.

#### BIBLIOGRAPHY

*Collected works:* Collections of St. Ignatius' works may be found in the *Monumenta Ignatiana ex Autographis vel ex Antiquioribus Exemplis Collecta: Sancti Ignatii de Loyola . . . Epistolae et Instructiones*, 12 vol. (1903-11); *Exercitia spiritualia sancti Ignatii de Loyola et eorum directoria* (1919); *Sancti Ignatii de Loyola Constitutiones Societatis Iesu*, 4 vol. (1934-48); and *Scripta de Sancto Ignatio de Loyola*, 2 vol. (1904-18). There is a Spanish collection, *Obras completas*,

ed. by I. IPARRAGUIRRE and C. DE DALMASES, 2nd ed. (1963). Selections include *Cartas espirituales de S. Ignasi de Loyola*, ed. by I. CASANOVAS, 2 vol. (1936); *Briefwechsel mit Frauen* (1956; Eng. trans., *Letters to Women*, ed. by H. RAHNER, 1960); and *Letters of St. Ignatius of Loyola*, selected and trans. by W.J. YOUNG (1959). English translations of Ignatius' two most important works are *The Spiritual Exercises of St. Ignatius*, trans. by L.J. PUHL (1951); and *The Constitutions of the Society of Jesus: Translated, with an Introduction and a Commentary*, by G.E. GANSS (1970).

*Lives:* The sources of the life of Ignatius have been published in more than 20 volumes in the *Monumenta Historica Societatis Iesu* (1894-1918, 1934-48). Loyola's *Autobiography* may be found in *Acta Patris Ignatii Scripta a P. Lud. González de Cámara, 1553/1555* (1943; Eng. trans., *St. Ignatius' Own Story As Told to Luis González de Cámara*, 1956). The most authoritative life in English is P. DUDON, *St. Ignace de Loyola* (1934; Eng. trans., 1949). Another excellent biography is A. GUILLERMOU, *St. Ignace de Loyola et la Compagnie de Jésus* (1965); while that of the poet FRANCIS THOMPSON, *St. Ignatius Loyola* (1909; rev. and ed. by J.H. POLLEN, 1962), is valuable as well as of literary interest. J. BRODRICK, *St. Ignatius of Loyola: The Pilgrim Years* (1956), is competent; while T. MAYNARD, *St. Ignatius and the Jesuits* (1956), is a much simpler work. L. VON MATT and H. RAHNER, *St. Ignatius of Loyola* (1956), is a pictorial biography.

*Special aspects:* H. RAHNER, *The Spirituality of St. Ignatius Loyola* (Eng. trans. 1953); G.E. GANSS, *St. Ignatius' Idea of a Jesuit University* (1956).

(E.A.R.)

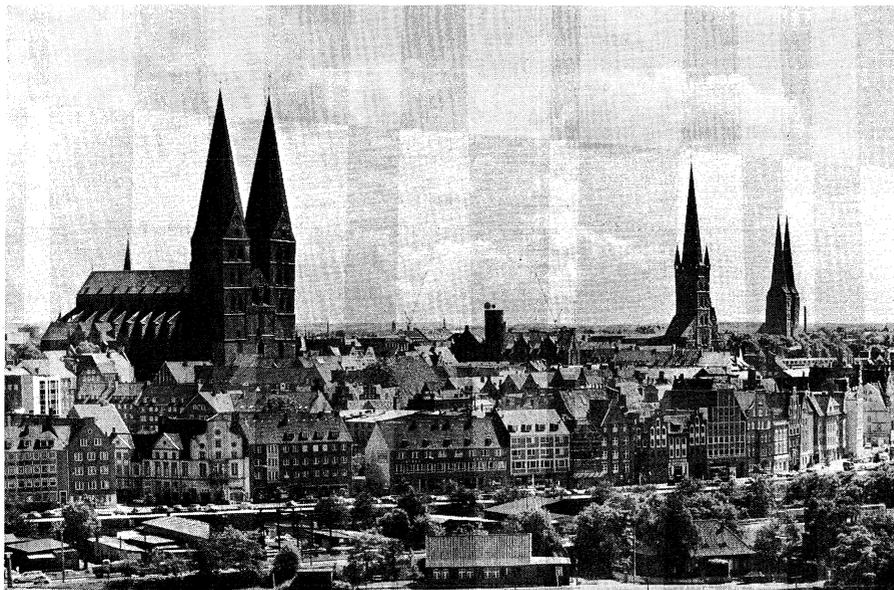

## Lübeck

Lübeck is a seaport of the *Land* (state) of Schleswig-Holstein, in the northern part of the Federal Republic of Germany (West Germany). In the Middle Ages, it was one of the main commercial centres of northern Europe and the chief city of the Hanseatic League (see below *History*).

The old city of Lübeck is built on a hill 52 feet (16 metres) above sea level, about nine miles (14 kilometres) from the Baltic Sea. It is bounded by the rivers Trave and Wakenitz. A modern highway connects it with Hamburg, and ferry traffic links Lübeck with 11 Scandinavian harbours. The border between West and East Germany lies just to the east of the city.

**History.** The original settlement on the site was Liubice, the seat of a Slavic principality consisting of a castle, settlement, harbour, and merchant colony, located at the mouth of the River Schwartau where it flows into the Trave River. Count Adolf II of Holstein founded the present German city about four miles (six kilometres) upstream in 1143. It grew rapidly, and Adolf's feudal lord, Henry the Lion, duke of Saxony, forced him to cede it in 1158. Henry the Lion rebuilt the city in 1159 after a destructive fire. This has traditionally been considered the date of the present city's foundation.

With the foundation of Lübeck, the type of settlement and law codes typical of German medieval cities began to appear on the coast of the Baltic Sea. The regular plan of the city, centred around the marketplace, was designed to serve the needs of its merchant inhabitants. The city's location was favourable: close to the Baltic and with inland access to Lower Saxony, Westphalia, and the lower Rhine regions. Hence, Lübeck was destined to become the focal point for trade between the raw-material-producing countries of northern and eastern Europe and the manufacturing centres in the west. Aided by privileges from their feudal overlords, the merchants of Lübeck were trading in all the important places along the Baltic coast as early as the end of the 12th century. After the overthrow of Henry the Lion (1180), the Holy Roman emperor Frederick I (Frederick Barbarossa) confirmed the special rights and the landholding privileges of the city (Barbarossa Privilege, 1188). For a short time (1201-26) Lübeck belonged to Denmark, but in 1226 the emperor Frederick II made it a free city, subject only to him. During this time Lübeck developed a form of self-government with its own laws and constitution. It also began to play an important role in the settling of Germans in the eastern Baltic area, supporting the colonizing efforts of the Teutonic Knights and promoting the efforts of already existing settlements to attain self-government

Lübeck, showing several of its famous church towers; left is the Marienkirche (c. 1250–1351); centre right is the Petrikirche (c. 1290–1350, tower completed 1427); right is the cathedral (1173–c. 1247). In the foreground are shops and warehouses, the oldest parts of which date from the Middle Ages.

in cooperation with local Slavic and Baltic rulers. The “Laws of Lübeck” were granted to more than 100 cities in the Baltic area in the next decades, including Elbing, Kolberg, Reval, Memel, Danzig, and Wismar. Lübeck influenced the economic structure and even the appearance of these cities, and its language became the lingua franca.

The leading merchant dynasties of these various German Baltic cities found it expedient to form a political association in order to guard their common interests. This became the Hanseatic League, and the cities of the league elected Lübeck as their administrative headquarters in 1358. With the Peace of Stralsund (signed on May 24, 1370), by which King Valdemar IV of Denmark officially recognized all its commercial rights and trading licenses, the Lübeckian–Hanseatic League reached its high point. Earlier, in 1350, the city was greatly depopulated by the Black Death (bubonic plague). The period that followed was marked by uprisings of the artisans and craftsmen of the guilds (1380–84 and 1408–16) against the city council, which was controlled by the merchants. The uprisings, however, failed to have any lasting effect. The opening of the Stecknitz Canal in 1398 greatly facilitated the shipping of salt from Lüneburg.

Lübeck was, after Cologne, the largest city in northern Germany; it had approximately 22,000 inhabitants at the beginning of the 15th century. Sweeping changes came with the Protestant Reformation (1529–30). The city council was expelled, and the revolutionary Jürgen Wullenwever became burgomaster of Lübeck. Wullenwever waged an unsuccessful war against Denmark, Sweden, and the Netherlands, which caused Lübeck to lose its position as a great northern European power. The political weakness of the city and the slowly increasing disintegration of the Hanseatic League became obvious with the Peace Treaty of Hamburg in 1536. Wullenwever was forced to leave the city and was executed at Wolfenbüttel in 1537. Lübeck’s success in a last war against Sweden (1563–70) had no lasting effects.

After the final breakup of the Hanseatic League (1630), Lübeck was still able to retain its position as the most important harbour on the Baltic Sea. It was able to remain neutral during the Thirty Years’ War. The city maintained its position as middleman between Scandinavia and the continent of Europe; the recuperation of its economy continued through the 18th century, partly in consequence of the newly established shipping connections with the new Russian Baltic port of St. Petersburg (now Leningrad). But, during the French Revolutionary

and Napoleonic Wars (1792–1815), the city’s trade was completely ruined, for it was caught between economic pressures exerted by the rival powers. It was under French rule from 1811 to 1813. After 1815 the city was a member state of the German confederation, and it experienced a revival of prosperity.

From 1866 Lübeck belonged to the North German Confederation and from 1871 to the German Empire. A vast new trading territory in the interior was opened up for Lübeck with the construction of the Elbe–Lübeck Canal in 1900. The city’s economic and social structure changed with the advancing industrialization after 1906. Its status as a separate, self-governing entity, dating from 1226, was finally ended in 1937, when the Nazi regime made the “Hanseatic city of Lübeck” part of the Prussian province of Schleswig-Holstein. An air attack by the British during World War II (March 28, 1942) destroyed a large part of the historic inner city, but it left the harbour and the industrial plants intact.

After the end of World War II, Lübeck’s population increased by 100,000 German refugees from the east. Postwar reconstruction restored the old inner city; new industrial plants and residential districts were built in the suburbs, and Lübeck’s economy was enhanced.

**The modern city.** Among Lübeck’s outstanding monuments are the Marienkirche (St. Mary’s Church, a 13th- to 14th-century brick structure in the Gothic style), the Romanesque cathedral (begun in 1173 under Henry the Lion), the magnificent Rathaus (town hall) built in a combination Gothic and Renaissance style, and two towered gates, the Burgtor (1444) and the Holstentor (1477), remnants of the city’s medieval fortifications.

The novelists Thomas Mann (1875–1955) and his brother Heinrich Mann (1871–1950) were both natives of Lübeck and belonged to one of its old patrician families. Thomas Mann created a vivid picture of life in 19th-century Lübeck in his novel *Buddenbrooks*.

The metropolitan area of Lübeck is divided into the inner city, four suburbs, and 23 urban municipalities; among the latter is the well-known Baltic sea resort Travemünde. Of Lübeck’s population of about 244,000 in 1970, 38.4 percent was of eastern or central German origin; 87.1 percent of the people were Protestants; and 7.8 percent were Roman Catholic.

Lübeck is the largest Baltic harbour of the Federal Republic of Germany. It has two inland-harbour basins and nine sea-harbour basins on the lower course of the Trave River, which was enlarged to admit seagoing vessels.

Role in the  
Hanseatic  
League

End of its  
self-  
governing  
status

In 1970, 38 percent of the city's total work force made its living from the activities of the port, and Lübeck's merchant fleet numbered 116 seagoing vessels. Employing approximately one-third of the total work force, the industry centred mainly on shipyards, metal foundries, iron-construction works, ceramics, wood and lumber production, clothing manufacture, manufacture of instruments for medical use, and food processing.

## Lubrication

Although one of the main purposes of lubrication, derived from the Latin verb *lubricare*, meaning "to make slippery," is to reduce friction, any substance—liquid, solid, or gaseous—capable of controlling friction and wear between sliding surfaces can be classed as a lubricant.

In controlling friction and wear by lubrication, one type of friction frequently is substituted for another, such as the much lower friction of a fluid in an oil-film bearing for that of dry, sliding surfaces.

### GENERAL CONSIDERATIONS

Nature has been applying lubrication since the evolution of synovial fluid, which lubricates the joints and bursas. Prehistoric man used mud and reeds to lubricate sledges for dragging game or timbers and rocks for construction. Animal fat lubricated the axles of the first wagons and continued in wide use until the petroleum industry arose in the 19th century, after which petroleum became the chief source of lubricants. The natural lubricating capacity of crude petroleum has been steadily improved through the development of a wide variety of products designed for the specific lubricating needs of the automobile, the airplane, the diesel locomotive, the turbojet, and power machinery of every description. The improvements in petroleum lubricants have in turn made possible the increase in speed and capacity of industrial and other machinery. There are, however, other lubricant materials in use, as will be seen below.

**Varieties of lubrication.** *Unlubricated sliding.* Metals that have been carefully treated to remove all foreign materials seize and weld to one another when slid together. In the absence of such a high degree of cleanliness, adsorbed gases, water vapour, oxides, and contaminants reduce friction and the tendency to seize but usually result in severe wear; this is called "unlubricated" or dry sliding.

*Fluid-film lubrication.* Interposing a fluid film that completely separates the sliding surfaces results in fluid-film lubrication. The fluid may be introduced intentionally, as the oil in the main bearings of an automobile, or unintentionally, as in the case of water between a smooth rubber tire and a wet pavement. Although the fluid is usually a liquid such as oil, water, and a wide range of other materials, it may also be a gas. The gas most commonly employed is air.

To keep the parts separated, it is necessary that the pressure within the lubricating film balance the load on the sliding surfaces. If the lubricating film's pressure is supplied by an external source, the system is said to be lubricated hydrostatically. If the pressure between the surfaces is generated as a result of the shape and motion of the surfaces themselves, however, the system is hydrodynamically lubricated. This second type of lubrication depends upon the viscous properties of the lubricant. Os-

borne Reynolds developed fluid-film lubrication theory in 1886, following Beauchamp Tower's discovery of hydrodynamic lubrication, when Tower studied railroad car journal bearings in England in 1885.

*Boundary lubrication.* A condition that lies between unlubricated sliding and fluid-film lubrication is referred to as boundary lubrication, also defined as that condition of lubrication in which the friction between surfaces is determined by the properties of the surfaces and properties of the lubricant other than viscosity. Boundary lubrication encompasses a significant portion of lubrication phenomena and commonly occurs during the starting and stopping of machines.

*Solid lubrication.* Solids such as graphite and molybdenum disulfide are widely used when normal lubricants do not possess sufficient resistance to load or temperature extremes. But lubricants need not take only such familiar forms as fats, powders, and gases; even some metals commonly serve as sliding surfaces in some sophisticated machines (see below *Solid lubricants*).

### FUNCTIONS OF LUBRICANTS

Although a lubricant primarily controls friction and wear, it can and ordinarily does perform numerous other functions, which vary with the application and usually are interrelated.

**Control functions.** *Friction control.* The amount and character of the lubricant made available to sliding surfaces have a profound effect upon the friction that is encountered. For example, disregarding such related factors as heat and wear but considering friction alone between two oil-film lubricated surfaces, the friction can be 200 times less than that between the same surfaces with no lubricant. Under fluid-film conditions, friction is directly proportional to the viscosity of the fluid (see Table 1).

lubricant	relative viscosity (air = 1)	typical minimum film thickness in bearing applications (in.)	typical unit load in bearing applications (pounds per sq in.)
Air	1	0.00005-0.0004	1-10
Water	33	0.0004-0.001	25-75
Oil	1,000	0.002-0.004	200-500

Some lubricants, such as petroleum derivatives, are available in a great range of viscosities and thus can satisfy a broad spectrum of functional requirements. Under boundary lubrication conditions, the effect of viscosity on friction becomes less significant than the chemical nature of the lubricant. For instance, delicate instruments must not be lubricated with fluids that would attack and corrode the finer metals.

*Wear control.* Wear occurs on lubricated surfaces by abrasion, corrosion, and solid-to-solid contact. Proper lubricants will help combat each type. They reduce abrasive and solid-to-solid contact wear by providing a film that increases the distance between the sliding surfaces, thereby lessening the damage by abrasive contaminants and surface asperities.

Corrosion wear is generally caused by the products of oxidation of petroleum lubricants. Use of oxidation inhibitors reduces deterioration of petroleum lubricants, and the addition of corrosion preventives protects metal surfaces from any oxidation products that do form.

*Temperature control.* Lubricants assist in controlling temperature by reducing friction and carrying off the heat that is generated. Effectiveness depends upon the amount of lubricant supplied, the ambient temperature, and the provision for external cooling. To a lesser extent, the type of lubricant also affects surface temperature.

*Corrosion control.* The role of a lubricant in controlling corrosion of the surfaces themselves is twofold. When machinery is idle, the lubricant acts as a preservative. When machinery is in use, the lubricant controls corrosion by coating lubricated parts with a protective film that may contain additives to neutralize corrosive materials. The ability of a lubricant to control corrosion is directly

Primitive lubricants

Balancing the load on sliding surfaces

Range of viscosities

related to the thickness of the lubricant film remaining on the metal surfaces and the chemical composition of the lubricant. Additives that react with the sliding surfaces enhance the corrosion control of the lubricant.

**Other functions.** Lubricants are frequently used for purposes other than the reduction of friction. Some of these applications are described below.

**Power transmission.** Lubricants are widely employed as hydraulic fluids in fluid transmission devices.

**Contaminant removal.** Lubricants are used to remove contaminants in many systems. Flushing action is used to remove chips and solid contaminants in metalworking. Detergent-dispersant additives suspend sludges and remove them from the sliding surfaces of internal-combustion engines.

**Insulation.** In specialized applications such as transformers and switchgear, lubricants with high dielectric constants act as electrical insulators. For maximum insulating properties, a lubricant must be kept free of contaminants and water.

**Shock dampening.** Lubricants act as shock-dampening fluids in energy-transferring devices such as shock absorbers and around machine parts such as gears that are subjected to high intermittent loads.

**Sealing.** Lubricating grease frequently performs the special function of forming a seal to retain lubricants or to exclude contaminants.

#### TYPES OF LUBRICANTS

**Liquid, oily lubricants.** *Animal and vegetable lubricants.* Animal and vegetable products were certainly man's first lubricants and were used in large quantities. But, because they lack chemical inertness and because lubrication requirements have become more demanding, they have been largely superseded by petroleum products and by synthetic materials. Some organic substances such as lard oil and sperm oil are still in use as additives because of their special lubricating properties.

**Petroleum lubricants.** Petroleum lubricants are predominantly hydrocarbon products extracted from fluids that occur naturally within the Earth. They are used widely as lubricants because they possess a combination of the following desirable properties: (1) availability in suitable viscosities, (2) low volatility, (3) inertness (resistance to deterioration of the lubricant), (4) corrosion protection (resistance to deterioration of the sliding surfaces), and (5) low cost.

Petroleum lubricants formerly were referred to as paraffin-base, naphthene-base, or mixed-base, depending on whether the crude oil from which the lubricant was extracted was higher in paraffin or naphthene molecules. With improvements in refining methods that have made it possible to produce high-quality lubricants from a wide variety of crudes, the terms are no longer widely used.

Lubricants are refined from the crude petroleum by various processes: (1) vacuum distillation, (2) solvent extraction (extracting specific products with solvents), (3) solvent dewaxing (using solvents to remove wax), (4) hydrofining (treating with hydrogen in the presence of a catalyst).

**Synthetic lubricants.** Synthetic lubricants generally can be characterized as oily, neutral liquid materials not usually obtained directly from petroleum but having some properties similar to petroleum lubricants.

Interest in synthetics has increased greatly—more to meet some of the advanced demands of technology than because of any critical shortage of petroleum lubricants.

Among the improved properties offered by synthetics are low volatility, stability of viscosity with temperature changes, resistance to scuffing and oxidation, and fire resistance. Since the properties of synthetics vary considerably, each synthetic lubricant tends to find a special application. Some of the more common classes of synthetics and typical (but by no means exclusive) uses of each are shown in Table 2.

**Lubricating greases.** A lubricating grease is a solid or semisolid lubricant consisting of a thickening agent in a liquid lubricant. Soaps of aluminum, barium, calcium, lithium, sodium, and strontium are the major thickening

**Table 2: Synthetic Lubricants and Typical Applications**

synthetic lubricant	typical uses
Dibasic acid esters	instrument oil, jet turbine lubricant, hydraulic fluid
Phosphate esters	fire-resistant hydraulic fluid, low-temperature lubricant
Silicones	damping fluid, low-volatility grease base
Silicate esters	heat transfer fluid, high-temperature hydraulic fluid
Polyglycol ether compounds	synthetic engine oil, hydraulic fluids, forming and drawing compounds
Fluorol compounds	nonflammable fluid, extreme oxidation-resistant lubricant

agents. Nonssoap thickeners consist of such inorganic compounds as modified clays, fine silicas, or such organic materials as arylureas or phthalocyanine pigments. Solids, usually referred to as fillers, are sometimes added in concentrations up to several percent. Fillers are normally inorganic materials such as asbestos, graphite, metal oxides, metal powders, or metal sulfides. Additives are frequently incorporated to resist oxidation and corrosion and to improve film strength.

Lubrication by grease may prove more desirable than lubrication by oil under conditions when (1) less frequent lubricant application is necessary, (2) grease acts as a seal against loss of lubricant and ingress of contaminants, (3) less dripping or splattering of lubricant is called for, or (4) less sensitivity to inaccuracies in the mating parts is needed.

**Solid lubricants.** A solid lubricant is a film of solid material interposed between two rubbing surfaces to reduce friction and wear. The films may consist of inorganic or organic compounds or of metal.

**Inorganic compounds.** There are three general types of inorganic compounds that serve as solid lubricants:

1. Layer-lattice, or laminar, solids: materials such as graphite and molybdenum disulfide, commonly called molybdenum disulfide, have a crystal lattice structure arranged in layers. Strong bonds between atoms within a layer and relatively weak bonds between atoms of different layers allow the lamina to slide on one another. Other such materials are tungsten disulfide, mica, boron nitride, borax, silver sulfate, cadmium iodide, and lead iodide. Graphite's low friction is due largely to adsorbed films; in the absence of water vapour, graphite loses its lubricating properties and becomes abrasive. Both graphite and molybdenum disulfide are chemically inert and have high thermal stability.

2. Miscellaneous soft solids: a variety of organic solids such as white lead, lime, talc, bentonite, silver iodide, and lead monoxide are used as lubricants.

3. Chemical conversion coatings: a number of inorganic compounds can be formed on the surface of a metal by chemical reaction. The best known such lubricating coatings are sulfide, chloride, oxide, phosphate, and oxalate films.

**Solid organic compounds.** There are two general classes of solid organic lubricants:

1. Soaps, waxes, and fats: this class includes metallic soaps of aluminum, calcium, sodium, lithium; animal waxes such as beeswax and spermaceti wax; fatty acids such as stearic and palmitic acids; and fatty esters, such as lard and tallow.

2. Polymeric films: these are synthetic substances such as polytetrafluoroethylene and polychlorofluoroethylene. One major advantage of such film-type lubricants is their resistance to deterioration during exposure to the elements. Thus, one-half-inch-thick plates of polymeric film are used in modern prestressed concrete construction to permit thermal movement of beams resting atop columns. Such expansion and contraction of the structural members is facilitated by the long-lived polymeric film plate. Very thin films of such polymers also serve as protective coatings, as well as lubricants, for many types of industrial machinery subjected to great variations in temperature and humidity.

Conditions under which grease is preferable to oil

Lubricating structural concrete

**Metal films.** Thin films of soft metal on a hard substrate can act as effective lubricants, if the adhesion to the substrate is good. Such metals include lead, tin, and indium.

**Bonded solid lubricant coatings.** Since solid lubricants as a class lack adhesion, they are frequently applied using a mixture made from lubricant in powder form and an adhesive bonding agent. Organic binders include corn syrup and acrylic, phenolic, and epoxy resins; inorganic binders are sodium silicate, the phosphates of sodium, and powdered, low-melting metals.

**Other types. Gases.** Lubrication with a gas is analogous in many respects to lubrication with a liquid, since the same principles of fluid-film lubrication apply. Although both gases and liquids are viscous fluids, they differ in two important particulars. The viscosity of gases is much lower and the compressibility much greater than for liquids. Film thicknesses and load capacities therefore are much lower with a gas such as air (see Table 1). In equipment that handles gases of various kinds, it is frequently desirable to lubricate the sliding surfaces with gas in order to simplify the apparatus and reduce contamination to and from the lubricant. The list of gases used in this manner is extensive and includes air, steam, industrial gases, and liquid-metal vapours.

**Special-purpose lubricants.** In a sense, every lubricant application is special and could be benefitted by a lubricant specially formulated to meet its unique requirements. Since such an inventory of lubricants is impractical, compromises are usually made to reduce the number of lubricants needed. A few applications in which special characteristics are desirable are given in Table 3.

lubricant application	lubricant properties of special interest
Aircraft jet engine	oxidation resistance, thermal stability, low-temperature properties, good temperature-viscosity characteristics, high film strength (for gears)
Hypoid gears	high film strength, oxidation resistance, corrosion resistance
Automatic transmission	low viscosity, good temperature-viscosity characteristics, oxidation resistance, corrosion resistance, high film strength
Steam turbine	high oxidation resistance, corrosion resistance, good water separation, low foaming
Vacuum pump	low vapour pressure, freedom from gas and moisture, oxidation resistance
Transformer	high dielectric strength, low viscosity, oxidation resistance, high resistivity
Refrigerator compressor	chemical stability in presence of refrigerant, freedom from moisture, chemical stability in presence of copper and iron
Fire-resistant hydraulic system	fire resistance, corrosion resistance, compatibility with seals and gaskets, low foaming

#### PROPERTIES OF LUBRICANTS

With so many types of materials capable of acting as lubricants under certain conditions, coverage of the properties of all of them is impractical. Mention will be made only of those properties usually considered characteristic of commercially significant fluid lubricants.

**Viscosity.** Of all the properties of fluid lubricants, viscosity is the most important since it determines the amount of friction that will be encountered between sliding surfaces and whether a thick enough film can be built up to avoid wear from solid-to-solid contact. Viscosity customarily is measured by a viscometer, which determines the flow rate of the lubricant under standard conditions; the higher the flow rate, the lower the viscosity. The rate is expressed in centipoises, reyns, or seconds Saybolt universal (SSU) depending, respectively, upon whether metric, English, or commercial units are used. In most liquids, viscosity drops appreciably as the temperature is raised. Since little change of viscosity with fluctuations in temperature is desirable to keep variations in friction at a minimum, fluids frequently are rated in terms of viscosity

index. The less the viscosity is changed by temperature, the higher the viscosity index.

**Pour point.** The pour point, or the temperature at which a lubricant ceases to flow, is of importance in appraising flow properties at low temperature. As such, the pour point can become the determining factor in selecting one lubricant from among a group with otherwise identical properties.

**Flash point.** The flash point, or the temperature at which a lubricant momentarily flashes in the presence of a test flame, aids in evaluating fire-resistance properties. Like the pour point factor, the flash point may in some instances become the major consideration in selecting the proper lubricant, especially in lubricating machinery handling highly flammable material.

**Oiliness.** Oiliness generally connotes relative ability to operate under boundary lubrication conditions. The term relates to a lubricant's tendency to wet and adhere to a surface. There is no formal test for the measurement of oiliness; determination of this factor is chiefly through subjective judgment and experience. Animal and vegetable oils and fatty acids are considered to be high in oiliness. The most desirable lubricant for a specific use need not necessarily be the oiliest; *i.e.*, long-fibre grease, which is low in oiliness as compared with machine oils, is usually preferable for packing rolling bearings.

**Neutralization number.** The neutralization number is a measure of the acid or alkaline content of new oils and an indicator of the degree of oxidation degradation of used oils. This value is ascertained by titration, a standard analytical chemical technique, and is defined as the number of milligrams of potassium hydroxide required to neutralize one gram of the lubricant.

**Penetration number.** The penetration number, applied to grease, is a measure of the film characteristics of the grease. The test consists of dropping a standard cone into the sample of grease being tested. Gradations indicate the depth of penetration: the higher the number, the more fluid the grease.

**Other properties.** Measurements of other properties have been designed to determine chlorine content, dielectric constant, specific gravity, and interfacial tension as well as to evaluate corrosion, emulsion, foaming, oxidizing, carbonizing, and saponification characteristics.

**Additives.** Additives in lubricants (1) limit chemical change or deterioration of the lubricant, (2) protect a machine from harmful deposits or from failure of the lubricant to function properly, and (3) improve existing physical properties of the lubricant or impart new characteristics to it. There are two general classes of additives: those that affect physical properties such as the pour point and those that affect chemical characteristics such as detergency. Table 4 lists the more common additive materials and their principal functions.

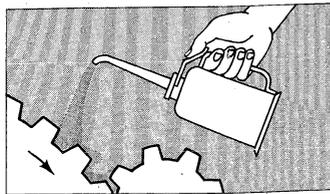

Table 4: Common Lubricant Additives

additive purpose	typical material used
Oxidation inhibitor	zinc dithiophosphate
Corrosion inhibitor	zinc dithiophosphate
Antiwear improver	tricresyl phosphate
Detergent dispersant	soap of sulfonic acid
Rust inhibitor	metallic soaps
Pour depressant	polymers of methacrylic acid esters
Viscosity-index improver	acrylate polymers
Oiliness agent	fatty oils
Film-strength improver	chlorine compounds
Antifoam agent	silicone polymers
Emulsifier	soaps of fatty acids
Thickening agent	soaps, fine clay
Water repellent	organic silicone polymers
Colour stabilizer	aliphatic amines
Odour-control agent	formaldehyde polymers
Antiseptic	phenol

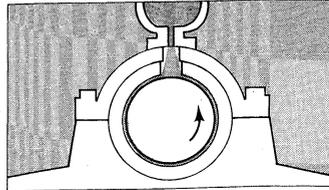

#### METHODS OF APPLYING LUBRICANTS

To control friction and wear, a lubricant must reach the sliding surfaces when and as needed. It may be applied manually or automatically in association with machine operation. The main methods of application are shown below.

#### Methods of applying lubrication.

From J.J. O'Connor and John Boyd (eds.), *Standard Handbook of Lubrication Engineering*, copyright 1968; used with permission of McGraw-Hill Book Company

In drop-feed lubrication, oil is supplied by gravity; in both splash and oil-ring lubrication, oil is picked up from a reservoir by contact with a moving surface. In waste-type lubrication, capillary action of oil in a fibrous material transfers oil from a reservoir to the sliding surfaces. Force-feed lubrication utilizes a pump to supply lubricant under pressure. If the pump furnishes oil to more than one point, the arrangement constitutes a centralized lubrication system; if the used lubricant is returned to the pump, it is classed as a pressure circulating system. In air-oil-mist lubrication, atomizing action of a liquid in a stream of air is used to pick up and transport the lubricant. In built-in lubrication, moving parts are lubricated in such a way that an external source of lubricant is not necessary. This can be done by supplying the sliding surfaces with a quantity of lubricant that is sealed against loss, as in sealed ball bearings, or by treating the parts with an adhesive coating containing solid lubricant. It also can be accomplished by making the sliding surfaces from porous materials impregnated with lubricant, as in "oilless" bearings, or by constructing the surfaces from self-lubricating materials.

The countries and regions that are the major world producers of lubricating oils are listed in Table 5.

**Table 5: World Production of Lubricating Oils**  
(in 000 metric tons)

major producers	1960	1970
Africa	...	180

## Lucian

The writings of Lucian, a Greek rhetorician, pamphleteer, and satirist of the 2nd century AD, are outstanding for their mordant and malicious wit, embodying a sophisticated and often embittered critique of the shams and follies of the literature, philosophy, and intellectual life of his day—which has been called the Golden Age of the Roman Empire. Lucian's sharply critical mind was, however, largely destructive and could suggest no new values to put in place of those that he attacked as outworn. Thus, ill at ease in a pretentious and superstitious world, he was condemned to a sterile pessimism. The only thing that had real value in his eyes and that provided him with a standard of judgment was classical Greek literature. In this turning toward a half-imaginary past Lucian was at one with his age. His own classicizing style served as a model for writers of the later Roman Empire and for the Byzantine period. He was the favourite Greek writer of the important 16th-century French comic and satirical writer François Rabelais and so has in turn influenced the development of European satire through such writers as Jonathan Swift, Henry Fielding, Cyrano de Bergerac, Voltaire, and Giacomo Leopardi. Today he interests the student of ideas as much as the student of literature.

One is entirely dependent on Lucian's writings for information about his life, but he says little about himself and not all that he says is to be taken seriously. Moreover, since the chronology of his works is very obscure, the events of his life can only be reconstructed in broad outline, and the order and dating of these events are matters of probability rather than certainty.

Lucian was born c. AD 120 in Samosata (the modern Samsat, in Turkey), formerly the capital of the kingdom of Commagene, which since AD 72 had been part of the Roman province of Syria. His mother's family had, for generations, been monumental sculptors, and his father's family were probably also artisans. Therefore, they would have been comfortably off, but not rich. They must have been strangers alike to political power in the city and to Greek culture, for the language of the people was Aramaic, though for centuries the upper classes had spoken Greek, the official tongue of the city. As a boy Lucian showed a talent for making clay models and was therefore apprenticed to his uncle, a sculptor. They quarrelled, and Lucian soon left home for western Asia Minor, in whose cities he acquired a Greek literary education.

So successfully did he master a new language and culture that he began a career as a public speaker, travelling from city to city giving model speeches to display his elo-

Career as a speaker

Built-in lubrication

quence, public lectures (much as a modern musician gives concerts), and probably also pleading in court. After a tour of Greece he went on to Italy and Gaul (modern France), where there was at the time an eager, if not always discriminating, public for Greek oratory. To this period of his life belong many of his surviving declamations on mythological and other stock themes (*Phalaris*, *The Tyrannicide*, *Hippias*, *In Praise of the Fly*) and rhetorical prologues (including *Herodotus* and *The Scythian*). Lucian was evidently successful in a profession that conferred much prestige and often great influence on its leading practitioners. He won the friendship of distinguished Romans, senators, and provincial governors and became well-known in literary circles throughout the empire. Doubtless he earned a comfortable fortune, too. He never seems, however, to have reached the first rank in his profession. Philostratus, who wrote biographies of the leading rhetoricians of the age, never mentioned him.

It may have been disillusion with the emptiness of his career that led him to give up his wandering life and settle in Athens in the late 50s of the 2nd century. From there he attended the Olympic Games of 157, doubtless as a public speaker. In Athens, then a centre of higher studies, he was able to extend his knowledge of Greek literature and thought far beyond anything required of a rhetorician. As well as Attic comedy and classical and Hellenistic philosophy, he read the satirical pamphlets and lampoons of the 3rd-century-BC Cynic philosopher Menippus of Gadara (a fellow Syrian), which deeply impressed him. In this early Athenian period Lucian gave up public speaking and took to writing critical and satirical essays on the intellectual life of his time, either in the form of dialogues or, in imitation of Menippus, in a mixture of prose and verse. To this period probably belong such works as *Nigrinus*, *Dialogues of the Gods* and *Dialogues of the Dead* (two of his best known works, the one making fun of aspects of Greek mythology and the other a grimly ironic revelation of the vanities of men while they are alive), *Dialogues of Courtesans*, *Prometheus*, *Charon*, *Zeus Confuted*, and *The Tragic Zeus*. Lucian's writings apparently sustained the reputation he had won as a public speaker. He attracted the attention of the emperor Verus, whose mistress Panthea he flattered in his *Imagines*. He probably accompanied Verus to Antioch in 162 when the Emperor went to take the field against the Parthians. At any rate, he spent some years in Antioch about this time. From there he made a return visit to his native Samosata, where, to an admiring audience of his fellow townsmen, he delivered a speech on his own career, *The Dream* (also known as *The Vision*). In view of the threatening military situation he decided to take his father back to Athens with him. They probably crossed Asia Minor and sailed westward from Amastris (Amasra). During this journey Lucian met the popular magician and wonder-worker Alexander of Abonouteichos (the modern Inebolu), a charlatan whom he depicted brilliantly in *Alexander*; or *The False Prophet*. Another whose acquaintance he made at this time was a convert from Christianity, the Cynic philosopher Peregrinus, his fellow passenger from the Troad (the district close by the city of Troy in Asia Minor) to Athens. Returning to Athens, Lucian visited the Olympic Games of 165, at which Peregrinus committed suicide by setting fire to himself. A few years later Lucian testified to the impression that the man and his macabre end had made upon him with his discerning, if somewhat malicious, *Death of Peregrinus*. He seems to have remained in Athens writing for some years and visited the Olympic Games again in 169. To this period probably belong such works as *Timon*, *The Assembly of the Gods*, *Twice Accused*, *The Auction of Lives*, and *How to Write History*, a penetrating and amusing critique provoked by the spate of panegyric histories of Verus' Parthian campaign. He began, however, to grow dissatisfied with his life at Athens, where his biting wit no doubt made him many enemies. Thanks to the patronage of his Roman friends—perhaps in particular Gaius Calvisius Statianus, prefect of Egypt from 170 to 175—he obtained a post in Alexandria as *archistator*, a kind of chief court usher. The appointment

was one normally given to members of the equestrian order (next in rank below senators) who had held several military commands. It carried a substantial salary and could have been the prelude to a career in the higher ranks of the civil service, but Lucian was already too old to begin a new career and was temperamentally unfitted to be a functionary. For him it was an escape. During his years in Egypt he probably wrote his *Apology*, *On His Failure to Give Greetings*, and other works. After some years he returned to Athens and took up public speaking again. (It may be that he lost his post in the purge that followed the revolt of Avidius Cassius in 175.) Works written during this second Athenian period include *Lexiphanes*, *The Eunuch*, *The False Sophist*, and *Hercules*. He was married and had one son, born late in his life. Lucian died some time after 180.

Lucian's works were doubtless published one by one. In late antiquity an unknown editor prepared a collected edition of such works as he could find, and this is the ancestor of the medieval Lucian manuscripts. The oldest of these was written down in 913, and several others also belong to the 10th century. They contain a corpus of 83 works, of which a few are spurious.

## Lucretius

Titus Lucretius Carus was a Latin poet and philosopher of the earlier half of the 1st century BC, whose single, long poem, *De rerum natura* (Eng. trans., *On the Nature of Things*, 1947), rendered in hexameters the atomic theory of Epicurus, the founder of a Greek school of moralists. Its declared purpose was to free mankind from religious fears by proving that the soul is material and is born and dies with the body and that, though gods exist, they cannot intervene to help or harm men.

**Life and death.** Apart from Lucretius' poem almost nothing is known about him. What little evidence there is, is quite inconclusive. Jerome, a leading Latin Church Father, in his chronicle for the year 94 BC (or possibly 96 or 93 BC), stated that Lucretius was born in that year and that years afterward a love potion drove him insane; and in lucid intervals having written some books, which Cicero afterward emended, he killed himself in his 44th year (51 or 50 BC). Aelius Donatus, a grammarian and teacher of rhetoric, in his "Life" of Virgil noticed that Virgil put on the *toga virilis* (the toga of an adult) in his 17th year, on his birthday (i.e., 54 or 53 BC), and that Lucretius died that same day. But Donatus contradicted himself by stating that the consuls that year were the same as in the year of Virgil's birth (i.e., Crassus and Pompey, in 55 BC). This last date seems partly confirmed by a sentence in Cicero's reply to his brother in 54 BC (*Ad Quintum fratrem* 2, 9, 3), which suggests that Lucretius was already dead and also that Cicero may have been involved in the publication of his poem: "The poems of Lucretius are as you write in your letter—they have many highlights of genius, yet also much artistry." Excepting the single mention in Cicero, the only contemporary who named Lucretius was a Roman historian, Cornelius Nepos (*Atticus* 12, 4), in the phrase "after the death of Lucretius and Catullus," and the only contemporary

The medieval manuscripts

Best known works

Allusions to Lucretius by his contemporaries

whom Lucretius named was one Memmius, to whom he dedicated his poem, probably Gaius Memmius (son-in-law of Sulla, praetor of 58 BC, and patron of Catullus and Gaius Helvius Cinna), for whose friendship Lucretius "hopes."

**Philosophical content of "De rerum natura."** The title of Lucretius' work translates that of the chief work of Epicurus, *Peri physeōs* (*On Nature*), as also of the didactic epic of Empedocles, a pluralist philosopher of nature, of whom Lucretius spoke with admiration only less than that with which he praised his master Epicurus. The poem is the fullest extant statement of the physical theory of Epicurus, and it also alludes to his ethical and logical doctrines.

**Structure of the poem.** Lucretius distributed his argument into six books, beginning each with a highly polished introduction. Books I and II established the main principles of the atomic universe, refuted the rival theories of the pre-Socratic cosmic philosophers Heraclitus, Empedocles, and Anaxagoras, and covertly attacked the Stoics, a school of moralists rivalling that of Epicurus. Book III demonstrated the atomic structure and mortality of the soul and ended with a triumphant sermon on the theme "Death is nothing to us." Book IV described the mechanics of sense perception, thought, and certain bodily functions and condemned sexual passion. Book V described the creation and working of this world and the celestial bodies and the evolution of life and human society. Book VI explained remarkable phenomena of the Earth and sky, in particular, thunder and lightning. The poem ends with a description of the plague at Athens, a sombre picture of death contrasting with that of spring and birth in the invocation to Venus, with which it opened.

**Argument of the poem.** The argument in outline is as follows:

1. No thing is either created out of or reducible to nothing. The universe has an infinite extent of empty space (or void) and an infinite number of irreducible particles of matter (or atoms)—though their kinds are finite. Atoms differ only in shape, size, and weight and are impenetrably hard, changeless, everlasting, the limit of physical division. They are made up of inseparable minimal parts, or units. Larger atoms have more such parts; but even the larger are minute. All atoms would have moved everlastingly downward in infinite space and never have collided to form atomic systems had they not swerved at times to a minimal degree. To these indeterminate swerves is due the creation of an infinite plurality of worlds; they also interrupt the causal chain and so make room for free will. All things are ultimately systems of moving atoms, separated by greater or smaller intervals of void, which cohere more or less according to their shapes. All systems are divisible and therefore perishable (except the gods), and all change is explainable in terms of the addition, subtraction, or rearrangement of changeless atoms.

2. The soul is made of exceedingly fine atoms and has two connected parts: the *anima* distributed throughout the body, which is the cause of sensation, and the *animus* in the breast, the central consciousness. The soul is born and grows with the body, and at death it is dissipated like "smoke."

3. Though the gods exist, they neither made nor manipulate the world. As systems of exceedingly fine atoms, they live remote, unconcerned with human affairs, examples to men of the ideal life of perfect happiness (absence of mental fear, emotional turmoil, and bodily pain).

4. Men know by sense perception and argue by reason according to certain rules. Though the senses are infallible, reason can make false inferences. Objects can be seen because they discharge from their surface representative films, which strike the eye just as smells strike the nose. Separate atoms are in principle imperceptible, having no dischargeable parts. The senses perceive the properties and accidents of bodies; reason infers the atoms and the void, which exists to explain the perceived movement of bodies.

5. Men naturally seek pleasure and avoid pain. Their aim should be so to conduct their lives that they get, on

balance, the maximum of pleasure and the minimum of pain. They will succeed in this only if they are able, through philosophy, to overcome the fear of death and of the gods.

**Literary qualities of "De rerum natura."** The linguistic style and spirit of the poem are notable. The problem of Lucretius was to render the bald and abstract Greek prose of Epicurus into Latin hexameters at a time when Latin had no philosophic vocabulary. He succeeded by applying common words to a technical use. Thus, he used *concilium* ("assembly of people") for a "system of atoms" and *primordia* ("first weavings") for the "atoms" that make up the texture of things. When necessary, he invented words. In poetic diction and style he was in debt to the older Latin poets, especially to Quintus Ennius, the father of Roman poetry. He freely used alliteration and assonance, solemn and often metrically convenient archaic forms, and old constructions. He formed expressive compound adjectives of a sort rejected by Augustan taste; e.g., "the light-sleeping hearts of dogs," "forest-breaking winds." He imitated or echoed Homer; the dramatists Aeschylus and Euripides; Callimachus, a poet and critic; the historian Thucydides; and the physician Hippocrates. His hexameters stand halfway between those of Ennius, who introduced the metre into Latin, and Virgil, who perfected it. There is also some incoherence of rhythm, as well as harsh elisions and examples of unusual prosody.

The influence of Lucretius on Virgil was pervasive, especially in Virgil's *Georgics*; and it is in clear allusion to Lucretius that Virgil wrote "Happy is the man who can read the causes of things" (*Georgics* II, 490).

Lucretius spoke in austere compassion for the ignorant, unhappy human race. His moral fervour expressed itself in gratitude to Epicurus and in hatred of the seers who inculcated religious fears by threats of eternal punishment after death, of the Etruscan soothsayers with their lore of thunder and lightning, of the false philosophers—Stoics with their belief in divine providence or Platonists and Pythagoreans who taught the transmigration of immortal souls. The first appearance of *religio* in the poem is as a monster that thrusts its fearful head from the regions of the sky. Epicurus, not intimidated by these spectres, had ranged beyond the "flaming ramparts of the world" through the infinite universe, broken into the citadel of nature, and brought back in triumph the knowledge of what can and what cannot be, of that "deep-set boundary stone" that divides the separate properties of things, the real from the not real. And "so religion is crushed beneath our feet and his [Epicurus'] victory lifts us to the skies."

**BIBLIOGRAPHY.** *De Rerum Natura*, ed., with prolegomena, critical apparatus, translation, and commentary by CYRIL BAILEY, 3 vol. (1947, reprinted 1963), the most authoritative text, translation, and commentary currently available; PIERRE BOYANCE, *Lucrece et l'Épicurisme* (1963), a comprehensive and well-balanced account of the author, subject matter, and literary form of the *De rerum natura*; D.R. DUDLEY (ed.), *Lucretius* (1965), a collection of essays by eminent scholars on various aspects of the poem; RICHARD MINADEO, *The Lyre of Science: Form and Meaning in Lucretius' De Rerum Natura* (1969), a demonstration of how the formal design of the poem is derived from the cycle of creation and destruction; DAVID WEST, *The Imagery and Poetry of Lucretius* (1969), a perceptive study of the sources of Lucretius' images and their importance in the poem.

### Ludendorff, Erich

Among the great number of able chiefs of staff of the German Army during World War I, one man, Gen. Erich Ludendorff, distinguished himself through his exceptional gift of strategic planning. Always under the patronage of the elderly Field Marshal Paul von Hindenburg, he directed from 1914 to 1916 the campaign against Russia, and from 1916 to 1918, as "first quartermaster general," he determined the decisions of the supreme command.

His opponents—above all, the French generals—regarded him as the most effective strategist on the German

Theory of  
"total war"

side. Consistently pursuing a purely military line of thought, Ludendorff developed, after the war, the theory of "total war," which in 1935 he published in a book bearing this title. In the first half of the 19th century, the great military theorist of the Prussian general staff, Carl von Clausewitz, had advanced the doctrine of war as an extension of politics with different means. Ludendorff advocated the diametrically opposite view that politics should serve the conduct of war, for which the entire physical and moral forces of the nation should be mobilized, because, according to him, peace was merely an interval between wars. He appears as an "anti-Clausewitz."

Ludendorff was born on April 9, 1865, in Kruszewnia, in Prussian Poland, the son of an impoverished landowner and cavalry captain. His mother was a member of an aristocratic military family. Ludendorff was educated in the cadet corps, became an infantry officer, and, because of his outstanding military qualities, was soon promoted to the general staff.

In 1908 he was put in charge of the 2nd (German) department in the army general staff, the institution generally known as the "great general staff," which was responsible for preparing contingency employment and mobilization plans. Under the chief of the general staff, Gen. Helmuth von Moltke, Ludendorff played a significant part in the revision of the Schlieffen Plan. This plan envisaged a gigantic outflanking movement involving the infringement of Belgian neutrality with the aim of crushing France with one blow. Moltke and Ludendorff decided to secure more firmly the extended southern flank between Switzerland and Lorraine. They also discarded the idea of forcing a way through southern Holland and instead made preparations for the surprise capture of Liège, the most important fortress in eastern Belgium, often characterized as "impregnable."

In Germany, supreme political and military power was traditionally wielded by the commander in chief and the emperor, and general staff officers were not expected to engage in politics. Ludendorff, however, violated this tradition by campaigning for a strengthening of the army, both in personnel and equipment, which the general staff considered essential in view of the general armaments race in Europe. His contact with extreme nationalist political circles favouring increased armament convinced him that, if policy was influenced by "strong men," a vigorous conduct of war was assured.

The excessively active departmental chief irritated the military authorities, and in 1913 Ludendorff was transferred to the infantry as regimental commander. When war broke out in 1914, he was appointed quartermaster in chief (supply and maintenance) of the 2nd Army in the west.

It was not until two Russian armies in August 1914 threatened to overrun the German 8th Army in East

Prussia that Ludendorff was appointed chief of staff of the 8th Army. Ludendorff, dynamic but occasionally harsh and in times of crisis often nervous, was assigned to the elderly Gen. Paul von Hindenburg, who was renowned for his iron nerves. Ludendorff regarded the problems with which he and his commander in chief were faced as difficult but never insoluble.

The spectacular victory of Hindenburg and Ludendorff over the Russians in August 1914 at Tannenberg, in East Prussia, a battle that brought Hindenburg worldwide fame, was followed by the German defeat on the Marne in the west that signalled the failure of Ludendorff's revised Schlieffen Plan. For two years Hindenburg and Ludendorff fought the Russians in the east. Ludendorff's plan of a general offensive against Russia by means of a temporary reduction of the German forces in the west was not approved by the supreme army command in the summer of 1915.

Only in August 1916, after the failure of the German offensive at Verdun and in view of the allied onslaught in both east and west, did the Emperor finally appoint the two generals to assume supreme military control. They attempted to conduct a sort of total war by mobilizing the entire forces of the home front, which was already suffering from the effects of the British blockade. Ludendorff staked everything on a single card, the stubborn pursuit of a "victorious peace" that was to secure German territorial gains in east and west. In 1917 he approved the unrestricted submarine warfare against the British that led to the entry of the United States into the war against Germany but not to England's collapse. After the Tsar had been deposed in March 1917, Ludendorff gave his blessing to the return of the Russian Bolshevik emigrants (including the as yet unknown Lenin), in the hope of persuading the Russians to conclude peace. Hindenburg and Ludendorff, who now exercised a sort of military semi-dictatorship, also brought about the dismissal of Chancellor Theobald von Bethmann Hollweg in the delusory hope that "a strong man" could be found to assume the leadership of the *Reich*.

On March 21, 1918, Ludendorff opened a general offensive on the Western Front with the object of smashing the Anglo-French armies and forcing a decision in Europe before the Americans landed. But he had overestimated the strength of the German armies; the offensive failed, and, when in the autumn of 1918 the collapse of the German allies—Austria-Hungary, Bulgaria, and Turkey—was imminent, Ludendorff demanded immediate negotiations for an armistice. For a while, the nerves of the hopelessly overworked general gave way, and a psychiatrist had to be summoned to supreme headquarters. When Ludendorff realized the severity of the armistice conditions, he insisted that the war be carried on. When he saw that the political leaders were not prepared to do this, he offered his resignation, which William II accepted on October 26, 1918. At the same time, the Emperor, much to Ludendorff's distaste, ordered Hindenburg to remain at his post. A titan of willpower and energy who had attempted the impossible was suddenly torn away from his sphere of activity; the shock was immense. Ludendorff met the revolution that broke out in November 1918 with complete resignation and went into exile in Sweden for several months.

While, according to Prussian custom, general staff officers were jointly responsible for all decisions, they had to preserve strict anonymity. Ludendorff, however, whose ambition was as immense as his strategic gifts, at the end of the lost war claimed to have been the sole real "commander" of World War I. He asserted that he had been deprived of victory by sinister forces operating behind the scene; he was, he claimed, like Siegfried in the heroic Germanic sagas, a victim of a stab in the back. By propagating the legend that the German Army, undefeated in the field, was sabotaged by the "home front," he did much to poison public life in the Weimar Republic.

During the next 20 years Ludendorff led a bizarre life. Adopting the role of the betrayed and misunderstood commander, he took part in the unsuccessful coups d'état of Wolfgang Kapp in 1920 and of Hitler in 1923, and in

1925 he ran for president against his former commander in chief, Hindenburg, whom he now bitterly hated. From 1924 to 1928 he was a National Socialist member of parliament.

Ludendorff had always had a weakness for the female sex; his first wife, a striking beauty, divorced her husband in order to marry Ludendorff. In 1926, however, he insisted on dissolving this marriage and married the neurologist and popular philosopher Mathilde von Kemnitz. Ludendorff succumbed completely to this eccentric woman, who regarded him as the real "commander in chief" of the Germans and had developed a belief in the activities of "supernatural powers"—Jewry, Christianity, Freemasonry. From then on he joined with his second wife in fighting against these imaginary foes who were supposed to have deprived him and Germany of victory. Both preached a German "divine faith." Over this faith he quarrelled both with the old officer corps and with Hitler and his National Socialists. Just as he had not permitted the Emperor to make him a count, he now forbade Hitler to promote him to field marshal. Apart from a group of fanatical followers, he was henceforth completely isolated. When, during the 1930s, he began to utter warnings against Hitler's tyranny, he found no echo. He died on December 20, 1937, in Tutzling. Many old soldiers mourned him, but most of them had long ceased to understand him.

**BIBLIOGRAPHY.** Among Ludendorff's memoirs and studies are *Meine Kriegserinnerungen, 1914–1918* (1919; Eng. trans., *My War Memoirs, 1914–1918*, 2 vol., 1919); *Mein militärischer Werdegang* (1933); *Kriegführung und Politik*, 2nd ed. (1922); and *Der Totale Krieg* (1935; Eng. trans., *The Nation at War*, 1936). JOHN W. WHEELER-BENNETT, "Ludendorff: The Soldier and the Politician," *Virginia Quarterly Review*, 14: 187–202 (1938); and D.J. GOODSPEED, *Ludendorff* (1966), contain some critical views. See also WALTER GOERLITZ, *Der deutsche Generalstab: Geschichte und Gestalt*, 2nd ed. (1953; Eng. trans., *History of the German General Staff, 1657–1945*, 1953).

## Lugard, Lord

Frederick John Dealtry Lugard, later Lord Lugard, played a major part in Britain's colonial history between 1888 and 1945 in the opening up of Africa, in the administration of Nigeria, and, finally, as a national and international figure in colonial affairs.

Born in Madras, India, on January 22, 1858, of missionary parents, he was educated in England and after briefly attending the Royal Military Academy, Sandhurst, joined the Norfolk Regiment. Posted to India and swept into the British imperial advance of the 1880s, he served in the Afghan, Suakin (Sudan), and Burma campaigns. An officer with a promising career ahead of him in British India, he experienced a catastrophic love affair with a married woman. Highly strung and undermined by Bur-

Lugard, painting by W.J. Carrow, 1936. In the National Portrait Gallery, London.

ma fever, he sought oblivion by following the explorer David Livingstone's lead in fighting Arab slave raiders in eastern Africa. In 1888 he was severely wounded while leading an attack upon a slaver's stockade near Lake Nyasa. But he had found his life's work in service for Africa and for Britain—work that he saw as having a mutually beneficial purpose.

His next enterprise was under the imperial British East Africa Company, one of the chartered companies that preceded imperial annexation in Africa. Leaving Mombasa in August 1890, he led a caravan for five months along an almost untrodden route of 800 miles (1,300 kilometres) to the advanced kingdom of Buganda. Here he found a complex struggle going on among pagans, Muslims, Protestants, and Roman Catholics—the latter two groups converted by British and French missionaries who had reached Buganda earlier by a southern route—and the nominal king, or *kabaka*. Within 18 months—not without a brief use of his one operative Maxim gun—Lugard imposed peace, carried out an immense march to the west, and won a treaty of allegiance from the Kabaka. Hearing that his company meant to abandon Uganda because of mounting expenses, he hurriedly returned to England to fight a successful two-pronged campaign to defend, first, the retention of Uganda plus imperial annexation, and, second, his own reputation against accusations of harshness and injustice.

In 1894–95 Lugard accepted another dangerous mission, this time for the Royal Niger Company, to race the French in a treaty-making exploration on the Middle Niger. He succeeded in that enterprise in spite of great hardships—including a poisoned arrow in his head. From the Niger he went, again at some risk to his life, to the semidesert of the Bechuanaland Protectorate for the private British West Charterland Company, which was prospecting for diamonds. There he was tracked down by a runner sent by the colonial secretary, Joseph Chamberlain, who was offering him his first official government appointment. He was to create a British-officered African regiment that he was to employ in a second attempt to fend off the French, who then were competing with the British right across Africa from the Niger to the Nile. This was to become the famous West African Frontier Force. Lugard's success in this difficult undertaking led to his appointment as high commissioner for Northern Nigeria.

Most of this vast region of 300,000 square miles (800,000 square kilometres) was still unoccupied and even unexplored by Europeans. In the south were pagan tribes and in the north, historic Muslim city-states with large walled cities whose emirs raided the tribal territories to the south for slaves. In three years, by diplomacy or the swift use of his small force, Lugard established British control, though in hastening to take the major states of Kano and Sokoto he forced the hands of his more cautious home government. Only two serious local revolts marred the widespread acceptance and cooperation that Lugard obtained. His policy was to support the native states and chieftainships, their laws and their courts, forbidding slave raiding and cruel punishments and exercising control centrally through the native rulers. This system, cooperative in spirit and economical in staff and expense, he elaborated in his detailed political memorandums. It greatly influenced British administration in Africa and beyond. Though sometimes misapplied or overprolonged, it helped to bridge the gap between tribal systems and the new movements toward democracy and unity. Lugard's main fault as an administrator was an unwillingness to delegate responsibility, but the variety of the conditions and the vast distances acted as a check on this fault. If some of his officers were critical, the majority greatly respected their chief, and a number of "Lugard's men" went on to govern other territories in Africa.

In 1902 Lugard married Flora Shaw, a beautiful and famous woman, herself a great traveller, an authority upon colonial policy, and a member of the staff of *The Times* of London. A very deep devotion and partnership grew up between them. As she could not stand the Nigerian climate, Lugard felt obliged to leave Africa and to accept the governorship of Hong Kong, which he held

Early  
colonial  
career

High  
commissioner  
for  
Northern  
Nigeria

from 1907 to 1912. No greater contrast could be imagined than that between the vast untamed expanse of Northern Nigeria and the small island of Hong Kong with its highly civilized Chinese and sophisticated commercial British community. But the bushwhacker from Africa achieved a surprising degree of success and, on his own initiative, founded the University of Hong Kong.

Unification  
of  
Nigeria

He could not, however, resist the great opportunity offered to him in 1912 to unite the two parts of Nigeria into one vast state. The south and north showed wide contrasts in their original character and in their traditions of British rule. It was an immense task to unify their administration. Lugard did not attempt a complete fusion of their systems and retained a degree of dualism between south and north. He found the south, especially the sophisticated Africans of Lagos and the southeast, less easy to understand than the northerners; and in 1918 he had to deal with a serious outbreak in the important city-state of Abeokuta. Nor did he find it easy to extend the principles of indirect rule to the loosely organized societies of the Ibo and other southeastern tribes. His tenure of office also was made more difficult by World War I, with its interruption of communications, its resultant shortages of staff, and the war with the Germans in the Cameroons along his eastern frontier. Yet, in the main, Lugard carried through an immense task of unification, which was officially declared on January 1, 1914. Historians must judge the event by the decision of the Nigerians to obtain their independence in 1960 as a united state and to defend it against the attempted Ibo secession to set up an independent state, Biafra, in the late 1960s.

Years as an  
elder  
statesman

In 1919 he retired, but only to a life of unceasing activity in his role as the leading authority on colonial government. He wrote his classic *Dual Mandate in British Tropical Africa*, published in 1922. In 1928 he became Baron Lugard of Abinger and spoke with authority in the House of Lords on colonial subjects. He became British member of the Permanent Mandates Commission and of the International Committees on Slavery and Forced Labour and chairman of the International Institute of African Languages and Cultures. To the end of his life, deeply saddened by the death of his wife in 1929, he worked almost incessantly in his secluded house on a survey of matters affecting the interests of native races both inside and outside the British Empire.

Though to modern critics of colonialism there may seem much to criticize in his ideas and actions, there can be no questioning the great range and effectiveness of the three periods of his work: in the opening up of Africa, in its government at a most formative stage in its history; and as elder statesman working during his so-called retirement almost up to his death at Abinger, Surrey, on April 11, 1945.

**BIBLIOGRAPHY.** MARGERY PERHAM, *Lugard*, vol. 1, *The Years of Adventure, 1858-1898* (1956), vol. 2, *The Years of Authority, 1898-1945* (1960), is a major study, based upon Lugard's own voluminous papers, official sources, upon the writer's travels and researches in the African regions where Lugard operated, and upon a close association between the author and Lugard during the last 15 years of his life. While not uncritical in parts, it is, in the main, a favourable as well as an intimate and lively portrayal. The same author's *Native Administration in Nigeria* (1937, reprinted 1962), gives the longer background against which Lugard's work can be set; *Lugard: The Dual Mandate in British Tropical Africa*, 5th ed. (1965), the classic book on the subject for its period, sets Lugard's own experience against a wider background. See also *The Diaries of Lord Lugard*, ed. by MARGERY PERHAM and M. BULL, 3 vol. (1959). C.L. TEMPLE, *Native Races and Their Rulers*, 2nd. ed. (1968); and C.W.J. ORR, *The Making of Northern Nigeria* (1911), books by two of Lugard's senior officials, reflect contrasting views. D.J.M. MUFFETT, *Concerning Brave Captains* (1964); and I.F. NICHOLSON, *The Administration of Nigeria, 1900-1960* (1969), also by officials who served in Nigeria, represent a reaction against the almost universal approval of Lugard's achievements in Nigeria. They reflect the later, more critical attitude to colonialism. Other studies include A.H.M. KIRK-GREENE, *The Principles of Native Administration in Nigeria: Selected Documents, 1900-1947* (1965) and *Lugard and the Amalgamation of Nigeria* (1968).

(M.Pm.)

## Luke, Saint

St. Luke, in Christian tradition, is the author of the third Gospel and the Acts of the Apostles, a companion of St. Paul, and the most literary of New Testament writers.

Luke is first mentioned in the letters of the Apostle Paul as the latter's "co-worker" and as the "beloved physician." The former designation is the more significant one, for it identifies him as one of a professional cadre of itinerant Christian "workers," many of whom were teachers and preachers. His medical skills, like Paul's tentmaking, may have contributed to his livelihood; but his principal occupation was the advancement of the Christian mission.

Details  
of Luke's  
life

By courtesy of the Kunsthistorisches Museum, Vienna

St. Luke drawing a picture of the Virgin, detail of a painting by Jan Gossaert, called *Mabuse* (d. c. 1533). In the Kunsthistorisches Museum, Vienna.

If Luke was the author of the third Gospel and the Acts of the Apostles, as is very probable, the course and nature of his ministry may be sketched in more detail. He excludes himself from those who were eyewitnesses of Christ's ministry. His participation in the Pauline mission, however, is indicated by the use of the first person in the so-called "we" sections of Acts. They reveal that Luke shared in instructing persons in the Christian message and possibly in performing miraculous healings.

The "we" sections are analogous to the style of travel reports found elsewhere in writings of the Greco-Roman period. They place the author with St. Paul during his initial mission into Greece; that is, as far as Philippi, in Macedonia (c. AD 51). At that place also Luke later rejoins Paul and accompanies him on his final journey to Jerusalem (c. AD 58). After Paul's arrest in that city and during his extended detention in nearby Caesarea, Luke may have spent considerable time in Palestine working with the Apostle as the occasion allowed and gathering materials for his future two-volume literary work, the Gospel and the Acts. In any case, two years later he appears with Paul on his prison voyage from Caesarea to Rome and again, according to II Tim. 4:11, at the time of the Apostle's martyrdom in the imperial city (c. AD 66). Further direct information about Luke is scanty in the New Testament, but certain inferences may be drawn. The literary style of his writings and the range of his vocabulary mark him as an educated man. The distinction drawn between Luke and other colleagues "of the circumcision" (Col. 4:11) has caused many scholars to conclude that he was a Gentile. If so, he would be the

only New Testament writer clearly identifiable as a non-Jew. This conclusion, however, rests upon a doubtful equation of those "of the circumcision" with Jewish Christians. Actually, the phrase probably refers to a particular type of Jewish Christian, those who strictly observed the rituals of Judaism. It offers no support, therefore, to the view that Luke was a Gentile. His intimate knowledge of the Old Testament and the focus of interest in his writings favour, on balance, the view that he was a Jewish Christian who followed a Greek life-style and was comparatively lax in ritual observances.

Later traditions about Luke

Writings from the latter half of the second century provide further information. A number of them—St. Irenaeus' *Against Heresies*, the Anti-Marcionite Prologue to the Gospel, and the *Muratorian Canon* listing the books received as sacred by the Christians—identify Luke as the author of the third Gospel and Acts. The Prologue begins:

Luke is a man from Antioch, Syria, a physician by profession. He was a disciple of the apostles, and later he accompanied Paul until his martyrdom. Having neither wife nor child, he served the Lord without distraction. He fell asleep in Boeotia at the age of 84, full of the Holy Spirit. Moved by the Holy Spirit, Luke composed all of this Gospel in the districts around Achaia . . .

The assertion that St. Luke was "a man from Antioch, Syria" who wrote "moved by the Holy Spirit"—that is, as a prophet—receives a measure of support from the Lukan writings: the city of Antioch figures prominently in Acts, and there is a special interest in contemporary (Christian) prophets and prophecy. Whether Luke is to be identified, as some scholars believe, with the prophet Lucius mentioned in Acts 13:1 and with St. Paul's "fellow worker" (and kinsman) in Romans 16:21 is more questionable, although not impossible. Less than certain also is the comment of the prologue placing the writing of the Gospel and Luke's death in Greece; but, on the whole, it is more probable than the later traditions locating his literary work in Alexandria (or Rome) and his death in Bithynia. The identification of St. Luke as "a disciple of the Apostles," although true in a general sense, probably reflects the concern of the 2nd-century church to place all canonical Christian writings under an apostolic umbrella. Later notions that Luke was one of the 70 disciples appointed by the Lord, that he was the companion of Cleopas, and that he was an artist appear to be legendary. In liturgical tradition Luke's feast day is October 18.

Luke's writings

Luke had a cultivated literary background and wrote in good idiomatic Greek. The Gospel bearing his name and the Acts of the Apostles were probably written during or shortly after the Jewish revolt (AD 66–73), although a somewhat later date is not to be excluded. Together they make up more than a fourth of the New Testament, and in them Luke is revealed to be not only Christianity's first historian but also a theologian of unusual perception. Some scholars have also associated Luke with the Pastoral Letters and the Letter to the Hebrews, either as author or as amanuensis, because of linguistic and other similarities with the Gospel and the Acts.

Some scholars, on the other hand, doubt that Luke is in fact the author of the two New Testament books traditionally ascribed to him. In some respects the issue is similar to that raised about the authorship of the works of Shakespeare or, in the classical field, of Plato's letters. But it is unlike the Shakespearean controversy in that no alternative author has been suggested and is unlike the problem of Plato's letters in that no larger Lukan corpus is available for comparison. Those questioning Luke's authorship point to the fact that the theological emphases of his Gospel and the Acts differ considerably from those of Paul's writings and that the description of the Council of Jerusalem (Acts 15) is divergent from the description of the conference in Galatians 2. These objections are based upon the assumption that Luke was the disciple of Paul (and would, therefore, reflect his theology) and upon the traditional identification of Acts 15 with the conference in Galatians 2. Both of these premises, however, are quite probably mistaken. A more serious objection is the difference between the portrait of Paul in Acts

and the impression one receives of him in his letters. But it has sometimes been exaggerated, and it does not in any case exceed the variation that might be expected between a sometime colleague's impressions of a man and the man's own letters. The Gospel and Acts were, in all likelihood, tagged with the name Luke when they were deposited in the library of the author's patron, Theophilus (Luke 1:3). Within a century there was a widespread and undisputed tradition identifying that Luke with an otherwise insignificant physician and colleague of Paul. The tradition is on the whole consistent with the literary and historical character of the documents, and one may be reasonably certain that it is correct.

Jesus' parting words, "It is not for you to know times [of the consummation of this age] . . . but you shall receive power . . . and you shall be my witnesses . . ." (Acts 1:7ff), provide a guideline for Luke's theology. Thus, he called the church back from overeager speculation about the precise time of the Lord's return and the end of the age to its proper task of faithful mission in the lengthening interim. By the selection and interpretation of his sources, he charted the path by which the church would understand both its own uniqueness in the world and also its continuing relationship to Judaism and to the world. His work was no small achievement, and through the centuries it has served the church well.

(E.E.E.)

## Luminescence

Luminescence is the emission of light by certain materials when they are relatively cool. It is in contrast to light emitted from incandescent bodies, such as burning wood or coal, molten iron, and wire heated by an electric current. Luminescence may be seen in neon and fluorescent lamps; television, radar, and X-ray fluoroscope screens; organic substances such as luminol or the luciferins in fireflies and glowworms; certain pigments used in outdoor advertising; and also natural electrical phenomena such as lightning and the aurora borealis. In all these phenomena, light emission does not result from the material being above room temperature, and so luminescence is often called cold light. The practical value of luminescent materials lies in their capacity to transform invisible forms of energy into visible light.

Luminescence emission occurs after an appropriate material has absorbed energy from a source such as ultraviolet or X-ray radiation, electron beams, chemical reactions, and so on. The energy lifts the atoms of the material into an excited state, and then, because excited states are unstable, the material undergoes another transition, back to its unexcited ground state, and the absorbed energy is liberated in the form of either light or heat or both (all discrete energy states, including the ground state, of an atom are defined as quantum states). The excitation involves only the outermost electrons orbiting around the nuclei of the atoms. Luminescence efficiency depends on the degree of transformation of excitation energy into light, and there are relatively few materials that have sufficient luminescence efficiency to be of practical value.

*Luminescence and incandescence.* As mentioned above, luminescence is characterized by electrons undergoing transitions from excited quantum states. The excitation of the luminescent electrons is not connected with appreciable agitations of the atoms that the electrons

Luminescence a quantum process

belong to. When hot materials become luminous and radiate light, a process called incandescence, the atoms of the material are in a high state of agitation. Of course, the atoms of every material are vibrating at room temperature already, but this vibration is just sufficient to produce temperature radiation in the far infrared region of the spectrum. With increasing temperature this radiation shifts into the visible region. On the other hand, at very high temperatures, such as are generated in shock tubes, the collisions of atoms can be so violent that electrons dissociate from the atoms and recombine with them, emitting light: in this case luminescence and incandescence become indistinguishable.

**Luminescent pigments and dyes.** Nonluminescent pigments and dyes exhibit colours because they absorb white light and reflect that part of the spectrum that is complementary to the absorbed light. A small fraction of the absorbed light is transformed into heat, but no appreciable radiation is produced. If, however, an appropriate luminescent pigment absorbs daylight in a special region of its spectrum, it can emit light of a colour different from that of the reflected light. This is the result of electronic processes within the molecule of the dye or pigment by which even ultraviolet light can be transformed to visible—e.g., blue—light. These pigments are used in such diverse ways as in outdoor advertising, blacklight displays, and laundering: in the latter case, a residue of the “brightener” is left in the cloth, not only to reflect white light but also to convert ultraviolet light into blue light, thus offsetting any yellowness and reinforcing the white appearance.

**History of luminescence.** Although lightning, the aurora borealis, and the dim light of glowworms and of fungi have always been known to mankind, the first investigations (1603) of luminescence began with a synthetic material, when Vincenzo Cascariolo, an alchemist and cobbler in Bologna, Italy, heated a mixture of barium sulfate (in the form of barite, heavy spar) and coal; the powder obtained after cooling exhibited a bluish glow at night, and Cascariolo observed that this glow could be restored by exposure of the powder to sunlight. The name *lapis solaris*, or “sunstone,” was given to the material because alchemists at first hoped it would transform baser metals into gold, the symbol for gold being the sun. The pronounced afterglow aroused the interest of many learned men of that period, who gave the material other names, including phosphorus, meaning “light bearer,” which thereafter was applied to any material that glowed in the dark.

Today, the name phosphorus is used for the chemical element only, whereas certain microcrystalline luminescent materials are called phosphors. Cascariolo's phosphor evidently was a barium sulfide; the first commercially available phosphor (1870) was “Balmain's paint,” a calcium sulfide preparation. In 1866 the first stable zinc sulfide phosphor was described. It is one of the most important phosphors in modern technology.

**Bioluminescence and chemiluminescence.** One of the first scientific investigations of the luminescence exhibited by rotting wood or flesh and by glowworms, known from antiquity, was performed in 1672 by Robert Boyle, an English scientist, who, although not aware of the biochemical origin of that light, nevertheless established some of the basic properties of bioluminescent systems: that the light is cold; that it can be inhibited by chemical agents such as alcohol, hydrochloric acid, and ammonia; and that the light emission is dependent on air (as later established, on oxygen).

In 1885–87 it was observed that crude extracts prepared from West Indian fireflies (*Pyrophorus*) and from the boring clam, *Pholas*, gave a light-emitting reaction when mixed together. One of the preparations was a cold-water extract containing a compound relatively unstable to heat, luciferase; the other was a hot-water extract containing a relatively heat-stable compound, luciferin. The luminescent reaction that occurred when solutions of luciferase and luciferin were mixed at room temperature suggested that all bioluminescent reactions are “luciferin–luciferase reactions.” In view of the complex nature of

bioluminescent reactions, it is not astonishing that this simple concept of bioluminescence has had to be modified. Only a small number of bioluminescent systems have been investigated for their respective luciferin and the corresponding luciferase, the best known being the bioluminescence of fireflies from the United States; a little crustacean living in the Japanese sea (*Cypridina hilgendorffii*); and decaying fish and flesh (bacterial bioluminescence). Although bioluminescent systems have not yet found practical applications, they are interesting because of their high luminescence efficiency.

The first efficient chemiluminescent materials were non-biological synthetic compounds such as luminol (with the formula 5-amino-2,3-dihydro-1,4-phthalazinedione). The strong blue chemiluminescence resulting from oxidation of this compound was first reported in 1928.

**Phosphorescence and fluorescence.** The name luminescence has been accepted for all light phenomena not caused solely by a rise of temperature, but the distinction between the terms phosphorescence and fluorescence is still open to discussion. With respect to organic molecules, the term phosphorescence means light emission caused by electronic transitions between levels of different multiplicity (explained more fully below), whereas the term fluorescence is used for light emission connected with electronic transitions between levels of like multiplicity. The situation is far more complicated in the case of inorganic phosphors.

The term phosphorescence was first used to describe the persistent luminescence (afterglow) of phosphors. The mechanism described above for the phosphorescence of excited organic molecules fits this picture in that it is also responsible for light persistence up to several seconds. Fluorescence, on the other hand, is an almost instantaneous effect, ending within about  $10^{-8}$  second after excitation. The term fluorescence was coined in 1852, when it was experimentally demonstrated that certain substances absorb light of a narrow spectral region (e.g., blue light) and instantaneously emit light in another spectral region not present in the incident light (e.g., yellow light) and that this emission ceases at once when the irradiation of the material comes to an end. The name fluorescence was derived from the mineral fluor spar, which exhibits a violet, short-duration luminescence on irradiation by ultraviolet light.

**Luminescence excitation. Chemiluminescence and bioluminescence.** Most of the energy liberated in chemical reactions, especially oxidation reactions, is in the form of heat. In some reactions, however, part of the energy is used to excite electrons to higher energy states, and, for fluorescent molecules, chemiluminescence results. Studies indicate that chemiluminescence is a universal phenomenon, although the light intensities observed are usually so small that sensitive detectors are necessary. There are, however, some compounds that exhibit brilliant chemiluminescence, the best known being luminol, which, when oxidized by hydrogen peroxide, can yield a strong blue or blue-greenish chemiluminescence. Other instances of strong chemiluminescences are lucigenin (an acridinium compound) and lophine (an imidazole derivative). In spite of the brilliance of their chemiluminescence, not all of these compounds are efficient in transforming chemical energy into light energy, because only about 1 percent or less of the reacting molecules emit light. During the 1960s, esters (organic compounds that are products of reactions between organic acids and alcohols) of oxalic acid were found that, when oxidized in nonaqueous solvents in the presence of highly fluorescent aromatic compounds, emit brilliant light with an efficiency up to 23 percent.

Bioluminescence is a special type of chemiluminescence catalyzed by enzymes. The light yield of such reactions can reach 100 percent, which means that almost without exception every molecule of the reacting luciferin is transformed into a radiating state. All of the bioluminescent reactions best known today are catalyzed oxidation reactions occurring in the presence of air.

**Triboluminescence.** When crystals of certain substances—e.g., sugar—are crushed, luminescent sparkles

investiga-  
tion

nescence

Role of  
enzymes

are visible. Similar observations have been made with numerous organic and inorganic substances. Closely related are the faint blue luminescence observable when adhesive tapes are stripped from a roll, and the luminescence exhibited when strontium bromate and some other salts are crystallized from hot solutions. In all of these cases, positive and negative electric charges are produced by the mechanical separation of surfaces and during the crystallization process. Light emission then occurs by discharge, either directly, by molecule fragments, or via excitation of the atmosphere in the neighbourhood of the separated surface: the blue glow coming from adhesive tapes being unrolled is emitted from nitrogen molecules of the air that have been excited by the electric discharge.

**Thermoluminescence.** Thermoluminescence means not temperature radiation but enhancement of the light emission of materials already excited electronically by the application of heat. The phenomenon is observed with some minerals and, above all, with crystal phosphors after they have been excited by light.

**Photoluminescence.** Photoluminescence, which occurs by virtue of electromagnetic radiation falling on matter, may range from visible light through ultraviolet, X-ray, and gamma radiation. It has been shown that, in luminescence caused by light, the wavelength of emitted light generally is equal to or longer than that of the exciting light (*i.e.*, of equal or less energy). As explained below, this difference in wavelength is caused by a transformation of the exciting light, to a greater or lesser extent, to nonradiating vibration energy of atoms or ions. In rare instances—*e.g.*, when intense irradiation by laser beams is used or when sufficient thermal energy contributes to the electron excitation process—the emitted light can be of shorter wavelength than the exciting light (anti-Stokes radiation).

The fact that photoluminescence can also be excited by ultraviolet radiation was first observed by a German physicist, Johann Wilhelm Ritter (1801), who investigated the behaviour of phosphors in light of various colours. He found that phosphors luminesce brightly in the invisible region beyond violet and thus discovered ultraviolet radiation. The transformation of ultraviolet light to visible light has much practical importance.

Gamma rays and X-rays excite crystal phosphors and other materials to luminescence by the ionization process (*i.e.*, the detachment of electrons from atoms), followed by a recombination of electrons and ions to produce visible light. Advantage of this is taken in the fluoroscope used in X-ray diagnostics and in the scintillation counter that detects and measures gamma rays directed onto a phosphor disk that is in optical contact with the face of a photomultiplier tube (a device that amplifies light signals).

**Electroluminescence.** Like thermoluminescence, the term electroluminescence includes several distinct phenomena, a common feature of which is that light is emitted by an electrical discharge in gases, liquids, and solid materials. Benjamin Franklin, in the United States, for example, in 1752 identified the luminescence of lightning as caused by electric discharge through the atmosphere. An electric-discharge lamp was first demonstrated in 1860 to the Royal Society of London. It produced a brilliant white light by the discharge of high voltage through carbon dioxide at low pressure. Modern fluorescent lamps are based on a combination of electroluminescence and photoluminescence: mercury atoms in the lamp are excited by electric discharge, and the ultraviolet light emitted by the mercury atoms is transformed into visible light by a phosphor (see LIGHTING AND LIGHTING DEVICES).

The electroluminescence sometimes observed at the electrodes during electrolysis is caused by the recombination of ions (therefore, this is a sort of chemiluminescence). The application of an electric field to thin layers of luminescing zinc sulfide can produce light emission, which is also called electroluminescence.

A great number of materials luminesce under the impact of accelerated electrons (once called cathode rays); *e.g.*, diamond, ruby, crystal phosphors, and certain complex salts of platinum. The first practical application of catho-

doluminescence was in the viewing screen of an oscilloscope tube constructed in 1897; similar screens used in television, radar, oscilloscopes, and electron microscopes are made possible by the production of efficient and colour-selective crystal phosphors.

The impact of accelerated electrons on molecules can produce molecular ions, ions of molecule fragments, and atomic ions. In gas-discharge tubes these particles were first detected as "canal rays" or anode rays. They are able to excite phosphors but not as efficiently as electrons can.

**Radioluminescence.** Radioactive elements can emit alpha particles (helium nuclei), electrons, and gamma rays (high-energy electromagnetic radiation). The term radioluminescence, therefore, means that an appropriate material is excited to luminescence by a radioactive substance. When alpha particles bombard a crystal phosphor, tiny scintillations are visible to microscopic observation. This is the principle of the device used by an English physicist, Ernest Rutherford, to prove that an atom has a central nucleus. Self-luminous paints, such as are used for dial markings on watches and other instruments, owe their behaviour to radioluminescence. These paints consist of a phosphor and a radioactive substance, *e.g.*, tritium or radium. An impressive natural radioluminescence is the aurora borealis: by the radioactive processes of the sun, enormous masses of electrons and ions are emitted into space in the solar wind. When they approach the earth, they are concentrated by its geomagnetic field near the poles. Discharge processes of the particles in the upper atmosphere yield the famous luminance of the auroras.

**Luminescent materials and phosphor chemistry.** The first phosphor synthesized was probably an impure barium sulfide preparation with very low luminance efficiency and with the serious shortcoming that it was rather quickly decomposed in moist air, yielding hydrogen sulfide. A more stable sulfide-type phosphor was produced in 1866 by heating zinc oxide in a stream of hydrogen sulfide. In 1887 it became known that these sulfides do not luminesce in a chemically pure state but only when they contain small quantities of a so-called activator metal. Later, other materials, such as certain metal oxides, silicates, and phosphates, were found to luminesce if they were prepared by special procedures.

**Sulfide-type phosphors, activators, fluxes.** The sulfides of zinc and of cadmium are the most important basic materials of sulfide-type phosphors. An important condition of getting highly efficient phosphors is that these sulfides must first be prepared to the highest possible chemical purity before the necessary amount of activator can be added precisely. The emission of zinc sulfide can be shifted to longer wavelengths by increasing substitution of the zinc ions by cadmium ions. Zinc sulfide and cadmium sulfide phosphors are especially efficient in electroluminescence.

Sulfide-type phosphors are produced from pure zinc or cadmium sulfide or their mixtures by heating them together with small quantities (0.1–0.001 percent) of copper, silver, gallium, or other salts (activators) and with about 2 percent of sodium or another alkali chloride at about 1,000° C (1,832° F). The role of the alkali halides is to facilitate the melting process and, above all, to serve as coactivators (fluxes). Only small quantities of the alkali halide are integrated into the phosphor, but this small quantity is highly important for its luminescence efficiency. Copper-activated zinc and cadmium sulfides exhibit a rather long afterglow when their irradiation has ceased, and this is favourable for application in radar screens and self-luminous phosphors.

**Oxide-type phosphors.** Certain oxide-type minerals have been found to luminesce when irradiated. In some of them, activators must first be introduced into the crystal. Examples are ruby (aluminum oxide with chromium activator—bright-red emission) and willemite (zinc orthosilicate with manganese activator—green emission). On the other hand, scheelite (calcium tungstate) emits a blue luminescence without activator. All of these minerals have been made synthetically, with remarkably higher efficiencies than those that occur naturally. Silicates, bor-

Electric  
discharge

Synthetic  
phosphors

ates, and phosphates of the second group of the periodic table of elements, such as zinc silicate, zinc beryllium silicate, zinc and cadmium borates, and cadmium phosphates, become efficient phosphors when activated with manganese ions, emitting in the red to green region of the spectrum. They have been incorporated into colour television screens to emit the colours blue (silver-activated zinc sulfide), green (manganese-activated zinc orthosilicate), and red (europium-activated yttrium vanadate).

**Centres, activators, coactivators, poisons.** The study of phosphor chemistry has yielded a detailed picture of the role of the above-mentioned activators and fluxes. Philipp Anton Lenard, a physicist in Germany, was the first (1890) to describe activator ions as being distributed in zinc sulfide and other crystalline materials that serve as the host crystal. The activator ions are surrounded by host-crystal ions and form luminescing centres where the excitation-emission process of the phosphor takes place. These centres must not be too close together within the host crystal lest they inactivate each other. For high efficiency, only a trace of the activator may be inserted into the host crystal, and its distribution must be as regular as possible. In high concentration, activators act as "poisons" or "killers" and thus inhibit luminescence. The term killer is used especially for iron, cobalt, and nickel ions, whose presence, even in small quantities, can inhibit the emission of light from phosphors.

Phosphors, such as calcium tungstate or zinc sulfide, that need no activator appear to have their luminescing centres in special groups of atoms different from the symmetry of their own crystal lattice, such as the group  $WO_4$  in the compound calcium tungstate, formula  $CaWO_4$ , or, similarly, the  $SiO_4$  group in zinc orthosilicate, formula  $Zn_2SiO_4$ . That luminescing properties of a centre are strongly dependent on the symmetry of neighbouring ion groups with respect to the whole phosphor molecule is clearly proved by the spectral shifts of certain phosphors activated with lanthanide ions, which emit in narrow spectral regions. Because of this altering effect on the symmetry of luminescing centres, small quantities (about 0.2 percent) of titania incorporated in zinc orthosilicate give a remarkable increase in luminescence. Titania is called an intensifier activator because it increases the host-crystal luminescence, whereas a substance that produces luminescence not exhibited by the chemically pure host crystal is called an originative activator.

The fluxes (e.g., sodium chloride) act as coactivators by facilitating the incorporation of activator ions. Copper ions, for instance, are used as activators of zinc chloride phosphors and are usually introduced in the copper(II), or cupric, form (the Roman numeral indicates the oxidation state; that is, I means that the element has one electron involved in a chemical bond and II that it has two electrons involved; the larger oxidation state is indicated by the *-ic* ending and the smaller by the *-ous* ending). If a copper(II) compound is incorporated into the zinc sulfide by heating, copper(I) sulfide (or cuprous sulfide, formula  $Cu_2S$ ) will be produced with crystals that will not fit into the host-crystal zinc chloride because their form is so different, and only a relatively few luminescent centres will be possible. On the other hand, if a coactivator such as sodium chloride is introduced along with the copper(II) salt, the copper(II) ions are reduced to form copper(I) chloride (or cuprous chloride, formula  $CuCl$ ) crystals with the same structure as the host crystal. Thus, many luminescent centres will be produced, and strong activation will result.

In describing a luminescent phosphor, the following information is pertinent: crystal class and chemical composition of the host crystal, activator (type and percentage), coactivator (intensifier activator), temperature and time of crystallization process, emission spectrum (or at least visual colour), and persistence. A few phosphors and their activators are listed in Table 1.

**Organic luminescent materials.** Although the inorganic phosphors are industrially produced in far higher quantities (several hundred tons per year) than the organic luminescent materials, some types of the latter are becoming more and more important in special fields of

Table 1: Visual Properties of Some Luminescent Materials

phosphor (phosphor/activator; coactivator)	emission	
	colour*	persistence
rhomboidal $Zn_2SiO_4$ /Mn 0.3% (rhomboidal zinc orthosilicate/ manganese 0.3%); 1,200° C 60 min, slow cooling	green (525 nm)	short (0.01 sec)
$\beta$ - $Zn_2SiO_4$ /Mn 0.3% (beta zinc orthosilicate/manganese 0.3%); 1,600° C 10 min, quench cooling	yellow (610 nm)	short (0.01 sec)
cubic $ZnS$ /Cu 0.03%; Cl (cubic zinc sulfide/copper 0.03%; chloride); 950° C 10 min, slow cooling	green-blue (516 nm)	long (hours)
hexagonal $ZnS$ /Cu 0.03%; Cl (hexagonal zinc sulfide/ copper 0.03%; chloride); 1,250° C 10 min, slow cooling	green (528 nm)	very long (up to 24 hours)

\*The wavelengths of the respective emission maxima are given in parentheses. 1 nanometre (nm) =  $10^{-9}$  metre = 1 millimicron = 10 angstroms.

practical application. Paints and dyes for outdoor advertising contain strongly fluorescing organic molecules such as fluorescein, eosin, rhodamine, and stilbene derivatives. Their main shortcoming is their relatively poor stability in light, because of which they are used mostly when durability is not required. Organic phosphors are used as optical brighteners for invisible markers of laundry, banknotes, identity cards, and stamps and for fluorescence microscopy of tissues in biology and medicine. Their "invisibility" is due to the fact that they absorb practically no visible light. The fluorescence is excited by invisible ultraviolet radiation (black light).

**Photoradiation in gases, liquids, and crystals.** When describing chemical principles associated with luminescence, it is useful, at first, to neglect interactions between the luminescing atoms, molecules, or centres with their environment. In the gas phase these interactions are smaller than they are in the condensed phase of a liquid or a solid material. The efficiency of luminescence in the gas phase will be far greater than in the condensed phases because in the latter the energy of the electrons excited by photons or by chemical-reaction energy can be dissipated as thermal, nonradiative energy by collision of the atoms or by the rotational and vibrational energy of the molecules. This effect has to be taken into account even more when the radiation of single atoms is compared with that of multi-atomic molecules. For molecules, radiative (electronic-excitation) energy is internally converted to vibrational energy; that is, there are radiationless transitions of electrons in atoms. This is the explanation for the fact that only a relatively small number of compounds are able to exhibit efficient luminescence. In crystals, on the other hand, the binding forces between the ions or atoms of the lattice are strong compared with the forces acting between the particles of a liquid, and electron-excitation energy, therefore, is not as easily transformed into vibrational energy, thus leading to a good efficiency for radiative processes.

**Luminescence physics. Mechanism of luminescence.** The emission of visible light (that is, light of wavelengths between about 690 nanometres and 400 nanometres, corresponding to the region between deep red and deep violet) requires excitation energies the minimum of which is given by Einstein's law stating that the energy ( $E$ ) is equal to Planck's constant ( $h$ ) times the frequency of light ( $\nu$ ), or Planck's constant times the velocity of light ( $c$ ) in a vacuum divided by its wavelength ( $\lambda$ ); that is,

$$E = h\nu = \frac{hc}{\lambda}$$

The energy required for excitation therefore ranges between 40 kilocalories (for red light), about 60 kilocalories (for yellow light), and about 80 kilocalories (for violet light) per mole of substance. Instead of expressing these energies in kilocalories, electron volt units (one electron volt =  $1.6 \times 10^{-19}$  erg; the erg is an extremely

Killers

Effect of binding force

small unit of energy) may be used, and the photon energy thus required in the visible region ranges from 1.8 to 3.1 electron volts.

The excitation energy is transferred to the electrons responsible for luminescence, which jump from their ground-state energy level to a level of higher energy. The energy levels that electrons can assume are specified by quantum mechanical laws. The different excitation mechanisms considered below depend on whether or not the excitation of electrons occurs in single atoms, in single molecules, in combinations of molecules, or in a crystal. They are initiated by the means of excitation described above: impact of accelerated particles such as electrons, positive ions, or photons. Often, the excitation energies are considerably higher than those necessary to lift electrons to a radiative level; for example, the luminescence produced by the phosphor crystals in television screens is excited by cathode-ray electrons with average energies of 25,000 electron volts. Nevertheless, the colour of the luminescent light is nearly independent of the energy of the exciting particles, depending chiefly on the excited-state energy level of the crystal centres.

Electron  
excitation

Electrons taking part in the luminescence process are the outermost electrons of atoms or molecules. In fluorescent lamps, for example, a mercury atom is excited by the impact of an electron having an energy of 6.7 electron volts or more, raising one of the two outermost electrons of the mercury atom in the ground state to a higher level. Upon the electron's return to the ground state, an energy difference is emitted as ultraviolet light of a wavelength of 185 nanometres. A radiative transition between another excited state and the ground-state level of the mercury atom produces the important ultraviolet emission of 254-nanometre wavelength, which, in turn, can excite other phosphors to emit visible light. (One such phosphor frequently used is a calcium halophosphate incorporating a heavy-metal activator.)

This 254-nanometre mercury radiation is particularly intensive at low mercury vapour pressures (around  $10^{-5}$  atmosphere) used in low-pressure discharge lamps. About 60 percent of the input electron energy may thus be transformed into near-monochromatic ultraviolet light; *i.e.*, ultraviolet light of practically one single wavelength.

Whereas at low pressure there are relatively few collisions of mercury atoms with each other, the collision frequency increases enormously if mercury gas is excited under high pressure (*e.g.*, eight atmospheres or more). Such excitation leads not only to collisional de-excitation of excited atoms but also to additional excitation of excited atoms. As a consequence, the spectrum of the emitted radiation no longer consists of practically one single, sharp spectral line at 254 nanometres, but the radiation energy is distributed over various broadened spectral lines corresponding to different electronic energy levels of the mercury atom, the strongest emissions lying at 303, 313, 334, 366, 405, 436, 546, and 578 nanometres. High-pressure mercury lamps can be used for illumination purposes because the emissions from 405 to 546 nanometres are visible light of bluish-green colour; by transforming a part of the mercury line emission to red light by means of a phosphor, white light is obtained.

When gaseous molecules are excited, their luminescence spectra show broad bands; not only are electrons lifted to levels of higher energy but vibrational and rotational motions of the atoms as a whole are excited simultaneously. This is because vibrational and rotational energies of molecules are only about  $10^{-2}$  and  $10^{-4}$ , respectively, those of the electronic transition energies, and these many energies can be added to the energy of a single electronic transition, which is represented by a multitude of slightly different wavelengths making up one band. In larger molecules, several overlapping bands, one for each kind of electronic transition, can be emitted. Emission from molecules in solution is predominantly bandlike caused by interactions of a relatively great number of excited molecules with molecules of the solvent. In molecules, as in atoms, the excited electrons generally are outermost electrons of the molecular orbitals.

The terms fluorescence and phosphorescence can be used

here, on the basis not only of the persistence of luminescence but also of the way in which the luminescence is produced. When an electron is excited to what is called, in spectroscopy, an excited singlet state, the state will have a lifetime of about  $10^{-8}$  second, from which the excited electron can easily return to its ground state (which normally is a singlet state, too), emitting its excitation energy as fluorescence. During this electronic transition the spin of the electron is not altered; the singlet ground state and the excited singlet state have like multiplicity (number of subdivisions into which a level can be split). An electron, however, may also be lifted, under reversal of its spin, to a higher energy level, called an excited triplet state. Singlet ground states and excited triplet states are levels of different multiplicity. For quantum mechanical reasons, transitions from triplet states to singlet states are "forbidden," and, therefore, the lifetime of triplet states is considerably longer than that of singlet states. This means that luminescence originating in triplet states has a far longer duration than that originating in singlet states: phosphorescence is observed.

Phospho-  
rescence

The interactions of a large number of atoms, ions, or molecules are greater still in solution and in solids; to obtain a narrowing of the spectral band, subzero temperatures (down to that of liquid helium) are applied in order to reduce vibrational motions. The electronic energy levels of crystals such as zinc sulfide and other host crystals used in phosphors form bands: in the ground state practically all electrons are to be found on the valence band, whereas they reach the conduction band after sufficient excitation (see SEMICONDUCTORS AND INSULATORS, THEORY OF). The energy difference between the valence band and the conduction band corresponds to photons in the ultraviolet or still shorter wavelength region. Additional energy levels are introduced by activator ions or centres bridging the energy gap between valence band and conduction band, and, when an electron is transferred from the valence band to such an additional energy level by excitation energy, it can produce visible light on return to the ground state. A rather close analogy exists between the forbidden transitions of certain excited molecular electronic states (triplet-singlet, leading to phosphorescence) and the transition of an electron of an inorganic phosphor kept in a trap: traps (certain distortions in the crystal lattice) are places in the crystal lattice where the energy level is lower than that of the conduction band, and from which the direct return of an electron to the ground state is also forbidden.

When a solid is bombarded by photons or particles, the excitation of the centres can occur directly or by energy transfer. In the latter case, excited but nonluminescent states are produced at some distance from the centre, with the energy moving through the crystal in the form of excitons (ion-electron pairs) until it approaches a centre where the excitation process can occur. This energy transfer can also be realized by radiation in inorganic phosphors containing two activators, as well as in solutions of organic molecules.

*Decay; stimulated emission.* The radiative return of excited electrons to their ground state occurs spontaneously, and when there exists an assembly of excited electrons their individual spontaneous radiative transitions are independent of each other. Therefore, the luminescence light is incoherent (the emitted waves are not in phase with each other) in this case. Sometimes the emission of luminescence can be stimulated by irradiation with photons of the same frequency as that of the emitted light; such stimulated transitions are used in lasers, which produce very intensive beams of coherent monochromatic light.

The spontaneous luminescent emission follows an exponential law that expresses the rate of intensity decay and is similar to the equation for the decay of radioactivity and some chemical reactions. It states that the intensity of luminescent emission is equal to an exponential value of minus the time of decay divided by the decay time, or  $L = L_0 \exp(-t/\tau)$ , in which  $L$  is the intensity of emission at a time  $t$  after an initial intensity  $L_0$ , and  $\tau$  is the decay time of the luminescence; that is, the time in which the

Exponen-  
tial decay

assembly of the excited atoms would decrease in luminescence intensity to a value of 0.368  $L_0$ .

When excited atoms of the centres are in contact with other atoms, as is the case in condensed phases (liquids, solids, in gases of not-too-low pressure), part of the excitation energy will be transformed into heat by collisional deactivation (thermal quenching). The decay time, therefore, has to be replaced by an effective excited-state lifetime, resulting in a more complicated exponential decay law that depends on the collision frequency, the energy imparted to the excited atoms of the centre that causes the transfer of excitation energy into heat (activation energy), a constant, and the temperature of the luminescent material. This law describes the actual luminescence decay of a great number of luminescent materials; e.g., calcium tungstate.

Increase of activation energy for nonradiative deactivation of excited-centres luminescence decay can be achieved by changing the host crystal or by electron traps. The traps are imperfections in the crystal lattice where electrons are captured after they have been ejected from a luminescent centre by excitation energy. That the luminescent properties of phosphor centres are strongly dependent on the chemical nature of the host crystal may be seen in Table 2, showing that the same activator ions

host crystal	activator	time (second)	emission colour
Tetragonal zinc fluoride, ZnF <sub>2</sub>	manganese(II)	0.1	orange
Rhombohedral cadmium sulfate, CdSO <sub>4</sub>	manganese(II)	0.05	orange
Rhombohedral magnesium sulfate, MgSO <sub>4</sub>	manganese(II)	0.03	red
Rhombohedral zinc phosphate, Zn <sub>3</sub> (PO <sub>4</sub> ) <sub>2</sub>	manganese(II)	0.02	red
Cadmium silicate, CdSiO <sub>3</sub>	manganese(II)	0.019	orange
Zinc orthosilicate, Zn <sub>2</sub> SiO <sub>4</sub>	manganese(II)	0.018	yellow
Cadmium pyroborate, Cd <sub>2</sub> B <sub>2</sub> O <sub>5</sub>	manganese(II)	0.015	red orange
Rhombohedral zinc orthosilicate, Zn <sub>2</sub> SiO <sub>4</sub>	manganese(II)	0.013	green
Rhombohedral zinc germanate, Zn <sub>2</sub> GeO <sub>4</sub>	manganese(II)	0.0105	green yellow
Cubic zinc aluminate, ZnAl <sub>2</sub> O <sub>4</sub>	manganese(II)	0.0055	blue green
Cubic zinc gallate, ZnGa <sub>2</sub> O <sub>4</sub>	manganese(II)	0.0043	green blue
Hexagonal zinc sulfide, ZnS	manganese(II)	0.0004	orange

(manganese ions with two positive charges, indicated as Mn<sup>2+</sup>, or Mn[II]), in different host crystals yield remarkably different-coloured emissions and decay times (measured in fractions of a second).

Prolonging the emission time of phosphors up to days or even longer (production of phosphorescence of the phosphors) is possible by inserting traps into the host crystal. Trapped electrons cannot return directly to the centre. In order to be released from the traps they must first obtain additional thermal energy—in this case, thermal energy stimulates luminescence—after which they recombine with a centre and undergo radiative transition. Trapping in crystals has its analogy to forbidden transitions in molecules (triplet-singlet transitions) or in radiation processes from metastable atomic-energy levels.

An example of a practical application of stimulated emission of a phosphor with trapped electrons is cubic strontium sulfide/selenide activated with samarium and europium ions, the coactivators being strontium sulfate and calcium fluoride. This phosphor has been used in devices for viewing scenes at night by reflected infrared light emitted by infrared lamps. The traps in this phosphor have been identified as samarium ions, whereas europium ions are the active ions in the centres. The phosphor is first excited by photons of about three electron volts (blue light), which results in an ejection of an electron from a europium ion (Eu<sup>2+</sup>) centre. This excited

electron is trapped by a triply charged samarium ion (Sm<sup>3+</sup>), which is transferred to a doubly charged samarium ion (Sm<sup>2+</sup>). Heat or irradiation by infrared photons releases one electron from the doubly charged samarium ion (Sm<sup>2+</sup>). The electron is then recaptured from a triply charged europium ion (Eu<sup>3+</sup>), yielding an excited doubly charged europium ion (Eu<sup>2+</sup>), which returns to its ground state by emitting a photon of 2.2 electron volts energy (yellow light). The trap depth of this phosphor (*i.e.*, the energy required for release of an electron from it) is large compared to the thermal energy of the lattice of the host crystal, and, therefore, the lifetime of the traps at room temperature is many months long. Bombarding this phosphor with photons of energy higher than that of infrared photons but not sufficient for excitation can lead to photoquenching: the traps are emptied far more rapidly, and thermal deactivation of the centres is enhanced.

When iron, cobalt, or nickel ions are present in a phosphor, an excited electron can be captured by these ions. The excitation energy is then emitted as infrared photons, not as visible light, so that luminescence is quenched. These ions, therefore, are called killers—the killing process being opposite to stimulation.

In chemiluminescence, such as the oxidation of luminol, light emission depends not only on radiative and quenching or intramolecular deactivation processes but also on the efficiency of the chemical reaction leading to molecules in an electronically excited state.

In bioluminescence reactions, the production of electronically excited molecules, as well as their radiative transitions back to their ground state, is efficiently catalyzed by the enzymes acting here, and bioluminescence light output is therefore high.

The luminescence photons emitted by one kind of excited atom, molecule, or phosphor can excite another to emit its specific luminescence: this type of energy transfer is observed with inorganic as well as organic substances. Thus, excited benzene molecules can excite naphthalene molecules by radiative-energy transfer. The radiation produced by the luminol chemiluminescence can produce fluorescence when fluorescein is added to the reaction mixture. In most of these cases the acceptor molecules have luminescent electrons with energy levels lower than those of the primary excited molecules, and emitted secondary luminescence is therefore of longer wavelength than the primary. Practical application of this phenomenon, called cascading, is used in radar kinescopes, which have composite fluorescent screens consisting of a layer of blue-emitting zinc sulfide/silver (chloride) phosphor—the hexagonal crystal, ZnS/Ag(Cl) deposited on a layer of yellow-emitting zinc or cadmium sulfide/copper [chloride] phosphor [the hexagonal crystal, (Zn,Cd)S/Cu(Cl)].

Cascading

The cathode-ray electrons excite the blue-emitting phosphor, whose photons, in turn, excite the yellow-emitting phosphor, which has traps with a decay time of about 10 seconds. Excitation of the blue-emitting phosphor alone would be unfavourable, as the sharply focussed cathode rays are absorbed by the blue phosphor to a small extent only, and its decay time is too short; also, direct excitation of the yellow-emitting phosphor alone would yield poor efficiency because the traps are emptied too rapidly by the heat produced by the relatively high-energetic electron impact.

Another energy-transfer mechanism is called sensitization: a calcium carbonate phosphor (rhombohedral CaCO<sub>3</sub>/Mn), for example, emits orange light under cathode-ray irradiation but is not excited by the 254-nanometre emission of mercury atoms, whereas this emission produces the same orange light with calcium carbonate (rhombohedral CaCO<sub>3</sub>) activated by manganese and lead ions. This is not cascade luminescence, because a mechanical mixture of a manganese and a lead-activated calcium carbonate exhibits no emission under ultraviolet radiation. In a phosphor containing both activators, the lead ions act as sensitizers in introducing an additional excitation band into the system from which the manganese ions get their excitation energy in a nonradiative

## Quantum efficiency

**Efficiency of luminescence; luminance.** The efficiency of luminescence emission must be regarded on an energy and a quantum basis. When every exciting photon yields an emitted photon of the same energy (which is the case for resonance excitation—i.e., excitation of fluorescence by a monochromatic light of exactly the same wavelengths as the resulting fluorescence—and radiation of isolated atoms in very dilute gases), the luminescence efficiency is 100 percent with respect to input energy as well as to the number of quanta. When the number of secondary photons is equal to that of the primary, but their energy is less because some of the energy is dissipated as heat, the quantum efficiency is 100 percent, but the luminescence efficiency is less than 100 percent. The quantum efficiency of most luminescences is far lower than 100 percent, especially in the liquid and solid states; zinc sulfide phosphors have about 20 percent efficiency, and solid state electroluminescence is less than 10 percent efficient.

In chemiluminescence, the quantum efficiency of "brilliant" reactions, such as luminol, is about one percent and up to 23 percent in the oxalate chemiluminescence. Solid-state electroluminescence, or electroluminescence of gases excited by high-frequency electric fields, is usually less than 10 percent.

The light intensity of luminescent processes depends chiefly on the excitation intensity, the density, and the lifetime of the radiative atoms, molecules, or centres. For practical purposes this luminous intensity per unit area is called photometric brightness or luminance of a material and is measured in lambert or millilambert (0.001 lambert) units (one lambert is equal to one candle per square centimetre divided by  $\pi$ ). The luminance of some luminescent light sources is listed in Table 3.

sources	lamberts
Fluorescent lamps	
20-watt T 12 standard warm white	1.67
40-watt T 12 standard warm white	2.1
96-watt T 12 standard warm white	2.052
Television screens	0.10
Fresh snow in full sunlight	10.
Sun (observed from Earth's surface at meridian)	519,000.
Lasers	exceeding that of Sun

## BIBLIOGRAPHY

**History:** E.N. HARVEY, *A History of Luminescence: From the Earliest Times Until 1900* (1957), a classical work dealing rather extensively with the historical development of the different types of luminescence, especially bioluminescence and chemiluminescence.

**General works:** E.J. BOWEN (ed.), *Luminescence in Chemistry* (1968), a textbook for students and research workers, particularly in the biological and biochemical fields, that provides a good introduction to the whole field; C.A. PARKER, *Photoluminescence of Solutions* (1968), a detailed explanation of the basic principles of luminescence as applied to photoluminescence in solutions, kinetics, apparatus, and analytical applications; M. ZANDER, *Phosphorimetry* (1968), the first modern monograph dealing exclusively with phosphorescence of organic materials, with a complete bibliography; G.G. GUILBAULT (ed.), *Fluorescence: Theory, Instrumentation, and Practice* (1967), a fairly technical account written by outstanding specialists in their respective fields (good background knowledge is necessary); D.M. HERCULES (ed.), *Fluorescence and Phosphorescence Analysis* (1966), chapters of different grades of detail covering the luminescence field; G.F.J. GARLICK, "Luminescence," *Handbuch der Physik*, vol. 26, pp. 1-128 (1958), an extended text (written in English) systematically explaining the physical phenomena and theory of luminescence.

**Chemiluminescence and bioluminescence:** F. MCCAPRA, "The Chemiluminescence of Organic Compounds," *Q. Rev.*, 20:485-510 (1966), a review article on recent chemiluminescence investigations that attempts to find a general theory of transforming chemical energy into electronic excitation energy; W.D. MCELROY and B. GLASS (eds.), *A Symposium on*

*Light and Life* (1961), a collection of papers useful as an introduction to modern luminescence physics and chemistry, mainly concerned with chemiluminescence and bioluminescence; F.H. JOHNSON and Y. HANEDA (eds.), *Bioluminescence in Progress* (1966), a collection of papers, a continuation of the above source, that may be used as an advanced-level textbook; H.H. SELIGER and W.D. MCELROY, *Light: Physical and Biological Action* (1965), a textbook useful as an introduction to luminescence and photochemistry.

**Cathodoluminescence:** L. MARTON and A.B. EL-KAREH (eds.), "Electron Beam and Laser Beam Technology," *Advances in Electronics and Electron Physics*, suppl. vol. 4 (1968), a handbook article useful for detailed information concerning cathodoluminescence; L. MARTON (ed.), "Photo-Electronic Image Devices," *ibid.*, vol. 22A (1966), an article on the most recent literature and developments in photoelectronic image devices.

**Lasers and masers:** A.E. SIEGMAN, *Microwave Solid-State Masers* (1964), a monograph giving a general introduction to the field.

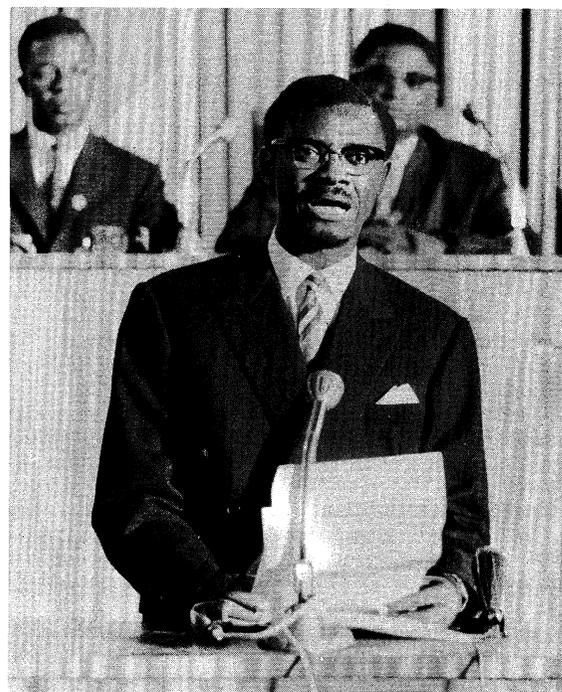

**Miscellaneous:** R.D. CADLE and E.R. ALLEN, "Atmospheric Photochemistry," *Science*, 167:243-249 (1970), a condensed survey of new investigations of photochemistry of the lower atmosphere and production of excited molecules by radical reactions in the gas phase; R.P. GODWIN, "Synchrotron Radiation As a Light Source," in *Springer Tracts in Modern Physics*, vol. 51 (1969), an advanced discussion of the theory and applications of the "synchrotron light"; F. GUTMANN and L.E. LYONS, *Organic Semiconductors* (1967), a survey of solid-state physics, band models, and excited states of organic molecular crystals; B.J. O'BRIEN, "Auroral Phenomena," *Science*, 148:449-460 (1965), facts and theory of Aurora Polaris and related phenomena, including instructive illustrations and short bibliography.

## Lumumba, Patrice

The first prime minister of the Democratic Republic of the Congo (now Zaire) after it achieved independence from Belgium, the radical nationalist leader Patrice Lumumba saw his regime disintegrate through a revolt of the army, the secession of the wealthiest province, and invasion by the country's former masters. He was evicted from office by the president less than three months after he assumed office and murdered by his political enemies four months later. But at the time of his death he was hailed throughout the continent as "the hero of Africa," and in his own country he has been officially proclaimed by successors who opposed him during his lifetime as "the national hero." He was thus the strange paradox of

Agence Dalmás—Pix

Lumumba.

the hero who failed, the hero whose memory evokes aspiration, not achievement.

Patrice Hemery Lumumba was born on July 2, 1925, in the village of Onalua in Kasai Province, Belgian Congo. He was a member of the small Batetela tribe, a fact that was to become significant in his later political life. His two principal rivals, Moïse Tshombe, who led the break-away of the Katanga Province, and Joseph Kasavubu, who later became the nation's president, both came from large, powerful tribes from which they derived their major support, giving their political movements a regional character. In contrast, Lumumba's movement emphasized its all-Congolese nature. Lumumba's parents were Catholics. At 13, however, he went to a Protestant mission school to receive training as a male nurse. He attended the school for two years but left before getting a diploma.

Education  
and early  
career

Lumumba then went to Kindu-Port-Empain, where he obtained employment and became active in the club of the *évolués* (educated Africans). He began to write essays and poems for Congolese journals. He applied for and received, not without difficulty, the *carte d'immatriculation*, the document that conferred full Belgian citizenship.

Lumumba moved to Léopoldville (now Kinshasa) to become a postal clerk and went on to become an accountant in the post office in Stanleyville (now Kisangani), the capital of Orientale Province. There he contributed his energy and intelligence to many organizations, and he continued to contribute to the Congolese press. In 1954 he applied to enter the opening class of the first Congolese university, Lovanium. He was refused admission because he was married and the university authorities insisted that all its students live on campus.

In 1955 Lumumba became president for Orientale Province of the APIC, a purely Congolese trade union of government employees which was not affiliated, as were other unions, to either of the two Belgian trade-union federations (Socialist and Catholic). He also became active in the Belgian Liberal Party in the Congo. Although conservative in many ways, the party was not linked to either of the trade-union federations, which were hostile to the APIC. In 1956 Lumumba was invited with others to make a study tour of Belgium under the auspices of the Minister of Colonies. On his return, as he disembarked from the airplane, he was arrested on a charge of embezzlement from the post office. He was convicted and condemned one year later, after various reductions of sentence, to 12 months imprisonment and a fine. Lumumba's friends collected money to pay his fine and support his family.

The year 1956 was a turning point in Congolese political life and the beginning of the expression of nationalist ideas. When Lumumba got out of prison, he obtained a position in a private firm, a beer concern, of which he became sales director in Léopoldville. He grew even more active in politics. In October 1958 he founded the Congolese National Movement (Mouvement National Congolais; MNC), the first nationwide Congolese political party. In December he attended the first All-African People's Conference in Accra, Ghana, where he met nationalists from all over the African continent and was made a member of the permanent organization set up by the conference. His outlook and terminology, inspired by pan-African goals, now took on the tenor of militant nationalism.

In 1959 the Belgian government announced a program intended to lead in five years to independence, starting with local elections in December 1959. The nationalists regarded this program as a scheme to install puppets before independence and announced a boycott of the elections. The Belgian authorities responded with repression. On October 30, there was a clash in Stanleyville that resulted in 30 deaths. Lumumba was imprisoned on a charge of inciting to riot.

The MNC now decided to shift tactics, entered the elections, and won a sweeping victory in Stanleyville (90 percent of the votes). In January 1960 the Belgian government convened a Round Table Conference in Brus-

sels of all Congolese parties to discuss political change, but the MNC refused to participate without Lumumba. Lumumba was thereupon released from prison and flown to Brussels. The conference agreed on a date for independence, June 30, with national elections in May. Although there was a multiplicity of parties, the MNC came out far ahead in the elections; it was the only party to compete in all the provinces and gained 41 of 137 seats (the nearest other party having 13 seats). Lumumba emerged as the leading nationalist politician of the Congo. Manoeuvres to prevent his assumption of authority failed, and he was asked to form the first government, which he succeeded in doing on June 23, 1960.

A few days after independence, some units of the army rebelled, largely because their Belgian commander refused to acknowledge that independence should improve the Congolese soldiers' treatment, pay, and prospects of promotion. In the confusion, the mineral-rich province of Katanga proclaimed secession. Belgium sent in troops, ostensibly to protect Belgian nationals in the disorder. But the Belgian troops landed principally in Katanga where they sustained the secessionist regime of Moïse Tshombe.

The Congo appealed to the United Nations to expel the Belgians and help them restore order. As prime minister, Lumumba did what he could to redress the situation, but it was not easy. His army was an uncertain instrument of power, his civilian administration untrained and untried, the United Nations forces (whose presence he had requested) condescending and assertive, and the political alliances underlying his regime very shaky. The Belgian troops did not evacuate and the Katanga secession continued.

Since the United Nations forces refused to aid him in ending the Katanga secession, Lumumba decided to use his army. He appealed to the Soviet Union for planes to assist in transporting his troops to Katanga. He asked the independent African states to meet in Léopoldville in August to unite their efforts behind him. His moves alarmed many inside and outside the country, particularly the Western powers and the supporters of President Kasavubu, a political rival of Lumumba's who pursued a moderate course in the coalition government and favoured some local autonomy in the provinces.

On September 5 President Kasavubu dismissed Lumumba. The legalities of the move were immediately contested by Lumumba. There were thus two groups now claiming to be the legal central government. The United Nations Secretariat was uncertain in its response but tended to favour Kasavubu. On September 14 power was seized by the Congolese army leader Col. Joseph Mobutu, (president of Zaire as Mobutu Sese Seko), who later reached a working agreement with Kasavubu. In October the General Assembly of the United Nations, by a divided vote, recognized the credentials of Kasavubu's government. The independent African states split sharply over the issue.

On November 27 Lumumba sought to travel from Léopoldville, where the United Nations had provided him with physical protection within the confines of his home, to Stanleyville, where his supporters had control. He was caught by the Kasavubu forces and arrested on December 2. On January 17, 1961, he was placed in an airplane and delivered to the Katanga secessionist regime, where he was murdered. Conflicting reports on the manner of his death were subsequently issued by Katanga, but even after a United Nations inquiry, the exact circumstances of the murder have not been established. His death caused a scandal throughout Africa, and later, retrospectively, his enemies proclaimed him a "national hero."

What was it about Lumumba that caused such intense emotion? His viewpoint was not exceptional. He was for a unitary Congo and against division of the country along tribal or regional lines. He supported pan-Africanism and the liberation of colonial territories. He proclaimed his regime one of "positive neutralism," which he defined as a return to African values and rejection of any imported ideology, including that of the Soviet Union. Many other African leaders have said the same.

Role in  
independence  
movement

Assessment

There were probably two things about Lumumba that aroused the wrath of his enemies. He was a man of strong character who intended to pursue his policies, regardless of the enemies he made within his country or abroad; and the country he headed was a key area in terms of the geopolitics of Africa. Its wealth, its size, and its contiguity to white-dominated southern Africa made his opponents fear the consequences of a radical or radicalized Congo regime. Moreover, in the context of the Cold War, the Soviet Union's support for Lumumba appeared as a threat to many in the West.

Lumumba developed in his own brief political life from an incipient nationalist member of an educated elite with grievances about the racial limitations of a colonial situation, to a radical nationalist tribune of the people who sought the liberation of the masses. It took a man of ambition, intelligence, energy, and courage to make this transition, although it led him to a confrontation with problems he was unable to master. Murdered for his virtues more than for his deeds, he has become a myth. As such, he has continued to play a role in emergent Africa.

**BIBLIOGRAPHY.** A good critical biography does not yet exist. PIERRE DE VOS, *Vie et mort de Lumumba* (1961), is a journalist's account. G. HEINZ and H. DONNAY, *Lumumba: Les cinquante derniers jours de sa vie* (1966; Eng. trans., *Lumumba: The Last Fifty Days*, 1970), is a detailed reconstruction of the last critical period of his life. The articles by JEAN VAN LIERDE and PIERRE CLEMENT in *Présence Africaine* (1961, 1962), both by Belgian friends of Lumumba, help create a portrait of the man. His own book *Le Congo* (1956; Eng. trans., *Congo: My Country*, 1962), is useful if taken in context. Far more important is the posthumous collection of essays edited by JEAN VAN LIERDE, *La Pensée politique de Patrice Lumumba* (1963).

(I.W.)

## Luria, Isaac ben Solomon

Isaac ben Solomon Luria was the founder of an influential school of Kabbala (Jewish esoteric mysticism) named after him. In Kabbalistic literature after his time he was called ha-Ari (the Lion), an acronym of the Hebrew appellation ha-Elohi Rabbi Yitzḥaq (the Divine Rabbi Isaac) or possibly of ha-Ashkenazi-Rabbi Yitzḥaq (the Ashkenazi Rabbi Isaac). His father was an Ashkenazi (that is, a German or Polish Jew), while his mother was a Sefardi (that is, of Iberian-North African Jewish stock). Luria was born in Jerusalem in 1534. Legend has it that the prophet Elijah appeared to his father and foretold the birth of the son, whose name was to be Isaac. As a child, Luria was described as a young genius, "a Torah scholar who could silence all opponents by the power of his arguments," and also as possessed of divine inspiration.

The main source for his life story is an anonymous biography, *Toledot ha-Ari* ("Life of the Ari"), written or perhaps edited some 20 years after his death, in which factual and legendary elements are indiscriminately mingled. According to the *Toledot*, Luria's father died while Isaac was a child, and his mother took him to Egypt to live with her well-to-do family. While there, he became versed in rabbinic studies, including Halakha (Jewish law), and even wrote glosses on a famous compendium of legal discussions, the *Sefer ha-Halakhot* of Isaac ben Jacob Alfasi. He also engaged in commerce during this period.

While still a youth, Luria began the study of mystical learning and lived for nearly seven years in seclusion at his uncle's home on an island in the Nile. His studies concentrated on the *Zohar* (late 13th-early 14th centuries), the central and revered work of the Kabbala, but he also studied the early Kabbalists (12th-13th centuries). The greatest Kabbalist of Luria's time was Moses ben Jacob Cordovero of Safed (modern Zefat), in Palestine, whose work Luria studied while still in Egypt. During this period he wrote a commentary on the *Sifra di-tzeni-uta* ("Book of Concealment"), a section of the *Zohar*. The commentary still shows the influence of classical Kabbala and contains nothing of what would later be called Lurianic Kabbala.

Early in 1570 Luria journeyed to Safed, the mountain town in the Galilee that had become a centre of the Kabbalistic movement, and he studied there with Cordovero. At the same time, he began to teach Kabbala according to a new system and attracted many pupils. The greatest of these was Ḥayyim Vital, who later set Luria's teachings down in writing. Luria apparently expounded his teachings only in esoteric circles; not everyone was allowed to take part in these studies. While he devoted most of his time to the instruction of his pupils, he probably made his living in trade, which prospered at that time in Safed, situated as it was at the crossroads between Egypt and Damascus.

At the time of Luria's arrival in Safed, the group of Kabbalists gathered there around Cordovero had already developed a unique style of living and observed special rituals, going out, for instance, into the fields to welcome the sabbath, personified as the Sabbath Queen. With Luria's arrival, new elements were added to these excursions, such as communion with the souls of the *tzaddiqim* (men of outstanding piety) by means of special *kawwanot* (ritual meditations) and *yihudim* ("unifications") that were in essence a kind of lesser redemption whereby the souls were lifted up from the *kelipot* ("shells"; i.e., the impure, evil forms) into which they were banned until the coming of the messiah.

The strong influence of Luria's personality helped to bring about in Safed an atmosphere of spiritual intensity, messianic tension, and the fever of creation that accompanies the sense of a great revelation. Deep devoutness, asceticism, and withdrawal from the world marked the Kabbalists' way of life. Luria apparently looked upon himself as the messiah ben Joseph, the first of the two messiahs in Jewish tradition, who is fated to be killed in the wars (of Gog and Magog) that will precede the final redemption. In Safed there was an expectation (based on the *Zohar*) that the Messiah would appear in Galilee in the year 1575.

Even though he did not distinguish himself as a writer, as is evident from his own remarks about the difficulty of writing, Luria composed three hymns that became widely known and part of the cultural heritage of the Jewish people. These are hymns for the three sabbath meals, which became part of the Sefardic sabbath ritual and were printed in many prayer books. The three meals were linked by means of mystical "intention" or meditation (*kawwana*) to three *partzufim* (aspects of the Godhead). The hymns are known as "Azamer be-she-vaḥim" ("I Will Sing on the Praises"), "Asader se'udata" ("I Will Order the Festive Meal"), and "Bene hekh-ala de-khesifin" ("Sons of the Temple of Silver"). They are mystical, erotic songs about "the adornment (or fitting) of the bride"—i.e., the sabbath, who was identified with the community of Israel—and on the other *partzufim*: *arikh anpin* (the long-suffering: the countenance of grace) and *ze'ir anpin* (the impatient: the countenance of judgment).

During his brief sojourn in Safed—a scant two years before his death—Luria managed to construct a many-faceted and fertile Kabbalistic system from which many new elements in Jewish mysticism drew their nourishment. He set down almost none of his doctrine in writing, with the exception of a short text that seems to be only a fragment: his commentary on the first chapter of the *Zohar*—"Be-resh hormanuta de-malka"—as well as commentaries on isolated passages of the *Zohar* that were collected by Ḥayyim Vital, who attests to their being in his teacher's own hand. Luria died, in an epidemic that struck Safed, on August 5, 1572.

What is called Lurianic Kabbala is a voluminous collection of Luria's Kabbalistic doctrines, recorded after his death by Ḥayyim Vital and appearing in two versions under different editorship. Because of this work Lurianic Kabbala became the new thought that influenced all Jewish mysticism after Luria, competing with the Kabbala of Cordovero. Vital laboured much to give Lurianic Kabbala its form as well as to win legitimization for it.

Lurianic Kabbala propounds a theory of the creation and subsequent degeneration of the world and a practical

Years  
at Safed

Lurianic  
Kabbala

method of restoring the original harmony. The theory is based on three concepts: *tzimtzum* ("contraction" or "withdrawal"), *shevirat ha-kelim* ("breaking of the vessels"), and *tiqqun* ("restoration"). God as the Infinite (En Sof) withdraws into himself in order to make room for the creation, which occurs by a beam of light from the Infinite into the newly provided space. Later the divine light is enclosed in finite "vessels," most of which break under the strain, and the catastrophe of the "breaking of the vessels" occurs, whereby disharmony and evil enter the world. Hence comes the struggle to rid the world of evil and accomplish the redemption of both the cosmos and history. This occurs in the stage of *tiqqun*, in which the divine realm itself is reconstructed, the divine sparks returned to their source, and *Adam Qadmon*, the symbolic "primordial man," who is the highest configuration of the divine light, is rebuilt. Man plays an important role in this process through various *kawwanot* used during prayer and through mystical intentions involving secret combinations of words, all of which is directed toward the restoration of the primordial harmony and the reunification of the divine name.

The influence of Luria's Kabbala was far-reaching. It played an important role in the movement of the false messiah Shabbetai Tzevi in the 17th century and in the popular Hasidic (mystical-pietistic) movement a century later. (For a more detailed presentation of Lurianic Kabbala see JEWISH MYSTICISM.) (R.S.-U.)

**BIBLIOGRAPHY.** A definitive biography of Isaac Luria does not exist. MEIR BENAYAHU, *Sefer Toledoth ha-Ari* (1967), an historical-literary analysis (in Hebrew) of the various medieval collections of legends about Luria, brings together much of the material necessary for a modern biography. Other useful studies include GERSHOM G. SCHOLEM, "Isaac Luria and His School," in his *Major Trends in Jewish Mysticism*, 3rd rev. ed., pp. 244-286 (1954), an epitome of the salient features of Lurianic Kabbalah by the leading modern historian of Jewish mysticism; and SOLOMON SCHECHTER, "Safed in the Sixteenth Century: A City of Legists and Mystics," in his *Studies in Judaism*, 2nd Series, pp. 202-285 (1908), a dated but vivid portrayal of the intellectualism and romanticism that permeated Safed during Luria's lifetime. Luria's teachings are known mostly from the writings of his disciples, most notably Hayyim Vital (1543-1620). SAMUEL A. HORODEZKY, *Torath ha-Kabbalah shel Rabbi Yizhoq Ashkenazi* (1947), offers a representative anthology of Lurianic teaching (in Hebrew), culled from the writings of Luria's disciples, and arranged topically. ISAIAH TISHBY, *Torath ha-Ra v'eha-Qelipah be-Kabbalath ha-Ari* (1942), analyzes the notions of evil and "breaking of the vessels" in Lurianic thought (in Hebrew).

## Luther, Martin

The founder of the 16th-century Reformation and of Protestantism, Martin Luther is one of the pivotal figures of Western civilization, as well as of Christianity. By his actions and writings he precipitated a movement that was to yield not only one of the three major theological units of Christianity (along with Roman Catholicism and Eastern Orthodoxy) but was to be a seedbed for social, economic, and political thought.

### LUTHER AS EDUCATOR AND MONK

**Early life and education.** Martin Luther was born on November 10, 1483, at Eisleben in Thuringian Saxony (Germany). His parents, Hans and Margarethe Luther, who had moved there from Möhra, soon moved on again to Mansfeld where Hans Luther worked in the copper mines, prospering enough to be able to rent several furnaces and to obtain a position among the councillors of the little town in 1491. Luther's few recollections of childhood that have survived reflect a sombre piety and strict discipline common in that age. His schooling seems to have been unremarkable: the Latin school at Mansfeld, a year at a school in Magdeburg (run by Brethren of the Common Life, a medieval lay group dedicated to Bible study and education) and at Eisenach in his 15th year, where he made valued older friends. In the spring of 1501 he matriculated in arts at the University of Erfurt, one of

the oldest and best attended universities in Germany. There he talked long and enough to be nicknamed "the Philosopher," and played the lute. He took the usual arts course and graduated with the B.A. degree in 1502. He took his M.A. in 1505, placing second among 17 candidates. In an age when few students got as far as the master of arts degree, he had fulfilled his parents' hopes. Like many other parents of his time, Hans Luther intended his son to become a lawyer, and he paid cheerfully enough for the expensive textbooks when Martin began legal studies. He was chagrined to learn that his son, without consulting his parents, had decided to enter religion and had sought admission to the house of Augustinian Hermits in Erfurt.

**Brother Martin Luther.** Evidence on the reason for his decision to enter the religious life is scanty. In his later, not always reliable, *Tischreden* ("Table Talk"), it is related that on July 2, 1505, he was returning from a visit to his parents when he was overtaken by a thunderstorm near the village of Stotternheim and cried out in terror, "Help, St. Anne, and I'll become a monk." In his *De votis monasticis* ("Concerning Monastic Vows," 1521) Luther says "not freely or desirously did I become a monk, but walled around with the terror and agony of sudden death, I vowed a constrained and necessary vow." He sold most of his books, keeping back his Virgil and Plautus, and on July 17, 1505, entered the monastery at Erfurt.

*Augustinian Order at Erfurt.* In joining the eremitical order of St. Augustine, Luther had joined an important mendicant order, which by the middle of the 15th century had over 2,000 chapters. As a result of reforms carried through in 1473, the house at Erfurt, to which Luther went, accepted the strict, observant interpretation of the rule. Under Johann von Staupitz, Luther's mentor and vicar general to the order, a revised constitution was made in 1504. Luther made his profession as a monk in September 1506 and was then prepared for ordination. He was ordained priest in April 1507 and his first mass took place at the beginning of May. He had studied a treatise on the canon of the mass by a famous Tübingen Nominalist Gabriel Biel (d. 1495), who, like other "modern" Nominalists, claimed that only named particulars exist and that universal concepts are formed through intuition, and he approached the ceremony with awe. To this occasion his father came with a group of friends, and Luther took this first opportunity to explain personally the imperious nature of his vocation. His father's disgruntled retort, "Did you not read in Scripture that one shall honour one's father and mother?" struck deep into his memory.

The thunderstorm experience

*Wittenberg University.* Luther was selected for advanced theological studies; some of his university teachers were Nominalists of the "modern" way of the English philosopher theologian William of Ockham, whose views tended to undercut the prevailing rationalism of Scholasticism, the theological school of thought founded in the 11th century that attempted to reconcile revelation with reason. In 1508 Luther went to the new University of Wittenberg (founded 1502), where, though Ockhamism had a foothold, the school of Realism that claimed that universals exist and can be known by reason was championed by scholars such as the Realist Martin Pollich. The little town was a contrast to Erfurt, but at least the university was young and forward-looking, and to its comparative remoteness Luther would one day owe his life. The Schlosskirche (called the Church of All Saints) was closely connected with the university, and the elector of Saxony, Frederick III the Wise (1463–1525), lavished generous patronage on both. In March 1509 Luther took the degree of *baccalaureus biblicus* at Wittenberg, returning to Erfurt for his next degree, of *sententiarius*, which involved expounding on the *Sententiae* (*Sentences*), a medieval theological textbook by Peter Lombard. He had begun his teaching with a course on Aristotle's *Nicomachean Ethics* and now began his career as a theologian with lectures on the *Sentences*. Some of his notes have survived, and if their theology is unexciting there is apparent an acid vehemence at the intrusion of philosophy and above all of Aristotle into the realm of theology.

Influence  
of  
Johann  
von  
Staupitz

Johann von Staupitz, vicar general of the German Augustinians, was very important in Luther's career as his teacher, friend, and patron. Staupitz seems to have been theologically trained as a Thomist (Realist) and was also influenced by the Augustinian tradition of his order, though his theology shows elements derived from the conflation in the late 15th century of the *devotio moderna* (modern devotion, a term used to describe the spirituality of the Brethren of the Common Life) with German mysticism. His attempt to revive stricter discipline and to unite the observant and conventual Augustinians in Germany led to dispute, and Luther was one of two monks chosen to go to Rome to present the appeal of some dissident houses. He made the journey, the longest of his life, probably late in 1510, and his earnestness was shocked by the levity of the Roman clergy and by the worldliness so evident in high places. The appeal failed, and Luther returned to become a loyal supporter of Staupitz.

Staupitz became interested in his gifted pupil and, perhaps alarmed by his introspectiveness, encouraged him to proceed to his doctorate and to a consequent public teaching career. Luther took his D.Th. on October 19, 1512. The degree was important for Luther, with its implications of public responsibility. He soon took on the duties of a professor in succeeding Staupitz in the chair of biblical theology. This was his lifelong calling, and the exposition of the Bible to his students was a task that called forth his best gifts and energies, one that he sustained until ill health and old age made him relinquish it at the end of his life. In between lectures, in a manner of speaking, he began the Protestant Reformation.

*Religious and theological questions.* Meanwhile, Luther's own religious and theological difficulties were becoming acute. He had entered into the search for evangelical perfection with characteristic and serious zeal, and sought exactly to fulfill the rule of his order. Nonetheless, he soon found himself in problems difficult for him to understand, struggling against uncertainties and doubts, unhappily bearing a crippling burden of guilt, which neither the sacramental consolations (*e.g.*, the Lord's Supper and penance) of the church nor the wise advice of skilled directors was able to assuage. This distress, which had its centre in his unquiet conscience, brought him into states of anxiety and despair. Nor were his difficulties lessened by the emphases of the Ockhamist theology, which encouraged an extroverted moralism, stressed the human will, and left aspects of uncertainty at the very points where Luther needed most to be reassured. "Temptation" (*Anfechtung*) was to become an important word for Luther's theology, a term that suggests the fight for faith, of

which Staupitz could say that such experiences were meat and drink to Martin Luther. These inward, spiritual difficulties were enhanced by theological problems.

**Discovery of "the righteousness of God."** At the entrance to the world of the thought of St. Paul, Luther was halted—the road blocked by a word that intensified his difficulties to an almost intolerable degree. This was the conception of the "righteousness of God." His sombre childhood piety had made him intensely aware of God's judgment, and as a lecturer in the arts faculty at Wittenberg he had had to expound the Hellenic conception of justice, as he found it in the *Nicomachean Ethics* of Aristotle. Encouraged by the use of *justitia* ("righteousness" or "justice") in the works of several Nominalists, he came to think of God's justice as being primarily the active, punishing severity of God against sinners—*i.e.*, in particular actions. It was for him a final aggravation of his trouble that in Rom. 1:17 it is asserted that the justice of God is revealed in the gospel. Thus, Luther concluded, the divine demand was shown as extending beyond outward obedience to the Law, revealed in the Commandments, to purity of heart, to inward motive and intention, so that grace itself became a demand and an exaction. Such a God could be feared but not loved, could be obeyed out of constraint but never with that happy spontaneity that Luther felt to be of the essence of Christian obedience.

*Luther's inner conflict.* To Luther's sense of failure to obey the Law was added the feeling of hypocrisy, which drove him to the edge of what moral theologians described as "open blasphemy." In 1545, in a celebrated autobiographical fragment that he prefaced to his complete works, he thus described his feelings:

Luther's  
sense of  
hypocrisy

For however irreproachably I lived as a monk, I felt myself in the presence of God to be a sinner with a most unquiet conscience, nor could I believe that I pleased him with my satisfactions. I did not love, indeed I hated this just God, if not with open blasphemy, at least with huge murmuring, for I was indignant against him, saying "as if it were really not enough for God that miserable sinners should be eternally lost through original sin, and oppressed with all kind of calamities through the law of the ten commandments, but God must add sorrow on sorrow, and even by the gospel bring his wrath to bear." Thus I raged with a fierce and most agitated conscience, and yet I continued to knock away at Paul in this place, thirsting ardently to know what he really meant.

Thus, the dilemma. Illumination came at last, as in prayer and meditation he pondered the text, examining the connection of the words.

At last I began to understand the justice of God as that by which the just man lives by the gift of God, that is to say, by faith, and this sentence, "the justice of God is revealed in the Gospel," to be understood passively, that by which the merciful God justifies by faith, as it is written. "The just man shall live by faith." At this I felt myself to have been born again, and to have entered through open gates into paradise itself.

Justification  
by  
faith

There has been great controversy about this inner conflict, but it seems certain that there was for Luther just such a crisis as he later described and that it was resolved in the manner he narrates. There has also been argument about the novelty of this discovery. There is in fact a profound difference between the Hellenic conception of distributive justice and the biblical doctrine of the righteousness of God as a divine, saving activity displayed in the field of history and of human experience, and Luther had penetrated deeply into the Pauline vocabulary at this point. The accuracy of Luther's memory about this and, indeed, his integrity have sometimes been impugned, but the verdict of a modern Catholic historian, Joseph Lortz, may stand: that if the discovery were not new, it was at any rate "new for Luther."

*Salvation as grace.* Had Luther not written this account, it would have been necessary to conjecture something like it to account for the new importance that he gave to justification by faith, a priority it retained in the new theological framework of Protestantism. This became for him the nerve of the gospel, that salvation is to be thought of primarily in terms of grace, and of a divine

gift; that God's free, forgiving mercy is displayed in Jesus Christ; that the conscience, forgiven and cleansed, may be at peace, and that the soul, free from the burden of guilt, may serve God with a joyful, spontaneous, creative obedience. In his translation of the Bible Luther came to add "alone" after the word "faith" (*sola fide*) in the verse "For we hold that a man is justified by faith apart from works of law" (Rom. 3:28) because he felt it was demanded by the German language. The word alone or only was retained by the Reformers after him because it seemed to safeguard this important doctrine against such perversions as might seem to make salvation dependent on human achievement or a reward for human merit.

*Evaluation of Luther's experience of justification.* This experience ought not to be isolated, for Luther speaks of other problems of vocabulary (e.g., the conception of "repentance," *poenitentia*), and it cannot be assumed that this was for him a catastrophic personal experience such as befell St. Augustine, who had a mystical experience of God in the garden at Milan, or the 18th-century founder of Methodism John Wesley, who had a conversion experience at Aldersgate Street, London. About the date of the occurrence there has been much controversy. The publication of Luther's early lectures led naturally to the examination of these firstfruits of the young professor. Though an early view that it must have occurred during the period of Luther's first lectures on the Psalms (1513-15) has been damagingly criticized, Luther's use of the many-sided allegorism of the Middle Ages, which often found three or four levels of meaning in a single text, his concentration on the one historical meaning, and the Christ-centred core of theology of justification have led some scholars to believe that the illumination must have come to him before his lectures on the Letter to the Romans (1515-16).

Something depends on how the discovery itself is assessed: if it was a discovery that justification is a gift, that it is to be taken passively rather than actively, then (as the reference to Augustine's *De spiritu et littera*—"Concerning the Spirit and the Letter"—suggests) Luther was hardly moving beyond the Augustinian framework and it is probably from an early period. If, on the other hand, it was the more mature discovery of the relation of saving faith to the Word of God, then it must be placed later, perhaps in 1518-19. Many scholars now tend in this later direction and they emphasize how Luther's thinking was stimulated and redirected by the urgent pressure of the church struggle that began in 1517.

The net gain of this chronological discussion has been to demonstrate how important is the whole period of Luther's development from 1509 to 1521, and that his technical vocabulary and the categories of his theology were in movement throughout the whole of this period. Certainly his great courses of lectures on the Psalms (1513-15), on Romans (1515-16), Galatians (1516-17), and Hebrews (1517-18) reveal the growing richness and maturity of his thought.

*Luther as preacher and administrator.* Meanwhile, his other duties had accumulated. From 1511 he had been preaching in his monastery and in 1514 he became preacher in the parish church. This pulpit became the centre of a long and fruitful preaching ministry wherein Luther expounded the Scriptures profoundly and intelligibly for the common people and related them to the practical context of their lives. Within his order, he had become prior, and, in April 1515, district vicar over 11 other houses. Thus he became involved in a world of practical administration and of pastoral care that gave him valuable experience, standing him in good stead in later years when a large part of his vast correspondence would be concerned with the care of the German churches and the cure of needy souls.

The new University of Wittenberg found it must take sides in an academic crisis that faced the European universities of that day, the tension between an old and a new academic program. Before Luther's advent Martin Pollich, a leading professor at Wittenberg, had shown himself hospitable to Humanist influences, despite his preference for the older Thomism. Now Luther took the

lead in inaugurating a new program, involving the displacement of Aristotle and the Scholastic theologians by a biblical humanism that turned to the direct study of the Bible, using as tools the revival of Greek and Hebrew and a renovated Latin and as a dogmatic norm the "old Fathers" (the early Church Fathers, or teachers) and especially St. Augustine. Such a program Luther planned with the help of his senior colleague, Karlstadt, and his young friend Philipp Melancthon. In February 1517 he penned a series of theses against the Scholastic theologians, which he offered to defend at other universities. Though this attempt to export the Wittenberg program met with no success he could write in May that the battle was won at least in Wittenberg—"our theology, and that of St. Augustine reign." But if his theses remained dormant, a very different fate awaited those that he wrote later in that same year. He could hardly have thought that these would fire a train that would explode the Western Christian world.

#### LUTHER AS REFORMER

*The indulgence controversy.* The nature of indulgences. The nature and scope of indulgences had been more and more defined during the later Middle Ages, but there was still an element of that dogmatic uncertainty that has been called a theological weakness of the age. Indulgences were the commutation for money of part of the temporal penalty due for sin, of the practical satisfaction that was a part of the sacrament of penance, which also required contrition on the part of the penitent and absolution from a priest. They were granted on papal authority and made available through accredited agents. At no time at all did they even imply that divine forgiveness could be bought or sold, or that they availed for those who were impenitent or unconfessed. But during the Middle Ages, as papal financial difficulties grew more complicated, they were resorted to so often that the financial house of Fugger of Augsburg had to superintend the sacred negotiations involved in them.

The way was open for further misunderstanding when in 1476 Pope Sixtus IV extended their authority to souls in purgatory. The appeal to cupidity and fear, the pomp and circumstance with which these indulgences were attended, the often outrageous statements of some indulgence sellers were a matter of complaint. Luther himself had frequently preached against these abuses, for his patron, the elector Frederick, had amassed a great collection of relics in the castle church at Wittenberg, to which indulgences were attached. But the immediate cause of Luther's public protest was an indulgence that Frederick had prohibited from his lands, though it was available in nearby territory. This was a jubilee indulgence, offering special privileges, the ostensible purpose of which was the rebuilding of St. Peter's basilica in Rome. By a secret arrangement, half of the German proceeds were to go to the young Albert, archbishop of Mainz, who was deeply in debt owing to his rapid promotion to and payment for a number of high ecclesiastical offices.

*The Ninety-five Theses.* Of this Luther knew nothing until some time afterward. For him, the provocation lay in the extravagant claims of an old, tried hand at this kind of thing, the Dominican salesman of indulgences Johann Tetzel. With these claims in mind, Luther drew up the Ninety-five Theses, "for the purpose of eliciting truth," and fastened them on the door of All Saints Church, Wittenberg, on October 31, 1517, the eve of All Saints' Day and of the great exposure of relics there. These were tentative opinions, about some of which Luther himself was not committed. They did not deny the papal prerogative in this matter, though by implication they criticized papal policy; still less did they attack such established teaching as the doctrine of purgatory. But they did stress the spiritual, inward character of the Christian religion, and the first thesis, which claimed that repentance involved the whole life of the Christian man, and the 62nd, that the true treasure of the church was the most holy gospel of the glory and the grace of God, showed the author's intention. The closing section attacked the false peace, that "security," which as a young lecturer Luther had so often

The immediate cause of the indulgence controversy

Luther's growth in theological thought

attacked, of those who thought of divine grace as something cheaply acquired and who refused to recognize that to be a Christian involved embracing the cross and entering heaven through tribulation. Luther sent copies of the theses to the archbishop of Mainz and to his bishop. And here the invention of printing intervened. Copies were circulated far and wide, so that what might have been a mere local issue became a public controversy discussed in ever widening circles.

*Reaction to the Ninety-five Theses.* The archbishop of Mainz, alarmed and annoyed, forwarded the documents to Rome in December 1517, with the request that Luther be inhibited, at the same time reprimanding the indulgence sellers for their extravagance. At the time, it seemed to many that this was simply another squabble between the Dominicans and the Augustinians. Colour was given to this belief by the counter-theses prepared by a theologian, Konrad Wimpina, that Tetzel had defended before a Dominican audience at Frankfurt at the end of January 1518. When copies of these reached Wittenberg in March they were publicly burned by excited students. At Rome the pope merely instructed Gabriel della Volta, the vicar general of the Augustinians, to deal with the recalcitrant monk through the usual channels, in this case through Staupitz. Luther himself prepared a long Latin manuscript with explanations of his Ninety-five Theses, publication of which was held up until the autumn of 1518; it is a document of some theological importance, and shows how far from superficial Luther's original protest had been. Meanwhile, the chapter of the German Augustinians was held at Heidelberg, April 25, 1518. Luther was relieved of his extra duties as district vicar, in the circumstances a great relief and intended as such. He found great comfort in the support of his friends, and was himself in great form, winning over two young men, Martin Bucer, a Dominican, and Theodor Bibliander.

At this period Luther's theology was most especially a "theology of the cross"; i.e., a theology that stressed the revelation of Christ on the cross. According to Luther, the "theology of the cross" seems foolishness to the wisdom of the world and is opposed to the natural theology of divine power and majesty, which he attacked as a Scholastic "theology of glory." Important for him at this time was the inward religion preached by the 14th-century German mystic Johann Tauler and a short 14th-century mystical tract, the *Theologia Germanica*, that he himself edited and published (1516-18). In these months, therefore, he lay great stress on the need for the Christian to share the cross of Christ, in suffering and in temptation. Though these stresses were to recede into the background of Luther's developing theology, they were to remain important for the radical Reformation, for which the *Theologia Germanica* would be an important and seminal document.

*Involvement of Johann Eck.* During Luther's absence, and perhaps catastrophically, his senior colleague, Karlstadt, had taken action that was greatly to widen the scope and publicity of the controversy. The scholar Johann Eck (1486-1543) of Ingolstadt, a man of some learning, and with a zest for disputation, with whom Luther was already in friendly contact through a common friend, became involved in the controversy. He had written some observations on the Ninety-five Theses for his friend, the bishop of Eichstätt, and these manuscript observations, the so-called Obelisks, reached Wittenberg shortly before Luther went off to his chapter at Heidelberg; Luther himself replied with a few "Asterisks," but Karlstadt, concerned to defend the Wittenberg program, sprang into the fray with 379 theses, adding another 26 before publication. In some of these Eck was impugned. The Dominicans continued to press for Luther's impeachment, and proceedings against him for heresy began to move slowly in Rome. Luther himself did not improve matters by publishing a bold sermon on the power of excommunication that made it clear that here was not a man who would accept unquestioned whatever might be decided by the pope in terms of some undefined plenitude of power.

*The Augsburg interview, 1518.* *Luther before Cajetan.* A papal citation summoning Luther to Rome was sent to the cardinal Cajetan (1468-1534), a renowned Tho-

mist, at Augsburg. But at this perilous moment politics fatefully intervened, and the period during which the Luther affair might have been swiftly, drastically disposed of without wider disaster to the church was eroded by considerations of policy. The elector Frederick, as one of the seven prince electors of the Holy Roman Empire, was most important to the pope, in view of the imminent choice of a new emperor, and the pope could not afford to antagonize him. The result was that Luther was bidden to a personal interview with Cajetan at Augsburg. He arrived there on October 7 with an imperial safe-conduct. The discussion had moved from indulgences to the discussion of the relation between faith and sacramental grace (the unmerited gifts of God in such acts as Baptism and the Lord's Supper), when an argument developed between the two theologians about the meaning of the "treasure" of merits that the papal definition of Sixtus IV said that Christ had acquired, and the incensed cardinal dismissed Luther from his presence, telling him to stay away unless he would unconditionally recant.

*Luther's flight from Augsburg.* While Luther waited uneasily, the Saxon councillors reported rumours that he would be taken in chains to Rome. Eventually, bundled through a postern by his friends, he fled the city. Now he wrote an appeal from the pope to a general (or ecumenical) council and a full defense of his actions to his prince. Cajetan, meanwhile, lost no time in denouncing Luther to Frederick, who was in something of a dilemma, though it counted much for Luther that he had the admiring friendship of the elector's secretary, the Humanist Georg Spalatin. At this time, too, the Wittenberg theological faculty addressed the prince on Luther's behalf, pointing out that the fate of the university and its reputation would be involved in Luther's disgrace. At one moment, it seemed that Luther might have to depart, perhaps for France or Bohemia. There then appeared Karl von Miltitz, a papal diplomat, who applied "stick and carrot" tactics to the elector, dangling before him at one moment threats against Luther and at the next the signal compliment of the golden rose, symbol of high papal honour and recognition. The diplomat promised more than he could possibly perform, and after an interview with him at Altenburg, in January 1519, Luther sensed this and came to distrust him. A papal definition about indulgences, issued at Cajetan's request, seemed to show that Luther had indeed put his finger on some fatal ambiguities.

*The Leipzig disputation, 1519.* *Debate between Luther and Eck.* At Augsburg Luther had been in touch with Eck and arrangements were made for a public disputation at Leipzig in the summer. This was to be in the first place a debate between Eck and Karlstadt, though Luther was Eck's ultimate objective, but the hostility of George, duke of Saxony (the elector Frederick's first cousin), toward the Reformer raised difficulties about Luther's participation. Eventually it was arranged that Eck should debate with the two Wittenberg theologians in turn, in the castle of the Pleissenburg, Leipzig, at the end of July. There was a preliminary pamphlet skirmish. The issue between Eck and Karlstadt was the Augustinian doctrine of grace and free will, and Karlstadt wished to meddle neither with indulgences nor with papal authority. Among the preliminary matters, the origin of the papal power was raised and so Luther turned to a study of church history and Canon Law in the fateful weeks before the debate. A large contingent from Wittenberg attended, and in the presence of theologians from both universities, Duke George and notables of church and state, the debate began. Eck showed some skill in manoeuvring Luther into a position in which he cast doubt on the authority of the great General Council of Constance (1414-18), and also defended some of the propositions of Jan Hus, a Bohemian Reformer who had been declared a heretic at Constance and burned to death at the stake. Leipzig was a part of Germany with a strong feeling against Bohemia, and the admission was received as damaging, giving ground for Eck's loud boast that the disputation had been his personal triumph. Luther, who had earlier said of the debate that it had not begun in God's

Counter-theses and student reaction

"Theology of the cross"

Dispute over meaning of merits

Luther's relationship to Jan Hus

name and would not end in his name, left Leipzig somewhat shaken and disturbed by Eck's verbal manoeuvring.

*Luther's questioning of authority.* Eck was able to go off to Rome with new prestige to give sharpness to the process of Luther's official condemnation. Luther had now to examine the further implications of his actions to date, in relation to the authority of the church, of councils and of Scripture; his correspondence shows that he was reaching something like a crisis in his attitude to papal authority. There had been a small pamphlet war after the disputation that made it plain that there was strong support for Luther among the Humanists in Germany and Switzerland. Luther himself became involved in controversy with diverse theologians of Leipzig, and if he now wrote in the vernacular with increasing power and violence, his polemical writings reveal also his deep perceptions of the issues between himself and contemporary theology. Two Catholic universities, strongholds of tradition, Cologne and Louvain, next condemned Luther's teaching. But polemic was not Luther's main concern, and his *Sermon von den guten Werken* ("Sermon on Good Works"), issued in June 1520, is an important exposition of the ethical implications of justification by faith. As a tract it deserves to be associated with Luther's more famous tract on Christian liberty issued in the next months. On June 15, 1520, there appeared the papal bull (a decree issued under the papal seal) *Exsurge Domine* or "Lord, cast out," against 41 articles of Luther's teaching, followed by the burning of Luther's writings in Rome. Eck and the Humanist diplomat and cardinal Girolamo Aleandro (1480-1542) were entrusted with the task of taking the bull to the cities of Germany.

**The Reformation treatises of 1520.** Eck and Aleandro were alarmed to discover how swiftly German opinion had moved to Luther's side. In contrast to his treatment the year before, Eck had to seek refuge in Leipzig from physical violence. Aleandro did what he could in agitated correspondence to shock the Curia (papal administrative bureaucracy) into realizing the grave danger facing the church in Germany. Luther's friends, aware of how precarious his position was, sought to moderate his violence, but he now moved well beyond their horizon. In Luther's own opinion of himself, he was far too temperate in view of all the ecclesiastical hypocrisy and offenses. The result was the defiant tracts of the summer of 1520. The first, the real manifesto, was his *An den christlichen Adel deutscher Nation* ("Address to the Christian Nobility of the German Nation"), addressed to the rulers of Germany, princes, knights, cities, under the young emperor Charles V. It argued that in the crisis, when the spiritual arm had refused to take in hand the amendment of the church and the often expressed grievances of the German people against Rome (*i.e.*, the papacy), it was necessary for the secular arm to intervene and call a reforming council. The document was ill arranged and tailed off, but it found deep response among sections of the nation, and in the next months Luther was carried along with the tide of national resentment against Rome.

His second treatise, *De captivitate Babylonica ecclesiae praeludium* ("A Prelude Concerning the Babylonian Captivity of the Church"), intended for clergy and scholars, was an act of ecclesiastical revolution. It inevitably estranged many moderate Humanists, for it reduced to only three (Baptism, the Lord's Supper, and penance) the seven sacraments of the church, denied mass and attacked transubstantiation (the doctrine that the substance of the bread and wine is changed into the body and blood of Christ in the sacrament of the Lord's Supper), made vehement charges against papal authority, and asserted the supremacy of Holy Scripture and the rights of individual conscience. The third work, dedicated to the pope, was, as a still, small voice after the uproar, a minor classic of edification, *Von der Freiheit eines Christenmenschen* ("Of the Freedom of a Christian Man"), which made clear the ethical implications of justification by faith, and showed that his thought and his public actions were connected by a coherent theological core. On December 10, 1520, the students lit a bonfire before the Elster Gate in Wittenberg, and as they fed the works of

the canonists to the flames Luther added the papal bull (*Exsurge Domine*) against himself with suitable imprecation—"Because you have corrupted God's truth, may God destroy you in this fire."

In January 1521 the pope issued the bull of formal excommunication (*Decet Romanum pontificem*), though it was some months before the condemnation was received throughout Germany. Meanwhile, the imperial Diet was meeting at Worms, and there was a good deal of lobbying for and against Luther. In the end, Frederick the Wise obtained a promise from the emperor that Luther should not be condemned unheard and should be summoned to appear before the Diet. This enraged Aleandro, who asserted that the papal condemnation was sufficient and that the secular arm had only to carry out its orders. It also alarmed Luther's friends, who did what they could to dissuade him. Luther was firm in his determination to go, and began the journey in April 1521, undeterred by the news, on the way, that the emperor had ordered his books to be burned. What was meant to be the safe custody of a heretic turned out to be something like a triumphal procession, and when Luther entered Worms on April 16 he was attended by a cavalcade of German knights and the streets were so thronged as to enrage his enemies.

**The Diet and Edict of Worms, 1521.** *Luther's defiance of the Diet.* In the early evening of April 17, 1521, Luther appeared before the notables of church and state and faced the young emperor Charles V, whom he found cold and hostile. A pile of writings lay before him, but when he was formally asked whether he acknowledged them, his legal adviser insisted that the titles be read. In view of the gravity of recantation, Luther asked for time to think, a request that may have taken his enemies off guard. A day's respite was granted, and the following afternoon, in a larger hall, and before an even more crowded assembly, Luther reappeared. This time he could not be prevented from making a long speech. He distinguished between his writings: for the works of edification he need not and ought not to recant, for the violence of his polemic he would apologize, but for the rest he could not recant; and, as he went on to explain why, the demand was brusquely made for a plain, simple answer. This he now gave in words of unyielding defiance. He would recant if convinced of his error either by Scripture or by evident reason. Otherwise he could not go against his conscience, which was bound by the Word of God. Though evidence is now tilted against the authenticity of the famous conclusion, "Here I stand. I can do no other," it at least registers the authentic note of Luther's reply in a moment that captured the imagination of Europe. There was a moment of confusion with Eck and Luther shouting, and then the emperor cut short the proceedings. Luther strode through his thronging enemies to his friends, his arm raised in a gesture of relief and triumph.

There followed a diplomatic flurry. It was evident that Luther had powerful friends; there was some sabre rattling from the knights and the peasant emblem appeared in the streets. There is evidence to support Luther's boast that had he wished he could have started such a game that the emperor's life would not have been safe. The radical Reformer and social revolutionary, Thomas Müntzer, later asserted that had Luther recanted the angry knights would have killed him. At any rate, Luther was now given what he had long asked for in vain, something like a real hearing before reasonably impartial judges, while he was kindly handled by the archbishop of Trier. But he could not now make even minor concessions, and the discussions broke down on the fallibility of councils. He was formally dismissed and departed under his safe-conduct.

Despite his spectacular moral triumph, Luther's enemies, nonetheless, achieved something important at this point when a rump Diet passed the Edict of Worms. It declared Luther to be an outlaw whose writings were proscribed. The edict was to shadow him and fetter his movements all his days. It meant also that his prince must, for a time at least, walk delicately and could not publicly support his protégé. The result was the pretended

Excommunication

"Address to the Christian Nobility"

"Here I stand. I can do no other."

kidnapping of Luther who was lodged secretly in the romantic castle of the Wartburg, near Eisenach.

*Luther at the Wartburg.* In this aerie among the trees Luther remained until March 1522. Known as Junker Georg, or Knight George, he dressed as a layman, grew a beard, and put on weight. The lack of exercise and the unwontedly rich diet brought on physical distress, whereas his mind, flung back on itself after months of crisis, knew intense reaction in a period of acute depression of the kind that Luther ranked high among temptations. But he was far from idle. He finished a beautiful exposition of the Magnificat (the song of Mary, the mother of Christ, in the liturgy) and prepared an edition of sermons on the Epistles and Gospels at mass, which he thought was perhaps his best writing. Although away from books, he wrote his ablest controversial piece, *Rationis Latomianae pro Incendiariis Lovaniensis Scholae sophistis reddita Lutheriana confutatio* ("Refutation of the argument of Latomus"—who was a member of the theological faculty of the University of Louvain), containing a luminous exposition of justification. Most important of all, he began to translate the New Testament from the original Greek into German. He did not believe that such work should be left to one mind, and soon enlisted his colleagues, notably Melancthon, in the enterprise. But Luther's was the controlling genius, and the resulting New Testament (published in September 1522), like the Old Testament, translated from the Hebrew, which followed later (1534), was a monumental work, which had deep and lasting influence on the language, life, and religion of the German people. He had now to deal with some of the practical implications of his revolt. Private masses, celibacy of clergy, religious vows were no theoretical questions, but were themselves entangled in a network of legal, financial, and liturgical affairs. He wrote about these things forthrightly, and Spalatin tried in vain to hold up their publication, for in Wittenberg there were growing difficulties, and the prince, the university, and the cathedral chapter were all, for various reasons, anxious to go slowly.

**Commotion in Wittenberg, 1521–22.** *Radical reform.* There was a lively section of the town and of the university, however, that was determined to force the pace, and there were violent scenes in the streets and churches early in October 1521. Yet Luther, on a secret visit to his friends early in December, was not alarmed, and it was his influence that led the Augustinians to decide, in the new year, that those of them who wished might return to the world. Two radical leaders now appeared, the incorrigible troublemaker Karlstadt and Gabriel Zwilling, an ebullient spellbinder from the Augustinians. When Karlstadt announced his betrothal to a girl of 16, and at Christmas administered Communion in both kinds (bread and wine) while dressed as a layman, attacked images in a violent tract and in innumerable theses denounced vows and masses, and demanded a vernacular liturgy, it was evident that here was a program that in timing and method differed from Luther's. Moreover, its appeal to Scripture was legalistic and made matters of necessity things that for Luther lay within the option of Christian liberty. In the new year, the town council issued a notable and pioneering ordinance regulating religion, public morals, and poor relief, a document that owes much to Luther's teaching and perhaps something to the initiative of Karlstadt. At the end of 1521 confusion was increased by the arrival of the so-called Zwickau prophets, radicals on the run from the town of Zwickau, who spoke impressively of revelations given them through dreams and visions, claiming that the end of the world was near and that all priests should be killed. A flustered and outmanoeuvred Melancthon wrote urgently for advice to Luther, who sent wise and calm counsel.

*Restoration of balanced reform.* In the next months the situation worsened and in March 1522 Luther returned to Wittenberg, explaining the reason for his disobedience to instructions in a justly famous letter to his prince. Then, deliberately habited as an Augustinian monk once more, he took charge of his town pulpit and in a powerful series of sermons redressed the balance of reform. In these important utterances, the difference be-

tween Luther's conservatism and the radical pattern of reform is made plain. Luther deplored the use of violence, for the Word of God must be the agent of reform. He believed that revolt could not take place without destruction and the shedding of innocent blood; that the real idols are in the hearts of men and if their hearts are changed the images on church walls must fall into disuse. Moreover, the pace of reform must take into account the unconverted, weaker brethren. From this time onward Luther fought a war on two fronts, against the Catholics and against those whom he lumped together as *Schwärmer* ("fanatics"). One result of the Wittenberg crisis was to slow down the practical reforms, and though Luther introduced a reformed rite (*Formula Missae* or "Formula of the Mass," 1523) it was not until 1526 that he provided a vernacular liturgy (*Deutsche Messe*, or "German Mass"). Throughout Germany the evangelical movement continued to grow, and it was apparent that the Edict of Worms would not be everywhere enforced. A Diet at Nürnberg, 1522–23, refused to suppress the evangelical preachers and demanded a reforming, national council; though Catholic pressure was stronger in the following year, the Diet again pressed for a council and would consent only to the enforcement of the edict "as far as possible."

**The Peasants' War.** *Activities of the radical Reformers.* On his journeys to and from Worms Luther had been dismayed by the evident social and political unrest. In the next months he wrote open letters, warning the rulers of Saxony and the councils of such cities as Strassburg of the danger that the new radical teaching would provoke revolution. In 1523 he made his own views of secular government plain in an important treatise *Von weltlicher Obrigkeit* ("Of Earthly Government"), in which he firmly asserted the duty of a Christian prince and the place of secular government within God's ordinances for mankind; he distinguished between the two realms of spiritual and of temporal government, through which the one rule of God is administered, and stressed the duty of civil obedience and the sinfulness of rebellion against lawful authority.

In Saxony the radical teachers posed a problem for their untheological rulers. In Orlamünde, after having been rebuked at Wittenberg, Karlstadt had converted the community to his own brand of mystical quietism. Luther made a preaching tour of the area at the request of his prince, and was greeted with hostility and ridicule. Luther himself denounced such social evils as usury, but in Eisenach the fiery preacher Jakob Strauss conducted a violent campaign against usury and tithes. Most formidable of all, in the little town of Allstedt, Thomas Müntzer, an unruly genius, combined his own ingenious liturgical reforms with a program of holy war. Himself a former "Martinian" (or follower of Martin Luther), he not only shared Karlstadt's enthusiasm for the mystics but added an explosive element (perhaps influenced by Hussite teaching) that gave point to Luther's worst fears. Müntzer threatened revolution and claimed that God would rid the world of its shame. Luther's warnings and events themselves forced the rulers to take action, and in the summer of 1524 Müntzer fled and Karlstadt was exiled. Müntzer wrote in a pamphlet that Luther was nothing more than a shameless monk, "whoring and drinking," and called him Dr. Liar. Karlstadt also wrote a series of tracts against his former comrades, denouncing, among other things, the corporeal presence in the Eucharist. Luther replied in a devastating and profound treatise, *Wider die himmlischen Propheten, von den Bildern und Sakrament* ("Against the Heavenly Prophets in the Matter of Images and Sacraments"). He claimed that the radical Reformers sought glory and honour, not the salvation of men's souls.

*Luther's response to the Peasants' War.* In the summer of 1524 the Peasants' War had broken out in the Black Forest area. Their program was variously motivated. Their demands were for concrete medieval liberties connected with the game and forest laws or with tithes. Some of them drew on Catholic teaching, others on the theology of Zwingli and of Luther, who had set an example of

Luther's dislike for violence

Influence of Luther's translation of the Bible on the German language

The two realms theory

successful defiance of authority, had been no respecter of dignities, and whose teachings about Christian liberty and a priesthood in which all believers shared were plainer than his subtle distinctions between two kingdoms. Thus, both where he was understood and where he was misunderstood, Luther's influence in the Peasants' War has to be taken into account. Some of the moderate peasants included Luther among possible arbitrators. He himself published in May 1525 the *Ermahnung zum Frieden* ("Exhortation for Freedom"), an analysis of the "12 articles" of the Swabian peasants, sympathizing with just grievances, criticizing the princes, but repudiating the notion of a so-called Christian rebellion: "My dear friends, Christians are not so numerous that they can get together in a mob." Luther also claimed that the worldly kingdom cannot exist without inequality of persons.

Luther's  
view of  
rebellion

In the spring of 1525 the Thuringian peasants rose, with Thomas Müntzer among their leaders, and at first seemed likely to carry all before them. Faced with imminent political chaos, Luther wrote a brutal, virulent broadsheet, *Wider die räuberischen und mörderischen Rotten der andern Bauern* ("Against the Murdering and Thieving Hordes of Peasants"). The writing was less violent than Müntzer's hysterical manifestos, but it was bad enough. It appeared, however, as an appendix to his moderate tract about the "12 articles." Moreover, words written at the height of the peasant success read very differently after their collapse at the Battle of Frankenhausen, May 15, 1525, and in the bloody reprisal that followed. It was typical of Luther that he refused to climb down, to regain lost popularity, and neither thereafter nor at any time can he be accused of subservience to rulers. As he had once refused to become the tool of the knights, so he had never "taken up" the peasant cause. But he confirmed many peasants in their preference for the radical ideology, which was soon to find more peaceful coherence in the Anabaptist movement.

**Watershed year, 1525.** *Luther and Erasmus.* In other ways, too, 1525 was a watershed in Luther's career. At the height of the Peasants' War in June 1525, "to spite the devil" he had married Katherina von Bora, a former nun. He certainly needed looking after, and she proved an admirable wife and a good businesswoman. His home meant a great deal to him and was an emblem for him of Christian vocation, so that he included domestic life among the three hierarchies (or "orders of creation") of Christian existence in this world, the other two being political and church life. In the same year there came his open break with the great Humanist Erasmus. The differences between the two men had long been apparent, and Erasmus, who found in Luther the type of violent, dogmatic mendicant theologian he had always detested, liked what he saw of the Reformation less and less. Nonetheless, both men had a common band of admirers and friends and entered the arena with reluctance. Erasmus, in his *De libero arbitrio*, or "Concerning Free Will" (1524), attacked Luther's doctrine of the enslaved will and provoked a resounding reply in Luther's *De servo arbitrio*, or "Concerning the Bondage of the Will" (1525), a one-sided, violent treatise that, nevertheless, includes profundities still fruitfully debated. In that year, too, Frederick the Wise died. The two men had met only once, but Luther owed much to this prince. The new ruler, the elector John, and his successor John Frederick were Luther's devout supporters and with other princes, notably Philip, landgrave of Hesse, and Albert of Brandenburg, formed a coherent group in the imperial Diet.

Luther's  
marriage

*The Diets of Speyer.* The hostility of Charles V to the Reformers and his devotion to the Catholic faith never altered, but he had to take account of political exigencies, his quarrels with the Pope and with the king of France, and the need for support against the Turks. At the Diet of Speyer in 1526, the Edict of Worms was suspended, pending a national council; in the interval it was ruled that each prince must behave as he could answer to God and to the emperor. Luther stated that there was no fear or discipline any longer and that everyone did as he pleased. As a result, it was possible to plan the reorganization of

the Saxon Church, and a visitation was carried out by jurists and theologians (1527-28). Some scholars have seen a tension between Melancthon's *Instruktion für die Visitatoren*, or "Instructions for the Visitation" (1528), and Luther's comments, which may reveal his distrust of secular intervention in spiritual affairs; and though he thoroughly approved of the development of the evangelical *Landeskirchen* ("territorial churches") there were to be aspects of Lutheranism that blurred rather than reflected Luther's theological distinctions. At the second Diet of Speyer in 1529, renewed Catholic pressure led to the reversal of earlier concessions, drawing from the evangelical princes, and from a number of cities, a protest that won them, for the first time, the name Protestant.

**The eucharistic controversy.** *Doctrinal differences among the Reformers.* Doctrinal differences about the Eucharist broke the common evangelical front. Though all the Reformers repudiated the sacrifice of the mass, they were deeply divided about the nature of the divine Presence. Luther, with simple biblicism, insisted that Christ's words "This is my body" must be literally interpreted, because allegory is not to be used in interpreting Scripture unless the context plainly requires it. Karlstadt's fanciful argument (that the word *this* referred not to bread and wine but the Lord's physical body) was soon dropped. Zwingli won many to his view that "is" must be taken as "means," and his learned friend, the Humanist John Oecolampadius, brought support from the early Church Fathers for a spiritual Presence and stressed the idea of the 2nd-century Tertullian that "body" meant "sign of the body." Thus, the initial debate was about interpretive principles, about the words of institution, though the scriptural argument moved to the relevance or irrelevance of the Gospel According to John (*e.g.*, "he who eats my flesh and drinks my blood has eternal life" [John 6:54]).

The debate turned to the intricate matter of Christology (*i.e.*, doctrine of Christ). Zwingli insisted on the distinction between the two natures of Christ and that because it is the property of a human body to be in one place, Christ's human body was not here but in heaven. Luther, on the other hand, stressed the indivisible unity of the one Person of Jesus Christ, the mediator. Without going into a metaphysical doctrine of "ubiquity," or Presence everywhere (which was developed by other Lutherans), he asserted that Christ is present wherever he wills to be and that we are not to think of him in heaven "like a stork in a nest." Martin Bucer and the Strassburg theologians echoed the more positive stresses of the Swiss, and Bucer used the Realist language of the early Church Fathers to support a true, spiritual Presence. Luther's treatise *Dass diese Worte Christi "Das ist mein Leib" noch fest stehen wider die Schwärmgeister* ("That these words of Christ 'This is my Body' still stand firm against the Fanatics," 1527) showed that in three years of controversy he had not budged. Zwingli's Latin tract *Amica exegesis* ("A Friendly Exegesis," 1527) was far less amicable than the title suggests and brought a great outburst from Luther, the impressive *Vom Abendmahl Christi, Bekenntnis* ("Confession of the Lord's Supper," 1528). This convinced Bucer that he had misunderstood Luther, who did not mean a local, confined Presence; and from then on he intensified his awkward, well-intended attempts to make peace.

*The Marburg Colloquy and the Diet of Augsburg.* The political advantages of a common front were obvious, not least to the vulnerable Zwingli and Philip, landgrave of Hesse, and the prince invited theologians of both sides to a private colloquy at Marburg in October 1529. Luther began by saying that in his opinion Zwingli did not know much about the gospel. When Zwingli asked if it was permissible for a Christian to ask how Christ could be present in the bread and wine of the Lord's Supper, Luther replied that if the Lord commanded him to eat crab apples and manure, he would do it because it was a command. After three days' debate, there was no agreement about the Eucharist, though the air had been cleared of many misunderstandings. But if the conference failed, there were agreements on other

Luther  
and  
Zwingli

The  
Augsburg  
Confession

issues, and these might have been fruitful had not the coming imperial Diet caused the Wittenberg theologians to draw away from the Swiss. As an outlaw, Luther could not attend this fateful Diet of Augsburg and had to fidget in the castle of Coburg, leaving the care of the gospel to Melanchthon, who did very well and produced in the Augsburg Confession (1530), one of the great documents of the Reformation as well as a normative confession of Lutheranism.

Luther used his influence to stiffen the elector against compromise, though from this time onward he could not refuse his consent to political Protestantism as it took a more and more military shape in the Schmalkaldic League, which was established by Protestant princes in preparation for armed resistance to Catholic aggression. The political situation again changed swiftly, however, and, confronted with the Turkish invasion, the Emperor agreed to a truce with the Protestants in the Religious Peace of Nürnberg (1532). This was a valuable breathing space, and its effects are evident in Luther's writings in the next years. Now, more and more, Luther left matters to the action of Melanchthon. Opponents attempted to break up the friendship of the two. Luther said, regarding this matter, that if Melanchthon would allow himself to be won over by their opponents, "he could easily become a cardinal and keep wife and child."

**Growth of Lutheranism, 1530-46.** *Melanchthon's leadership.* Luther acquiesced in the eucharistic agreement—by which the south Germans reached agreement on the Lord's Supper—that the triumphant Bucer brought off with Melanchthon in 1536 (the Wittenberg Concord), though Bucer was unable to widen the agreement and bring in the Swiss. When an English embassy from Henry VIII arrived to discuss joining the Schmalkaldic League, it was Melanchthon who drew up the theological agenda (the Wittenberg Articles, 1535) with an ambiguous statement of justification of which Luther wrote "this agrees well with our teaching." But he would not follow Melanchthon when he thought he wrote too irenically about the papacy, and as the papal council loomed near he penned his own uncompromising Schmalkaldic Articles (1537).

Melanchthon's great work in the field of education was to earn him the name preceptor of Germany, but Luther too was important in this matter. His open letter to the councillors of Germany about the need for schools (1524), and his published sermon *Dass man Kinder zur Schulen halten solle* ("On Keeping Children at School," 1530) show how wise and forward looking was his concern for education. He himself composed two important catechetical documents, the lovely classic, *Kleiner Katechismus* ("Small Catechism"), and *Grosser Katechismus* ("Large Catechism," 1529), for teachers and pastors.

In Wittenberg Luther had a group of able colleagues: Justus Jonas, Johannes Bugenhagen, Feliks Krzyzak (Cruciger). In scores of cities his disciples and friends spread the evangelical teaching that formed the Lutheran pattern of church life. Luther, though not pre-eminent as a liturgist, provided orders of worship from which numerous other *Kirchenordnungen* ("church orders") were derived. The influence of Luther's writings was everywhere felt in the Western Christian world. It was in Scandinavia that the Lutheran Church struck its deepest roots and won its most complete ascendancy, but it also had deep influence in Austrian and Hungarian lands. Luther realized the importance of hymns and encouraged his friends to write them. He wrote a score of fine hymns, four of which appeared in his first Protestant hymnbook in 1524. The famous "Ein feste Burg ist unser Gott" ("A Safe Stronghold Our God is Still" or "A Mighty Fortress Is Our God") became almost an event in European history. During the last decade of his life, John Calvin (1509-64) was the rising portent in Switzerland, though Luther's personal contact with him was slight. He continued to attack bitterly the *Schwärmer* ("fanatics"), who then included besides the Anabaptists a number of radicals such as Kaspar Schwenckfeld, a Reformer who tried to mediate between various groups. Although he maintained to the end his view that error can be con-

Luther's  
hymns

quered only by the Word, Luther came to accept the punishment of the Anabaptists.

*The affair of Philip of Hesse.* In 1540 Bucer and Melanchthon took the initiative in conniving at the deplorable bigamy of Philip of Hesse, but Luther was involved and had he willed could have stopped it. It would have been easy for Philip to remedy his incorrigible incontinence by taking a mistress, but this he refused to do, though his guilty conscience kept him from the sacrament. The desperate device, as a lesser of evils, was to grant him a secret dispensation to take a second wife. When the affair became public Luther angrily threatened to expose the whole story. He himself was so far from lowering moral standards that in the next years he threatened to leave Wittenberg because public morals there were a shame on a city that had known the evangelical teaching so long. After a serious illness in 1537 he was an almost chronic invalid, prematurely aged, seldom free from discomfort, often in pain, and he brought his teaching career to an end with lectures on Genesis. In the last decade of his life he had to witness the recovery of the papacy, which he thought to have been mortally wounded, in the preparations for the Council of Trent (1545-63), and the growing menace of Catholic military might. His last outstanding controversial treatise was *Von den Conciliis und Kirchen* ("Of Councils and Churches," 1539). Among his last writings, *Against the Anabaptists, Against the Jews, Against the Papacy at Rome, Founded by the Devil*, the most violent is the last, coarse and angry but still defiant.

*Luther's last activities.* Early in 1546 Luther was asked to go to Eisleben to mediate in a quarrel between two arrogant young princes, Counts Albrecht and Gebhard of Mansfeld. He was old and ill, but they were his *Obrigkeiten* ("authorities") to whom he owed obedience, and he set off in the snowy winter, leaving his wife stiff with anxiety. His letters to her teased her, comforted her, and spoke at last of a mission successfully accomplished. But he had overtaxed his strength, and in a few hours the chill of death came upon him. He died in Eisleben, the town where he was born, on February 18, 1546, and his body was interred in the Church of All Saints, Wittenberg. The great funeral orations by Bugenhagen and Melanchthon, who knew him so well, are not to be dismissed as simply panegyric. They witness that his intimates regarded him as a really great man, standing within the historic succession of prophets and doctors of the church, through whose life and witness the Word of God had gone forth, conquering and to conquer.

Luther's  
death

#### LUTHER AS THEOLOGIAN

Luther was no systematizer, like Melanchthon or Calvin, though the dissensions among Lutheran theologians after his death, each appealing to one aspect of his thought, testify to the width, coherence, and delicate balance of Luther's own teaching. The basis of his theology was Holy Scripture; and though the differences between his own and Augustine's thought are important, Augustine must stand next to the Bible among the influences upon his mind. The doctrines of salvation were of prime importance for him, and here the two great, many-sided complex conceptions of the Word and of faith are important. His often subtle doctrine about civil obedience was not always understood by his later followers, and non-theological factors in German history perpetuated and even perverted this misunderstanding. His doctrine of Christian vocation in this world and the importance of human life in the world became part of the general Protestant and Puritan inheritance. In other matters—in the room allowed for Christian liberty, in his conception of the part played by law in Christian life, and in his insistence on the Real Presence in the Eucharist—his theology differs from the patterns that emerged in the Reformed (Presbyterian) churches, in Puritanism, and in the sects such as the Anabaptists.

#### MAJOR WORKS

##### *In Latin*

THEOLOGICAL WORKS: *Epistola Lutheriana ad Leonem decimum summum pontificem. Dissertatio de libertate Christiana*

*per autorem recognita* (1519; "Concerning Christian Liberty"); *De votis monasticis* (1521); *De captivitate Babylonica ecclesiae praeludium* (1520; "A Prelude Concerning the Babylonian Captivity of the Church"); *De servo arbitrio* (1525; "Concerning the Bondage of the Will").

CONTROVERSIAL WRITINGS: *B. Martini Lutheri theses Tezeli, indulgentiarum institori oppositas* (1517; Ninety-five Theses); *Rationis Latomianae pro incendiariis Lovaniensis scholae sophistis reddita Lutheriana confutatio* (1521).

EXEGESIS: *Enarrationes epistolarum et evangeliorum, quas postillas vocant* (1521).

#### In German

THEOLOGICAL WORKS: *Von den guten Wercken* (1520; "Of Good Works"); *Von weltlicher Uberkeytt, wie weytt man yhr gehorsam schuldig sey* (1523; "Of Earthly Government"); *Das diese wort Christ (Das ist mein leib etc.) noch fest stehen widder die Schwermgeister* (1527; "That These Words of Christ 'This is My Body' Still Stand Firm Against the Fanatics"); *Vom Abendmal Christi, Bekenntnis* (1528; "Confession of the Lord's Supper"); *Von den Conciliis und Kirchen* (1539; "Of Councils and Churches").

CONTROVERSIAL WRITINGS: *An den christlichen Adel deutscher Nation* (1520; "Address to the Christian Nobility of the German Nation"); *Widder die hymelischen Propheten von den Bildern und Sacrament* (1525; "Against the Heavenly Prophets in the Matter of Images and Sacraments"); *An die Radsherrn aller Stedte deutsches Lands: Das sie Christliche Schulen aufrichten und hallten sollen* (1524); *Ermanunge zum Friden auff die zwelff Artikel der Bawrschafft ynn Schwaben* (1525); *Wider die mordischen un reubischen Rotten der Bawren* (1525); *Wider Hans Worst* (1541); *Wider das Bapstum zu Rom vom Teuffel gestift* (1545).

TRANSLATIONS AND EXEGESIS: *Das Newe Testament Deutsch* (1522); *Biblia, das ist, die gantze Heilige Schrift Deusch* (1534); *Das Magnificat vertueschet und ausgelegt* (1521).

OTHER WORKS (LITURGICAL): *Deutsche Messe* (1526). (DIDACTIC): *Der kleine Catechismus* (1559; "Small Catechism"); *Deusch Catechismus* (1529; "Large Catechism"). Among his hymns the most famous is probably "Ein feste Burg ist unser Gott" ("A Mighty Fortress Is Our God").

#### BIBLIOGRAPHY

*Luther's writings*: *The Works of Martin Luther*, 6 vol. (Philadelphia edition, 1915-32); *Luther's Works* (American edition), ed. by J. PELIKAN and P. LEHMANN, 56 vol. (1955-), henceforth an indispensable tool for English study. There is a single-volume anthology edited by J. DILLENBERGER, *Martin Luther: Selections from His Writings* (1961); and also E.G. RUPP and W.B. DREWERY, *Martin Luther* (1970). The following are important volumes in the "Library of Christian Classics": vol. 15, *Luther's Lectures on Romans*, ed. by W. PAUCK (1961); vol. 16, *Early Theological Writings*, ed. by J. ATKINSON (1962); vol. 17, *Luther and Erasmus*, ed. by E.G. RUPP and P.S. WATSON (1969); vol. 18, *Letters of Spiritual Counsel*, ed. by T.G. TAPPERT (1955). See also *A Commentary on St. Paul's Epistle to the Galatians*, ed. by P.S. WATSON (1953). In German the definitive edition is the Weimar edition by J.C.F. KNAAKE et al. (1883-).

*Studies*: Of biographical studies in English, the most readable are: R.H. BAINTON, *Here I Stand!* (1950); FRANZ LAU, *Luther* (1959; Eng. trans., 1963); and W.J. KOORMAN, *Maarten Luther* (1946; Eng. trans., *By Faith Alone*, 1954). P. SMITH, *The Life and Letters of Martin Luther* (1911), is the best of the older studies. For a broad survey, see E. G. SCHWIEBERT, *Luther and His Times* (1950); on the young Luther: R.H. FIFE, *The Revolt of Martin Luther* (1957); for a brief account: E.G. RUPP, *Luther's Progress to the Diet of Worms, 1521* (1951); on Luther and his age: J. ATKINSON, *Martin Luther and the Birth of Protestantism* (1968); A.G. ## Lutheran Churches

Lutheran churches, numerically the largest (over 75,000,000) of the Protestant churches, have, since the 16th century, spread throughout much of the world. They are, along with Calvinist and Anglican churches, one of the three classical Protestant churches of the Reformation.

#### NATURE AND SIGNIFICANCE

The Reformation, which broke upon Western Christendom in the 16th century, was inspired and guided in its early stages chiefly by Martin Luther, whose thought has remained a continuing influence in Protestantism. The major effect of the Reformation on the external structure of the Christian Church was to dissolve the unity of Western Christendom and to create a Lutheran, a Calvinist, an Anglican, and a Spiritualist type of Protestant Church.

Lutheranism's existence as a distinct church dates to the presentation of the Augsburg Confession at the Diet of Augsburg in 1530. The name Lutheran, which was at first used derogatorily by Luther's opponents (such as Johann Eck at the Leipzig Debate in 1519), was avoided as a self-designation until the 17th century. The Lutheran confessions spoke of the "evangelical churches" or the "churches of the Augsburg Confession," and the theologians of the time used "apostolic catholic church" or "catholic evangelical church" as a designation.

Lutheranism has contributed to Christianity a distinct theology (Luther, P. Melancthon, A. Ritschl, P. Tillich); a distinct mysticism (J. Böhme, J.G. Hamann, E. Swedenborg, J.G. Fichte); philosophical developments (G.W. Leibniz: mathematical theory, monadology; I. Kant and G.W.F. Hegel: critical and speculative Idealism; F.W.J. Schelling and S. Kierkegaard: Existentialism); philosophies of religion (Rudolf Otto, Lundensian school, Tillich); a method of biblical interpretation (Luther, R. Bultmann); historical-critical studies of the Scriptures (J.S. Semler, D.F. Strauss, F.C. Baur, J. Wellhausen, H. Gunkel); a linguistically oriented classical educational system (Melancthon); a distinct theory of law (Werner Elert); ecumenical initiatives (Leibniz, N. Söderblom); choral and instrumental music (Paul Gerhardt, J.S. Bach).

Lutheranism's specific character has resulted from the mixture of theological, cultural, and personal factors that marked Luther's career and its effects—his religious struggle with the judgment of God upon man ("Where will I find a gracious God?"), the emergence of individuality in persons and of the sense of sound (rhetoric, music) in culture, and the convergence of ecclesiastical and national or territorial interests. Its inner development has been shaped by the tension and conflict between the conservative element (preservation of the ancient faith) and the revolutionary element (a radical trust in God who justifies man). This tension has affected both the understanding of the Bible (is it a sourcebook of unalterable teachings or a witness to the trustworthiness of God manifest in the grace of Christ?) and the understanding of Lutheranism's central article of justification (is it a formulation to be accepted and believed or the basis of a new relation to the world and man?).

Lutherans today number about 75,200,000 throughout the world. Seven countries have a Lutheran population of more than one million: Germany (37.6), the United States (8.9), Sweden (7.0), Finland (4.6), Denmark (4.5), Norway (3.5), and Indonesia (1.26). By continents, the distribution is 60,400,000 in Europe, 9,200,000 in North America,

The sources of its characteristics

1,800,000 in South America, 2,200,000 in Asia, 1,800,000 in Africa, and 500,000 in Australia.

#### HISTORY

**The Reformation period.** By attacking the indulgence traffic of the church (in the Ninety-five Theses of 1517), Luther ultimately struck at the foundation of the papal church. His Leipzig Debate with Johann Eck was a decisive turning point when Eck elicited from him the claim that church councils could err (Luther contended that the Council of Constance of 1415 had wrongly condemned some views of the Bohemian reformer Jan Hus) and the denial that the papal church was necessary for salvation. Thus labelled a heretic, Luther was first threatened with excommunication (in the papal bull of 1520, *Exsurge Domine*) and then excommunicated (Jan. 3, 1521, in the papal bull *Decet Romanum Pontificem*) after he had publicly burned the bull of 1520.

The impact of political ferment

The religious conflict was soon intertwined with political developments. Emperor Charles V of the Holy Roman Empire summoned Luther to give account of his teaching at the Diet of Worms. The result was the Edict of Worms (signed May 26, 1521), placing Luther and his followers under imperial ban and decreeing the burning of his writings. But Luther's thought continued to spread. Since political circumstances in Europe were not favourable for a forceful suppression of the movement, Charles sought a negotiated settlement at the Diet of Augsburg in 1530. The Protestants presented the Augsburg Confession, composed by Luther's associate Philipp Melancthon, as a statement of their teaching. It emphasized the continuity between what they taught and the faith of the whole catholic church ("the whole dissension is about a few small abuses"). Charles rejected both the Augsburg Confession and the Apology of the Augsburg Confession, which Melancthon wrote in reply to the Catholics' rebuttal. The Protestants then left the Diet, and the remaining majority reinstated the Edict of Worms coupled with a promise to convoke a general church council within the year.

Religious wars

In 1531 the Protestants formed the Schmalkaldic League for military protection against execution of the imperial edict. Aided by renewed threats of war from the Turks, the efforts of the league led to the armistice of Nürnberg (1532), in which the Protestants were granted tolerance until the promised general council. (That council was not held until 1545-63, the Council of Trent.) There were further threats of war (Catholic League of Nürnberg of 1538, Frankfurt armistice of 1539) and more negotiations (colloquies of Worms and Regensburg, 1540-41), followed by the defeat of the Schmalkaldic League and its subsequent recovery when Maurice of Saxony, a master diplomat, switched allegiance to the Protestant cause. The Treaty of Passau (1552) granted armistice to the Protestants. The Religious Peace of Augsburg (1555) officially acknowledged the churches of the Augsburg Confession and related churches, but it contained ambiguities that were not resolved until the Peace of Westphalia (1648) after the Thirty Years' War, in which King Gustavus II Adolphus of Sweden played a decisive role for the Lutheran forces.

A far-reaching consequence of these events for the Lutheran churches lay in the fact that the territorial princes had in the process become primates of the territorial churches. At first regarded as an emergency measure, this arrangement was justified by Lutheran theologians in the 17th century by the claim (today regarded as historically inaccurate) that the suspension of episcopal powers in Protestant lands at Passau and Augsburg had transmitted that power to the territorial princes. Luther's conception (in the 1520s) of the autonomy of the Christian congregation was not put into practice nor theoretically developed until later (e.g., by N.F.S. Grundtvig in Denmark, C.F.W. Walther in the U.S.).

In some measure the Lutheran movement affected all European lands. It gained exclusive dominance in the Scandinavian countries (Sweden, after 1527; Denmark and Norway, 1536; Iceland, 1539), in Prussia (1525), and in the Baltic provinces (1523-39). It influenced Italy

and Spain hardly at all and France very little. Among eastern European countries, Protestantism made the largest gain in Hungary (Lutheran until 1543, then Calvinist) and Transylvania (a Lutheran Church after 1545). The Lutheran Church of Sweden was unique in the extent to which it kept continuity with the pre-Reformation church (retention of vestments, titles of bishop and archbishop, apostolic succession, and such ceremonies as elevation of the host at mass).

**The Post-Reformation in Germany.** During the 16th century, Lutheranism was torn by the conflicts between the Philippists, centred in Wittenberg, who represented a Melancthonian humanism, and the Gnesio-Lutherans (Genuine Lutherans), centred in Jena. A mediating settlement was adopted in the Formula of Concord of 1577 (published in the Book of Concord in 1580 on the 50th anniversary of the Augsburg Confession), but not all Lutheran churches accepted it.

From 1580 to 1700 the dominant power was orthodoxy, characterized by an exactness in theological formulation and by large-scale doctrinal theologies in the form either of *loci* (main topics) or of systems. The standard work from this period is Johann Gerhard's *Loci theologici* (finished in 1622). Orthodox theology was school theology in the sense that it carefully defined Lutheran theology as against Catholic, Calvinist, Spiritualist, anti-Trinitarian, and other theologies. It was strictest at Wittenberg, least strict at Altdorf and Helmstedt, with Jena between. Toward the end of the 17th century it became sterile, though it had in the meantime contributed to studies in theological method, in logic, and patristics (writings of the early Church Fathers). In addition to orthodox there were also irenic theologians, notably George Calixtus of Helmstedt, who proposed a unity of churches on the basis of the teachings of the first five centuries (*consensus quinquesaecularis*); and the mysticism of Johann Arndt's *True Christianity* had a wide influence.

Orthodoxy was superseded by Pietism (1670-1760), characterized by its emphasis on the inwardness of religion, a consciousness of separateness from the world and its pleasures, and an inner estrangement from the state church. Its prime mover was Philipp Jakob Spener. It developed at three centres. At Halle (led by August Hermann Francke), it affected the nobility and promoted schools for the poor, orphanages, and missionary work. In Württemberg it affected all levels of society and did not become separated from the church leaders. Two of its representatives were the biblical scholar J.A. Bengel and the theosophist F.C. Oetinger. The Herrnhut Brethren, founded by Count von Zinzendorf, constituted a third type. Their theology was Lutheran in origin, but the different accent on the Person of Jesus and the cultic devotion to the blood and wounds of Jesus gave it a distinct character.

Pietism was followed by the Enlightenment (1750-90), characterized by its intellectualism, its thrust for new knowledge, and its rejection of authoritarianism. In Germany its character was prepared by the philosophers G.W. Leibniz (*Theodicy, New Essays Concerning Human Understanding*), who sought to unite Christianity and the new mechanics, and Christian Wolff. It reached its high point under Frederick II of Prussia in such men as H.S. Reimarus, J.A. Ernesti, and J.G. Toellner. The "neology" of J.S. Semler, the critical philosophy of Immanuel Kant, and the literary work of G. Lessing, J.G. von Herder, and J.W. von Goethe represented, but also transcended, the Enlightenment.

The Enlightenment brought about a general split between Supernaturalists (e.g., F.V. Reinhard) and Rationalists (e.g., P.K. Henke and H.E.G. Paulus) in theology that has continued to the present day, although Rationalism began to wane after the 1830s (thoroughly attacked in K.A. von Hase's *Hutterus redivivus* of 1828). Supernaturalism maintains that faith is permanently dependent upon external authority (revelation), whereas Rationalism maintains that authoritative revelation serves only a pedagogical purpose for precritical reason.

In the 19th century Lutheranism was shaped by Idealism (1790-1835) and its aftermaths, by a new Confessional-

Lutheran orthodoxy and pietism

The Enlightenment

ism (1835–75), and also by neo-Idealism (1875–1915). Idealism overcame the Rational–Supernatural split, though not in a form that could be appropriated by most churchgoers. It began as critical Idealism (in Kant), that is, the rational self-limitation of human reason; but it developed into romantic Idealism (e.g., Herder, Goethe, F.D.E. Schleiermacher), in which reason is subordinated to feeling and the immediacy of living; and it culminated in speculative or absolute Idealism (e.g., J.G. Fichte, F.W.J. Schelling, G.W.F. Hegel, the Hegelians Karl Daub, Philipp Konrad Marheineke, Richard Rothe, and D.F. Strauss), in which human reason is a retracing or recapitulation of the divine reason.

The reactions to Idealism (in the Existentialism of Kierkegaard and the later thought of Schelling and the pessimism of A. Schopenhauer) affected the educated laity and were in part the cause of increasing alienation from the institutional church.

Lutheran Confessionalism took a reprimating (restorative) direction in a few theologians (e.g., A. Vilmar, F.A. Philippi), but it was chiefly an attempt to mediate between the Lutheran tradition and Idealism. Its chief seat was the Erlangen school (represented by A. von Harless, J.C.K. von Hofmann, and F.H.R. von Frank), but others took part (e.g., Theodosius Harnack, C.E. Luthardt).

At the end of the century, Idealism re-emerged in the Neo-Kantianism of Albrecht Ritschl, Wilhelm Herrmann, Martin Kähler, and Adolf von Harnack as well as in a Neo-Hegelianism (Otto Pfleiderer).

The event most decisive for Lutheran churches in Germany and the Americas was the Prussian Union of 1817, bringing the Lutherans and Reformed into one church. At first it met with welcome, but it soon became entangled in Frederick William III's liturgical reform (introducing a new, somewhat archaic, liturgy) and new church order (Schleiermacher was a leading opponent). It had two important results. The territorial regent now served as chief bishop of the church, not in his capacity as head of the state but as the person who had highest status in the congregation; and a number of Lutherans refused to join the Union, some forming the "Old Lutheran" church and others emigrating to America and Australia.

In the 20th century several new factors appeared. A delayed appreciation of Kierkegaard and the "dialectical theology" of the 1920s (e.g., F. Gogarten, Karl Barth) gave wide currency to the problems broached in 19th-century Idealism at the same time as they reinforced Supernatural tendencies in theology. Nihilism (e.g., F. Nietzsche), atheistic Existentialism, and the implications of science and technology provided major problems for attention. The ecumenical movement altered the focus of traditional controversies.

The National Socialism of Hitler brought the church in Germany into a grave crisis. The fall of the government of William II and the princes in 1918 had ended the relation of church and state existing since the Reformation. In the next years the desperate economic and political conditions had complicated the situation and prepared the way for the nationalism fostered by Hitler. The struggle between the nationalist church, which Hitler tried to erect (i.e., the German Christians under Bishop Müller), and the Confessing Church, which issued the Declaration of Barmen, 1934, was intense and protracted; some 7,000 pastors had been denounced or arrested by 1939 (Martin Niemöller was imprisoned, and Dietrich Bonhoeffer martyred). The Confessing Church, emerging as the clear victor in 1945, however, was a major force in rebuilding the country and in making reparations for the persecutions under Hitler.

**Lutheran churches in Scandinavia.** In the Scandinavian countries the history of Lutheranism followed basically the same pattern as in the German lands. These countries used the works of orthodoxy and received the currents of Pietism (Erik Pontoppidan's catechism, widely used in Denmark and Norway, was a blend of orthodoxy and Pietism); they had their representatives of the Enlightenment (e.g., Ludvig Holberg in Denmark–Norway, Christian Bastholm in Denmark, Johannes Gunnerus in Norway), their Rationalists (e.g., Henrik Clausen), and

their Idealists (e.g., Hans Martensen in Denmark, Henry Reuterdahl in Sweden).

Sweden (and Finland) remained somewhat apart, less affected by the new movements. Pietism was limited by the Conventicle Act of 1726 for a century; the Enlightenment made few inroads; Idealism was mixed with Supernaturalism; and Emanuel Swedenborg produced a distinct mystical Rationalism.

In Denmark the 19th century brought developments of international significance. Through N.F.S. Grundtvig the church received a folk character—based on the Apostles' Creed, the Lord's Prayer, and Baptism—that prevented the various tensions (i.e., Pietism, Rationalism, Revivalism) from causing a split. The writings of Kierkegaard were to become a worldwide influence in the 20th century. In Norway, independent of Denmark, Lutheranism was shaped by the moralism of Hans Nielsen Hauge, whose disciple E. Eilsen came to America in 1839 and founded a Norwegian Lutheran church.

The Neo-Kantianism of the last third of the 19th century produced a distinctive type in the "Lundensian school" (G. Aulén, A. Nygren), that made special contributions to philosophy of religion and theology (motif-research). A prime mover for ecumenicism in the 20th century was Nathan Söderblom, archbishop of Uppsala.

**Lutheran churches in America.** In the 17th century, the devastation of the Thirty Years' War led some Lutherans to emigrate to America (New York, Pennsylvania, the Carolinas), where they were served at first by pastors from European missionary societies. Henry Melchior Muhlenberg, the most prominent of the early Lutherans, came from the Francke Halle mission in 1742. He was instrumental in organizing the Lutherans in America, and his congregational constitution for St. Michael's Church in Philadelphia became a prototype for American Lutheran churches. During the 19th century some 5,000,000 German and 2,000,000 Scandinavian immigrants—reacting against the Prussian Union and the state churches as well as to the revolutions—greatly increased the numbers of Lutherans in America.

A turning point of Lutheran history in America came in the 1860s and 1870s when, spurred by the Ministerium of Pennsylvania, several synods united on the basis of the Unaltered Augsburg Confession (1860); the Synodical Conference was formed (1872) to unite the stricter Lutherans under the leadership of the Missouri Synod.

There was a continuous struggle with the question of language (i.e., whether English could replace German, Swedish, or Danish in worship), the problem of adapting to the new environment without losing a Lutheran identity (e.g., S. Schmucker, Frederick H. Quitman), and the doctrinal controversies concerning the church and ministry (are they essentially congregational or institutional?), and predestination.

The 20th century has brought new mergers (United Lutheran Church in America, constituted in 1918; American Lutheran Church, 1930) and councils (National Lutheran Council, 1918). By 1970 most Lutherans were included in the Lutheran Church in America (3,280,000 members), the American Lutheran Church (2,580,000), and the Lutheran Church—Missouri Synod (2,870,000). The Lutheran Council in the U.S.A. (LCUSA, 1966), formed by these three groups and the Synod of Evangelical Lutheran Churches, brought almost all Lutherans into one cooperative organization.

**Lutheran missions.** Early Lutheranism was not oriented to missionary work. The first mission impulses came from the pietists and the 19th-century Awakening. By the 20th century, missions had been established in all parts of the world. The chief agencies for the missionary work were the German and Scandinavian mission societies (Dresden Mission, Leipzig Mission, Neuendettelsau Mission, and others in Germany; Danish Missionary Society; Norwegian Missionary Society; Finnish Missionary Society; plus the Board of Missions of the Church of Sweden) and later on the mission boards of the several Lutheran churches in America.

**Present status.** In the last third of the 20th century the Lutheran churches face the same questions as the church-

es generally: urbanization, secularization, increasing technology, planetary concern, re-examination, and transformation of the traditions. Symptomatic of the last concern is the fact that the Fourth Assembly of the Lutheran World Federation in 1963 dealt with the meaning of Lutheranism's central article of justification in the present day. The extent to which Lutheran unity will be achieved is not yet clear, but the question is now interwoven with the more general question of the ecumenical movement, as well as with the meeting of the world religions and the fate of religious institutions generally in the future.

#### TEACHINGS

**Lutheran Confessions.** The official teaching of the Lutheran churches is that of the Book of Concord (1580), which contains the three ancient creeds (Apostles', Nicene, and Athanasian), the Augsburg Confession, the Apology of the Augsburg Confession, Luther's Schmalckald Articles, Luther's Small and Large Catechism, Melancthon's "Treatise on the Power and Primacy of the Pope," and the Formula of Concord. Of these Lutheran symbols, only the Augsburg Confession and Luther's Small Catechism are accepted by all Lutheran churches. No general confessions of faith were adopted after 1580 by the Lutheran churches, although other doctrinal statements have served a confessional purpose for particular churches.

Partly because of the circumstances of its composition and partly because the Reformers understood their work to be a restoration of Christianity amidst contemporary corruptions, the Augsburg Confession emphasizes the continuity of the Lutheran teaching with the ancient Christian Church.

**Justification.** The teaching centres in the *Gospel*, or "justification": the doctrine that men "are justified freely on account of Christ through faith when they believe that they are received into grace and their sins forgiven on account of Christ, who by his death made satisfaction for our sins"; God "imputes [this faith] as righteousness in his sight" (Augsburg Confession, IV). Recent Lutheran theologians (e.g., Ménégoz, Kähler, Bultmann, Tillich) have applied this doctrine to doubt as well as to guilt and have called attention to the change in the cultural and religious situation since the 16th century. Thus, Paul Tillich interprets justification through faith as a man's accepting his having been accepted in spite of his inacceptability.

This doctrine ("the article by which the church stands or falls") provides the key for understanding the Bible (Apology, IV. 3-5) as a book that has two kinds of content—law and promises. Law demands a perfect inward as well as outward obedience to the divine will, which reason can never achieve. As such it drives men to despair, but the despair is conquered by the promise that God justifies the unjust man. Theologically, the doctrine of justification gives a Christocentric (i.e., what honours Christ) stress and a practical (i.e., whether afflicted consciences are consoled) emphasis to the other articles of faith.

**Man.** The doctrine of man, as shaped by the article of justification, defines man's natural state as one in which he does not fear or love God and is self-seeking. Man has freedom of will concerning the outward observance of laws (civic righteousness) but not before God (where he is inevitably unrighteous). He has a knowledge of God but not a true knowledge (he thinks, for example, that righteousness is what God has rather than what God gives).

Similarly, the meaning of predestination is to be sought not in the hidden counsel of God but in his revelation (Formula of Concord, Epitome XI). Lutheran teaching differs from the Calvinist double predestination by accepting the formal inconsistency of saying that believers are predestined to salvation without saying that unbelievers are predestined to damnation, for the purpose of the article on predestination is to console the troubled conscience. The mechanism of predestination has been the subject of controversy within Lutheranism (whether the decision of God is made "in view of faith"), but the basic position expressed in the symbols has been maintained.

**Church, sacraments, and ministry.** In opposition to the claim that the Roman Catholic Church was the only legit-

imate ecclesiastical organization, as well as to the biblicist demand to restructure the Christian Church according to the New Testament pattern, the Augsburg Confession (Art. VII) defines the church as the "congregation of saints [believers] in which the gospel is purely taught and the sacraments rightly administered." "Gospel" is interpreted to mean that God justifies believers on account of Christ, not on account of their merits (Augsburg Confession, V). Right administration includes the practice of communion under both kinds (bread and cup). For the unity of the church it is sufficient to agree concerning the gospel and administration of the sacraments.

Luther regarded the church as essentially hidden or invisible in the sense that it is as weak and sinful an institution as any other one, but one can believe that God works in and through it because it is founded on God's word.

This doctrine has undergone transformations since the 16th century. Orthodoxy and Pietism understood the invisibility of the church to mean that only God knows who among the assembled people are true believers (the invisible church as distinguished from the visible congregation). In the 19th century a sacramental-institutional conception was formulated by some Lutheran theologians (e.g., T. Kliefoth, W. Löhe, F. Stahl), a congregational conception by others (e.g., C.F.W. Walther), a national or folk conception by others (e.g., N. Grundtvig), and a historical-evolutionary conception (i.e., the church as the first actualization of the Kingdom of God to be progressively realized in history) by others. Though these differences worked divisively in the 19th century, particularly in America, they are today competitive conceptions within Lutheranism.

Of the three sacraments (Baptism, Lord's Supper, penitence-absolution) recognized by Luther and the Lutheran symbols in the Book of Concord, the Lutheran churches generally hold to two by combining absolution in part with Baptism (daily repentance is the repeated actualization of Baptism) and in part with the Lord's Supper (confession and absolution). The criterion used in determining the number of sacraments was that they were actions instituted by Christ and connected with God's promise (Apology XIII). The symbols do not define the relation between word and sacraments except to say that they come together, and both have the effect of creating and strengthening faith. This rejects the view that sacraments are effective *ex opere operato* (operative apart from faith) and that they are only memorial actions.

The Formula of Concord's teaching on the Lord's Supper is that Christ is really bodily present "in, with, and under the bread and wine" (Solid Declaration, 35 ff., adopting Luther's terminology over Melancthon's "with the bread and wine"). The Formula of Concord left undecided whether the presence is ubiquity (i.e., the Swabian view that Christ is present because he is everywhere) or ubivolipresence (i.e., the northern German view that Christ is present because he chooses to be).

In the 19th century some Lutherans (e.g., G. Thomasius) distinguished word and sacrament by saying that the sacraments are intended for man's natural life as the word is for his conscious personal life. This view in some cases was carried so far (e.g., in Martensen and Stahl) as to subordinate the word (as the presentation of salvation) to the sacrament (as the participation in salvation).

The ministry is conceived of as a service in word and sacrament but not a special status. Every baptized Christian is a priest by status (universal priesthood of believers), but the public preaching and administration of sacraments devolves upon "rightly called" ministers, who are priests by office.

**Church and state.** The Lutheran churches generally have understood the relation of church and state on the basis of God's two ways of ruling in the world (two kingdoms). Through the "laws, orders, and estates" of the world, God rules by compelling external obedience through fear and threat of punishment. Through preaching and sacrament he rules in apparent weakness by converting man's heart. This conception has provided Lutherans with a basis for understanding the constitutional separation of state and church in America.

Book of  
Concord

Law and  
Gospel

The  
church

The  
sacraments

The two domains of power and grace

The two domains of power and grace are interdependent because the word alone cannot preserve peace and justice—so the civil government must even protect the freedom of the church to proclaim the Gospel—and civil power alone cannot effect salvation.

Lutheranism has rejected the view that civil power is of itself evil and the view that civil obedience has merit for salvation in the sight of God.

To define a citizen's relation to government one may say that in ordinary circumstances a Christian obeys the powers that be (except in matters of faith) as the agent of God's rule. But if a law or government is unjust, a Christian has the right and duty to resist it, passively accepting the consequences of disobedience for himself but actively defending his fellow man against that law or government. If the government is tyrannical, a Christian not only resists but rebels. Those Christians who also are holders of civil power have an obligation to resist and oppose misuse of such power by other rulers (as the territorial princes opposed the emperor in Luther's time).

The view so described was apparently held by Luther (there is no complete agreement among scholars) as it is by recent theorists (e.g., E. Berggrav).

In the 19th century the romantic view of the national state as expressing the spirit of a people was widely influential, but later it became suspect because of the demonic character of nationalism in the 20th century.

**Scripture and tradition.** The Lutheran confessions, unlike the Reformed, have no article on Scripture, although the Formula of Concord does designate the Scriptures of the Old and New Testaments as the "sole and most certain rule" for judging teachings and teachers.

Toward tradition the attitude of Luther and the confessions was conservative; they retained whatever did not conflict with the Gospel of justification through faith. They viewed the written tradition of the fathers as useful for interpreting the Scriptures but not as a source or norm of teaching. Some Lutheran theologians in the 19th century (e.g., A. Vilmar and G. Thomasius) developed an organic view of the relation of the two (i.e., Scripture contains a truth that is unfolded in the course of history) not unlike that of the Catholics J. Möhler and John Henry Newman.

**Ethics.** Lutheran teaching on ethics is determined by the perspective of the two kingdoms—the domain of law is not to be confused with that of the Gospel—and by the relation of faith and love implicit in justification. Works of love are the result, rather than the condition, of faith. Man has freedom from his self-concern by the act of God and is enabled to direct his concern to his fellow men.

The works a man is to do are specified in part by his status in the world (as father, as ruler, as subject, and other roles). Though early Lutherans thought of status in more natural terms (as "orders of creation"), recent Lutheran thought gives the concept a historical reference (e.g., a person's particular destiny or opportunities). A man's calling is to do well whatever his status requires.

A second factor defining the works a man is to do is the concrete need of his fellowman.

**Controversies.** Lutheran teaching has been shaped in part by the theological controversies in its history, almost all of which were at one time divisive. They had to do with such questions as the relation between divine and human agency (synergistic controversy, predestinarian controversy); whether works are indifferent, necessary, or dangerous for salvation (antinomian controversy, Majoristic controversy); whether in a state of confessional disagreement any questions are neutral (adiaphoristic controversy); what the nature of the sacramental presence is; whether the divine power resides in the Scriptures only when they are being used or also apart from their use (Rathmann controversy); what are sufficient grounds for church unity (syncretistic controversy); and whether God's election of believers is made "in view of faith" or not (predestinarian controversy).

#### WORSHIP AND ORGANIZATION

**Liturgy and music.** The worship service also was affected by the theology of the Reformers. Luther's "Ger-

man Mass" of 1526 reflects changes that began about 1523. Apart from shifting the emphasis from sacrifice to thanksgiving, Luther's chief innovation here was to take the words of institution out of the framework of prayer and make of them a proclamation of the Gospel. This change has been preserved to the present day, although there is now a tendency to put the words again into a eucharistic prayer.

Because of the Reformers' emphasis upon the importance of the word, the sermon took an essential place in the service. Preaching is usually based upon a biblical text, a biblical story or doctrine, or a theological theme. Partly in reaction to the 19th century, there is an effort to keep preaching biblically oriented, though not necessarily tied to specified texts.

The term mass, at first retained, is not normally used except in the Church of Sweden (*högmessa*) as a name for the main service of worship. The other minor services disappeared from use during the 17th century, though some have been recovered in the liturgical reforms of the last century. Only Matins and Vespers are used with any regularity.

The basic order of service in most Lutheran churches is the same. It consists of two main portions (preaching and sacrament) in which the Kyrie, Introit, Gloria, Credo, and Agnus Dei are incorporated. Under the impact of the liturgical movement in this century, the didactic emphasis has given way to an emphasis on celebration in the service. Liturgical revisions (Swedish order of 1942, German of 1954, in the United States in 1941 and 1958) have brought an even greater uniformity in the basic order. They have also restored communion as a normal part of the regular Sunday service.

Lutherans observe two sacraments, Baptism and the Lord's Supper (communion, Eucharist). The common practice is to baptize children and adults who have not been baptized previously. The frequency of communion has increased in recent years, but there are still many congregations where it is celebrated only once a month or less often. Though the usual practice has been that only those who have been confirmed may participate in the Eucharist, in 1970 the Lutheran Church in America and the American Lutheran Church approved participation for ten-year-old baptized children, whether they have been confirmed or not.

The rites of the Lutheran churches are confirmation, ordination, marriage, and burial. In the rite of confirmation (usually between the ages of 10 and 15) a member makes public profession of the faith received in his Baptism. In the rite of marriage the church ceremony may replace the civil ceremony or it may serve as an invocation of blessing on the civil ceremony. Ordination of the clergy does not endow them with a special character or give them a special status, but it sets them apart for the particular office of preaching the word and administering the sacraments. This rite is interpreted either institutionally (i.e., preaching is an order instituted by Christ and transmitted from generation to generation [succession]) or congregationally (i.e., the congregations call certain of their members to assume the functions of preaching and administering the sacraments for them). In 1970 the Lutheran Church in America and the American Lutheran Church approved the ordination of women. There is no sacrament of extreme unction, but there is a burial service for the dead.

An important role was played in the Reformation by the hymns, which not only conveyed the evangelical teaching but also allowed for popular participation in the church services. The best known Lutheran hymns come from the 16th and 17th centuries (e.g., "A Mighty Fortress Is Our God" by Luther, "All Glory Be to God on High" by N. Decius, "O Sacred Head Now Wounded" by Paul Gerhardt, "Wake, Awake, for Night Is Flying" by P. Nicolai, "Now Thank We All Our God" by M. Rinkart). But each nation has made its contribution (e.g., Thomas Kingo in Denmark and Norway), and Lutheran hymnals today include hymns from all ages and countries.

Among composers of choral music (cantatas, motets, masses, settings of the Passion of Christ) Johann Sebas-

The service, sacraments, and rites

Man's works

Hymnody

tian Bach ranks highest (e.g., *Mass in B Minor*, *St. Matthew Passion* and *St. John Passion*). But others of importance were Michael Praetorius, Heinrich Schütz, and Dietrich Buxtehude. To this music should be added the Scandinavian folk tunes (e.g., L.M. Lindeman in Norway).

**Education.** Education of the laity and clergy was an early problem for the Reformers. The means developed to meet it have had a formative influence on Lutheranism to the present day.

To instruct the people in Christian teaching, Luther not only translated the Bible into the vernacular but wrote his Small and Large Catechisms (1528–29). The small one was to be used by heads of households to instruct those under their care. It includes not only the three parts that had been in use before (the Ten Commandments, the Creed, and the Lord's Prayer) but also three additional parts on Baptism, the Lord's Supper, and absolution. Each topic in the various parts is connected with an explanation in the form of an answer to the question, "What does this mean?", a device Luther used in order to avoid mechanical memorization.

The Small Catechism, with various expositions, has remained a basic instructional tool in the Lutheran churches, though it has been supplemented by other materials (e.g., Bible courses, Sunday school literature, projects).

In the last century efforts have been made to connect the secular world and the Christian tradition by establishing institutions such as the academies for laymen in Europe (which provide opportunity for regular meetings of laity from specific vocations to discuss the relevance of Christianity to those vocations) and the church colleges in the United States.

**Organization.** The polity of the Lutheran churches varies from country to country. The Church of Sweden has maintained the episcopal succession unbroken, and congregations there are given great freedom to appoint their own pastors. The Danish church lost but later regained the episcopacy. In Norway there is a closer tie between church and state than in the other Scandinavian countries. Since 1869, by an arrangement with Russia, the Finnish Church is independent of state control but is supported by public funds.

Until the end of World War I the churches in Germany were under secular authority, administered by a commission of laymen and clergy, a system that grew out of the emergency situation of the Reformation. After the collapse of the government in 1918, the churches drew up new constitutions placing the congregations under a General Synod in some provinces and under a bishop in others; and the several provincial churches (*Landeskirchen*) were united in the German Evangelical Church Federation (1922). At the end of World War II, after the conflicts under Hitler, the Evangelical Church in Germany was organized under Bishop Wurm and Pastor Niemöller, adopting the Declaration of Barmen (1934) as a binding statement. The United Evangelical Lutheran Church of Germany, formed in 1948, became a unit within the Evangelical Church in Germany.

In America the Lutheran churches have the same denominational standing as other churches. The polity is congregational, and the local congregations are united in regional and national groups with elected officials. Elected heads are called presidents rather than bishops or superintendents. Recent efforts to restore episcopal titles and polity had not made much progress before 1970, when the American Lutheran Church adopted the title supervising bishop for its newly elected head. Other developments in that direction are possible.

Besides these larger Lutheran churches, there are a number of Lutheran free churches in Europe (e.g., Evangelical Lutheran [Old Lutheran] Church, Germany) and America (e.g., Church of the Lutheran Confession), which have complete congregational autonomy.

The Lutheran World Federation, established in 1947—the Fifth Assembly, which was to have met in Pôrto Alegre, Brazil, in 1970, was moved to France because of information regarding alleged political persecutions in Brazil—is a cooperative organization.

SCHLINK, *Theologie der lutherischen Bekenntnisschriften* (1946; Eng. trans., *The Theology of the Lutheran Confessions*, 1961), a study of the theology from the point of view of a Lutheran dialectical theology; PAUL TILLICH, *Systematic Theology*, 3 vol. (1951–63), a systematics by the most original Lutheran theologian of the 20th century; L.D. REED, *The Lutheran Liturgy* (1947), a detailed examination of the origin and function of each of the sections of the Lutheran service of worship; K.F. MULLER and W. BLANKENBURG, *Leiturgia: Handbuch des evangelischen Gottesdienstes*, 5 vol. (1954), a historical and theological examination of the Lutheran service.

(R.P.S.)

## Lutuli, Albert

A South African tribal chief, Albert Lutuli was the first African to be awarded the Nobel Prize (1960), in recognition of his long nonviolent struggle against racial discrimination. Teacher, Christian leader, and African patriot, he led the African National Congress (ANC) from 1952 until its proscription by the South African government in 1960.

Albert John Mvumbi (Zulu: "continuous rain") Lutuli was born in 1898 in Rhodesia, where his father, John Bunyan Lutuli, a missionary interpreter, had gone from Zululand. After his father's death, the ten-year-old Albert returned to South Africa and learned Zulu traditions and duties in the household of his uncle, the chief of Groutville, a community associated with an American Congregational mission in Natal's sugar lands. Educated through his mother's earnings as a washerwoman and by a scholarship, he graduated from the American Board Mission's teacher training college at Adams, near Durban, and be-

The catechisms

Lutheran World Federation

Lutuli, 1961.  
PHOTOWORLD—FPG

came one of its first three African instructors. In 1927 Lutuli married Nokukhanya Bhengu, a teacher and granddaughter of a clan chief.

In 1936 Lutuli left teaching to become the elected chief of the community of 5,000 at Groutville. Though confronted by land hunger, poverty, and political voicelessness, he did not yet recognize the need for political action. In those early years he was, variously, secretary of the Natal African Teachers' Association and of the South African Football Association, founder of the Zulu Language and Cultural Society, and member of the Christian Council Executive, of the Joint Council of Europeans and Africans, and of the Institute of Race Relations in Durban.

Membership in African National Congress

Lutuli's first political step in joining the African National Congress in 1945 was motivated by friendship with its Natal leader; far more significant was his election to the Natives Representative Council (an advisory body of chiefs and intellectuals set up by government), at the very time in 1946 when troops and police were crushing a strike of African miners at the cost of eight lives and nearly a thousand injured. Lutuli immediately joined his people's protest against the council's futility. When he toured America in 1948 as a guest of the Congregational Board of Missions, he warned that Christianity faced its severest test in Africa because of racial discrimination. On return home he found that the Afrikaner Nationalists had newly come to power with their policy of apartheid.

At this crucial time, Lutuli was elected president of the Natal African National Congress. Since its founding in 1912, the ANC's efforts to achieve human rights by deputation, petition, or mass protests had met with increasing repression. In 1952, stimulated by young black intellectuals, the ANC joined the South African Indian Congress in a countrywide campaign to defy what were deemed unjust laws; 8,500 men and women went voluntarily to prison. As a result of Lutuli's leadership in Natal, the government demanded that he resign from the ANC or from chieftainship. He refused to do either, stating, "The road to freedom is via the cross." The government deposed him. Not only did he continue to be affectionately regarded as "chief," but his reputation spread. In that same year, 1952, the ANC elected him president general. Henceforth, between repeated bans (under the Suppression of Communism Act), he attended gatherings, visited towns, and toured the country to address mass meetings (despite a serious illness in 1954).

Trial for treason

In December 1956 he and 155 others were dramatically rounded up and charged with high treason. His long trial failed to prove treason, a Communist conspiracy, or vio-

lence; and in 1957 he was released. During this time Lutuli's quiet authority and his inspiration to others profoundly impressed distinguished foreign observers, leading to his nomination for the Nobel Prize. Nonwhite people responded in large numbers to his call for a stay-at-home strike in 1957; later whites also began attending his mass meetings. In 1959 the government confined him to his rural neighbourhood and banned him from gatherings—this time for five years—for "promoting feelings of hostility" between the races.

In 1960, when police shot down Africans demonstrating against the pass laws at Sharpeville, Lutuli called for national mourning, and he himself burned his pass. (Too ill to serve the resulting prison sentence, he paid a fine.) The government outlawed the ANC and its rival offshoot, the Pan-Africanist Congress.

In December 1961 Lutuli was allowed to leave Groutville briefly when, with his wife, he flew to Oslo to receive the Nobel Prize. His acceptance address paid tribute to his people's nonviolence and rejection of racialism despite adverse treatment, and he noted how far from freedom they remained despite their long struggle. A week later, throughout South Africa, a sabotage group called the Spear of the Nation attacked installations; the policy of nonviolence had at last been abandoned, and Lutuli, back in enforced isolation, was an honoured elder statesman, dictating his autobiography and receiving only those visitors permitted by the police.

On July 21, 1967, in Stanger, South Africa, as he made a habitual crossing of a railway bridge near his small farm, Chief Lutuli was struck by a train and died.

**BIBLIOGRAPHY.** ALBERT LUTULI, *Let My People Go* (1962), a comprehensive autobiography; MARY BENSON, *Chief Albert Lutuli of South Africa* (1963), a short biography, and *South Africa: Struggle for a Birthright*, rev. ed. (1969), Lutuli's life in the history of the African National Congress; COLIN and MARGARET LEGUM, *The Bitter Choice: Eight South Africans' Resistance to Tyranny* (1968), contains an essay on Lutuli.

(D.M.B.)

## Luxembourg

The Grand Duchy of Luxembourg is a tiny sovereign state of only 998 square miles (2,586 square kilometres) surrounded by Belgium, France, and Germany. A natural and historical meeting point of, and crossroads for, these countries, Luxembourg has come under the control of many states and ruling houses in its long history, but it has been a separate, if not always autonomous, political unit since the 10th century. The ancient Saxon name of its capital city, Lucilinburhuc ("little fortress"), symbolized its strategic and long impregnable position as "the Gibraltar of the north," astride a major military route linking Germanic and Frankish territories.

Strategic location

The heterogeneous peoples of Luxembourg and their language, economic pursuits, and ways of life reflect the grand duchy's multiplicity of common interests with its neighbours as well as the close historical relations. The farming villages and agricultural landscapes that abound across the broad and high northern tableland and the lower plateaus of the south delight the tourists, but in the few urban centres the smokestacks of industry signal an economic diversity. Luxembourg was an original member of the Benelux customs union, established in 1944, that linked its economic life with that of The Netherlands and of Belgium (the acronym is derived from the initial letters of each nation) and that formed the core of the European Economic Community, a broader union created in 1958 that comprised France, Italy, and West Germany as well.

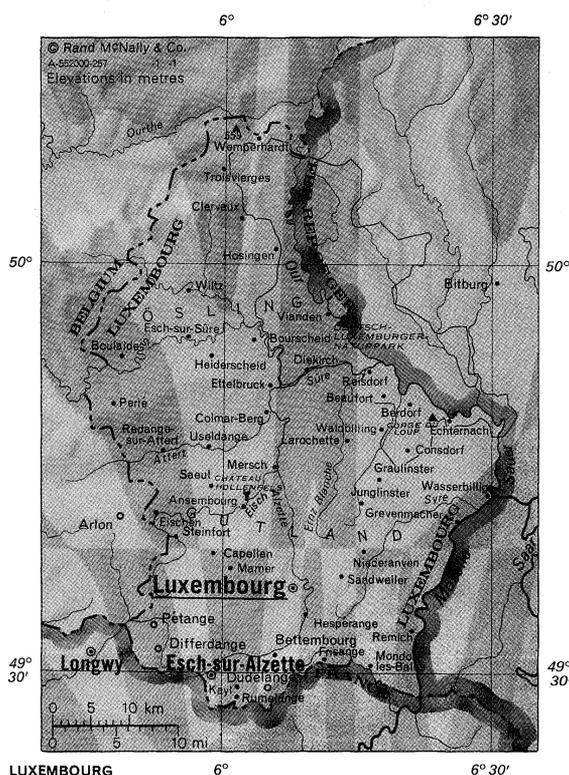

**The land.** The northern third of Luxembourg, known as the Oesling, comprises a corner of the Ardennes Mountains, which lie mainly in southern Belgium. A very level plateau 1,300 to 1,600 feet in altitude, it is a region of broad vistas and few forests. Its rocky valleys support the ruins of numerous castles, a major attraction for its tourists. The relatively thin mountain soil of the Oesling was much improved by the introduction in the 1890s of a basic slag fertilizer that is a by-product of the

Main regions

grand duchy's steel industry. The iron mines are located in the south near the French border.

In contrast, the heavily wooded south, known as the Gutland or Bon Pays (German and French: "good land"), has more fertile soil and rich pasturelands, and along the Moselle and lower Sûre valleys vineyards producing a good white wine. At an average altitude of 900 feet, the Gutland contains the capital, the city of Luxembourg, founded in 963, as well as Eschur-Alzette and other major industrial centres. In the east central section, near the German border, lies a great beech forest, the Muellertal (Müllerthal). Nearby is the small town of Echternach, to which a traditional dancing procession, with roots deep into the past, attracts many visitors.

From both the Oesling and the Gutland, the rivers flow into the Moselle, a tributary of the Rhine. Most farming is mixed, including both gardening and animal raising. The mean temperatures in Luxembourg City range from 37° F (3° C) in January to 67° F (19° C) in July, but in the Oesling both extremes are slightly lower. The Oesling generally has more precipitation than the Gutland, but the greatest amount, about 40 inches, and the least, about 27 inches, fall in the southwest and southeast, respectively.

Ethnologists have identified an interesting array of types in human dwelling and in the physical organization of villages throughout Luxembourg. Many date from ancient Celtic and Roman times to the circular villages of the Germanic and Frankish settlements after about AD 400. In addition, many castle villages continue to thrive, centuries after the castles themselves fell to ruin.

**The people.** Luxembourg has been one of the historic crossroads of Europe, and myriad peoples have left their bloodlines as well as their cultural imprints on the grand duchy. The Celts, the Ligurians and Romans from Italy, the Belgic peoples known as the Treveri, and especially the Franks were most influential. The dialect spoken by all of Luxembourg's 340,000 inhabitants is Letzeburgesch, a member of the Germanic language group. Most Luxembourgers speak French and German as well, and all three are designated as official national languages. There is a strong sense of national identity among Luxembourgers despite the prevalence of these foreign influences, which can be seen in their country's past as well as present.

Luxembourg's people are over 94 percent Roman Catholic, with a small number of Protestants, mainly Lutherans, and Jews. The nearly 60,000 foreigners in the country include many workers in the mining and steel industries or in foreign firms and international organizations located in the capital. Over 67,000 persons are engaged in industry, nearly 16,000 in agriculture, and some 61,000 in various service occupations. There has been a continued trend away from the countryside to urban areas. This has led the government to locate some industries in rural areas, which in turn has altered somewhat the character of rural life, most noticeably in housing and modern amenities of living.

In 1970 births and deaths numbered 4,411 and 4,154, respectively, with marriages and divorces at 2,156 and 217.

**The national economy. Business and industry.** During the 1960s the economy of Luxembourg altered its directions somewhat. Although the steel and iron-producing industries continued to account for nearly a quarter of the national output, there was a definite trend toward the production of finished goods. U.S. companies pro-

National languages

ducing tires, plastics, and synthetic fibres were among the industries that found the economic climate to be advantageous. There are also large food-processing and chemical plants, and tourism played an increasing role in the economic picture.

In 1929 the government began a policy of encouraging the formation in Luxembourg of holding companies, large corporations that each control a number of subsidiary companies but are heavily taxed in many areas of the world. The liberal tax climate produced by this policy led many financial corporations as well to maintain offices, often as the European headquarters, in Luxembourg City. The main offices of the European Investment Bank are there, as are the representatives of many banking institutions from around the world who keep in contact with the European Economic Community, or Common Market.

**Agriculture.** In the late 1960s, about three-quarters of the 55,000 acres under cultivation in Luxembourg were in farms of under 50 acres. Grains, root vegetables, and animal fodders are produced in about equal quantities. Mechanization had replaced animal and human labour in most areas, but the farmer still looked for further help from Common Market agreements. Cattle raising remained important, sheep raising less so than in former years.

**Power and transportation.** Luxembourg is without indigenous coal deposits, but much of the nation's electricity is supplied by the steel mills. In addition, three hydroelectric plants have been built, one of them in conjunction with the reservoir supplying water to most of the country.

Internal road systems are not extensive, but they are well maintained. More extensive highways linking Luxembourg with its neighbours are among the objectives of the European economic planners. During the 1960s the opening of a new harbour on the Moselle and of a canal connecting it with the system of Rhine waterways opened a new avenue for the international movement of goods.

The state has operated the railroads since World War II. They are electrified, mostly double decked, and modern. Most international transportation to and from Luxembourg is by train, and the country is connected with its neighbours by a large number of lines. Findel Airport outside Luxembourg has become a major European air terminal served by the lines of many countries. A national company, Luxair, is in the process of growth in the early 1970s.

**Administration and social conditions.** The grand duchy is a constitutional monarchy with hereditary succession. The constitution, which vests sovereign power in the people and provides guarantees of numerous liberties and freedoms, was revised in 1956 to anticipate the possible transfer of certain sovereign powers to future supranational organs linking several European nations.

**Government.** Executive power lies with the grand duke and is executed through a ministerial council, or cabinet. It is responsible to the Chamber of Deputies, comprising 56 members popularly elected. Voting by all adult citizens, begun in 1919, is compulsory. In addition, a 21-member council of state named by the grand duke functions essentially as a second legislative chamber. It is consulted on all draft legislation and can postpone the enactment of bills. Six official groups, representing agriculture, handicrafts, commerce, civil servants, private employees, and labour, are consulted before the passage of legislation affecting their particular segment of the national working force. Justice is in the hands of magistrates appointed by the grand duke, the final appeal lying with the Superior Court of Justice. In the criminal court of assizes, six magistrates sit as jury as well as judge. The army, under command of the grand duke, is voluntary. Its main functions are to recruit municipal and state police.

Public works, health, and education are among the responsibilities of the 126 communes throughout Luxembourg, which are governed by an elected council. The mayor and aldermen are appointed by the grand duke. These bodies also maintain liaison with the central government and act as its local agents.

**Social conditions and services.** After World War I, a broad system of social security and health services was introduced. Sickness benefits, in which patients pay only a small part of medical costs, as well as birth, family, and unemployment payments, are included in the plans. Existing facilities that require further development include nursing homes for the aged and mental institutions. Housing standards are generally above the European average. There has been some difficulty, however, in assimilating the many thousands of foreign workers and their families.

**Education.** Education is compulsory from ages 6 to 15. Primary and secondary education are run by state and local governments and by religious institutions. Great stress is laid on language studies. Instruction is generally given in German in the early years, with an increasing use of French later on. There are no universities in the grand duchy, leading many young Luxembourgers to study abroad, but the International University of Comparative Sciences in Luxembourg City offers, among other courses, postgraduate work in law and economics.

**Cultural life and the future.** The major cultural institution of Luxembourg is the Institut Grand-Ducal, which has sections devoted to history; natural sciences; medical sciences; languages, folklore, and toponymy, the study of place names; arts and letters; and moral and political sciences. It functions as an active promoter of the arts, humanities, and culture in general rather than as a conservator. The Museum for History and Fine Arts has a special section devoted to education in the fine arts. There is considerable public use of the National Library, the Public Archives, and the Conservatory of Music. Luxembourg maintains cultural agreements with several European and other nations that provide the grand duchy with the finest in the musical and theatrical arts. The orchestra of Radio Luxembourg is considered outstanding. There is an extensive market for works of painting and sculpture, both traditional and modern.

**Communications.** A small publishing industry exists, printing literary works in French, German, and Letzeburgesch. The grand duchy's seven newspapers express diverse political points of view—conservative, liberal, socialist, and communist. The government operates all postal and telegraph services and has some control in the private corporation running Radio Luxembourg, which is heard throughout Europe. Some of its multilingual programming is beamed to the resident foreign workers.

**Prospects.** Luxembourg is very much a pan-European country, as by accident of geography and history it has always been. Among its most famous sons was Robert Schuman, founder of the European Coal and Steel Community, a European federation that anticipated the growing European economic unity of the 1970s. Many of its hopes for the future are directed toward a realization of a broader European union, both economically and politically. "Rather friends than enemies" is the rule of conduct for its rising generations. Its supranational outlook is underscored by the number of foreign and international companies and bodies within its borders and the great increase during the late 1960s in the number of its students scattered abroad and studying the languages of the world. It is a small country looking hopefully beyond its borders for more understandings with the larger members of the community of nations.

#### BIBLIOGRAPHY

*History and politics:* ARTHUR HERCHEN, *Manuel d'histoire nationale*, 5th ed. enl. (1947; Eng. trans. by A.H. COOPER-PRICHARD, *History of the Grand Duchy of Luxembourg*, 1950), provides a wide-ranging account. JOSEPH PETIT, *Luxembourg, Yesterday and To-day*, 6th ed. (1966); AUGUSTE COLLART, *Am Wege zur Unabhängigkeit Luxemburgs* (1938); and ALBERT CALMES, *Au Fil de l'histoire*, 2nd ed. (1968), are also useful. PAUL MARGUE, *A Short History of Luxembourg* (Eng. trans. 1970), is a briefer account; CHRISTIAN CALMES, *1867, L'Affaire du Luxembourg* (1967), covers an important moment in Luxembourg's history. PIERRE MAJERUS, *L'État luxembourgeois*, 3rd ed. (1970; Eng. trans., *The Institutions of the Grand Duchy of Luxembourg*, 1970), explains the constitution.

Other writings include G.L. WEIL, *The Benelux Nations: The Politics of Small-Country Democracies* (1970); K.C. EDWARDS, *Luxembourg: The Survival of a Small Nation* (1967); and W.J. TAYLOR-WHITEHEAD, *Luxembourg: Land of Legends* (1951), interesting on national lore.

**Topography:** TUDOR EDWARDS, *Belgium and Luxembourg* (1966), has a useful section on the country, while BERYL MILES, *Attic in Luxembourg* (1956); and ROGER PILKINGTON, *Small Boat to Luxembourg* (1967), are personal accounts. JEAN ROUBIER and JOSEPH DELMELLE, *Benelux: Holland, Belgium, Luxembourg* (1958), is a picture book.

**Economics:** THE ORGANIZATION FOR ECONOMIC CO-OPERATION AND DEVELOPMENT, *Belgium-Luxembourg Economic Union* (annual), provides a general guide to the economy, supplemented by J.R. YONGE and G. FRANKIS, *Transport in the Grand Duchy of Luxembourg* (1966).

## Luxemburg, Rosa

Polish-German revolutionary theoretician and agitator, Rosa Luxemburg was one of the recognized leaders of the radical left wing of the German Social Democratic Party. She played a key role in the founding of the Polish Social Democratic and German Communist parties and developed a humanitarian theory of Marxism that was at once internationalist, anti-revisionist, and dynamic, stressing democracy and revolutionary mass action to achieve Socialism.

Interfoto—Friedrich Rauch, Munich

Rosa Luxemburg.

Rosa Luxemburg was born on March 5, 1871, in Zamość, Russian Poland (now Poland), the youngest of five children of a lower middle class Jewish family. She became involved in underground activities while still in high school. Like many of her radical contemporaries from the Russian empire who were faced with prison, she emigrated to Zürich, Switzerland (1889), where she studied law and political economy, receiving a doctorate in 1898. In Zürich she became involved in the international Socialist movement and met Georgy Valentinovich Plekhanov, Pavel Axelrod, and other leading representatives of Russian Social Democracy with whom, however, she soon began to disagree. Together with a fellow student, Leo Jogiches, who was to become a lifelong friend and sometime lover, she challenged both the Russians and the established Polish Socialist Party because of their support of Polish independence. Consequently, she and her colleagues founded the rival Polish Social Democratic Party, which was to become the nucleus of the future Polish Communist Party. The national issue became one of Luxemburg's main themes. To her, nationalism and national independence were regressive concessions to the class enemy, the bourgeoisie. She consistently underrated nationalist aspirations and stressed Socialist internationalism. This became one of her major points of disagreement with Lenin and his theory of national self-determination.

In 1898, after marrying Gustav Lübeck to obtain German citizenship, she settled in Berlin to work with the

largest and most powerful constituent party of the Second International, German Social Democracy. Almost at once, she jumped into the revisionist controversy that divided the party. In 1898 the German revisionist Eduard Bernstein had argued that Marx was essentially outdated and that Socialism in highly industrialized nations could best be achieved through a gradualist approach, with parliamentary and trade-union pressure on the establishment. This, Luxemburg denied categorically in *Sozialreform oder Revolution?* (1889, Eng. trans., *Reform or Revolution*, 1937), in which she defended orthodoxy and the necessity of revolution, arguing that parliament was nothing more than a bourgeois sham. Karl Kautsky, the leading theoretician of the Second International, agreed with her, and revisionism consequently became a Socialist heresy both in Germany and abroad, though it continued to make headway, especially in the labour movement.

The Russian Revolution of 1905 proved to be the central experience in Rosa Luxemburg's life. Until then, she had believed that Germany was the country in which world revolution was most likely to originate. She now believed it would catch fire in Russia. She went to Warsaw, participated in the struggle, and was imprisoned. From these experiences emerged her theory of revolutionary mass action, which she propounded in *Massenstreik, Partei und Gewerkschaften* (1906; Eng. trans., *The Mass Strike, the Political Party, and the Trade Unions*, 1925). Luxemburg represented the mass strike as the single most important tool of the proletariat, Western as well as Russian, in attaining a Socialist victory. The mass strike, the spontaneous result of "objective conditions," would radicalize the workers and drive the revolution forward. In contrast to Lenin, she de-emphasized the need for a tight party structure, believing that organization would emerge naturally from the struggle. For this, she has been repeatedly chastized by orthodox Communist parties.

Released from her Warsaw prison, she taught at the Social Democratic Party school in Berlin (1907-14), where she wrote *Die Akkumulation des Kapitals* (1913; Eng. trans., *The Accumulation of Capital*, 1951). In this analysis, she described imperialism as the result of a dynamic capitalism's expansion into underdeveloped areas of the world. It was during this time also that she began to agitate for mass actions and broke completely with the established party leadership of August Bebel and Karl Kautsky, who disagreed with her incessant drive toward proletarian radicalization.

The Social Democratic Party backed the German government at the outbreak of World War I, but Rosa Luxemburg immediately went into opposition. In an alliance with Karl Liebknecht and other like-minded radicals, she formed the Spartakusbund, or Spartacus League, which was dedicated to end the war through revolution and the establishment of a proletarian government. The organization's theoretical basis was Luxemburg's pamphlet *Die Krise der Sozialdemokratie* (1916; Eng. trans., *The Crisis in the German Social Democracy*, 1919), written in prison under the pseudonym Junius. In this work she agreed with Lenin in advocating the overthrow of the existing regime and the formation of a new International strong enough to prevent a renewed outbreak of mass slaughter. The actual influence of the Spartacus group during the war, however, remained small.

Released from prison by the German revolution (November 1918), Luxemburg and Liebknecht immediately began agitation to force the new order to the left. They exercised considerable influence on the public and were a contributing factor in a number of armed clashes in Berlin. Like the Bolsheviks, Luxemburg and Liebknecht demanded political power for the workers' and soldiers' soviets but were frustrated by the conservative socialist establishment and the army. In late December 1918, they became founders of the German Communist Party, but Luxemburg attempted to limit Bolshevik influence in this new organization. In fact, her *Die russische Revolution* (1922; Eng. trans., *The Russian Revolution*, 1940) chastized Lenin's party on its agrarian and national self-determination stands and its dictatorial and terrorist methods.

Theory of the mass strike

Formation of the Spartacus League

Opposition to nationalism

Assassination

Luxemburg always remained a believer in democracy as opposed to Lenin's democratic centralism. She was never able, however, to exercise a decisive influence on the new party, for she and Liebknecht were assassinated in Berlin, on January 15, 1919, by reactionary troops.

Rosa Luxemburg's writings inspired a generation of radicals and challenged the whole of the international Social Democratic establishment for two decades. That she was unable to put her theories into practice was the result of that Socialist establishment's rejection of her theories, the conservatism of German society, and the Communist parties' process of Stalinization that took place after Lenin's death (1924). Rosa Luxemburg is still revered by Marxists, however, despite her unorthodox views, and interest in her has revived recently with the liberalization of the post-Stalin period.

**BIBLIOGRAPHY.** There is as yet no complete edition of Rosa Luxemburg's works; the most comprehensive survey of her writings, however, is OSSIP K. FLECHTHEIM (ed.), *Rosa Luxemburg. Politische Schriften*, 3 vol. (1966-68). In English, the most useful edition of her works is DICK HOWARD (ed.), *Selected Political Writings of Rosa Luxemburg* (1971). ROSA LUXEMBURG, *Die Akkumulation des Kapitals* (1921; Eng. trans., *The Accumulation of Capital*, 1951), is one of her most important theoretical pieces giving her views on imperialism. The best biography by far is PETER NETTL, *Rosa Luxemburg*, 2 vol. (1966; abridged one-volume paperback, 1969), the most objective and comprehensive study based on a wealth of primary sources, placing its subject in a historical perspective. PAUL FROLICH, *Rosa Luxemburg: Her Life and Work* (1940, reprinted 1969), is another good biography written by one of Luxemburg's contemporaries—Frölich is a Marxist, which is reflected in his writings, but with a strong anti-Stalinist bias. For the orthodox Stalinist view, FRED OELSSNER, *Rosa Luxemburg: Eine kritische biographische Skizze* (1951), is the standard work. For an excellent in-depth analysis of the struggle between the Social Democratic left and right wings during most of Rosa Luxemburg's active political life, CARL E. SCHORSKE, *German Social Democracy, 1905-1917* (1955), is invaluable.

(H.D.S.)

## Lycopsidea

The Lycopsidea are generally considered to constitute a class of spore-bearing vascular plants comprising the club mosses and their allies, living and fossil. Present-day lycopsids are grouped into four genera and between 900 to 1,000 species of wide distribution, but especially numerous in the tropics: *Lycopodium*, the club mosses or "ground pines"; *Selaginella*, little club mosses or spike mosses; the unique tuberous plant *Phylloglossum*; and *Isoetes*, the quillworts. Representative extinct genera are *Lepidodendron* and *Stigillaria*, which are the tree lycopsids, and *Protolopodendron*, a herbaceous *Lycopodium*-like plant. Lycopsids are known from rocks of the Devonian Period (about 395,000,000 years ago) of the Paleozoic Era. The remains of *Lepidodendron* and other extinct lycopsids form most of the great coal beds of the world.

**General features.** Many of the ancient lycopsids, such as *Lepidodendron*, were trees that often exceeded 30 metres (100 feet) in height. The living genera are all small plants, some erect and others low creepers. Regardless of their size or geological age, all share certain group features. Branching is fundamentally dichotomous; that is, the shoot tip forks repeatedly. The two branches that result may become either equal in length or of different lengths. The leaves (or sporophylls) are generally small, although they sometimes achieved a length of one metre (three feet) in the giant lycopod *Lepidodendron*. Generally each leaf (microphyll) is narrow and has an unbranched midvein in contrast to the megaphyll of the ferns and seed plants (Pteropsida), which generally has branched venation. The sporangia (spore cases) occur singly on the upper side facing the stem (adaxial side) of the leaf.

The lycopsids in general have conelike structures called strobili, which are aggregations of sporophylls telescoped down.

**Life cycle.** As with other vascular plants there is an alternation of generations between a small sex-cell producing phase (gametophyte) and the conspicuous spore-

producing phase (sporophyte). The lycopsids represented by the order Lycopodiales commonly have terrestrial or subterranean gametophytes that vary in size and shape depending on the species.

Although gametophytes are rarely found in nature, enough is known about them to recognize two types, based principally upon the mode of growth and nutrition. In some species, the gametophyte, which develops from a spore, becomes a small, green plant growing on the surface of the soil; the time interval between spore germination and sexual maturity of the gametophyte may be eight months to one year. In other species, including nearly all those of the north Temperate Zone, the gametophyte is subterranean, slower growing, and dependent upon an associated fungus for continued growth. The underground plant may become carrot-shaped or disk-shaped and one to two centimetres (less than an inch) in length or width. It is yellow to brown but, apparently, can develop chlorophyll and thus turn green if the plant is growing near the soil surface where light can reach it. Generally, a gametophyte of this type remains subterranean, and five or more years are required before it becomes sexually mature. Gametophytes are monoecious (bisexual)—i.e., the sperm-producing antheridia and the egg-producing archegonia occur on the same plant. Fertilization occurs after a flagellated sperm swims to the archegonium. The embryo, or young sporophyte, consists of a shoot, root, and a food-absorbing outgrowth called a haustorial "foot." One gametophyte may support more than one sporophyte for a period of time, but ultimately the sporophyte becomes physiologically independent of the gametophyte, and the latter dies.

In the other two extant orders—Selaginellales and Isoetales—the gametophytes are microscopic and undergo most of their development while still within the spore wall (endosporic development).

Definite strobili are formed in *Selaginella*, and the sporophylls generally differ from the vegetative leaves, but not as much as in the species of *Lycopodium* that form definite strobili. There are two types of sporangia in *Selaginella*, called microsporangia and megasporangia, and the sporophylls associated with them are termed microsporophylls and megasporophylls. A mature microsporangium may be red, yellow, or brown, from the colour of the microspores within the sporangium. Megasporangia are usually a pale green or whitish. Numerous microspores are produced, and cell division within the microspore wall initiates male gametophyte development. These divisions may occur before the spores are shed from the microsporangium. Final development of the "male" gametophyte, or microgametophyte, usually occurs on the soil prior to the release of sperm. Usually only four large megaspores are produced in a megasporangium. Development of the "female" gametophyte, or megagametophyte, may also begin while the megaspore is still within the megasporangium: free nuclear divisions (without wall formation) occur for a time, but ultimately walls appear, and the megagametophyte ruptures the megaspore wall. These final stages in development usually occur on the soil after the megaspore with the enclosed female gametophyte is shed from the megasporangium. Fertilization occurs when a sperm swims to an archegonium. The young sporophyte remains in physical contact with the megaspore and the enclosed female gametophyte tissue for some time.

*Selaginella* is said to be heterosporous because it produces two types of spores that give rise to two different types of sexual gametophytes.

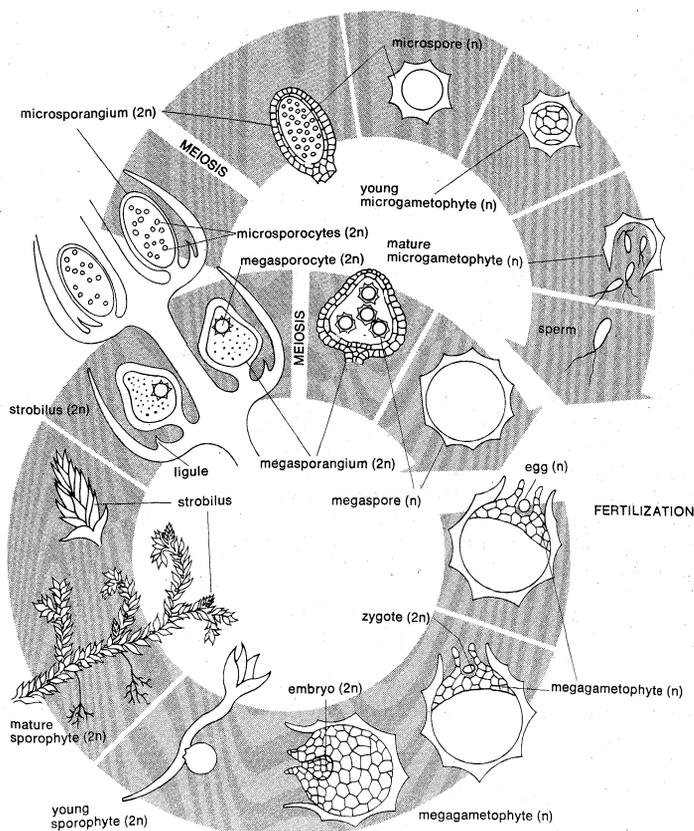

The general processes of sexual reproduction of *Isoetes*, or quillworts, are very similar to those in *Selaginella*, except that many more spores are formed per sporangium. In fact, the microsporangia of some species are the largest in vascular plants and produce immense numbers of spores.

**Form and function.** In growth habit the sporophytes of *Lycopodium* species may arise erect from a system of rhizomes (underground stems), or they may creep. Many are epiphytes; i.e., they grow attached to tree branches or other supports. Branching is fundamentally dichotomous,

The underground plant

Contributors to the coal beds

Growth habit

Life cycle of *Selaginella*.

but, in species with well-developed rhizomes, one branch of a dichotomy usually becomes much longer and larger than the other one and remains close to the surface. The shorter one may undergo several limited dichotomies, the ultimate upright branches terminating in strobili. The leaves may be spirally arranged or grouped in four vertical rows along the shoot. Each leaf has one unbranched midvein. Adventitious roots, initiated near the shoot tip, may grow within the stem cortex for some distance before emerging. The roots branch dichotomously, but no extensive root system is formed. In terrestrial species, the roots have root hairs that function for a long time.

The stem is protostelic (without a central pith), but there is great variety in the disposition of xylem and phylls may be aggregated into definite strobili, or there phloem in the central vascular cylinder. Either spore may be simply fertile and sterile regions along a stem, the sporophylls resembling vegetative leaves. Often the sporophylls of compact strobili differ from the vegetative leaves of the same plant. The kidney-shaped sporangia are yellow or orange and have short stalks.

The foliage leaves of *Selaginella*, only a few millimetres long, may be dark green or bluish and in some species are iridescent. As in *Lycopodium*, branching is fundamentally dichotomous. The sporophyte may consist of several upright branches from a rhizome; prostrate branches creeping along the surface of the soil; or large, flat, erect frondlike side branches from strong rhizome systems. The entire branch system is often considered to be just a leaf by the untrained observer. One distinctive feature of *Selaginella* is the rhizophore, a proplike structure that originates at points of branching and that forms roots after making contact with the soil or a hard surface. Rhizophores are most readily seen in clambering species. Morphologically the rhizophore is considered by some botanists to be a leafless stem that can give rise to leafy branches if the normally leafy branches of a dichotomy are cut off. The leaves are arranged as in *Lycopodium*, the occurrence of four vertical rows being common. Anisophylly (the occurrence of two sizes of leaves) is common in creeping and strongly rhizomatous species. As the rhizophore is a distinctive feature for *Selaginella*, so is the

presence of an unusual structure on the adaxial side (upper side facing the stem) of a leaf. This is the ligule, a peculiar tongue-like outgrowth from the leaf surface near the leaf base. Leaves of *Lycopodium* and *Selaginella* can be distinguished on this basis. The ligule, which appears very early in the development of a leaf, is a surprisingly complex structure at maturity. Its evolutionary origin is obscure. Functionally, the ligules are believed to be secretory organs that, by exuding water and possibly mucilage, serve to keep young leaves and sporangia moist. Short-lived structures, they become shrunken and inconspicuous in older leaves. The ligule was a characteristic feature of the extinct giant lycopods (e.g., *Lepidodendron*).

The species of *Isoetes*, or quillworts, have a plant body that is relatively small, consisting of a short axis and tufts of leaves and roots. Many species are similar in appearance to certain aquatic grasses, which are seed plants. The majority of species occur in the cooler climates of the world and are often immersed continuously in water. Each leaf is actually a sporophyll, bearing either a microsporangium or a megasporangium at its base on the adaxial side. Each leaf also has a ligule, a morphological feature similar to *Selaginella*. *Isoetes* differs from both *Selaginella* and *Lycopodium* in the occurrence of secondary growth in the stem and the possession of a definite root-producing meristem that gives rise to sets of roots in a definite sequence. Annual top growth rises from a cormlike base that persists from one growing season to the next.

**Evolution and classification.** The lycopsids represent a wide range of extinct and living plants that have contributed important data on evolutionary trends in primitive vascular plants. The earliest lycopsids included *Baragwanathia* and *Protolopodendron*, dating from the Devonian Period (beginning 395,000,000 years ago). Both were small herbaceous plants. During the Carboniferous Period (beginning 345,000,000 years ago), the treelike forms of the Lepidodendrales appeared.

Over the years, fossil parts of lepidodendronic plants have been discovered and assigned to so-called form genera, or organ genera: *Lepidophylloides*, for detached leaf fossils; *Lepidostrobilus*, for fossil strobili. These form genera are now recognized as portions of one main fossil genus designated *Lepidodendron*. Other lycopsids coexisting with the tree lycopsids were small herbaceous plants that resemble the modern *Lycopodium* and *Selaginella* species.

**Annotated classification.** The class Lycopsida is often divided into five orders, as listed below. Some authorities recognize six orders. Groups with a dagger (†) are extinct and known only from fossils.

#### CLASS LYCOPSIDA

Primitive seedless vascular plants with true roots, stems, and leaves. Four extant genera, with 900 to 1,000 species, worldwide but concentrated in the tropics.

##### Order Lycopodiales

Living and extinct plants with primary growth only. Homosporous (producing spore of 1 type). Two living genera, *Lycopodium*, with 200 species, mostly tropical; *Phylloglossum*, with 1 species, restricted to Australia. Among the extinct members were *Lycopodites*, *Protolopodendron*, and *Baragwanathia*.

##### Order Selaginellales

Living and extinct plants with primary growth only. Heterosporous (producing 2 types of spores). The sole living genus is *Selaginella*, with more than 700 species, widely distributed round the world. *Selaginellites* is an extinct genus.

##### † Order Lepidodendrales

Extinct tree lycopsids, and, therefore, capable of secondary growth. Heterosporous, with some strobili (cones) forming seedlike structures. Included are *Lepidodendron* and *Sigillaria* (and their form genera).

##### Order Isoetales

Living and extinct plants with secondary growth. Heterosporous, with endosporic gametophytes (i.e., gametophytes that begin development within the spore wall). *Isoetes* includes more than 60 species in swampy, cooler parts of the world. *Isoetites* is an extinct genus.

##### † Pleuromeiales

Extinct unbranched plants, with subterranean rootlike rhizophores. Heterosporous. A single fossil genus, *Pleuromeia*.

The form genera

**Critical appraisal.** Paleobotanical consensus favours the recognition of this group as a class; however, some authorities would raise it to a subdivision or even to a higher category, a division, LycopHYta.

The five orders given above are occasionally expanded to six by separation of *Protolpidodendron* from the Lycopodiales as a separate order, the Protolpidodendrales.

Certain species of *Isoetes*-like plants are sometimes split off to form an additional genus, *Stylites*.

**BIBLIOGRAPHY.** F.O. BOWER, *Primitive Land Plants* (1935), dated but still useful; H.N. ANDREWS, *Studies in Paleobotany* (1961); and THEODORE DELEVORYAS, *Morphology and Evolution of Fossil Plants* (1962), textbooks of college-level difficulty on paleobotany with extensive bibliographies to specific works; H.P. BANKS, *Evolution and Plants of the Past* (1970), a short introduction to newer concepts of plant evolution as revealed by extinct (fossil) plants; A.S. FOSTER and E.M. GIFFORD, JR., *Comparative Morphology of Vascular Plants* (1959); and D.W. BIERHORST, *Morphology of Vascular Plants* (1971), both general textbooks of college level on vascular plant morphology to include living and extinct plants. Selected list of journals that publish articles on vascular plant morphology: *American Journal of Botany* (10/year), *Botanical Gazette* (quarterly), *Phytomorphology* (quarterly), *Annals of Botany* (5/year), *Paleontographica* (1-3 vol./year).

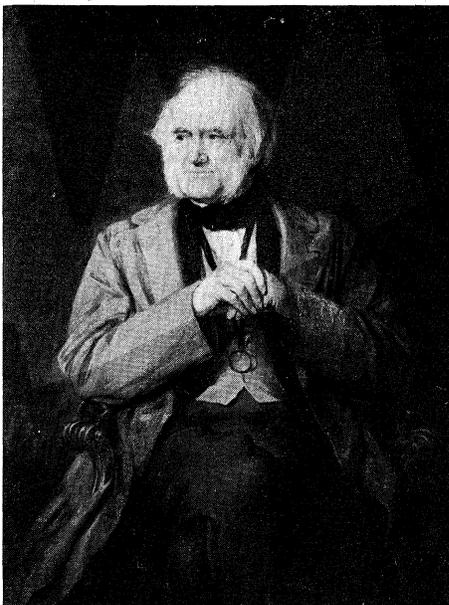

(E.M.G.)

## Lyell, Sir Charles

Charles Lyell was a leading geologist of early- to mid-Victorian Britain whose great contribution was to insist upon and prove that all features of the Earth's surface, including even its mountains, are produced by natural processes operating, often imperceptibly, over very long periods of time. In doing this, he also proved that the rocks of the Earth's crust record a history of thousands of millions of years that could be interpreted objectively, without recourse to the biblical explanations or catastrophes customarily invoked in his century. These achievements laid the foundations for evolutionary biology as well as for an understanding of the Earth. Lyell's predecessor, James Hutton, who died the year of Lyell's birth, had clearly seen that the Earth was molded by agents still at work, such as rivers, ice, and volcanism, but his work had received little appreciation. Lyell raised Hutton's findings from obscurity, adding much that was new concerning the most recent rocks, faunas, floras, and movements of the Earth's crust.

**Early life.** Lyell was born November 14, 1797, at Kinnordy, the stately family home at the foot of the Grampian Mountains in eastern Scotland. His princi-

pal childhood associations, however, were with the New Forest near Southampton, England, where his parents moved before he was two years old. His father, a talented naturalist who later turned to more literary pursuits, kept the study well-stocked with books on every subject, including geology. The eldest of ten children, Charles attended a series of private schools, where he was not a particularly diligent student; he much preferred rambles in the New Forest and his father's instruction at home to those places, with their schoolboy pranks and pecking orders whose spirit he never really shared. His first scientific hobby was collecting butterflies and aquatic insects, an activity pursued intensively for some years, even though labelled unmanly by local residents. His observations went far beyond those of any ordinary boy, and later this instinct for collecting and comparing led to important discoveries.

At 19 Lyell entered Oxford University, where his interest in classics, mathematics, and geology was stimulated, the latter by the enthusiastic lectures of William Buckland, later famous for his attempt to prove Noah's Flood by studies of fossils from cave deposits. Lyell spent the long vacations between terms travelling and geologizing. Notes made in 1817 on the origin of the Yarmouth lowlands clearly foreshadow his later work. The penetrating geological and cultural observations Lyell made while on a continental tour with his family in 1818 were as remarkable as the number of miles he walked in a day. In December 1819 he earned a B.A. with honours and moved to London to study law.

**Career.** Lyell's eyes were weak and were so hurt by hard law study that he sought and found relief by spending much time on geological work outdoors. Among these holidays was an 1822 visit to see evidence of vertical movements of the Earth's crust in Sussex. In 1823, on a visit to Paris, he met the famous naturalists Alexander von Humboldt and Georges Cuvier and examined the Paris Basin with the French geologist Louis-Constant Prévost. In 1824 Lyell studied sediments forming in freshwater lakes near Kinnordy. When in London, Lyell participated in its vigorous intellectual life, meeting such literati as Sir Walter Scott and taking active part in several scientific societies.

**New approach to geology.** Prodded to finish his law studies, Lyell was admitted to the bar in 1825, but with his father's financial support he practised geology more than law, publishing his first scientific papers that year. Lyell was rapidly developing new principles of reasoning in geology and began to plan a book which would stress that there are natural (as opposed to supernatural) explanations for all geologic phenomena, that the ordinary natural processes of today and their products do not differ in kind or magnitude from those of the past, and that the Earth must therefore be very ancient because these everyday processes work so slowly. With the ambitious young geologist Roderick Murchison, he explored districts in France and Italy where proof of his principles could be sought. From northern Italy Lyell went south alone to Sicily. Poor roads and accommodations made travel difficult, but in the region around Mt. Etna he found striking confirmation of his belief in the adequacy of natural causes to explain the features of the Earth and in the great antiquity even of such a recent feature as Etna itself.

The results of this trip, which lasted from May 1828 until February 1829, far exceeded Lyell's expectations. Returning to London, he set to work immediately on his book, *Principles of Geology*, the first volume of which was published in July 1830. A reader today may wonder why this book filled with facts purports to deal with principles. Lyell had to teach his principles through masses of facts and examples because in 1830 his method of scientific inquiry was novel and even mildly heretical. A remark of Charles Darwin shows how brilliantly Lyell succeeded: "The very first place which I examined . . . showed me clearly the wonderful superiority of Lyell's manner of treating geology, compared with that of any other author, whose work I had with me or ever afterwards read."

In France and Italy

During the summer of 1830 Lyell travelled through the geologically complex Pyrenees to Spain, where the closed, repressed society both fascinated and repelled him. Returning to France, he was astonished to find King Charles X dethroned, the tricolour everywhere, and geologists able to talk only of politics. Back in London he set to work again on the *Principles of Geology*, finishing Volume II in December 1831 and the third and final volume in April 1833. His steady work was relieved by occasional social or scientific gatherings and a trip to a volcanic district in Germany close to the home of his sweetheart, Mary Horner, in Bonn, whom he married in July 1832, taking a long honeymoon and geological excursion in Switzerland and Italy. Mary, whose father had geological leanings, shared Charles's interests. For 40 years she was his closest companion; the happiness of their marriage increased because of her ability to participate in his work.

During the next eight years the Lyells led a quiet, regular life. Winters were devoted to study, scientific and social activities, and revision of Lyell's *Principles of Geology*, which sold so well that new editions were frequently required. Data for the new editions were gathered during summer travels, including two visits to Scandinavia in 1834 and 1837. In 1832 and 1833 Lyell delivered well-received lectures at King's College, London, afterward resigning the professorship as too time-consuming.

*Scientific eminence.* Publication of the *Principles of Geology* placed him among the recognized leaders of his field, compelling him to devote more time to scientific affairs. During these years he gained the friendship of men like Darwin and the astronomer Sir John Herschel. In 1838 Lyell's *Elements of Geology* was published; it described European rocks and fossils from the most recent, Lyell's specialty, to the oldest then known. Like the *Principles of Geology*, this well-illustrated work was periodically enlarged and updated.

In 1841 Lyell accepted an invitation to lecture and travel for a year in North America, returning again for nine months in 1845–46 and for two short visits in the 1850s. During their travels, the Lyells visited nearly every part of the United States east of the Mississippi River and much of eastern Canada, seeing almost all of the important geological "monuments" along the way, including Niagara Falls. Lyell was amazed at the comparative ease of travel, although they saw many places newly claimed from the wilderness. A veteran of coach and sail days, Lyell often praised the speed and comfort of the new railroads and steamships. Lyell's lectures at the Lowell Institute in Boston attracted thousands of people of both sexes and every social station. Lyell wrote enthusiastic and informative books, in 1845 and 1849, about each of his two long visits to the New World.

Unlike the majority of well-off Victorians, Lyell was a vocal supporter of the Union cause in the American Civil War. Familiar with both North and South, he admired the bravery and military skill of the South but believed in the necessity and inevitability of a Northern victory.

In the 1840s, Lyell became more widely known outside the scientific community, socializing with Lord John Russell, a leading Whig; Sir Robert Peel, founder of Scotland Yard; and Thomas Macaulay, the historian of England. In 1848 Lyell was knighted for his scientific achievements, beginning a long and friendly acquaintance with the royal family. He studied the prevention of mine disasters with the English physicist Michael Faraday in 1844; served as a commissioner for the Crystal Palace Exposition in 1851–52; and in the same year helped to begin educational reform at Oxford University—he had long objected to church domination of British colleges. Lyell's professional reputation continued to grow; during his lifetime he received many awards and honorary degrees, including, in 1858, the Copley Medal, the highest award of the Royal Society of London; and he was many times president of various scientific societies or functions. Expanding reputation and responsibilities brought no letup in his geological

explorations. With Mary, he travelled in Europe or Britain practically every summer, visiting Madeira in the winter of 1854 to study the origin of the island itself and of its curious fauna and flora. Lyell especially liked to visit young geologists, from whom he felt "old stagers" had much to learn. After exhaustive restudy carried out on muleback in 1858, he proved conclusively that Mt. Etna had been built up by repeated small eruptions rather than by a cataclysmic upheaval as some geologists still insisted. He wrote Mary that "a good mule is like presenting an old geologist with a young pair of legs."

In 1859 publication of Darwin's *Origin of Species* gave new impetus to Lyell's work. Although Darwin drew heavily on Lyell's *Principles of Geology* both for style and content, Lyell had never shared his protégé's belief in evolution. But reading the *Origin of Species* triggered studies that culminated in publication of *The Geological Evidence of the Antiquity of Man* in 1863, in which Lyell tentatively accepted evolution by natural selection. Only during completion of a major revision of the *Principles of Geology* in 1865 did he fully adopt Darwin's conclusions, however, adding powerful arguments of his own that won new adherents to Darwin's theory. Why Lyell was hesitant in accepting Darwinism is best explained by Darwin himself: "Considering his age, his former views, and position in society, I think his action has been heroic."

After 1865 Lyell's activities became more restricted as his strength waned, although he never entirely gave up outdoor geology. His wife, 12 years his junior, died unexpectedly in 1873 after a short illness, leaving Lyell to write, "I endeavour by daily work at my favourite science, to forget as far as possible the dreadful change which this had made in my existence." He died February 22, 1875, in London, while revising his *Principles of Geology* for its 12th edition and was buried in Westminster Abbey.

*Assessment.* Lyell typified his times in beginning as an amateur geologist and becoming a professional by study and experience. Unlike most geologists then and now, however, he never considered observations and collections as ends in themselves but used them to build and test theories. The *Principles of Geology* opened up new vistas of time and change for the younger group of scientists around Darwin. Only after they were gone did Lyell's reputation begin to diminish, largely at the hands of critics who had not read the *Principles of Geology* as carefully as had Darwin and attributed to Darwin things he had learned from Lyell. Lyell is still underestimated by some geologists who fail to see that the methods and principles they use every day actually originated with Lyell and were revolutionary in his era. The lasting value of Lyell's work and its importance for the modern reader is clear in Darwin's assessment:

The great merit of the *Principles* was that it altered the whole tone of one's mind, and therefore that, when seeing a thing never seen by Lyell, one yet saw it partially through his eyes.

**BIBLIOGRAPHY.** KATHERINE M. LYELL (ed.), *Life, Letters, and Journals of Sir Charles Lyell, Bart.*, 2 vol. (1881), is the best source of Lyell's own observations. CHARLES LYELL, *Principles of Geology, Being an Attempt to Explain the Former Changes of the Earth's Surface by Reference to Causes Now in Operation*, 3 vol. (1830–33, reprinted 1969), and *Principles of Geology, or The Modern Changes of the Earth and Its Inhabitants*, 11th ed., 2 vol. (1872), are the two best editions to consult and compare. T.G. BONNEY, *Charles Lyell and Modern Geology* (1895), is a perceptive 19th-century view. J.M. DRACHMAN, *Studies in the Literature of Natural Science* (1931), is excellent on Lyell and Darwin. L.C. EISELEY, "Charles Lyell," *Scient. Am.*, 201:98–106 (1959), is concise, original, informative, and moving. See also M.J.S. RUDWICK, "Lyell on Etna, and the Antiquity of the Earth," in C.J. SCHNEER (ed.), *Toward a History of Geology* (1969), splendid on Lyell's formative experiences; and *Sir Charles Lyell's Scientific Journals on the Species Question* (1970), written by the leading student of Lyell's life and work, L.G. WILSON, who also provided the definitive biography *Charles Lyell. The Years to 1841: The Revolution in Geology* (1972).

(R.W.Ma.)

## Lymphatic System, Human

The lymphatic system helps to maintain the proper fluid balance in the tissues and the blood, to conserve protein, and to remove bacteria and other particles from the tissues. It consists of a network of fluid-filled vessels that open into the blood-vessel system, together with masses of lymphoid tissue, the structure and activity of which will be discussed below. The lymphoid tissue is, in part, intimately associated with the network of vessels, as in the lymph nodes or glands, is less intimately associated with the vessels, as in the tonsils and thymus, or has no obvious connection with the vessel network, as in the spleen.

The fluid in the lymphatic vessels, called lymph, is as a rule clear or faintly opalescent, except the lymph called chyle, which comes from the intestines. Chyle at times may be white and milky in appearance because of the minute globules of fat that it contains. The thin-walled vessels through which chyle flows are referred to as lacteals because of their milky appearance. Modern knowledge of the lymphatic vessels may be said to date from the observations of Gaspare Aselli (Gaspar Asellius), who gave (1627) the first description of these vessels after observing the white lacteals in the mesentery (a fold of membrane such as that which attaches the small intestine to the dorsal wall of the abdomen) of a well-fed dog. Since these first observations of Asellius, it has become well established that the lymphatic vessels are constantly receiving fluid from the bloodstream, to which they ultimately return it. There is thus a continuous circulation of lymph.

**The lymphocytes.** Of the variety of cells in the lymph nodes, the most numerous are lymphocytes, which are also found in the lymph, in blood, and elsewhere. Lymphocytes vary in size, but the smallest are about the size of red blood cells and consist almost entirely of nucleus with very little cytoplasm—the cell substance outside the nucleus. The nuclear chromatin (the most readily stainable substance in the nucleus) is disposed in dense clumps. The cytoplasm has no distinctive granules, such as are to be found in most of the other white cells (leukocytes) of the blood. Lymphocytes are capable of active movement and can migrate through the walls of blood vessels and through the various tissues. Until a few years ago they were thought to be incapable of growth or differentiation. In the late 1950s it was shown that an extract of the red bean (*Phaseolus vulgaris*), which has since been termed phytohemagglutinin, is capable of stimulating the growth and subsequent division of small lymphocytes; these are now regarded as primitive cells capable of growth and proliferation if suitably stimulated. Since this discovery, a number of substances have been found capable of stimulating the growth of small lymphocytes. Consequently, the small lymphocyte is now regarded as the temporarily inactive phase of a cell, which on appropriate stimulation can enter upon a period of great activity. In the inactive phase the lymphocyte has been compared to a cellular spore form since it can remain inactive for a long time.

Lymphocytes exist in a number of places in addition to the lymph nodes—namely, the spleen, the lymphoepithelial tissues, the thymus, and the bone marrow—and large numbers of the cells are scattered throughout the connective tissues of the body. The lymphoepithelial tissues are masses of lymphocytes in close relation to the epithelium (covering) of the alimentary canal. At the upper end, they form both the tonsils and the tissues at the back of the nose that when enlarged are called adenoids. The appendix is made up largely of lymphoepithelial tissue; and throughout the intestine there are lymphoid nodules, arranged either singly or in groups, known as the aggregated nodules, or Peyer's patches. The lymphoepithelial tissues are separated from the bacterial contents of the mouth or the intestine only by thin epithelial layers through which bacteria may pass; hence, the tonsils and the appendix are notoriously subject to infection. The thymus is a lymphoid organ that is particularly well developed at birth and during the growth period. After

puberty it undergoes progressive atrophy. The bone marrow contains a large population of lymphocytes scattered among its other cells and not arranged in dense nodules. A considerable number of lymphocytes are to be found in the connective tissues all over the body. It is now known that these various lymphoid masses and scattered lymphocytes do not exist in watertight compartments but, on the contrary, are integrated by the continual migration of lymphocytes between them. These migrations are described as cellular migration streams.

**The lymphatic vessels.** The lymphatic vessels commence as a network of closed microscopic vessels—capillaries—whose walls consist essentially of a single layer of cells, the endothelium. This resembles the endothelium of the blood capillaries but is much more freely permeable to large molecules such as proteins and even to particles such as India ink. The classical method of demonstrating lymphatics, interstitial injection, has depended upon the great permeability of lymphatic endothelium. A solution of a dye or a suspension of particles is injected into the tissue spaces or interstices and immediately enters the lymphatic capillaries by passing through their endothelium. This can be demonstrated in man by injecting a dye into skin, the colour appearing as streamers in the lymph vessels leaving the site of injection. In general, with certain exceptions due to special local circulatory arrangements, wherever there are blood capillaries, lymphatic capillaries also are to be found.

The lymphatic capillaries join to form progressively larger vessels whose walls become somewhat thicker because of their small amounts of muscle and elastic tissue. These larger collecting vessels usually accompany the veins, and, like the veins, they possess valves, but in far greater numbers. The compression of valved lymphatic trunks by surrounding muscles is an important factor in the propulsion of lymph; in addition, lymphatic vessels themselves may possess a rhythmic contractility. At the points at which valves are attached, the walls of lymphatic trunks are thicker than elsewhere, and, consequently, distended lymph trunks usually have a beaded appearance.

The intermediate vessels join to form a series of main lymph trunks. The main lymph trunk draining the lower limbs enters the abdomen; after passing through lymph nodes in the lumbar region (the small of the back), it becomes known as the lumbar trunk and enters the cisterna chyli; the latter also receives the large common intestinal trunk, which conveys the lymph from the greater part of the intestine. The cisterna chyli is a dilated sac lying at the back of the abdomen opposite the first lumbar vertebra, and from its upper end the thoracic duct ascends through the chest, or thorax; it inclines slightly to the left and ends at the base of the neck by entering the left innominate vein formed by the junction of the great veins draining the left side of the head and neck and the left arm. The thoracic duct thus returns to the bloodstream the lymph from both legs, the pelvis and abdomen, the left side of the thorax, the left arm, and the left side of the head and neck—in other words, the lymph from the greater part of the body. Lymph from the right side of the head and neck, the right arm, and the right side of the thorax returns to the blood through the right lymph duct, which opens into the great veins at the base of the neck on the right side. There are valves in both the thoracic duct and the right lymph duct, including a particularly well-developed valve close to their termination.

**Lymph nodes.** Lymph nodes are a relatively recent evolutionary development and in their characteristic form are present only in mammals, though a rudimentary type of lymph node is found in birds. Lymph nodes are found in both superficial and deep situations. There is a well-marked node—or nodes—at the back of the knee, while there are a number of both superficial and deep nodes in the region of the groin. There is a large collection of nodes in the armpit. There are numerous nodes in the thorax and abdomen, especially in the mesentery. It is distinctive of man and primates that lymph passes through chains of several small lymph nodes instead of through one or two large nodes, as in other mammals.

cytes

Main  
trunks

This is readily seen in the mesentery, where in man there are many scattered small nodes, while in the dog the nodes are all gathered together in a large mass at the root of the mesentery. Asellius thought that this was a small pancreas, and it is still sometimes known as the pancreas of Asellius.

The human lymph node is enclosed in a fibrous capsule; in the interior are masses of cells, mainly lymphocytes, which in the outer part of the node—the cortex—are in dense masses, whereas in the interior, the medulla, they form a series of branching cords of cells, the medullary cords; between the cords are clearer spaces, the lymph sinuses. In some animals, though not in man, there is a well-developed system of partitions (trabeculae) extending into the node from the capsule and partially subdividing the node into segments. Nodes tend to be more or less bean shaped; lymph vessels bring lymph to the outer convex surface of the node, where they pierce the capsule. Immediately under the capsule there is a lymph channel termed the subcapsular (or cortical) sinus; from this sinus other sinuses extend radially into the node to reach the network of medullary sinuses. The medullary sinuses converge to the concave side of the bean-shaped node and leave the node in the form of two or three lymphatic vessels that quickly join to form a single vessel. Vessels bringing lymph to the lymph node are termed afferent; vessels draining lymph away, efferent. Freshly formed lymph that has not passed through a node is called peripheral lymph. Lymph that has passed through only one node is called intermediate lymph. Lymph that has passed through all the nodes that it is going to traverse and is on its way to the blood without further interruption is termed central lymph.

Peripheral,  
inter-  
mediate,  
and  
central  
lymph

Peripheral lymph contains a small number of lymphocytes, around 500 to 1,000 per cubic millimetre, whereas intermediate and central lymph contain many more, up to 40,000 or more per cubic millimetre. For many years this difference in cell content between peripheral and intermediate lymph was taken to mean that large numbers of cells were constantly being formed in the node and entering the blood via the lymph stream. This view found further support because of the presence in the cortex of the node of lymphoid nodules with a clear central area called the germinal centre. Walter Flemming (1885), the German biologist who first described the germinal centre, observed that it contained numerous cells in the process of dividing. It was, in fact, one of the first animal tissues in which cell division was observed.

It is now known that the position is far from being as simple as was first thought. In addition to the new formation of cells, there is appreciable migration of lymphocytes through the node. A small number of these reaches the node through its afferent lymph, while a larger number reaches it via the bloodstream. Lymph nodes contain a special type of blood vessel, the postcapillary veins, through the walls of which lymphocytes pass from the blood into the lymph node substance; the cells then move out of the node either into the efferent lymph or through the walls of other blood vessels into the bloodstream again. In either case, there is extensive recirculation of lymphocytes in lymph nodes as well as new formation. Cells that leave the node thus may be newly formed, or they may have been derived from the afferent lymph or from the blood.

Cells that reach the blood via the lymph stream are termed indirect-entry lymphocytes, as opposed to the direct-entry cells that obtain access to the bloodstream directly by migrating through the walls of blood vessels in lymphoid tissue without first entering the lymph. Considerable numbers of lymphocytes are of the direct-entry variety. The few cells reaching the node via peripheral lymph are derived from the blood, passing first from the blood capillaries into connective tissue and thence into peripheral lymph. The steady drift of a small number of lymphocytes through the connective tissues of the body may possess much greater importance than the numbers suggest. Furthermore, under abnormal conditions the number of lymphocytes in peripheral lymph may be greatly increased.

The lymph sinuses are not, as a rule, clear channels but are broken up by a network (reticulum) of cells that are capable of engulfing bacteria and other foreign particles; *i.e.*, they are phagocytic. Foreign particles, whether inert, such as carbon, or living, such as bacteria or fragments of cancerous growths, may all be held up for a time in the lymph node, where they are mechanically trapped by the cells of the sinus reticulum. This led Rudolf Virchow, in the middle of the last century, to ascribe a defensive, or barrier, function to lymph nodes; these observations on lymph nodes led to assignment of a defensive function to lymphoid tissue generally. It is now known that Virchow was to a large extent right, though for the wrong reasons. When bacteria reach a lymph node, they stimulate rapid proliferation of a small part of the total lymphocyte population of the node, and this proliferation is accompanied by a gradual change of the lymphocytes into another type of cell, the plasma cell, that forms antibodies to the bacteria. The plasma cells may be formed in large numbers and would quickly swamp the lymph node were it not that large numbers of young plasma cells leave in the efferent lymph to settle in various parts of the organism where they go on producing antibodies. In this way a relatively small amount of lymphoid tissue can give rise to a large number of plasma cells. At the same time, through the migration of plasma cells, the lymph node is cleared, as it were, for further action.

Formation  
of plasma  
cells and  
antibodies

Little is known, as yet, about the origin of the cells migrating to the lymph node either in peripheral lymph or through the bloodstream. Although it has been established that some lymphocytes are derived from the bone marrow and others from the thymus, it is not known what determines the extent of these cell migrations or their direction. Among the best established groups of cellular migration streams are those that originate in the bone marrow. Cells from the bone marrow seem ultimately to colonize the remainder of the lymphomyeloid complex—*i.e.*, the rest of the lymphatic system and the bone marrow. In addition, it is highly probable that there are not only single but also serial migration streams from one part of the complex to another. It is possible, for example, that the thymus is an intermediate station to which cells migrate from the bone marrow and that the cells undergo some change there before continuing their migration to other parts of the complex such as the spleen and lymph nodes. The most extensive and rapid migration streams pass through the blood and consist to a large extent of direct-entry lymphocytes that have been formed in the bone marrow. The indirect-entry cells of the lymph contain a varying number of lymphocytes that have been conditioned to respond to an immunological stimulus. It is also clear that cells originating in the marrow can find their way into the connective tissues in considerable numbers. In most of these migrations the majority of the migrating cells are small lymphocytes. It seems that the small lymphocyte is the stage in the life history of the lymphocyte that is best adapted for speed of mobilization, ease of transport, and economy of storage in the minimum of space.

Lympho-  
cyte  
migrations

**Other aggregates of lymphoid tissue.** One of the many problems that arise out of the diffuseness of distribution of the lymphoid tissues is that of determining how much there is in the body as a whole. In the smaller laboratory animals, such as the rat or rabbit, the more clearly defined members of the complex have all been dissected out and weighed. In practice this has meant thymus, spleen, most of the lymph nodes, the appendix, and Peyer's patches, but it does not take into account the large population of lymphocytes present in the bone marrow and the connective tissues nor the numerous solitary nodules found in the alimentary canal. It is also clear that usually not all the lymph nodes are identified in such procedures; in man, in whom there are many hundreds of nodes, the attempt to dissect them all out is fraught with even greater difficulty. On the basis of the animal data, in the young adult the lymphoid tissue of the body as a whole is somewhere between 1. and 1.5 percent of the body weight. If all the scattered elements could be collected into a single mass, they would form an organ of approxi-

mately the same weight as the liver, which in the normal man ranges from 1.2 to 1.6 kilograms. This lymphoid "organ" undergoes marked changes with age. The thymus, in particular, which is large in infancy, begins to shrink fairly rapidly after puberty. Tonsils and adenoids are also large and well developed until puberty. Before this was fully appreciated, perfectly normal tonsils were sometimes removed under the impression that their large size was due to disease.

**Composition of lymph.** Lymph contains all the protein fractions present in blood plasma (the blood except for its cells) but at a lower level. Thus, in one set of observations in man, the total protein was 7.08 percent in the blood plasma and 4.89 percent in the lymph of the thoracic duct. The difference between plasma and lymph was due mainly to the globulin fraction, which was 4.16 percent in plasma against 2.56 percent in lymph; the albumen was 2.86 percent in plasma compared with 2.34 percent in lymph. The protein content of lymph varies in different regions. Liver lymph contains the highest percentage of protein, whereas lymph from the skin and subcutaneous tissues usually contains the lowest. Antibodies are associated with serum globulins, and it is the globulin content of lymph that is relatively more reduced in relation to blood plasma than the albumin content; hence, as a rule, lymph contains less antibody than blood plasma, a fact that may on occasion affect the efficiency with which the body can deal with infections. Apart from proteins, lymph—and more especially intestinal lymph—contains appreciable amounts of fat after a fatty meal. The fat particles have a surface membrane that consists largely of protein enclosing the fatty core. This structure can be readily seen under the electron microscope. It should be noted that cholesterol is absorbed almost entirely by means of the lymph stream, whereas fats are absorbed only in part.

Electrolytes, sugar, and urea

Electrolytes (*e.g.*, calcium, sodium, potassium, chloride) in lymph are found in virtually the same concentration as in blood plasma. The same is basically true of glucose and urea. After a carbohydrate meal or the injection of glucose into a vein, the blood sugar rises rapidly, and the sugar content of lymph lags behind for a short time until equilibrium is re-established. The levels of non-protein nitrogen and of the nitrogen components urea, amino acid, and creatinine are approximately the same in plasma and lymph except in the kidney, where the level of urea is slightly higher in lymph than in plasma. Some hormones are absorbed in small amounts through the lymph stream—*e.g.*, testosterone and progesterone. Enzymes present in the blood plasma behave, in general, like the other plasma proteins and are therefore found in lymph also. They are usually in smaller amounts in the lymph, although there are exceptions to this—*e.g.*, serum alkaline phosphatase, which is derived to a considerable extent from the intestines and obtains access to the blood stream mainly through the lymphatics, is found in higher levels in the lymph.

**Formation, pressure, and flow of lymph.** Lymph is derived from the blood by a process that begins with filtration through the wall of the blood capillary. This primary filtrate then undergoes some modifications as it passes through the tissues that it finally leaves by entering the lymphatics. The amount of tissue fluid at any time represents an equilibrium between the amount of fluid leaving the blood capillary and the amount entering the lymphatic capillary. The normal functioning of the tissues depends to a large extent on the effective control of the tissue-fluid balance.

Small molecules, such as those of oxygen, carbon dioxide, or sodium chloride, diffuse rapidly through the blood capillary endothelium in both directions and have little effect on the fluid balance. The mechanical (hydrostatic) pressure of the blood inside the capillaries forces fluid out of the blood into the surrounding tissues. On the other hand, since the capillary lining (endothelium) functions almost as a semipermeable membrane, the osmotic pressure of the plasma proteins, mainly the albumin, exerts a force in the opposite direction and absorbs fluid from the tissue spaces into the capillaries. This essentially is the

basis of the hypothesis first put forward by the English physiologist Ernest H. Starling; if this were all that happened, lymphatics would be unnecessary, and fluid balance could be adequately maintained without them.

There is one complication in this apparently simple arrangement for maintaining the tissue-fluid balance: the endothelium of the blood capillaries functions almost as a semipermeable membrane, but not completely, since now and again the relatively high pressure of the blood inside the capillary forces out a few molecules of plasma protein. This protein cannot be reabsorbed, since the tissue pressure outside the capillaries is far too low to drive it back into the bloodstream. Consequently, this slight but steady leak of protein would lead to its gradual accumulation in the tissues if it were not for the presence of lymphatics with their much more permeable endothelium. The prime purpose of the lymphatics, therefore, is to return extravascular protein to the bloodstream. Though what is now usually known as the Starling hypothesis is fundamentally correct, its operation can be modified in a number of ways. It is now thought, for example, that the blood capillary is more permeable at its arterial than at its venous end. Furthermore, in some tissues the blood capillaries let little or no protein through.

In the central nervous system, only small amounts of protein escape from the blood vessels, and this protein is removed by the cerebrospinal fluid. In the thymus, similarly, little protein escapes from the blood. This so-called blood-thymus barrier is believed to be the reason that the thymus does not normally share in the reaction to foreign proteins. In the bone marrow the specialized blood capillaries known as sinusoids possess numerous small apertures that allow blood plasma to pass quite freely in either direction; thus, here too, the need for lymphatics is obviated.

The pressure of lymph is much lower than that of blood. It ranges from 1 to 25 millimetres of mercury, though under conditions of severe exercise the pressure of lymph in the limbs may rise on rare occasions to as much as 60 millimetres of mercury.

The flow of lymph is caused by a variety of factors. The lymph hearts found in lower vertebrates are absent in higher vertebrates, including man. In some parts of the body the flow of lymph may be aided by the contraction of the smooth muscle in the walls of the lymphatic vessels. Although such contraction occurs to a greater extent than had previously been realized, it is probably true that the propulsion of lymph is still, in the main, caused by forces from outside the vessels, such as muscular contraction and respiratory movement.

**Conditions that increase the flow of lymph.** Provided that the endothelium of the blood capillary remains healthy, the flow of lymph can be increased by altering the two major factors that control it. Either lowering the osmotic pressure of the blood or raising its hydrostatic pressure will upset the normal balance and will result in increased formation of lymph. Compared with the blood vascular system, the lymphatic vessels can transport relatively small amounts of fluid; hence, they can deal with only a moderate increase in lymph flow. Beyond this point lymph accumulates in the tissues, which become waterlogged, or are said to have developed edema. The commonest cause of lowering the plasma proteins is starvation, or a diet deficient in protein. The key protein from the point of view of osmotic pressure is serum albumin; if this falls beyond a certain point, nutritional edema develops.

Most commonly a rise in the venous pressure is reflected almost at once by a rise in the capillary pressure and a corresponding increase in lymph formation. This is one of the reasons that edema often develops in cases of heart disease, when the back pressure from the heart results in increased venous pressure, as shown clearly by the distended veins. Increased capillary pressure is most likely to occur in the legs when a person is upright, since, in addition to other factors, the force of gravity is exerted through a long column of blood extending downward from the heart. This effect will be maximal at the lower

Structures lacking lymphatics

Edema in heart disease

end of the venous column, so that even in normal individuals prolonged standing will not infrequently cause some edema with a resultant feeling that the shoes have become tight. In pregnancy, when the enlarged uterus presses in the abdomen on the veins draining blood from the lower limbs, the tendency toward edema is accentuated, and some degree of swelling of the feet and legs is not uncommon.

Even if the osmotic pressure of the blood plasma and the hydrostatic pressure of the blood in the capillaries are within the normal range, edema can still develop if the wall of the blood capillary is unduly permeable. This can result from injury, as from the ultraviolet rays of the sun in sunburn. The capillary endothelium is especially sensitive to oxygen deficiency, and in heart disease, when there is a combination of increased capillary pressure and oxygen deficiency, edema may be especially well marked.

Other  
causes  
of edema

In some people the capillary endothelium is readily damaged by cold; such persons tend to develop chilblains, which are essentially local patches of edema. In others prolonged warmth, which causes enlargement of the blood vessels, may also bring about some edema. In sensitive persons the capillaries may be damaged by allergic stimuli; *e.g.*, small amounts of foreign proteins absorbed in undigested form and giving rise to local "spots," which are small patches of edema. Many types of injury result when damaged cells form substances that increase the permeability of the neighbouring capillaries. In some persons firmly stroking the skin liberates these substances—either histamine or histamine-like compounds—so that a wheal develops.

The fluid balance also may be upset through varying degrees of lymphatic obstruction. In a few individuals whose lymphatic vessels do not reach full development, some degree of lymphatic obstruction may be said to exist almost from birth. The obstruction in these cases is never great, but its effects are continuous. If every day even two or three drops more of tissue fluid are formed than the lymph trunks can cope with, there is a slowly developing but progressive edema. This usually occurs in the leg; as the edema becomes greater and greater, elephantiasis is said to have developed. Other forms of lymphatic obstruction may be due to involvement of collecting trunks in scar tissue; *e.g.*, the vessels in the armpit after extensive removal of the breast, in which case the edema involves the arm.

**Functions of the system.** *Return of protein and tissue fluid to blood.* The essential function of the lymph is to return to the blood the extravascular protein that is continually leaking out in small quantities. Though the rate of leakage is slow, it is continuous, so that in the course of 24 hours well over 50 percent of the total plasma proteins have left the bloodstream. Without the operation of the lymphatics and the steady return of protein to the blood, the delicate balance of the tissue fluids would be rapidly upset. Some of the protein that passes through the tissues en route from blood to lymph is actually made use of by the tissue cells. For tissues that manufacture proteins of various kinds, the lymphatics provide the main channel of entry of the proteins into the bloodstream.

*Removal of bacteria and foreign particles.* Foreign particles in the tissues are usually removed by the lymphatic vessels and then are held up in the sinus reticulum of the lymph nodes draining the region affected. If the particles are antigens—*i.e.*, if they stimulate antibody formation—they may initially give rise to pain and tenderness in the nodes, which undergo considerable swelling while the antibody-forming cells are developing. The fate of bacteria when they reach the lymph node has been investigated by many observers in an effort to elucidate the basic mechanisms of immunity.

Trans-  
plantation  
antigens

In the case of bacteria, the antigen can be readily identified. In recent years great interest has developed in "transplantation antigens" that are discharged from grafted foreign tissue and stimulate the development of immune reactions resulting in rejection of the graft. Although transplantation antigens cannot be identified with certainty, their existence must be postulated to explain the phenomena of graft acceptance and rejection. In

some types of graft the immune mechanism operates through lymph nodes. Five or six days after a tissue or organ has been grafted, if lymphatic connections have been re-established, a stream of "sensitized" lymphocytes leaves the nodes, reaches the bloodstream, and then obtains access to the graft; there, together with nonsensitized cells, the lymphocytes bring about rejection of the graft. Lymphatics and lymph node connections do not seem essential for rejection, however, since apparently lymphocytes can become sensitized while circulating in the bloodstream, thereby coming into contact with the blood vessels of the graft. Lymphocytes sensitized to the foreign cells can destroy them by producing antibodies that circulate in the blood or are liberated only when the lymphocytes come into contact with their target cells, the cells of the foreign graft to which they have become sensitized. One of the great practical problems in organ and tissue grafting is how to suppress the capacity of the host to mount an immune response against the foreign tissue. In practice, this usually means destroying a sufficient number of lymphocytes. The danger of too successful a program of immunosuppression is that the body is not left with sufficient lymphocytes to help it overcome infections that it would normally take in its stride.

Though cancer cells are not foreign cells in quite the same way as a foreign graft, they have nevertheless somehow become foreign to the body in which they are growing. The available evidence indicates that the mechanisms by which the body deals with cancerous growths are similar to, if not identical with, those by which it deals with grafts of foreign organs. In each case the lymphocyte seems to play a leading role (see also LYMPHATIC SYSTEM DISEASES).

## Lymphatic System Diseases

The lymphatic system, made up of a network of vessels, the lymph channels, and of masses of tissue, including the lymph nodes, serves (1) to drain fluid and proteins from the tissues and return them to the blood circulatory system and (2) to resist invasion of the body by disease organisms and other foreign particles. The second of these functions—largely immunological in nature—and the disorders concerned with it are discussed in the article IMMUNITY.

Diseases of the lymphatic system include a variety of unrelated conditions whose common feature is that they involve abnormalities of the lymphatic vessels or tissues. This group of diseases is conveniently subdivided into those in which it is the drainage function of lymphatic vessels that is impaired and those in which there is abnormality in the lymphatic tissues. Lymphedema, or swelling of tissue due to inadequate lymph drainage, is the commonest manifestation of the first group, although drainage of lymph by abnormal routes also falls into this category. The second group most often becomes evident as some unusual degree of enlargement of lymph nodes (sometimes still referred to as lymph "glands" though they are not generally thought to have any strictly glandular function) or of the spleen.

In each main group, disease may be either primary, involving the lymphatic system first or most obviously, or secondary, in which some process that has begun elsewhere comes to involve the lymphatic system.

Types of  
lymphatic  
system  
disease

This article outlines the conditions most commonly responsible for the main abnormalities of lymphatic system structure or function, and briefly characterizes currently available treatments.

It must be stressed that the identification of the cause of enlarged lymph nodes, while often straightforward, may on occasion present great difficulty and may require blood analysis, X-ray investigation, and even microscopic examination of the affected tissue, before it can be firmly established.

**Disorders of lymphatic vessels.** *Impairment of lymph drainage.* Impairment of lymph drainage from any tissue leads to swelling as tissue fluid accumulates in excessive amounts in the spaces between the cells. This variety of swelling is known as lymphedema and is characteristically harder and less easily dispersed than that seen in other forms of edema. Chronic inflammation and formation of scar tissue occur often in lymphedematous tissues.

Simple obstruction of a major lymphatic trunk such as that draining a limb rarely results in lymphedema because of the great capacity of other, smaller lymphatic vessels to grow and bypass the obstruction. The presence of lymphedema, therefore, implies a widespread involvement of lymphatic vessels in the disease process. Once the obstruction is established, it is unlikely to disappear spontaneously. Elephantiasis is the name often given to advanced lymphedema, from the increase in size and thickening of the affected part, often a limb.

Causes of lymphedema include inherited, infective, and malignant conditions. Milroy's disease, which often appears in childhood or early adult life and causes enlargement of one or both legs, has a familial incidence and is thought to result from some inherited abnormality of the lymphatics. Lymphatic cysts, seen in the neck as swellings under the skin, also appear early in life and probably represent disorders of development of lymphatic vessels.

Infective lymphedema most frequently results from filariasis, a tropical disease in which small worms, spread by mosquitoes, grow and proliferate in the lymphatics, causing mechanical obstruction and chronic inflammation. The result is lymphedema, which may be extremely severe, of the lower limbs and sometimes of the external genitalia. This is the condition of tropical elephantiasis.

Cancer may produce lymphedema either by the invasion and consequent obstruction of lymphatic vessels by the malignant process or by damage to the lymphatics resulting from surgery or radiation therapy. Removal of the breast and of local lymph nodes is not infrequently followed by lymphedema of the arm on the affected side. In this, and in other circumstances, malignant changes occasionally develop in the walls of the lymphatic vessels (lymphangiosarcoma) with consequent further obstruction.

Treatment of lymphedema, apart from attention to any causative condition, such as chemotherapy to eliminate the worms in filariasis, is in severe cases usually surgical, involving the bridging of the area of obstruction by a grafted strip of tissue with healthy lymphatics, to bypass the blockage.

*Abnormal drainage of lymph.* Abnormal drainage of lymph, or lymph fistula, is nearly always associated with some obstruction to lymph drainage, although it can also occur as a result of injury. The effects depend on the site involved and include the chronic discharge of lymph through a skin wound, or into the urinary tract (chyluria), the abdominal cavity (chylous ascites), or the thoracic cavity (chylothorax). If substantial lymphatics are involved, the volume of fluid lost may be considerable, leading to dehydration and collapse. If the lymph includes that draining from the intestinal tract, it has a characteristically milky appearance because of the fat absorbed by lymph in this area.

Treatment is essentially surgical and is directed to relieving any obstruction that may be present as well as to closing the fistula and restoring a route by which the lymph may find its way to its normal destination, the venous system.

*Lymphangitis.* Inflammation of lymphatics, or lymphangitis, is seen in certain inflammatory conditions of

the skin, particularly in infections with streptococcus organisms. The striking picture of discrete red lines along the course of the subcutaneous lymphatic vessels that drain the area of the primary infection is usually accompanied by painful enlargement of the local lymph nodes. Treatment is directed to the primary infection, if it is still present.

**Disorders of lymphoid tissue.** Lymphoid, or lymphatic, tissue is found in the lymph nodes, spleen, and thymus, and also in the tonsils, adenoids, and the walls of the intestine. Enlargement or overgrowth of such tissue may be local or generalized, acute or chronic, and primary or secondary. To determine the cause of a particular person's lymphoid tissue enlargement it is necessary to take account of the history of the condition, associated local or general disorders, and the nature and distribution of the enlarged lymphatic tissue. If the cause is still not apparent it is necessary to investigate further with blood tests, X-ray examination, or even microscopic examination of a specimen of the affected tissue.

*Generalized lymph node enlargement.* In primary lymphoid tissue diseases the first or most prominent site of the disease process is in the lymphatic tissues, and there is no condition in some other tissue to account for the lymphatic tissue involvement. Many of the diseases in this category have features of malignant disease. This group includes the diseases known as the reticuloses and also lymphatic leukemia. (Leukemia is characterized by the presence of abnormally high numbers of white cells in the blood; in lymphatic leukemia the white cells in abnormal numbers are lymphocytes.) The cause of this group of diseases is unknown; although the diseases have many of the features associated with malignant disease, such as spread of the condition at and beyond the site of origin and a uniformly fatal outcome in the absence of treatment, there is a school of thought that holds that there may be an infective, possibly viral, basis for the conditions. These two views are not mutually exclusive, since several types of animal and human tumour are known to be virus induced.

Lymphatic leukemia is distinguished from the reticuloses by the presence in the circulating blood of numerous lymphocytes. These cells are characteristic cells of the lymphatic system and normally form some 20 to 30 percent of the white blood cells in adults (up to 60 percent in children), being present in concentrations of 1,000 to 3,000 per cubic millimetre. This figure may rise as high as 500,000 per cubic millimetre in lymphatic leukemia. Two forms of the disease occur: the acute, which is predominantly a disease of children, and the chronic, which affects mainly those over 45 years old and is more common in men than in women. Enlargement of lymph nodes and spleen is a feature of both types but is generally more marked in the chronic form.

In acute leukemia the onset is usually sudden, and the course rapidly progressive to a fatal conclusion, with severe anemia requiring blood transfusion, with spontaneous hemorrhages, and with uncontrollable infection among the clinical manifestations. The lymphatic form of acute leukemia is, however, somewhat amenable to treatment, and remissions of two years or more have been produced by corticosteroid (adrenal hormone) and cytotoxic (cell-poisoning) therapy. The greatest hope for improvement in therapeutic results in this as in certain other malignant conditions seems at present to lie in the technique of intensive cytotoxic chemotherapy combined with nursing in completely sterile conditions to protect the patient from the increased susceptibility to infections that results from the inevitable depression of the normal white blood cells.

Chronic lymphatic leukemia runs a much slower and more insidious course and may come to the affected person's notice as generalized enlargement of lymph nodes. The characteristic abnormalities in the blood and bone marrow enable this condition to be differentiated from other causes of generalized lymph node enlargement. Treatment is often confined to correcting the resulting anemia; the disease is often quite slow to progress, a course of five years being not uncommon. If the disease

Causes of lymphedema

Lymph fistula

Lymphatic leukemia

enters a more acute phase, X-ray therapy, particularly to the spleen, and cytotoxic therapy may be employed.

The reticulososes have certain similarities to chronic lymphatic leukemia, but without the changes in the blood. Involvement of the lymph nodes may be generalized from the start—in which case the outlook is rather more serious—or localized to a single node or group of nodes. Diagnosis of reticulosis, and determination of the type, rests largely on microscopic examination of affected tissue; in the localized forms of these conditions the affected tissues may be surgically removed for this purpose, this operation being apparently curative in a certain small proportion of cases. Usually there is recurrence sooner or later, often in several sites distant from the site of onset. It is not known whether these conditions always spread from a single, sometimes unobtrusive, site of origin, or whether they genuinely originate at several different points. The clinical features of the other reticulososes—that is, lymphosarcoma and reticulum-cell sarcoma—are similar to those of lymphadenoma, the outlook being rather worse.

Hodgkin's  
disease

The commonest and least malignant of the reticulososes is lymphadenoma, often known as Hodgkin's disease. This typically starts in early adult life and occurs in both men and women. Apart from enlargement of accessible lymph nodes, which may cause the affected person to notice a lump in the neck, armpit, or groin, there may be symptoms from enlargement of deeper node groups, such as those in the chest or abdomen. Such enlargement commonly causes some obstruction of the alimentary or respiratory tracts, leading to vomiting, difficulty in swallowing, or cough. Some degree of anemia is often present, as is fever, which may point misleadingly to the possibility of a systemic infection as the cause of the enlarged nodes. Pain in the affected nodes following the taking of alcoholic drinks is a mysterious but not uncommon feature of Hodgkin's disease. Weight loss, as in many other malignant conditions, is often noted as the disease progresses. Treatment by irradiation or cytotoxic drugs may produce remissions of ten to 20 years or even apparent cures, particularly when the disease is diagnosed in its localized form. Untreated, the course varies greatly from case to case, being sometimes slow, sometimes rapidly progressive to a fatal end.

Syphilis  
and other  
infections

Syphilis in both primary and secondary stages involves lymph node enlargement. In the primary stage it is the inguinal (groin) glands that are most likely to be involved; generalized enlargement follows in the secondary stage and persists, if untreated, longer than any other feature of this stage.

Glandular fever, also called infectious mononucleosis, is a virus disease that is accompanied by general lymph node enlargement, often most marked in the neck region. The spleen, too, is often involved, as in many conditions in this category.

Rubella (German measles) can be distinguished from measles and some of the other childhood rashes by enlargement of the lymph nodes, especially those at the back of the neck.

Plague in some cases leads to marked lymph node enlargement, the masses of glands swollen to prominence in the inguinal region being the "buboes" that give their name to the bubonic form of this condition.

Primary amyloid disease and sarcoidosis are diseases, of unknown cause, in which generalized lymph node enlargement may occur. (In amyloidosis an abnormal protein substance, superficially like starch, accumulates in various bodily organs such as the heart, lungs, and skin. In sarcoidosis, small lumps, or tubercles, of epithelioid cells develop in any of a number of the bodily organs. Epithelioid cells are connective tissue cells that form layers like the coverings and linings of the body.)

If sufficiently widespread, infections of the skin with staphylococci or other organisms may result in generalized enlargement of lymph nodes.

Just as all the conditions mentioned may on occasion be confined for a time at least to an isolated group of nodes, or even to a single node, so most of the conditions in the next category will sometimes give rise to misleadingly widespread involvement.

*Local lymph node enlargement.* By far the commonest cause of local lymph node enlargement is infection in the area drained by the nodes concerned. So common is this that most normal people will be found on careful examination to have one or more nodes in the armpits or groins that are enlarged enough to be perceptible by touch. The primary infection responsible may be trivial or may have subsided some weeks previously and thus may have been forgotten. Before any serious significance is placed on the presence of such nodes, a thorough search must be made of the relevant skin areas and of the person's memory. Sometimes the affected nodes themselves become involved in the infective process to the point of pus and abscess formation. Staphylococcal skin infections are the usual cause of such lymph node involvement when nodes in the groin or the armpit are acutely involved in this way, the enlarged nodes being typically tender to the touch. When nodes in the neck are thus involved, the likely sites of primary infection include the throat and particularly the tonsil. Acutely enlarged tender nodes in this region, as frequently seen in childhood, are most often due to streptococcal throat infections. Dental infections also may involve lymph nodes.

Skin and  
other  
infections

Chronic infections also may give rise to local lymph node enlargement, the best known example of this being tuberculosis. When the tuberculosis organism gains entrance to the body by the respiratory tract, the pharynx, or the alimentary tract, it most often gives rise to a small lesion at the site of entry, and shortly afterward the lymph nodes to which the site drains become involved in the tuberculous process. Thus nodes at the root of a lung (near the point where bronchi, nerves, and blood vessels enter), in the neck, or in the abdomen may become infected. Frequently, in the case of the lung, the condition progresses no further than this stage, and the patient recovers, being left with a small scar and sometimes with a lymph node that is calcified. Calcification is a typical reaction of the body to healed tuberculosis in any site. If the condition is not arrested by the natural defenses of the body, or by chemotherapy, the affected nodes, like other tissues affected by tuberculous infection, may progress from overgrowth to caseation (the tissue dies and turns into a cheese-like substance) and to discharge of tuberculous pus. This picture is known as a cold abscess, as it lacks the acute inflammatory features of, for example, a staphylococcal abscess. Tuberculous lymph node enlargement is often the first abnormality noted when it occurs in the neck. In this situation it is almost always associated with the bovine form of the disease, acquired from drinking infected milk, and virtually eliminated in some countries by immunization and testing of dairy herds. There are still many people to be seen who bear on their necks the scars of the drainage or surgical removal of such nodes.

Tuber-  
culosis

The other main category of lymph node enlargement confined to local areas is that of secondary malignant disease, the appearance of a cancerous growth at a distance from its original site. As with the infections, such involvement may on occasion be the first sign of the cancer to be seen, particularly when the primary tumour is deeply situated. Certain types of tumour are much more likely to spread by the lymphatic route than others. Carcinomas, or malignant tumours of skin, lining membranes, and glandular tissues, are much more susceptible to this type of spread than are sarcomas, malignant tumours of connective tissues, such as bone, cartilage, and muscle. The malignant cells find their way from the primary growth along lymphatics to the lymph nodes, where they tend to be held up and may grow to form a secondary cancer or metastasis. If the primary source is not apparent, inspection of a specimen of tissue from the secondary tumour may be able to settle the question, particularly when the tumour is a well-differentiated one. A knowledge of the lymphatic drainage pathways helps the physician to select likely sites to investigate for primary tumour. The typical malignant lymph node metastasis is hard and painless and is often fixed to surrounding tissues. Such metastases sometimes appear months or even years after the apparently successful removal of the primary tumour. Some surgical operations for cancer aim to

remove not only the primary tumour but the local lymph nodes and the lymphatic vessels between. The operation of radical mastectomy (breast removal) for breast cancer is one such operation, in which the armpit is cleared of all visible nodes, even if apparently normal, in case there are present malignant cells that might persist if only the primary growth were removed.

Occasionally lymph node metastases appear at sites surprisingly distant from the primary tumour, as when an abdominal growth such as a stomach carcinoma gives rise to a solitary metastasis in the neck, having spread there by the thoracic lymph duct.

**Significance of enlargement of accessible lymph nodes.** The lymph nodes that are most likely to draw attention to themselves when enlarged are those in the easily accessible subcutaneous groups. Nodes in the neck, the armpit, and the groin fall into this group, also occasionally nodes behind the knee or near the elbow. Deeper groups of nodes, when they become enlarged, may take some time to draw attention to themselves; thus enlarged nodes in the chest may cause cough, shortness of breath, difficulty in swallowing, or congestion of the veins in the upper part of the body, but by the time such symptoms are present the enlargement is likely to be considerable. Similarly, abdominal nodes have to be much enlarged before they give rise to a mass that can be felt through the abdominal wall or that causes symptoms of alimentary tract obstruction. Establishing that such symptoms are due to an enlarged mass of lymph nodes and the elucidation of the cause of such enlargements require X-rays and other investigation, including exploratory surgery and securing of specimens of the tissue.

Below are summarized the possible causes of localized enlargements of subcutaneous nodes at various sites. It should be borne in mind, first, that any of the causes of generalized enlargements may initially become evident by localized involvement; second, that many people, particularly if their work or mode of life involves repeated minor trauma or chronic infection of their hands or feet, have permanently palpable nodes in the armpits or groin; and, third, that inflammatory causes are more common than cancer.

The undermentioned causes apply mainly when the stated group of nodes is the only group affected.

**Cervical nodes.** Enlargement of nodes in the neck (cervical nodes) may be due to tonsillitis and other acute inflammatory diseases of the throat or mouth and teeth; infections or infestations of the skin of the face or scalp; tuberculosis (see above); secondary carcinomas, the most likely site for the primary being the mucous membrane of the mouth, the skin of the face, the larynx (voice box), or the esophagus. Enlarged nodes low in the neck or just above the collar bone may contain secondary tumours from cancer in the chest or the abdomen. Posterior or occipital nodes are enlarged in scalp infections.

**Axillary nodes.** Nodes in the armpit, axillary nodes, are involved in infections of the arm. When malignant enlargement occurs in the armpit, a common primary source is carcinoma of the breast.

**Inguinal nodes.** Inguinal nodes (nodes in the groin) are enlarged in infection of the skin of the feet, legs, buttocks, abdomen, or external genitalia. Primary or secondary stages of syphilis, gonorrhoea, and other venereal diseases may be responsible. Carcinoma of the external or internal genitalia or of the skin anywhere in the drainage area may result in secondary growths in these nodes.

In summary, enlargement of subcutaneous lymph nodes, unless associated with a recent infection in the drainage area of the nodes concerned, requires elucidation of the cause. If generalized, such enlargement is most often part of some generalized infection, such as glandular fever, but occasionally is due to leukemia or reticulosis. Localized enlargement in the absence of nearby infection raises the possibility of tuberculosis or secondary cancer from some deep-seated primary growth. Microscopic inspection of a specimen of the affected node may in some cases be the only way of firmly establishing the cause.

## Lyon

By virtue of its population, the importance and variety of its economic and cultural activity, the extent of its commercial ties, and the often dramatic role it has played in French history, Lyon (Lyons) must be counted among the great cities of Europe. In terms of national importance, it is in many respects second only to Paris. Lyon may be said to owe its 2,000 years of vigorous development and a future of dramatic opportunities to its location. Situated in southeastern France, at the strategic junction of the Rhône and Saône rivers and at the termination of major routes across the Alps, it dominates that portion of the European continent that has historically served as a bridge between the ancient cultures of the Mediterranean and the societies that evolved in the lands bordering the North Sea. From its foundation, Lyon functioned both as a crossroads and as a warehouse: as far back as the 16th century, it was also a manufacturing centre and the French capital of the silk industry. For nearly 500 years, the silk industry distinguished Lyon from other similar cities and impressed its mark on the life of the inhabitants as well as on the physical appearance of the city.

**Historical development.** Before the spectacular development which it experienced in the mid-20th century, Lyons went through three remarkable periods—the Roman conquest, the Renaissance, and the industrialization of the 19th century—each, in its own way, worthy of the admirable geographic situation of the city. Together, they represented three major opportunities for the development of the city, as well as three stages in its physical formation and growth.

**Foundation.** At the time of Caesar, the settlement at Lyons was a village inhabited by fishermen and boatmen at a spot where the Saône narrowed, facilitating contact between what were to become the districts of Saint-Vincent and Saint-Paul. This early dwelling site bore the name of Condate. In 43 BC Lucius Munatius Plancus, a former lieutenant of Caesar, founded a military colony, Lugdunum, on the nearby hill of Fourvière, overlooking the Rhône-Saône confluence. The Roman emperor Augustus subsequently made Lyons the capital of the Gauls, while his son-in-law, Agrippa, created a network of roads converging on the city. Lyons reached the peak of its classical development in the 2nd century AD, when the youthful settlement was composed of three clusters: the Roman city around the forum (*forum vetus* ["old forum"]=Fourvière); the Gallic city on the slopes of the hill of Croix-Rousse, between the Rhône and the Saône, with the altar of Rome and Augustus and the amphitheatre; and finally the lower city, on the frequently flooded lands of the narrow peninsula at the river confluence, where the tradesmen and the boatmen had their quarters. It was in this cosmopolitan environment—in which dealers from as far away as Asia were numerous—that the first Christian community of Gaul was established. In 177, under the reign of Marcus Aurelius, the community was persecuted, and in 197 the aristocracy of Lyons, which had sided with the Roman Albinus in his bid for imperial power, was decimated by his rival, Septimius Severus. The decline of the city began shortly after, the decisive blow being the destruction of the aqueducts that brought water to Lyons. The many vestiges of this period of the first flowering of Lyons have made the city of today one of the main centres of Gallo-Roman archaeology.

**The Middle Ages.** The turbulent Middle Ages coincided with a period of relative obscurity for Lyons, whose inhabitants deserted their hills to settle in a close com-

The rise and fall of the classical city

munity around the churches of Saint-Nizier and Saint-Jean on either side of the bridge across the Saône. The city came under the domination of the archbishop and the church lords of Lyons, whose influence was sufficient to cause important ecumenical councils to be held there in 1245 and again in 1274. Situated in a strife-torn border zone between the Holy Roman Empire and the emergent kingdom of France, Lyons was finally annexed to the latter in 1312, after a long struggle between rising mercantile elements—who had asked the king for aid—and ecclesiastical forces, who were forced, in 1320, to accept the creation of a secular town.

The Renaissance ushered in a period of economic prosperity and intellectual brilliance. The establishment, in 1464, of commercial fairs together with the arrival in the city of Italian merchant bankers, who were welcomed by the local merchants, enabled Lyons to participate in the great economic prosperity which spread across the whole of the contemporary Western world. For a century or more, the city was to be one of the major commercial and banking capitals of Europe. Merchants, notably from Italy and Germany, flocked to Lyons in large numbers, and the local exchange established relations with all the great banking centres of the Continent. Through the abundance of its credit, the city supported the adventures of the king of France in Italy. In 1536 Lyons became a centre for the manufacture of silks in its own right, having initially served as a market for Italian silks in France. Surviving the banking and commercial collapse at the end of the 16th century, the industry, by the 17th century, attained a high degree of perfection in the manufacture of the fine materials that were then captivating Europe. Nor did Lyons fail to shine in the intellectual realm. Printing was introduced as early as 1473, and Lyons soon became one of the most active printing centres in Europe. Poets and architects were among the leading cultural figures of the period during which the city was, in effect, the political, economic, and cultural centre of France.

*The French Revolution and its aftermath.* For Lyons, the French Revolution brought uneasy times. The collapse of the domestic market and the closing of foreign markets brought a slump in the silk industry, and the political crisis culminated in the tragedy of 1793, when the city—hitherto a supporter of royalist and moderate factions—was besieged by republican forces of the Montagnards and subjected to ruthless reprisals.

The First Empire, by contrast, witnessed another period of reconstruction. Until the end of the 19th century, the commercial prosperity of Lyons was to be based on the manufacture of silk. The city became famous as the home of the *soyeux* (merchants and manufacturers) and the *canuts* ("weavers"). Through the medium of the silk industry, the reputation of Lyons was carried all the way to China. At the same time, Lyons became the seat of workers' uprisings; riots that took place in November 1831 and April 1834 were the prototypes of the class struggles that were soon to characterize the modern industrial era. Furthermore, the silk industry, as a consequence of the large amounts of capital required at all stages of the production and distribution process, brought new prosperity to the banking system. The Credit Lyonnais, founded in 1863 by the financier Henri Germain, developed, through the volume of its transactions, from a purely regional institution into a national and international bank and, for a few years toward the end of the 19th century, the largest in the world in the amount of its deposits.

In the 1880s and 1890s Lyons's overall economic growth accelerated, bringing about a considerable expansion of the silk industry and creating chemical and metallurgical industries. It was the takeoff point for the fourth phase of urban development, one that did not really assert itself until the 1950s, after the periods of stagnation and depression between 1920 and the end of World War II. Only then did Lyon assume the distinctive urban character that continued to pattern its life during the 1970s.

**The contemporary city.** *Demography.* The vitality of the city has been reflected in its population growth. During the Renaissance, the population grew from approxi-

mately 20,000 to between 60,000 and 80,000, placing it among the largest European cities of the period. In the 18th century, the population reached 100,000. Subsequent regular census figures provide an index to the ensuing rate of growth.

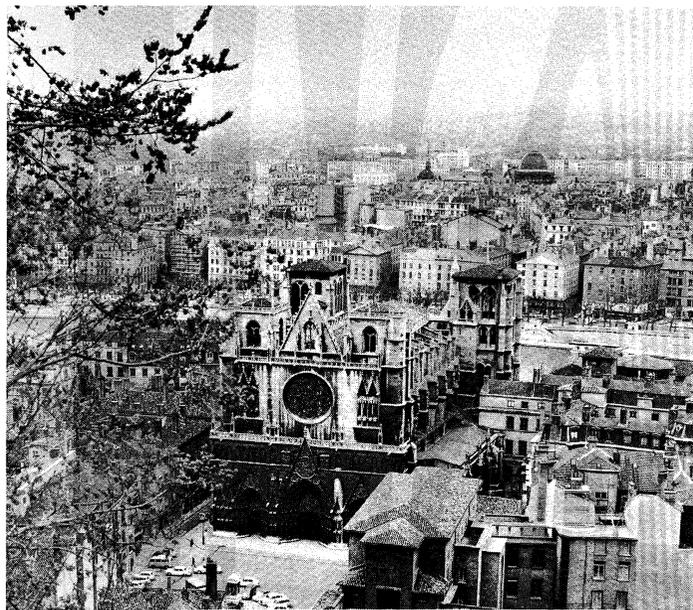

Population Growth of Lyon (000)		census dates						
		1851	1876	1901	1911	1931	1946	1962
Lyons	177	343	459	524	580	461	536	528
Greater Lyons*	—	—	412	655	702	883	943	1,075

\*Includes the city proper and 31 neighbouring communities.

More than two-thirds of the total increase is due to immigration. From 1954 to 1962, for example, 180,000 people settled in Lyons: of these 68 percent were French, and 32 percent were of foreign extraction, of whom 34 percent were North Africans, 31.5 percent Italians, and 18.2 percent Spaniards.

*Economic growth.* Diversification has been the distinguishing feature of Lyon economic development to the early 1970s. In the mid-19th century, the textile industry, dominated by the manufacture of silk, represented 90 percent of the industrial output. By 1970 this figure had dropped to 20 percent; the production of synthetic fibres such as rayon ranked first. Lyons remains one of the great world centres for the production of high-quality silk, but the production of chemicals has become the key industry. Originally connected with the treatment of textiles, it was given fresh impetus by the manufacture of dyes, synthetic fibres, and—quite markedly in recent years—oil products. At Feyzin, an oil refinery—the largest French unit for steam cracking—is the key factor behind the local organic chemistry industry, which is the most advanced in the country. The important metallurgical industry includes a wide variety of processes, varying from foundries to the construction of mechanical, electrical, and electronic equipment. The Berliet works at Vénissieux, southeast of Lyons, are responsible for more than 50 percent of the national output of buses and trucks. The construction, food, and printing industries are prosperous.

*City regions.* Throughout its history, Lyon had expanded to meet the needs created by a succession of new activities. As the city gradually spread to the left bank of

Early  
worker  
uprisings

Sources of  
émigrés

The urban core

the Rhône, its centre of gravity moved steadily toward the east. In the 10th century, it was located on either side of the bridge crossing the Saône, shifting to the centre of the nearby peninsula in the 18th and 19th centuries. It then ran along an axis running from the Place des Terreaux and the town hall—a masterpiece of French civic architecture—to the north, and to Perrache, the main railroad station, to the south. This urban core consisted of several large parallel streets laid out during the Second Empire, a period marked for Lyon no less than for Paris by energetic town planning. By the early 1970s the centre of gravity seemed permanently established on the left bank of the Rhône, where an ambitious project was under construction at Part-Dieu.

There is a zone of factory and residential suburbs encircling Lyon, a belt whose total population exceeds that of the city proper. On the right bank of the Saône, Vieux Lyon ("Old Lyon") remains as one of the finest surviving architectural complexes of the Renaissance era. The peninsula is now the heart of the business district, crowded with banks, offices, and hotels. The east bank of the Rhône is divided between a wealthy area, the Brotteaux, sited around a diverted portion of the river near the Parc de la Tête d'Or, and a district with factories and workers' houses extending east toward the fringing communities of Villeurbanne and Bron. To the south, along the Rhône, Feyzin and Saint-Fons constitute one of the largest oil-refining complexes in France. On the plateau between the Saône and the Rhône, the old district of La Croix-Rousse, once the home of the *canuts*, has now grown toward the north and has become a suburb characterized by factories and residential buildings.

**Administration.** This recent urban expansion has affected the administrative and political organization not so much in terms of overall structure but rather in the way that structure functions. The city is administered by a mayor assisted by a municipal council. One man, Édouard Herriot, a powerful local figure, held the position of mayor for half a century (1905–57). The Paris government is represented by a *préfet* ("prefect"), combining the powers of *préfet* of the Rhône *département* and *préfet* of the Rhône-Alps region, grouping eight *départements*. In an effort to meet new problems common to the city and to its rapidly growing suburbs, new institutions have been created. These are the *agglomération urbaine* ("urban agglomeration"), made up of 31 towns including Lyon; the *communauté urbaine* ("urban community"), established in 1969 and made up of 56 towns; and the *région métropolitaine* ("metropolitan area"), in which Lyon is associated with the urban and industrial centre of Saint-Étienne to the southwest.

**Transportation.** Caught in fierce competition with the other French metropolitan centres, which act as counterweights to Paris, the Lyon of the 1970s found its future closely linked with the availability and quality of transportation facilities. By train, Lyon is only four hours away from Paris and three from Marseille. Navigation on the Saône has benefitted from improvements that make it accessible to the type of heavy barges (up to 1,350 tons) that are used on the Rhine; likewise, considerable work has been done on the Rhône (*q.v.*), resulting in the development of irrigation and electric energy and opening the river to navigation. Crude oil is carried by pipeline from the Gulf of Berre on the Mediterranean coast to the oil refinery of Feyzin, while another pipeline brings natural gas from Lacq in the southwest of France. An expressway provides a strong road link between Paris, Lyon, and Marseille, while in the 1960s Lyon became an important centre for domestic air travel. The rapid growth of air traffic, coupled with the construction of a new airport at Satolas, seemed certain to make Lyon one of the major international travel centres.

**Culture.** First and foremost a business centre, Lyon is nevertheless a city with a remarkable cultural tradition. In the 16th century culture and wealth went hand in hand, but it was not until the 19th century that Lyon became a university town. In 1896 the schools of law, medicine and pharmacy, sciences, and liberal arts were merged into one university that 75 years later had over 43,000 students. A

few prestigious schools helped give Lyon the reputation of being the most important educational centre outside Paris. Educational reforms in 1968 provided for the development of several interdisciplinary universities. Cultural life is reflected in the riches of the local museums, which include a textile collection, the archaeological museum at Fourvière, a museum of fine arts, and a museum of printing and banking. The collections of the municipal library are noted for their specimens of items from the first 50 years of printing and rare books. City theatres include the Opéra, the Célestins (a municipal theatre), and some avant-garde companies that have gained national recognition. Music and drama festivals, held every year in June in the Roman theatre at Fourvière, provide a reminder of the long history of the city.

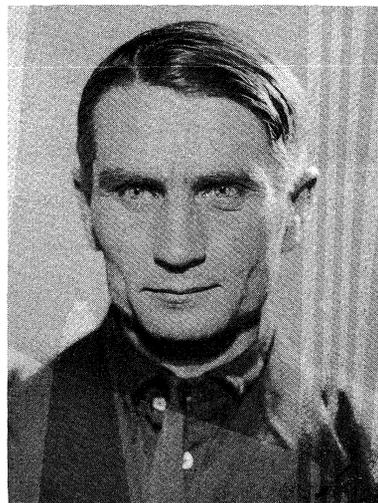

**BIBLIOGRAPHY.** R. GASCON, *Grand Commerce et vie urbaine au XVIème siècle: Lyon et ses marchands* (1971), deals with economic history in the 16th century, and, together with A. AUDIN, *Lyon, miroir de Rome dans les Gaules* (1965), on ancient history; C.M. LEONARD, *Lyon Transformed: Public Works of the Second Empire, 1853–64* (1961); J. BOUVIER, *Le Crédit Lyonnais de 1863 à 1882: les années de formation d'une banque de dépôts*, 2 vol. (1961), an economic history; M. LAFERRERE, *Lyon, ville industrielle* (1960), an industrial-historical study; F. RUDE, *L'Insurrection lyonnaise de novembre 1831*, 2nd ed. (1969), a study of 19th-century riots; and A. KLEINCLAUSZ, *Histoire de Lyon*, 3 vol. (1939–52), all offer pictures of Lyon's history at different times. C.G.E. BUNT, *The Silks of Lyons* (1960), deals with the city's longest established industry, while J. LABASSE, *Les Capitaux et la région* (1955), studies its economic supremacy. R. JULIAN, *Lyon, ville d'art* (1960), describes Lyon and its monuments from an aesthetic standpoint.

(R.Ga.)

## Lysenko, Trofim Denisovich

Trofim Denisovich Lysenko, a Soviet biologist and agronomist, became the virtual dictator of biology in the Communist world in the 1930s, during the regime of Josef Stalin. As such, Lysenko succeeded in having his own biological theories officially adopted throughout the Soviet Union, even though Lysenkoism was rejected by virtually all scientists elsewhere. After Stalin's death in 1953, he was supported by Nikita Khrushchev and was not removed from his administrative duties until 1965, after Khrushchev himself had lost his position of authority.

Sovfoto

Lysenko, 1938.

Lysenko was born in 1898 in Karlovka (now Poltava oblast [region]). He was graduated from the Uman School of Horticulture in 1921 and was stationed at the Belaya Tserkov Selection Station in the same year. After his 1925 graduation from the Kiev Agricultural Institute, with the degree of doctor of agricultural science, he was stationed at the Gandzha (now Kirovabad) Experimental Station until 1929. From 1929 to 1934 he held the office of senior specialist in the department of physiology of

Advocacy  
of  
vernalization

the Ukrainian All-Union Institute of Selection and Genetics in Odessa. Rising rapidly to the top of his profession, he became, in turn, the scientific director of the All-Union Selection and Genetics Institute at Odessa from 1935 to 1936 and its director from 1936 to 1938. Ultimately, he became the director of the Institute of Genetics of the U.S.S.R. Academy of Sciences (1940–65).

Lysenko first rose to prominence through his advocacy of vernalization, a method of breaking the rest period of the seeds that are normally shed in autumn. The method involves immersing the seeds in water, which is then frozen. Lysenko was credited with the discovery of this technique, although it was an ancient practice and had been used elsewhere since the 19th century. It speeded the germination of winter wheat so that even seeds planted in the spring could mature before the killing frosts of autumn. Lysenko promised quick results without time-consuming field tests. He also tried vernalization of spring varieties. The practice had been abandoned in the United States after the development of new varieties of wheat. In 1929, however, the practice became official in the Soviet Union. Lysenko claimed that the changes induced by vernalization were inherited and that the practice need not be repeated year after year. A number of biologists outside the Soviet Union promptly called attention to the fact that this was a revival of the doctrine of the inheritance of acquired characters (Lamarckism), which had long been discredited. Even though vernalization failed to increase farm production, Lysenko in 1935 obtained the public support of Stalin.

As his influence increased, Lysenko undertook to modify and redefine all biological theory. Some of his innovations, such as his doctrine of the phasic development of plants, were mere exercises in semantics. According to this concept, the plant develops in recessive phases, each of which has requirements that differ from those of the other phases; and each plant requirement manifests itself in its own way. Altering one stage in development by environmental means would cause successive stages to be changed, he claimed; such changes, presumably beneficial adaptations, would be inherited. He redefined heredity as the capacity of the living body to demand definite conditions for its life and development and to react in a definite way to any given set of conditions. Heredity, he stated, is the end result of environmental changes that have been assimilated during the course of the preceding generations. Ultimately, of course, this concept of heredity led Lysenko to attack Mendelian genetics, which was universally accepted by biologists elsewhere. Even though by the 1930s sound ideas concerning the biochemistry of the gene were being advanced in the West, and the process of natural selection was indeed explained by Mendelian genetics, Lysenko dismissed the chromosome theory of heredity as "idealistic" and anti-Darwinian. Lysenko was so successful with the attack that the topic could not be taught in the Soviet Union from 1948 to 1964.

Lysenko also claimed that he could produce new types of developmental cycles in plants by regulating the quality of their nutrients. To do this he first had to shatter the conservatism of the plant and thus render it more sensitive to environmental changes. He shattered this conservatism by using adverse environmental conditions, hybridization, and grafting. He was especially impressed with the consequences of grafting and held that the stock and the scion (or cutting) so influenced each other that they fused to form a true hybrid.

Lysenko was not alone in the Soviet Union in his advocacy of an aberrant biology, nor was genetics the only biological science that came under attack. By the early 1930s a powerful antisemitic cabal had developed; ultimately it succeeded in gaining complete control of all biological teaching and research in the Soviet Union. Lysenko was the spearhead of the group, but he was ably seconded by the theoretician Isaak Israilovich Prezent and the agronomist Vasily Robertovich Vilyams. At first other Soviet biologists resisted, but the strength of the attackers was soon evident. Genetics had made such progress in the Soviet Union that under the leadership of N.I. Vavilov the International Congress of Genetics scheduled

its 1937 meeting to be held in Moscow. Vavilov was widely respected outside the Soviet Union because of his expeditions in many parts of the world to study the origin, diversity, and distribution of cultivated plants. In December 1936, however, the Soviet government suddenly cancelled the meeting, an unmistakable indication of the political strength of the Lysenko group. In 1939 Lysenko, in his report as chairman of the Lenin All-Union Academy of Agricultural Science, assailed Vavilov personally. The next year Vavilov was arrested and exiled to Siberia, where he died in 1943. With the elimination of Vavilov, Lysenko and his group secured complete control of biology in the Soviet Union.

Lysenko succeeded in extirpating Mendelian genetics when he presided at the 1948 meeting of the Lenin All-Union Academy of Agricultural Science. Five geneticists who had defended Mendel recanted and committed themselves to the biology that Lysenko advocated. The entire transactions of the meeting were published in the Soviet newspaper *Pravda*, and the official *Proceedings* was soon issued in both Russian and English. At this meeting, Lysenko reached the full height of his political power. Previous honours included election to the U.S.S.R. and Ukrainian academies of science, proclamation as a Hero of Socialist Labour, and receipt of the Order of Lenin eight times and the Stalin Prize three times. He served as president of the Lenin All-Union Academy of Agricultural Science from 1938 to 1956 and from 1961 to 1962.

In 1948 Soviet authorities apparently were anticipating a worldwide revolution in biology, which did not occur. Wherever biologists were free to reject Lysenko's views, they did so. Even in the Soviet Union, he did not persuade scientists in other fields. By 1952 his interpretations were being assailed by men in his own field, and in 1954 his personal honesty was questioned. (A dissertation of one of Lysenko's students was rejected, and it took all of his political power and a vicious struggle later to have it accepted.) The rehabilitation of Vavilov's reputation was begun, and the struggle in biological theory was soon resumed. Lysenko was weakened because he had personally made it impossible for the collective farms to grow hybrid corn. His position against hybrid corn gave his opponents the opportunity to continue their own work, and only the support of N.S. Khrushchev kept Lysenko in a position of importance.

Following Khrushchev's fall in 1964, Lysenko was stripped of his political authority. He and his followers, however, retained their degrees, their titles, and their academic positions, and remained free to support their aberrant trend in biology. Lysenko died on November 20, 1976.

**BIBLIOGRAPHY.** Lysenko's rise to power and the beginning of his fall are recorded in CONWAY ZIRKLE (ed.), *The Death of a Science in Russia* (1949), and in "L'Affaire Lysenko," *J. Hered.*, 47:46–54 (1956). DAVID JORAVSKY, *Soviet Marxism and Natural Science* (1961) and *The Lysenko Affair* (1970), contain excellent factual accounts of the entire imbroglio. ZHORES A. MEDVEDEV, *The Rise and Fall of T.D. Lysenko* (Eng. trans. 1969), which was circulated in typescript in the Soviet Union, gives a detailed inside view of the entire controversy. LYSENKO's own books, in translation, *Heredity and Its Variability* (1946) and *The Science of Biology Today* (1948), record his views.

(C.Z.)

## MacArthur, Douglas

Brilliant and the subject of controversy throughout his long career, Gen. Douglas MacArthur was summoned from retirement in 1941 and achieved greatness as Allied commander of the Southwest Pacific Theatre in World War II, of the postwar Japanese occupation, and finally of the United Nations forces in Korea, 1950–51. Earlier he had won fame in World War I as a heroic general and during the Great Depression as the United States Army's chief of staff.

MacArthur was born January 26, 1880, at Little Rock, Arkansas, the third son of Arthur MacArthur, later the army's senior ranking officer, and Mary Hardy MacArthur, an ambitious woman who strongly influenced Douglas. He graduated from West Point in 1903 with the

Suppression  
of  
Mendelian  
genetics

Early  
life

highest honours in his class and served the next ten years as an aide and a junior engineering officer, following this with four years on the general staff. He spent several months with the U.S. troops that occupied Veracruz, Mexico, in 1914.

By courtesy of the Bureau of Archives, MacArthur Memorial; photograph, U.S. Signal Corps

MacArthur, 1945.

On the 42nd Division's staff in 1917–19, MacArthur was variously chief of staff, brigade commander, and divisional commander during combat operations in France during World War I and in the Rhine occupation that followed. During the 1920s he initiated far-reaching reforms while superintendent at West Point, served on William ("Billy") Mitchell's court-martial, held two commands in the Philippines, commanded two U.S. corps areas, and headed the 1928 American Olympic Committee.

Having advanced in rank to brigadier general in 1918 and to major general seven years later, MacArthur was promoted to general when he was selected as army chief of staff in 1930. His efforts as military head for the next five years were largely directed toward preserving the army's meagre strength during the Depression. MacArthur was widely criticized in mid-1932 when he sent regular troops to oust the Bonus Army of veterans from Washington. In 1935–41 he served as Philippines military adviser (and field marshal), endeavouring, despite inadequate funds, to build a Filipino defense force. He retired from the U.S. Army in December 1937.

MacArthur married Mrs. Louise Cromwell Brooks in 1922, but the childless union ended in divorce seven years later. In 1937 he married Jean Faircloth; Arthur, their only child, was born in Manila the next year.

Recalled to active duty in July 1941, MacArthur conducted a valiant delaying action against the Japanese in the Philippines after war erupted in December. He was ordered to Australia in March 1942 to command Allied forces in the Southwest Pacific Theater. He soon launched an offensive in New Guinea that drove the Japanese out of Papua by January 1943. In a series of operations in 1943–44, MacArthur's troops seized strategic points in New Guinea from Lae to Sansapor, while capturing the Admiralties and western New Britain. The simultaneous northward movement of South Pacific forces in the Solomons, over whom MacArthur maintained strategic control, neutralized Rabaul and bypassed many Japanese units.

After winning a decision to invade the Philippines next rather than Formosa, MacArthur attacked Morotai, Leyte, and Mindoro in autumn 1944. Not until the Leyte operation did he have overwhelming logistical support; his earlier plans had been executed despite inadequacies of personnel and matériel and with little assistance from the Pacific Fleet. MacArthur seriously questioned his superiors' decision to give priority to the European war over the Pacific conflict and to the Central Pacific Theater over his Southwest Pacific area.

His largest, costliest operations occurred during the seven-month Luzon campaign in 1945. That spring he also undertook the reconquest of the southern Philippines and Borneo. Meanwhile, he left the difficult mopping-up operations in New Guinea and the Solomons to the Australian Army. He was promoted to general of the army in December 1944 and was appointed commander of all U.S. army forces in the Pacific four months later. He was in charge of the surrender ceremony in Tokyo Bay on September 2, 1945.

As Allied commander of the Japanese occupation, 1945–51, MacArthur effectively if autocratically directed the demobilization of Japanese military forces, the expurgation of militarists, the restoration of the economy, and the drafting of a liberal constitution. Significant reforms were inaugurated in land redistribution, education, labour, public health, and women's rights. While he was in Japan, MacArthur also headed the army's Far East command.

When the Korean War began in 1950, MacArthur was soon selected to command United Nations forces there. After stemming the North Korean advance near Pusan, he carried out a daring landing at Inch'ön in September and advanced into North Korea in October as the North Korean Army rapidly disintegrated. In November, however, massive Chinese forces attacked MacArthur's divided army above the 38th parallel and forced it to retreat to below Seoul. Two months later MacArthur's troops returned to the offensive, driving into North Korea again. On April 11, 1951, Pres. Harry S. Truman relieved MacArthur of his commands because of the general's insubordination and unwillingness to conduct a limited war. Returning to the United States for the first time since before World War II, MacArthur at first received widespread popular support; the excitement waned after a publicized Senate investigation of his dismissal.

In 1944, 1948, and 1952, conservative Republican groups tried in vain to obtain MacArthur's nomination for the presidency. MacArthur accepted the board chairmanship of the Remington Rand Corporation in 1952; thereafter, except for these duties and rare public appearances, he lived in seclusion in New York City. He died in Washington, D.C., on April 5, 1964, and was buried at Norfolk, Virginia.

In personality MacArthur was enigmatic and contradictory. To many he seemed imperious, aloof, egotistical, and pretentious. To others, especially his headquarters staff, he appeared warm, courageous, unostentatious, and even humble. Most authorities agree that he possessed superior intelligence, rare command ability, and zealous dedication to duty, honour, and country.

CLAYTON JAMES, *The Years of MacArthur*, vol. 1, 1880–1941 (1970), the first volume of a projected three-volume study by a United States historian; FRAZIER HUNT, *The Untold Story of Douglas MacArthur* (1954), by an admiring correspondent; GAVIN LONG, *MacArthur As Military Commander* (1969), a candid Australian view; DOUGLAS MACARTHUR, *Reminiscences* (1964), completed just before his death; CHARLES A. WILLOUGHBY and JOHN R. CHAMBERLAIN, *MacArthur, 1941–1951* (1954); CHARLES A. WILLOUGHBY (ed.), *Reports of General MacArthur*, 4 vol. (1966), by MacArthur's intelligence chief, covering the years 1941–48; COURTNEY WHITNEY, *MacArthur* (1956), by a general close to MacArthur.

(D.C.J.)

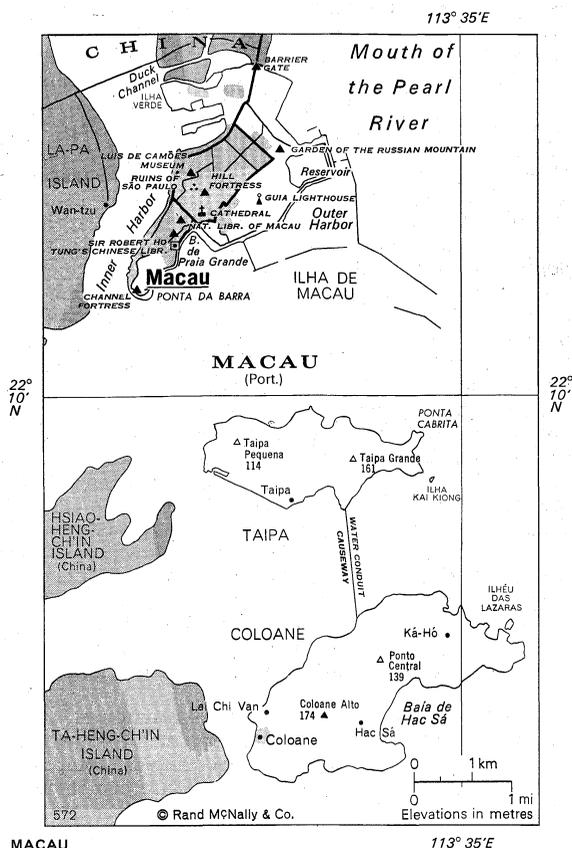

## Macau

Macau, or Macao, is an overseas province of Portugal situated on the south China coast. It is located on the western side of the Chu Chiang (Pearl River) Estuary, at the head of which is the Chinese port of Kwang-chou (Canton), and it stands opposite the British crown colony of Hong Kong, on the eastern side of the estuary. It has a total area of six square miles (16 square kilometres) and a population in the early 1970s of about 250,000. Macau consists of a small and narrow peninsula projecting from the Chinese mainland province of Kwangtung, from which it is separated by the symbolically imposing Barrier Gate, and of two small offshore islands, Taipa and Coloane. The city of Macau stands on the peninsula,

UN  
command  
in Korean  
War

Duty in  
World  
War II

overlooking the Chinese island of La-pa Shan (Lappa), from which it is separated by Duck Channel. The name Macau is derived from the Chinese A-mangao, or Bay of the Goddess A-ma, the patroness of sailors.

MACAU

113° 35'E

A possession of Portugal for more than 400 years, Macau is now Portuguese by the terms of a treaty with China concluded in 1887. Despite a veneer of Portuguese architecture and custom, it has retained its Chinese character, and during the 20th century the province has been much affected by events in China. Macau's existence has always been closely related to trade activities, and trade has been restricted by the government of the People's Republic of China. Since about 1950 a large number of refugees from China have crossed the border into Macau. While the province's frontiers are not definitely agreed upon, a conciliatory policy by the Portuguese has met with a favourable response from the Peking government, so that peaceful relations based upon mutual advantage are maintained between the small province and its powerful neighbour. Apart from being a focus for trading with mainland China, Macau is renowned for its gambling and gold-smuggling activities. While Portugal continues to view Macau as an overseas province, the United Nations in 1960 declared it to be a Portuguese non-self-governing territory. (For articles on political units in the immediate vicinity, see HONG KONG; KWANGTUNG; see also CANTON; for associated physical features, see CHINA SEA; HSI CHIANG; for historical aspects see CHINA, HISTORY OF; PORTUGAL, HISTORY OF).

**The natural landscape.** *Relief.* The peninsula of Macau occupies a total area of about two square miles; the island of Taipa has an area of about 1.5 square miles, and the island of Coloane is some 2.5 square miles in area. No part of Macau is of any great height, though the peninsula is undulating enough to form an attractive urban site. The highest point, 571 feet, is on the island of Coloane. There are no permanent rivers, and water either is collected during rains or is imported from China.

Both the peninsula and the islands consist of small granite hills surrounded by limited areas of flatland formed by recent alluvial deposits from the Chu Chiang. Additional

flatland has been created on the peninsula by reclamation, primarily on the eastern side. Between the western side of the peninsula and the Chinese mainland, at the mouth of Duck Channel, is a narrow stretch of sheltered water known as the Pôrto Interior (Inner Harbour). This formed a safe anchorage in the earliest days of the Portuguese presence and was subsequently developed with wharves and jetties. Today, it is the anchorage for Macau's fishing fleet and is also a berthing place for freighters and for the large river steamers that ply as ferries between Macau and Hong Kong, 40 miles to the east. The newer Pôrto Exterior (Outer Harbour) is protected by a breakwater on the eastern side of the peninsula. Over the years it has become heavily silted, but access is still possible by the hydrofoil service that runs between Macau and Hong Kong, operated by two companies that have interests in both places.

**Climate.** Macau lies just within the tropics. Four-fifths of its total annual rainfall of between 40 and 100 inches falls within the summer rainy season, when the southwest monsoon blows from April to September. Besides being rainy, the summer months are also hot, humid, and unpleasant. The hottest month of the year is July, when temperatures average 82° F (28° C). Relative humidities of over 80 percent are quite usual in the summer. Winters, on the other hand, can be delightful. Very little rain falls, and the relative humidity is low. November is the best month; bright and sunny weather can be expected almost without interruption. The coldest month is January; its average temperature is 59° F (15° C).

**Vegetation and animal life.** The natural vegetation is evergreen monsoonal forest, but the hills have long since been stripped of their timber for firewood and construction. For the most part, they are covered with short grasses and patches of scrub. Reforestation has been undertaken on Coloane. There is very little animal life apart from a few civet cats.

**Settlement patterns.** Only small, restricted patches of farmland exist on the islands, and the rural settlements are small. Rectangular wooden buildings roofed with sheets of corrugated metal are scattered among irrigated patches of farmland. The chief crops are vegetables, especially Chinese cabbage, onions, lettuce, and beans. Almost the entire peninsula is occupied by Macau city, which has a placid atmosphere. The tempo of life is nevertheless increasing, especially because of the growing volume of tourists. In the early 1970s there were still relatively few buildings of more than five stories in height, and the Portuguese imprint was clear in much of the architecture and in the wash colouring—pink, lime, and pale yellow—of many of the buildings, some of which remain from the early days of the occupation.

**History.** The history of Macau as a Portuguese possession spans more than four centuries. The first Portuguese ship anchored in the Chu Chiang Estuary in 1513, and further Portuguese visits followed regularly. Trade with China was placed on an official basis in 1553. Although Chinese records indicate that the Portuguese used Macau as early as 1535, the occupation of the colony is traditionally recognized as dating from 1557. The Roman Catholic diocese of Macau was created by the Holy See in 1575 and was initially given jurisdiction over the whole of the Far East. Trade flourished, and Macau became the principal entrepôt for international trade with China and Japan.

Toward the end of the 18th century, however, China's trade with the outside world was gradually centralized in Canton, where trading posts were opened for the use of foreign merchants. But since merchants were allowed into Canton only during the trading season—from November to May—the international merchant community established itself at Macau. A period of prosperity for Macau followed, but it soon ended because of disputes between the Chinese authorities and the European merchants over the opium trade, the consequent war between Great Britain and China, and the occupation of Hong Kong as a British colony in 1841. In 1849 the Portuguese abolished the Chinese customhouse in Macau and established Portuguese jurisdiction over the territory. But

Taipa and Coloane

Macau city

Decline of trade

Hong Kong quickly eclipsed Macau in trade, and within a few years the merchants had largely deserted the Portuguese possession, which never again became a major entrepôt. The Outer Harbour was built in 1926. In 1939, after the capture of Canton by the Japanese and the closure of the Hong Kong-Kowloon border, much of southern China's trade was briefly diverted to Macau.

The ethnic composition

**The people.** There have always been relatively few Portuguese in Macau, and many of the Portuguese residents have come from other Portuguese possessions, rather than from Portugal itself. The Chinese element in the population, until recent years, had been largely local in character. But, with the unsettled state of China since the 1920s, refugees have arrived even from relatively distant Chinese provinces. Between 1920 and 1927 the population showed a sudden increase, due to immigration, from about 80,000 to some 160,000, and by 1939 it had reached a total of 245,000. Many returned to China during the 1940s, when the war with Japan reached southern China, but refugee immigration increased immediately after World War II. By 1960 the population numbered 169,000. Census figures in 1970 showed an increase to about 1939 levels.

There were 7,460 Portuguese nationals living in Macau in 1970, 240,000 Chinese (97 percent of the total population), and about 1,170 foreigners. Most members of the civil service, the police, and the armed forces are Portuguese, 89 percent of whom were born in Macau. In contrast, more than half of the Chinese—53 percent—were born outside Macau. Although during the course of its history Macau achieved fame as an evangelical centre, the number of Roman Catholics in 1970 was only 23,000. There were also about 2,000 Protestants. Non-Christians, including Buddhists and Taoists, numbered 191,000, and those of no stated religion about 30,000.

**The economy.** *Fishing, trade, and industry.* Except for fish in the nearby Chu Chiang Estuary, Macau has few natural resources. It is, however, a free port, and trade continues to be economically important. In recent years the fishing industry encountered difficulties because of China's insistence that the limits of its territorial waters be respected, with the result that nearby Chinese communes exact a proportion of each catch from Macau boats. The pattern of trade has also changed radically, because China has restricted the entry of goods from Macau. Yet China continues to be of major importance to Macau as a supplier of food and certain cheap consumer goods, such as textiles, clothing, toys, and cheap electrical goods; in fact, Macau ranks second only to Hong Kong in the importation of goods from China. Some industrialization has taken place in Macau during the 1950s and 1960s, largely in response to the availability of the settlement's relatively cheap labour. As a result, textiles now form by far the most important export, and footwear and enamelware industries are also developing. The free movement of industrial goods produced in Macau to the Portuguese overseas provinces has been permitted since 1957. This concession has greatly helped Macau's export industries.

Manufactures for export

In addition to the newer products, Macau has long manufactured firecrackers (largely for use in the United States), Chinese wines, incense sticks, and camphorwood chests. At present Hong Kong is Macau's biggest export market, followed by West Germany. Tourism is grow-

ing rapidly in importance, often in the form of day visits of hydrofoil parties of Japanese tourists, who come via Hong Kong. Macau has long had a reputation for gold smuggling. Certainly, far more gold is imported into Macau than could ever be used in the province. Imported as ingots, the gold is converted into easily transportable form and is then believed to find its way into India, China, and Southeast Asia, where people often prefer gold to other currency. Total visible trade amounts to almost 650,000,000 patacas a year (6.0533 patacas = \$1 U.S.; 14.5279 patacas = £1 sterling, on December 1, 1970).

**Tourism.** Since gambling is prohibited in Hong Kong and the People's Republic of China, Macau attracts large numbers of tourists to its casinos, which offer all manner of betting games and are open 24 hours a day, and to its dog races. All gambling is controlled by a government-licensed syndicate that pays an annual tax of almost \$1,000,000 and maintains the upkeep of the Outer Harbour and transportation with Hong Kong.

**Transportation.** Macau has no airport and is not on international passenger-shipping routes; there are, however, half-hourly hydrofoil connections to Hong Kong, and the trip takes only a little over one hour. The traditional but slower river ferries still also ply between Macau and Hong Kong. Internal transport is good. There are local ferries between the peninsula and the islands. Taipa and Coloane are connected by a causeway over which an auto road runs, and construction was begun in the early 1970s on a bridge to connect the peninsula to Taipa. Roads on the peninsula are kept in good repair, and the city is adequately served by buses and taxis, as well as by numerous pedal trishaws. The health facilities in Macau are good, and there are few serious crime problems.

**Administration and social and cultural conditions.** Macau is administered by a governor appointed from Portugal, who is advised by the Legislative Council, composed of residents and officials. Education is not compulsory, and there are about 168 schools, offering elementary, secondary, and technical curriculums. About 80 percent of the population over the age of 10 is literate.

Chinese culture is dominant in the province; it is manifest in Macau city's many pleasant gardens, in its statue of the Chinese Nationalist leader Sun Yat-sen, and in the local passion for the Chinese game of Mah-Jongg, a form of rummy played with painted tiles instead of cards. Portuguese influence can be seen in the frequent performances of traditional dancers and fado singers, who present plaintive Portuguese folk tunes at the leading hotels. The cuisine is a delicious blend of Chinese, Portuguese, and African cooking. Cultural institutions include the Biblioteca Nacional de Macau (National Library of Macau), Biblioteca Sir Robert Ho Tung (Sir Robert Ho Tung's Chinese Library), and the Museu Luis de Camões (Luis de Camões Museum), commemorating the 16th-century Portuguese poet. There is no television broadcasting, though programs can be received from Hong Kong. There are several Chinese newspapers, both Communist and non-Communist. English-language newspapers arrive from Hong Kong daily.

Chinese and Portuguese cultural influences

**Prospects for the future.** Macau was seriously affected by pro-Communist riots early in 1967, which led to, among other things, the withdrawal of the British consulate and a perhaps greater measure of concealed control over Macau from Peking than before. Yet, with the rapid development of tourism and the expansion of manufacturing that has characterized the period since the riots, the economic future of Macau in the mid-1970s seemed brighter than for many years, provided the *modus vivendi* that prevailed with Peking could be maintained.

**BIBLIOGRAPHY.** J.M. BRAGA, *Macau: A Short Handbook*, rev. ed. (1968), a readable general survey, strong on the historical side, but also dealing with contemporary Macau, especially its trade; PROVINCIA DE MACAU, *X Recenseamento Geral da População em Macau, Taipa e Coloane* (1960), the latest census report available; INSTITUTO NACIONAL DE ESTATISTICA, DELEGACAO DE MACAU, *Anuário Estatístico de Macau* (1969), a convenient handbook of official statistics covering

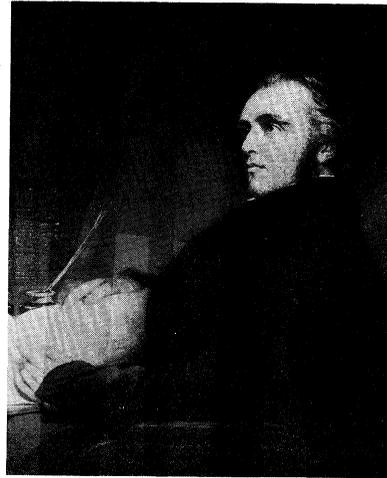

climate, population, trade, cultural life, religious affiliation, public administration, and other matters; and *Comércio Externo* (annual), the official trade statistics.

## Macaulay, Thomas Babington

English politician, orator, administrator, essayist, and historian, Macaulay, after early years in political life, achieved celebrity with his *Critical and Historical Essays* and lasting fame with his *History of England*, which brought him contemporary acclaim and a secure, if diminished, place among English historians as the founder, with his contemporary Henry Hallam, of what is now known as the Whig interpretation of history. Fostered in the traditions of sturdy evangelical piety and liberal reform, he saw the origin and triumph of these values in the Revolution of 1688, which firmly established the supremacy of Parliament and restricted the monarchy to a constitutional status. He planned to write the history of England from 1688 to 1820 (the death of George III) but died before he had completed the reign of William III, who became king at the revolution and died in 1702. Macaulay's work is thus an account of that revolution, with a narration of the years preceding and following it. In stressing the unique importance for England of the revolution and, by implication, the superior virtues of those who brought it about, traditionally the Whig Party (though the Tories were also involved), Macaulay popularized a view of English history that was notably followed by his nephew Sir George Otto Trevelyan and his great-nephew George Macaulay Trevelyan and that affected the teaching of history as late as World War II. His essays helped to mold the outlook of a generation of Englishmen and to give to many their first vivid glimpse of the past, together with a conviction that their own institutions would serve the best interests of developing countries under their care. His style, clear, emphatic, and insensitive, with short sentences forming a self-contained paragraph, came to be for half a century the characteristic English style in higher journalism and exposition of all kinds. Macaulay's reputation, immense during the last decade of his life, fell steadily in the 50 years that followed. His undisguised political partisanship, his arrogant assumption that English bourgeois standards of culture and progress were to be forever the norm for less favoured nations, and the materialism of his judgments of value and taste all came under heavy fire from such near-contemporary critics as Thomas Carlyle, Matthew Arnold, and John Ruskin. Moreover, a revolution in the realm of historical studies, already accomplished in Germany during Macaulay's lifetime but never appreciated by him, soon affected English historiography. Wide as was Macaulay's reading, his approach was largely uncritical, as his enthusiasm often carried him away. By taste and training an orator, his writing was special pleading rather than impartial presentation. Yet, despite these severe limitations, his greatness is incontrovertible, and, regarded solely as a work of art, the status of his *History* remains unassailed. In the grasp and range of his knowledge, in his powers of vivid and sustained narrative, and in his marshalling of topics to serve a great design, his *History* is unsurpassed among the work of English historians, save, perhaps, by *The History of the Decline and Fall of the Roman Empire* of Edward Gibbon.

*Early life and political career.* Macaulay was born at Rothley Temple, the house of an uncle in Leicestershire, on October 25, 1800. His father, Zachary Macaulay, the son of a Presbyterian minister from the Hebrides, had been governor of Sierra Leone; an ardent philanthropist and an ally of William Wilberforce, who fought for the abolition of slavery, he was a man of severe evangelical piety. Macaulay's mother, a Quaker, was the daughter of a Bristol bookseller. Thomas was the eldest of their nine children and devoted to his family, his deepest affection being reserved for two of his sisters, Hannah and Margaret. When eight years old he had written a compendium of universal history and also "The Battle of Cheviot," a romantic narrative poem in the style of Sir Walter Scott. After attending a private school, in

Macaulay, oil painting by J. Partridge, 1840. In the National Portrait Gallery, London. By courtesy of the National Portrait Gallery, London

1818 he went to Trinity College, Cambridge, where he held a fellowship until 1831 and where he gained a reputation for inexhaustible talk and genial companionship in a circle of brilliant young men. In 1825 the first of his essays, that on Milton, published in *The Edinburgh Review*, brought him immediate fame and the chance to display his social gifts on a wider stage; he was courted and admired by the most distinguished personages of the day.

He studied law and was called to the bar in 1826, but never practiced seriously. When his father's commercial interests failed, he undertook the support of his whole family by writing and teaching, and obtained a minor government post. He aspired to a political career, and in 1830 he entered Parliament as member for Calne in Wiltshire.

During the debates that preceded the passage of the Reform Act (1832), he eloquently supported the cause of parliamentary reform and was regarded as a leading figure in an age of great orators. He became a member and later the secretary of the Board of Control, which supervised the administration of India by the East India Company. Working on Indian affairs by day and attending the House of Commons in the evenings, he nevertheless found time to write a ballad, "The Armada," as well as eight literary and historical essays for *The Edinburgh Review*.

In the first parliament elected after the act of 1832, Macaulay was one of the two members from the newly enfranchised borough of Leeds. He soon faced a problem of conscience when the question of slavery was debated. As a holder of government office he was expected to vote for an amendment proposed by the ministry but disapproved by the abolitionists. He offered his resignation and spoke against the government; but since the House of Commons supported the abolitionists and the government gave way, he remained in office.

*Administration in India.* In 1834 Macaulay accepted an invitation to serve on the recently created Supreme Council of India, foreseeing that he could save from his salary enough to give him a competence for life. He took his sister Hannah with him and reached India at a vital moment when effective government by the East India Company was being superseded by that of the British crown. In this he was able to play an important part, throwing his weight in favour of the liberty of the press and of the equality of Europeans and Indians before the law. He inaugurated a national system of education, Western in outlook, and as president of a commission on Indian jurisprudence he drafted a penal code that later became the basis of Indian criminal law. Meanwhile, he suffered two personal blows: his sister Margaret died in England, and in 1835 his sister Hannah left him to marry a promising young servant of the East India Company, Charles Trevelyan.

Develop-  
ment of  
a new  
view of  
history

Parlia-  
mentary  
career

*Later life and writings.* Macaulay returned to England in 1838 and entered Parliament as a member for Edinburgh. He became secretary for war in 1839, with a seat in Lord Melbourne's cabinet, but the ministry fell in 1841, and he found the leisure to publish his *Lays of Ancient Rome* (1842) and a collection of *Critical and Historical Essays* (1843). He was made paymaster general when Lord John Russell became prime minister in 1846, but spoke only five times in the parliamentary session of 1846–47. In the latter year he lost his seat at Edinburgh, where he had neglected local interests. He had, in fact, lost much of his interest in politics, and retired into private life with a sense of relief, settling down to work on his *History of England*. His composition was slow, with endless corrections both of matter and style; he spared no pains to ascertain the facts, often visiting the scene of historical events. The first two volumes appeared in 1849 and achieved an unprecedented success, edition after edition selling well both in Britain and in the United States. When the Whigs returned to power in 1852 he refused a seat in the cabinet, but was returned to Parliament by Edinburgh, and took his seat. Soon afterward he developed a heart disease and thenceforth played little part in politics. The third and fourth volumes of his *History* were published in 1855 and at once attained a vast circulation. Within the generation of its first appearance more than 140,000 copies had been sold in the United Kingdom, and sales in the United States were correspondingly large. The work was translated into German, Polish, Dutch, Danish, Swedish, Hungarian, Russian, Bohemian, French, and Spanish.

In 1856 Macaulay left Albany in Piccadilly, where he had lived since 1840, and moved to Holly Lodge, Campden Hill, then a district of lawns and trees. In the following year he was raised to the peerage, with the title of Baron Macaulay of Rothley. His health was now visibly failing; he never spoke in the House of Lords, and he accepted that he would live scarcely long enough to complete the reign of William III in his *History*. He died at Campden Hill on December 28, 1859, and was buried in Westminster Abbey. The fifth volume of his *History*, edited by his sister Hannah, was published in 1861.

*Character.* Macaulay's exceptional gifts of mind were never, as they have been for many men of genius, a source of calamity or mental anguish. Had he wished, he could have risen to high political place, perhaps to the highest; instead, he chose to devote his powers to the portrayal of England's past. His command of literature was unrivalled. That of Greece and Rome, stored in his extraordinary memory, was familiar from college days, and to it he added the literature of his own country, of France, of Spain, and of Germany. He had limitations. In later life he never gave expression to any religious conviction, and he had no appreciation of spiritual, as distinct from ethical, excellence. All religious and philosophical speculation was alien to his mind, and he showed no interest in the discoveries of science as distinct from technology. Of art he confessed himself ignorant, and to music he was completely deaf. At games, sports, and physical skills—even those of shaving or tying a cravat—his incompetence was complete. In appearance he was short and stocky, with plain features that reflected a powerful mind and a frank and open character.

Macaulay never married. His great capacity for affection found its satisfaction in the attachment and close sympathy of his sisters, particularly of Hannah, later Lady Trevelyan, who remained in almost daily contact with him even after her marriage, and whose children were to him as his own. He had a keen relish for the good things of life and welcomed fortune as the means of obtaining them for himself and others, but there was nothing mercenary or selfish in his nature; when affluent, he gave away with an open hand, often rashly, and his last act was to dictate a letter to a poor curate and sign a check for £25.

**BIBLIOGRAPHY.** The standard edition of Macaulay's complete works is that originally edited by LADY TREVELYAN, in the Albany edition, 12 vol. (1898). JOHN CLIVE and THOMAS

PINNEY, *Thomas Babington Macaulay: Selected Writings* (1972), include further material. For the *History*, see SIR CHARLES H. FIRTH, *A Commentary on Macaulay's History of England* (1938, reprinted 1964); and for his speeches, G.M. YOUNG, *Speeches by Lord Macaulay* (1935). There is no complete or critical edition of his *Essays*.

*The Life and Letters of Macaulay*, 2 vol. (1876; enlarged 1908, and with full index 1959), by his nephew, SIR GEORGE OTTO TREVELYAN, is acknowledged as one of the best biographies in the English language. Of shorter, derivative studies J.A.C. MORISON, *Macaulay* (1882); and SIR ARTHUR BRYANT, *Macaulay* (1932), deserve mention. JOHN CLIVE has used previously unpublished material for *Thomas Babington Macaulay: the Shaping of the Historian* (1973). Scholarly research on Macaulay, long dormant, has recently awakened, and a complete edition of his letters, now preserved at Trinity College, Cambridge, is being prepared by THOMAS PINNEY, while ROBERT ROBSON is editing Macaulay's unpublished *Journal of 1838–59*. There is no bibliography of Macaulay. The best lists are in *The New Cambridge Bibliography of English Literature*, vol. 2 (1969); and BRYANT (*op. cit.*).

(M.D.K.)

## Maccabees

The Maccabees were a priestly family from the vicinity of Jerusalem who during the 2nd century BC led an armed rebellion against King Antiochus' suppression of Judaism and its law. The name Maccabee was a title of honour given to Judas, a son of Mattathias, the hero of the Jewish wars of independence, 168–164 BCE (Before the Common Era, or BC). Later, the name the Maccabees was given to his whole family, specifically to Mattathias, Judas' father, along with all Mattathias' other sons; that is, Judas' four brothers—John, Simon, Eleazar, and Jonathan. Its use was stretched to include even John Hyrcanus, Simon's son, who was next in succession once all the brothers were dead.

There is no unanimity about the meaning of the title Maccabee. The Hebrew may be read as (1) Hammer, (2) Hammerer, or (3) Extinguisher. Since Judas held the initiative in the long war against the Syrians, he was probably regarded in the same light as King Edward I of England, known as the "Hammer of the Scots."

Throughout the 2nd century BCE the city-state of Jerusalem–Judah lay between the two great powers of Egypt and of Syria. The Ptolemies ruled in Egypt and the Seleucids in Syria. These were residual states that had been left when Alexander the Great's empire had broken up about 20 years after his death. Antiochus IV ruled Syria from 175 to 164/163 BCE. He carried the substitute name of Epiphanes, a Greek word meaning "god manifest." A conqueror of overweening pride, as the Bible remembers him (Daniel), he set out to seize Judaea (or Judah), which till then had been a province of Egypt. He aimed incidentally to rid the world of the annoying (and to him peculiar) exclusive "nonconformist" religion of the Jewish people. In order to unify his vast and racially heterogeneous empire, which stretched as far as the Caspian Sea, he planned to create one religion for all.

In Antiochus' day the Syrians were devotees of the culture of Greece. Antiochus sought to continue what he regarded as the "civilizing" colonization process of Alexander. For him culture meant the pursuit of the "good." The restless, inquiring, creative spirit of Greece—what might today be called the scientific spirit—was based on the assumption that "man is the measure of all things." The Jewish view of life, on the other hand, was totally in opposition to that of the Hellenism that had spread throughout the Near East. It, too, was a total way of life, one lived in accordance with what the Jewish people believed was revelation. They regarded Hellenism as basically a form of nature worship. They saw it as the spiritual continuation of the religion of the Canaanites who had presented their views against Israel's for all the centuries since the days of Joshua. They were aghast that Antiochus encouraged the Semitic peoples of the Mediterranean coast to regard him as the ancient god Baal of the Canaanites. The Canaanite gods, they asserted, were merely the mythologizing of the anger, hate, lust, envy and greed of unregulated human hearts.

Israel, on the other hand, its prophets insisted, was the

Historical  
context  
of the  
Maccabees

chosen instrument of the transcendent God, whose name was Yahweh. Yahweh was utterly "other" than man, that is to say, he was "holy." It was God who had created man, not man the gods. And Israel was God's chosen instrument to be "a light to lighten the nations" (Isaiah). To make the meaning of its special relationship to Yahweh evident to the world was therefore Israel's reason for being. Its task was to put the revelation of God into purposeful use by producing an ordered human society that was ruled by God's justice and love and not by man's force and greed.

Antiochus' prohibition of Jewish religious practices

This conception of revealed religion and of loyalty to the Word of God, rather than to a human king, Antiochus could not appreciate, particularly since he himself delighted in the name "god manifest." In order to extirpate the faith of Israel, therefore, he attacked Israel's religious practices. He thus forbade the observance of the sabbath and of the traditional feasts, for these had been ordained by a "jealous" or intolerant God. All sacrifices were to come to an end. He forbade the reading of the Law of Moses and gave orders to search out and burn any copies that could be found. He forbade the practice of circumcision; for it was this that set the Jews off from other peoples as the one "people of God." In place of these practices Antiochus encouraged the development of cultural clubs called gymnasia, in which people gathered to study, to learn, and to enjoy each other's company. After competing in various forms of athletics, men and women used to soak themselves in hot baths. But because the pursuit of the "good" included a delight in the body beautiful, such activities were performed naked. A circumcised Jew taking part in the games in a gymnasium could not therefore hide where his loyalty lay. Finally, in 168 BCE, Antiochus invaded Jerusalem and desecrated the Holy of Holies in the Temple. This was the one place on earth about which Yahweh said "My name" (the expression of his Person) "shall be there" (I Kings).

A number of Jews, under their leader Jason the high priest, took the easy way of conformity with the new universal trends. But with Antiochus' impious act a strong general reaction set in. Thus, when, later in the same year, Antiochus again entered Jerusalem, this time plundering and burning and setting up his citadel, the Acra, on the hill overlooking the Temple courts, he went too far; for his final act of spite, on December 25, 167 BCE, was to rededicate the Temple in Jerusalem to the Olympian god Zeus.

Resistance to Antiochus

The home of Mattathias, a priest at Modein, 17 miles (27 kilometres) northwest of Jerusalem, quickly became the centre of resistance. With him were his five sons, John Gaddi, Simon Thassi, Judas Maccabeus, Eleazar Avaran, and Jonathan Apphus. Josephus, the Jewish historian, gives Mattathias' great-grandfather the surname Asamonaios. From this title comes the name Hasmonean that was applied to the dynasty that descended from the Maccabees in the following century. Mattathias sparked the resistance movement by striking a Jew who was preparing to offer sacrifice to the new gods and by killing the king's officer who was standing by. Then he and his family took to the hills. Many joined them there, especially the Hasideans, a pious and strict group deeply concerned for the Law of Moses. These at first refused to fight on the sabbath day and at once lost a thousand lives. Mattathias then insisted that all groups of resisters should fight if required on the holy sabbath. The guerrilla war that followed was as much a civil war as a war of national resistance. Mattathias treated all degrees of collaborators with the same bitterness as he did the Syrian enemy.

After the death of Mattathias (c. 166 BCE), Judas Maccabeus, the third son, became the leader of the resistance movement. In his first battle he seized the sword of Apollonius, governor of Samaria, the general leading the opposing army. But he was also a man of faith in the God of his fathers. He saw himself as a charismatic, divinely appointed leader, like Gideon of old. He would pause in his guerrilla tactics to assemble his men to "watch and pray" and to read the Torah (the divinely revealed Law of Moses) together. Judas saw his task as that of the successor of Moses and Joshua. "Re-

member how our fathers were saved at the Red Sea," he told his men, "When Pharaoh with his forces pursued them" (I Maccabees 4:9). Then they would blow their trumpets, as in the days of Joshua, and engage the enemy with a vigour that was not their own. Moreover, Judas could be as cruel as Joshua was. After the manner of his time and also of his enemies he was ready to exterminate all the males of a conquered city. Some of his activities are in accord with what today would be called the "Rules for holy war" as found scattered in sections of Deuteronomy and as developed in great detail in one of the scrolls from the Dead Sea, written within the century following Judas, and now entitled *The War of the Sons of Light Against the Sons of Darkness*.

In December 164 BCE, three years after Antiochus had defiled it, Judas recaptured Jerusalem, all except the Acra. Judas then had "blameless priests" cleanse the Holy Place and erect a new altar of unhewn stones. They then reconsecrated the sanctuary. The Hebrew word for this act, *Hanukkah* ("dedication"), is the name used till today for the Jewish eight-day Festival of Lights that commemorates the event. Beginning on Kislev 25 in the Jewish religious year, it occurs near or at the same time as the Christian celebration of Christmas.

Judas next continued the war elsewhere—in Galilee and even in Transjordan. His name was greatly honoured "in all Israel and among the Gentiles" (I Maccabees 5:63). The Syrians, in the war against him, fastened wooden towers on elephants' backs, and the beast then charged into battle with a thousand armoured warriors surrounding it. Eleazar, Judas' second youngest brother, lost his life in 163 BCE when he stabbed an elephant from underneath. In dying, the beast fell on top of him and crushed him.

When Antiochus Epiphanes died in 164 or 163 BCE, others administered the kingdom because his son, Antiochus Eupator, was still a minor. Lysias, the Syrian general, was now the real power. A peace of a sort was agreed between Judas and the Syrian general, who was having trouble elsewhere; and the Jews secured liberty of conscience and worship. The war, however, soon resumed. Judas sent a delegation to Rome at one point in the war to seek for help. This marked the first step toward the eventual take-over by Rome. Judas was killed in battle after more than five years of leadership.

Jonathan, his brother, succeeded him as general. Jonathan more than sustained the dignity of Judas. King Alexander Balas (also known as Alexander Epiphanes), now in control, made peace with Jonathan, calling him his "friend." In 153 or 152 BCE he elected Jonathan as high priest in Jerusalem. Thus was born the high priestly Hasmonean line. The strict upholders of the Law, however, were alienated, because the Law held that no man should be high priest who was not of priestly descent from Aaron. From now on this group formed a strong opposition party, later to be known as the most conservative section of the Pharisees (the religious group whose interpretations and applications of the law, written and oral, became accepted tradition in later Judaism).

The war continued. The Acra was still in enemy hands, and Jonathan sought to wall it off from the city. He died by treachery and was succeeded by his brother Simon, a man of character and prudence as well as a born leader who had quietly and loyally served under his other brothers. On his own initiative Simon brought peace and security to Jerusalem. He was the second Hasmonean high priest. In about 134 BCE he was assassinated.

Thus it was that none of the five brothers died a natural death. The succession was maintained by Simon's son John, known later as Hyrcanus I. He remained as high priest in Jerusalem until his death in 104 BCE. His was a long and disturbed reign; but he consolidated and extended Jewish control, bringing Samaria into subjection, and even forcing the Idumaeans (the descendants of the ancient Edomites who lived southeast of the Dead Sea) into the fold of Judaism. That is how the Idumaeen King Herod of Jesus' day was a Jew by religion.

John Hyrcanus' reign marked a turning point in the history of the Maccabees. The movement that had begun with intense conviction and deep patriotic zeal had so

Hyrcanus I

completely succeeded that all memory of its first wild enthusiasm had gone. John did not inherit the Pharisaic tendencies of his grandfather Mattathias. He had become a Sadducee in spirit. The Sadducees were an upper class conservative sect that accepted only the Written Law as divinely revealed and authoritative. In outlook he was worldly, agnostic, and urbane. The Revolution had become the Establishment.

**BIBLIOGRAPHY.** *The First Book of Maccabees*, found in any edition of the Bible that includes the Apocrypha, especially the *Oxford Annotated Apocrypha*, R.S.V. (1965), an anonymously written, sober account of events between 175 and 135 BC; *The Second Book of Maccabees*, also in the Apocrypha, popular, hero-worshipping, with miraculous tales—covering only 175–161 BC; *The Apocrypha and Pseudepigrapha of the Old Testament*, 2 vol., ed. by R.H. CHARLES (1913), a critical study of the text of the two above books; J.C. DANCY, *A Commentary on I Maccabees* (1954), a popular yet detailed guide; J.H.P. ## McCormick, Cyrus Hall

United States industrialist and inventor, Cyrus Hall McCormick is generally regarded as the man who, in the early 19th century, gave the world its most formidable weapon in its battle against hunger: the mechanical reaper. In tribute to his achievement, the emperor Napoleon III himself affixed the cross of the Legion of Honour to McCormick's chest, and the French Academy of Sciences honoured him as "having done more for the cause of agriculture than any other living man." If the Legion of Honour was a tribute to McCormick the inventor, his competitors' hatred may well be considered a tribute to McCormick the tough, aggressive, innovative manufacturer and businessman who founded what was later to become the International Harvester Company.

McCormick's inventions

Cyrus Hall McCormick was born February 15, 1809, on Walnut Grove farm in Rockbridge County, Virginia, eldest son of Robert McCormick, a farmer, blacksmith, and inventor. McCormick's education, in local schools, was limited. Reserved, determined, and serious-minded, he spent all of his time in his father's workshop.

The elder McCormick had invented several practical farm implements but, like other inventors in the United States and England, had failed in his attempt to build a successful reaping machine. In 1831 Cyrus, aged 22, tried his hand at building a reaper. Resembling a two-wheeled, horse-drawn chariot, the machine consisted of a vibrating cutting blade, a reel to bring the grain within its reach, and a platform to receive the falling grain. The reaper embodied the principles essential to all subsequent grain-cutting machines.

For farmers in the early 19th century, harvesting required a large number of labourers, and, if they could be found, the cost of hiring them was high. When McCormick's reaper was tested on a neighbour's farm in 1831, it offered the hope that the yield of the farmer's fields would soon not be limited to the amount of labour available. The machine had defects, not the least of which was a clatter so loud that slaves were required to walk alongside to calm the frightened horses.

McCormick took out a patent in 1834, but his chief interest at that time was the family's iron foundry. When the foundry failed in the wake of the Bank Panic of 1837, leaving the family deeply in debt, McCormick turned to his still unexploited reaper and improved it. He sold two reapers in 1841, seven in 1842, 29 in 1843, and 50 the following year.

An 1844 visit to the prairie states in the Middle West convinced McCormick that the future of his reaper and of the world's wheat production lay in this vast fertile land rather than in the rocky, hilly East. In 1847, with further patented improvements, he opened a factory in the then small, swampy, lakeside town of Chicago in partnership with the mayor, William Ogden, who capitalized the venture with \$50,000 of his own money. The first year, 800 machines were sold. More were sold the next year, and McCormick was able to buy out Ogden.

McCormick's main rival was Obed Hussey, whose machine proved to be inferior as a reaper but superior as a mower. When McCormick's basic patent expired in 1848, competing manufacturers—Hussey among them—tried to block renewal. The ensuing legal battle was but one of many in McCormick's career. He was involved in endless litigation not only with rival manufacturers and infringers but also with the New York Central Railroad, which he sued for \$20,000 damages following an altercation over an \$8.75 overcharge on his wife's baggage. He fought this particular case up to the Supreme Court three times—and won, even though it took 20 years. He did not win his 1848 patent renewal battle, however. Except for improvements on the reaper patented after 1831, the basic machine passed into the public domain. McCormick then set out to beat his manufacturing competitors another way: by outselling them.

Pockets stuffed with order blanks, McCormick rode over the plains selling his reaper to farmers and would-be farmers. To increase sales, he used innovations such as mass production, advertising, public demonstration, warranty of product, and extension of credit to his customers. Soon the factory expanded, and the company had a travelling sales force. By 1850 the McCormick reaper was known in every part of the United States, and at the Great Exhibition of 1851 in London it was introduced to European farmers. Although mocked by *The Times* of London as "a cross between an Astley Chariot, a wheelbarrow, and a flying machine," the reaper took the Grand Prize. In 1855 it won the Grand Medal of Honour at the Paris International Exposition. There followed a long series of prizes, honours, and awards that made the McCormick reaper known to farmers throughout the world.

By 1856 McCormick was selling more than 4,000 machines a year. In the 1858 account of his marriage at age 49 to Nancy (Nettie) Fowler, the *Chicago Daily Press* referred to him as the "massive Thor of industry." Business did not absorb all of his energy, however. He became active in the Democratic Party and in the Presbyterian Church, establishing McCormick Theological Seminary in Chicago.

In 1871 the Chicago fire gutted his factory. Then—over 60 years old, his fortune long since made—he rebuilt.

Career as a businessman

When he died on May 13, 1884, his business was still growing. In 1902 the McCormick Harvesting Company joined with other companies to form International Harvester Company, with McCormick's son, Cyrus, Jr., as its first president.

### McGillivray, Alexander

In the ten years following the American Revolution, Alexander McGillivray (born c. 1759) was the principal chief of the Creek Indians. Though not a warrior, he held the loose association of Creek towns together, strengthened their posture with their Indian neighbours, and skillfully directed relations with the whites who encircled the Creek homeland, which comprised western Georgia and most of Alabama. He dealt successfully with the states of Georgia and South Carolina, the United States government, encroaching American settlers, British and American traders, and the revitalized Spanish regime in East and West Florida and Louisiana. Thanks largely to his exertions, the Creeks retained their tribal identity and the major part of their homeland for another generation.

McGillivray's  
parentage

In a letter to the Spanish commandant at Pensacola in 1783, McGillivray identified himself as "a Native of and a chief of the Creek Nation." The penmanship and the name made that statement seem improbable, but it was correct. McGillivray was, in fact, of mixed Indian and European blood. His father was Lachlan McGillivray, a Scottish trader. His mother was Sehoy Marchand, a half-breed French-Creek woman. By blood McGillivray was thus only one-quarter Indian. But the Creeks, with whom descent was matrilineal, had no difficulty in claiming Alexander as Creek. As was the custom, his early upbringing was primarily by his mother and, though bilingual, was in the ways of her people.

At 14 Alexander was sent to Charleston, South Carolina, for tutoring and served a short apprenticeship in a countinghouse in Savannah, Georgia. He might have stayed on, but the Revolution intervened. His father was proscribed as a loyalist, and his properties were confiscated. Father and son decided to go home, Lachlan to Scotland and Alexander to the Creek nation, where he was given status as a chief and where the British commissioned him colonel and Indian agent. During the War of Independence the Creeks were opportunists. Some of them fought alongside the patriots. McGillivray contributed toward keeping a larger number on the loyalist side.

By 1782 British military defeats made it clear that the Creeks would lose their British connection. Deeply distrusting American land speculators and encroaching settlers, McGillivray put out feelers for Spanish support and suggested a council at Pensacola, West Florida. There, on June 1, 1784, he and governors Estevan Miró and Arturo O'Neill signed a treaty headed "Articles of Agreement, Trade, and Peace." Spain would extend a protectorate over the Creeks within Spanish territorial limits and would supply an adequate trade. McGillivray's more remarkable success was in persuading the Spanish that the trade should be in English goods and that a contract for the purpose should go to a British merchant, William Panton.

Over the next several years, McGillivray staunchly resisted overtures from Georgia and the United States to concede lands and trading privileges. On occasion he sent raiding parties to clear the Indian hunting grounds. Then, in 1788, Miró gave notice that Spanish support would be reduced. McGillivray indicated that in the circumstances he could not refuse discussions with commissioners sent by Georgia and the American Congress.

In 1789 President Washington sent distinguished commissioners to negotiate with the Creeks. They proposed a boundary well into the Creek hunting lands and recognition of American sovereignty over the entire Creek

area. Bolstered by reactivated Spanish support, McGillivray objected. Obtaining no concession, he and his companions decamped. Washington then sent another commissioner to invite McGillivray and a delegation of chiefs to come to New York City to make a treaty "as strong as the hills and as lasting as the rivers."

With the commissioner, the delegation members travelled overland to New York City, where they were welcomed by the newly formed political Society of St. Tammany. Secretary of War Henry Knox and McGillivray worked out the terms of a treaty specifying American sovereignty over Creek lands within the limits of United States territory and setting a line near the Altamaha River separating Georgian and Creek lands. McGillivray accepted an American Army commission as a brigadier general and a salary of \$100 a month, but he did not promise American trade except in the event of war between Britain and Spain, at the time a possibility.

In 1792 McGillivray went to New Orleans, Louisiana, to establish a better understanding with the Spanish. The new treaty specified that the Creeks would order Americans off their lands and that Spain would guarantee territorial integrity within Spanish limits and provide sufficient arms and ammunition. Although the Spanish urged that the Americans be driven back, McGillivray wisely pursued a much less aggressive course.

En route home, McGillivray contracted a violent fever that immobilized him for months. He had never been robust and was sickly, plagued by severe headaches and afflicted by gout, rheumatism, and the symptoms of venereal disease. On February 17, 1793, in his 34th year, he died at Pensacola. Panton, in whose garden he was buried, attributed his death to "gout of the stomach" and "pneumonia." Neither Panton nor the Spaniards found a suitable replacement for him, nor did his tribesmen the Creeks, though the policies he had put into effect carried on and served the Creek nation well.

**BIBLIOGRAPHY.** J.W. CAUGHEY, *McGillivray of the Creeks* (1938), reproduces much McGillivray correspondence; A.P. WHITAKER, "Alexander McGillivray," *North Carolina Historical Review*, 5:181-203, 289-309 (1928), is a masterly summation of his post-Revolution work; R.S. COTTERILL, *The Southern Indians* (1954), devotes a chapter (pp. 57-99) to McGillivray.

(J.W.C.)

### Machiavelli, Niccolò

The Italian statesman and writer Niccolò Machiavelli, a patriot and thinker of genius whose acute understanding of contemporary politics and profound insight into human nature produced masterpieces that have often been misjudged as immoral or cynical, was born in Florence on May 3, 1469. His family, from the 13th century onward, had been counted among the wealthy and prominent houses of the city, holding on occasion the most important offices. His father, a doctor of laws, was nevertheless among the poorest members of the family; he lived frugally, administering his little landed property near the city and supplementing his meagre income from it with small earnings from the restricted and almost clandestine exercise of his profession, since he was debarred from any public office as an insolvent debtor of the commune of Florence. Niccolò was to write later that he had "learnt to do without before he learnt to enjoy"; and this poverty may have been the reason why he did not have the education suited to his ability. In the years when young Florentines crowded to the lectures of Politian, then Italy's leading scholar of Greek and Latin, Machiavelli never embarked on the study of Greek. His father's memoirs show Niccolò working at Latin under obscure teachers: he learned more by himself in the books that were the only luxury of his home than he did at school. This kind of education saved him from the faults and excesses of humanist erudition and preserved the originality of his thought and the unequalled force of his style, which was elevated and popular at the same time.

**Under the republic.** In 1498, after the changes in the Florentine government following the execution of Savonarola—the ascetic monk who tried to impose extreme

political and religious reforms on the republic—and the triumph of the opposing faction, Niccolò Machiavelli was made head of the second chancery (*cancelleria*) at the early age of 29. He was then completely unknown; the tradition of his having an apprenticeship in the lower grades of the chancery from 1494 onward is not confirmed by documentary evidence, and his own statements tend to disprove it. The office to which he was appointed, though not comparable in power with that of first chancellor, was an important one. Originally it dealt only with internal affairs of the republic, but it was later merged with the secretariat of the Ten (*i Dieci*), the executive council. Machiavelli was, moreover, secretary to the magistracy, which, in the name of the Signoria, the governing council, and under its authority, directed foreign affairs and defense. The chancellors were often entrusted with diplomatic missions to Italian and foreign courts when it was not desirable to send ambassadors. Machiavelli's first important mission was to the French court in 1500. Five months spent beyond the Alps enriched his experience, introducing to his eager mind the people and customs of a strong nation united under the rule of a single prince.

On his return to Florence, Machiavelli found much to do, as the republic was on the verge of being ruined by the ambitions of Cesare Borgia, who was then in the midst of attempting to create a principality for himself in central Italy. Besides dictating letters in the chancery, Machiavelli undertook missions whenever the need arose; he was always ready to ride off and to face danger and hardship, being fonder of action than of words. His short work *Del modo di trattare i sudditi della Val di Chiana ribellati* (1503; "On the Way to Deal With the Rebel Subjects of the Valdichiana") belongs to this period. In it, the fundamental principle of a new doctrine is enunciated for the first time: "The world has always been inhabited by human beings who have always had the same passions." He was sent twice to Cesare Borgia; and he was a witness to the bloody vengeance taken by Cesare on his mutinous captains at the town of Sinigaglia (December 31, 1502), of which he wrote a famous account, *Descrizione del modo tenuto dal Duca Valentino nello ammazzare Vitellozzo . . .* ("On the Manner Adopted by the Duke Valentino to Kill Vitellozzo . . ."). That strong, sinister prince caught the imagination of the Florentine statesman with his natural bent for abstraction and theory. Implacable, resolute, ferocious, and cunning, Cesare Borgia had conquered a dominion for himself in a few months; and Machiavelli adapted Cesare's qualities and methods to his own ideal of a "new prince" who would provide a desperate remedy for the desperate ills of Italy.

It is clear that this was a case of idealization and that his admiration for the Prince did not go hand in hand with admiration for the man. When Pope Alexander VI, the father of Cesare Borgia, died in 1503 and his successor, Pius III, also died shortly afterward, Machiavelli was sent to Rome for the duration of the conclave that elected Julius II, an implacable enemy of the Borgias. There, with ever-increasing scorn, Machiavelli witnessed the inglorious decline of his hero and finally celebrated Cesare's imprisonment "which he deserved as a rebel against Christ."

In Florence, meanwhile, Piero Soderini had been elected gonfalonier (chief magistrate) for life, and Machiavelli was immediately able to win his favour and become his right-hand man. This remarkable influence over the head of state encouraged him to realize his military ideas. For centuries the states of Italy had used mercenary troops in their wars, and Machiavelli had seen in practice their lack of discipline, their faithlessness, and their unbearable arrogance. Inspired both by the military enterprises of ancient Rome and by his own observations in France (where he went on a second mission early in 1504) and in Romagna (where Cesare Borgia had replaced mercenaries with levies from his own territory), Machiavelli ardently pursued the idea of giving the Florentine state a militia of its own, recruited from the peoples under its control. Age-old prejudices had to be overcome, as well as the reluctance of suspicious townsmen, to arm men from the country districts around. Having set to work immediately after his return from the Roman legation, he succeeded in persuading the gonfalonier to risk an experiment and then to have a law passed in order to establish a militia (1505). His first "Decennale"—a short poem in terza rima (three lines in interlocking rhyme), somewhat prosaic, like the rest of his verses—ends with a call to arms. In 1506, as the importance of the new militia increased, the council of the Nine (*i Nove*) was created to control it, and Machiavelli was made secretary of this body also. To get the law on the militia passed, he had also written a *Discorso dell'ordinare lo stato di Firenze alle armi* ("Discourse on Arming the State of Florence"), a lucid and closely argued work. The territory of the republic was divided into districts, and Machiavelli himself went out to see to the levies and to carry out inspections, alternating these military tasks with those of the chancery and with a further mission (1506) to Julius II, whose armies, moving up to free the states of the Church from their various usurpers, entered Bologna in triumph.

In December 1507 the Holy Roman emperor, Maximilian I, was preparing an invasion of Italy from Germany. Florence's gonfalonier, who did not trust his own ambassador at the imperial court, accordingly sent Machiavelli on another journey beyond the Alps. On the journey Machiavelli passed through Switzerland, and three days spent in that country were enough for him to produce some brief but acute observations on it. He did the same, at greater length, for Germany, composing on the day after his return to Florence (June 17, 1508) a *Rapporto delle cose della Magna* ("Report on the State of Germany"). In this work, compiled in the course of his official duties, and likewise in the literary version made four years later under the title *Ritratto delle cose della Magna* ("Portrait . . ."), he was able to pick out with great acumen the reasons both for the strength of the German nation and for its political weaknesses. Yet all his official reports, though marvelously intuitive, are marred by a tendency to theorize; they are bold syntheses, not complete and accurate sources of information.

On his return from Germany, as the Florentines were showing new strength in an effort to recapture the city of Pisa, which had temporarily freed itself from Florentine rule, Machiavelli was able to try out the militia that he had created. He went to command his troops at the front and put all his usual enthusiasm into the task: when the Ten begged him to remain at headquarters, he answered that they must let him be with his soldiers, since behind the lines he would die of melancholy. Such was the patriotism and passion of a man who has been represented as skeptical, cautious, and cynical. Pisa capitulated on June

Promotion  
of a  
Florentine  
militia

8, 1509, and Machiavelli with his militia had no small share in this success for Florence.

After a mission to Mantua (Mantova) in connection with yet another invasion by Maximilian, Machiavelli had to go again to France, in July 1510, to persuade Florence's ally Louis XII to make peace with Pope Julius II or at least not to drag Florence into a war that would bring the republic to certain, swift, and needless ruin, emphasizing that a neutral Florence could be very useful to the French. The French, however, "who knew nothing about statecraft," were not influenced by what Machiavelli had to tell them. From this mission, which resulted in the *Ritratto di cose di Francia*, he returned in October 1510 convinced that there would be a major war between the French king and the pope and that the Florentines would be involved. All of his efforts now were to arm his country. As he carried out his military duties and those of the chancery, he was continually travelling about. At the end of the summer of 1511 he went once more to France to persuade Louis XII to remove the schismatic council that he was sponsoring in Pisa, since this had brought upon the Florentines the rage of Julius II. As soon as he was back from France, Machiavelli himself went to Pisa to remove this council and did so without much ceremony. For the free republic, however, the last hour had already come: the army of the pope's Holy League was already on its way to punish Florence. The gonfalonier Soderini was deposed, and in 1512 the Medici returned as masters of the city.

**Under the Medici.** Machiavelli lost his position and was forbidden to enter the Palazzo della Signoria. Also, when a conspiracy against the Medici was found early in 1513, Machiavelli, already an object of suspicion to the new government, was accused of complicity. Thrown into prison, he maintained his innocence even under tortures that often persuaded the innocent to declare themselves guilty. His name, however, was on a list taken from the conspirators (perhaps merely a list of persons attached to the old regime); and finally, though he was released from prison, restrictions were put on his freedom of residence. In the meantime, Julius II had died, and Giovanni de' Medici had become pope under the name of Leo X. Machiavelli composed for the celebrations on that occasion a pious "Canto degli spiriti beati" ("Song of the Blessed Spirits"). He sought in vain to get into the good graces of the Medici through the intercession of Francesco Vettori, his old colleague in the German legation and now Florentine ambassador to a Florentine pope; but his brilliant letters to Vettori were powerless to stir that selfish and opportunistic friend.

Reduced to poverty, Machiavelli sought refuge in the little property near Florence that he had inherited from his father. In a letter to Vettori, which is one of the most remarkable in any language, he describes his life in the country with its violent contrasts, its mixture of coarse living conditions and dreams of greatness. There he employed his leisure in writing, between spring and autumn 1513, his two most famous works, *Il principe* (*The Prince*) and a large part of the *Discorsi sopra la prima deca di Tito Livio* ("Discourses on the First Decade of Tito Livy").

Machiavelli's affections always lay with the republic, and all of his theories were intended for its betterment; but the corruption of the times, the weakness of the states of Italy, and the threat of foreign conquest made him long for that "new prince" who might give reality to his great dream of the redemption of Italy. This "redeemer," to whom he sought in vain to give a face and a name, would have had to overcome superhuman difficulties; nor could there be much choice of means in attaining such ends. Machiavelli, in a book that is not a moral treatise, attempted to indicate to the prince those means that were compatible with the conditions of the time and with human nature. Even religion—for which he had a deep feeling though he was not outwardly pious—was subordinated by him, in matters of state, to the state's iron necessity and made into an *instrumentum regni*, or tool of power. Indeed, Machiavelli is regarded as the inventor of the "reason of state" (*ragione di stato*), though that

expression appears for the first time 20 years after his death. *Il principe*, while its underlying ideas are the same as those of the *Discorsi*, won a greater reputation, thanks to its concision, its vigorous imagery, and the bluntness of some of its aphorisms, which were taken too literally by contemporaries and by posterity. He remarked of certain cynical precepts that he would not have proffered them if mankind had not been wicked. This bleak pessimism is certainly not refuted by the annals of his own time. Yet his longing was for a society of good and pure men; he sought it in ancient times and, in his own day, admired less civilized nations as being less corrupt. Machiavelli's great hope was that *Il principe*, dedicated to Lorenzo de' Medici, ruler of Florence from 1513, would obtain from the Medici an office to support his family and satisfy his love of action; but the hope was in vain. Full of bitterness, he then dedicated the *Discorsi* (of which he had been giving public readings in the Oricellari Gardens) not to a prince but to two private citizens.

From this time also dates the marvelous comedy first entitled *Commedia di Callimaco e di Lucrezia*, later *La Mandragola* (1518; "The Mandrake"). What has already been said about Machiavelli's hidden but strong and deep morality could be repeated in connection with *La Mandragola*, in which the wickedness and corruption of men, particularly of the clergy, are the subject of laughter—but of a bitter and painful laughter that is never an end in itself. It reminds the reader of what was written about the author by his friend and critic Francesco Guicciardini: "He laughs at the failings of men because he cannot cure them."

Machiavelli's hopes were raised when, on the death of Duke Lorenzo, the cardinal Giulio de' Medici came to govern Florence. He was presented to the cardinal by Lorenzo Strozzi, to whom in gratitude he dedicated the dialogue *Dell'arte della guerra* (1520; "On the Art of War"). In this, as in the *Discorsi* and in *Il principe*, his study of classical authors was combined with his experience of modern affairs; i.e., his recent military adventures. The *Arte della guerra*, properly considered, is merely complementary to Machiavelli's two political treatises, but it is more closely linked with *Il principe* and its great dream of Italian unity than with the *Discorsi*. Like the *Discorsi*, it has the defect of taking the ancient Romans in everything as its model; and this fault appears greater in the *Arte* because too little attention is paid in it to technical advances, such as the use of artillery—which in those very years was beginning to make its weight felt decisively in battle. Even so, Machiavelli can be said to have laid the foundations of modern tactics.

The first employment given him by the cardinal was to go to Lucca on a matter of small importance. Presently, however, the cardinal agreed to have Machiavelli elected official historiographer of the republic, a post to which he was appointed by the Studio or University of Florence in November 1520 with a salary of 57 gold florins a year, later increased to 100. The university's terms allowed for Machiavelli's also being employed in other ways. In the meantime, he was to compose for the Medici pope Leo X a *Discorso* on the organization of the government of Florence after the death of Duke Lorenzo; in this he boldly advised the Pope to restore the city's ancient liberties. Shortly after, in May 1521, he was sent to the Franciscan chapter at Carpi. The commission was an insignificant one; but on this occasion he met Francesco Guicciardini, governor of nearby Modena, and the friendship, resulting in a lively and perceptive correspondence, was to have a great importance for Italian literature.

After Pope Leo X's death (December 1521), the cardinal Giulio de' Medici, who remained sole master of Florence, was more than ever inclined to reform its government. He sought the advice of Machiavelli, who simply refurbished the *Discorso* composed for Leo X. After the death of Pope Adrian VI in September 1523, Giulio de' Medici was himself elected pope, taking the name of Clement VII. Machiavelli now worked with more enthusiasm on the *Istorie fiorentine*, his official history of Flor-

ence; in June 1525 he was able to present the pope with eight books, and he received in return 120 florins and encouragement to continue the work. The *Istorie fiorentine*, like his earlier writings, bears the impress of a powerful and original mind. In this work, written by fits and starts and unwillingly and wearily dragged on into his later years, Machiavelli enters on a new road, leaving behind him the traditions and methods of humanist historiography. His love of truth often in conflict with the necessity to avoid offending his powerful patrons, he writes history more as a politician than as a historian set on discovering the truth, often accepting sources uncritically and accommodating facts to his thesis. It is not narrative exactitude that is to be sought in the *Istorie* but the power of synthesis, the brilliant coordination and organization of facts. Early in the same year he had written the *Clizia*, a free imitation of the *Casina* of Plautus, which he produced within a few days for a festival. In this comedy he probably intended to satirize himself and his affair with Barbera, a singer with whom he was infatuated.

In April 1526 Machiavelli was elected secretary of the Cinque Provveditori Alle Mura, a five-man body lately constituted to superintend the fortifications. Next, the pope having formed the League of Cognac against the Holy Roman emperor Charles V, Machiavelli went with the army to join Francesco Guicciardini, the pope's lieutenant, with whom he remained almost continuously until the sack of Rome by the emperor's forces brought the war to an end in May 1527. Florence having regained its freedom by casting off the Medici, Machiavelli on his return hoped to be restored to his old post in the chancery; but the little favours that the Medici had so meagrely doled out to him caused the supporters of the free republic to forget the love that he had always had for his native city and for freedom. It was the last of his disappointments and the greatest. Machiavelli fell ill and died, with the comforts of religion, on June 21, 1527, at the age of 58.

**Character and thought.** Machiavelli was of medium height, thin, with a bony face, a high forehead, black hair, piercing eyes, and thin lips compressed in an enigmatic smile. He was an upright man, a good citizen, and a good father. He was not by any means a faithful husband but lived in affectionate harmony with his wife Marietta Corsini (whom he had married in the latter part of 1501) and had five children by her. As he said in a letter, he loved his native city "more than his own soul"; and even in his devotion to the state he must often have written "state" while thinking "native land."

Out of a desire to shock his contemporaries, Machiavelli liked to appear more wicked than he was. This, together with certain blunt maxims in his works, gave him a reputation for immorality. In fact, those maxims were purely theoretical abstractions of an art itself not always based on moral scruples, least of all in Machiavelli's time; but their bold, lapidary style made it easy to detach them from their context and to ignore the purpose that had inspired and the needs that had conditioned them. The maxims thus became a target for attacks by the Catholic Counter-Reformation; and the word "Machiavellianism" was coined as a term of opprobrium by the French, out of hatred for all things Italian, during the rule of the Italian-born Catherine de Médicis. On the other hand, Machiavelli was an innovator and, as such, was inclined to give extreme form to his utterances. He himself, in the *Discorsi*, forecast the dangers that awaited him and all of those who have sought "new methods and new orders . . . undiscovered seas and lands." He "was a scapegoat because he was a great man and because he was unfortunate."

In judging Machiavelli one must likewise take account of his anguished despair of ever seeing virtue triumphant and of his tragic sense of evil. Again, on the basis of sentences taken out of context and of outward appearances, he was judged a cold and cynical man, a sneerer at religion and virtue; but, in fact, there is hardly a page of his writings and certainly no action of his life that does not show him to be passionate, generous, ardent, and

basically religious. Nothing conveys a better understanding of Machiavelli than the self-portrait that he drew in two lines of verse:

*Io rido, e il rider mio non passa dentro:  
Io ardo, e l'arsion mia non par di fore*

("I laugh, and my laughter is not within me; I burn, and the burning is not seen outside.")

As a thinker and writer, Machiavelli displayed a very speculative mind. Unlike Guicciardini, who was empirical and pragmatic, he was irresistibly drawn to reduce human actions to scientific formulas and rules, to go beyond particular facts and to seize on universal motives. As one of the founders of the philosophy of history, he well knew (as he wrote in the preface to the *Discorsi*) that he was opening "a road as yet untrodden by man." As he had been the first to appreciate in histories "that flavour which they possess in themselves" beyond any merely literary or entertaining ends, so he was the first to propound the thesis of historical cycles and—starting from the principle that human nature does not change—the first to build a political science based on the study of man. Machiavelli's fallacy of always referring to the example of the Romans, without taking account of changed conditions, was criticized—even in his own day—by Guicciardini; but the latter was by nature inclined to concern himself rather with particular errors and inaccuracies than with his friend's universal theories.

Machiavelli was a great writer because he was a great thinker. He was also a poet; his poetry, however, is to be found not so much in his verse as in his prose, which has no equal in Italian literature. It is also noteworthy that his great gifts showed themselves in nearly all the genres that he attempted: in historical writings, in political treatises, in the short story and, particularly, in comedy.

**BIBLIOGRAPHY.** R. RIDOLFI, *Vita di Niccolò Machiavelli*, 4th enlarged ed., 2 vol. (1969; Eng. trans., 1964), is the best informed and most up-to-date biography. P. VILLARI, *Niccolò Machiavelli e i suoi tempi*, 3 vol. (1877–82; 3rd ed., 1912–14; Eng. trans., *Niccolò Machiavelli and His Times*, 2 vol., 1878), is still perceptive and fundamental, especially for the numerous documents in the appendix. O. TOMMASINI, *La vita e gli scritti di Niccolò Machiavelli*, 2 vol. (1883–1911), is a confused work, very weak in its judgments but an inexhaustible source of bibliographical and archival materials. G. SASSO, *Niccolò Machiavelli, storia del suo pensiero politico* (1958), is the most modern and complete study on this aspect of his thought. A. GERBER, *Niccolò Machiavelli: Die Handschriften, Ausgaben und Uebersetzungen seiner Werke*, 3 parts with a sheaf of facsimiles (1912–13), is important for its description of manuscripts and old editions of Machiavelli's works. A. NORSA, *Il principio della forza nel pensiero politico di Niccolò Machiavelli* (1936), is valuable chiefly for its appendix, which contains a bibliography citing 2,143 publications on Machiavelli. The basic translation of the *Discourses* is by LESLIE J. WALKER, 2 vol. (1950).

## Machines and Machine Components

The word machine has been given a wide variety of definitions, but for the purpose of this article it is a device, having a unique purpose, that augments or replaces human or animal effort for the accomplishment of physical tasks. Tools, which may be regarded as the simplest class of machines, are described in separate articles, chiefly HAND TOOLS and CARPENTRY.

### GENERAL CONSIDERATIONS

The operation of a machine may involve the transformation of chemical, thermal, electrical, or nuclear energy into mechanical energy, or vice versa, or its function may simply be to modify and transmit forces and motions. All machines have an input, an output, and a transforming or modifying and transmitting device.

Machines that receive their input energy from a natural source, such as air currents, moving water, coal, petroleum, or uranium, and transform it into mechanical energy are known as prime movers. Windmills, waterwheels, turbines, steam engines, and internal-combustion engines are prime movers. In these machines the inputs vary; the outputs are usually rotating shafts capable of

Philosophy  
of history

republic

Prime  
movers

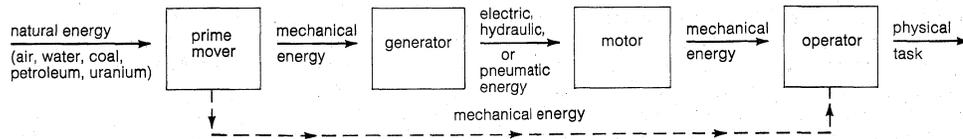

Figure 1: Flow of energy in machines.

being used as inputs to other machines, such as electric generators, hydraulic pumps, or air compressors. All three of the latter devices may be classified as generators; their outputs of electrical, hydraulic, and pneumatic energy can be used as inputs to electric, hydraulic, or air motors. These motors can be used to drive machines with a variety of outputs, such as materials processing, packaging, or conveying machinery, or such appliances as sewing machines and washing machines. All machines of the latter type and all others that are neither prime movers, generators, nor motors may be classified as operators. This category also includes manually operated instruments of all kinds, such as calculating machines and typewriters.

If the operator is a washing machine driven by an electric motor, the flow of energy from the prime mover at the power plant through the generator and motor to the operator is as shown in Figure 1. The operator can also be driven directly by a small, direct-connected prime mover, such as a gasoline engine, as shown by the dotted line in Figure 1; for most power-driven operators, however, the flow of energy from the prime mover follows the solid lines.

In some cases, machines in all categories are combined in one unit. In a diesel-electric locomotive, for example, the diesel engine is the prime mover, which drives the electric generator, which, in turn, supplies electric current to the motors that drive the wheels.

As part of an introduction to machine components, some examples supplied by an automobile are of value.

Machine components in an automobile

In an automobile, the basic problem is harnessing the explosive effect of gasoline to provide power to rotate the rear wheels. The explosion of the gasoline in the cylinders pushes the pistons down, and the transmission and modification of this translatory (linear) motion to rotary motion of the crankshaft is effected by the connecting rods that join each piston to the cranks (Figure 21) that are part of the crankshaft. The piston, cylinder, crank, and connecting rod combination is known as a slider-crank mechanism; it is a commonly used method of converting translation to rotation (as in an engine) or rotation to translation (as in a pump).

To admit the gasoline-air mixture to the cylinders and exhaust the burned gases, valves are used; these are opened and closed by the wedging action of cams (projections) on a rotating camshaft that is driven from the crankshaft by gears or a chain.

In a four-stroke-cycle engine with eight cylinders, the crankshaft receives an impulse at some point along its length every quarter revolution. To smooth out the effect of these intermittent impulses on the speed of the crankshaft, a flywheel is used. This is a heavy wheel, attached to the crankshaft, that by its inertia opposes and moderates any speed fluctuations.

Since the torque (turning force) that it delivers depends on its speed, an internal-combustion engine cannot be started under load. To enable an automobile engine to be started in an unloaded state and then connected to the wheels without stalling, a clutch and a transmission are necessary. The former makes and breaks the connection between the crankshaft and the transmission, while the latter changes, in finite steps, the ratio between the input and output speeds and torques of the transmission. In low gear, the output speed is low and the output torque higher than the engine torque, so that the car can be started moving; in high gear, the car is moving at a substantial speed and the torques and speeds are equal.

The axles to which the wheels are attached are contained in the rear axle housing, which is clamped to the rear springs, and are driven from the transmission by the drive shaft. As the car moves and the springs flex in response to bumps in the road, the housing moves relative

to the transmission; to permit this movement without interfering with the transmission of torque, a universal joint is attached to each end of the drive shaft.

The drive shaft is perpendicular to the rear axles. The right-angled connection is usually made with bevel gears having a ratio such that the axles rotate at from one-third to one-fourth the speed of the drive shaft. The rear axle housing also holds the differential gears that permit both rear wheels to be driven from the same source and to rotate at different speeds when turning a corner.

Like all moving mechanical devices, automobiles cannot escape from the effects of friction. In the engine, transmission, rear axle housing, and all bearings, friction is undesirable, since it increases the power required from the engine; lubrication reduces but does not eliminate this friction. On the other hand, friction between the tires and the road and in the brake shoes makes traction and braking possible. The belts that drive the fan, generator, and other accessories are friction-dependent devices. Friction is also useful in the operation of the clutch. Some of the devices cited above, and others that are described below, are found in machines of all categories, assembled in a multitude of ways to perform all kinds of physical tasks. Because of this diversity of function and the lack of common characteristics, this article will not be concerned with specific operators. Neither will it deal with the overall performance of prime movers, nor with the operation of hydraulic, pneumatic, or electrical devices. It will consider only the operation and structure of the basic mechanical devices that are the constituent parts of machines. The function of most of these devices is to transmit and modify force and motion. Other devices, such as springs, flywheels, shafts, and fasteners, perform supplementary functions.

For the purposes of this article a machine may be further defined as a device consisting of two or more resistant, relatively constrained parts that may serve to transmit and modify force and motion in order to do work. The requirement that the parts of a machine be resistant implies that they be capable of carrying imposed loads without failure or loss of function. Although most machine parts are solid metallic bodies of suitable proportions, nonmetallic materials, springs, fluid pressure organs, and tension organs such as belts are also employed.

The most distinctive characteristic of a machine is that the parts are interconnected and guided in such a way that their motions relative to one another are constrained. Relative to the block, for example, the piston of a reciprocating engine is constrained by the cylinder to move on a straight path; points on the crankshaft are constrained by the main bearings to move on circular paths; no other forms of relative motion are possible.

On some machines the parts are only partially constrained. If the parts are interconnected by springs or friction members, the paths of the parts relative to one another may be fixed, but the motions of the parts may be affected by the stiffness of the springs, friction, and the masses of the parts.

If all the parts of a machine are comparatively rigid members whose deflections under load are negligible, then the constraint may be considered complete and the relative motions of the parts can be studied without considering the forces that produce them. For a specified rotational speed of the crankshaft of a reciprocating engine, for example, the corresponding speeds of points on the connecting rod and the piston can be calculated. The determination of the displacements, velocities, and accelerations of the parts of a machine for a prescribed input motion is the subject matter of kinematics of machines. Such calculations can be made without considering the forces involved, because the motions are constrained.

According to the definition, both forces and motions are

Constrained motion

Mechanism  
of a  
machine

transmitted and modified in a machine. The way in which the parts of a machine are interconnected and guided to produce a required output motion from a given input motion is known as the mechanism of the machine. The piston, connecting rod, and crankshaft in a reciprocating engine constitute a mechanism for changing the rectilinear motion of the piston into the rotary motion of the crankshaft.

Although both forces and motions are involved in the operation of machines, the primary function of a machine may be either the amplification of force or the modification of motion. A lever is essentially a force increaser, while a gearbox is most often used as a speed reducer. The motions and forces in a machine are inseparable, however, and are always in an inverse ratio. The output force on a lever is greater than the input force, but the output motion is less than the input motion. Similarly, the output speed of a gear reducer is less than the input speed, but the output torque is greater than the input torque. In the first case a gain in force is accompanied by a loss in motion, while in the second case a loss in motion is accompanied by a gain in torque.

Although the primary function of some machines can be identified, it would be difficult to classify all machines as either force or motion modifiers; some machines belong in both categories. All machines, however, must perform a motion-modifying function, since if the parts of a mechanical device do not move, it is a structure, not a machine. It is customary for machinery designers, when studying the motions of the parts, to speak of the mechanism of a machine.

While all machines have a mechanism, and consequently perform a motion-modifying function, some machines do not have a planned force-modifying purpose; the forces that exist are caused by friction and the inertia of the moving masses and do not appear as a useful output effort. This group would include measuring instruments and clocks.

The "work" referred to in the definition will be interpreted in its scientific sense. In the science of mechanics, work is something that forces do when they move in the direction in which they are acting, and it is equal to the product of the average force and the distance moved. If a man carries a weight along a horizontal path, he does no work according to this definition, since the force and the motion are at right angles to one another; that is, the force is vertical and the motion horizontal. If he carries the weight up a flight of stairs or a ladder, he does work, since he is moving in the same direction in which he is applying a force. Mathematically, if  $F$  equals force (in pounds or kilograms), and  $S$  equals distance (in feet or metres), work is then equal to the applied force  $F$  multiplied by the distance this force moves  $S$ ; or  $\text{WORK} = F \times S$ .

When a force causes a body to rotate about a fixed axis, or pivot, the work done is obtained by multiplying the torque ( $T$ ) by the angle of rotation.

Calculating  
efficiency

These concepts of work are fundamental in defining the mechanical work function of machines in terms of forces and motions, and they bring out the inseparability of forces and motions in machines. Because of friction, the work output from a machine is always less than the work input, and the efficiency, which is the ratio of the two, is always less than 100 percent.

The ratio of the output to input forces is the mechanical advantage (MA), and it defines the force-modifying function, while the ratio of the input to output motions is the velocity ratio (VR), and it defines the motion-modifying function. When the efficiency is high, these ratios are approximately equal; if the output force is ten times the input force, the input motion must be ten times the output motion; *i.e.*, what is gained in force is lost in motion. Friction affects the mechanical advantage but not the velocity ratio.

To calculate the efficiency from the ratio of output to input work, it would be necessary to know the work done by the output and input forces over a specified distance. Since this would entail the determination of average forces over the interval, it would be inconvenient. The

efficiency of a machine is more easily determined from instantaneous values of load and the rate at which the load is moving. For this purpose, power formulas are most useful.

Power is the rate at which work is done. If a man carries a ten-pound weight a vertical height of 12 feet (*i.e.*, up a ladder or stairs) in half a minute, his power expenditure is  $10 \times 12$  or 120 foot-pounds in half a minute; his rate of doing work is then 240 foot-pounds per minute.

The unit of power or rate of doing work in English-speaking countries is the horsepower (hp), which is equal to 33,000 foot-pounds per minute, so that 240 foot-pounds per minute equals  $\frac{240}{33,000} = 0.00727$  hp.

In dealing with simple force-amplifying machines such as the lever and the wheel and axle, it is convenient to call the input force the "effort" and the output force the "load." The mechanical advantage is then the ratio of the load to the effort, and the velocity ratio is the motion (displacement or velocity) of the effort divided by the corresponding motion of the load.

#### THE SIMPLE MACHINES

**History.** The origin of the five simple machines—the lever, wedge, wheel and axle, pulley, and screw—is largely conjectural. All early people used the lever in some form, for moving heavy stones or as digging sticks for land cultivation. The principle of the lever was used in the swape, or shadoof, a long lever pivoted near one end with a platform or water container hanging from the short arm and counterweights attached to the long arm. A man could lift several times his own weight by pulling down on the long arm. This device is said to have been used in Egypt and India for raising water and lifting soldiers over battlements as early as 1500 BC.

The  
Egyptian  
shadoof

Another interesting lever device, probably used in Egypt about 5000 BC, was a balance beam for weighing, consisting of a bar pivoted at its centre and weights that were hung on one end to balance the object being weighed on the other end.

The wedge was used in prehistoric times to split logs and rocks; for rocks, wooden wedges, caused to swell by wetting, were employed. The wheel and axle is believed to have been first employed around 3000 BC for bringing ore up mine shafts and for raising water buckets in wells. The pulley came later, probably in the 8th century BC.

Although the Pythagorean philosopher Archytas of Tarentum (5th century BC) is the alleged inventor of the screw, the exact date of its first appearance as a useful mechanical device is obscure. Though invention of the water screw is usually ascribed to Archimedes (3rd century BC), evidence exists of a similar device used for irrigation in Egypt at an earlier date.

The screw press, probably invented in Greece in the 1st or 2nd century BC, has been used since the days of the Roman Empire for pressing clothes. A drawing of a clothes press with right- and left-hand screws was found in the ruins of Pompeii, which was destroyed by the eruption of Vesuvius in AD 79. In the 1st century AD, wooden screws were used in wine and olive-oil presses, and cutters (taps) for cutting internal threads were in use.

In the notebooks of Leonardo da Vinci (1452–1519) there are sketches of a screw-operated printing press and a machine for cutting screws. James Watt (1736–1819) invented a screw press in which a letter, written in special ink, was squeezed against moist copy sheets to obtain duplicates.

The mathematical relationships between loads and displacements in the "simple" machines did not appear in permanent written form until many years after their estimated dates of origin; practice preceded theory. Archimedes, however, traditionally associated with the lever, did understand the mathematical theory of its operation. Since he is reported to have used compound pulleys (employing two or more wheels to obtain a mechanical advantage) to pull a ship onto dry land, and was primarily interested in theoretical relationships, he was doubtless well informed on the theory of all the simple machines.

To Hero of Alexandria (1st century AD), a Greek writer and inventor, the five simple machines were all devices for moving heavy weights whose main attribute was a high mechanical advantage. Hero was also aware of the reciprocal relation between mechanical advantage and velocity ratio, and is credited with recognizing the need for a precise technical definition of "work" in terms of force and distance.

It is believed that the wheel, as applied to transportation vehicles, evolved from the logs or rollers used to move heavy objects. Apart from its value in transportation, the wheel made controlled rotary motion a reality and was therefore of particular importance in machine design. The rotating treadmill operated by men or animals and the waterwheel activated by running water were among the first prime movers. Rotating machines performing repetitive operations, and driven by steam engines, were important elements in the Industrial Revolution of the 18th century. Rotary motion permits a continuity in magnitude and direction that is impossible with linear motion, which, in a machine, always involves reversals and changes in magnitude.

### The crank

Next to the wheel, the crank is the most important motion-transmitting device, since, with the connecting rod, it provides means for converting linear to rotary motion, and vice versa. There are many conflicting claims concerning the origin of the crank, but it has been reasonably well established that the first recognizable crank appeared in China early in the 1st century AD.

The first cranks had two right-angle bends and were hand-operated. The carpenter's brace, invented about AD 1400 by a Flemish carpenter, may be considered the first complete crank, since it had four right-angle bends, with the arm and wrist of the operator forming the connecting rod. The first mechanical connecting rods were used, it is said, on a treadle-operated machine in AD 1430. About this time flywheels were added to the rotating members to carry the members over the "dead" positions when the rod and the crank arm are lined up with each other (collinear).

Until the invention of the steam engine, the waterwheel was the greatest source of power for driving machinery. The most important waterwheel, invented by the 1st-century-BC Roman engineer Vitruvius, was a vertical wheel with a horizontal axis driven by a stream of water flowing beneath it; *i.e.*, it was undershot. This wheel was the first notable achievement in the design of power-driven machinery and the most important contribution of the Romans to mechanical engineering.

In the Middle Ages, the waterwheel was applied to a variety of tasks, such as grinding corn, operating weaving machines, and hammering hot metal into a desired shape (forging). For centuries, wire was drawn through dies by manual labour, and the amount of reduction in cross-sectional area that could be obtained was limited by the strength of the drawer. About the middle of the 14th century AD, waterwheels were harnessed for wire-drawing in Germany; they were used for this purpose until the introduction of the steam engine.

Many machine components have little history. For those with substantial historical backgrounds it will be convenient to treat the history individually.

**Operation.** Figure 2 shows three arrangements of a straight lever; in each case  $f$  is the fulcrum;  $P$  the effort, applied at  $b$ ; and  $W$  the load, applied at  $c$ . When the lever is balanced or in equilibrium, the tendency of  $P$  to turn the lever about  $f$  in one direction must be balanced by the tendency of  $W$  to rotate the lever in the opposite direction. Neglecting friction at the fulcrum, this relation can be expressed mathematically as

$$P \times bf = W \times cf, \quad (1)$$

which states that the applied effort multiplied by the distance to the fulcrum on one side is equal to the same product on the other side. From this can be derived a quantity known as the mechanical advantage, which is equal to the load divided by the effort:

$$\text{mechanical advantage} = \frac{W}{P} = \frac{bf}{cf} \quad (2)$$

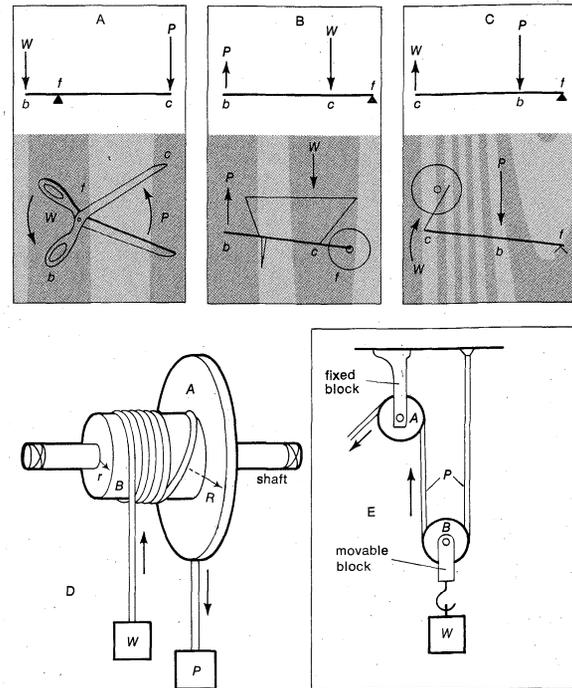

Figure 2: Simple machines. (A-C) Straight lever arrangements. (D) Wheel and axle. (E) Pulley and blocks (see text).

In Figure 2A, if  $bf/cf = 3$ , it means that a load  $W$  of 30 pounds, for example, can be balanced by an effort  $P$  of 10 pounds. If  $P$  exceeds this value slightly, the bar will rotate about  $f$  with  $P$  moving farther and faster than  $W$  by the ratio of  $bf$  to  $cf$ , the velocity ratio, which again is the mechanical advantage, neglecting friction. Obviously, the shorter the distance between  $f$  and  $c$  the greater the force-amplifying ability of the lever, and the shorter the distance  $c$  will move for a given movement of  $b$ .

The arrangement in Figure 2A is found on pliers and scissors, while that in Figure 2B is found on wheelbarrows;  $f$  represents the wheel,  $W$  the load, and  $P$  the effort exerted on the handles by the operator. In Figure 2C the lever functions as a motion-multiplying device. It is used on foot treadles for driving small looms and manually operated grindstones and sewing machines. A small movement of the foot at  $b$  produces a larger movement at  $c$ .

The wheel and axle shown in Figure 2D operates basically on a leverage principle. The wheel  $A$ , of radius  $R$ , and the axle  $B$ , of radius  $r$ , are fastened to the shaft, which can rotate. The effort  $P$  is applied by means of a cord lying in a groove on the periphery of the wheel, and the load  $W$  is raised by a cord wrapped around the axle. When the axle is stationary, the tendencies of  $P$  and  $W$  to cause rotation are equal and opposite. Neglecting bearing friction, the product of the effort  $P$  and the wheel radius  $R$  is equal to the product of the load  $W$  and the axle radius  $r$ :

$$P \times R = W \times r.$$

The mechanical advantage is again equal to  $W/P$ , which is equal to the ratio of the radius of the wheel  $R$  to the radius of the axle  $r$ .

The situation is similar to that for the lever. A lever, however, can move a load for only short distances, while the wheel and axle can move the load for a distance limited only by the available lengths of the cords.

With the wheel  $A$  and cord replaced by a spoked wheel, the wheel and axle is well suited for raising buckets of water from a well. More importantly, however, the wheel-and-axle principle is perceptible in many tools and machines. On a screwdriver, for example, the force applied by the hand on a large radius is converted to a larger force on the screw at a smaller radius.

The pulley is one of the most useful of the basic simple machines. It consists essentially of a wheel with a grooved rim carrying a flexible cord and supported in either a

Wheel  
and  
axle

fixed or a movable bearing block. When used singly with a fixed bearing block, like pulley *A* in Figure 2E, a downward pull creates an upward force of the same magnitude. In Figure 2E this pulley and one with a movable block *B* are combined. If friction is neglected, the tension *P* in the cord is the same at all points, and consequently a given downward pull on the loose end of the cord will lift twice as much weight at *W*, and the weight *W* will move half as far as the cord. The mechanical advantage is therefore two. Mechanical advantages greater than two can be obtained by using a variety of combinations of pulleys having both fixed and moving blocks. Such an arrangement, known as a block and tackle, is basically a force-amplifying device.

Consider now the action of the wedge in Figure 3, which is being driven to the left by the force *P*. The smaller the angle  $\theta$  and the smaller the frictional force *F*,

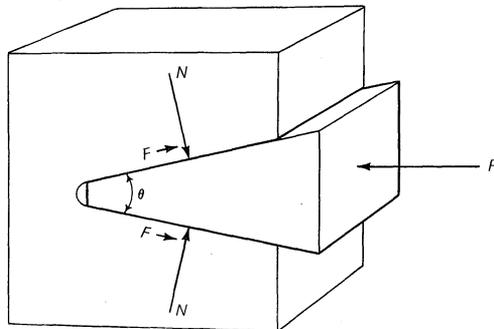

Figure 3: Wedge action (see text).

the greater the splitting force *N* in terms of *P*. For any surface smoothness of the wedge, and corresponding frictional resistance, if  $\theta$  is greater than a given value the wedge will fall out of its own accord when *P* is removed; if  $\theta$  is less than a given value, the wedge will stay in place or "stick" when *P* is removed.

Sticking tapers are used for holding cutting tools such as drills and reamers in machine tool spindles. Other mechanical devices that operate on the wedge principle are wood planes, chisels, knives, metal-cutting tools, and cams.

The screw may be thought of as a wedge wrapped around a cylinder. A screw is formed by cutting a continuous groove in a solid circular cylinder, successive turns of the groove being separated by the remaining solid material, called the thread. Both the thread and the groove are helical in form; *i.e.*, shaped like a corkscrew. The geometry of the helix was developed by the Greek mathematician Apollonius of Perga about 200 BC.

If the sheet of paper *ACC'A'* at the right in Figure 4, with the lines *AB'* and *BD* drawn on it, were wrapped around the cylinder of diameter *d* at the left, the lines

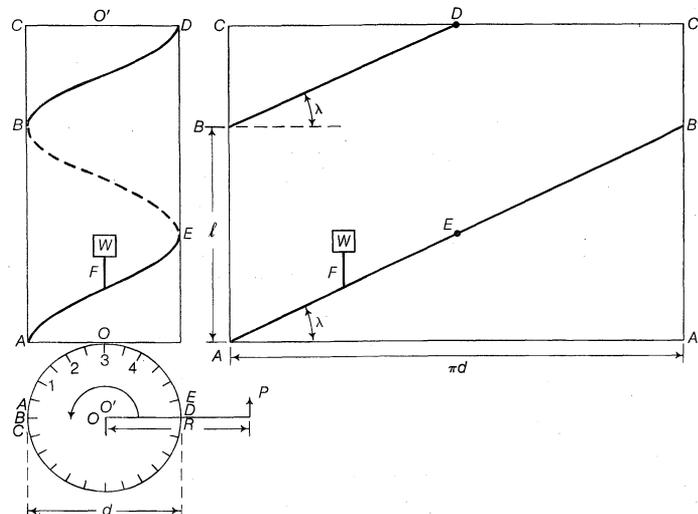

Figure 4: Graphical construction of a helix (see text).

would form one and one-half turns of a helix. The distance *l*, which is the axial distance corresponding to one turn of the helix, is called the lead. The lead angle  $\lambda$  is a measure of the slope of the helix.

Some early screws were cut by a method that resembles the method used to develop the helix at the left in Figure 4. A thin sheet of pliable material in the form of a right triangle was wrapped around the cylindrical "blank" so that one arm of the right angle was parallel to the axis. The hypotenuse would then form a helix on the cylinder and serve as a guide for the tool when cutting the helical groove.

If a sliding member such as *F* in Figure 4 were constrained to move parallel to the axis of the cylinder, such as along the axis *OO'*, it could be actuated either by a rotation of the cylinder and helix or a translation of the straightened-out helix. In either case the wedging action is apparent. If the member *F* were part of a nut constrained against rotation but free to move axially, the screw-nut combination would constitute a mechanism for converting rotary to rectilinear motion.

As a force amplifier, the screw has few equals. In the form of a screw jack its capacity for lifting weights is limited only by the strength of the material from which it is made. On a screw jack the nut is fixed, the load is carried on the end of the screw, and the effort is applied as a turning moment or torque on the screw.

In Figure 4 (left) let *P* be the effort, applied to the screw at a radius *R*, and *W* the load, moving with *F*. In one revolution the effort moves a distance equal to the circumference of the circle of radius *R*, or  $2\pi R$ , while the load is raised a distance *l*. Thus the velocity (and the distance) ratio is  $2\pi R/l$  and, if friction is neglected, this is also the mechanical advantage. Since the screw acts like a wedge, however, the force relationships are heavily dependent on friction. If a screw-nut combination is used for motion conversion, a high efficiency is desirable; if the efficiency is high enough (that is, if friction is reduced sufficiently) and  $\lambda$  is large enough, the nut can drive the screw. Such a high efficiency is undesirable on a screw jack since the load would descend by itself if the force *P* were removed; that is, a screw jack should be self-locking. Stated in other words, the screw taper must be less than the sticking taper. High efficiency and self-locking are incompatible.

In addition to its usefulness as a fastening device, a force amplifier, and a motion converter, the helix appears in many mechanical devices. Among these are a corkscrew, a helical gear, a meat grinder, a propeller, a carpenter's drill bit, a screw conveyor, and a twist drill for metal. In the latter, the helical groove provides the proper angle for the cutting point and a channel for the escape of chips.

Most of the simple machines have been shown to be essentially hand-operated devices for lifting heavy weights or creating large forces with smaller ones. Some writers claim that all machines, no matter how complicated, are combinations of these simple machines. This may have been true when human or animal muscle was the only source of power; it is certainly not true today.

The effectiveness of any of the simple machines is based on either the leverage principle or a wedging action. Insofar as these effects are built into many of the mechanical devices found in machinery, the simple machines do exert an influence on machine operation. The devices that have the greatest influence on machine performance, however, are the basic mechanisms. It is from combinations of these that most machines are created.

**MECHANISMS**

**History.** Linkages, cams, and gears are usually grouped together in books on the kinematics of mechanisms. The major portion of the history of mechanisms below deals with linkages, partly because few historical facts exist concerning cams and partly because the history of gears is covered later in this article.

In 1806 the first course in the study of mechanisms, separate from both general mechanics and the science of machines, was introduced at the École Polytechnique in Paris. For use in this course, a synoptic chart of elemen-

The screw

Origin of kinematics

tary mechanisms was prepared that classified them by the means employed to effect transformations of motion; this chart was the prototype for several subsequent charts. The French physicist André-Marie Ampère gave the new science the name *cinématique* in 1834 and outlined its scope, which, according to him, was the study of the motions that occur in mechanisms without considering the forces that produce them. Thus, kinematics as a separate study was born in France; almost all the early kinematicians were French.

The next forward step in the analysis of mechanisms was made in England by Robert Willis, who published a book on the subject in 1841. Willis presented another synoptic table of elementary mechanisms, but his main contribution was in the analysis of relative motion. Though he had hoped to develop formulas that would enable a designer to determine all the possible ways in which a problem in motion conversion could be solved, he did not succeed.

A noteworthy contribution to applied kinematics was made in Germany by Franz Reuleaux in a book that presented a new way of looking at mechanisms. In older books on machinery, each machine was analyzed as a whole; Reuleaux recognized that all machines have common elements connected by joints that permit only certain kinds of relative motion. All joints have two co-acting surfaces that Reuleaux called pairs. A turning, or revolute, pair, for example, is a pin joint with axial restraints and permits relative rotation only; a prismatic pair is a sliding joint that permits relative translation (linear motion) only. A closed chain of links joined together by pairs forms a kinematic "chain," and when one of the links is fixed a mechanism is obtained. Reuleaux also showed that, depending on which link in the chain is fixed, mechanisms with different characteristics can be created; this is the principle of inversion, which has great analytical significance.

The analysis of mechanisms, particularly linkages, was greatly enhanced by the work of A.B.W. Kennedy (translator of Reuleaux's book in 1876) and R.H. Smith in England. In 1885 Smith presented methods for obtaining velocities and accelerations in linkages by means of graphical analysis. This was a real contribution to kinematic analysis; no simpler or more direct method has been devised. In certain cases, however, additional procedures may be necessary to effect a solution; in the 1950s two of these procedures were devised, so that practically any problem in velocity and acceleration analysis of a linkage can be solved by graphical constructions. Until recently, Germany was the leader in both quality and quantity in the field of kinematic analysis and synthesis, and most of the graphical procedures for the synthesis of linkages were worked out there. In recent years the Soviet Union has shown an increasing interest in kinematics, particularly in analytical procedures for the synthesis of linkages. In the United States, considerable interest in kinematics developed after World War II, and many computer programs for the analysis and design of linkages are available.

**Basic types.** The purpose of a mechanism is to transmit motion, either with or without modification, and although mechanisms are made in a wide variety of forms, there are only three general classes or types, as shown in Figure 5.

In each of the mechanisms in the figure, links 2 and 4 are pivotally connected at  $O$  and  $Q$  to the fixed link 1. The three ways of transmitting motion shown in Figure 5 are: (A) by a flexible wrapping connector such as a

belt, rope, cable, or chain; (B) by direct contact, as in cams, gears, or friction wheels; and (C) by a rigid connecting link, or coupler. In each case, link 2 is the driver, rotating at  $n_2$  revolutions per minute, while link 4 is the follower, rotating at  $n_4$  revolutions per minute. For all three cases, the ratio of the rotary speed of link 4 to the rotary speed of link 2 is given by the ratio of the length  $Of$  to the length  $OQ$ . In Figure 5A, since point  $f$  remains fixed on the line of centres  $OQ$ , the speed ratio is constant; in Figures 5B and 5C, since  $f$  will move as the bodies rotate, the speed ratio will vary. Direct-contact bodies can be designed only to oscillate, like those in Figure 5B, or to rotate continuously. In all cases, point  $f$  lies at the intersection of the common normal and the line of centres.

**Direct-contact mechanisms.** In the most general case, the surfaces of bodies in direct contact slide on one another, and the more sliding that occurs, the greater will be the deterioration of the surfaces. Under certain conditions, pure rolling contact, which results in lower surface wear, can be effected; if other conditions are satisfied, the bodies will transmit motion with a uniform (constant) velocity ratio. These special cases are of interest in connection with gears and cams. The condition for pure rolling is that the point of contact lies on the line of centres.

There are three types of pure rolling contact. When the two bodies are circular cylinders, the common normal will lie on the line of centres, and the load that can be transmitted will depend on the friction between the surfaces. This is known as friction-dependent rolling. For a positive drive (one independent of friction) the common normal must not pass through the centre of either the driver or the follower. Since, neglecting friction, the force between two bodies in direct contact acts along the normal, the follower will be positively driven when the line of action of the force does not pass through the pivotal axis of the follower. The bodies in Figure 5B, making contact at point  $P$ , provide a positive drive.

Bodies can be designed so that continuous rolling takes place. A pair of identical ellipses pivoted at their foci will contact one another on the line of centres in all positions (see Figure 9B).

For any pair of direct-contact bodies the only variable in the formula for velocity ratio is the position of  $f$  in Figure 5B. Consequently, the condition for a uniform or constant velocity ratio is that the common normal cut the line of centres at a fixed point. The normal may rotate, but as long as it cuts the line of centres at the same point the velocity ratio will remain constant.

For almost any given body shape or profile, another profile can be constructed that will transmit motion with a uniform velocity ratio. This is called a conjugate profile. There are also mathematically describable curves inherently capable of conjugate action; two of them, the cycloid and the involute, are used for gear teeth. A cycloid is the path traced in space by a point on the rim of a rolling wheel. The profile of a gear tooth is obtained from the path traced by a point on the rim of a small circle rolling on the inside and outside of a larger circle. An involute is the path traced by a point on a string as it is unwound from a circular cylinder. The way in which the contacting surfaces of involute gear teeth co-act with one another can best be understood by studying a pair of involutes in contact. In Figure 6, two involutes generated from base circles 1 and 2 are shown in contact at three points,  $m$ ,  $f$ , and  $n$ . Note that since base circle 2 is larger than base circle 1, the involutes have different shapes.

Since two contacting curves must have a common tangent and a common normal at the point of contact, the common normal for the involutes in all of the three positions shown in Figure 6 must be  $xy$ , the common tangent to the base circles. The intersection of this normal and the line of centres  $OQ$  is at  $f$ , which remains fixed, and, consequently, the bodies are conjugate. All involutes are conjugate to one another.

If the involutes in Figure 6 were generated on metal plates mounted on pivots at  $O$  and  $Q$ , and if 1 were the driver, rotating counterclockwise, then contact between the involutes would begin at  $r$  and end at  $s$ . During this

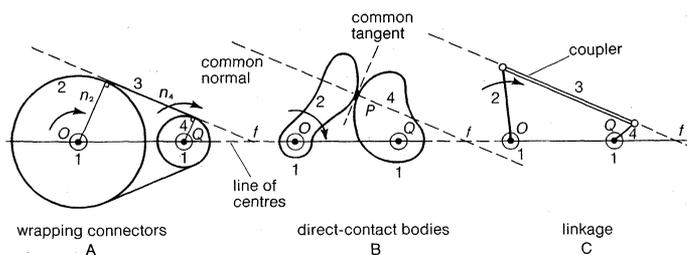

Figure 5: Methods of transmitting motion (see text).

Pure rolling contact

The involute

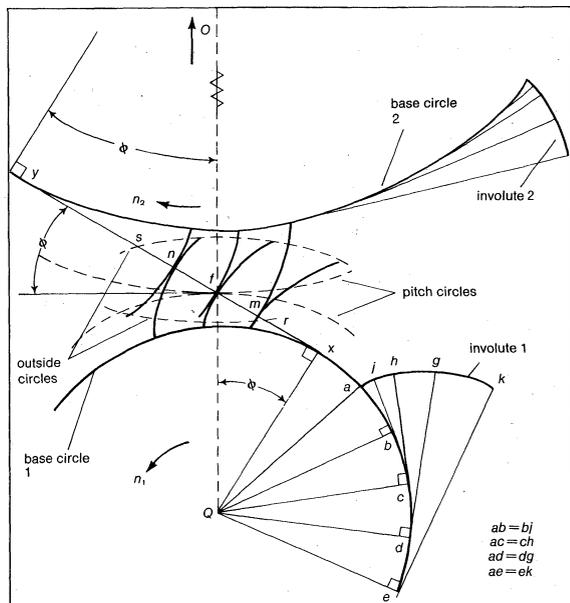

Figure 6: Involute gear surfaces in contact. Involute 1 and 2 are examples of involutes that may be generated from the base circles (see text).

partial rotation the point of contact between the involutes would move along the line  $xy$  from  $r$  to  $f$  to  $s$ . At  $f$ , since the condition for pure rolling is satisfied, the involutes would roll on one another; at all other points there would be sliding contact.

The two circles of radii  $Of$  and  $Qf$  in Figure 6 are known as the pitch circles, and  $f$  is the pitch point. The circles are useful for reference purposes in analyzing gears, and when the shafts are parallel they represent the pair of friction disks that, by pure rolling contact, would transmit the motion at the same rate as the gears. The outside circles are the circles represented by the outer periphery of the gear teeth.

The two involutes in Figure 6 would remain in contact for only part of a revolution. To obtain continuous rotation, as in gears, a number of equally spaced involutes would be required on each base circle.

The possibility of obtaining pure rolling, a positive drive, and a uniform velocity ratio simultaneously and continuously has long challenged inventors. It is easy to demonstrate that any two of the states can coexist continuously, but not all three. The rolling ellipses in Figure 9B provide a positive drive, except in the end positions, but the velocity ratio is not uniform. Rolling circular disks or truncated cones provide a uniform velocity ratio, but the drive is not positive. A positive drive is always a requirement of gear teeth and so also, in most cases, is a uniform velocity ratio. When the teeth touch on the line of centres they also have pure rolling contact, but only for an instant.

#### GEARS

Gears are direct-contact bodies, operating in pairs, that transmit motion and force from one rotating shaft to another, or from a shaft to a slide (rack), by means of successively engaging projections called teeth. The four main types of gears (spur, helical, worm, and bevel) and a rack and pinion are shown in Figure 7.

**History.** The earliest known gears were those in the Chinese South-Pointing Chariot in the 27th century BC. The gear teeth were wooden pins arranged in a complex gear train that drove a statuette with outstretched arm that always pointed in the same direction, regardless of the direction in which the chariot was moving. The earliest written descriptions of gears were made by Aristotle in the 4th century BC. Ctesibius (3rd century BC), a Greek inventor, used spur and bevel gears in his water clocks and organs, and Archimedes mentions worm gears in his writings. Vitruvius, who invented the vertical waterwheel, used a right-angle pin-gear drive from the

horizontal wheel shaft to the vertical shaft of the millstone. The notebooks of Leonardo da Vinci contain sketches of spur, bevel, and worm gears. It is probable that none of these men paid much attention to the problem of kinematically correct tooth profiles that would provide a constant velocity ratio (conjugate profiles).

Although the cycloid curve had been known for over 200 years, it was not until 1674 that its suitability for gear-tooth profiles was demonstrated. For the next century and a half the respective merits of the cycloid and involute were debated; since the 1830s involutes have been preferred for power drives; for clocks and watches, cycloids have advantages.

The first spur and bevel gears were cut with form cutters shaped to correspond to the spaces between the teeth. The oldest known rotating cutter of this type was hand-made by a French mechanic, Jacques de Vaucanson, in 1782. This cutter was used on a milling machine; special machines for cutting gears did not appear until about the mid-19th century.

**Tooth profiles.** The contacting surfaces of gear teeth must be aligned in such a way that the drive is positive; *i.e.*, the load transmitted must not depend on frictional contact. As shown in the treatment of direct-contact bodies, this requires that the common normal to the surfaces must not pass through the pivotal axis of either the driver or the follower.

Most gears are also required to have tooth profiles of such a shape that the velocity ratio of the gears remains constant (unless otherwise noted, this article will deal with such gears only). This requires that the common normal must cut the line between the pivots at a fixed point.

As shown in the section on direct-contact bodies, cycloidal and involute profiles provide both a positive drive and a uniform velocity ratio; *i.e.*, conjugate action.

Some of the advantages of the involute as a gear-tooth profile have already been enumerated. The factors to be considered in evaluating a gear-tooth profile include ease of manufacture, sensitivity to maladjustment, and load-carrying capacity. On all of these counts the involute is superior or equal to the cycloid. Involute, however, are unsuitable for the teeth of driven gears having as few as six or seven teeth and capable of action through 60 degrees of rotation. This is a requirement for watch and clock gears, and since they can supply it, cycloidal teeth or ogival (circular arc) approximations thereto are used on watches, clocks, and small instruments. Another type of pinion (small gear) used in clockwork is the lantern pinion, or pin gear. The teeth are short lengths of hard, polished, steel wire held between two end plates, and the teeth on the mating gear are conjugate epicycloids. By using rollers in place of fixed pins, the friction is reduced.

Circular profiles have been proposed for gears, most recently in the Soviet Union. Since contacting involutes are both convex, the contact stresses are higher than in a convex-concave pair such as can be obtained with circular profiles. In spite of their higher surface load-carrying capacity, however, circular-profile gears are seldom used, because they lack the profile interchangeability of involute gears, are difficult to manufacture, and are sensitive to centre-distance variations.

In spite of some deficiencies, the involute is still the most commonly used gear-tooth profile. As far as the transmission of motion is concerned, it does not matter what shape the teeth on a gear pair have as long as they are conjugate to one another; *i.e.*, transmit the motion with a uniform velocity ratio. The dominating considerations are manufacturing convenience and interchangeability.

A worm and its mating gear are inseparable, and the gear is cut with a tool (hob) that is basically a replica of the worm. Some British manufacturers prefer the involute profile for worms; in the United States, involutes are seldom used for this type of gear.

**Basic relations.** The smaller of a gear pair is called the pinion and the larger is the gear. When the pinion is on the driving shaft, the pair acts as a speed reducer; when the gear drives, the pair is a speed increaser. Gears are more frequently used to reduce speed than to increase it.

Gear-tooth profiles

Gear  
ratio  
and  
speed  
ratio

If a gear having  $N$  teeth rotates at  $n$  revolutions per minute, the product  $Nn$  has the dimension "teeth per minute." This product must be the same for both members of a mating pair if each tooth is to acquire a partner from the mating gear as it passes through the region of tooth engagement.

For conjugate gears of all types, the gear ratio and the speed ratio are both given by the ratio of the number of teeth on the gear to the number of teeth on the pinion. If a gear has 100 teeth and a mating pinion 20, the ratio is  $\frac{100}{20} = 5$ . Thus the pinion rotates five times as fast as the gear, regardless of the speed of the gear.

If the shafts are parallel, the gear and pinion could be replaced by a pair of cylinders that would transmit the motion by pure rolling contact at the same speed ratio as the gears. On the gears, the circles that represent these imaginary cylinders are called the pitch circles; these are useful for reference purposes in the analysis of gears. Their point of tangency is called the pitch point, and since it lies on the line of centres, it is the only point at which the tooth profiles have pure rolling contact. Gears on nonparallel, non-intersecting shafts also have pitch circles, but the rolling-pitch-circle concept is not valid.

Gear types are determined largely by the disposition of the shafts; in addition, certain types are better suited than others for large speed changes. This means that if a specific disposition of the shafts is required, the type of gear is more or less fixed. On the other hand, if a required speed change demands a certain type, the shaft positions are fixed.

**Spur and helical gears.** A gear having tooth elements that are straight and parallel to its axis is known as a spur gear. A spur pair can be used to connect parallel shafts only. Parallel shafts, however, can also be connected by gears of another type, and a spur gear can be mated with a gear of a different type.

In Figure 6, if the involutes are on a single pair of teeth on mating involute spur gears, then, since contact begins at  $r$  and ends at  $s$ , to obtain continuous transmission of motion, a pair must come into contact at  $r$  before the preceding pair goes out of contact at  $s$ . Whether this does or does not occur depends on the tooth spacing and the length of the line  $rs$ , which depends on the amounts that the teeth project above and below the pitch circles. Satisfactory values of those dimensions have been standardized.

Since the pitch circles roll on one another, the spacing of the teeth on these circles on a mating pair must be equal. This spacing, which is known as the circular pitch  $p$  and is a measure of tooth size, is the distance between corresponding points on adjacent teeth, measured on the pitch circle.

To prevent jamming as a result of thermal expansion, to aid lubrication, and to compensate for unavoidable inaccuracies in manufacture, all power-transmitting gears must have backlash. This means that on the pitch circles of a mating pair, the space width on the pinion must be slightly greater than the tooth thickness on the gear, and vice versa. On instrument gears, backlash can be elimi-

nated by using a gear split down its middle, one half being rotatable relative to the other. A spring forces the split gear teeth to occupy the full width of the pinion space.

If an involute spur pinion were made of rubber and twisted uniformly so that the ends rotated about the axis relative to one another, the elements of the teeth, initially straight and parallel to the axis, would become helices. The pinion then in effect would become a helical gear.

Helical gears have certain advantages; for example, when connecting parallel shafts they have a higher load-carrying capacity than spur gears with the same tooth numbers and cut with the same cutter. Because of the overlapping action of the teeth, they are smoother in action and can operate at higher pitch-line velocities than spur gears. The pitch-line velocity is the velocity of the pitch circle. Since the teeth are inclined to the axis of rotation, helical gears create an axial thrust. If used singly, this thrust must be absorbed in the shaft bearings. The thrust problem can be overcome by cutting two sets of opposed helical teeth on the same blank. Depending on the method of manufacture, the gear may be of the continuous-tooth herringbone variety or a double-helical gear with a space between the two halves to permit the cutting tool to run out. Double-helical gears are well suited for the efficient transmission of power at high speeds. An important application of such gears is for geared-turbine ship drives. On the former British passenger liner "Queen Mary," of 80,000 tons displacement, there were four single-reduction, double-helical gearboxes transmitting a total of 160,000 horsepower from turbines rotating at 1,500 and 1,050 revolutions per minute to a propeller shaft rotating at 180 revolutions per minute. Each large driven gear was approximately 13.5 feet (4 metres) in diameter.

Helical gears can also be used to connect nonparallel, non-intersecting shafts at any angle to one another. Ninety degrees is the commonest angle at which such gears are used. When the shafts are parallel, the contact between the teeth on mating gears is "line contact" regardless of whether the teeth are straight or helical. When the shafts are inclined, the contact becomes "point contact." For this reason, crossed-axis helical gears do not have as much load-carrying capacity as parallel-shaft helicals. They are relatively insensitive to misalignment, however, and are frequently employed in instruments and positioning mechanisms where friction is the only force opposing their motion.

As stated above, the rolling-pitch-circle concept, which applies to gears on parallel shafts, does not apply to gears on nonparallel, non-intersecting shafts. This means that a large speed ratio on one pair of gears, 100 for example, is more easily obtained when the axes are crossed than when they are parallel. With parallel shafts, the pinion pitch diameter would have to be  $\frac{1}{100}$  of the gear pitch diameter, an impractical proportion. With crossed axes, the pinion could have only one helical tooth—or thread—and be as large as necessary for adequate strength. The pinion would look like a screw, and the gear would have 100 teeth.

Ship  
propulsion  
gears

**Worm and bevel gears.** In order to achieve line contact and improve the load-carrying capacity of the crossed-axis helical gears, the gear can be made to curve partially around the pinion, in somewhat the same way that a nut envelops a screw. The result would be a cylindrical worm and gear. Worms are also made in the shape of an hourglass, instead of cylindrical, so that they partially envelop the gear. This results in a further increase in load-carrying capacity.

Worm gears provide the simplest means of obtaining large ratios in a single pair. They are usually less efficient than parallel-shaft gears, however, because of an additional sliding movement along the teeth. Because of their similarity, the efficiency of a worm and gear depends on the same factors as the efficiency of a screw. Single-thread worms of large diameter have small lead angles and low efficiencies. Multiple-thread worms have larger lead angles and higher efficiencies. For lead angles of about 15 degrees and a coefficient of friction less than 0.15, the efficiency ranges from about 55 percent to 95 percent, and the gear can drive the worm. Such units make compact speed increasers; they have been used for driving superchargers on aircraft engines. In self-locking worms, the gear cannot drive the worm, and the efficiency is less than 50 percent.

For transmitting rotary motion and torque around corners, bevel gears are commonly used. The connected shafts, whose axes would intersect if extended, are usually but not necessarily at right angles to one another. The pitch surfaces of bevel gears are rolling, truncated cones, and the teeth, which must be tapered in both thickness and height, are either straight or curved. Although curved-tooth bevel gears are called spiral bevel gears, the curve of the teeth is usually a circular arc. The curvature of the teeth results in overlapping tooth action and a smoother transmission of power than with straight teeth. For high speeds and torques, spiral bevel gears are superior to straight bevel gears in much the same way that helical gears are superior to spur gears for connecting parallel shafts.

When adapted for shafts that do not intersect, spiral bevel gears are called hypoid gears. The pitch surfaces of these gears are not rolling cones, and the ratio of their mean diameters is not equal to the speed ratio. Consequently, the pinion may have few teeth and be made as large as necessary to carry the load. This permits higher speed ratios than with intersecting axes, just as crossed-axis helicals and worm gears can provide higher ratios than parallel helicals. The absence of the proportional rolling-pitch surface requirement is a benefit.

Hypoid gears are used on automobiles to connect the drive shaft to the rear axles. The axis of the pinion on the drive shaft is below the gear axis, which permits lowering of the engine and the centre of gravity of the vehicle. Since the shafts do not intersect, several gear shafts may be driven from pinions mounted on a single pinion shaft, as in tandem axles for trucks.

The profiles of the teeth on bevel gears are not involutes; they are of such a shape that the tools for cutting the teeth are easier to make and maintain than involute cutting tools. Since bevel gears come in pairs, as long as they are conjugate to one another they need not be conjugate to other gears with different tooth numbers.

**Planetary and differential gears.** The external spur gears in Figure 7 rotate in opposite directions, and the centre distance is the sum of their pitch radii. A pinion and an internal or ring gear rotate in the same direction, and the centre distance is the difference of their pitch radii. The teeth on an internal gear, which may be straight or helical, are cut on the inside of a cup-shaped member.

A useful arrangement of external gears and an internal gear is shown in Figure 8 (left). The sun gear *S* on shaft 1 meshes with three planet gears *P* that are carried on bearings on a carrier *A* attached to shaft 2. The planet gears also mesh with the internal ring gear 3, whose supporting hub, not shown, is coaxial with shafts 1 and 2.

Since there are three rotatable coaxial shafts, any two of them must be inputs if the arrangement is to have con-

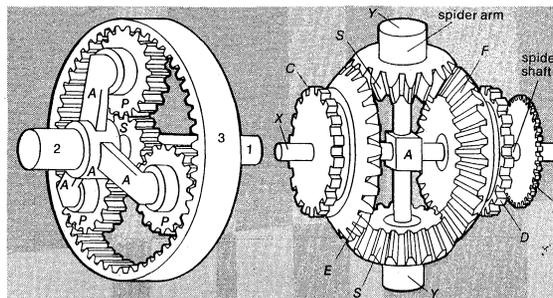

Figure 8: Two types of gear assemblies (see text). (Left) Planetary or epicyclic gear train. (Right) Bevel gear differential (see text).

strained motion and serve a useful purpose. Usually, one of the shafts is fixed, which corresponds to a zero input, and the other two shafts serve as either inputs or outputs. The three different speed ratios that can be obtained depend on which of the three shafts is fixed, and the ratio of the number of teeth on the ring gear to the number of teeth on the sun gear. If this ratio is three, for example, the following different speed ratios can be obtained. If the arm (shaft 2) is fixed, the sun gear and shaft 1 rotate three times as fast as the internal gear and shaft 3, and in the opposite direction. Since all gears rotate about fixed axes, this is an ordinary gear train.

If the internal ring gear 3 is locked, a planetary or epicyclic system results; shaft 1 rotates at four times the speed of shaft 2 and in the same direction. The planet gears have a planetary motion, moving around the sun gear in a circular orbit while rotating relative to the arm. When the sun gear (shaft 1) is fixed, for every three revolutions of shaft 2, shaft 3 makes four revolutions in the same direction. This is also a planetary system.

Planetary arrangements of the type described are used in the automatic transmissions of automobiles; in these, the fixing and interconnecting are done automatically with brakes and clutches.

Gears can be arranged to form planetary systems in a variety of ways. The planet gears may be compounded (*i.e.*, have more than one gear on the same shaft) and mesh with other sun and internal gears. None of the gears may be fixed; in this case any two (including the arm) may be attached to input shafts and the remainder to output shafts. Speed ratios of 10,000 and higher can be obtained.

Planetary arrangements with bevel gears are also available. The bevel gear differential in Figure 8 (right; invented in 1827 by a French mechanic for steam-powered road vehicles) is such an arrangement; it can perform many useful functions in the operation of machines. The strictly planetary action is confined to the two pairs of equal bevel gears (*SS* and *EF*), which are free to rotate on the arm and shaft of the cross-shaped "spider" *A*, which in turn can rotate about the fixed axis *XX*; the axis *YY* of the spider arm sweeps out a plane perpendicular to the spider shaft and carries the gears *S* with it. If gear *E* is fixed and gear *F* rotated about the spider shaft, the gears *S* will act like levers, with fulcrums at gear *E*, efforts at gear *F*, and loads perpendicular to the axis *YY*. Since *YY* is halfway between *E* and *F*, it (and shaft *A*) will rotate only half as much as gear *F*. Mathematically, with *E* fixed,  $A = F/2$  in which *A* and *F* are either the angular displacements or angular velocities of the spider arm and the gear *F*, respectively. With *F* fixed,  $A = E/2$ , and combining the two effects, the fundamental equation for the bevel gear differential is  $A = \frac{E + F}{2}$ . This means that

the rotation of the spider shaft is half the sum of the rotations of the side gears.

Since there are three variables in this equation, any two must be known before the third can be calculated. This means that the bevel gear differential must have two inputs. Usually the inputs come from outside sources to the spur gears *C* and *D*, which are fixed to the side gears *E* and *F*, respectively; the output is delivered to another outside source through the spur gear *B*, which

Hypoid gears

Differential gears

is fixed to the spider shaft  $A$ . If  $E$  makes 100 revolutions while  $F$  makes 80 revolutions in the same direction, then  $A = 180/2 = 90$  revolutions. If  $E$  and  $F$  rotate in opposite directions at the same speed, then  $E - F = 0$  and the spider shaft will stand still. This effect can be used to synchronize the speeds of two engines or to detect errors in automatic-control mechanisms. Differentials of the type shown in Figure 8 (right) are widely used in analogue computers and instrument systems.

In an automobile, the differential permits the driving wheels to rotate at different speeds (as when turning) while both are being driven from the same source. The spider shaft is the input or driving member, while the side gears are connected to the wheel axles. The road acts as a gear train that controls the ratio of the wheel speeds.

Since the tooth loads between gears  $S$  and  $E$  and between  $S$  and  $F$  in Figure 8 (right) are always equal, the torques on both rear axles in an automobile are always equal. If one wheel slips on the ice, it can develop little torque and neither can the other wheel. To correct this basic weakness of the automobile differential, "limited slip" differentials have been developed.

**Gear trains and reducers.** The maximum gear ratio obtainable with a single pair of gears varies with the type of gear and the application. The following are approximate maxima for the various types for average load conditions: spur, 8; parallel-shaft helical, 10; straight bevel, 6; spiral bevel, 8; hypoid, 12; and worm, 80. For lightly loaded, instrument, and positioning gears, these ratios can be exceeded. Ratios as high as 400 or higher can be obtained with gears that resemble tapered worms meshing with hypoid gears. For heavily loaded gears, the given ratios may be so high that a reasonable gear size precludes a satisfactory pinion.

Since the ratio in a single pair of gears is the quotient of the tooth numbers, and since there usually are limitations on both the minimum and maximum numbers of teeth on the available gears, it follows that the number of ratios obtainable in a single pair is limited. To enlarge the coverage it is necessary to use multiple pairs, or trains (Figure 9A). The overall speed ratio in a train is the product

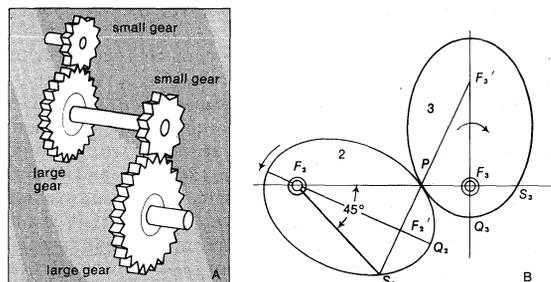

Figure 9: (A) Compound gear train. (B) Pitch curves of elliptical gears (see text).

of the ratios in each pair. In certain cases an exact ratio cannot be obtained with gears, but by using two or more pairs, the desired ratio can be approximated to any degree of precision.

As a convenience for machine builders and users, packaged speed reducers, following an industry-accepted pattern, are manufactured in a wide variety of types, configurations, speed ratios, and capacities; these consist of a box or housing containing bearings, shafts, gears, lubricant, and shaft oil seals. Speed increasers are usually custom built.

All speed reducers when operating continuously become hot because of friction in the teeth, in the lubricant, in the bearings, and in the oil seals. If the heat is generated at a faster rate than it can be dissipated to the atmosphere, the lubricant may deteriorate and the gears or bearings fail.

**Materials and cutting methods.** The first toothed wheels were made of wood, and wooden gears are still to be found in rural gristmills driven by waterpower. These "mortise" wheels consist of maple teeth set in a grooved rim. Many of the early metallic gears were cast to shape in sand molds. The hard skin on the surface of uncut as-

cast iron and steel has excellent wearing qualities, and gears with cast teeth are still used on low-speed agricultural machinery and on equipment that is exposed to the atmosphere.

Zinc, brass, aluminum, and magnesium gears of the smaller sizes are made in die-casting machines. These machines have permanent metallic cavities or dies into which molten metal is forced. Many small gears of nylon, Bakelite, and other thermoplastic materials are produced in large quantities in injection molding machines. Sintered gears are made by pouring a metallic powder into a mold, compressing the powder into a briquette with a punchlike tool, stripping the briquette from the mold with another tool, and then baking the briquette in an oven. Cold-drawn pinion stock, in the form of a long rod with continuous teeth, is also available. Pinions of any required length can be cut from the rod.

The machining of gears involves the cutting of grooves to form teeth on a previously machined blank; it always requires special tools and, in most cases, special machines. Practically all gear-cutting processes can be classified as either forming, in which the shape of the tool is reproduced on the blank, or generating, in which the shape produced depends on both the shape of the tool and the relative motion between the tool and the blank.

Spur gears can be form-cut, one space at a time, with a disk-type or an end-mill-type milling cutter (see also MACHINE TOOLS). They can also be cut with a broach, which forms all the tooth spaces simultaneously. These cutters resemble long internal gears, with teeth of continuously increasing depth and relieved to provide cutting edges. The broach is pushed over the gear blank, usually in a hydraulic press, and all the tooth spaces can be cut in one pass. Broaches for internal gears resemble long spur gears. Since the shape of an involute depends on the size of the base circle, a form cutter is accurate for only one number of teeth of a given pitch.

Because all involutes are conjugate to one another, any one of a set of involute spur gears (including a rack) of the same pitch but different numbers of teeth could be used to generate all other gears in the set if it were provided with cutting edges and reciprocated parallel to its axis as it rotated, as if in mesh with the blank. This is the principle of operation of a gear shaper, which can generate both external and internal spur and helical gears.

Worms are usually cut with disk-shaped milling cutters in thread-milling machines and finished with a grinding wheel. Worm gears are cut on hobbing machines with a hob (a replica of the worm with longitudinal gashes) and, as both rotate, it is fed to depth in a radial or tangential direction relative to the blank. If a hob has teeth with straight sides similar to a rack, and after being fed to depth radially is fed longitudinally parallel to the blank axis, it will generate a spur gear. One involute hob of a given pitch can generate all gears of that pitch, regardless of the number of teeth. Hobbing machines are used extensively for the rapid production of spur and helical gears of medium and small pitches.

Bevel gears with straight teeth are roughed out with a form cutter and then generated on special generating machines. Spiral bevel gears are cut with a special cutter on a special machine that can be set up to cut with either a forming or a generating action.

For improving the surface finish and profile accuracy of cut gears, shaving and grinding machines are available. Shaving machines are used extensively in the automotive industry for spur and helical gears. Gear grinding wheels and machines operate on both the forming and generating principles.

A recent development (1969) gives promise of superseding traditional gear finishing methods. This new process is known as roll forming, or "chipless machining," and involves the squeezing of a pre-hobbed gear with finish-roll allowance between two diametrically opposed hardened master gears or dies. Tests on roll-formed gears indicate that the new method reduces manufacturing costs and improves the physical properties of the gears.

**Non-circular gears.** The rolling-pitch-circle concept applies only to gears connecting parallel shafts. Parallel

Nylon gears

Hobbing gears

shafts can also be connected by gears with non-circular pitch curves. These non-circular gears transmit the motion with a varying speed ratio and can be designed for almost any prescribed spectrum of speed ratios. Their speed-changing capabilities depend entirely on the shapes of their rolling pitch curves. As indicated in the section on direct-contact bodies, rolling contact between two bodies rotating about fixed pivots requires that the point of contact remain always on the line of pivot centres, and the speed ratio is the inverse ratio of the segments into which the distance between the pivots (the centre distance) is divided by the point of contact.

The pitch curves of non-circular gears may be open (like a circular arc) or closed (like a complete circle). Those with open curves can oscillate only through angles less than 360 degrees and are usually employed to generate mathematical functions in analogue computers; those with closed curves can make complete revolutions and are used to convert uniform to variable rotary motion.

Figure 9B shows two identical ellipses pivoted at their foci  $F_2$  and  $F_3$ ; the other foci are  $F_2'$  and  $F_3'$ . These ellipses will always touch on the line of centres  $F_2F_3$ , and they could represent the pitch curves of a pair of non-circular gears. From symmetry, arc  $PQ_2S_2$ , which corresponds to 45 degrees on ellipse 2, will roll on arc  $PQ_3S_3$ , which corresponds to 180 degrees on ellipse 3. With the scale shown, ellipse 3 will make half a revolution while ellipse 2 makes only one-eighth of a revolution during one portion of a complete cycle; during another portion, ellipse 3 will make half a revolution while ellipse 2 makes seven-eighths of a revolution. If ellipse 2 were rotating at a constant speed, ellipse 3 would have a fluctuating speed. The cyclically repeating quick-slow rotations obtained with elliptical gears are useful on machines that operate intermittently and perform useful work during only a part of the revolution of a shaft or during only one stroke of a reciprocating member. On a printing press, for example, the motion of the platen should be rapid when the press is open but slow and powerful when the impression is being made.

Elliptical gears

#### CAMS

A cam is the driving or input member of a pair of bodies in direct contact, so shaped that its reciprocation, oscillation, or rotation, combined with a wedging action, imparts a prescribed motion of reciprocation or oscillation to a follower or output member. The shape of the cam is determined by the prescribed motion and the profile of the follower, which is usually flat or circular.

Cam-follower mechanisms can be designed to satisfy almost any input-output relationship within their scope. For some applications the capabilities of cams and linkage mechanisms overlap; in fact, German engineers use linkages to perform tasks American engineers do with cams. Cams are easier to design than linkage mechanisms for mutually appropriate applications, and they can do many things that a linkage cannot do. Linkages, on the other hand, are easier to make than cams.

Cam-follower mechanisms are particularly useful when a simple motion of one part of a machine is to be converted to a more complicated prescribed motion of another part that is accurately timed with respect to the simple motion and combined with periods of rest. The motion of the camshaft on an automobile engine, for example, is a simple rotation that is a fixed ratio of the crankshaft speed, while the valve motion produced by the cams is accurately timed relative to the crankshaft rotation and includes rest periods, or dwells, when the valves remain closed. Cams are essential elements in automatic machine tools, textile machinery, wire-drawing machines, shoe machinery, sewing machines, and printing machines.

On some machines the cam is a fixed disk with a suitably shaped periphery around which the follower, in its support, is rotated. In other cases, the roles of the cam and follower can be reversed; *i.e.*, the follower can drive the cam. These are known as inverse cam mechanisms and are not common. Because of their wedging action, cams make effective locking devices or force and torque amplifiers when rotatably mounted on fixed pivots.

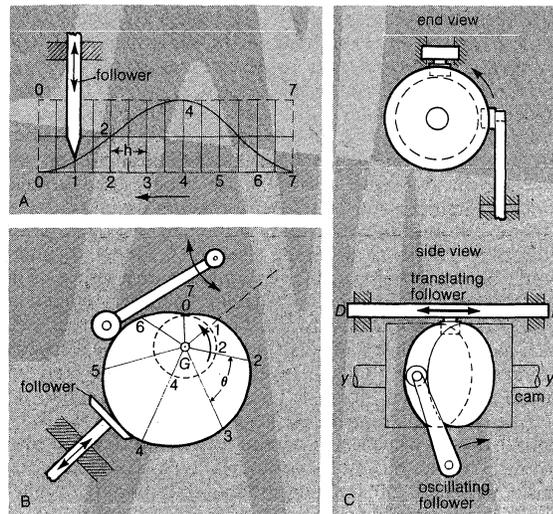

Figure 10: Types of cams. (A) Translation cam. (B) Disk cam. (C) Cylindrical cam (see text).

The translation cam, Figure 10A, produces a vertical motion of the follower when the cam is moved horizontally. The disk cam, Figure 10B, is a flat, rotating plate with a curved contour. The disk cam can be conceived as having been formed by bending the translation cam around a disk of radius  $OG$ ; the seven equal angular increments, such as  $\theta$ , in Figure 10B, correspond with the seven equal linear increments, such as  $h$ , in Figure 10A. The cylindrical cam (Figure 10C) can be envisioned as having been formed by bending a rectangular plate such as 0077 of Figure 10A and a groove like the curved line into a circular cylinder. The groove would resemble the thread on a screw, but it would be endless and a follower fitting in the groove could be guided to move on the straight path  $DE$  parallel to the axis by a rotation of the drum about the  $yy$  axis. Oscillating arms with rollers fitting the groove in the drum are also used on these cams. The level-winding device on a fishing reel is a cylindrical cam.

If the relation between the motion of the cam and the motion of the follower can be expressed by a mathematical equation, then the velocity and acceleration equations can be obtained by differentiation, and the displacement, velocity, and acceleration curves can be drawn. On high-speed cams the acceleration of the follower and the resulting inertial forces are important considerations. For this reason, certain types of follower motions that can be expressed in simple formulas are commonly employed by cam designers; among these are uniformly accelerated and retarded motion and harmonic motion (the motion of a simple pendulum).

On the end that contacts the cam, reciprocating followers usually have either a roller or a flat face (Figure 10B). Oscillating followers are also made with flat faces. In all cases, the follower must be constrained to follow the cam either by a spring or by gravity.

In addition to disk and cylindrical cams there are many other types. Among these are the disk cam with dual rollers or an encircling yoke that keeps the follower and cam in contact at all times; the face cam with a follower groove cut in the face of a disk; the rolling cam, in which the cam and follower are in continuous pure rolling contact; and the three-dimensional cam. In the latter, the cam, which resembles a stack of infinitesimally thin disk cams of smoothly changing contour, rotates and translates so that the motion of the follower is a function of two variables. One application of three-dimensional cams is in the computation of the flight time of guided missiles.

#### LINKAGES

A linkage may be defined as an assemblage of solid bodies, or links, in which each link is connected to at least two others by pin connections (hinges) or sliding joints. To satisfy this definition, a linkage must form an endless, or closed, chain or a series of closed chains.

Cams and linkages compared

It is obvious that a chain with many links will behave differently from one with few. This raises the vitally important question regarding the suitability of a given linkage for the transmission of motion in a machine. This suitability depends on the number of links and the number of joints.

**Degrees of freedom.** A three-bar linkage (containing three bars linked together) is obviously a rigid frame; no relative motion between the links is possible. To describe the relative positions of the links in a four-bar linkage it is necessary only to know the angle between any two of the links. (Including the fixed link  $OQ$ , the mechanism in Figure 5C has four links and is thus a four-bar linkage.) This linkage is said to have one degree of freedom. Two angles are required to specify the relative positions of the links in a five-bar linkage; it has two degrees of freedom.

Linkages with one degree of freedom have constrained motion; *i.e.*, all points on all of the links have paths on the other links that are fixed and determinate. The paths are most easily obtained or visualized by assuming that the link on which the paths are required is fixed, and then moving the other links in a manner compatible with the constraints.

**Four-bar mechanisms.** When one of the members of a constrained linkage is fixed, the linkage becomes a mechanism capable of performing a useful mechanical function in a machine. On pin-connected linkages the input (driver) and output (follower) links are usually pivotally connected to the fixed link; the connecting links (couplers) are usually neither inputs nor outputs. Since any of the links can be fixed, if the links are of different lengths, four mechanisms, each with a different input-output relationship, can be obtained with a four-bar linkage. These four mechanisms are said to be inversions of the basic linkage.

When the shortest link  $a$  in Figure 11 (top) is fixed, links  $b$  and  $d$  can make complete revolutions. This is known as a drag-link mechanism. If crank  $b$  rotates at a constant

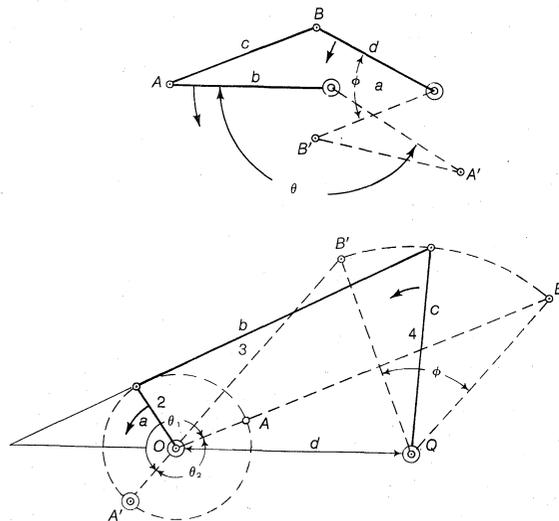

Figure 11: Linkage mechanisms (see text). (Top) Drag-link mechanism. (Bottom) Crank-rocker mechanism.

speed, the crank  $d$  will rotate in the same direction at a varying speed. By itself, or in series with other mechanisms, the drag link can provide useful kinematic effects. In the figure, crank  $b$  is the driver, rotating counterclockwise at a uniform rate; crank  $d$  is the follower. Both cranks make a complete revolution in the same time, but while  $b$  sweeps out the angle  $\theta$ , which is 150 degrees, the follower  $d$  sweeps out the angle  $\phi$  which is only 50 degrees. This means that crank  $d$  will move more slowly than crank  $b$  when moving from  $B$  to  $B'$  and more quickly than  $b$  when moving from  $B'$  to  $B$ . If crank  $d$  were attached to a shaft in a packaging machine, for example, the slow part of its motion, which with some link proportions is almost a pause or a dwell, could be utilized for performing operations that must be done at a slow speed.

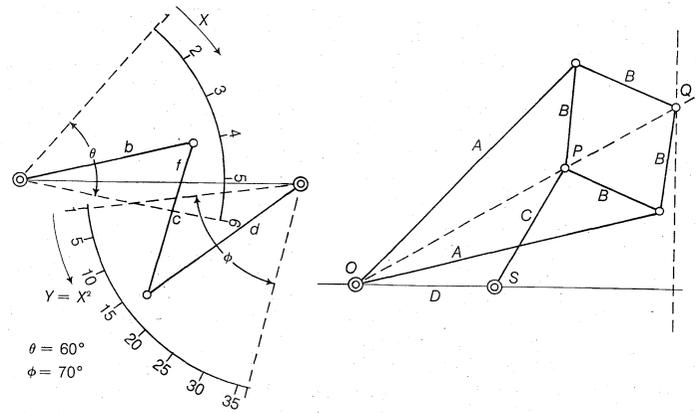

Figure 12: Representative four-bar linkages and their applications. (Left) Function generator. (Right) Peaucellier straightline mechanism (see text).

The second inversion of the four-bar mechanism is obtained by using the shortest link  $a$  as the driver. As shown in Figure 11 (bottom), link  $a$  can make complete revolutions while the opposite link, which may be either  $b$ ,  $c$ , or  $d$ , can only oscillate through the angle  $\phi$ . This is called the crank-rocker mechanism; it is a useful device for producing oscillatory motion combined with a quick-return action that results from the fact that for counterclockwise rotation of  $a$ , the oscillation of  $c$  from  $B$  to  $B'$  corresponds with angle  $\theta_1$ , while oscillation from  $B'$  to  $B$  corresponds with angle  $\theta_2$ . Since crank  $a$  rotates at a constant speed and  $\theta_1$  is greater than  $\theta_2$ , the rocker will take longer to swing from right to left than the other way. On machines that do useful work only when the active members are moving in one direction, quick-return devices return the members quickly to their initial position.

In the extreme positions, shown dotted in Figure 11 (bottom), the crank  $a$  and the coupler link  $b$  are lined up (collinear), and if the rocker  $c$  were the driver, means would have to be provided to carry the follower link  $a$  past these dead positions. On foot-operated grindstones the foot pedal is attached to link  $c$  and the grindstone shaft to link  $a$ . The angular momentum of the grindstone is utilized to carry the links past the dead positions.

On the third inversion of the four-bar mechanism, the shortest link  $a$  is the coupler, and the other moving links can only oscillate. This is called the double-rocker mechanism.

**Linkage synthesis.** Graphical and analytical methods can be readily employed for determining the displacement, velocity, and acceleration of the links in a linkage mechanism. The design, or synthesis, of linkages to satisfy specific requirements is much more difficult. There is no known method for designing a drag-link mechanism to satisfy a given spectrum of input-output relationships. The best that can be done is to survey the performance characteristics of a selected number of specific configurations and pick the optimum.

On the crank-rocker mechanism the designer can control the angle of oscillation of the rocker and, to a degree, the quick-return ratio. The crank and rocker displacements, velocities, and accelerations cannot be correlated.

If the cranks in a four-bar mechanism always rotate in the same or in opposite directions, and if their rotations are limited to considerably less than 180 degrees, it may be possible to correlate the crank rotations in three, four, five, or even a larger number of positions. Both analytic and graphic methods are available for making the correlations.

Figure 12 (left) shows a function generator that correlates the rotation of crank  $b$  over a 60-degree range with the rotation of crank  $d$  over a 70-degree range. The correlation is such as to satisfy the relationship  $Y = X^2$ , with  $X$  varying from 1 to 6 and  $Y$  from 1 to 36. The rotation of crank  $b$  is the mechanical analogue of  $X$ , while the rotation of crank  $d$  is the analogue of  $Y$ . The relation between  $X$  and  $Y$  is accurate at  $X = 1.19, 2.54, 4.46$ , and

Con-  
strained  
motion

Crank-  
rocker  
mecha-  
nism

5.81; at other positions it is in error, but the error has been minimized by the odd spacing of the above precision points.

A function generator is not ordinarily used to indicate corresponding values of two functionally related variables such as  $X$  and  $Y$ . The scales shown in Figure 12 (left) are not usually provided; they have been added to bring out the most important feature of a function generator, namely, that the scales are uniform; *i.e.*, graduated in equal divisions. This means that, since  $\phi$  is 70 degrees and the range of  $Y$  is 35, each two-degree rotation of crank  $d$  corresponds with one unit of  $Y$ , and if  $d$  is used to operate a valve in response to a signal from  $b$ , the rotation of  $d$  corresponding to a given change in  $Y$  is the same at all points in the range.

**Special-purpose linkages.** In the extreme positions  $OAB$  and  $A'OB'$  in Figure 11 (bottom), the links 2 and 3 are said to be in toggle and most effective for the transmission of torque from link 2 to link 4. The toggle principle is used extensively in machine construction for obtaining large force or torque amplification or as a self-locking clamp; the latter effect is obtained if the links are allowed to go slightly past the toggle position and held there by a stop.

There are a number of useful linkage devices that derive their characteristics from the properties of a parallelogram. Among these are the drafting machine and the pantograph. The links in Figure 11 (bottom) will form a parallelogram when  $a=c$  and  $b=d$ ; then the coupler link  $b$  will have motion of translation so that any line fixed on  $b$  will not change its inclination to  $d$  as the links move. If the link  $d'$  of another parallelogram linkage is fixed to  $b$ , then its coupler  $b'$  will also have translatory motion, and a straight edge adjustably fixed to  $b'$  will maintain its inclination to  $d$  in all positions of the links; this is how a drafting machine operates.

The linkage next to be described was invented in 1873 by Captain Charles-Nicolas Peaucellier of the French corps of engineers. It was the first linkage capable of describing a circle of any radius, including an infinite one (a straight line), in the manner of a pair of compasses. When he first operated a working model of the linkage, Lord Kelvin, the famous physicist, is reputed to have remarked that it was the most beautiful thing he had ever seen.

Peaucellier straight-line mechanism

The Peaucellier straight-line mechanism, shown in Figure 12 (right), consists of a parallelogram of equal links  $B$  connected with two equal links  $A$  pivoted to the frame at  $O$ . From symmetry, points  $O$ ,  $P$ , and  $Q$  will always lie on the same straight line, and if  $P$  is guided on a circular path by link  $C$  pivoted at  $S$ , then  $Q$  will have a circular path concave to the right when  $D$  is greater than  $C$ ; for  $D$  less than  $C$  the curve will be concave to the left; for  $D=C$  (as in the figure) the radius of the path of  $Q$  is infinite and the curve is a straight line. The letters refer to the lengths of the links.

There are other linkage mechanisms that will produce exact straight-line motion, but in all of them either there are more than four pin-connected links or one of the links is a sliding block. No point on the coupler of a four-bar, pin-connected linkage can generate an exact, straight-line motion. There are techniques, however, for designing four-bar linkages to generate approximate straight-line motions; in practice these are usually satisfactory and are preferred because of their simplicity. One such linkage was designed by James Watt to guide the piston rod of his steam engine on a straight path. Another generates a D-shaped coupler-point curve that is used for the intermittent movement of the film in some motion-picture cameras.

An infinite variety of closed curves can be generated by points on the coupler of a four-bar linkage. An atlas is available that contains over 7,000 curves drawn to a large scale. By paging through the atlas a designer may find a shape suitable for a specific application.

**Slider-crank inversions.** When one of the pin connections in a four-bar linkage is replaced by a sliding joint, a number of useful mechanisms can be obtained from the resulting linkage. In Figure 13 (top) the connection between

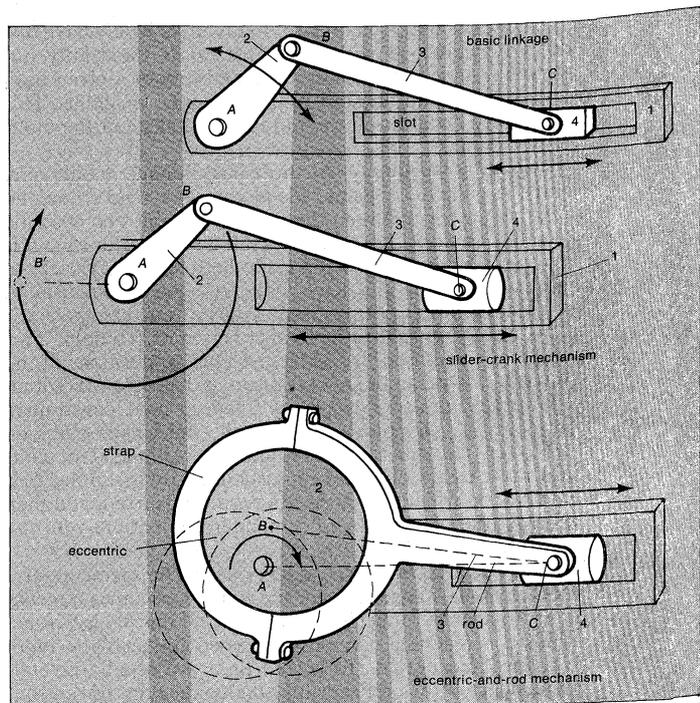

Figure 13: Types of linkages (see text).

links 1 and 4 is a sliding joint that permits block 4 to slide in the slot in link 1. It would make no difference, kinematically, if link 1 were sliding in a hole or slot in link 4.

If link 1 in Figure 13 (top) is fixed, the resulting slider-crank mechanism is shown in Figure 13 (centre). This is the mechanism of a reciprocating engine. The block 4 represents the piston; link 1, shown shaded, is the block that contains the crankshaft bearing at  $A$  and the cylinder; link 2 is the crankshaft and link 3 the connecting rod. The crankpin bearing is at  $B$ , the wrist pin bearing at  $C$ . The stroke of the piston is twice  $AB$ , the throw of the crank.

The slider-crank mechanism provides means for converting the translatory motion of the pistons in a reciprocating engine into rotary motion of the crankshaft, or the rotary motion of the crankshaft in a pump into a translatory motion of the pistons. In Figure 13 (centre), when  $B$  is in position  $B'$ , the connecting rod would interfere with the crank if both were in the same plane. This problem is solved in engines and pumps by offsetting the crankpin bearing from the crankshaft bearing. By using an eccentric-and-rod mechanism in place of a crank, no offsetting is necessary and very small throws can be obtained.

In Figure 13 (bottom) the crankpin bearing at  $B$  has become a large circular disk pivoted at  $A$  with an eccentricity or throw  $AB$ . The connecting rod has become the eccentric rod with a strap that encircles and slides on the eccentric. The mechanisms in the centre and bottom drawings of Figure 13 are kinematically equivalent.

By fixing links 2, 3, and 4 instead of link 1, three other inversions of the linkage in Figure 13 (top) are obtained.

**Space linkages.** All of the linkages considered so far have been planar; *i.e.*, their motions have been confined to a single plane or to parallel planes, and the shafts they connect have been parallel. Space linkages operate in three dimensions and are used to transmit motion between nonparallel shafts. Although some well-known linkage mechanisms in use for many years are special forms of space linkages, it was not until about the 1950s that kinematicians became seriously interested in developing procedures for describing, analyzing, and synthesizing these linkages. Though some advances in this field have been made, many problems remain unsolved.

Whereas a plane linkage can be described with a two-dimensional drawing and analyzed and synthesized with plane geometrical constructions, this is not possible with a space linkage. At least two views are required to define a link in three-dimensional space, and the additional dimension complicates the analysis of velocity and accel-

Uses of the slider-crank mechanism

ation. Thus, analysis of space linkages involves the use of higher mathematics.

In plane linkages there are only two types of connectors or joints, namely, pin or hinge joints and sliding joints (crossheads). Since it takes two elements to make a joint, kinematicians call them kinematic "pairs." Thus a pin joint is a revolute, or turning, pair and a sliding joint is a prismatic pair. In space linkages there are additional pairs, namely, the cylindric pair, which permits both relative translation and rotation, the screw pair (screw and nut), and the spheric pair (ball and socket joint).

The space linkage in Figure 14 could be used to link the butterfly valve on the throttle of a carburetor (the output) to the shaft rotated by the foot pedal (the input).

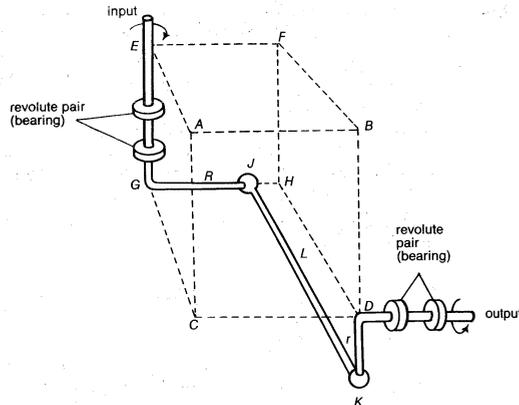

Figure 14: Space linkage (see text).

The L-shaped input shaft oscillates in bearings lying along the edge  $GE$  of the box  $ABCDEFGH$ , and the arm  $R$  swings about the mid-position shown and in the plane  $CDGH$ . The L-shaped output shaft oscillates in bearings lying along the edge  $CD$  of the box, and the arm  $r$  swings about the midposition shown and in the plane  $BDFH$ . The link  $L$  connects the shafts with spheric pairs (ball and socket joints) at  $J$  and  $K$ .

#### FLYWHEELS

A flywheel is a heavy wheel attached to a rotating shaft in a machine for the purpose of opposing and moderating any fluctuations in the speed of the machine caused by irregularities in the rate at which power is supplied to, or required by, the machine. Flywheels are also used for testing brakes and for storing energy that can be used in emergencies or, when dissipated quickly, can produce large forces.

Moment of inertia

The measure of the opposition of a rotating body to having its speed changed is its moment of inertia. This property depends on the disposition of the material of the body about the axis of rotation. It is proportional to the sum obtained by multiplying the weight of each particle of the body by the square of its distance from the axis of rotation. Moments of inertia of bodies of common geometric shapes are given in handbooks; for uncommon shapes they can be determined with integral calculus or by experiment. From the nature of the moment of inertia it follows that the material in a flywheel is most effective when it is concentrated as far from the axis of rotation as possible. Thus the best flywheel has a heavy rim connected to a central hub by spokes or a circular plate.

The behaviour of a flywheel depends entirely on the torque, or turning force, applied to it. If a clockwise torque is applied to a stationary flywheel for a period of time, the flywheel will acquire a clockwise angular velocity proportional to the product of the average torque multiplied by the time period, and inversely proportional to the moment of inertia of the wheel. If a rotating flywheel is subjected to a torque acting in the same direction in which it is rotating, its speed will increase; the converse is also true. The larger the moment of inertia of the flywheel the smaller the speed changes produced by a given torque. If no torque acts on a flywheel, its speed will not change.

On a reciprocating engine the torque applied to the crankshaft varies during each revolution. This variation is caused by the non-uniformity of the steam or gas pressure in the cylinders and the varying angle between the connecting rod (which converts the piston pressure to the crankshaft torque) and the crankshaft. When the crank and connecting rod are collinear, which happens twice during each revolution, no torque can be transmitted to the crankshaft. A subsidiary function of the flywheel on an engine is to carry the crankshaft past these "dead centre" positions.

All rotating machine members have moments of inertia and respond, like flywheels, to torque variations. The torques that are required to start, stop, or vary the speed of these members are known as inertia torques or loads. Inertia loads exist in all machines, and their presence is particularly noticeable when machines are being started.

Flywheels are especially useful on machines that deliver mechanical work intermittently. On a punch press, for example, the large forces required to punch or form sheet metal are exerted during a part of the downward stroke of the ram only. During the remainder of the downward stroke, throughout the upward stroke, and between strokes, the machine is idling, and the power required from the driving motor is low. It would be uneconomical to use a driving motor capable of delivering a torque large enough to create the large forces required for punching and forming. A flywheel acts as a reservoir of energy that is built up by a comparatively low-powered motor while the machine is idling and partially dissipated during the active portion of the downstroke.

A spinning flywheel was used as a power source for a propulsion system on a torpedo in 1884; it is reported that a speed of 24 knots (24 nautical miles per hour) was obtained for a distance of 500 yards (450 metres). A flywheel 10 inches (25 centimetres) in diameter, rotating at 52,000 revolutions per minute, has sufficient energy to raise and lower the landing gear on a B-70 aircraft. This flywheel energy-storing system weighs 200 pounds (90 kilograms) less than a hydraulic system for accomplishing the same function. A recent (1970) application to bus transportation is the proposal to use flywheels on the trolleybuses for San Francisco's Municipal Railway. New high-density steel wheels, of special design, weighing 700 pounds (300 kilograms) and rotating at 20,000 revolutions per minute, would permit the buses to leave the power lines to serve undeveloped adjacent areas for distances up to six miles (about ten kilometres). The key to obtaining a high energy-storing capacity in a flywheel is the magnitude of the centrifugal stresses, produced by rotation, that the material can take. With the same material, a plain disk can store about 50 percent more energy than a rim-type wheel, while a tapered, constant-stress disk can store about 100 percent more.

Flywheels as power sources

#### BELT AND CHAIN DRIVES

Quite probably, wrapping connectors in the form of ropes were among the earliest devices used by man for transmitting forces over long distances; for this purpose they are still unmatched. Commonly used connectors today also include bands, belts, and chains.

**Belt drives.** *Bands and flat belts.* Band, or tape, drives are useful substitutes for gears when the connected shafts do not make complete revolutions. The band drive in Figure 15 (left) provides a positive drive and the equivalent of pure rolling contact between the drums  $A$  and  $B$  that are pivoted on fixed axes. The ends of the thin, flexible, metallic bands 12 and 34 are clamped to the drums. If drum  $A$  or drum  $B$  drives counterclockwise, band 12 will be in tension, while for clockwise rotation of the drums, band 34 will be in tension. The bands lie side by side on the surface of the drums; there is no backlash as there would be in a gear drive; for the arrangement shown in Figure 15 (left), drum  $A$  can rotate about 145 degrees, while drum  $B$  can rotate about 240 degrees. Band drives can also operate with non-circular drums; they are used on the dial indicator mechanism of weighing machines.

When used to connect shafts that rotate continuously in one direction, the ends of ropes and belts cannot be

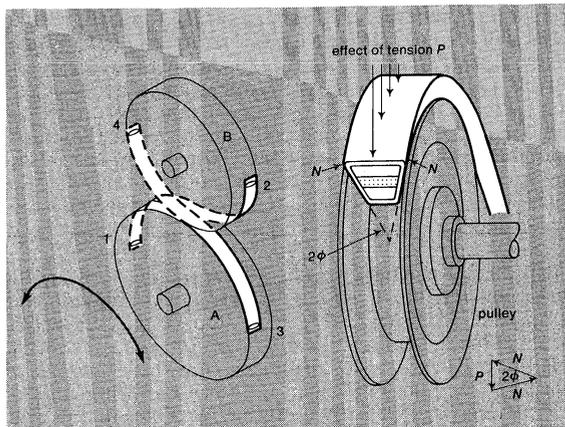

Figure 15: (Left) Band drive. (Right) V-belt drive (see text).

clamped to the drums; they must be wrapped around them so that the forces are transmitted by the frictional grip of the rope or belt on the drum. The force that can be carried without slip by a rope wrapped around a drum, such as a capstan, increases rapidly as the number of wraps is increased.

Frictional grip of a belt

Flat belts can be used to connect any pair of shafts in space, but when the shafts are not parallel it is necessary to exercise greater care in locating the pulleys than when the shafts are parallel. The pulleys must be so arranged that the centre line of a belt as it approaches a pulley lies in the plane that bisects the pulley and is perpendicular to its axis; otherwise, the belt will run off. To satisfy this requirement it may be necessary to use additional (idler) pulleys to guide the belt.

Flat belts are most often used to connect parallel shafts. Figure 16 shows a pair of parallel shafts connected by an open flat belt on pulleys *A* and *B* and by a crossed flat belt on pulleys *C* and *D*. To prevent the belts from running off the pulleys, the surfaces of the pulleys are crowned (that is, the pulley diameter is greater at the midsection than at the edges) or the pulleys are provided with low flanges.

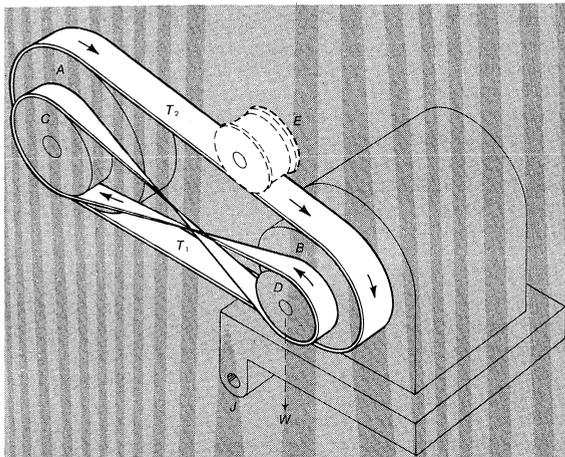

Figure 16: Flat-belt drives.

If there are no slip losses and belt thickness is neglected, the surface (peripheral) speeds of the pulleys must be equal; their angular velocities will be inversely proportional to their diameters. For pulleys *A* and *B*,

$$\frac{\text{speed of } A}{\text{speed of } B} = \frac{\text{diameter of } B}{\text{diameter of } A}$$

An equation of similar kind can be written for pulleys *C* and *D*.

A phenomenon known as creep causes the driven pulley to rotate at a slower speed than that given by the formula. Creep is unavoidable on belts made of any material that stretches elastically under load and contracts when the load is reduced. The amount of creep in a given drive

depends on the belt material and the magnitude of the load; it seldom results in the surface speed of the driven pulley being more than 2 percent less than that of the driving pulley.

If the initial tension in a belt is inadequate, the frictional grip of the belt may be insufficient to carry the load without some forward slip of the driving pulley relative to the belt and some forward slip of the belt relative to the driven pulley. On a well-designed flat-belt drive the combined creep and slip seldom exceed 4 percent.

Although successful friction drives with steel belts have been reported, most flat belts are made of more flexible materials such as leather, rubber, fabric, rubberized fabric, or reinforced plastic. In the days when all machines in a shop were driven by overhead belts connected to countershafts or long lineshafts, leather was the most commonly used belt material; it may still be.

Leather belts develop an excellent frictional grip on pulleys, and if periodically lubricated with a suitable belt dressing such as neat's-foot oil and not overloaded they will last as long as or longer than any other belt material. Because of variations in humidity, however, leather belts stretch and shrink, and with time they always get longer. If the pulleys are a fixed distance apart and means are not provided for keeping the belts tight, they must be "taken up" (shortened) periodically by cutting the belt and joining the cut ends.

The strongest leather-belt joint is made by gluing together the scarfed (chamfered) and overlapped ends of the belt. This is known as a cemented lap joint, and belts joined in this way are classified as endless. As an everyday procedure for joining belts, cemented lap joints are impractical. There are several commercially available metallic belt-lacing devices. One of these involves the insertion of a row of steel loops in the ends of the belt by means of a special press, and hinging them together with a rawhide pin. This joint is easily made and separated.

Speed ratios as high as 16 to 1 have been obtained with flat leather belts. If the shaft centre distance is short, high ratios with an open belt will result in the angle of wrap on the smaller pulley being considerably less than 180 degrees. To increase the angle and keep the belt tight, an idler pulley can be used. The one shown at *E* in Figure 16 could be mounted on a weighted arm pivoted at the right and would normally occupy a position closer to pulley *B*.

Short-centre electric motor drives can be improved by using a pivoted mount for the motor. In Figure 16 the base of the motor is pivoted at *J*, and the clockwise turning moment about *J* of the motor weight *W* is balanced by the counterclockwise turning moment of the belt tensions *T*<sub>1</sub> and *T*<sub>2</sub>. Belt tensions are controlled by the position of the motor on the base.

Flat-belt pulleys usually are made either of cast iron or of pressed steel, although some are wood, and others have cast-iron centres and paper rims. At all speeds the grip of a belt on a pulley is lessened by centrifugal action, and at approximately 6,000 feet (1,800 metres) per minute the power that a leather belt can transmit starts to drop off on account of this effect. When possible, pulley diameters for leather belts should be chosen so that the belt speed is between 4,500 and 6,000 feet (1,400 and 1,800 metres) per minute.

The driven pulley of an open-belt drive may be connected to the load shaft by a clutch, so that the load may be started and stopped while the belt pulleys rotate continuously. In place of a clutch, a loose (freely rotating) pulley may be installed next to the driven pulley. A belt shifter, consisting of two fingers that guide the belt between them, moves the belt from one pulley to another when actuated by a lever. A double-width driving pulley is required.

*V belts.* The frictional grip of a wrapping connector on a pulley can be greatly increased by using a belt with a V-shaped cross section fitting in a V-shaped groove in the pulley. In Figure 15 (right) the effect of tension in the V belt (called *P*) is to wedge the belt in the groove and create the normal forces *N*. The two normal forces and *P* must be in equilibrium as shown by the force triangle (lower right). On a flat pulley the angle  $2\phi$  is 180-

Advantage of the V belt

grees, and from the force triangle the sum of the normal forces  $N$  would be equal to  $P$ . Consequently, the V groove increases the normal forces created by a given belt tension. For standard commercial V belts the average angle  $2\phi$  is 35 degrees and the sum of the normal forces is 3.3  $P$ , which, since the frictional grip equals the normal force times the coefficient of friction, represents a substantial gain in capacity over a flat belt. In actual practice, gains of this magnitude are seldom realized, since satisfactory results can be obtained without the high tensions necessary on flat belts.

For a V-belt drive a thick belt is strained more than a thin belt on the same pulley, and a small-diameter pulley creates more bending in a belt than a large-diameter pulley. The amount of strain that a material can tolerate without permanent damage is given by its strength:stiffness ratio. For mild steel the ratio is approximately 1:1,000, which means that a fibre of steel can be stretched or compressed one one-thousandth of its original length without permanently changing shape. For some types of rubber the corresponding value is one.

Although the cross-sectional shapes of available V belts are more or less standardized, the composition of the structural elements and their distribution throughout the cross section are not. Nevertheless, most V belts are constructed in such a way that the bending strains are carried by a flexible material, while the transmitted load is carried by a stronger and stiffer material located near the neutral plane, where there is no bending strain.

V belts are available in a variety of sizes, types, and lengths for transmitting almost any amount of power. They operate best at belt speeds between 1,600 and 6,000 feet (500 and 1,800 metres) per minute, with an optimum speed of about 4,200 feet (1,300 metres) per minute. The narrow, high-capacity belts used on automobile engines for driving the fan, water pump, and generator can operate at higher speeds. As with flat belts, the speed-limiting factor is centrifugal action. Though maximum speed ratio for satisfactory performance is approximately 7:1, higher ratios can be used.

V belts may be used singly or in multiples. For some belt sizes sheaves with from 1 to 14 grooves are available as standard manufactured parts. Because of the wedging action in the grooves, less initial tension is necessary than with a flat belt. This reduces the load on the shafts and bearings.

V belts are well suited for short-centre drives. When the speed ratio is greater than about 3:1, the advantages of a V-belt drive can be obtained without using a large and expensive grooved pulley on the low-speed shaft. This is known as a V-flat drive and consists of a small grooved sheave, a large flat-belt pulley, and a set of V belts. Because of the comparatively large speed ratio, the angle of wrap on the large pulley is so great that, even without grooves, its frictional grip on the belt may equal or exceed that of the small grooved sheave. V-flat drives are frequently used on punch presses, the grooved sheave being on the driving motor and the flywheel with an uncrowned cylindrical periphery serving as the driven pulley.

*Grooved and timing belts.* Two other types of flexible belts, both of comparatively recent origin, are used for the transmission of power: the V-ribbed, or grooved, belt and the toothed, or timing, belt. The grooved belt is basically a flat belt with sharp-pointed, V-shaped longitudinal ribs on the side next to the grooved pulley. Although it resembles a set of V belts glued together, there is no wedging action. The overall width is less than for a multiple V-belt drive, and the belt-length matching problem, which always exists when a number of V belts are running on the same pulleys, is eliminated.

The toothed, or timing, belt (also called a synchronous belt) is basically a flat belt with a series of evenly spaced transverse teeth that fit in a series of matching grooves on the periphery of the pulley. These belts provide a positive no-slip drive and can be used at speeds as high as 16,000 feet (5,000 metres) per minute. They are used on automobile camshaft drives, machine tools, pumps, textile machinery, and on such business machines as electric type-

writers, card sorters, and electric calculating machines. Although the positive drive provided by these belts has many advantages, it lacks the overload and sudden-start protection provided by belts that slip.

**Chain drives.** For hoisting and moving materials, chains are reported to have been used in the Near East hundreds of years before the birth of Christ. A notebook of Leonardo da Vinci's contains a sketch of a chain like those used on modern bicycles, and there is evidence that chains of a similar type were actually in use in Europe in the 16th century. In 1879 the silent chain (see below) was invented by Hans Renold of Manchester, England.

The first chain-driven or "safety" bicycle appeared in 1874, and chains were used for driving the rear wheels on early automobiles. Today, as a result of modern design and production methods, chain drives that are much superior to their prototypes are available, and these have contributed greatly to the development of efficient agricultural machinery, well-drilling equipment, and mining and construction machinery. Since about 1930 chain drives have become increasingly popular, especially for washing machines, power lawnmowers, power saws, and motorcycles. They are also used on vending machines and escalators.

There are at least six types of power-transmission chain; three of these will be covered in this article, namely the roller chain, the inverted tooth, or silent, chain, and the bead chain. The essential elements in a roller-chain drive are a chain with side plates, pins, bushings (sleeves), and rollers, and two or more sprocket wheels with teeth that look like gear teeth. Roller chains are assembled from pin links and roller links. A pin link consists of two side plates connected by two pins inserted into holes in the side plates. The pins fit tightly into the holes, forming what is known as a press fit. A roller link consists of two side plates connected by two press-fitted bushings, on which two hardened steel rollers are free to rotate. When assembled, the pins are a free fit in the bushings and rotate slightly, relative to the bushings, when the chain goes on and leaves a sprocket.

Standard roller chains are available in single strands or in multiple strands. In the latter type, two or more chains are joined by common pins that keep the rollers in the separate strands in proper alignment. The speed ratio for a single drive should be limited to about 10:1; the preferred shaft centre distance is from 30 to 50 times the distance between the rollers; and chain speeds greater than about 2,500 feet (800 metres) per minute are not recommended. Where several parallel shafts are to be driven without slip from a single shaft, roller chains are particularly well suited.

An inverted tooth, or silent, chain is essentially an assemblage of gear racks, each with two teeth, pivotally connected to form a closed chain with the teeth on the inside, and meshing with conjugate teeth on the sprocket wheels. The links are pin-connected flat steel plates usually having straight-sided teeth with an included angle of 60 degrees. As many links as are necessary to transmit the power are connected side by side. Compared with roller-chain drives, silent-chain drives are quieter, operate successfully at higher speeds, and can transmit more load for the same width. Some automobiles have silent-chain camshaft drives.

Bead chains provide an inexpensive and versatile means for connecting parallel or nonparallel shafts when the speed and power transmitted are low. The sprocket wheels contain hemispherical or conical recesses into which the beads fit. The chains look like key chains and are available in plain carbon and stainless steel and also in the form of solid plastic beads molded on a cord. Bead chains are used on computers, air conditioners, television tuners, and venetian blinds. The sprockets may be steel, die-cast zinc or aluminum, or molded nylon.

#### COUPLINGS

A coupling is a device for connecting the ends of adjacent bodies. In machine construction, couplings are used to effect a semipermanent connection between adjacent rotating shafts. The connection is permanent in the sense

No-slip drive with a belt

Roller-chain drive

that it is not meant to be broken during the useful life of the machine, but it can be broken and restored in an emergency or when worn parts are replaced.

There are several types of shaft couplings; their characteristics depend on the purpose for which they are used. If an exceptionally long shaft is required for a line shaft in a manufacturing plant or a propeller shaft on a ship, it is made in sections that are coupled together with rigid couplings. A common type of rigid coupling consists of two mating radial flanges (disks) that are attached by key-driven hubs to the ends of adjacent shaft sections and bolted together through the flanges to form a rigid connection. Alignment of the connected shafts is usually effected by means of a rabbet joint on the face of the flanges; *i.e.*, a short cylindrical projection on the face of one flange fits snugly in a circular recess on the face of the other flange.

In connecting shafts belonging to separate devices (such as an electric motor and a gearbox), precise aligning of the shafts is difficult and a flexible coupling is used. This coupling connects the shafts in such a way as to minimize the harmful effects of shaft misalignment. Flexible couplings also permit the shafts to deflect under their separate systems of loads and to move freely (float) in the axial direction without interfering with one another. Flexible couplings can also serve to reduce the intensity of shock loads and vibrations transmitted from one shaft to another.

The flexibility provided by a coupling may be only spatial, or it may be both spatial and resilient (springy); in other words, the coupling may compensate for shaft misalignment but provide no resilience, or it may be resilient and provide also for a small amount of misalignment.

**Universal joints.** For connecting shafts whose axes intersect at angles up to about 40 degrees, the Hooke, or Cardan, joint can be used. Many commercial forms of the joint are available, but they all consist of two forked members that are connected to the shaft ends and a central connecting cross-shaped piece, or a block, on which the forks can turn (Figure 17A). This coupling is not

vary. By installing a Hooke joint between the motor and the crankshaft, the variation in the slider's velocity can be controlled by varying the angle of inclination of the joint. Still greater control of the slider's velocity can be obtained by using two Hooke joints and varying the relative positions of the forks on the intermediate shaft.

The Hooke joint is a member of a class of couplings known as universal joints, and in spite of its deficiencies it is a widely used machine component. Many other universal joints, embodying diverse means for connecting intersecting shafts, have been invented. At least three of these are constructed in such a way that they transmit rotary motion with a constant velocity ratio at shaft angles up to about 40 degrees.

Commercially available constant-velocity joints are considerably more complex than the Hooke joint. They are used on vehicles with front-wheel drives, or independently sprung rear-wheel drives; for driving helicopter rotors; and on high-speed drives where the speed variations produced by a single Hooke joint would cause vibrations.

**Flexible couplings.** For connecting shafts that are parallel but are not lined up with each other (non-collinear) the Oldham coupling, shown in Figure 17B, is useful. The centre piece *d* has two projecting rectangular bars at right angles to one another that fit into grooves on the faces of the flanges on the hubs *e* and *f*, which are attached to the ends of the coupled shafts. When the shafts are out of line (offset) the centre piece slides in the grooves in the flanges as the shafts rotate, but it cannot rotate relative to either of the flanges. Consequently, this coupling transmits motion with a uniform velocity ratio. The Oldham coupling can operate with considerable amounts of parallel misalignment.

A variation of the Oldham coupling is obtained by widening the bars on the centre member until it becomes a square block that engages widened slots on the flanges. The bearing surfaces of the block can be provided with replaceable strips of bronze or nonmetallic material that are lubricated by grease stored in the hollow block. On instrument assemblies, where the motion of a driving shaft must be transmitted accurately to a driven shaft, the Oldham coupling is frequently employed.

Some types of machinery require a torsionally rigid coupling that can tolerate slight amounts of angular and parallel misalignment and permit axial float. For such applications, gear couplings are well adapted. These consist of two identical hubs with external gear teeth that are attached to the shafts and coupled together by means of a sleeve with internal gear teeth that mesh with the teeth on the hubs. The hubs and the sleeve have the same number of teeth, so that there is no relative rotary motion between the internal and external gear teeth. Gear couplings are used on all types of equipment and are particularly well suited for high speeds and loads.

There are many types of commercially available resilient couplings in which the resilience is obtained by either metallic or nonmetallic elements. The widely used Falk Steelflex coupling (Figure 17C) utilizes a flat steel spring forming a series of hairpin bends to obtain its resilience. This coupling consists of two flanged members with tapered slots, connected by a continuous steel spring laced through the slots. When the coupling is unloaded, the unsupported length of the spring elements is a maximum and the coupling has its minimum torsional stiffness. At full load the spring elements contact the tapered sides of the slots, thus reducing their unsupported length and increasing the stiffness of the coupling. The stiffening effect of load application is a useful characteristic for shafts subject to torsional vibration.

The simplest form of nonmetallic resilient coupling is a rubber or fabric hose fitting over and clamped to the ends of the coupled shafts. The rubber elements are usually reinforced with corded material, and no lubricant is required. These couplings are particularly effective in reducing the transmission of shock loads and vibrations.

**Magnetic and hydraulic couplings.** The transmission of rotary motion through the wall of a hermetically sealed chamber without mechanical contact can be ac-

Rigid  
coupling

Constant-  
velocity  
universal  
joint

Gear  
couplings

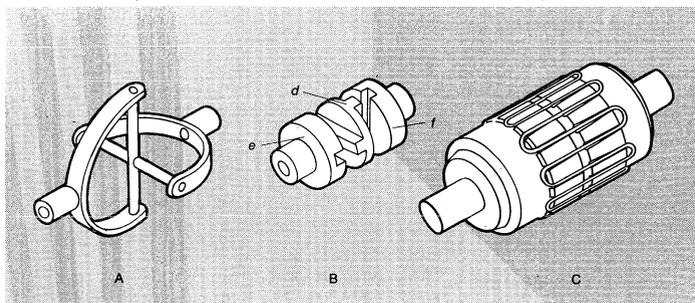

Figure 17: Types of couplings. (A) Hooke joint. (B) Oldham coupling. (C) Falk Steelflex coupling (see text).

resilient, and if the driving (input) shaft rotates at a constant speed the driven (output) shaft will rotate at a varying speed if the shafts are not collinear. A constant velocity ratio can be obtained by using two Hooke joints and an intermediate shaft. The intermediate shaft forks must lie in the same plane, and the output and input shafts must make the same angle with the intermediate shaft.

On an automobile, the rear axle moves up and down relative to the transmission as the springs deflect. To permit this movement without restraint, the transmission and rear axle are connected to the propeller or drive shaft by means of Hooke joints. One of these must have a sliding joint to permit free axial movement, or float, to allow for the slight changes in distance between the transmission and the rear axle.

On some machines a varying angular speed can cancel out or modify unwanted speed variations in one member produced by a constant-speed driver. If a slider-crank mechanism, for example, is being used to convert the uniform rotary motion of an electric motor to a translatory motion on a slider, the velocity of the slider will

complished by means of a magnetic coupling. If the wall is nonmagnetic and nonconductive, magnetic lines of force emanating from permanent magnets attached to the ends of the shafts will couple the shafts together. These couplings are particularly valuable for connecting pumps for corrosive fluids to their driving motors.

An overload release coupling is a torque-limiting device, and, as the name implies, it limits the torque that can be transmitted from one rotating member to another by either slipping or breaking the connection when the torque reaches a predetermined value. When the maximum torque of a magnetic coupling is exceeded, the driven member stops and cannot be restarted until the torque is removed and the driving member stopped and restarted. Other types of overload devices resemble mechanical friction clutches with spring-loaded friction members adjusted for prescribed torques. On some outboard motors the propeller is fixed to the shaft by means of a metal pin driven radially through the hub and the shaft. If the propeller is overloaded by striking an obstacle, the pin shears off and prevents further damage. This is probably the cheapest method of obtaining overload protection, but since a sheared pin must be replaced it is not the most convenient.

Hydraulic couplings have been used in passenger cars and buses since the 1920s. Functionally, they resemble automatic clutches and in many respects are unlike the other types of couplings that have been described. The driving and driven elements are housed in a circular container partially filled with a liquid (usually oil) and having coaxial input and output shafts. A fluid coupling provides a rotationally yielding connection and prevents the transmission of shock loads and torsional vibration; it does not provide for shaft misalignment.

Active elements of a hydraulic coupling

The two active elements of a hydraulic coupling resemble a pair of half-grapefruit sections with the pulp removed (the membranes remaining intact) and facing each other so that the dividing membranes become radial partitions. One of the elements acts like a pump and is known as the impeller, while the other element acts like a turbine and is known as the runner. In the impeller, which is attached to the input shaft, kinetic energy is imparted to the fluid; while in the runner, which is attached to the output shaft, the kinetic energy of the fluid is converted to mechanical torque. If no torque is applied to the output shaft, the impeller and the runner will rotate at the same speed, the fluid will not circulate from the impeller to the runner, and there will be no transfer of kinetic energy. When a torque is applied to the output shaft the runner will slow down, the fluid will circulate, and there will be a transfer of energy. The maximum torque is developed when the output shaft is stalled.

On an automobile, a fluid coupling permits a smooth pickup of speed and prevents the engine from stalling if the car is stopped with gears engaged. Under normal driving conditions the output speed is about 97 percent of the input speed; *i.e.*, the slip is about 3 percent. The input and output torques are equal.

Hydraulic couplings are sometimes placed between an electric driving motor and a gearbox. Since the hydraulic torque varies as the square of the input speed, the couplings permit the motor to come up to speed before any appreciable load is applied to it. When high-inertia loads must be started, hydraulic couplings are particularly useful.

#### CLUTCHES

A clutch is a device for quickly and easily connecting or disconnecting a rotatable shaft and a rotating coaxial shaft. Clutches are usually placed between the input shaft to a machine and the output shaft from the driving motor, and provide a convenient means for starting and stopping the machine and permitting the driver motor or engine to be started in an unloaded state.

The rotor (rotating member) in an electric motor has rotational inertia, and a torque is required to bring it up to speed when the motor is started. If the motor shaft is rigidly connected to a load with a large rotational inertia, and the motor is started suddenly by closing a switch, the

motor may not have sufficient torque capacity to bring the motor shaft up to speed before the windings in the motor are burned out by the excessive current demands. A clutch between the motor and the load shafts will restrict the starting torque on the motor to that required to accelerate the rotor and parts of the clutch only.

On some machine tools it is convenient to let the driving motor run continuously and to start and stop the machine by operating a clutch. Other machine tools receive their power from belts driven by pulleys on intermediate shafts that are themselves driven by belts from long lineshafts that serve a group of machines. Two pulleys that can be connected to the intermediate shaft by clutches, and driven in opposite directions by open and crossed belts from the line shaft, can provide forward and reverse rotations for the machine.

**Positive and friction clutches.** A mechanical clutch may provide either a positive drive with no slip, or the torque transmitted may depend on friction. In the latter case, the rate at which a stationary shaft is brought up to the speed of the driving shaft can be controlled; for this reason friction clutches are more common than positive clutches.

Positive clutches are collars with square jaws that interlock. One member is rigidly attached to its shaft while the other member slides on its shaft and on a key fixed to its shaft. Positive clutches must be engaged at low relative speeds if high shock loads are to be avoided. They are used on hoisting, conveying, and farm machinery and on punch presses and shears.

Friction clutches have pairs of mating conical, disk, or ring-shaped surfaces and means for pressing the surfaces together. The pressure may be created by a spring or by a series of levers locked in position by the wedging action of a conical spool. On a spring-loaded clutch the operator, by controlling the rate at which the spring pressure is applied to the clutch, can regulate the speed of clutch engagement and the torque applied to the driven shaft. There is always some slippage, however, and the efficiency of a friction clutch can never exceed 50 percent; *i.e.*, during a clutching operation at least one-half of the input energy is lost by friction in the clutch and produces heat.

The friction surfaces on clutches should have a high coefficient of friction and be able to conduct the heat away rapidly. These properties are difficult to obtain in a single material and for this reason, one of each pair of mating surfaces is usually metallic, while the other is either leather, cork, or an asbestos-based facing rivetted to a metal plate. Some friction clutches are run dry, while others operate in oil. Dry clutches have a higher coefficient of friction than wet clutches, but the oil helps to carry off the heat.

Cone clutches, with male and female cones, were widely used on the first automobiles. On cones with a slight taper, a small axial force can produce a large pressure between the surfaces because of the wedge effect. Cone clutches require close alignment of the shafts, and the development of asbestos-based friction disks has rendered them almost obsolete, at least for automobiles.

Cone clutches

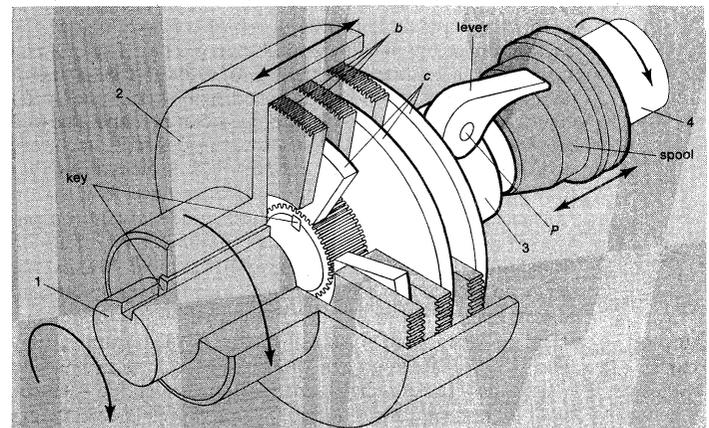

Figure 18: Multiple-plate disk clutch (see text).

Figure 18 shows a half-section of a multiple-plate disk clutch in which input member 2 is keyed to the driving shaft 1 and output member 3 is keyed to the driven shaft 4. The friction plates *b* have external gear teeth or splines that mate with teeth on the inside of member 2, while friction plates *c* have internal teeth that mate with external teeth on member 3. Plates *b* can slide axially in 2, while plates *c* can slide axially on 3. The clutch is engaged by moving the spool to the left, which, by a wedging action, rotates the lever about the pivot *P* and creates a force that squeezes the plates together.

**Automatic and magnetic clutches.** Automatic, smooth engagement is obtained with a centrifugal clutch. The friction shoes are segments of rings that are pivoted to or carried around by the driving member. As the driver's speed increases, the shoes gradually make firmer and firmer contact with the internal cylindrical surface of the driven member. Centrifugal clutches allow the driving motor to reach operating speed before being loaded. They are particularly useful on internal-combustion engines driving chain saws, and on helicopter rotor drives. They eliminate the need for a manually operated clutch, and the engine cannot stall when overloaded, since the clutch will slip when the speed drops below that necessary to create the torque required by the load.

An overrunning clutch transmits torque in one direction only and permits the driven shaft of a machine to "freewheel," or keep on rotating when the driver is stopped. Modern designs utilize the wedging action of rolls or sprags (struts). With rolls, a series of wedge-shaped pockets, with a roll in each, is formed between the periphery of one member and the inside of a ring on the other member. Rotation of either member in one direction causes the rolls to roll up the incline in the pocket and lock the members together. In sprag clutches a number of especially shaped rocking wedges are located in the annular space between concentric circular races, and are kept in contact with both races at all times by means of a spring.

On bicycles, freewheeling clutches permit the rider to coast without moving the pedals. They can also be used to prevent damage to machines by accidental reversal of the input rotation, and if one of the members is fixed they can function as brakes or "backstops" that prevent reverse rotation of a loaded output shaft when the driving effort is removed.

Magnetic-particle clutches have an annular (ring-shaped) gap between the driving and driven members that is filled with powdered iron and graphite. When a magnetic field is induced across the gap by a direct-current control coil, the iron particles form chains across the gap and transmit a torque that depends on the strength of the field. Controlled by varying the current, the load can be engaged smoothly and there is no slippage when the clutch is transmitting the torque for which it was designed.

#### BRAKES

Basically, brakes are devices for controlling the flow of motion in machines, and in this respect they resemble clutches; clutches start the flow while brakes arrest it. Before the engagement of a clutch or a brake, one of the two members in the device is moving while the other is stationary; after the engagement of a clutch both members are moving at the same speed, while after the application of a brake the moving member is either slowed down or stationary. In both cases the desired effects are produced by devices that are so alike, structurally, that they can sometimes serve in either capacity.

In arresting the motion of bodies, brakes must be capable of absorbing kinetic energy. Even when acting on translating bodies (like automobiles) most brakes are designed to act on rotating mechanical elements and to absorb energy either mechanically, hydraulically, or electrically. Mechanical brakes are the most common; they dissipate kinetic energy in the form of heat generated by mechanical friction between a rotating metallic element and a nonrotating friction element, when they are brought into contact by either mechanical, hydraulic,

pneumatic, or electrical means. The material in the friction element may be organic, metallic, or ceramic. Organic materials with an asbestos base are satisfactory for the majority of applications. When service requirements are severe, however, the heat generated may cause "fading" (a drop in braking effectiveness caused by a reduction in the coefficient of friction). In such cases sintered metallic linings are preferred because of their high thermal conductivity and freedom from fading. By adding ceramic particles to sintered metallic linings, extremely hard and fade-resistant linings can be produced.

The rotating element in a mechanical brake is either a drum, a disk, or a series of disks. The nonrotating friction element in a drum brake may be either a band or a pair of shoes (blocks) that contract around the outside of the drum or a pair of shoes that expand against the inside of the drum. A disk brake may be similar to a plate clutch, with alternate rotating metallic and nonrotating friction elements, or it may be of the caliper type, with a single rotating disk and two opposed friction pads that squeeze the disk between them in a pinching action.

**Shoe brakes.** Most of the early automobiles had band brakes with bands that almost completely encircled the drum. Since they were exposed to the elements and road debris, and the heat radiation was poor, they were superseded by other types. The shoe-type friction elements that are used on drum brakes in place of bands are usually arranged in diametrically opposite pairs that are pressed against the outside or the inside surface of the drum. In the external-shoe brake in Figure 19 (left) the

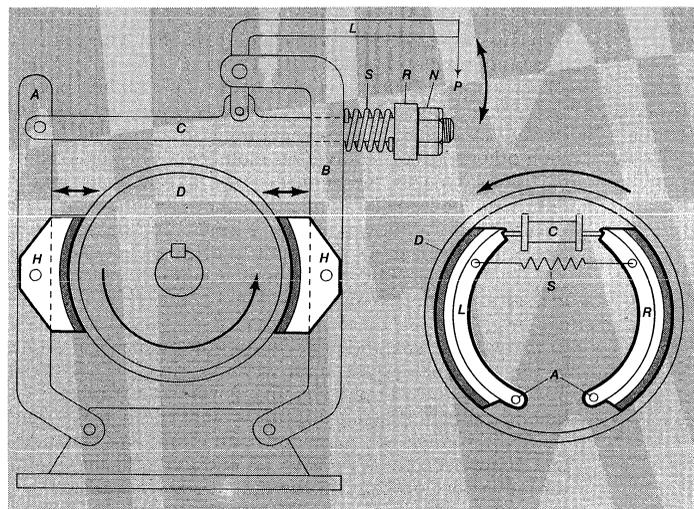

Figure 19: Types of shoe brakes. (Left) External-shoe brake. (Right) Internal-shoe brake (see text).

shoes *H* are pivoted to the arms *A* and *B* and are pressed against the outside of the drum *D* by the spring *S*, which is compressed between the end of the arm *B* and the collar *R*. The position of *R* and the spring pressure can be adjusted by means of the nut *N*. The rod *C* passes freely through the arm *B* and is pivotally connected to both the arm *A* and the lever *L*. The brake is released by applying a downward force *P*, which rotates the lever *L* clockwise, forces the arms *A* and *B* apart, and compresses the spring.

Spring-set brakes of the type just described are used on electric elevators. When the starting switch for the hoisting motor is closed, the current actuates a device that applies the brake-releasing load *P*. This device may create a magnetic pull or it may be a hydraulic unit driven by an electric motor.

The braking of railroad cars is effected by cast-iron shoes that bear directly on the periphery of the wheels, as the shoes in Figure 19 (left) act on the drum. These brakes are usually activated by compressed air.

Figure 19 (right) shows an internal-shoe brake. The friction shoes *L* and *R* rotate on the fixed pivots *A* and are pressed against the inner cylindrical surface of the rotating drum *D* by means of oil pressure in the cylinder *C*,

which contains two pistons that push outward on the upper ends of the shoes. The tension spring  $S$  retracts the shoes and releases the brake when the oil pressure is reduced. For counterclockwise rotation of the drum, the shoe  $L$  is self-energizing, since the frictional force tends to rotate it in the same direction as the piston in the cylinder  $C$ .

Because they provide better protection from water and dust and have superior mechanical characteristics, internal-shoe drum brakes are superior to band brakes, and they are still in widespread use on automobiles. The capacity of drum brakes to dissipate heat, however, is limited, and for heavy cars travelling at high rates of speed they are inferior to disk brakes.

**Disk, hydrodynamic, and electric brakes.** The simplest form of disk brake is the caliper brake, which consists of a rotating metal disk and two stationary circular pads or buttons fitted with friction linings that are pressed against opposite sides of the disk by hydraulic pressure. The buttons act on the disk as do the jaws of a pair of pliers. Because of the large area of the disk that is not covered by the pads, these brakes have a high heat-dissipating capacity. In addition, thermal expansion, since it acts principally to increase the thickness of the disk, has less effect on brake performance and there is less fading than on drum brakes. Disk brakes are used on airplanes, automobiles, and trains. Disk brakes are also made with multiple disks, and their action is similar to that of the multiple-disk friction clutch described above. The coaster brake found on bicycles and operated by reverse pressure on the pedals is an example of a multiple-disk brake.

A hydrodynamic brake has a rotor (rotating element) and a stator (stationary element) that resemble the impeller and runner in a hydraulic coupling. Resistance to rotation is created by fluid friction and the circulation of a liquid (usually water) from a series of pockets in the rotor to a series of complementary pockets in the stator. The magnitude of the resistance to rotation (torque) depends on the square of the angular velocity, so that a hydrodynamic brake is most effective at high speeds but cannot bring a rotating shaft to a dead stop. By circulating the liquid through a radiator, these brakes dissipate energy very effectively. They are used as supplemental brakes on oil-well drilling rigs for lowering drill pipe, tools, and casing into the well. They are also used as dynamometers for loading and measuring the output torque of machines and as auxiliary brakes on trucks to control their speed on long downgrades.

Electric brakes are commercially available in three types—eddy-current, hysteresis, and magnetic-particle. Eddy-current brakes have no braking capacity at zero speed, may require cooling fins or a liquid coolant, but are smooth in operation and do not wear. In hysteresis brakes the torque is independent of speed and can be controlled by varying the current. These brakes are sometimes used as dynamometers for testing small motors. Magnetic-particle brakes develop appreciable torque when stationary, but their thermal capacity is limited.

#### BEARINGS

A bearing is a connector that permits the connected members to either rotate or translate (move to and fro) relative to one another but prevents them from separating in the direction in which loads are applied. In many cases one of the members is fixed, and the bearing acts as a support for the moving member.

The relative motion in bearings is always opposed by friction, and the work done in overcoming friction is lost power in all machines. Consequently, much thought and effort have been devoted to the development of bearings with minimum friction. In all bearings there are two surfaces (one belonging to each of the connected parts) that move relative to one another. To minimize friction, the co-acting surfaces may be partially or completely separated by a film of liquid or gas; these are known as sliding-contact bearings. The surfaces may be separated also by an assemblage of rolling elements such as balls and rollers; these are known as rolling-contact bearings.

Sliding bearings are the simplest to construct and, con-

sidering the multitude of pin-jointed devices and structures in use, are probably the most commonly used. Nevertheless, man must have discovered thousands of years ago that it is easier to roll a log than to slide it and that heavy masses can be moved more easily when resting on rolling logs than on sliding skids. Recognition of the superiority of rolling over sliding motion resulted in most attention being devoted to the improvement of rolling rather than sliding bearings. This continued until the discovery in the 1880s that under certain conditions a film of oil sufficient to separate the surfaces could be built up in a sliding bearing, and that in this way the frictional resistance could be very substantially reduced.

Precise values of the frictional resistance between moving bodies are difficult to predict or measure, but rough comparisons between different types of friction can be made. To slide a 1,000-pound (450-kilogram) steel block on a dry cast-iron surface, for example, could require a force of 200 pounds (90 kilograms), while to roll a 1,000-pound dry cast-iron wheel on a dry steel surface might require only two pounds. If the block were separated from the cast-iron surface by an oil film, the required force could be only two pounds, and if the film were a gas, the needed force could be considerably less.

**Rolling-contact bearings.** *History.* The roller, in the form of a rolling log, was probably the predecessor of the wheel, which is reported to have been in use prior to 3000 BC. A Greek historian stated about 450 BC that rollers were used to transport ships on land, and about a hundred years later another Greek historian described a battering ram supported on rollers. Discoveries made in 1928 when Lake Nemi in Italy was drained revealed that primitive ball bearings were used by the Romans shortly before the birth of Christ.

Leonardo da Vinci made what was probably the first and most complete study of friction up to his time, and rolling bearings are shown on many of the sketches in his notebooks. Up to the middle of the 20th century many patents for ball and roller bearings were issued in France, Germany, Great Britain, and the United States. These patents cover a wide variety of methods of assembling and separating the rolling elements and the design of the races for the rollers or balls to roll on. Time and experience have shown, however, that although many of these designs were ingenious, they were complicated. Thus most have been superseded by simpler types that are easier to manufacture and more reliable.

The first patent for ball bearings for bicycles appears to have been issued in 1862, but the first successful applications took place in 1868, when ball-bearing bicycles appeared in both England and France. Further development resulted in a patent in 1879 for a bearing that closely resembles the present-day bicycle bearing. By this time the number of bicycles had increased to such an extent that the manufacture of steel balls had become a substantial industry. The success of ball bearings in bicycles had a significant influence on the growth of the ball-bearing industry. By 1898 many other uses for these bearings in machine construction had been found, and factories were turning out balls of assorted sizes by the millions every day.

*Ball bearings.* Figure 20 (top) shows two views of one quarter of the most widely used type of modern ball bearing. It consists of four parts: an inner race  $b$ , an outer race  $c$ , the balls  $d$ , and a separator or retainer  $e$ , which is also called a cage. The inside surface of the inner race fits snugly on the outside surface of one of the connected members, which is usually a fixed or rotating shaft, while the outside surface of the outer race fits snugly in the inside surface of the other member, which could be the base or frame of a machine, a rotating member such as a gear, a wheel, or a pulley. The dotted arrows in the figure indicate the directions of the rotations of the races relative to one another and the resulting rotation of the balls about their own geometric axes, assuming that there is no slip between the balls and the races; the balls also rotate bodily about the geometric centre of the bearing, just like the planet gears in a planetary gearset.

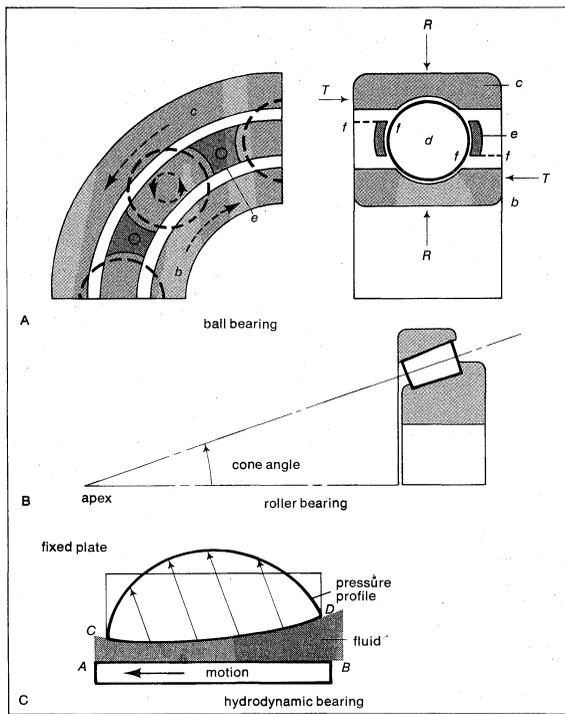

Figure 20: Types of bearings (see text).

The races in which the balls roll have grooves with radii of curvature slightly greater than the radius of a ball. Some bearings are assembled by moving the inner race radially, inserting the balls, centring the inner race, spacing the balls uniformly, and applying the retainer that holds the balls loosely in an equally spaced position. Other bearings have a notch in one of the races that permits more balls to be inserted. With more balls, the bearing can carry more radial load  $R$  (Figure 20 [top]) but less thrust load  $T$  on account of the notch.
